Chapter 4.14

Drivers for Wireless Technology Acceptance in Indian Healthcare

Raj Gururajan
University of Southern Queensland, Australia

ABSTRACT

The outcomes of clinical usefulness as a driver of wireless technology for Indian healthcare are reported here. Using both qualitative and quantitative techniques, 30 physicians were interviewed and 200 health professionals were surveyed. The outcomes established that in addition to technology factors, other factors such as clinical factors, administration factors and communication factors play a crucial role in determining the uptake of wireless technology for healthcare. These factors were further validated using a PLS model.

INTRODUCTION

In the last few years, high expectations, technological developments, and effective and efficient services have been shown to be prerequisites for improvements in the healthcare domain (Rogoski, 2005). Latest trends in the healthcare sector include the design of more flexible and efficient service provider frameworks aimed at providing health services to all stakeholders. In order to implement such frameworks, wireless technology is increasingly being used in the healthcare sector (e.g. data management automation). A decrease in the cost of wireless devices and improved awareness of the benefits that ensue by using related wireless applications are two of the contributing factors towards the increased use of wireless technology in this sector (Gururajan, R., Quaddus, M. et al., 2005). Even though the future of this technology and its usability is promising, its adoption is still in its infancy, which is attributed to the complex and critical nature of the healthcare environment. In the current competitive and complex business environment, technology developments have played a critical role in delivering high quality of care (Reinecke, 2004). However, there is limited knowledge and empirical research on the effectiveness and adoption of wireless technology in general, and in the Indian healthcare system in particular.

Recent research has established that investment in emerging Information Technology (IT), including Information Systems (IS), can lead to productivity gains only if they are accepted and effectively used by respective stakeholders. Consequently, acceptance and utilization of IT/IS in the healthcare environment have been central themes in the information systems literature. Therefore, the fundamental focus of this research is to investigate and examine the influence of internal and external determinants on the usefulness of wireless technology. Further, this research also assesses how its acceptance contributes to the adoption of wireless technology. It is believed that this research is the first of its kind attempted in the Indian healthcare domain and it employs empirical evidence to explore the impact of wireless technology and its usefulness in the Indian healthcare system. The Indian healthcare domain is at the forefront in adopting the latest medical technologies and applications, as evidenced by media reports and, as such, it constitutes an excellent context for validating existing adoption theories and extending them.

The main contribution of this research includes the identification of a set of drivers and barriers to using wireless technology in a given Indian healthcare setting. In addition to this, for the first time, a set of clinical factors influencing the adoption of wireless technology has been identified and validated using a second order regression model.

LITERATURE REVIEW

The concept of wireless technology in healthcare is discussed in many studies (Dyer, 2003; Hu et al., 2002; Sausser, 2003; Simpson, 2003; Wisnicki, 2002). For example, Wisnicki (2002) provides details of how broadband technology, an essential component of wireless technology, can be used in healthcare. While prior studies agree that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such applications (Gururajan, Raj et al., 2005; Gururajan et al., 2004). In general, the majority of the works reviewed are descriptive about the benefits of wireless handheld devices in healthcare in general, and medicine in particular. There is only a small number of studies that provide evidence-based information concerning these devices in healthcare (Fischer et al. 2003; Sax et al. 2005). Furthermore, five major studies in the area of healthcare (evaluated by (Spil & Schuring, 2006) testing the Technology Acceptance Model (TAM) produced findings which were inconsistent with the body of knowledge in non-healthcare settings. With ‘Perceived Ease of Use’ and ‘Perceived Usefulness’ as the major TAM attributes, these studies found that in the health environment, ‘Perceived Usefulness’ is an important attribute in technology adoption, while ‘Perceived Ease of Use’ was found to have no effect (Spil & Schuring, 2006). This is different to findings reported in non-health IS studies, where both attributes were found to be reliable technology adoption predictors. Therefore, further empirical investigation is required to explain the reasons why this variation exists in healthcare. In addition, there is a need to explore if further attributes exist which may influence the adoption of wireless applications in the healthcare environment.

TAM in Healthcare Context

In healthcare literature, the discussion on wireless technology falls into three periods. For example, studies prior to and including 2000 discussed the status of wireless technology and the possible role the technology can play in healthcare. Studies between 2000 and 2003 discussed how wireless technology can be deployed in healthcare and the potential benefits the technology can bring to healthcare. It should be noted that these studies were only 'discussion' type studies. Majority of these studies did not provide any empirical evidence as to the use or acceptance of wireless technology in healthcare domains. Studies from 2004 till current date have collected data to establish the usefulness of wireless technology in healthcare. These studies, to some extent have focussed on the PDAs as these devices have been found to be useful in nursing domain for clinical data management.

The studies between 2000 and 2003 discussed a number of potentials of wireless technology in clinical domains. For example, how broadband technology can be used in healthcare was discussed by Wisnicki (2002), ability to address prevailing healthcare staff crisis by adopting intelligent solutions using agent and wireless technology that can identify the need and match the need with available resources in a timely and efficient manner was outlined by Davis, R. (2002), better compliance with the rigorous regulatory framework was highlighted by Wisnicki (2002), reduction in medication errors and hence the benefits that can be realised was discussed by Turisco (2000), provision for greater flexibility and mobility of healthcare workers in performing their work was portrayed by Athey & Stern (2002), effective management of the increasingly complex information challenges and improved access to those information from anywhere at anytime was discussed by Stuart & Bawany (2001). Our review clearly identified that all these studies were only implying the potential of wireless technology and did not provide any empirical evidence.

While prior studies agreed that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such wireless applications in order to establish the adoption of technology in a given healthcare context (Gururajan et al., 2005; Gururajan et al., 2004). During the period of 2004—2006, studies emerged in the area of technology acceptance, specifically focussing on the acceptance of wireless technology in healthcare domains. These studies were empirical in nature and were testing the available models of technology acceptance or a variation in order to ascertain whether previous models hold good for a new technology in a specific domain. These studies were reported in a book titled 'E-Helth Systems Diffusion and Use', published by Idea Group Publishing in 2006 (Spil & Schuring, 2006). These studies are summarised below:

Predicting Internet Use: Applying the Extended Technology Acceptance Model to the Healthcare Environment (Chismar & Wiley-Patton, 2006)—This study empirically established that only perceived usefulness is significant and ease of use was not significant.

The dynamics of IT adoption in a major change process in health delivery (Lapointe et al., 2006)—This study established that TAM as devised by (Davies et al., 1989) is not adequate for health systems because adoption/resistance factors may be group related as opposed to the fundamental basis of TAM which is individualistic, influence of intra and inter organisational factors, linkages to cultures, environmental factors as well as the complexity of the environment.

Introducing electronic patient records to hospitals: Innovation adoption paths (Suomi, 2006)—This study found that relative advantage, strong network externalities available, rich availability of information through different communication channels are key factors for innovation and adoption. It should be noted that these are not discussed in the TAM models.

User acceptance and diffusion of innovations summarised (Spil & Schuring, 2006)—This summary established that perceived usefulness is a predictor of technology acceptance in healthcare. Ease of use was not found to be significant.

Understanding physicians' use of online systems: an empirical assessment of an electronic disability evaluation system (Horan et al., 2006)—This study found that in order to diffuse technology in an organisation, it is important to ascertain physicians' behaviour, their workflow practices and their perceptions regarding the value of specific information systems.

In essence, the recent studies appear to be indicating that the current models of technology acceptance or its derivatives are not suitable to predict the adoption factors of wireless technology in healthcare environment. Strong support can also be derived from three specific studies that have tested TAM models in healthcare. The first study conducted by Jayasuriya (1998) established that ease of use was not significant in a clinical domain. The second study by Chau & Hu (2002) echoed similar sentiments. The third study by Hu et al. Hu et al. (1999) also found similar findings.

Further, recent studies conducted by Howard et al. (2006) also established that ease of use was not significant while determining factors of adoption in a clinical domain in regard to wireless technology. Further, Ivers & Gururajan (2006) also found that there are other factors beyond the TAM models influencing the acceptance of technology.

Interviews conducted with 30 Queensland nursing staff members by Gururajan, R., Moloney, C. et al. (2005) revealed that clinical usefulness of wireless technology is far more significant than ease of use factor as established in TAM. Another focus group discussion with the Western Australian senior health managers by Gururajan, R., Quaddus, M. et al. (2005) also indicated that aspects of clinical usefulness such as integration of clinical data may be a significant factor than the ease of use factor. Howard et al. (2006) also identified clinical usefulness is far more influencing than the ease of use factor while determining factors of adoption of wireless technology in the Indian healthcare domain.

However, the recent findings that the ease of use factor not showing strong significance in healthcare domain while determining wireless technology adoption warrants explanation as this is different to many other reported studies in the generic IS domain where both attributes (ease of use and perceived usefulness) were reported to be reliable predictors.

This variation requires further empirical investigation in order to explain the reason behind this variation specific to healthcare. Therefore, there is a need to identify attributes that assist in the adoption of wireless applications in healthcare environment. It is argued that the initial validity of TAM was predominantly established by testing the model with students as surrogates in a generic software application domain. This environment is very different to the healthcare environment, where the skills are at different levels. Further, the healthcare environment is complex, sensitive and time critical. These could be some of the reasons why TAM did not perform as expected in healthcare settings.

In addition, in the recent variant of TAM, namely, UTAUT, Venkatesh et al (2003) reviewed eight prominent models of user acceptance and managed to create a unified view. The unified model comprised of seven constructs. The first four—performance expectancy, effort expectancy, social influence and facilitating conditions—were theorised to be direct determinants. The last three—attitude towards technology, self efficacy and anxiety—were theorised to be indirect. All the seven constructs were found to be significant determinants of technology usage by Venkatesh et al (2003).

In terms of attitude, Venkatesh et al. (Venkatesh et al., 2003) defined it as an individual's overall affective reaction to using a system. The model depicts four constructs relating to this determinant—attitude towards behaviour, intrinsic motivation, affect towards use and affect. Spil & Schuring (2006) verified that in three cases the relation between attitude and behavioural intention is significant. Therefore, this determinant cannot be indirect. If there is significance between attitude and behaviour intention, then there is a direct relationship.

Therefore, there appears to be a basis to identify factors that contribute to the adoption of technologies in healthcare settings. Given that wireless technologies have started making in-roads in healthcare, the overarching purpose of the research is to identify the factors that influence the adoption of wireless technology in the Indian healthcare system. The rationale of the purpose is justified by the fact that India is a leader in software technologies, especially medical applications. Further, India is emerging as 'health tourism', due to the advancement in medical technology and reduction in cost in offering high quality health services—as highlighted by various print media. However, our initial review of available literature indicated that this area is under-researched. Collectively, these aspects led to the following research question:

- What are the determinants for the adoption of wireless technology by physicians in the Indian healthcare system?

The first stage of this study is focused on answering the research question qualitatively and the second stage on answering the research question quantitatively. Details as to how the research question was answered are provided in the research methodology section below.

METHODOLOGY

An examination of existing IS studies indicated that there is a necessity for a suitable research method. Most of the reviewed studies follow a quantitative approach which involves an instrument being administered onto a domain with perhaps a lesser understanding of the domain issues. For this study it was felt that if technology issues are to be studied with respect to a specific domain, then user involvement with the technology issues forms a major part in establishing the adoption (or inhibiting) factors. By necessity, this would occur prior to administering quantitative instruments (e.g. survey). This, in turn, requires an understanding of research philosophy, values of inquiry that would guide the study, and the choice of relevant research techniques required to conduct the investigation in order to answer the research questions.

Further, there appears to be limited information available in the Indian IS domain to guide the principles of this study. This study is relatively new and, hence, requires a rigorous justification as to the choice of research methods employed. It is also believed that due to aspects associated with various regulatory issues impacting the Indian health system, unique factors of technology acceptance, as well as usefulness, may emerge. Our initial meetings with Indian physicians also suggested that there is a divide in terms of technology usage between private and public hospitals, where private hospitals are rich in technology use and public hospitals are not. On the other hand, in many traditional studies in IS, either quantitative or, to some lesser extent, qualitative methods are used—but not both. In recent years this has been cited as a weakness (see (Mingers, 2001) for a detailed argument on this). Taking this into account, this study investigates the suitability of both approaches in order to answer the research question.

It is recognised that the foundation for any research will be grounded on the researcher's fundamental philosophical view of the world (Myers, 1997). The choice of tools, including research techniques, instruments, and methods such as qualitative and quantitative, are not inherently linked to a particular philosophical position, as these positions are generic in nature. It is the contextual framework within which they are applied that provides consistency to an inquiry. While the choice of tools and methods are not linked to the philosophical view, the articulation—which is commonly the process of explaining choices of research methods and its related choice of research instruments—helps determine the philosophical disposition. This is usually achieved by asking questions on the beliefs, perceptions, experiences, advantages and disadvantages in order to determine this disposition. This may even include a researcher's personal experience within that domain, or their expertise in explicating the information using any approach that may be suitable to that domain. This has prompted us to follow a qualitative approach as the first phase of the study. It is argued that this approach facilitates direction to the second phase of the study where quantitative evidence can be collected to establish causality between the dependent and the independent variables.

The research question dictates the need for quantitative research methods, while the behavioural component of the same investigation dictates qualitative research methods. The rationale for this approach is based on the notion that behavioural components require a thorough understanding of how users apply wireless technology in a given setting in order to understand behavioural issues. To extract 'tacit' aspects, this is best accomplished by applying a qualitative approach. A quantitative instrument can then be developed to extract the quantitative aspects, such as the opinion scores.

Health professionals view the term 'wireless technology' in different ways, either as a product or a process. The combined domain of wireless technology and healthcare is relatively new in the Indian IS domain. While IS studies have discussed the impact of Information & Communication Technology (ICT) tools and associated behavioural intentions on healthcare users, limited information can be found as to how the combination of wireless technology and healthcare settings would influence users who are already conversant with novel and advanced medical technologies (Spil & Schuring, 2006). The workplace or organizational factors that influence such combinations are yet to be explored in detail. Such an exploration has close association with the choice of research method as these methods pave the way for proper inquiry into the factors that determine technology acceptance in a given setting. On this basis, the suitability of one research method over another has to be carefully weighed. Consequently, this study identified an exploratory approach to be suitable for the initial investigation. This approach is particularly favourable in confirming the direction of the study, variables chosen for the study, and in helping refine the literature. The exploratory study can also possibly eliminate some variables, while providing opportunities for including emerging variables.

Qualitative Data Collection

As argued, for the first stage of this research the investigators used a qualitative approach to collect initial sets of themes for the adoption of wireless technology in the Indian healthcare system. For this purpose, 30 physicians operating in Indian healthcare were identified randomly. These physicians were interviewed by an independent member (external to the team) who identified the attributes for the adoption of wireless technology by physicians in the Indian healthcare system. This approach was deliberate to address criticisms of 'bias' in the interview process. Further, due to linguistic issues, a person with linguistic proficiency in both Indian language and English is required. The interview questions were derived from existing literature. The first stage of the data collection concentrated on Indian hospitals with some form of wireless technology already in use. The physicians were also chosen based on their wireless technology awareness or working experience. They were drawn from both private and government hospitals. The interviews were conducted over a 45-60 minute period and recorded using a digital recorder. Once they were recorded, the interviews were transcribed.

Quantitative Data Collection

This study developed a survey instrument from the interview data. The main reason for this digressed attitude was that previously tested instruments in the technology domain were not relevant to healthcare setting and were found to be inadequate in answering the research question. The data from the interviews were used to develop specific ranges of questions to gather a more detailed view from the wider population. This survey instrument was pilot tested to capture the information reflecting the perceptions and practice of those adopting the wireless technology in the Indian healthcare system. Particularly, it focussed on what internal and external environmental factors affect the adoption of wireless technology and the extent of this influence. The survey was then distributed to over 300 physicians randomly chosen from the telephone book and a total of 200 responses were received. The survey responses were then entered into a spreadsheet file. A Visual Basic interface was written to generate numerical codes for various elements of the survey for data analysis using SPSS. The coded spreadsheet file was then copied onto a SPSS file format.

DATA ANALYSIS

Qualitative data was analysed using the NVivo (version 7) application, which helped identify the initial themes from the interviews. Quantitative data were analysed using SPSS, which helped identify the factors and their correlation for the adoption of wireless technology in the Indian healthcare setting.

Qualitative Data Analysis

Qualitative data was manually coded to extract themes that had an impact on wireless technology acceptance as stated by the physicians. In total, 63 themes were extracted from the interviews. The initial themes include awareness, cost factors, advantages and disadvantages, medical errors, information sharing, current state of technology, usefulness and role of wireless technology, and technology awareness. On the basis of the interviews and the literature review, the themes were

Table 1. The factors driving and inhibiting wireless technology adoption in healthcare

Drivers	**Barriers**
• Save-time • Improve-clinical-workflow • Efficiency-in-communication • Delivery-of-high-qual-info • Better-quality-of-service • Save-effort • Improve-clinical-performance • More-contact-time-with-patients • Improved-delivery-of-information • Reduce-overall-cost • Positive-impact-on-patient-safety • Reduce-inaccuracies • Improve-public-image • Reduce-medical-errors • Easy-access-to-data • Attract-more-practitioners • Reduce-workload	• Legal barriers • Administrative purpose • Communication with physicians • Patient education • Communication with colleagues • Obtain lab results • Note taking • Electronic medical records • Device usage barrier • Benefit evaluation barrier • Resource barrier • Electronic prescribing

classified into drivers and inhibitors as shown in the following table. This list of drivers and inhibitors was expected to provide a direction for the development of the survey instrument for the collection of quantitative data to capture the wider community views and to generalize the outcome of the research. This grouping is presented in Table 1.

The content of the Table 1 is consistent with findings of previous studies conducted by Gururajan et al. (2004; 2005). This prompted conducting a quantitative study in order to establish causality among dependent and independent variables, as well as external validity and generalisability.

Quantitative Data Analyses

In order to ensure statistical reliability, suitable tests were run on the entire instrument, as well as selected group of variables. For example, the reliability test returned a Cronbach alpha value of 0.965 for the instrument indicating high reliability (Zikmund, 1994). This test was conducted because the instrument was generated from the interview data and, hence, it was necessary to establish statistical reliability. In addition, reliability tests were also run for three factor groupings, namely, drivers, inhibitors of adoption and other technology factors. The reliability tests returned values of 0.941, 0.447 and 0.536, respectively, indicating that the data were suitable for factor analysis testing.

As a second step, survey data were analysed for factor analysis using SPSS. It is evident from the table below that two factor component matrix identified drivers and the barriers for the adoption of wireless technology in the Indian healthcare setting. This finding is consistent and aligned with the findings of the qualitative data collection stage (i.e. first stage) of this research.

The drivers were further tested for factor groupings. The analysis resulted in Table 3.

The driving factors of adoption yielded three categories of factors, namely, 'organisational', 'management' and 'clinical'. The organisational components include wireless technology drivers that can generate specific benefits for organisations. The management components represent the benefits that healthcare managers can realise using wireless technology. The clinical components encompass clinical drivers of using wireless technology.

A similar factor model was generated for the inhibitors. The model resulted in Table 4:

Similar to the drivers, the inhibitors also resulted in three specific categories. The 'technology' category includes technology factors that inhibit wireless adoption in the Indian healthcare. The 'resource' category encompasses resource barriers that are currently being encountered in the healthcare setting. Finally the 'usage' category is comprised of inhibiting factors, which are associated with usage issues.

In addition to the two factor groups, namely drivers and inhibitors, A third factor was also identified and named as 'clinical usefulness' and its components are shown in Table 5.

This factor group yielded three components. The first component deals with the general communication aspects facilitated by wireless technology in healthcare settings. The second component refers to clinical communication using wireless technology. The third component is specific to records management. In summary, the data analyses yielded three specific categories of factors which can affect the adoption of wireless technologies in the healthcare setting. These comprise adoption drivers, inhibitors, and clinical usefulness.

Hypotheses Formulation and Testing

Based on the evidence collected, the three sets of factors, namely, drivers, barriers and clinical usefulness, contribute to the acceptance of wireless technology in healthcare. It is hypothesised that the drivers positively impact clinical usefulness,

Table 2. The factors driving and inhibiting wireless technology adoption in healthcare from data analysis of survey result

Drivers	Loading values	Barriers	Loading values
improve-clinical-workflow	.798	poor technology barrier	.605

improve-clinical-performance			.797

whereas the barriers have a negative impact on it. While the drivers and barriers include factors beyond the technology aspects, their respective influences are restricted to the clinical domain as this is where the usefulness of wireless technology can be experienced. Therefore, the following two hypotheses were generated for testing:

H1:*Drivers of wireless technology positively impact clinical usefulness.*

H2: *Barriers to wireless technology negatively impact clinical usefulness.*

A Partial Least Square (PLS) model was developed in order to test the hypotheses. The rationale for using PLS includes: PLS is used for confirmatory factor analysis (CFA); the pattern of loadings of items on the latent constructs is explicit; PLS provides strong convergent and discriminant validity; p-value of t-value is significant (over 0.50 level) for constructs; and measurement items load highly on theoretically assigned factors and not highly on other factors.

PLS MODEL DEVELOPMENT

In order to develop the PLS model, a PLS Graph prototype was used. Initially, the individual drivers, barriers and clinical usefulness were tested for CFA scores and these were found to be reliable. When the CFA was found to be satisfactory, a model was built with clinical infuences as dependent variable on drivers and barriers. The factors of these three constructs were linked using PLS Graph software and the model was run. The final outcome is shown in Figure 1.

Figure 1 shows that the factor loading (the number on the path: for example, for the construct Drivers, the 'esydataccs' has 0.763) and the factor weight (the number in the parantheses: for example, 0.101) for almost all factors are reliable. The drivers and clinical usefulness load very highly (over 0.8 for most of the items), indicating a high reliability. Further, all variables have a t-value of over 1.96 to indicate high convergent validity.

Upon construct validation, a simple PLS (consolidated) model was developed to test the hypotheses. The model consists of clinical usefulness as the dependent variable, and drivers and barriers as independent variables. The model was run with PLS Graph program and the screenshot shown in Figure 2 displays the values along the

link from Drivers to Clinical Usefulness, and Bariers to Clinical Usefulness. As hypothesised, drivers exhibited a positive loading (0.097) and the barriers exhibited a negative loading (-0.384). The number below the circle Clinical Usefulness is the construct R^2, which is calculated and displayed for each dependent variable. The lower the R^2, the minimum the error in the model. In the model the R2 values for the dependent variable 'Clinical Usefulness' is 0.167. This is not high and hence the error is minimal. This is shown in Figure 2.

IMPLICATIONS

Clearly, wireless technology can be used to facilitate access to clinical information and communications between clinicians, maximise clinician time, increase patient safety, and accomplish the strategic and business goals of health organisations. Taken together, these factors have a direct impact on clinical usefulness and its effectiveness. However, achieving clinical usefulness with wireless handheld devices can be a challenge and has several implications.

Firstly, the highest security standards must be achieved. This includes direct end-to-end data encryption, authentication, authorisation, maintenance of audit logs and session management (Chen et al. 2004). While high security standards are essential, their implementation is likely to affect usability. For example, the download and encryption of patient information from the server where it is stored into a wireless handheld device may not be prompt. Sax et al. (2005) argue that clinicians may experience increasingly longer time lags when they carry out increasingly more complex procedures. This is likely to adversely affect clinical usefulness and, hence, decrease user acceptance.

Closely associated with security is also the issue of patient confidentiality, which is of significant importance and concern. Although

Figure 1. PLS model of adoption of wireless technologies in Indian healthcare

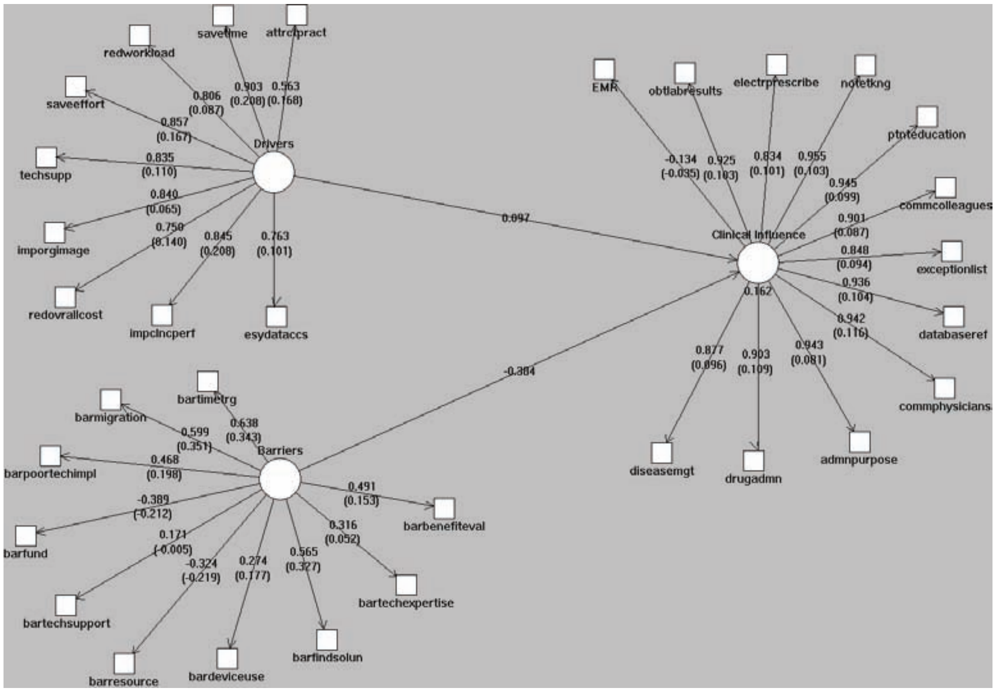

Figure 2. Result of model testing

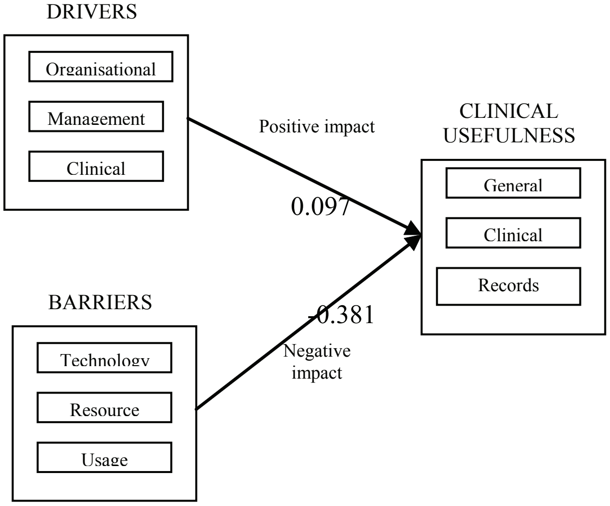

wireless handheld devices have locking security features and password protection functions which activate during periods of inactivity, the frequent use of these functions during the clinicians' busy daily schedules may have an impact on clinical usefulness.

Secondly, the design of an effective human-computer interface, while challenging, constitutes a key factor for the acceptance of the technology and its routine use by healthcare workers (Chen et al. 2004). This is an important development consideration as the relevant information should be easy to navigate and read, and has to be presented in an organised fashion when required within the resource limitations (e.g. screen size and bandwidth) of a wireless handheld environment. Usability factors are not only likely to constitute an acceptance barrier, but can also be the cause of medical errors. Bates et al. (2001) argue, 'While it may be easy and common to blame operators for accidents [or errors], investigation often indicates that an operator "erred" because the system was poorly designed' (p. 301). Therefore, medical errors can also occur due to poor usability. Taken together, these factors would contribute to reduce medical errors. By implication, it is important to involve users in the design of the wireless applications, thereby maximising their clinical usefulness.

Thirdly, simply acquiring and implementing wireless technology alone would be insufficient to accomplish clinical usefulness and, subsequently, drive adoption and diffusion. Wireless technology should be integrated with process improvement and organisational change. Process improvement requires the optimisation of clinical processes and should be supported by technology, rather than driven by it (Smith 2004). Ultimately, this is likely to generate significant patient outcomes and financial improvements with health organisations.

Fourthly, as suggested by the empirical evidence collected in this study, cost constitutes an important factor which will affect the integration and, subsequently, the success of wireless handheld devices in the healthcare setting (Sax et al. 2003). Typically costs include the software, the server, upgrades of healthcare organisations' existing networks and legacy systems, the costs of the handheld units themselves, as well as maintenance and support. While existing research in this area argues that such technology has the potential to decrease charting time and medical errors and enhance patient care quality, there is no evidence that comparisons of costs before and after the implementation of wireless technology have been made. This suggests that further research is required, but also, most importantly, it shows that, indirectly, costs have the potential to affect clinical usefulness and threaten widespread adoption.

CONCLUSION

This research, perhaps for the first time, identified derivers for technology acceptance for using wireless technology in an Indian healthcare context. While this is an exploratory study to identify clinical influences of wireless technology applicable to the Indian healthcare system, the bottom-up method identified drivers that are quite different to that of traditional technology acceptance models. In fact, this study revealed that technology acceptance is quite different in healthcare compared with that of IS studies. While the data were obtained on perceived opinions, it was not possible to actually measure the usefulness of wireless technology in a clinical setting. Currently, another project is being designed to enable the measurement of clinical influences of using wireless technology in an objective manner. It is expected that this new project will provide valuable insights into the efficiency gains of using wireless technology and the challenges people encounter in using this technology.

This study is confined to the Indian healthcare setting, which limits the generalisability of its findings. However, this study is also the first of its nature and, as a result, it has prepared the groundwork for further research which can confirm (or refute) whether the findings are applicable to other settings such as Taiwan as data collection is in progress. This data collection is expected to be completed by December 2009. This exercise, it is hoped, will enable to extend the notion to broader populations.

Chapter 4.15

A Centrist Approach to Introducing ICT in Healthcare:

Policies, Practices, and Pitfalls

David J. Finnegan

Wendy L. Currie
University of Warwick, UK

EXECUTIVE SUMMARY

The challenge to provide a nation-wide healthcare service continues unabated in the 21st century as politicians and managers drive through policies to modernize the UK National Health Service (NHS). Established around 60 years ago to offer free healthcare at the point of delivery to all citizens, the NHS now accounts for the largest portion of public expenditure after social security, with total spending around £84 billion in 2006/2007. Over the past 3 decades, the political agenda within healthcare has moved from one of professional dominance, where clinicians and their representative bodies dominated the leadership and management of healthcare organisations, to one where politicians have imposed new ideas in the form of market mechanisms and the "new public management" which extend the use of private sector firms. The political justification for these reforms is to make the NHS more efficient and cost effective and to develop an ethos of patient choice.

INTRODUCTION

The challenge to provide a nation-wide healthcare service continues unabated in the 21st century as politicians and managers drive through policies to modernize the UK National Health Service (NHS) (Harrison, 2004). Established around 60 years ago to offer free healthcare at the point of delivery to all citizens, the NHS now accounts for the largest portion of public expenditure after social security, with total spending around £84 billion in 2006/2007 (National Audit Office, 2006a, 2006b). Over the past 3 decades, the political agenda within healthcare has moved from one of professional dominance, where clinicians and their representative bodies dominated the leadership and management of healthcare organisations, to one where politicians have imposed new ideas in the form of market mechanisms and the "new public management" which extend the use of private sector firms (Burgoyne, Brown, Hindle, & Mumford, 1997; Callaghan & Wistow, 2006). The political justification for these reforms is to make the NHS more efficient and cost effective and to develop an ethos of *patient choice* (Department of Health, 2002).

Described as a *monolithic* organization (Mohan, 2002), implementing business and technical change in the NHS is difficult to manage given the competing interests of key stakeholders: politicians, clinicians, hospital managers, administrators, pressure groups, and patients (Pollock, 2005). A significant policy challenge currently facing the NHS is the implementation of a 10-year (£12.4bn estimated cost) government-led initiative to provide a National Programme for Information Technology (NPfIT) as a significant part of the NHS modernisation agenda (National Audit Office, 2006a).

The NPfIT comprises four main elements, each of which constitutes a nationwide large-scale information technology (IT) implementation: (1) a National Care Records Service for capturing, storing, retrieving, and modifying patient medical records on a national database; (2) the Choose & Book system, where GPs and patients can book hospital appointments using a computer system; (3) the Picture Archiving and Communications System (PACs) to capture and send digital images of x-rays and scans; and (4) an Electronic Prescription Service (EPS) to enable patients to collect their prescriptions from hospital and high street pharmacies more efficiently.

While NPfIT represents a serious commitment from government to use IT to drive through public sector reform, the history of embarking on large-scale public sector IT projects is mixed. A recent National Audit Office Report (2006b) identified 24 successful IT-enabled business change projects, but recognised that other public sector IT projects have not been successful. Criteria for the successful evaluation of projects included: senior management commitment, robust procurement processes, and carefully matching user requirements with desired benefits. These findings suggest that evaluating the implementation of NPfIT must be placed in the wider context of policy-making, procurement, processes, and people, and not simply examined as an isolated "technical" initiative introduced across healthcare organisations. This is supported by prior research which shows that evaluating the implementation of large-scale IT projects is a complex task which involves a combination of clinical, managerial and technical expertise, particularly if they are designed to transform or "re-engineer" existing clinical and/or administrative working practices (McNulty & Ferlie, 2002, 2004; Willcocks & Currie, 1997; Wyatt, 2005).

By tracking cross-national public policy on information and communication technology (ICT) over the past 2 decades, we observe the growing importance of linking ICT as a "change agent" for modernising publicly-funded healthcare services. In the U.S., research studies have focused upon introducing IT-enabled business change in healthcare, noting that conflicts may arise between stakeholder groups which resist changing highly institutionalized working practices (Scott, Ruef, Mendel, & Caronna, 2000). Similarly, in the Netherlands, Sweden, and UK, cost-containment programs and healthcare system reorganisations have been vigorously implemented with outcomes both expected and unexpected (Harrison, 2004).

This study focuses on the policies, practices, and pitfalls of introducing NPfIT, which is a centrist and politically-driven initiative intended to *"help deliver a better NHS that gives public and patients services that fit the twenty-first century"* (Department of Health, 2002, p. 2). We begin by looking at the policy antecedents of NPfIT, which led to its launch in 2002. We then discuss a case study on the electronic prescription service, which is one element of the NPfIT. Here, we are concerned to explore the issue of "best practice" in relation to the EPS, highlighting both its strengths and weaknesses. We conclude by discussing the debate surrounding NPfIT on whether a centrist approach to ICT implementation is preferable to a decentralised or localised approach. We develop our conclusions based upon our empirical and archival data collection and analysis.

Building out the National Programme for Information Technology

The antecedents of NPfIT began with the Department of Health (1998) report on "Information for Health," which identified the key strands in the recently elected 1997 Labour government policy to introduce lifelong electronic records of patients. This was followed by further government reports including the "NHS Plan (Department of Health, 2000) outlining an information strategy for the "modern NHS" and "Building the Information Core" (Department of Health, 2001) on how to implement the NHS plan. These publications contain important policy recommendations that influenced the publication of the Wanless Report (Department of Health, 2002) that spearheaded the NPfIT.

From these earlier documents on IT in healthcare, we can observe the changing policy recommendations of government and how IT has become infused with the wider policy agenda to reform the NHS. A consistent theme in UK healthcare over the past 3 decades has been continuous policy change and reform. Successive governments have used healthcare in their political armoury to demonstrate to the electorate that improving healthcare services is a key priority (Klein, 2001; Pollock, 2005). The NHS has witnessed numerous attempts at restructuring with some examples being, the introduction of strategic health authorities (SHAs), primary care trusts (PCTs), foundation hospitals, practice-based commissioning, the private finance initiative (PFI) and patient choice.

To facilitate these changes, IT-enabled change is perceived to play a critical role as, "Better IT is needed in the NHS because the demand for high-quality healthcare continues to rise and the care now provided is much more complex, both technically and organizationally" (Connecting for Health, 2004). Moreover, the NHS is an information-intensive industry. There are over 300 million consultations in primary care annually. In 2003, there were around 650 million prescriptions dispensed in the community; and nearly 5.5 million people were admitted to hospital for planned treatment. In addition, there were 13.3 million outpatient consultations, and nearly 13.9 million people attended Accident and Emergency (A&E), of whom 4.3 million were emergency admissions (Connecting for Health, 2004, p. 7). Management and administration costs in the NHS are around £170 million, and a further £14 bn is spent on IT (National Audit Office, 2006a).

Notwithstanding the increase in the annual NHS budget, the concept of IT-enabled business change remains contentious. From a period of virtually no computers in the 1960s and 1970s, the NHS has developed a vast array of disparate IT systems. Primary care is relatively advanced compared with secondary care, as GPs have tended to invest in IT systems for patient administration and medical record keeping. Similarly, retail pharmacies have invested in IT to improve the efficiency and operations of their business. Conversely, IT investment in secondary care has been slow. Among the first IT systems were patient administration systems (PAS) in the early 1960s. This was followed by laboratory and radiology systems in the 1970s, and hospital information support systems (HISS) and resource management in the 1980s (Brennan, 2005). As computer technology proliferated during the 1980s and 1990s, the NHS began to develop an IT strategy to maximise the potential data and information management benefits from IT in healthcare.

This culminated in the late 1990s with a succession of government reports advocating the development of lifelong electronic patient records (EPRs) (Department of Health, 1998; Hendy, Reeves, Fulop, Huchings, & Masseria, 2005). The NHS Executive aimed to transform IT-enabled healthcare services by establishing a target for all NHS hospitals to have EPR introduced by 2005 (Department of Health, 2002). Recognising that, "historically, the NHS has not used or developed IT as a strategic asset in delivering and managing healthcare" the Wanless Report (Department of Health, 2002) advocated a much higher annual IT spend to compare with other industries like financial services. The report produced comparative figures to show that, whereas financial services spend around £9k *per employee per annum* on ICT, the figure for healthcare was only £1k. The Wanless Report therefore recommended the development of "stringent and centrally managed national standards for data and IT management" which resulted in the policy to develop NPfIT in October 2002 (Wanless, 2002).

However, as with all large scale IT-enabled business change, the success or otherwise of the policy or strategic plan is in its implementation and evaluation (Currie, 1989; Doolin, 2004; Hendy et al., 2005; Herzlinger, 1989). Many past IT projects have failed to deliver the desired benefits, but have produced a number of important lessons for decision-makers. These lessons are well documented in the literature and involve the lack of alignment between the business and IT strategy (Luftman, 2000); a lack of ownership and leadership of the IT project among senior decision makers (Brown, 2001); poor risk assessment skills (Heathfield, Pitty, & Hanka, 1998); over-scoping of the functional and technical specification leading to IT projects becoming over-budget and late (NAO, 2004); poor communication between program/project managers and potential users of the system (Currie, 1997); and inadequate resources to deliver/implement IT system (Wyatt, 1998).

In this regard, the NPfIT is not simply a large-scale, 10-year IT implementation, but a long-term, root and branch change initiative that will transform clinical and administrative working practices across a variety of healthcare settings. Unlike other industries such as finance and manufacturing, where rapid change is a key characteristic, healthcare, especially hospitals, for example, display highly institutionalized structures and practices, which, by definition, are more amenable to *incremental* rather than *abrupt, discontinuous change* (Scott et al., 2000). So against the current background of relative stability and persistence in working practices (institutionalised practices) and efforts to introduce large-scale business and IT change (market reforms), this exploratory study offers an evaluation of the implementation of one particular element of NPfIT: the Electronic Prescription Service (EPS).

METHOD

Data Collection and Analysis

Three methods of data collection were used. First, the researchers undertook a full literature review of the academic, government, and practitioner material on ICT policy and practice in healthcare. This literature was supplemented by clinical studies on patient safety, particularly those surrounding prescribing and adverse drug reactions (ADRs). Literature on e-health and electronic health/patient records was sought to inform the research enquiry. Second, the researchers attended conferences, workshops, and exhibitions on healthcare and ICT policy and practice. Data was gathered at the annual Egton Medical Information Systems (EMIS) national user group conference on the development, implementation and evaluation of ICTs in healthcare (EMIS being a major system used by GPs and other clinicians) and more specifically on the EPS. This data source is essential for providing up-to-date material about the communities of practice using ICT and other related topics (e.g., IT in policy healthcare, patient safety, hospital management, professional best practice, and performance measurement and risk assessment). Third, the researchers visited six GP practices and four retail pharmacies to conduct interviews with key stakeholders of the EPS. Our primary data collection was undertaken between January and September 2007. GP practices were selected in the South of England (3) and West Midlands (3) and retail pharmacies split equally between the two regions.

Research protocol for conducting social science research followed Yin (1994) and Miles and Huberman (1994) which include advice and techniques on developing a conceptual framework, pilot study design, formulating research questions, case study definitions (i.e., boundary and territory), sampling, ethical issues and bias, and cross-case analysis.

Since qualitative research methods, that is, ethnographies, may generate voluminous amounts of data, it is essential to deploy techniques that structure and organise the data for analysis. This study delineated the data into key research themes. Examples of potential themes include: ICT policy in healthcare, IT strategy, implementation and evaluation, patient safety, process, performance and risk assessment, and project management. The decision to adopt interviews as the key source of data collection enabled researchers to visit interviewees "on-site" to elicit data and information on the EPS "in practice." Since clinicians are unlikely to fill out questionnaire surveys (by post or over the Internet) due to time constraints and other reasons, our decision to adopt an interview protocol using face-to-face interviews on site enabled us to observe the material surroundings of the technology implementation. The data obtained from interviews and archival sources was analysed using a conceptual framework developed from prior research (Currie & Finnegan, 2007). We present our conceptual framework and results below.

A CONCEPTUAL MODEL FOR EVALUATING AN ELECTRONIC PRESCRIPTION SERVICE

This study delineates the EPS into four key themes for analysis as shown in Table 1: patient safety, process, performance, and public perception. Each theme incorporates important clinical and social science research questions in relation to the implementation and evaluation of the EPS. Increased automation of the prescription service demands particular attention to issues of patient safety, both at the clinical level and the practical level of using the EPS. We give an overview of three elements to patient safety in relation to monitoring data that may highlight adverse responses to medicine: the use of personalised medicines in prescribing and the need for more effective communication between stakeholder groups. This discussion focuses mainly on clinical concerns about patient safety in deploying EPSs. Next, we consider the process of using the EPS across healthcare organisations. A processual analysis of ICT encompassing all the three implementation stages is important since a static representation is unable to pinpoint issues of interoperability, at both the human and technical levels.

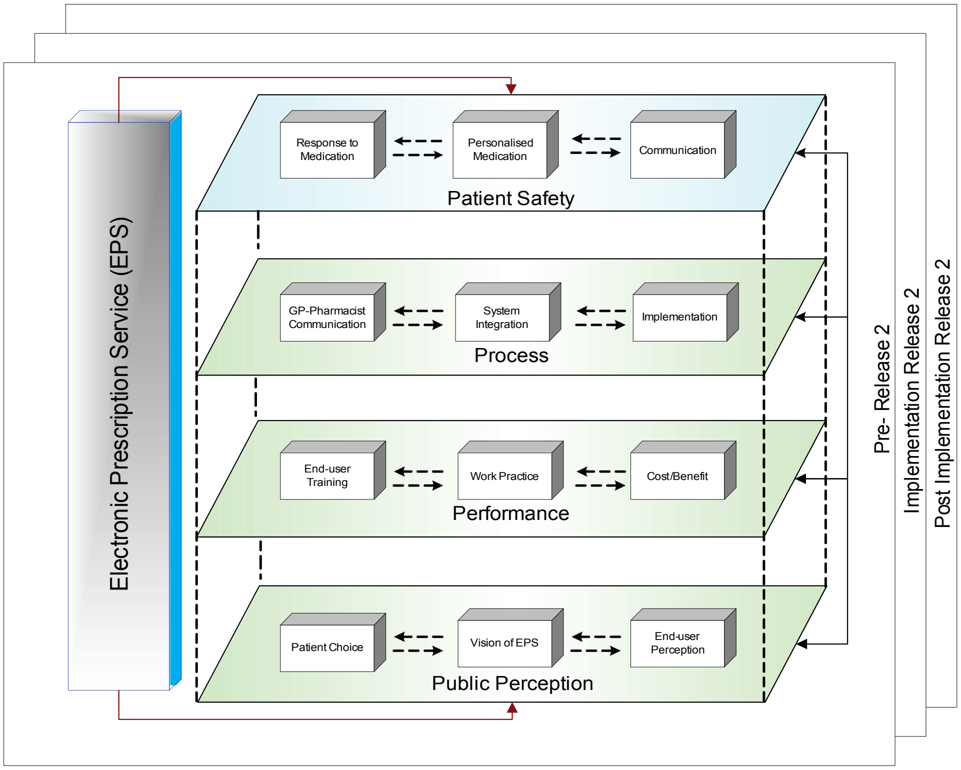
Patient Safety

There are two elements to patient safety that are critical to EPS implementation. The first involves clinical practice and the second, the administrative processes and performance of moving from paper to electronic health records. Ensuring optimal patient safety in prescribing requires relevant information on patient, medicine, and disease to be current at the time of issuing the prescription and effective communication with the patient regarding safe use of the medicine and clear advice regarding adverse reactions and when early health advice contact may be needed. This advice is needed to complement the

Table 1. Empirical data collection

	Type of Organization	Location	Size of GP Practice	Interviewee
1	GP Surgery	West Midlands	5 GP Practice serving ca 6000 patients	3 GPs
2	GP Surgery	West Midlands	4 GP Practice serving ca 4000	2 GPs
3	GP Surgery	West Midlands	4 GP Practice serving ca 5000	2 GPs
4	GP Surgery	Central London	8 GP Practice serving ca 11,500	3 GPs
5	GP Surgery	Central London	7 GP Practice serving ca 9,000	4 GPs
6	GP Surgery	East Sussex	4 GP Practice serving ca 4,500	2 GPs
7	Retail Pharmacy	West Midlands	5000 – 6000 customers	1 Pharmacist
8	Retail Pharmacy	West Midlands	4000 – 5000 customers	1 Pharmacist
9	Retail Pharmacy	Central London	6000-9000 Customers	2 Pharmacists
10	Retail Pharmacy	Central London	5500-8000 Customers	2 Pharmacists

Figure 1. Conceptual framework for evaluating electronic prescription service implementation



voluminous information in medicine packaging inserts. Adverse drug reactions (ADRs) are one of the largest preventable problems facing health services in the UK and beyond (Acute hospital portfolio—medicines management 2005/2006 (www.healthcarecommission.org.uk), contributing up to 7% of hospital admissions in the UK, at an estimated 2004 NHS cost of at least £0.5billion *per annum* (Pirmohamed et al., 2004) and over 100,000 deaths annually in the USA. Furthermore ADRs during long term treatment often lead to poor concordance with treatment (Davidsen et al., 1988) and increased pressures on primary and secondary care services. Serious adverse reactions are reported to contribute to around 1 in 20 admissions to hospital. Many of these are thought to be preventable within current medical knowledge and practice. Here, we are concerned with the potential risks and benefits of EPS in the context of the broad categories of preventable serious ADRs.

1. Failure to record and act on previous history of adverse response to the medicine in question, whether this is immune-mediated or predictable from current knowledge, for example, penicillin allergy, nonsteroidal anti-inflammatory drug (NSAID) dyspepsia. There are two major concerns here. First there is still an early stage in the development of robust electronic health records (EHRs) across diverse public and private primary and secondary care services and secure services in psychiatry and HIV management. Second, there are administrative delays in data being entered on electronic systems. Therefore, the new EPSs need a failsafe prompt to patients regarding previous and recent medicine related reactions before a prescription is issued.
2. Failure to personalise medicines within current medical knowledge, for example, to recognise that B-blockers exacerbate Chronic Obstructive Airways Disease (COAD), that there is need for caution in renal and liver impairment, prescribing in pregnancy, drug interactions. Limiting risk of drug interactions, therefore, means that the prescribing decision must be in the light of an up-to-date clinical history, current evidence based guidelines and "medicines reconciliation" at the time of each prescription issue/renewal. Concern about effective ways to improve current NHS problems with "medicines reconciliation" is currently the focus of joint action by National Institute for Clinical Excellence (NICE) and the National Patient Safety Association (NPSA) to develop new standards (http://guidance.nice.org.uk). There is increasing evidence on the impact of ethnicity on response to and risk of medicines. Ethnicity is not obvious from patient's name and formal prospective recording of ethnicity in primary care has only recently been introduced. To avoid an increase in preventable adverse drug reactions, the new EPS should replace the prescribers' previous role in checking risk markers before prescriptions are issued. Examples include checking whether there is dyspepsia or the haemoglobin has fallen before reissuing aspirin; checking. plasma sodium in patients on anti-depressant treatment with Selective Serotonin Reuptake Inhibitors; checking plasma potassium in patients before prescribing Angiotensin Converting Enzyme (ACE) inhibitors, angiotensin receptor blockers and potassium sparing diuretics; checking for infection and white blood count before reissuing carbimazole. These checks in some cases involve targeted interaction with patients, in others making sure that safety blood testing is in place and that results are integrated with EPS.
3. Failure to communicate effectively risks to the patient so that if adverse effects do occur the patient is prompted to seek medical attention early so that risk of progression to

> serious ADRs is minimised, for example, aspirin and dyspepsia. The new EPS removes a direct patient prescriber contact step. It is therefore vital that alternative, evidence-base validated, communication steps are in place regarding specific alerts for patients, re high probability and high risk adverse reactions and what steps the patients should take to prevent/limit progression of possible ADRs. Pharmacogenetics is now impinging on clinical practice as a way to reduce risk of ADRs with clinical licensing of suitable tests and clinical application of PG testing to high risk cancer chemotherapy, for example, to assess genetic variability in the enzyme thiopurine s-methyltransferase. Within the software life of the new EPS, trigger tools will be increasingly needed to make sure that need for and results of relevant new clinical tests are integrated within the EPS.

Process

The EPS has undergone a rigorous design, test, and build process to ensure that the system is capable of coping with the 1.3 million prescriptions handled each day across England. This process has been informed by the creation of a number of user groups, comprising GPs, pharmacists and patients, who meet regularly to discuss specific issues. In order to reduce the probability of any implementation issues affecting patients, the EPS is being introduced alongside the existing paper-based system. Initially, this will allow users to become familiar with the new software and processes before any significant changes affecting patients are introduced. The EPS process is intended to save time for GPs with regard to administering prescriptions, and is anticipated to bring a range of other benefits for patients and pharmacists. From a pharmacy perspective, it will reduce the possibility of incorrect medicines being dispensed to patients, by alleviating the need to manually input prescription data, and also give scope to improve pharmacy workflow and stock control. A significant benefit of the EPS is to reduce the paper administration with current prescribing and dispensing processes by enabling prescriptions to be generated, transmitted and received electronically. Dispensers will further submit reimbursement endorsements electronically to support claims for payment for medication and appliances supplied. Paper-based prescriptions will thus be reduced over time.

The EPS is being delivered in two main stages: Release 1 and Release 2. Moving from Release 1 to 2 is not expected to cause patients confusion. An addition is a barcode on the prescription form (which does not contain any patient details). When a GP prints out this "barcoded" form, an electronic copy of the prescription is automatically sent to the EPS. The barcode on the form contains a unique reference number which matches the prescription to the electronic copy. When a patient takes this prescription to a pharmacy that has also implemented Release 1, the dispenser will scan the barcode to retrieve the prescription details onto their system. If a patient takes a prescription form to a pharmacy that has not yet implemented Release 1 of the service, they can still obtain their medication in the usual way.

When Release 2 is implemented, the GP will be able to apply an electronic signature to the electronic prescription, making the need for a paper version obsolete. If they wish to, patients will be able to nominate a pharmacy for their prescriptions to be sent to automatically, meaning they will not need to visit their GP to collect repeat prescriptions. Patients will still be able to request a paper copy of their prescription if they prefer. Release 1 of the service is now in use at a number of GP and pharmacy "initial implementer sites." Wider rollout of Release 1 has commenced and it is planned for the Electronic Prescription Service to be fully operational across England potentially by the end of 2007. While patients currently collect repeat prescriptions from dispensers without having to go into the GP surgery, the EPS is intended to streamline this service by reducing pharmacy waiting times enabling dispensers to prepare prescriptions in advance. Other benefits for prescribing staff and dispensers include: signing and cancelling prescriptions electronically, nominating dispensing contractors using the EPS rather than by post, reducing the need to re-key data, managing stock control, and managing the submission of reimbursement endorsements electronically.

Performance

Performance is very much related to effectiveness of the process, its monitoring, and constant evaluation. To evaluate the performance of the EPS, we used process mapping tools to capture an end-to-end picture of the system. End-user perceptions, ownership and training are crucial elements to achieve "best practice" performance. Performance evaluation is not merely based on quantitative assessments but also on qualitative data to highlight the user perceptions of the strengths and weaknesses of the system.

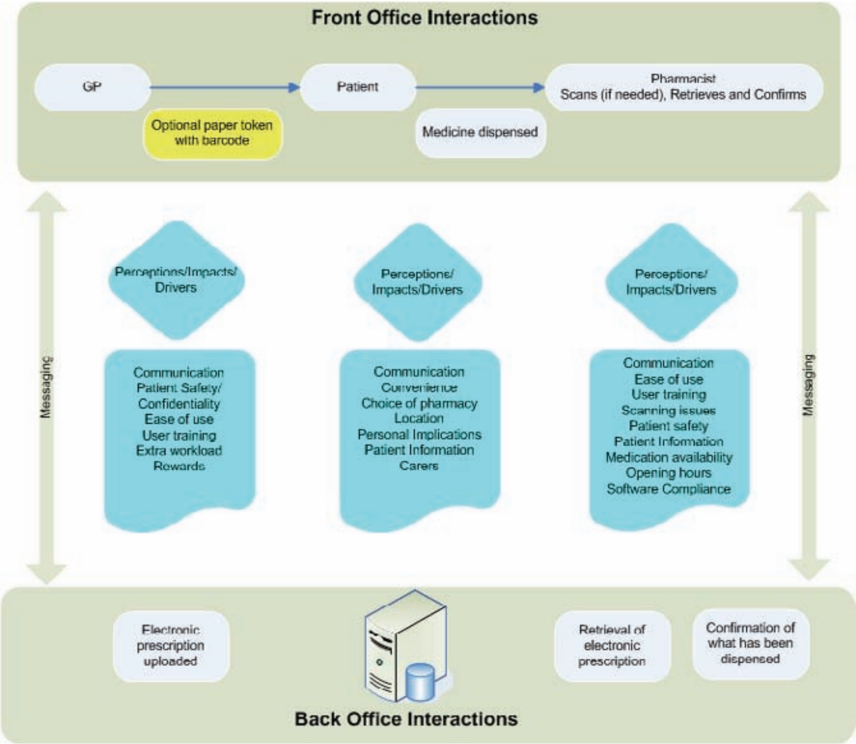
A preliminary study to understand the contemporary environment of EPS was carried out. Our interviews with GPs and retail pharmacists in London and the West Midlands about Release 1 of the EPS and also to gain insights into the Pre Release 2 of EPS highlighted the following performance issues:

1. A clear schedule is needed for the availability of EPS compliant systems from the suppliers
2. Dispensing practices need for EPS compliant software may create financial pressure on PCT
3. Neighbouring PCTs may be applying different registration rules causing confusion for pharmacists
4. Server problems and download times may affect the prescription download
5. All the GP practices would need to be equipped with modern printing technology in order to avoid the scanning issues if paper tokens are provided
6. EPS implementation may increase the Choose & Book system problems experienced in GP practices and vice-versa
7. EPS R2 may increase GP workload without offering any operational benefits
8. PCTs may be dragged into resolving pharmacy system EPS problems because of their responsibility for Role Based Access Control (RBAC) card issue
9. Pharmacists may be given extra work load and may choose to use the paper version of the repeat medication—the usefulness of EPS for repeat medication needs further investigation
10. The impacts of EPS on communication between the GPs and Pharmacists needs to be investigated further. Especially during and post implementation of release 2
11. The aligning of implementation of release 2 whilst release 1 is running in parallel is crucial

Public Perception

Incorporating the public perceptions in the evaluation highlighted issues relating to the vision of EPS and patient choice. The three phases of the EPS implementation—Pre Implementation, Implementation, and Post Implementation—are all relevant as public perceptions may change during each stage. Public perceptions are also related to the ease of use of the system. Part of the rationale for EPS is to provide patients with a more efficient and effective way of getting their medication. The stakeholders identified by Connecting for Health include: general practitioners, community pharmacies, patient and public groups, and an EPS implementation board. One of the key concerns identified by patient groups, for example, is around security of the system. Access to the EPS is controlled through the use

Figure 2. A process map of the EPS



of smartcards and pin numbers enabling different users varying degrees of access appropriate to their role. The PCT has overall responsibility to issue smartcards to users.

Figure 2 gives an example of the EPS. This diagram captures the formal process of the EPS incorporating key stakeholder groups (i.e., GPs, pharmacies, patients). The Front Office interactions present the interactions between the three key stakeholders namely the GP, the Patient, and the Pharmacist. The Back Office interactions highlight the processes needing to be qualified to complete the EPS cycle. While a linear presentation of the EPS is an "ideal type" (Weber, 1947) of the activity under scrutiny, it is recognised that, in reality, formal systems run in parallel with informal systems (Currie, 1989). An understanding of key issues identified in our conceptual framework (i.e., patient safety, process, performance, and public perceptions) must therefore be evaluated in conjunction with those actions and behaviours that reside alongside the explicit ICT design. Failure to recognise this is routinely found to be the cause of numerous ICT failures in both the private and public sectors (Currie, 1995; Willcocks & Lester, 1999).

Figure 2 offers a conceptual tool for evaluating the three phases (pre, during, and post) of the EPS implementation. Interviews with GPs suggested that EPS was one of the least contentious elements of the NPfIT. One GP commented,

The initial problems with the EPS have largely been technical, rather than human. For example, we had some issues with the printers here as they needed to be laser jet printers. Inkjet didn't work. The new printers seem to work now and can produce a barcode without smudge.

While this example may seem trivial, the consequences of poor images through using the wrong type of printer has major implications for the effectiveness of the EPS. Clearly, smudged images could lead to human error at the retail pharmacy and this could have implications for patient safety.

Another GP said, “Our system is not yet compatible but we are told we can get it updated. There has not been sufficient support from above for EPS I think.”

The GPs in the sample tended to think the centrist approach to NPfIT and EPS more specifically was not the most appropriate way to introduce ICTs into healthcare. Part of the problem of this approach is because decision making on ICTs is influenced by financial and practical considerations within a market which is becoming increasingly fragmented. For example, the GPs and pharmacies were independent businesses with profit/loss statements. So the decision to purchase new technology was linked to financial considerations which could conflict with the implementation timescales set out by Connecting for Health.

DISCUSSION AND CONCLUSION

This exploratory research into the EPS, which is part of the NPfIT highlighted some interesting issues concerning patient safety, the process of executing prescriptions, performance indicators, and how GPs and the public perceive ICT-enabled change. While EPS is designed to give patients more flexibility and choice in how they collect their prescriptions, we identified some issues relating to how GPs would interact with retail pharmacies to improve this service. Our conceptual model points to the criticality of evaluating the EPS as an ongoing implementation rather than at particular points in time. For example, the successful transaction between a patient receiving their prescription and collecting it at a retail pharmacy depends not simply on their own input in this process, but whether the GP and pharmacy have invested in technology that facilitates this process. As we saw from the interview data, a simple issue of using the wrong type of printer is likely to disrupt the service, particularly where retail pharmacies are unable to read the data printed.

At the macro level, the EPS is designed as a nation-wide ICT solution, yet our research suggests that its implementation is likely to be patchy rather than seamless across GP and retail pharmacies. The staged approach used by Connecting for Health, where particular sites will be first-mover implementers of the EPS may offer some advantages to others who can learn from past mistakes and errors. However, the standardised approach to this large-scale ICT implementation will also depend on how it will be developed and upgraded and this will depend on the cooperation between GP and pharmacies, particularly as these groups run their own businesses and thus develop their own ICT policies and practices.

An interesting issue relates to the translation at local level of centrist ICT policies, of which NPfIT belongs. Clearly, for EPS to work effectively, GP practices and pharmacies need to invest in the appropriate technology. But as with all technical expenditure, an evaluation of the likely return on investment (ROI) is needed. The perception of whether EPS will result in additional business for pharmacies, or even GP surgeries, is therefore likely to be central to the purchasing decision, as improved service delivery is not an end in itself.

Our conceptual framework offers a general and integrated approach to evaluating the EPS, recognising that each of the four levels represent serious challenges to ICT implementation. We suggest that even minor changes to work practices, for example, are likely to engender significant resources, not least because GPs, retail pharmacies, and patient groups are likely to interpret change differently. Equally, cost savings and performance enhancements may not be perceived as benefits in their own right by different stakeholders. One of the critical elements in large scale ICT change is how to manage expectations. This softer and less tangible aspect of change management is rarely given enough priority by policy-makers, managers, and suppliers, as technology "solutions" are often over-sold to clients. As such, the imposition of performance targets invariably results in a mis-match between client expectations and the supplier's ability to deliver on ICT policy issues. This has resulted in many critical judgements on the NPfIT in the media, often highlighting the failure to meet strict implementation targets. While these issues are relevant, more important concerns relate to managing change as a continuous, iterative process rather than as a linear one. Such an approach does not separate strategy from implementation, but recognises that these areas are linked. Managers need, therefore, to continuously assess how ICTs are changing working practices and whether business processes are being integrated or disjointed as a result.

In summary, we suggest our case data highlights some relevant issues that need to be evaluated on a continuum rather than as a staged activity. Our conceptual model is multidimensional and the variables contained within each layer may change over time, as new issues and concerns are raised. We concur with the findings of the National Audit Office (2006a, 2006bb) that clinical buy-in is imperative in the NPfIT initiative, but we also suggest that concepts of "patient choice" also need to be clarified, particularly as patient experiences do not include ICT design, yet do include participation in using systems, such as EPS, even where there are problems and pitfalls. An evaluation of EPS, and NPfIT more generally, should therefore include not only a silo assessment of how each stakeholder group interacts with technology, but how all the pieces of the jigsaw fit together in terms of patient safety, process, performance, and the public.

ACKNOWLEDGMENT

The authors would like to thank professor Donald Singer, Warwick Medical School, for his comments relating to patient safety issues.

Developing a User Centered Model for Ubiquitous Healthcare System Implementation:

An Empirical Study

ABSTRACT

In the advent of pervasive computing technologies, the ubiquitous healthcare information system, or u-health system, has emerged as an innovative avenue for many healthcare management issues. Drawing upon practices in healthcare industry and conceptual developments in information systems research, this article aims to explain the latent relationships amongst user-oriented factors that lead to individual's adoption of the new technology. Specifically, this study focuses on the introduction of chronic disease u-health system. Using the ordinary line square (OLS) regression analysis, we are able to discover the insights concerning which constructs affect service subscriber's behavioral intention of use. Based on the data collected from over 440 respondents, empirical evidences are presented to support that factors such as medical conditions, perceived need, consumer behavior, and effort expectancy significantly influence the formation of usage intention.

INTRODUCTION

Ubiquitous computing can be defined as the "contemplation of today's computers communicating each other through wireless network in actual activities of everyday life" (Weiser, 1993a; 1993b).

Some articulate such a concept as the embedded computers in walls, refrigerator, tables, and objects in the surrounding environment (Rhodes & Mase, 2006). In other words, the computer is expected to become a ubiquitous resource, much similar to the light with a switch and water with a tap. Two functionalities, computing tasks and telecommunications, are required to realize the features of ubiquitous computing such as localized information, localized control, and resource management (Weiser, 1993a; Rhodes & Mase, 2006). The evolving mobile technology has expanded the applicability of ubiquitous computing to areas including virtual reality, head mounted display (HMD), wearable computing, and smart office room (Weiser, 1993b).

An agile, responsive, and location-aware service delivery system is highly desired by the healthcare management business. Correspondingly, ubiquitous computing allows patients to receive prompt medical care anywhere (home, office, outdoor, or hospital) and any time (24 hours/7 days), thus improving the service quality and decreasing the risk of medical treatment failures. For example, a doctor can check the status of a patient in a real-time manner using the sensor which is installed in patient's home or attached to the patient's body. In case of emergency, the sensor can detect changes of the patient's health condition in the early stage and automatically contact the designated hospital to initiate treatment procedure. In summary, we define the u-health system as the use of ubiquitous computing technologies to support expeditious and personalized communications, activities, and transactions between a medical service provider and its various stakeholders. In the literature review section, Figure 3 describes the layout of the u-health system and its associated stakeholders.

Despite the strong potential of the technology, however, the studies of ubiquitous healthcare services are not widely conducted. Existing literature has focused mostly on pure technical concerns or system development process; whereas managerial issues and behavior perspectives of the u-health system application are largely overlooked. In this article, the authors discuss the issue of applying ubiquitous computing technology to healthcare management from end user's perspective. The main goal of this article is to identify and investigate the factors and their inter-relationships that affect end user's intention of adopting u-health system. For example, one critical factor is effort expectancy, which refers to the degree to which the user believes it is easy to use the technology. Theoretically, the effort expectancy is positively correlated with behavioral intention of use, namely, the easier the user finds to use the product, the more likely s/he will adopt it. A more thorough articulation of these factors can be found in the Research Model and Hypotheses section.

Realizing that the scope of healthcare discussion can be extremely broad, we focus our attention on chronic disease treatment in this research. A main question to be addressed is what factors influence end user's perception about the u-health system and how these factors are related with each other. Therefore, an investigation of people's subjective perception is warranted. The authors select South Korea as the place for data collection because first, people in South Korea have a high level of concern about health issues, especially chronic diseases. Largely due to the rapidly changing socio-economic structure, more than 16% of total population is reported to suffer from chronic diseases. According to a report by the Korean National Insurance Corporation (2007), South Korea is among one of the top countries that are mostly concerned with chronic diseases; second, South Korea has one of the highest mobile technology penetration rates in the world, thus providing a suitable environment for studying ubiquitous healthcare technology. In South Korea, more than 85% of Koreans use at least one cellular phone and subscribe wireless value added service (Shim, 2007).

Regarding the organization of this study, the authors first examine the current knowledge base in both medical research and supportive technology aspects. Such literature review process enables us to consolidate theoretical and practical findings so that a research model is developed to cater for our core research issue—understanding the perceptions of chronic disease patient towards u-health system. Next, we present the data analysis results that empirically validate the proposed hypotheses. At last, we conclude our findings and contributions.

LITERATURE REVIEW

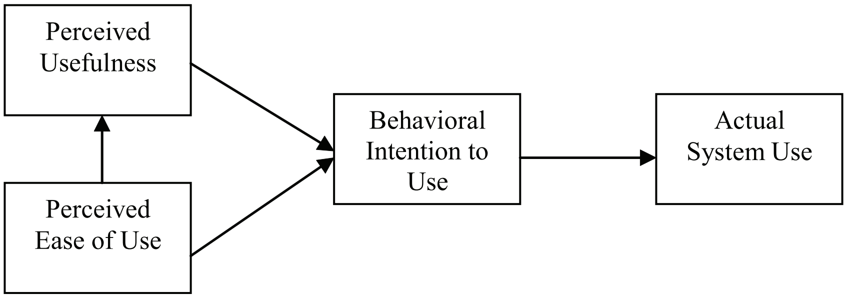
It is widely recognized that the IT innovation has historically and continually benefited healthcare business in numerous aspects. For instance, collaborative computer system allows healthcare workers to reengineer and streamline business processes within medical service life cycle by leveraging software and network applications. In the case of u-health system implementation, we need to consider both soft and hard factors. Soft factors are subtle factors containing people's experiences, feelings and perceptions; whereas hard factors refer to the instantiations of computing technology (e.g,. a HIPPA-compliant patient accounts management system). Following such idea, the purpose of reviewing previous literature is two-fold: to establish the scope of this study; to build preliminary ground work for utilizing earlier findings in the area of healthcare management to guide our research activities.

Prior Research in Healthcare Management Information Systems

The evolution of HMIS can be summarized as a transferring process from isolation to integration (Briggs, Nunamaker, & Sprague, 2005). Initially installed in stand alone PCs, HMIS took shape among segments of healthcare management process, such as drug inventory and account administration (Tan, 1995). Due to the soaring operational cost of healthcare and increasing need for cross-boundary collaboration (Bandyopadhyay & Schkade, 2000), a true HMIS was introduced and adopted by organizations including the Health Maintenance Organization (HMO). Information and communication technology provides healthcare industry with capabilities to perform tasks that are deemed impossible in the past. For instance, a medical center uses broadband video conferencing technology to enable a group of specialists to examine the patient, who is located in a far- distanced hospital.

Since technology adoption has been considered as one of the main driving forces behind the growth of healthcare expenditures (Barros, Pinto, & Machado, 1999), numerous studies have been done to investigate the factors influencing HMIS adoption on the organization's side (Wong & Legnini, 2000; Berta et al., 2005). These studies make contributions in terms of designing and validating cost-effective procedures that facilitate system adoption process and identifying envi-

Figure 1. The TAM model (Davis, 1989)



ronmental factors that influence the success of systems adoption. On the other hand, the authors found that extensive attention has been put on physicians' intention of using invested information technology (IT) products. However, further research is needed to investigate the role of the patient, who is the ultimate service subscriber, in the process of healthcare system implementation (Hu, Chau, Sheng, & Tam, 1999). Another viable lens for explaining subscriber side information system usage is the technology adoption model (TAM), which was formalized by F.D. Davis in 1989. Davis argued that the user's intention of use is essentially determined by two constructs: perceived usefulness (PU) and perceived ease of use (PEOU), as seen in Figure 1.

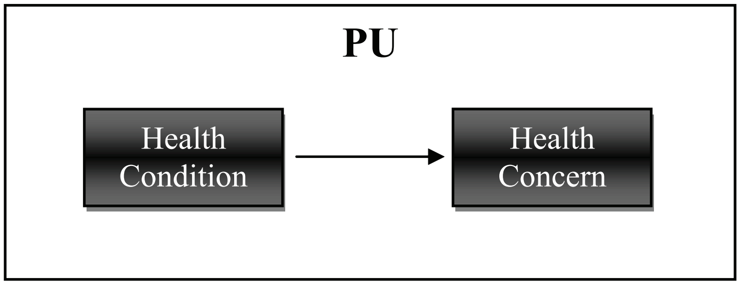
Parsimonious and generalizable notwithstanding, TAM becomes less robust in this research context because it fails to address some unique dimensions of u-health technology adoption. Therefore, we need modifications (e.g., broken down PU) that customize TAM constructs so as to accommodate the issue of chronic disease healthcare management. For instance, PU can be articulated as the formative relationship between health condition and health concern, as shown in Figure 2. The patient's awareness of his/her health condition leads to health concerns, which essentially form the evaluation of PU of suggested medical solutions. In this way, an example has been set up concerning how PU can be adjusted to apply technology acceptance theory under different research topics. A comprehensive discussion of research model construction is presented in the Research Model and Hypotheses section.

The U-Health System Concept and Targeted Problem Domain

Leveraging computing devices that are available yet invisible in the physical environment , u-health system is a built-in application combining technologies, methods, and procedures that aim to monitor, maintain, and improve individual's health condition (Park, 2003). One salient feature of u-health system is the anytime anywhere accessibility, which allows the real-time information of patient to be collected and then transmitted to medical organization for a cure or diagnosis (Yoo, 2006). With its surging penetration rate in global range, personal mobile device such as cellular phone offers an important platform on which the u-health system concept can be realized. The challenge, however, lies in the seamless integration between mobile technology and the existing data network infrastructure.

This study put a specific focus on the implementation of the u-health system in South Korea for chronic disease patients, whose number is increasing steadily and raises health concerns of the society. Treating chronic disease such as diabetes, tuberculosis, and anemia requires long-term treating efforts and care from both patient and medical center. In addition, effective communication between patients and medical service provider is critical in stabilizing patient's condition

Figure 2. Modifying PU (Davis, 1989)



(e.g., diabetes). Hence, the u-health system offers a promising solution that enhances information dissemination throughout the healthcare service delivery cycle. A visual description of a typical the u-health system implementation is presented in Figure 3. Using wired and wireless network, the u-health system has the following advantages (Korean National Insurance Corporation, 2007):

- Delivering a time-efficient medical service
- Automating communications among stakeholders
- Real-time detection of patient's conditions
- Easy portability of patient's historical medical records and prescriptions
- High level of accessibility and flexibility mitigating the effects of time and place constraints

In Figure 3, a sensor, which can be a patient's cellular phone or wearable computing device, measures the health status of the patient and transmits the information to u-health service provider, who maintains a large collection of patients' records in a database server. The patient's status is then forwarded to medical personnel in the hospital for diagnosis and possible treatment, which can be transmitted back to the patient over the same network.

RESEARCH MODEL AND HYPOTHESES

Many of the contemporary health problems, especially chronic diseases, are mostly related with life style changes such as smoking or unhealthy dietary pattern (McKeown, 1971; Riska, 1982). The medical research model that is based on individualistic-mechanistic notion of disease argues that an individual's willingness to improve his/her health status results in the changes of his/her behavior and thus promotes health status positively (Cohen & Cohen, 1978). Such willingness can be generated and motivated by the perceived personal health condition, namely, the medical concern. An individual who has a negative evaluation of his/her health condition is proactive to adopt healthcare service or activity that is believed to improve one's health condition (Lahiri & Xing, 2004). Further, health condition is considered a critical starting point in the healthcare utilization process (Windmeijer & Santos Silva, 1997). Therefore, it is assumed that a negatively perceived health condition leads to more medical service usage or activity to improve the health status.

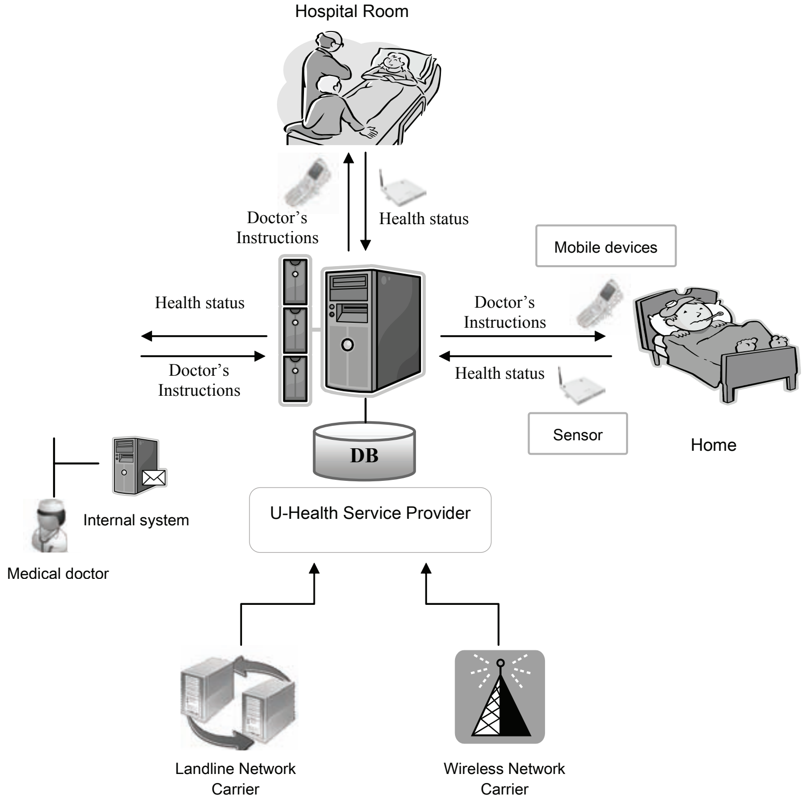
When people perceive health problems, they are likely to raise their health concerns about subsequent medical consequences. Such concern, in turn, can lead to certain activities including health information seeking, adherence to treatment, and interpretation of symptoms (Uskul & Hynie, 2007). Earlier studies have argued that the Internet has become the new alternative source of healthcare information (Eysenbach & Köhler, 2003; Madden, 2003; Morahan-Martin, 2004). Other research has suggested that patients diagnosed with chronic diseases appear to be active in seeking the medical information. Therefore, a high level of concern about health problem and consequence leads to more active medical service usage. Hence, it is important to specify and validate the mediating effect of medical concern, as shown in Figure 4, between medical condition and action taking.

Following the previous discussion, the authors contend that individuals who are actively involved with preventive or restorative healthcare measures are more likely to use the u-health service. Such argument can be further decomposed into the following hypotheses:

H1: *High level of medical concern leads to active medical activity.*

H2: *Perceived medical condition leads to active medical activity.*

Figure 3. The u-health system

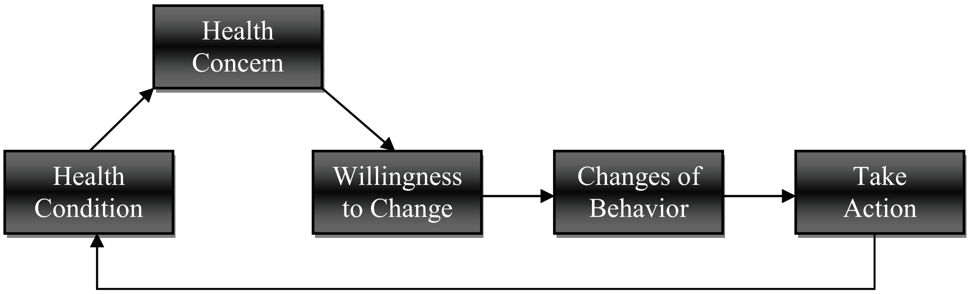


H3: *Perceived medical concern mediates the relationship between medical condition and medical activity.*

H4: *Active medical activity leads to behavioral intention of use.*

Specifying the relation between consumer needs and purchase intention has been a major research topic across various fields (Bhaskaran & Hardley, 2002; Odom, Kumar, & Saunders, 2002; Burke & Payton, 2006; Chae, Black, & Heitmeyer, 2006; Kervenoael, Soopramanien, Elms, & Hallsworth, 2006). The capability of identifying and satisfying the consumer's needs basically determines the success

Figure 4. Mediating effect of medical concern



of promoting a certain product or service (Lahiri & Xing, 2004). Several studies (e.g., Junginger et al., 2006; Zhang, Fang, & Olivia, 2007) have provided strong evidence indicating the effects of consumer's perceived need on the purchase intention. On the other hand, such need is positively correlated with perceived quality and perceived usefulness of the service or product. Moreover, users accept new technology when they expect certain performance improvement in completing tasks. If people believe the technology will be useful in increasing their job performance, they are more likely to adopt the technology (Davis, 1989; Venkatesh et al., 2003). Hence, we hypothesize that:

H5: *High level of perceived need for the u-health system leads to behavioral intention of use.*

It has been established in previous IS adoption literature that the behavioral intention of use is affected, although not exclusively, by effort expectancy, which is defined as the degree of ease associated with the use of the system (Venkatesh et al., 2003). The concept of effort expectancy is rooted in earlier constructs such as perceived ease of use in technology adoption model (TAM) (Davis, 1989) and perceived level of difficulty in theory of reasoned action (TRA) (Ajzen & Fishbein, 1975). In our research model, we articulate effort expectancy in two dimensions: experience and consumer behavior. Several studies have identified how significantly experience (e.g., learning) is related to job performance (Guido, 2007; Ngwenyama, Guergachi, & McLaren, 2007). These results strongly support the argument that experienced workers are more efficient and more productive in performing tasks than less experienced ones. Hence, it is inferred that experienced users of ubiquitous or mobile technology are more likely to use the medical service offered through

Figure 5. The Research Model

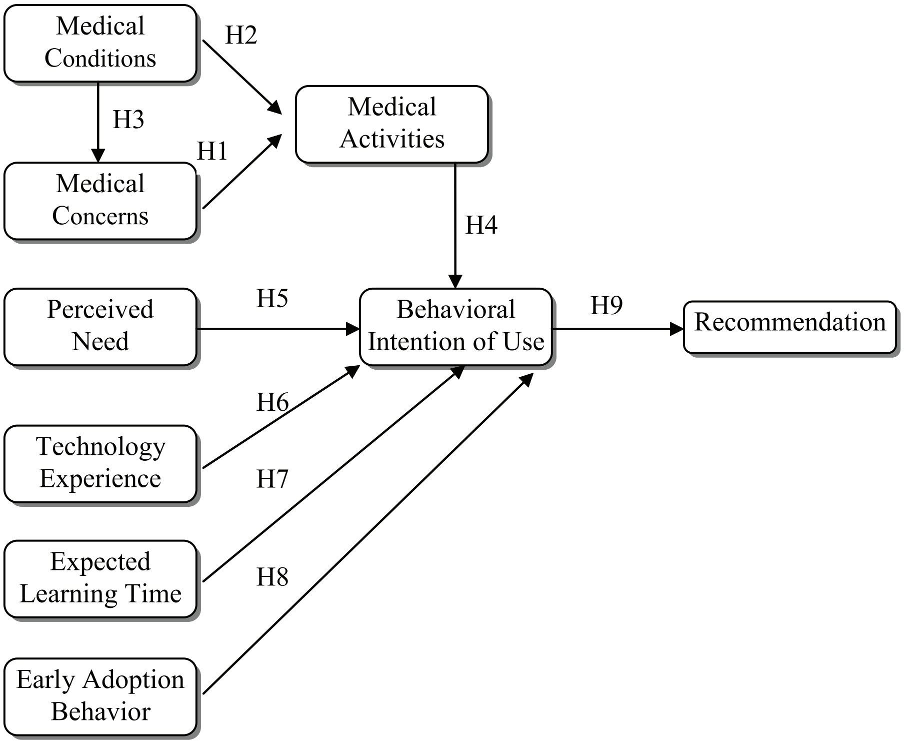


Table 1.The nine hypotheses

	Independent Variable	Dependent Variable	Description
H1	Medical Concerns	Medical Activities	High level of medical concern leads to active medical activity.
H2	Medical Conditions	Medical Activities	Perceived medical condition leads to active medical activity.
H3	Medical Conditions	Medical Concerns	Perceived medical concern mediates the relationship between medical condition and medical activity.
H4	Medical Activities	Behavioral Intention	Active medical activity leads to behavioral intention of use.
H5	Perceived Need	Behavioral Intention	High level of perceived need for u-health system leads to behavioral intention of use.
H6	Technology Experience	Behavioral Intention	High level of mobile technology experience leads to behavioral intention of use.
H7	Expected Learning Time	Behavioral Intention	Low level of expected time to learn how to use u-health system leads to behavioral intention of use.
H8	Early Adoption Behavior	Behavioral Intention	Early adopter behavior leads to behavioral intention of use.
H9	Behavioral Intention	Recommendation	High level of behavioral intention of use leads to recommendation.

the u-health system, namely, the less time a user needs to learn how to use u-health system indicates a lower level of adoption barrier.

Consumer behavior theory classifies the types of consumers according to how early they purchase the products. Innovators, or early adopters, are willing to take perceived risks to adopt newly introduced technology. So it is expected that an individual who follows the behavior of innovator would adopt the u-health service earlier than the follower or late adopter. Some researchers have identified certain correlation between the early adoption behavior and business success on the organizational level. For instance, Hendricks and his colleagues (2007) point out that early adopter firms report higher profitability improvements of ERP systems than late ERP adopter firms. Moreover, Smith (2006) suggests that large companies are inclined to be the early adopter of mobile commerce and thus reap the first mover benefits. To sum up, we hypothesized that:

H6: *High level of mobile technology experience leads to behavioral intention of use.*

H7: *Low level of expected time to learn how to use u-health system leads to behavioral intention of use.*

H8: *Early adopter behavior leads to behavioral intention of use.*

Finally, the recommendation construct is considered in our model because, for managers, it is critical to estimate the future purchase or repurchase of the services or products (Gupta & Stewart, 1996; Morgan & Rego, 2006). Hence, the hypothesis of the inter-relationship between behavioral intention of the u-health system use and customer recommendation is stated as the following:

H9: *High level of behavioral intention of use leads to recommendation.*

Based on the above hypotheses, we propose our research model in Figure 5. In addition, we summarize the previous hypotheses in Table 1.

RESEARCH METHODOLOGY

To test the hypotheses, the authors employ the ordinary line square (OLS) regression analysis to pinpoint predictor variables' contribution in explaining the variances of dependent variable—behavioral intention of use, which is also a mediator variable that describes how recommendation effects will occur. In academia, it has always been a fundamental dilemma for social researchers when attempting to maximize the three dimensions of research methodology: generalizability, precision, and realism. In other words, one cannot increase one of these three features without reducing the other one or two (McGrath, 1982). Therefore, it is up to researchers to justify their selection of research process that has the best goodness of fit with the research context. In this case, the authors determine to focus on the generalizability dimension mainly because the aim of this research is to obtain a finding that can be generalized to wider population, namely, chronic disease patients. Although a certain level of the in-depth knowledge is lost, it would essentially lead to another research project, such as a qualitative case study, that can make up for the deficiency.

As mentioned earlier, the research design of this study aims to account for usage intention formulation of u-health system that provides services to chronic patients. However, it is generally difficult to directly assess the quality of prescription service, especially in the case of chronic patient. The expertise of healthcare professional, the capability of healthcare system, and communication with the customer play respective roles in determining the service quality. The authors contend that it is not our top priority to validate strengths of u-health system in the aspect of service quality improvement, but to scrutinize the factors influencing the user's perception of adopting the system. To administrate the data collection process, a broad range of survey was distributed in South Korea, where there is a high level of concern about chronic disease. As a rule of thumb in social research, the satisfactory sample size is 200 effective responses at least. In this research, the authors were able to obtain effective surveys from 447 respondents and thus achieving a good sample size in order to warrant the significance of statistical findings. In terms of respondents' characteristics, most of feedbacks were collected from people who are aware of or understand chronic disease and have experience in using wireless computing technology.

Data Analysis and Results

In this section, the results are presented according to the following order: healthcare- related factors, perceived need, effort expectancy, and recommendation.

Healthcare Related Factors

As shown in Table 2, the medical concerns (H1) and medical conditions (H2) positively affect medical activities. In other words, individuals with a high level of medical concern, or poor medical condition, are more likely to be involved with medical activities such as taking medicine and regular exercising to maintain or to improve their health status.

To test the mediate effect, in which medical condition leads to medical activity through medical concern, the authors employ the four-step

Table 2. Test of the influence of medical concern and condition on medical activities

Model	Un-standardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	1.214	.204		5.949	.000
medical concern	.241	.037	.270	6.541	.000
medical condition	.225	.023	.399	9.670	.000

F=73.698, p=0.000, R^2=0.249.

approach proposed by Baron and Kenny (1986). The first step is to examine the direct effect of independent variable (medical condition) on dependent variable (medical activity). The second step is to test the relation between independent variable and mediate variable (medical concern). The third step is to conduct regression analysis focusing on the inter-relationship between mediate variable and dependent variable. The final step is to conduct regression analysis of the overall effects of independent variable and mediate variable on dependent variable. The mediate effect is proved to be significant when the effect of the coefficient in the first step is *not* significantly different from zero *and* the coefficient in the third step is significantly greater than zero. If both conditions are satisfied, a fully mediated model is said to be found (Frazier & Tix, 2004). In this study, Table 3 indicates that the effect of medical condition on the medical activity through the medical concern (H3) denotes partially instead of fully mediated relationship. The major reason is because the coefficient of medical condition is significantly different from zero while the coefficient of the medical concern is also significantly greater than zero. Hence, it is argued that medical concern partially mediates the formative relationship between perceived health condition and medical activity.

The results in Table 4 show that the effect of medical activities on the behavioral intention (H4) is not significant in this case. However, the scatter plot, as shown in Figure 6, provides an alternative explanation that the relationship between the two variables is not linear. In the plot, behavioral intention (Y-axis) appears to be significant in the left and right areas across the line of medical activities (X-axis). In the middle area of medical activities, however, the correlation is scattered and loose.

Table 3. Test of the influence of medical condition on medical concerns

Step	Model	Un-standardized Coefficients		T	Sig.
		B	Std. Error		
Step 1	Medical condition → medical activity	.237	.024	9.779	.000

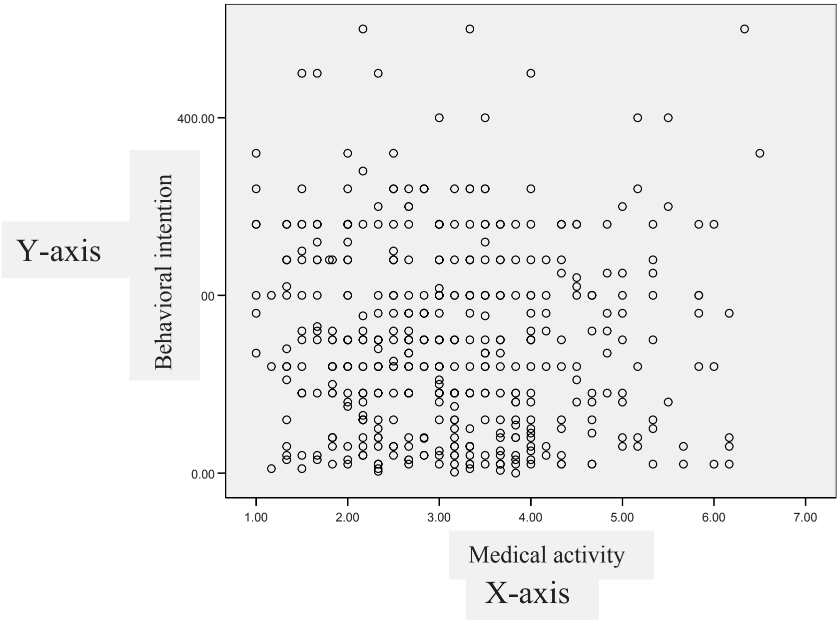
medical activities	-2.869	4.237	-.032	-.677	.499

F=.458, p=.499.

Figure 6. The scatter plot between medical activities and behavioral intention



Such u-shaped regression curve is subject to receiving two transformations in statistical analysis: logarithmic form and quadratic form. In this study, quadratic model is applied and the correlation between medical activities and behavioral intention is significant at LOS .05, as shown in Table 5 and Figure 7.

It can be inferred from previous discussion that individuals in two extreme groups are more prone to use u-health system. Those in the right extreme (high medical activity group) have higher concerns and poorer health condition than other groups. Such concerns and conditions would lead to the usage of innovative technology that might be helpful to improve their health status. On the other hand, the individuals in the left extreme (low medical activity group) do not give much attention to their health status due to several restrictions. For example, because of high work pressure, many employees have a difficult time arranging healthcare consulting service on a regular basis, which serves as a complementary reason for increasing cases of chronic diseases. Therefore, these people may realize the potential advantage of u-health system and thus believe that u-health system is able to eliminate the restrictions of accessing medical services. Individuals who are in the middle group may be satisfied with the current treatments for

Table 5. Test of the influence of medical activities on behavioral intention (Quadratic model)

Equation	Parameter Estimates		
	Constant	b1	b2
Quadratic	236.413	-55.900	7.737

F=3.889, p=0.021, R^2=0.017.

their health status management and find few benefits in seeking other solutions due to the economic lock-in effect.

Perceived Need

Referring back to the literature review, we have found a plethora of theoretical arguments validating and explaining the relationship between the customer's perceived need and purchase attention. Such argument is also verified in this research context. According to the statistical results shown in Table 6, the perceived need (H5) for u-health system positively affects behavioral intention. It strongly supports the fact that individuals having a high demand for u-health system are more likely to use the service than those who have lower need.

Effort Expectancy

In Table 7, the analysis of effort expectancy indicates that early adoption behavior (H8) and expected learning time (H7) for considering adoption are negatively connected with behavioral intention at the 0.05 level of significance. It is relatively easy

Figure 7. The scatter plot of quadratic estimation between medical activities and behavioral intention

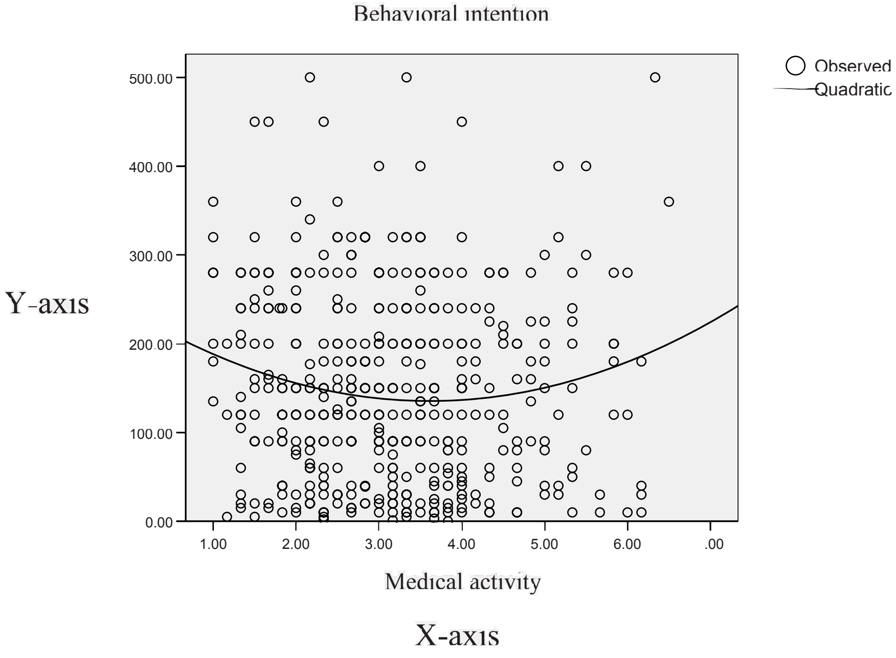


Table 6. Test of the influence of perceived need on behavioral intention

Model	Un-standardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	51.293	16.126		3.181	.002
Perceived Need	20.586	3.229	.323	6.375	.000

F=40.640, p=0.000, R^2=0.104.

to consider that the less learning time is needed to use the system, the more likely the behavioral intention of use can be formed. Whereas for H8, since we use a reverse scale, that is, 1 represents strong and 5 means weak, for measuring early adoption behavior, there is negative correlation between those two factors. In congruence with the theory, individuals who are early adopters are more likely to accept u-health service. However, experience of using mobile technology (H6) is not significant at the 0.05 level. It can be attributed to the high mobile technology penetration rate in South Korea. Since people are already skillful in using mobile device, there is lack of concern in technology experience that leads to behavioral intention of u-health system use.

Recommendations

According to the data analysis (shown in Table 8), higher behavioral intention leads to higher recommendation, which encourages the continuance of system use and reuse through customer recommendation after initial adoption behavior.

The results for all hypotheses testing are summarized in Table 9. An individual would not take action until s/he perceives his/her medical condition, which are supported in H1, H2 and H3. The impact of medical activities to behavioral intention of using medical product (e.g., u-health system) is non-linear. Tow groups of individuals, high medical activity group, those who have higher concerns and poorer health condition, and low medical activity group, those who do not give much attention to their health status due to some restrictions (e.g., tight working schedule), are estimated to have a high desire of adopting convenient healthcare services enabled by IT. The perceived need of individual leads to positive formation of behavioral intention of use. Whereas people will be reluctant in adopting the product if it takes too much efforts and the learning curve is too long, which leads to another inference

Table 7. Test of the influence of adoption behavior, experience, and expected time on behavioral intention

Model	Un-standardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	311.662	21.742		14.335	.000
Adoption behavior	-13.440	6.803	-.126	-1.976	.049
Experience	2.143	1.266	.100	1.693	.092
Expected time	-23.756	4.215	-.352	-5.637	.000

F=18.103, p=0.000, R^2=0.180.

Table 8. Test of the influence of behavioral intention on recommendation

Model	Un-standardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	.511	.035		14.498	.000
Behavioral Intention	.001	.000	.314	6.980	.000

F=48.718, p=0.05, R^2=0.099.

that the early adopters of new technology is estimated to have a lower barrier to embrace the new system. Once the behavioral intention is formed, the user is likely to recommend the product to others based on the previous positive experience obtained.

DISCUSSION AND CONCLUSION

The authors argue that consumer's intention of using the u-health system can be better understood if it is viewed through a multi-faceted framework. In this article, we draw upon literature from different paradigms including specific medical research and technology acceptance and use. The article's basic premise is that medical factors, perceived economic needs, and effort expectancy exert formative impacts on the consumer's behavioral intention. Such premise is then broken into a series of hypotheses in Table 9 extending the discussion to a further detailed level. By validating these assumptions, we are able to obtain more insights in terms of how key adoption factors interact with each other.

Table 9. Summary of Hypotheses Testing

	Independent Variable	Dependent Variable	Hypothesized Effect	Support
H1	Medical Concerns	Medical Activities	Positive	Yes[1]
H2	Medical Conditions	Medical Activities	Positive	Yes
H3	Medical Conditions	Medical Concerns	Positive	Yes (Partially)
H4	Medical Activities	Behavioral Intention	Positive	No (Non-linear)
H5	Perceived Need	Behavioral Intention	Positive	Yes
H6	Technology Experience	Behavioral Intention	Positive	No
H7	Expected Learning Time	Behavioral Intention	Negative	Yes
H8	Early Adoption Behavior	Behavioral Intention	Negative[2]	Yes
H9	Behavioral Intention	Recommendation	Positive	Yes

1. *The default level of significance for all hypotheses testing is .05.*
2. *Revere scales are used for the measurement.*

The statistical findings contend that a high level of health concern and perceived health condition positively lead to relevant medical activities including regular sport exercises and consulting with doctors. Although the data analysis does not support direct formative relationship between medical activities and actual u-health system adoption (e.g., people who visit doctors might not intend to use the u-health system), a further investigation on the data indicates that two groups of potential users—people who have a high level of health concerns and poor health condition and people who are unable to manage their health issues due to limitations such as severe work pressure—are more likely to use the system. Moreover, as many other studies have argued, the perceived need or perceived value of the system is found positively related with behavioral intention of use. In congruence with seminal theories including TAM, the study shows that individuals who are early adopters are more likely to accept u-health service since the expected learning cycle is short, or, the system is easy to use. The expected learning time is measured using reversed scale hence it has a negative relationship with the behavioral intention of use. Some of the limitations in this study lie in the measurements development and some insignificant statistical findings, which hinder us from better validating our proposal. Future efforts are required to shed light on designing and validating measures that would fill the voids in this study. Also, since no single research can maximize the three features of research process: generalizability, precision, and realism (McGrath, 1982), a different perspective can be obtained through a qualitative case study of u-health system or other innovative healthcare services.

Chapter 4.17

Current Practices in Select Healthcare Systems

Venkat Sadanand
University of Saskatchewan, Canada

ABSTRACT

In this chapter, current practices of healthcare delivery in three economically advanced countries will be reviewed. Is healthcare delivery commensurate with economic prosperity? Countries with technological and economic advantages may be better poised to deliver healthcare efficiently. However, this is not the case in fact. The following review will show that medico-legal and technological prowess may not translate into a healthier life and better healthcare delivery. It will be argued that poor allocation of ample resources is tantamount to resource insufficiency. The chapter will cite anonymous but true cases of patients to illustrate the salient points.

DOI: 10.4018/978-1-60566-772-0.ch001

INTRODUCTION

In this chapter, current practices of healthcare delivery in three G8 countries will be reviewed. Does economic prosperity lead to a better quality of delivered healthcare? Countries with technological and economic advantages may seem to be better poised to deliver healthcare efficiently. However, this may not be the case in fact. The following review will show that medico-legal and technological prowess may not translate into a healthier life and better healthcare delivery. Distribution of wealth does not necessarily correlate with the distribution of health. It will be argued that poor allocation of ample resources is tantamount to resource insufficiency.

In the attempt to provide improved healthcare for its citizens, many of the G8 countries have tried everything in the spectrum from a publicly funded healthcare system to a fully private system. Common to all these are the intimidating waiting lists for doctors' appointments or surgeries. Some may argue that a waiting list is an inevitable by-product of an economically efficient healthcare system. Patients who are deemed to be surgical candidates are obviously quite ill and possibly in pain. If you ask such a patient if a waiting list is acceptable, the answer would be a resounding rejection of such a concept.

The issue at hand is more than an argument about what constitutes a welfare system. The concept of economic efficiency in healthcare is a red herring. To be efficient from an economic standpoint may not be the same as efficiency in the distribution of healthcare. One may argue that a competitive market resulting in economic efficiency may result in a distribution of wealth with people holding extremes of wealth or poverty. Inequities in health distribution may be a similar outcome of an economically efficient system. The United States of America is an example of this disparity in healthcare. There can be no such tradeoffs in healthcare. In an efficient healthcare system, one cannot accept a dichotomy with some people having ready access to healthcare and some having none. The existence of such a state of society is, admittedly, a failure of the healthcare system. Society must see to it that the last person who needs healthcare receives it.

Some may be quick to interpret this as an advocacy of socialism. In truth however, there is no such thing as socialism in healthcare. Socialism is an economic concept. Wealth distribution is an economic concept. But an equitable distribution of healthcare is as much a necessity as the distribution of oxygen. Everyone ages and every aging person is a potential healthcare consumer. Healthcare is a prime example of market failure. Therefore the allocation of healthcare by free markets is inherently inefficient. The reason a market for healthcare fails is due to (a) the existence of externalities discussed below and (b) the existence of transaction costs and asymmetric information. President Barrack Obama and Secretary of State Hillary Clinton have both strongly emphasized the philosophy that "every American has the right to affordable healthcare" during their 2008 presidential campaigns. Yet a waiting list is a denial of that essential service of healthcare.

In such a context what is a surgical or patient care waiting list? One may have a society where all its citizens have access to healthcare but are placed in a waiting list to see their doctor or to receive appropriate surgical intervention. How does this differ from a society where some have immediate treatment of their illnesses and some do not? The emergence and establishment of surgical waiting lists must therefore be considered a cost to society due to pain and suffering of those waiting patients. The impact on the patients' quality of life and society's productivity is obvious. In the written words of the Supreme Court of Canada Chief justice Beverly McLachlin in the 2005 *Chaoulli v. Quebec (Attorney General)* case, "Access to a waiting list is not access to healthcare."

Consider, for example, patient D.L. from Canada who has a brain tumor compressing on her optic nerve. She was virtually blind in one eye and was losing vision in the other. She was placed on a waiting list and it took several months for the surgery to decompress the tumor. On the day of the scheduled surgery, she was "bumped" and the surgery was cancelled due to unavailability of beds. One month later, her vision now worse, she was taken to surgery emergently. As another example, in the specialty of ophthalmology, the mean waiting time for cataract surgery in Canada was 17 weeks in 2005 (Conner-Spady, B.L., Sanmugasunderam, S., et al., 2005). Patients in the U.K. have had to endure long waiting lists for surgery, some as long as six to nine months (Martin, R., Sterne, J.A.C., Gunnel, D., et al., 2003). Even in the U.S. with a mostly private healthcare system, waiting lists are not uncommon (Hurst, J., & Siciliani, L., 2003).

How then do these waiting lists emerge? Can anything be done to improve such a system which tolerates the pain incurred by waiting patients in stark contradiction to its mission to care for the health and suffering of its citizens? In the Supreme Court of Canada judgment (Chaoulli v. Quebec, 2005) above, all justices of the Supreme Court agreed that such delays can affect the patient physically and psychologically and may cause irreparable harm.

This chapter will compare the healthcare systems of Canada, the United Kingdom and the United States of America. The purpose of this comparison is not only to understand the genesis of surgical waiting lists in economically advanced countries, but also to find solutions by increasing efficiencies in existing allocation of resources rather than additional capital investment. For example, it is seen in what follows that increasing capital expenditures or hospital capacity does not strongly correlate with improved healthcare status in the U.K. but it does in the U.S. This is possibly related to the way the healthcare system is financed.

CANADA

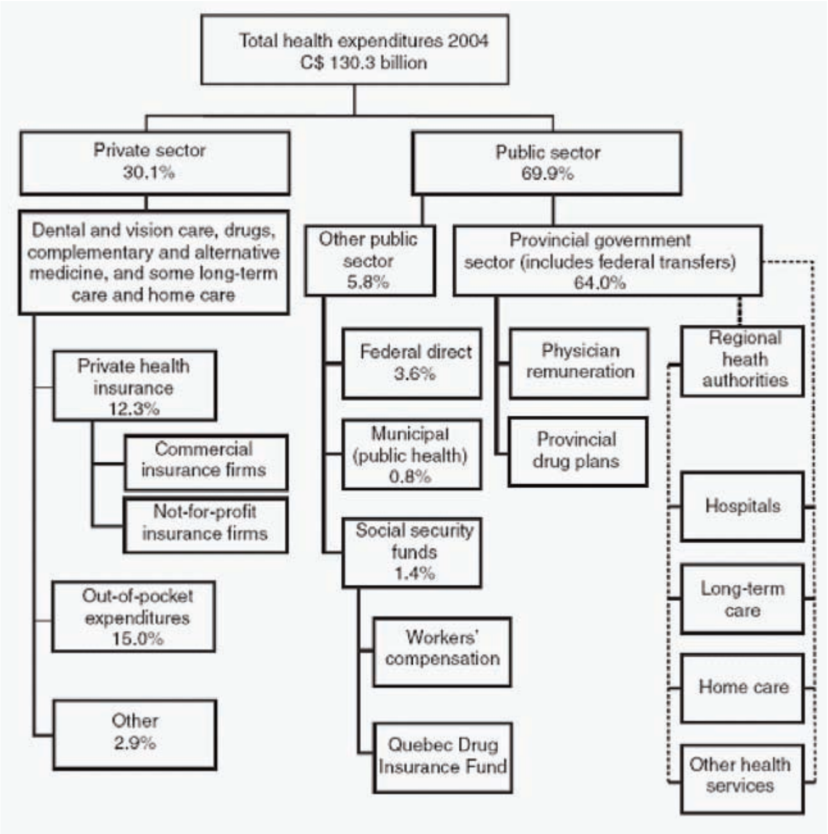
An attempt at universal healthcare was first legislated in Canada in the province of Saskatchewan in 1946. This eventually led to the Medical Care Act in 1966, which provided a framework for each province to offer a universal healthcare system. The success of this led to the Canada Health Act of 1984 and a commitment by the federal government to support the well-developed healthcare system predicated on the principles of universality, portability, comprehensiveness, public administration and accessibility (Lewis, S., Donaldson, C., et al., 2001). Thus, the government insures every Canadian and this insurance is portable anywhere in Canada. The Canada Health Act requires that every hospital and physician should be financed only by the government with no individual user charges. In addition, there cannot be any third party coverage for these services nor can a hospital or physician accept third party insurance for their services for Canadians. The fiduciary responsibility of healthcare delivery is relegated to individual provinces. However, there is a complex revenue sharing agreement between the federal government and the provinces that serves as a financial spigot, which can be turned off if individual provinces do not abide by the Act. This could potentially threaten the transfer of funds from the federal to the provincial government should a province choose to accept third party insurance or charge extra billings to patients.

Year after year the federal government sits with the provinces to renegotiate the transfer payment agreements. The little band-aid changes to the transfer agreements negotiated during these meetings did not do much to fundamentally alter the efficacy of healthcare delivery. Population demographics was changing with time and the healthcare budgets were falling behind unable to respond to these changes. Eventually, there was a stagnation in the real amount of spending for healthcare in the provinces leading to nation-wide reviews of the healthcare system. This led to a series of reforms, most notably, a decentralization of healthcare budgetary decision to regional health boards (Province of Alberta, 1994).

The key requirement in the Canada Health Act is that physician and hospital services be 100% publicly financed. But the provision of these services can be private. Doctors need not be government employees. Hospitals are non-profit corporations. However, there have been some recent developments in several provinces that have to be considered in assessing their impact on patient waiting lists. (Figure 1)

The Canada Health Act governs the financial conduct of hospitals and physicians. With an aging population, there has been an increase in the relative financial outlay for prescription drugs

Figure 1. Canada: Financing of health care, 2004 (Source: Chart data from CIHI (2004) Improving the health of Canadians. Ottawa, Canadian Institute for Health Information. Chart in Marchildon GP. Health Systems in Transition: Canada. Copenhagen, WHO Regional Office for Europe on behalf of the European Observatory on Health Systems and Policies, 2005.)



and community care. The latter is not under the purview of the Act. For example, in 1971, the median age in Canada was 26 and in 2001 it was 37.2. In addition, the percentage of people over 65 years of age is expected to grow from 8%in 1971 to 26.5% in 2051 (Statistics Canada, n.d.)

Second, the federal and provincial governments seem to have done little to respond to changing demographics and increasing demands on the healthcare system. The regionalization system appears to have divided the accountability for patient care between the provincial governments and the regional boards. Thus, if a patient in Saskatoon needs urgent medical or surgical care of a certain kind, the regional boards seem to have no moral responsibility to provide that and, in fact, may be better off sending the patient to another province or to the U.S for that care. Patient care costs for medical care received in another province are borne by the province, not by the regional board. The way the incentives work, regional boards may as well have more services rendered to patients from outside the province and thereby use their limited resources for their immediate needs. In the economics literature this is a classic problem of what is known as 'externalities.' The best examples of these inefficiencies are derived from the polluting factory. Consider a factory that produces computer hardware. Supposing the firm installs a production process by which the chemicals used in the process of etching circuit boards and microprocessors are washed away and deposited in a nearby flowing river. Or, for that matter, pollutants may be released underground and thereby pollute the water table. In either case, the cost of polluting the river or the water table is not borne by the factory. It is indeed borne by downstream fisherman or those who consume that water. Since those costs do not enter the balance sheet of the polluting company, its production decisions, which are guided by its costs, are completely blind to the enormous costs imposed on others. Such myopic decision-making by firms are rectified by taxing the firm for it's output so that the costs of cleaning up the river or water table is seen by the firm as a tax. This will enter its balance sheet and thereby affect its production decision. Such a process is called "internalization of costs". The costs of certain decisions taken by the health boards are not borne by the health boards but accrue to the governments and the patients. Excess use of carbon-based fuels and resulting high pollution levels is another example of externalities and wrong production decisions. In the context of Canadian healthcare and the recent regionalization, these externalities must be internalized. One possible approach to achieve this is by imposing an actual or implicit tax on the regional health boards for patient pain and suffering from waiting lists. The problem, however, with this approach is that health boards are not for-profit organizations and such taxes will do little to internalize the externalities.

The next approach to rectifying the problem of waiting lists is to view the situation from another perspective. The literature on Game Theory has looked into the problem of incentives in complex contracts under asymmetric information. One of the most popular theory is the principal-agent model. In these situations, one individual (the principal) contracts with another individual (the agent) to undertake a task whose outcome will affect the welfare of the principal and when the principal lacks information about the efforts or production process known only to the agent. In the context of Canadian healthcare, the Federal government is the principal who hands over a sum of money to the agent who is the provincial government who has to undertake the task of providing healthcare to its citizens. The Ministry of Health in the provincial government then pays its agent (the regional health boards) to deliver healthcare. So one has to examine the incentives to perform in a model where there is one principal-agent relationship (Federal Government – Provincial Government) and this, in turn, results in another principal-agent relationship (Provincial Government – Regional Health Board). The final output affects the welfare of the patients. The broader questions is: how can one structure incentives at all levels so that the healthcare is delivered with efficiency and patient welfare is maximized? This question and its solutions have been well-addressed by "Contract Theory". In their book on Economics, Organization and Management, Milgrom and Roberts (1992) develop the conditions for designing an efficient contract. One of the conditions is called the "informativeness principle". This states that any measure of performance that reveals information about the effort level chosen by the agent should be included in the compensation contract. Hence, waiting lists and underemployment of specialists are clearly monitored data. By including them in the Federal transfer of funds for healthcare, the two agents are given the proper incentives to reduce waiting times and hence patient suffering. Thus, if Federal transfer of funds are sensitive to patient waiting times and availability of specialists, then Provincial governments and regional health boards will find ways to reduce those waiting lists and provide an adequate supply of specialists for the patients. Short waiting lists should be rewarded with higher levels of funding while long waiting lists should trigger decreased funding. While this sounds counter-intuitive, the incentives it provides in a principal-agent setting will nevertheless achieve efficiency in healthcare delivery.

There is also the issue of strategic representation or misrepresentation by regional health boards with the current incentives. Larger waiting lists will provide sufficient rationale for the heath boards to request a budget increase. If the Provincial and Federal governments award such an increase, pursuit of higher budgets will result in increasing waiting lists and chronic shortage of specialists.

Finally, in some provinces, marginal privatization has developed. Day surgery clinics have sprouted that offer surgeries for which the patient does not require hospital admission.

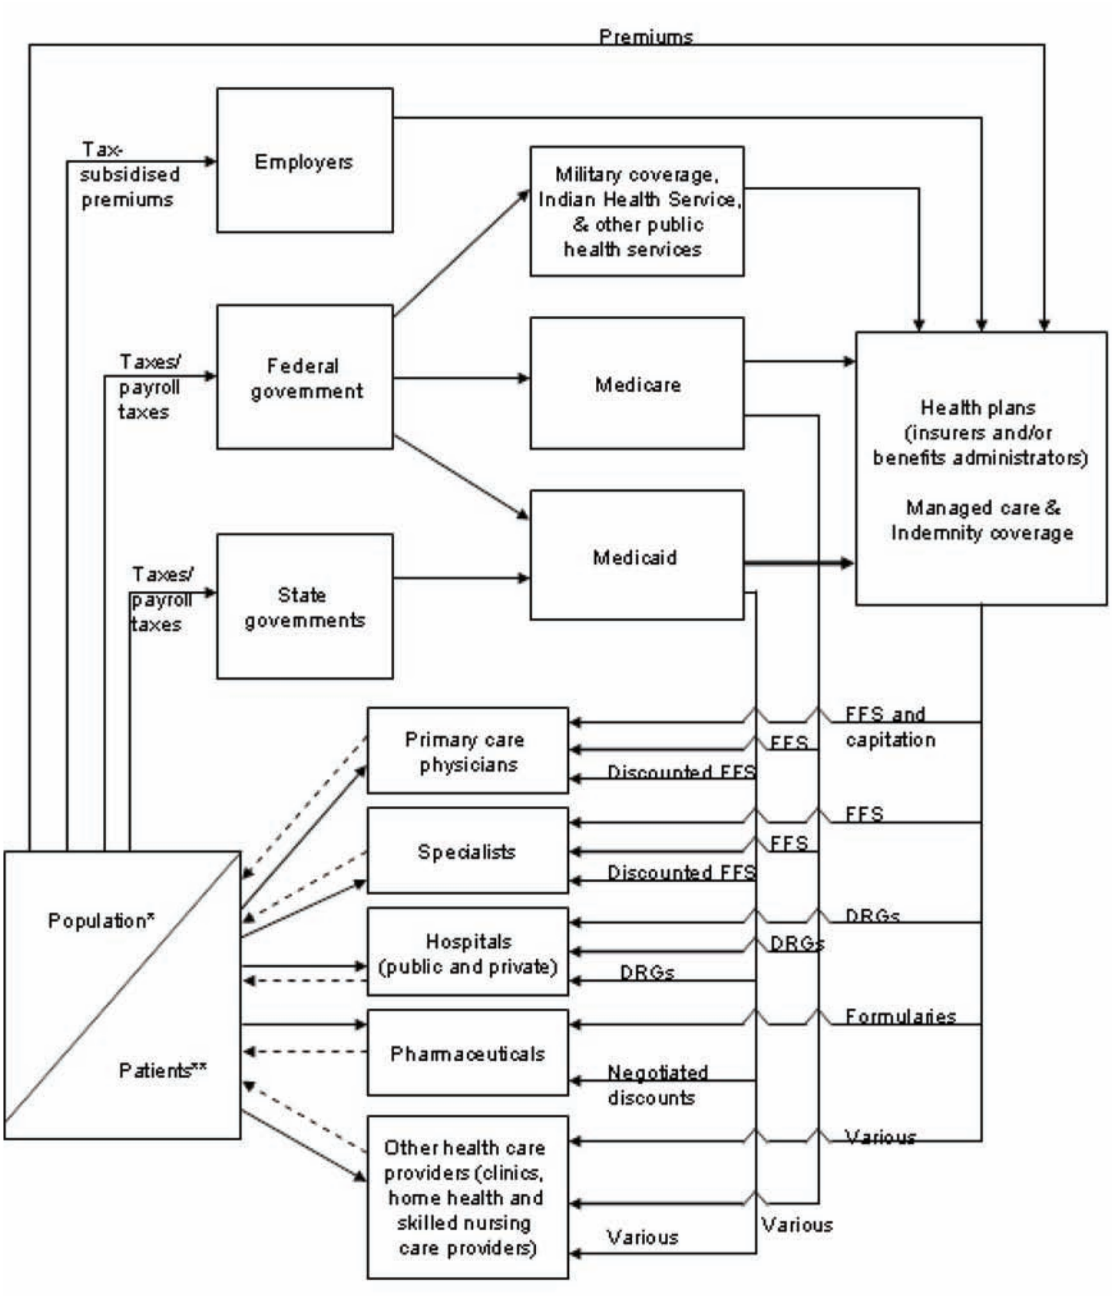
How then do these factors affect healthcare delivery in Canada? First, in contrast to a market driven healthcare system, a public healthcare system ignores the realities of demand and supply. Supply decisions are made with little concern for current or future demand. This leads to rationing and wait lists. Patients have to wait for diagnostic imaging, surgery, hospital emergency room and even access to a primary care physician (Esmail N., Hazel, M., & Walker, M.A., 2008). From the time a specialist decided to undertake treatment to the time the patient actually receives treatment is a waiting time during which all parties agree treatment is needed, but treatment is however not given. In the specialty of neurosurgery, for example, the 2008 waiting time from decision to treat to treatment is 19.4 weeks, which is one of the highest in any OECD country (Milgrom, P., & Roberts, J., 1992). Mean 2008 waiting time for an MRI scan was 9.4 weeks. Second, the availability of modern medical technology is restricted. For example, neuroendovascular techniques have evolved into a subspecialty in neurosurgery several years ago and most countries have nation-wide centers of excellence for these modalities of treatment for cerebral aneurysms. However, the province of Saskatchewan has yet (at the time of writing this book) to have a neuroendovascular facility, which is already the standard of care throughout the world. Third, the recent trend of new private day-surgery centers have eased the burden on surgical waiting lists and the government has so far looked the other way as these centers have clearly improved patient access to critical surgeries and physicians.

In summary, the Canadian healthcare system is founded on principles that are now ignored. Patients do not have timely access to healthcare and not having such access is, indeed, denial of healthcare. Suffering while on a surgical waiting list can only be appreciated by those who suffer, and least by those whose administrative decisions lead to waiting lists.

UNITED STATES OF AMERICA

In contrast to the Canadian healthcare system, the U.S. has adopted a market-based system. Private insurance companies cover a majority of individuals for their healthcare costs. Employers pay for the coverage. But employment is not a guarantee of health coverage. In 2005, nearly 15% of employees had no health insurance coverage from their employers (DeNavas-Walt, C.B.P., & Smith, J., 2007). In 2007, nearly 45 million Americans or about 16% of the population have no insurance coverage at all. Private insurance covered 68% of the population (DeNavas-Walt, C.B.P., & Smith, J., 2008). The insurance companies and the government depending upon the coverage held by the patients compensate physicians and hospitals. Most hospitals are private enterprises. Thus the purchase of medical equipment is viewed as an investment by the hospital, which reaps greater returns on the investment if more patients use the equipment. This is in contrast to Canada where new equipment is often viewed as a drain on a fixed budget. As a result of this availability of medical technology in the United States, it is currently one of the most advanced nations in the world in healthcare technologies. For example, in 1990, the number of MRI units per million population is 3.69 in the United States compared to 0.46

Figure 2. United States: Financing of health care, 2003 (Source: OCED Secretariat, 2003)



in Canada (DeNavas-Walt, C.B.P., & Smith, J., 2008). (Figure 2)

Despite market forces at work, patients in the United States do encounter waiting lists for surgeries, emergency medical care and physician appointments. Canada's rationing is supply based while the United States rations based on price. That is, those who cannot afford healthcare are doomed to a parallel inferior system where waiting lists and poor accessibility are the norm. In a market-based system, the allocation of resources is shifted in favor of those sectors where the marginal returns are higher. In 1986 the United States Congress passed an Act called EMTALA (Emergency Medical Treatment and Active Labor Act) requiring hospitals and ambulance services to provide care to anyone needing emergency treatment regardless of their ability to pay. Hence the uninsured patients crowd emergency rooms for routine ailments that are best managed in physician offices. This generates wait times for insured patients. The same price rationing consequences apply to surgical wait times. Although these times are much smaller than in Canada and the U.K. they nevertheless exist and represents a failure of a market based system.

A recent OECD study found that the major factors reducing waiting times for elective surgery are: higher number of acute care beds, higher surgical activity levels in hospitals, fee-for-service remuneration, a higher healthcare budget and a lack of fixed budgets for hospitals. Surprisingly, the study demonstrated that a younger population is not a factor in reducing waiting times. In a multivariate analysis in the same study it was found that the number of acute care beds and the number of physicians and specialists had the largest impact on waiting times (Fuchs, B.C., & Sokolovsky, J., 1990).

In summary, the United States does have waiting lists for elective surgeries, but the waiting times are an order of magnitude less than those in publicly funded systems. The humanitarian considerations for uninsured people, makes the system for insured people slightly inefficient. However, the principal (insurance company) – agent (doctors and hospitals) model in the United States is much closer to full efficiency than in Canada and the United Kingdom.

UNITED KINGDOM

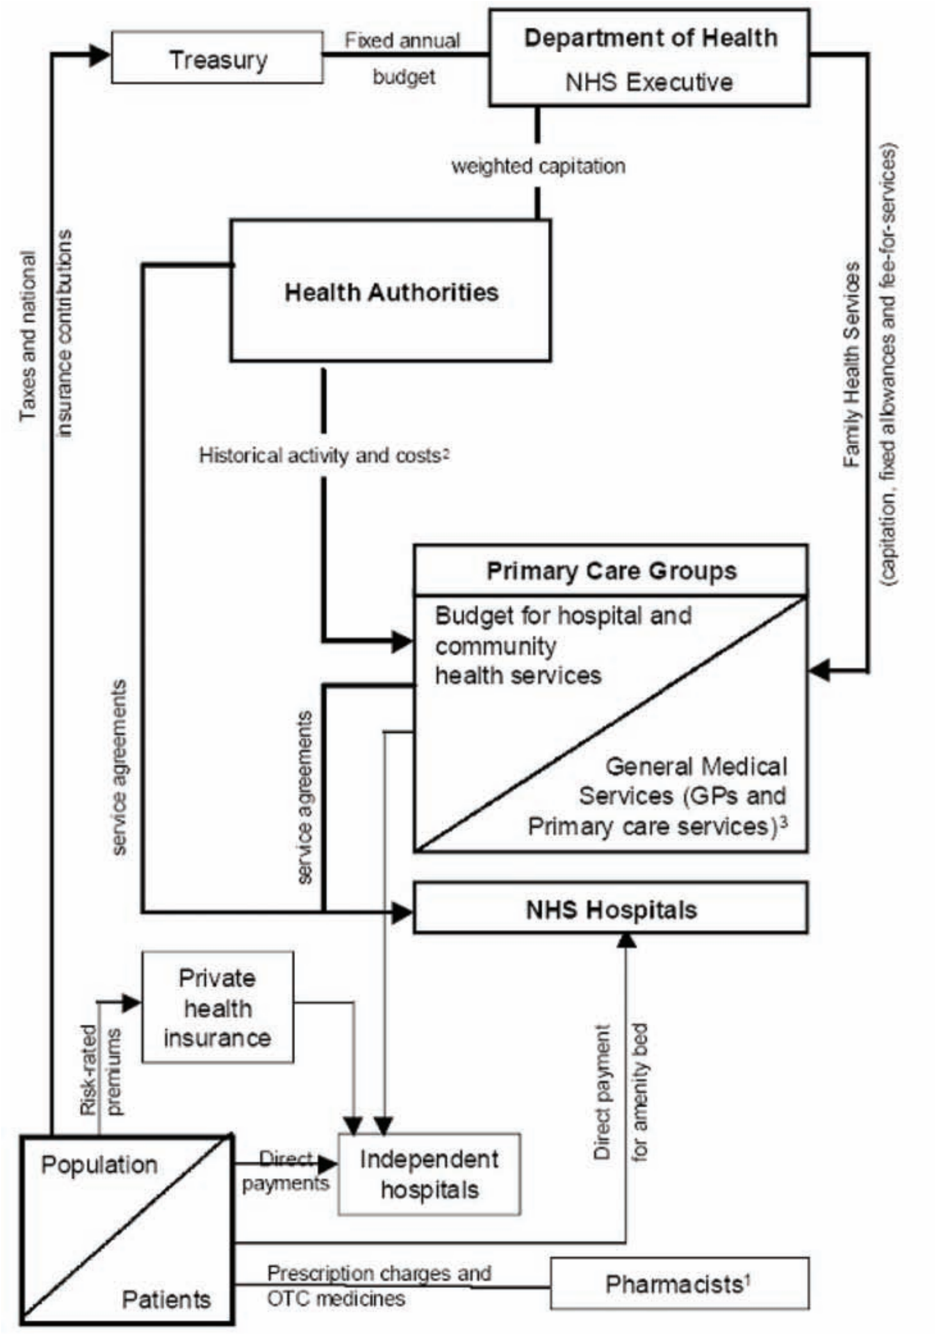
Healthcare in the United Kingdom works under a blend of public and private systems. The National Health Service (NHS) refers to four publicly funded healthcare systems in the U.K. with its components in England, Scotland, Wales and Northern Ireland. In addition, citizens may choose to purchase private medical insurance for hospital and doctor services. In 2001, 11.5% of the population held private medical insurance (Siciliani, L., & Hurst, J., 2003). Furthermore, 40% of adults with private medical insurance are in the top decile of income. As a percentage of total healthcare expenditure, public to private ratios were 83.3:16.7 (Laing, W., & Buisson, C., 2001). NHS does not cover all necessary medical treatment costs. The benefits are ill defined and its decisions are based on an analysis of costs and benefits of a particular medical technology, pharmaceutical or procedure. The National Institute for Clinical Excellence makes such recommendations. In some instances the health authorities may make rationing decisions. Drugs may be excluded because of poor therapeutic value or excessive costs. Employers mostly purchase private medical insurance provided by for-profit and non-profit organizations and most are group policies. NHS patients must have a referral from a GP to access secondary level care with specialists.

With poor hospital capacities and low per capita specialists figures, waiting times to see a specialist was on the average 13 weeks in 2001-2002 (Laing, W., & Buisson, C., 2001). NHS Trust hospitals had the longest waiting lists with between 52% and 83% of patients waiting longer than six months for elective surgery found in 25% of NHS hospitals (OECD Health Data, 2001). Interestingly, this study found that in contrast to the United States data, not much association was found between waiting times and hospital capacity and number of beds. Paradoxically increasing the number of specialists increased average waiting times suggesting that the supply of doctors induced demand. Individual level of employment, affluence and urgency of disease shortened waiting times. This mostly indicates the relative efficacy of the private medical insurance arm 40% of whose subscribers are in the top income decile as noted above. (Figure 3)

COMPARISONS

The three OECD countries discussed above have three different healthcare systems although many

Figure 3. United Kingdom: Financing of health care, 1999 (Source: Health Care Systems in Transition: United Kingdom, 1999. European Observatory on Health Care Systems)



would argue that the U.K. and Canadian systems are closer in principle to each other than to the United States. Recent OECD health data revels some interesting differences among these three countries (Martin, R., Sterne, J.A.C., Gunnel, D., et al., 2003).

Table 1 below, gives an estimate of waiting times for surgery in the United States compared to key OECD countries in 2001 (Mohan, R., Mirmirani, S., 2007).

The following comparisons of resource allocation in the three countries are from the OECD 2008 health data. (Table 2)

Table 1.

United States	5
Australia	23
Canada	27
New Zealand	26
United kingdom	38

An Example

Given an understanding of the heathcare systems in the three countries, this section will consider as an example the generation of waiting lists in one of the provinces in Canada. We will specifically consider two kinds of surgical waiting lists: waiting lists by the specialist to see the patient after referral by a GP and patient waiting lists after a decision is made to undertake surgery.

Consider the first waiting list. Family physicians or GPs send a referral letter to the specialist. The specialist then places the patient on a clinic waiting list. This waiting list is generated due to the limited hospital and outpatient facility resources as well as the limited number of specialists that the health boards have decided to recruit. Thus, a specialist can only run a fixed number of clinics per week. The number of clinics is independent of patient demand for referrals. There may be days when the specialist has time to see patients but the hospital and outpatient facilities do not have the resources to allow the specialist to see patients as the same resources are shared by several specialists. In one of the specialties, for example, the clinic waiting list is between 150-250 patients waiting to be seen. Patients scheduled to see a specialist may be pushed back due to a more urgent referral. This combination of triage and limited resources can render a waiting list long and increase patient dissatisfaction with the healthcare system. It also impedes timely care of patients who are suffering. Some patients wait for over a year to get to see their specialist.

Consider the second waiting list. This is divided into two parts: those patients who are placed on "the board" and those who are on an elective waiting list. The "board" is for emergency surgeries that are constrained by limited resources. When the day's scheduled surgeries are completed, the patients on the board get their turns. Due to

Table 2.

Countries	**#CT Scanners Per 1000 Pop.**	**#MRI Scanners Per 1000 Pop.**	**Health Expenditure % GDP**	**Practicing Physicians Per 1000 Pop.**	**Male Life Expectancy at Birth**	**%Public Asking for Complete Rebuild of System**
Canada	12	6.2	9.8	2.1	78	12
United States	33.9	26.5	15.2	3.7	75.2	34
United Kingdom	7.8	5.6	8	2.9	77.1	15

limited resources again, only one or in rare cases two operating rooms are allowed to run to clear the board. Board surgeries can fall under three categories: E1, E2 and E3. An E3 surgery has to be called within 24 hours. An E2 surgery has to be called within 8 hours of booking and an E1 has to be called within 1 hour of booking. In practice though an E3 can have patients waiting several days for their surgeries and, in some instances, patients have walked out of the hospital in frustration against medical advice. In addition, an E3 surgery cannot be started after midnight. An E2 surgery can only be started after the day's cases are done and an E1 case can "bump" a scheduled elective surgery usually from the same surgical specialty. A patient may join the board as an emergency arrival at the Emergency Room. That patient may be a new patient, a patient not on the scheduled waiting list or one who is already on the scheduled waiting list and his condition has deteriorated.

The second part of the second waiting list is the patients who are placed on a scheduled waiting list for elective surgery. This list is generated by the degree of urgency of the patient's ailment requiring surgery. Patients on this waiting list are called on a specific date to come for surgery. However, there is a chance that on the day of their scheduled surgery, they may be refused surgery because of limited resources on that day. They would they go back on the scheduled waiting list and once again, wait their turn. It is easy to see that the system has been patched up with disjoint solutions that disregard patient suffering while waiting and inappropriate use of limited resources.

The keys to the inefficiency in the system are the limitation of resources that is blind to demand and the sharing of these limited resources by all the surgical specialists. A surgeon may be given, for instance, 3 or 4 operating days per month. Thus, if he has 70 patients waiting for surgery, some of the patients would have to wait for 6-8 months provided none of the scheduled patients is "bumped" by non-availability of resources on the day of surgery or none is "bumped" by a more emergent patient who entered the system through the emergency room.

CONCLUSION

The analysis above suggests that surgical waiting times are generated from a lack of addressing the mechanisms underlying the generation of waiting lists. Statistical studies done in each of the three countries in this chapter appear to show different independent factors affecting waiting times. Specifically, in Canada, limited number of hospital beds, limited number of specialists, limited operating times, limited medical technologies and a system operates under economic externalities can all contribute to long waiting lists and increased patient suffering. In comparing the three countries and their healthcare systems, the issues are not the relative superiority of one system versus the others. It is the degree to which each country lacks the proper incentives to achieve efficiency within its system. The issue therefore is the inadequacy of ad hoc incentives in a system without a formal modeling-based understanding of the healthcare delivery. One cannot blame a given system for the inefficiencies generated by inappropriate or inadequate contracts and incentives.

Chapter 4.18

Computerised Decision Support for Women's Health Informatics

David Parry
Auckland University of Technology, New Zealand

ABSTRACT

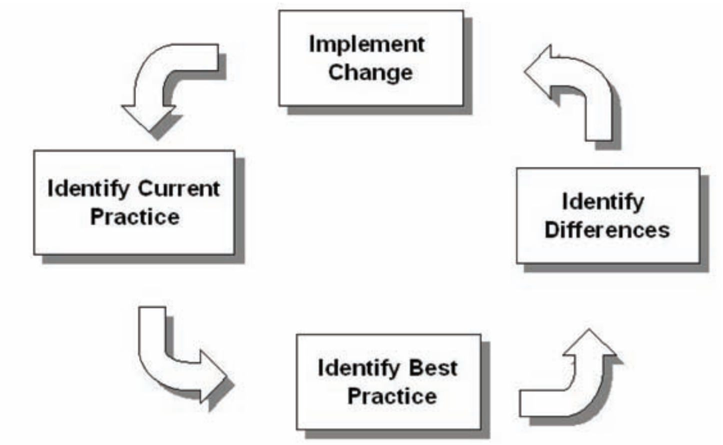
Decision analysis techniques attempt to utilize mathematical data about outcomes and preferences to help people make optimal decisions. The increasing uses of computerized records and powerful computers have made these techniques much more accessible and usable. The partnership between women and clinicians can be enhanced by sharing information, knowledge, and the decision making process in this way. Other techniques for assisting with decision making, such as learning from data via neural networks or other machine learning approaches may offer increased value. Rules learned from such approaches may allow the development of expert systems that actually take over some of the decision making role, although such systems are not yet in widespread use.

DOI: 10.4018/978-1-60566-078-3.ch015

INTRODUCTION

Decision analysis involves formally identifying the important aspects of making decisions in terms of the required information, the process followed, and the outcomes expected. Of course, people make decisions all the time without going through this process, so decision analysis is often reserved for situations where the decisions are particularly difficult because there is no good precedent or the decision maker is uncertain, the consequences of making the wrong decision are serious or because the decision making process needs to be particularly explicit and verifiable. As with all informatics activities, computer support is helpful, but not a complete replacement for clinical judgement, or a remedy for poor knowledge of the area.

Figure 1. The audit cycle



Computational intelligence involves the use of computers to make decisions themselves, in conjunction with humans, or independently.

Formalising decision making processes allows for a reflection on the decision-making process, and the sharing of this process with others such as colleagues, patients or researchers. The audit of behaviour is linked to the use of evidence–based practice (Rosenberg & Donald, 1995). As part of evidence based practice, clinicians are seen to need to justify their actions in the light of scientific research. Briefly, evidence based practice requires the following stages:

- Identification of a clinical problem
- A systematic search for evidence
- Assessment of the evidence in a structured way
- Synthesis of the evidence
- Decision on what is "best practice"

The best practice thus identified becomes the second part of the audit cycle (Figure 1). Decision analysis involves the incorporation of data from good sources of evidence, such as clinical trials in order to identify best practice. This best practice may involve a quite complex process of decision making that depends on many factors, and it may be that decisions need to be segmented in terms of whether they apply to individual cases, groups of patients or whole populations.

CLINICAL DECISION MAKING

Decision analysis is intended to both model and improve decision-making. The techniques used have a number of similarities but the importance of different aspects of the decision changes with the size of the group being affected. In general, as the groups affected get larger, the distribution of values for parameters are easier to predict, while as groups get smaller then the variation between individuals becomes more important. Dowie made an important point in a 1996 paper (Dowie, 1996) that the decision making process needs to incorporate evidence, cost effectiveness and preferences of the people involved. The use of evidence of clinical benefit, although it is necessary for the choice of action, is not always sufficient to make the decision obvious.

Decision Making for One Patient

Classically, clinical decision making concerns the actions taken to improve the health of one patient. This is at the heart of the clinicians role and has been expressed in the form of the Hippocratic Oath "*To practice and prescribe to the best of* *my ability for the good of my patients, and to try to avoid harming them.* "(Anonymous, 2007). In the case of decisions affecting a single patient, it is obviously important to know what the patient herself regards as an acceptable outcome. The acceptability or otherwise of an outcome is known as its "utility" in decision analysis terms. It is important to realise that these utilities can vary to quite a large degree. For example work described in (J. Thornton & R. Lilford, 1989; J. G. Thornton & R. J. Lilford, 1989) has shown that there is a very wide variation in the risk that women are prepared to accept, and that this is not simply a matter of lack of information, or an immediate emotional response. Thus, blanket policies for decision making may not reflect the patient's wishes, and reflects back on the importance of patient preference. This is not surprising if one accepts that healthcare is another part of life where autonomy and personal choice are important, just as for example the choice of whether to have a baby in the first place !

This problem cannot be solved simply by providing information – what is an acceptable risk to one person may not be to another. Indeed even within the professional body, there are wide variations in what the professional would perceive to be the best approach to a particular situation. Studies examining obstetricians attitude to decision –making in childbirth- for example whether a caesarean section is appropriate have show wide variations in preference. (Land, Parry, Rane, & Wilson, 2001).

A practical issue arises in that individuals react differently to therapy and have unique combinations of pre-existing conditions, genetic makeup and physiological response.

Decision Making for a Group of Patients

Complexity arises in treating pregnant women where there is more than one individual involved in the outcome. A detailed discussion of the ethics involved is out of the scope of this chapter but one should realise that there may be potential conflicts between the optimum outcomes for mothers, babies, twins and even siblings in the case of "saviour" embryos (Brownsword, 2004).

Decision Making for Population Health

When the focus changes to the population, then the emphasis changes from individual benefits and utilities, to the wider common good. However, strict utilitarian approaches are not acceptable in most cases, so individual rights, and general principles such as equity need to be taken into consideration. On the positive side, variation between individuals will tend to become less important when deciding on policies for populations, although the identification of subgroups may be important. Example of this sort of decision making may include screening for cervical cancer, and provision of HPV vaccination within a population(Jones et al., 2007)

DECISION ANALYSIS

Pubmed defines decision analysis as: "Mathematical or statistical procedures used as aids in making a decision. They are frequently used in medical decision-making."

Decision analysis techniques attempt to bridge the gap between knowledge and information – that is by somehow representing the knowledge that is available, they allow information to be used to inform decision making. In terms of the use of computers, the continuum ranges from an effectively paper-based approach, such as clinical algorithms, to computer –supported decision making, as may be seen in a decision analysis spreadsheet, to a fully automatic artificial intelligence system.

Sources of Information for Decision Making

Some decisions are relatively easy to support with even limited information. For example, early trials of penicillin-based antibiotics for peritonitis in the 1940's showed that only those patients given the drug survived. Fortunately, most decisions are not as stark as this, but in order to make use of decision analysis techniques, there are some important parameters to consider. Firstly, the information must be reliable and apply to this particular patient group. Thus it is important to have correct reference data for predicted growth charts depending on the ethnic background of the patient, such statistics are described in chapter 14. It is also very important to have the best possible evidence, and this has been made easier by the growth of evidence-based medicine (Rosenberg & Donald, 1995), and in particular the availability of systematic reviews. The Cochrane Collaboration Database on pregnancy and childbirth was one of the earliest libraries of systematic reviews available (Cochrane Collaboration, 1997), and has continued to grow as part of the wider Cochrane library. For many of the techniques such as statistical decision analysis and Bayesian methods, data on the prevalence or likelihood of certain conditions are important and these can be discovered form some of the sources described in the statistical measures chapter. For knowledge discovery techniques, comprehensive databases, which may be derived from electronic health records (see the chapter on the electronic health record), may be needed, these are particularly useful when multiple factors are included in the outcome calculation, or to gain an understanding of the expected outcome in local conditions.

When people make decisions without any decision support tools, it is also helpful if the available evidence and information is collated and available, and electronic sources such as the web are increasingly valuable for this purpose (see Chapter XIII). This can be especially useful in the case of rare conditions or unusual combinations of factors, where there may be no compelling evidence from good clinical trials.

Bayesian Methods

The reverend Thomas Bayes had his essay on probability published posthumously (Bayes, 1764). Bayesian methods involve trying to quantify the likelihood of a particular event occurring given what has happened before. This differs from classical statistics which deals with the frequency of observed events. In simple terms a Bayesian approach allows you to suggest how likely a diagnosis is given data about how often the diagnosis occurs in the population you are studying and the results of any diagnostic tests, given the sensitivity and specificity of them.

In addition, modern Bayesian approaches often include the use of utility values. In order to select a recommended course of action, the chance of something happening and the desirability of that outcome are combined. This is a very common human activity, and usually a simple multiplication is performed to produce a utility score (desirability*likelihood). It is important to note that the desirability of an outcome may vary hugely between and within populations, which supports the work of Dowie (Dowie, 1996). There has been extensive debate about the validity of Bayesian approaches to decision-making, with a number of authors making the point that the prior odds of an event may not be widely available, and that the different means of reporting trials of diagnostic tests can lead to confusion and incorrect estimates(Cooper, 1992; Harris, 1981)

One of the most important things that Bayesian approaches make plain is the importance of the prior likelihood of any condition. This is particularly helpful in the situation where

If A is an event that you are trying to detect and B is the result of a test. P(A) represents the prior probability of a particular event, and P(B) the prior probability of getting the result then:

$$P(A \mid B) = \frac{P(B \mid A)P(A)}{P(B)}$$

Where P(B|A) is the probability of getting the result B given the condition A, and P(A|B) is the probability that the patient has the condition A given the result B. This allows the accuracy of the test, in terms of true positive and false positive, of the test to be included in the calculation, along with the general prevalence. So for example, imagine the situation where there is a test such as Foetal Fibronectin (FF) for preterm labor. Assuming that the probability of having preterm labor in this population is .1, and the probability of getting a true positive result is 0.99 and the probability of a false positive result is .01 then the probability of a positive result when the patient actually has preterm labour is given by (0.99*0.1)/((0.99*0.1)+(0.01*0.9))=0.917. so that around 92% of the time, a positive test means that the patient is having preterm labor. Note that this calculation is sensitive to the base rate, or prior probability of having preterm labor, if this was halved (ie it was .05)then the calculation would be:

(0.99*0.05)/((0.99*0.05)+(0.01*0.95))=0.84 or 84%. Effectively Bayes theorem says in this case that the less common the condition, the less likely a positive result is likely to be true.

Bayesian networks (Heckerman & Wellman, 1995) are extensions of the Bayesian approach where the prior probability of a certain node being in a certain state is dependent on the posterior probability of nodes that lead to that state – a chain of causation.

Decision Trees

Decision trees are useful for mapping the data recorded in studies into potential outcomes. They have been used for deciding on the management of ectopic pregnancies (J. Elson et al., 2004). They can also be derived from data and may allow easier understanding of the processes involved. While they can be derived as part of the Knowledge Discovery process (see the section below) they can also be created by people directly from observations.

The fictional example shown below (Figure 2) concerns a hypothetical patient who is at 36 weeks gestation with pre-eclampsiapre-eclampsia. Induction of Labour (IOL) is suggested as being helpful, in this circumstance, but it may cause an increase in the chance of less- desired outcomes, such as emergency Lower segment caesarean section (LSCS). Utility values for different outcomes can be included in order to try to make the "best decision". In the example the utility value for each outcome is multiplied by the probability of each outcome. The overall result is that IOL has a utility of:

(0.1*0+0.2*0.25+0.3*0.5+0.2*1)=0.4,

but not inducing has a utility of

(0.2*0+0.2*0.25+0.3*0.5+0.4*1)=0.6,

so the non-IOL approach is preferred.

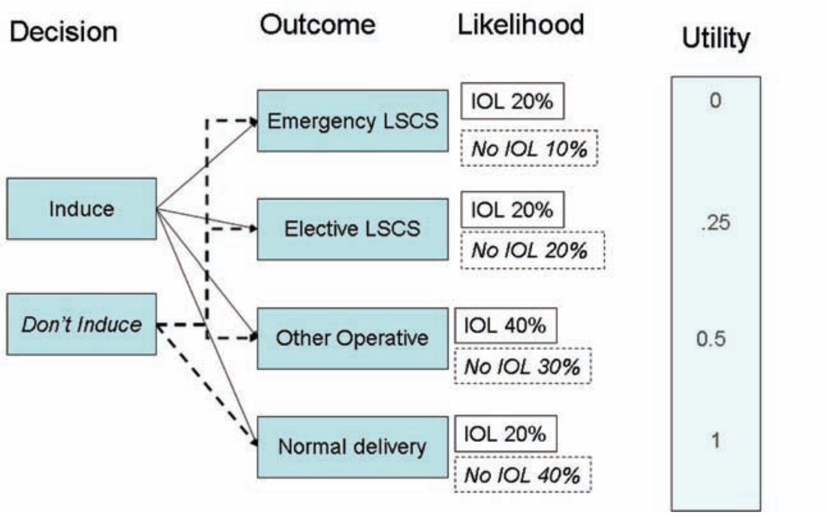
Sensitivity analysis can also be performed on these models, with the probability of each outcome being changed. More complex multi-stage trees can also be devised.

Decision Support Systems

Decision support systems (DSS), also known as decision aids, cover a wide range of approaches, as their name suggests the emphasis is on helping to make decisions, rather than removing the decision making process from the control of clinicians and patients.

A recent study (Montgomery et al., 2007) used a decision analysis tool to assist pregnant women in making a decision in the context of vaginal

Figure 2. Decision tree



birth after caesarean section (VBAC). VBAC is a particularly interesting area of study because there is no universally accepted approach, and the consequences of a simple decision rule –"all women who have had a caesarean section will have another one" leads to unwanted consequences for the healthcare system – a rise in the caesarean section rate and consequent costs– and harm to the women – the morbidity associated with a caesarean section. In VBAC there are essentially 3 possible outcomes –

1. Vaginal birth – lowest risk of morbidity to mother, but some possibility of requirement to go to 3.
2. Planned caesarean-
3. Emergency caesarean – highest risk of morbidity for mother

The tool used was effectively a decision tree, each women was asked how much she preferred each outcome on a scale of 0-100. After she had done this the program combined this information with the prior odds of each outcome to produce a decision tree, which was then printed out.. This study showed a small but significant increase in vaginal birth in the group that used the tool. Interestingly this effect was not seen when comparing patients who were given information only to help them make the decision. The degree of uncertainty in decision making measured by a decision conflict scale among the women also decreased when they used the DSS tool. However this level was even lower amongst the "information only" group. An accompanying editorial (Lauer & Betran, 2007) makes the point that this DSS is designed to allow the preferences to be made before the possible outcomes are known. It also acknowledges that this approach may be more successful than exhortation in reducing Caesarean section rates.

ARTIFICIAL INTELLIGENCE AND DECISION SUPPORT

Artificial Intelligence (AI) has been defined as "The study and implementation of techniques and methods for designing computer systems to perform functions normally associated with human intelligence, such as understanding language, learning, reasoning, problem solving," (U.S. National Library of Medicine, 2001). Some authors detect a difference between artificial intelligence as a way of mimicking human decisions, and as a way of studying them. More succinctly it can be thought of way of using computers to turn data into decisions.

Different techniques are covered by the use of the term AI – some involve discovering knowledge and some involve using existing or derived knowledge for decision-making.

KNOWLEDGE DISCOVERY FROM DATABASES (KDD)

KDD is also known as machine learning and involves the use of data that has been collected to understand the causes and outcomes of events. There are some broad categories of knowledge discovery (Fayyad, Piatetsky-Shapiro, & Smyth, 1996); classification, regression, clustering, summarisation, dependency modelling and change and deviation. The conversion from data to knowledge is at the heart of intelligence, and hence artificial intelligence. The interested reader is encouraged to experiment with freely available machine learning tools – one of the most well known is "WEKA" (Witten & Frank, 2005) available from the University of Waikato New Zealand (http://www.cs.waikato.ac.nz/ml/weka/). One particularly well known method of knowledge discovery is the use of artificial neural networks, but decision trees and Bayesian networks as well as more traditional statistical methods have their place.

Neural Network Techniques

Artificial Neural networks (ANN) attempt to model decision making on the processes existing in the brain of humans or animals. They have a perhaps surprisingly long history of development and use with early work beginning in the 1950's and 196o's. An excellent review of the history can be found in (Widrow, Widrow, & Lehr, 1990). Simply, ANN use one or more layers of "neurons" represented in a computer with connections between them (Figure 3).When a neuron is activated – i.e. the input values correspond to a particular value or range of values, then it "fires". The next layer then examines the input from the connections – which are assigned different weights -and this may then cause another layer to be stimulated, or an output to be produced. ANN are often used for learning the relationship between inputs and outputs, and can represent very complex relationships, more so than linear regression etc. They are also able to "learn" behaviour. This can be done in a number of ways, but essentially, it involves using a "training set" of data, where both the inputs and desired outputs are known, as each set of inputs as placed into the system the weights of the connections, number of connections and sometimes number of neurons are adjusted in order to create the desired outputs, using some appropriate adjustment scheme. The success of this process is then measured by using a "testing set" of data where the desired output is known but the network is not changed.

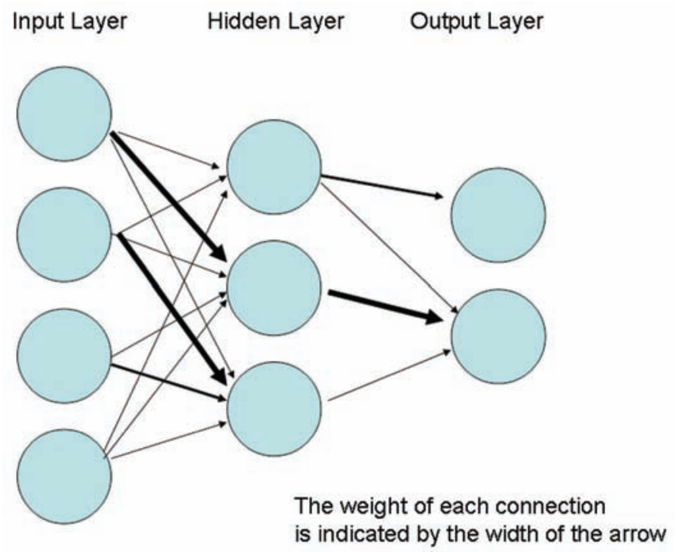
Various approaches such as accuracy of classification, a confusion matrix, sensitivity and/or specificity are then calculated. One of the issues to consider when training such a network is the danger of "overtraining" that is the situation where the network becomes extremely good at modelling the dataset used for training, but this dataset is not representative of the general case.

Classifiers – these are systems that use data about a person or condition to make a decision as to which class they belong – e.g. their diagnosis. These are usually learning systems that should get better as examples are presented to them.

If the classes are unknown – for example the outcome of the patients is not yet determined then similar techniques called *clustering* algorithms are used. Examples of classifiers are neural networks, decision trees such as C4.5and statistical methods.

Evolutionary computation methods such as genetic algorithms(Pena-Reyes & Sipper, 2000) and particle swarm optimisation (Kennedy, Kennedy, & Eberhart, 1995) can be thought of as systems

Figure 3. Example of a neural network



that attempt to model different solutions to the problem of linking input to output and choose the one that is best. In technical terms this is called traversing the solution space; essentially these techniques use different methods to find functions that best give the expected outputs from the known inputs.

Generally KDD systems act on data to produce knowledge, that is they induce rules. The opposite approach, using existing knowledge to deduce outcomes is also used, in particular in the form of the expert system.

EXPERT SYSTEMS AND KNOWLEDGE BASED APPROACHES

These systems attempt to encode expert knowledge about an area as a set of rules in a knowledge base. An Expert System is: 'a computer program that represents and reasons with knowledge of some specialist subject with a view to solving problems or giving advice' (Chard & Schreiner, 1990) (p. 185). Expert Systems have had chequered history in medicine, with work starting in the early 1960's. A number of systems such as MYCIN (a system for selecting anti microbial drugs) and INTERNIST (a general internal medicine diagnosis program) were produced in the 1970's and work has continued using this and similar models. Work up to the mid '80s was reviewed by Shortliffe (Shortliffe, 1997) and de Vries (de Vries & Robbe, P.F., 1985). Medicine is an attractive target for expert systems because there is a great deal of information available on how clinicians make decisions, and it seems reasonable to view diagnosis and treatment as the application of rules. Clinical expertise is expensive, the consequences of mistakes are serious and there are many situations where such expertise is not readily available in human form. Examples of the latter include systems developed for diagnosing the acute abdomen for use on ships (Grigorenko, Zaiats, Kleshchev, Lifshits, & Samsonov, 1989). However, because of the potential risks and the complexities of the problems involved most medical expert systems have been used as decision support rather than decision making systems e.g. (Sittig, Gardner, Pace, Morris, & Beck, 1989). In fact the practical systems have mostly been advisory, and linked to databases of medical records such as the HELP system (Haug, Gardner, & Tate, 1994) to flag unusual or undesirable events. The only major systems that have 'closed the loop' i.e. act autonomously, are those in electronic pacemakers and especially implantable defibrillators which decide on very simple rules whether to attempt to cardiovert the patient, but this is really more in the domain of signal processing than artificial intelligence (Reid et al., 1983). An explanation of why expert systems are not in general use is given in (Shortliffe, 1997) and (Berg, 1994) and many other authors. Because it is rare for systems in the medical domain to be given complete authority for decision making, the term *intelligent decision support systems* has been introduced. Although many evaluations have been performed, very few of these have had the rigour expected for the assessment of other medical developments. Interestingly, the study by Johnston (Johnston, Langton, Haynes, & Mathieu, 1994) found that the well-conducted studies they collected showed that decision support systems did generally provide benefits in terms of patient outcome.

Applications in Women's Health

Women's Health Informatics is a particularly interesting area for the application of AI techniques for the following reasons:

- Large amounts of data are routinely collected, particularly in the Maternity domain, and there is some agreement about what is collected and what outcomes are important, so that data can be compared over long series and between centres.
- Screening programmes – especially cervical cancer screening- have been in place for a long time and audit of these programmes has produced a large amount of data, along with the requirement to examine large numbers of images(see chapter 11).
- In maternity, decisions are often made under uncertainty – so support for decision making from AI techniques is attractive (see chapter 10)

However, there remain formidable obstacles to use, including the fact that each woman is different, and many variables are open to interpretation, such as severity of pre-eclampsiapre-eclampsia.

SYSTEMS IN ACTION

Decision Support for Obstetrical Interventions

Induction of Labour can be a difficult decision to make, because of the lack of definitive evidence of the best course of action in a particular case. It is difficult to study because:

- Indications are formulated in a vague way (i.e. severe pre-eclampsiapre-eclampsia, rather than blood pressure (BP)>140/90)
- Published indications may not reflect actual practice.
- The indications for IOL are not completely agreed between experts - or even consistently applied by individual experts. For example, Figure 2 shows the rate at which 3 clinicians perform IOL for post-dates at 40, 41 or 42 weeks. In theory, if each clinician was consistent and the number of weeks gestation was the only criteria being considered, all post-dates induction would be performed at the same gestation.

IOL decision making is also important because of the potential risk and cost of the procedure. IOL has been associated with higher rates of other interventions and with greater reported pain during delivery and use of analgesia (E. C. Parry, Parry, & Pattison, 1999). There is no doubt that IOL is a valuable procedure that can improve outcomes for mother and baby in the correct circumstances as systematic reviews by (The Cochrane Collaboration, 1997) have shown. It is of concern if it is under used as well as over-used. With rates of IOL rising to over 25% in some centres, small changes in the IOL rate affect large numbers of women. A more philosophical problem is that pregnancy and birth are a natural process and are being reclaimed from "medicalization" by women. If unnecessary IOL's are being performed, or even if the reasons cannot be clearly explained then women will not tolerate it.

IOL is an interesting problem to study because the problem is similar to a lot of medical decisions made under uncertainty. However it has the advantage over many medical decision-making problems that the parameters involved are generally agreed, the domain is relatively small, and there has been a large amount of work done to study the effect of different decision making schemes

Finally, the greatest problem confronting the study of the decision making process in IOL is the fact that each mother and baby is different, and the outcome if the other course of action was followed will never be known. Happily, the rate of foetal deaths and complications is very low and the safety of IOL is very high so it is impossible to tell from epidemiological, retrospective or even reasonably-sized prospective study such as reported by Hannah (Hannah et al., 1996) evidence whether the correct number of IOL's is being performed. In essence, any IOL strategy used in current 1st world practice is as good as any other for preventing bad outcomes. The title of a paper "Induction of Labour, not how but why" (O'Connor, 1994), sums up this paradox. In a similar context, it has been calculated (Grant, 1994) that 200 unnecessary Caesarean sections are performed for every life-saving one. Similarly, the IOL debate is not about reducing bad outcomes; it is about reducing the rate of unnecessary IOL's.

There has been a fair amount of work to try and simulate the decision making process in Obstetrics. This can be seen as the first step in trying to support or even automate the decisions. Neural networks have been used to try and model the decision making process using historical data (MacDowell et al., 2001) and simulated patients have been presented to obstetricians in order to try an ascertain what information they use (D. T. Parry, Yeap, & Pattison, 1998). Machine learning tools have been used to try and predict the likelihood of preterm birth (Woolery & Grzymala-Busse, 1995).

Machine learning and other types of knowledge discovery require large datasets, and future electronic records and datasets may begin to provide this sort of resource.

REMINDER SYSTEMS

There is another category of decision support tools that fall between the fully automatic, and the fully manual. Reminder or alert systems sit within an electronic health record and allow deviations from expected practice, or failure to follow protocols to be highlighted. Systems such as PRODIGY and other guideline-based approaches can integrate with the clinical record and alert clinicians during clinical episodes(Peleg, Tu, Bury, Ciccarese, & al., 2003).

DISCUSSION

There has been relatively little use of Artificial intelligence in clinical practise in women's health. This reflects the generally small impact that Artificial intelligence techniques have had in supporting the general decision making in medicine. However the picture is not all gloom for a number of reasons. Special purpose data-interpretion systems such as CTG expert systems and Cervical smear analysis tools (see chapters 10 and 11) have become more popular and effective, and embedded into diagnostic systems. However, general models designed to predict outcome or support decision-making are not widely used. This is partly because of their dependency on exact figures that may pot be available, (Harris, 1981), and partly because of their dependence on data being available in computerised form.

However a recent review (Kawamoto, Houlihan, Balas, & Lobach, 2005), has demonstrated that systems that fit into clinical workflow, are available in clinical settings, give recommendations and require justification for non-compliance with their recommendations, are likely to produce an improvement in clinical outcomes.

The increasing development of appropriate protocols, and the implementation of them within clinical systems is likely to assist in this process. With the rise of internet-based tools it is likely that such protocols may become increasingly easy to produce and maintain(D. T. Parry, Parry, Chebi, Dorji, & Stone, 2008 (in press)), especially in an open-source environment. The central relationship between clinician and woman must, however, be preserved and these developments represent an aid, rather than a replacement for clinical judgement.

FUTURE RESEARCH DIRECTIONS

Decision-making remains a key task for health professionals and it is unreasonable to expect them to meekly hand it over to machines. However, decision analysis and intelligent decision support tools offer a wide range of potential benefits to professionals and patients. Undoubtedly this area has suffered from a perception that it is dry and mathematical, and too hard to understand. It is heartening to see more efforts made to make such systems usable, and useful. Many of the most used systems are effectively hidden from the user, embedded within electronic health record or measurement systems. This follows a trend that has seen decision support tools incorporated into commercial database management systems, and particularly placed on the web.

This area is a potentially very rewarding one for clinical workers as they can help improve the care of many future patients by allowing their knowledge and experience to be reused.

Chapter 4.19

Exploiting Process Thinking in Health Care

Teemu Paavola
LifeIT Plc, Finland

ABSTRACT

In Finland, a project designed to modernize processes and reduce the waiting list for joint replacement surgery has recently been completed. The new surgery arrangements for artificial joint patients were monitored for a period of 1 year. The new arrangements involved relocating the anaesthesia phase outside the operating theatre. The reorganization of the patient care process for joint replacement surgery succeeded in achieving a 50% increase in operations. While conventional operations can often be pushed up a notch with state-of-the-art technology, for example, this article supports the argument that process thinking can be exploited effectively to support new ways of work and improve productivity in health care. Paying enough attention to this at the planning stage can be vital to the success of new IT system implementation.

INTRODUCTION

The Act on Specialized Medical Care concerning the maximum times to arrange treatment, which came into force in Finland in March 2005, has made many health care units look at the arrangement of the services they produce in a new light. Particular attention is fixed on the legal obligation concerning the waiting times between treatment decisions and treatment measures, which is to be no more than 6 months. The need to increase the number of operations has become a matter of current debate particularly in orthopaedics, where the length of queues has become unlawfully long at several hospitals in Finland. Improvements in controlling the queues have previously been achieved by the more efficient handling of referrals (Harno, Paavola, Carlson, & Vikinkoski, 2000), but with orthopaedics this was felt to be ineffective (Harno, Arajarvi, Paavola, Carlson, & Arnala, 2001). In special operative areas, making use of all the development potential available within the traditional treatment chains should be explored as a permanent remedy, after first-aid obtained in the form of outsourced services.

The literature on both IT and process development is quite unanimous in its belief that both are necessary for achieving more efficient operation and a productivity increase. Therefore an IT system project is often a change project by nature, which can make it challenging particularly in the field of health care (Berg, 2001; Littlejohns, Wyatt, & Garvican, 2003), where resistance to change is virtually a characteristic of the profession (Weick & Sutcliffe, 2003).

This article illustrates a case where process thinking and process development tools were exploited to support new ways of work and improve productivity in health care. In Finland, Seinäjoki Central Hospital implemented a project to revise processes in order to reduce queues in surgery, particularly artificial-joint surgery. The project was part of the ProViisikko project of the Hospital District of South Ostrobothnia and Finnish Funding Agency for Technology and Innovation. The project in question was originally classified as an IT project which also incorporated process development. Over the course of the project, however, the balance between the two components shifted, and there was no time to incorporate the new IT system before the changes were implemented. This article describes the results of the experiment for the benefit of, for example, other operation units that are taking a close look at their operations and of developers and management in health care as support for decision-making. Parts of the study have been published in Finnish language (Jokipii, Kalliovalkama, & Paavola, 2006).

LITERATURE REVIEW

The term "process thinking" refers to a number of management theories that have been used by industry in its quest for better operating processes over the last few decades. In many of these, the use of IT also has a significant role. Indeed, IT has become more important in a number of areas, including health care; yet process thinking has not always been employed.

The populations of Europe and the Americas are ageing quickly. The health care system is struggling with the combination of rising demand and escalating costs in specialist medical care, while at the same time, there is strong support for reduced public-sector health care spending but firm rejection of any cuts in service levels. If the two targets are to become reality simultaneously, the methods enabling them to be achieved should be chosen on the basis of how deep the cuts should be.

Cosmetic improvements would be fairly painless: for example, Total Quality Management (Crosby, 1979; Deming, 1991) would result in long-term improvements in operating processes as a more efficient use of resources would bring gradual savings. Some scholars have, however, likened some quality management theories to a rain dance (Schaffer & Thomson, 1992). In their view they look good, sound good and allow those involved to feel good, while at the same time they may have no influence on the rain itself. There are also other management theories in the field of process thinking.

According to the time-based management approach, all development should focus on process lead-time (Stalk & Hout, 1990). In such an approach all other positive aspects, improved quality, cost savings and customer satisfaction will follow automatically. However, development measures do not need to mean squeezing more out of the stages intended to boost the value of the treatment process. In fact, industrial companies have been able to find larger savings in the way they use the time that brings no added value, which, after all, accounts for more than 95% of the total (Stalk & Hout, 1990).

In contrast to total quality management, which emphasizes continuous development, business process reengineering (BPR) proposes a radical revision of the business process. The aim is to start from scratch without the burden of old operating approaches (Oliver, 1993; Hammer & Champy, 1993). The reengineering starts with a definition of the desired end result. This will form the basis for the planning of the new process functions and sequences. The aim is to maximize value-adding functions and to get rid of all operations not adding to the value. Extensive use of the information technology is often used as the means for achieving the desired results.

Effecting the operational changes required by BPR has been somewhat problematic. Resistance to change, which is inherent in human nature, and the fact that reengineering is often a zero-sum game, make the implementation of the change process more difficult (Buchanan, 1997). Besides, reengineering thinking emerged just as the recession of the early 90s began to bite, and was often used as a justification for drastic job cuts. In fact, for a while BPR was almost likened to the Black Death in the industrial sector. Since then it has lost some of its reputation and has evolved from a much-feared consulting tool into a set of practical measures. The theory, though somewhat worn-out, is still useful, as it underlines the importance of the information technology in performance improvement. Great potential for applying the theory and information technology can be found in sectors that for ages have relied on well-entrenched operating models, such as health care (Evans, Hwang, & Nagarajan, 1997).

The importance of IT for productivity in different organizations has been discussed for decades. The discussion led by Straussmann (1990) and Brynjolfsson (1993) has particularly focused on explaining what is known as the IT Productivity Paradox. Although Brynjolfsson (1993) and Brynjolfsson and Hitt (1996) later declared that the problem had disappeared by 1991, not all researchers have agreed, and interest in explaining the phenomenon remains high, so much so that Texas-based reseachers Anderson, Banker, and Ravindran (2003) proposed a new IT Productivity Paradox to replace the original. They observed a growth in the market worth of businesses after Y2K investments leading up to the turn of the millennium. These investments were made for replacing systems already in use, yet they still resulted in significant increases in productivity. Anderson et al. (2003) proposed this as a new, inverse phenomenon to be explained, calling it the New Productivity Paradox. According to their theory, the weak IT impact on productivity especially immediately after the turn of the millennium (2000-2002) can be attributed to companies simply not investing enough in IT, in direct contradiction to the IT Productivity Paradox.

Lee and Menon (2000) argue that hospitals that are characterized by high technical efficiency are no more productive than hospitals characterized counterwise. In fact, in the hospitals studied IT capital seemed to have a negative correlation to productivity. They explain this by the fact that although hospital's processes may have been efficient, resource allocation and budgeting between various categories of capital and labor had not been efficient. Devaraj and Kohli (2000) believe that the effect of IT on performance can been seen only after a time lag and cannot necessarily be observed in cross-sectional or snapshot data analyses. With data collected from eight hospitals, their study indicates support for the impact of technology contingent on BPR practiced by hospitals.

STARTING POINTS FOR CHANGE AND EXPERIMENT

Seinäjoki Central Hospital wanted to reorganize the operations for artificial-joint patients so that three operations could be performed in the same operating room in the course of a normal day's work instead of two. The introduction of a new IT system was also planned as part of the project. The experimental period lasted from November 2004 to November 2005.

The revision of the treatment process utilized process thinking and process development tools. Of these, the Theory of Constraints (Goldratt, 1990) was thought the best applicable for examining the process for treating artificial-joint patients. The point in this approach is to identify those stages in the process that dictate the maximum current throughput. By allocating additional resources and development action to these bottlenecks, the throughput can be improved without needing to interfere in the other stages of the process. The main change for increasing the usage of the operating room capacity was transferring the anaesthetic stage from the operating room to separate induction facilities. Experiments on this had been reported earlier in medical journals (Hanss et al., 2005; Sandberg et al., 2005; Torkki et al., 2005).

In the new arrangement, the anaesthetic stage was transferred outside the operating room. At the same time, one anaesthesia nurse was added to the operating team, working both in the operating room and in anaesthetic. Another anaesthetic nurse took the next patient in good time to the recovery room or to the operating room's induction facilities to be anaesthetized. As soon as the operating room was cleaned after the previous operation, the next patient could be prepared for surgery. The next patient was brought to the operating room already anaesthetized and in the correct position for the operation.

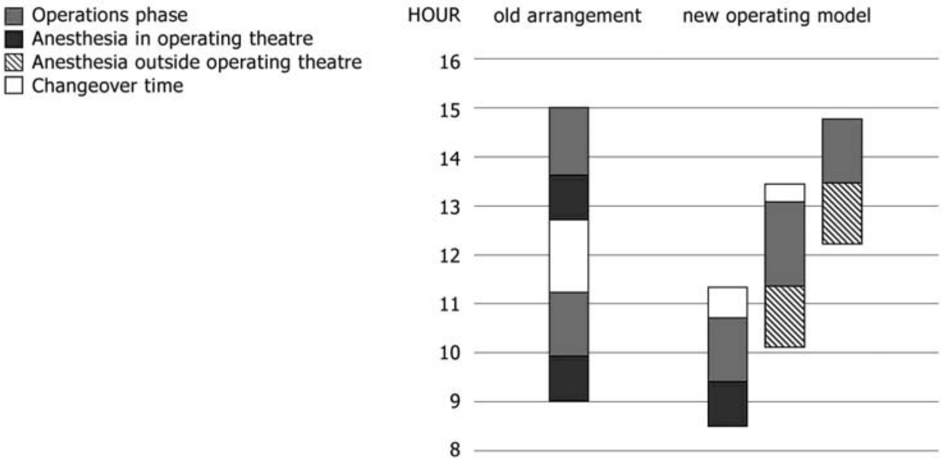
The duties of the orthopaedist that were not part of the operations or preparation for them were scheduled outside the operation days. Thus, the surgeon whose turn it was to operate was able to focus exclusively on the work in the operating room. At the beginning of the experimental period, the same orthopaedist operated for 1 week at a time, but this practice had to be changed so that the operation days were rotated among different practitioners. At the beginning of 2005, there were five orthopaedists working at Seinäjoki Central Hospital.

MATERIAL, METHODS AND RESULTS

In Finland, every year about 6,800 artificial joint operations are carried out on the hip and some 7,200 on the knee, and there are more than 1,700 instances of further surgery. These operations are performed in almost 70 hospitals, but the minimum number of 200 operations recommended by the Ministry of Social Affairs and Health is only exceeded in 25 units. Every year the Hospital District of South Ostrobothnia performs between 550 and 600 artificial-joint operations.

In the study, quantitative material was collected from the operating days in the experimental period on which three artificial-joint operations were

Figure 1. The old arrangement and the new operating model for artificial joint surgery



carried out (147 patients); because of the small number of orthopaedists, there were 2-3 of these days in a week. Comparative material consisted of the days on which two artificial-joint operations were carried out between January 1 and June 30, 2004 (54 patients).

The time when patients were in the operating room and changeover times were recorded in the operation database. The time-monitoring material consisted of the times when the operating room was in use. The median time that patients were in the operating room and the median changeover time, when there is no patient in the operating room, were used for comparison purposes.

Qualitative material was collected through interviews during the experimental period and by means of a work-satisfaction questionnaire carried out among doctors and nurses a year after the experiment started.

The new operating model made it possible to carry out three operations during a normal working day (see Figure 1). The orthopaedists examined the patients during a preoperative visit or on the day preceding the operation. The first patient of the morning was in the operating room in time, and the operation started on time at 8.30 a.m. The anaesthetization stages for the second and third patients, which were carried out staggered with the operation, took slightly longer than if carried out in the operating room.

As it was possible to separate some of the steps previously carried out in the operating room and have them done outside, the hospital succeeded in increasing the throughput of the process by 50%, even though the usage capacity of the operating room remained almost the same.

Adding a fourth nurse to the operating team (now 2 in anaesthetization and 2 in the operation) made it possible to shorten the changeover times considerably: the average time was reduced from 54 minutes to 13 minutes. This was because the team was able to take coffee and meal breaks in turn. One of the operation nurses was able to help the orthopaedist as necessary.

In the three-operation model, anaesthetizing the second or third patient of the day in separate facilities reduced the time the patient was in the operating room by 20 minutes (149 minutes vs. 129 minutes).

According to the questionnaire, 50% or more of the doctors who took part in the experiment felt that the meaningfulness of their work and work motivation had increased and thought that the three-operation experiment should become a permanent fixture. The nursing staff felt that minimizing the idle waiting improves the atmosphere and increases work motivation to some extent. The doctors felt the new operating model improves the meaningfulness of the work and work motivation more than the nursing staff did.

DISCUSSION

The usage capacity of the operating room is generally considered to be the bottleneck in the operation process. This generalization leads easily to a practice where outsourced services or increasing the number of a hospital's own operating rooms are seen as the only options for increasing output. From our experiences the throughput of the process for artificial-joint operations can be increased while the usage capacity of the operating room remains the same or even decreases. Focusing the operations on one operating room proved to be effective.

An increase in the throughput of the operation process was sought without increasing the workload of the staff. The hospital succeeded in doing this by firstly dealing with idle waiting. Targeting greater efficiency here and a simultaneous improvement in the throughput required development in several areas, for example, adding one nurse to the operating team, a bigger work contribution from the hospital attendant in preparing patients, preparing the anaesthetic in a new way and changing the orthopaedist's work schedule. The justification for adding one nurse was that in the revised staggered operation stage, there was also one patient more.

It was not possible to anticipate all the effects of the change. In order to ensure that things went smoothly, specialist experienced doctors acted as anaesthetists and orthopaedists during the experimental period, but at the same time the arrangement narrowed the opportunities for training specializing doctors. Furthermore, not enough preparation was made for the increase in the number of operations at all stages of the treatment process. At times, the growth in the throughput caused congestion on the ward and especially in further treatment at health centres.

In financial terms, the transfer to the practice of three operations was worthwhile. The resources for arranging three operations were obtained principally by utilizing the fixed costs of the hospital more efficiently. In alternative cost accounting comparing the additional cost caused by a hospital's own activities with the cost of an artificial-joint operation acquired from the private sector or another provider (minus the costs of the prosthesis, materials and cost of the treatment days) shows a difference of some USD 4,000 between the hospital's own work and outsourcing with regard to the added third primary operation per day. Because of the limited number of orthopaedists, however, it was not possible in the experimental period to run "flat out" five days a week.

Fifteen complete operations a week would be enough to meet the need for artificial-joint surgery in the entire hospital district, and the revised treatment process would generate annual savings of between USD 700,000 and USD 800,000 for the Hospital District of South Ostrobothnia, even taking into account the additional recruitment required. Savings come from cutting back on services purchased from private hospitals, as the hospital itself can now perform a larger percentage of the joint replacement surgery required.

Although planned as part of the project, the introduction of the new IT system did not take place during the present change project. The reason for this was that the software was not complete when the project was launched. Nevertheless, the IT system appears to have played a noteworthy role in the launching of the project because key players whose commitment was essential to the successful implementation of the change were motivated by the eventual benefits of the IT system to support the project. The IT system was intended to work as a tool for monitoring patients in rehabilitation and to make it easier to organize follow-up visits in a timely fashion and based on actual needs. The new IT system would further reduce the workload at the hospital by making it possible to carry out postoperative patient monitoring at local health centers rather than at the hospital outpatient clinic.

CONCLUSION

This article presents a succesful reorganization of the care process for an artificial joint patient. The project by a middle sized Finnish hospital offers an encouraging example of a way to exploit process thinking and process development tools in health care. Seinäjoki Central Hospital succeeded in obtaining a 50% increase in flow-through in the process for treating artificial-joint patients with the transfer of the anaesthesia stage outside the operating room in the reorganization. For every two joint replacement operations previously conducted, there were now three operations performed in the same theatre and in a normal working day. In the longer term, the arrangement would mean that in Finland the entire country's need for artificial joint surgery, about 15,600 operations per annum, could be dealt with in 30 operating rooms. This could considerably streamline the publicly-financed health care system in Finland, as these operations are currently performed in almost 70 hospitals.

The introduction of the new patient care process demonstrated that the operating theatre capacity was not causing a bottleneck, but that it was the orthopaedic surgeons brought in at the various intervals who formed the key resource. The reorganized care process for patients requiring joint replacement surgery should produce annual cost savings of USD 700,000 to USD 800,000 for the Seinäjoki Central Hospital. Following the experience gained in the project, the Seinäjoki Central Hospital has decided to adopt the project model on a permanent basis. A similar reorganization is also possible in other hospital districts. This observation, however, should only be applied to orthopaedic joint replacement surgery.

An interesting detail in this change project was that the role of the IT system itself was completely marginal. All kinds of justifications for investing in IT systems can be given, from economic calculations to managerial intuition (Paavola, 2007), but in the change project described in this article, IT seemed to act only as a catalyst. Perhaps the project could not have been successfully implemented to the extent it was had not an IT component, which "always requires changes in the operational process," been included. This observation of IT acting as a catalyst for performance enhancement and hence improved productivity deserves further study. It would be worth exploring to what extent indirect impact should be considered in making IT investments alongside direct effects, and how this phenomenon could be studied. Are there cases where IT investment was motivated as leverage for achieving a particular change in the operating environment, even though the same impact on productivity could have been achieved without IT investment?

ACKNOWLEDGMENT

The author would like to thank Pekka Jokipii, MD and Kari Kalliovalkama, MD for their contribution to this study. This project was partly funded by the Finnish Funding Agency for Technology and Innovation.

Section V

Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of health information systems around the world. Chapters included in this section analyze preparing healthcare organizations for IT adoption, demographic difference in telehealth outcomes, physician characteristics and electronic medical records, and patient perspectives and roles in creating health records and recording health data. The inquiries and methods presented in this section offer insight into the implications of health information systems at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1

Organizational Factors:
Their Role in Health Informatics Implementation

Michelle Brear
University of New South Wales, Australia

INTRODUCTION

The influence of organizational factors on the success of informatics interventions in healthcare has been clearly demonstrated. This health specific research, informed by a larger body of evidence emerging from interdisciplinary organizational, psychological and sociological research, has confirmed the view that organizational factors can be the decisive factor in the success of an intervention (Lorenzi *et al*, 1997).

However it remains rare for organizational factors to be explicitly addressed in the implementation process. As such their contribution to the success or failure of informatics applications is not properly understood. This has implications for future interventions. Applications which were not utilized or did not perform adequately in a particular setting may be dismissed, while other, less appropriate systems may be adopted because organizational factors influenced their success. Explicit study of the role of organizational factors on the implementation of health informatics interventions is necessary to develop an understanding of their influence in the healthcare context.

Healthcare organizations tend to be highly task oriented, labor intensive and dependent on interdisciplinary teamwork, so the influence of organizational factors within them may differ considerably from the business settings in which they have traditionally been studied (Chau, 2001). Health organisations are also increasingly under-resourced due to the global downturn in government social spending, health sector privatization and aging populations.

DOI: 10.4018/978-1-60566-078-3.ch016

It is these characteristics which necessitate rapid uptake of informatics applications, capable of automating aspects of healthcare provision and reducing labor intensity (Coiera, 2004).

From a technical perspective, rapid and fundamental transformation of the healthcare sector through informatics is achievable. However, without a clear understanding of, and ability to manage organizational factors it is unlikely that informatics applications will realize their potential in the health sector. This short review provides an overview of the key organizational factors influencing the success of informatics interventions. It begins by positioning informatics interventions in the broader context of organizational change, before discussing the current understanding of selected factors.

INFORMATICS IMPLEMENTATION AS ORGANIZATIONAL CHANGE

Implementing informatics applications is essentially “a politically textured process of organizational change” (Berg, 1999, p87), aimed at achieving user acceptance and utilization of informatics applications. Organizational change requires people to be aware of a need for change, identify a particular course through which the change can occur and take actions to make it happen (Lorenzi, 2004). Resistance to change occurs if users are not aware of the need for change, not convinced of the course of action set out or unable to carry out the necessary action. It is the users, not the technology that should be the centre of the change process, as the decision to utilise the system is ultimately theirs (Berg, 1999).

Even the best-designed and well-intentioned informatics interventions are likely to lead to productivity losses in the early stages and create major changes (Lorenzi, 2004). Timely and effective training of users can reduce the disruption, however is not enough to ensure success as even a correctly used system can have far reaching effects. Informaticians taking a ‘socio-technical’ approach, view the application as one component of a complex system, the health organisation, whose introduction will disrupt other components of the system (e.g. patients and clinicians). They advocate design approaches which aim to create technology which ‘fits’ within the complex system (Kaplan, 2001).

The multi-disciplinary nature of health sector organisations makes finding the correct ‘fit’ challenging (Kaplan, 2001). A range of professionals with different needs, expectations and work norms, are likely to use an application and each will expect it to ‘fit’ with their work practice. When an application does not fit resistance will increase. This is often due to valid concerns about increased workload or ability to care for patients (Timmons, 2003). When systems do not ‘fit’, the best way to overcome resistance is to change them. However when they are essentially effective, resistance can be overcome by changing people’s opinions or work norms. Organizational culture and social networks, from which many of these norms and opinions arise, need to be understood and managed.

ORGANIZATIONAL CULTURE

Organizational culture is the set of shared norms and values and tacit rules within which members of an organisation function (Lorenzi & Riley, 2000). “Every culture supports a political and social values system” (Lorenzi, 1997, p85) which will influence the reaction to an informatics application. Healthcare settings often involve a professional hierarchy between doctors and nurses, are characterized by high levels of informal and disruptive communication and place value on clinician/patient relationships and patient care.

It is necessary to identify and target the aspects of organizational culture presenting opportunities for and barriers to success when changing the organisation through an informatics intervention.

Managing change requires mediating the influence of culture on events, rather than necessarily aiming to change it (Demeester, 1999). Where organizational culture and informatics applications appear incompatible, adaptation of the application should be considered.

If it is not possible to modify the system, success is dependent on changing the organizational culture to make it compatible. Cultural change directly targeted at the strongly held values of users, may only increase resistance. If the organisational culture supports a belief that informatics applications undermine good clinician/patient relationships, attempting to convince clinicians that good relationships with their patients are not important is unlikely to be a successful strategy for winning acceptance of the application. However it may be possible, through an educational process, to convince clinicians that informatics applications do not necessarily undermine good relationships and in the right conditions can even enhance them. Users may already be convinced of the need to change some aspects of organizational culture which do not threaten the values they are most passionate about. The structure of an organisation and work patterns and roles of individuals within it are influential and may be appropriate areas to encourage change.

Organizational Structure

The structure of an organisation will affect the way in which decisions are made, the type of leadership which emerges and the way resistance is dealt with in the implementation process. 'Flatter' organizational structures tend to encourage the sharing of ideas, emergence of innovation and broader involvement in decision-making (Leonard *et al*, 2004). In these types of organisations management tends to adopt a collaborative approach, working alongside, listening to and involving those working on the ground, rather than making decisions on their behalf and communicating orders. Management is supportive, approachable and accountable and shows dedication to continuous learning (Zimmerman, 1993). These types of organisations are more likely to include practicing clinicians in formal decision-making bodies such as management committees. They are also more likely to recognize, encourage and legitimize the role of grass roots leaders with clinical credibility and presence and have a commitment to involving informatics users in the implementation process.

User involvement throughout the process "leads to increased user acceptance and use by encouraging realistic expectations, facilitating the user's system ownership, decreasing resistance to change, and committing users to the system" (Lorenzi, 1997, p86). It also allows better definition of problems and solutions, from the user's perspective and develops a better understanding amongst users of the application (Lorenzi, 1997). Involving users in the design and implementation of a system is more likely to result in applications suited to the current work patterns of the intended users.

Work Patterns and Roles of Clinicians

Any informatics application must be compatible with the current work practices and values of the organisation (Greenhalgh, 2004; Kaplan, 2001; Lorenzi & Riley, 2000). Compatibility will differ between organisations and cultures so applications require the capacity to be tailored to the needs of individual organisations. Take an electronic prescribing system for example. In one hospital it may be used to enter prescription orders during ward rounds via a laptop computer however a different hospital (or even another ward within that hospital) may find it more appropriate to install the system on a computer terminal at the nurses stations so that orders can be entered retrospectively. Bearing in mind the necessity to consider the unique context of individual organisations, it is possible to make some generalizations regarding the work patterns and roles of clinicians to broadly inform the design of informatics interventions.

Doctors have traditionally worked with a high degree of professional autonomy and status (Gagnon, 2003). Applications perceived to undermine their autonomy and status as professionals or "subvert the art of medical practice" (Kaplan, 2001, p4) are more likely to meet with resistance. In a qualitative study examining factors influencing adoption of a CDSS involving automatic clinical reminders, Rousseau et al (2004) found clinicians favored on-demand evidence systems to automatically generated reminders. The latter were perceived to be intrusive, often inapplicable and not particularly useful for making patient management decisions.

Clinicians tend to be patient focused, require an ability to maintain control of patient care and make decisions specific to individuals which computers are not capable of. They must be convinced that applications will not jeopardize their ability to care for patients (Timmons, 2003). Overly prescriptive systems, or those which attempt to take on the uniquely human quality of thinking, are unlikely to be successful. Rouseau et al (2004) noted inapplicable reminders were a barrier to effective use and found that practitioners formed a habit of ignoring all reminders. In a study of adherence to electronic HIV treatment reminders, Patterson *et al* (2004) found the inapplicability of reminders to many patients' specific situations, and the time taken to document why the reminders were not adhered to, were significant barriers to effective system use.

All applications will create some change to normal work patterns and roles. That is essentially what their implementation is intended to do (Berg & Toussaint, 2003). Users need to be realistically informed of and prepared for changes to normal work practice. It is inevitable that users will expect some future benefit from adapting their behaviors and realistic communication of the likely benefits, particularly if they are indirect or not clearly visible, should form an integral part of the communication strategy.

Communication

Communication binds individuals together and is integral to the implementation process. Without effective communication it is impossible to lead, learn, make decisions, prepare individuals for an intervention or use it effectively (Zimmerman, 1993). Lack of communication, or ineffective communication which lacks trust, can negatively influence the uptake of a technology (Ash, 1997). There is no 'magic formula' for effective communication, however there are some key principles which should be applied to enhance the effectiveness of communication.

Communication must be timely. People require time to digest information and prepare for changes (Tilley & Chambers, 2004). However they also forget. Users who are trained to use a system months before its implementation may not remember how to use it when it finally arrives. Information must also be communicated at an appropriate time. Disrupting a lunch break or patient care, may not be the most appropriate way to inform users about a new application.

Communication must be sincere and truthful. Users must be offered an honest and realistic assessment of the potential negative consequences and expected benefits of an application. For example if an electronic medical record application is introduced, it may be realistic to expect its use to be more time consuming in the initial stages while users master the system. However in time, its ability to provide comprehensive patient information at the click of a button may save time and provide better quality information. It is also important to acknowledge unexpected benefits and problems if they occur.

Sources of communication have an immense impact on the perceived message, its credibility and influence (Kaplan, 2001). A manufacturer's leaflet declaring the new system easy to use is unlikely to carry much weight with users, however a respected clinical peer conveying this information may be quite influential.

It is essential the communication be recognized as multi-dimensional, rather than a one-way channel from management to users. Mechanisms for receiving feedback must be created and where it is not forthcoming, should be actively elicited from users. Magrabi *et al* (2004) incorporated two mechanisms for feedback into an online DSS. Users could volunteer feedback at any time, however it was also actively elicited by randomly prompting users. Once received, feedback should be acted upon to adapt the application to meet user needs (Greenhalgh, 2004). For example, in response to clinician feedback, the patterns of automatically generated reminders in a clinical decision support system (CDSS) was altered to limit the number of reminders perceived by clinicians to be inapplicable. Communication through informal structures (e.g. gossiping in the tea room) is inevitable and ability to manage it directly, limited. However the less effective formal communication mechanisms are, the more likely it is that communication will take place through informal channels in the social network.

SOCIAL NETWORKS

A social network consists of the individuals, groups and organizations with whom, and patterns of communication by which individuals in an organisation interact. It is through social networks that organizational culture and behaviors are reinforced and adapted (Lorenzi, 1997). The culture represented within a social network can be influential. For example, Gagnon *et al* (2003) found that physicians who perceived social and professional responsibility to adopt telemedicine applications [from others in their social network] had a stronger intention to do so. The culture represented in each individual's social network will differ, and each individual within will interact and be influenced differently.

To properly understand a social network it is necessary to examine the interactions, not the individuals. Frequency of interaction is important but should not be viewed in isolation from the style of communication (e.g. formal or informal), type of communication (e.g. synchronous or asynchronous) the strength of ties between the participants in an interaction and power relations involved (Katz et al, 2004). When implementing an informatics application, interactions which occur in clinical teams and with respected opinion leaders, are particularly influential in relation to individuals decisions to utilise applications.

Effective Teamwork

The clinical team has been identified as the organizational unit most influential in the diffusion of innovation (Gosling *et al*, 2003). Well functioning teams facilitate effective communication, encourage continuous learning and offer a trusting environment in which ideas and issues can be raised. Through these interactions, teams develop shared visions and common goals which support the introduction of new innovations to fulfill these goals. As work in health organisations is highly dependent on teamwork and it is teams, not individuals, which must adopt informatics applications, well functioning teams are a prerequisite for successful informatics implementation (Goldstein *et al*, 2004).

In organisations where well functioning teams do not exist, an informatics intervention may be an opportunity to develop teams, by uniting individuals around a shared vision and common goals which the application can fulfill. Doctors and nurses take on different roles and responsibilities in the process of caring for patients so a shared vision may not be immediately apparent. However both groups ultimately work towards the goal of providing optimal patient care, so incorporating an application into a vision of improved patient care may be a way to unite users.

Consideration should also be given to the size and composition of teams. Teams of more than 15 tend to fragment into sub-teams, while very small teams have a tendency to become cliquish, so ideally they should consist of 10-15 members (Gosling *et al*, 2003). The work environment may largely dictate a team's composition. In healthcare settings teams are usually multidisciplinary. Individuals however, are more likely to create ties with those they perceive to be similar, so identifying similarities amongst multidisciplinary teams is pertinent (Katz *et al*, 2004). Identifying and utilizing the influence of respected clinicians within the team can also be useful.

Clinical Champions and Opinion Leaders

Respected clinicians with influence amongst their peers, who support the intervention play an important role in convincing others of an application's worth, as do those who oppose the intervention. They are commonly referred to as clinical champions or opinion leaders. As the name 'champions' tends to imply a positive influence and does not necessarily imply the champion has influence amongst peers (Lolock *et al*, 2001), 'opinion leader' will be used in this paper.

Opinion leaders are individuals with the ability to influence others in the social network, who make a major personal commitment to diffusing information about an informatics application (Lorenzi & Riley, 2000). Such diffusion may have a negative or positive influence, and can discourage or encourage the adoption of the application. For example Ash (1997) identified the presence of 'champions' as a significant factor in the diffusion of email in academic health science centres. Conversely Timmons (2003) discusses a "strong and articulate" ward sister whose resistance to using an electronic system in the ward was successful in preventing its implementation. It is not unusual to have both negative and positive opinion leaders within a network.

Whatever their persuasion they tend to be charismatic individuals with good interpersonal relationships based on trust and understanding. They act through clinical conviction, generally outside of the formal structures, and give applications credibility at a local level. Their role is essentially informal, and, on the proviso their colleagues respect them, they tend to be self-appointed (Lolock, 2001). The role is largely dependent on personal motivation and conviction and therefore difficult to formalize. The potential alienating effect of being an opinion leader means that those without sufficient commitment are likely to be reluctant to take on such a role (Lolock, 2001)

Despite a general consensus that successful interventions are more likely when champions are present, there is a lack of understanding about exactly what it is they do, the circumstances in which they will be influential and how best to describe them. As with each of the factors mentioned here, opinion leaders are one small component of a large and complex system (the health organisation) and it is difficult to isolate their effect. There is also considerable evidence to suggest that other factors, in particular the suitability of the application, influence the emergence of opinion leaders. As with all the factors mentioned here, further research is needed to identify how opinion leaders influence and how the 'champions' amongst them can be encouraged.

CONCLUSION

There is a general recognition that numerous organizational factors will influence the success of an informatics intervention. This is supported by a body of evidence from multi-disciplinary and health specific research. In particular research has noted the influence of: organizational culture and social networks. Organisational culture, the shared norms and values within which members of an organisation function influences the organization's structure and patterns of communication. Social networks, the individuals and groups with whom one interacts and the interactions which occur between them, are the social space in which teams are formed and work and individuals are influenced, particularly by those individuals known as opinion leaders or clinical champions. Organizational factors are highly inter-related and the exact nature and contribution of each to the success of an intervention is not clear. A health specific understanding and recognition of these factors is necessary if informatics applications are to reach their potential in healthcare settings.

KEY TERMS

Clinical Champion: Clinical Champions are opinion leaders who 'champion' or encourage the uptake of an application.

Opinion Leader: An opinion leaders is an individual, respected amongst their peers who acts out of clinical conviction to influence the opinions of others vis-à-vis an informatics application.

Organisational Culture: Organisational culture is the set of shared norms and values and tacit rules within which members of an organisation function.

Organisational Factors: In an informatics context, organisational factors are factors relating to the culture and functioning of an organisation which, negatively or positively, influence its ability to adapt to an informatics intervention.

Social Network: A social network consists of the individuals, groups and organisations with whom an individual interacts, and the interactions which take place between the individual and other components of their social network.

Socio-technical Approach: A socio-technical approach is one which views informatics applications as part of the broader social and political context within which they are implemented.

Teamwork: The co-operative effort of a small group to achieve a specified outcome.

Chapter 5.2

Changing Healthcare Institutions with Large Information Technology Projects

Matthew W. Guah
Erasmus University Rotterdam, The Netherlands

ABSTRACT

This article reviews the development of institutional theory in direct relations to historical changes within the UK's National Health Service (NHS) with an eye to contributing to the theoretical specification of healthcare information processes. This is done partly by extending certain paradigms (see Meyer & Rowan, 1991; Powell & DiMaggio, 1991; Tolbert & Zucker, 1994) through a proposed model of causes and consequences of variations in levels of institutionalisation in the healthcare industry. It reports findings from a 5-year study on the NHS implementation of the largest civil ISs worldwide at an estimated cost of $10 billion over a 10-year period. The theoretical basis for analysis is developed, using concepts drawn from neo-institutionalism, realisation of business value, and organisational logic, as well as mixed empirical results about the lack of IT investments value in the NHS. The findings suggest that large scale, IT change imposed upon a highly institutionalised healthcare industry is fraught with difficulty mainly because culturally embedded norms, values, and behavioural patterns serve to impede centrally imposed initiatives to automate clinical working practices. It concludes with a discussion about the nature of evaluation procedures in relation to the process of institutionalising IS in healthcare.

INTRODUCTION

An historical overview of IT projects in the UK's National Health Service (NHS) during the last six decades is presented here with the intention to both clarify the links between institutional theory and previous traditions of sociological work on organisational structure. The initial exposition of this theory by works of established institutionalists (Meyer & Rowan, 1991; Scott, Ruef, Mendel, &

Caronna, 2000; Tolbert & Zucker, 1994) focuses on the ways of challenging dominant theoretical and empirical traditions in organisational research. While this article clarifies some ambiguity and elaborates on the logical and empirical implications of a phenomenologically based version of institutional theory, the primary aims are to clarify the independent theoretical contributions of institutional theory to analyses of the NHS and to develop this theoretical perspective further in order to enhance its use in empirical research in other healthcare environments (internationally and globally).

Markus (1983) claims that interaction theory draws together three principal strands of resistance: (1) internal factors, (2) technical problems, and (3) political context. This theory has been highly influential in IS strategy and other social sciences generally since Markus first developed the ideas over two decades ago. The focus here (see Table 1) is on how interaction theory offers a new way of looking at IS implementation in the healthcare industry.

Much has been researched in the last few decades about the major lack of a coherent implementation strategy for IS (Sambamurthy & Zmud, 1994) in the healthcare industry (Stevens, Schade, Chalk, & Slevin, 1993; Vogel, 2003). Most of such claims have been levelled against an apparent "productivity paradox" with respect to investments in healthcare management (in general) and IS (in particular). The Wanless report (2002) and Committee on Quality Health Care in America assessment report by Institute of Management (2002)—both national government's mandated investigations into the UK and USA national healthcare systems respectfully—among others, have failed to find a convincing body of evidence that investment in healthcare IS is associated with increased output (refuting the productivity paradox), but not with healthcare value as measured by patient satisfaction.

WHAT IS INSTITUTIONALISM?

Institutionalism is continuously being used to mean different things by researchers of political science, economics, and sociology. Lowndes (1996, p. 182) presents institutionalism as informal codes of behaviour, written contracts, and complex organisations with four elements:

- A middle-level concept. Institutions are devised by individuals and therefore constrain individuals' actions. Institutions here are seen as part of the broad social fabric and medium for individuals' day-to-day decisions and other activities. DiMaggio and Powell (1994) argue that institutions shape human actions, imposing constraints while providing opportunities for individuals.

Table 1. Implementation theory: Usage, fitness, relationship and sufficiency

Authors	**IS Implementation**	**Theory Description**
Lucas, 1993	Appropriate use of IS	Process theory explaining appropriate IS use Variance theory linking use with business value
Grabowski & Lee, 1993	Strategic fitness of IS	Process-type relationship between strategic fit and performance of IS
Markus, 1983	Relationship of IS assets	How IS investment do or do not become IS assets How IS assets do or do not yield improved organisational performance
Sambamurthy & Zmud, 1994	Insufficient to produce impacts	Process model connecting raw material inputs to outputs Variance theory of IS management competencies and IS impacts Variance theory linking impacts and business value

- Having formal and informal aspects. Lowndes (1996) views institutions to involve formal rules or laws, which allows informal norms and customs to be practiced. That is because some institutions are not consciously designed nor neatly specified, yet part of habitual actions by its members. Such institutions may be expressed in organisational form and relate to the processes within.
- Having legitimacy. Legitimacy in institutions goes beyond the preferences of individual actors. Such preferences are valued in them and go beyond their immediate purpose and outputs.
- Showing stability over time. Lowndes (1996) views institutions as gaining their legitimacy due to their relative stability over time, and their links with a "sense of place."

New institutionalists generally view institutions to have "the humanly devised constraints that shape human interaction" (North, 1990, p. 3) what March and Olsen, (1989) refer to as "rules of the game" (p. 162) that organisations and individuals are constantly expected to play the game. Another stand taken by new institutionalists sees informal institutions (tradition, custom, culture, and habit) are embedded in culture and conventions defined as behaviour structuring rules (March & Olsen, 1989; North, 1990). New institutionalists stress embodied values and power relations of institutions together with interaction between individuals and institutions (Lowndes, 1996). They attempt to distinguish between informal institutional rules and personal habits. Such distinction forms the basis for the definition of institution in this research where informal conventions and their impact upon the NHS and its partners are being explored.

Research Methodology

The research study began in 2001, with the initial interest of conducting an exploratory-descriptive study in 10 NHS hospitals to explore why, "historically, the NHS has not used or developed IT as a strategic asset in delivering and managing healthcare" (Department of Health [DoH], 2000). Intensive literature review unveiled few longitudinal studies, which systematically and rigorously examined how IT systems were introduced and changed over time. There were very limited studies that examined inter-organisational relationships between different constituents in the adoption and diffusion of IT systems (NHS directorship, hospital management systems, or IT suppliers and patients). Not only were most of these studies descriptive and lacked a historical dimension, they presented IS in healthcare as largely theoretical with most contributions reporting the findings of a specific IT project implementation using simple success and failure criteria—Scott et al. (2000) being among the most significant contributions.

Using such a relevant and wide-ranging backdrop this research study recognised that it was important to extend the empirical enquiry for two reasons: (1) exploratory-descriptive case studies on a single organisation (or one hospital) would not elicit in-depth and rich data to develop any meaningful analysis and conclusions on how IT was being deployed and managed; and (2) the introduction of a large scale, IT-enabled change program needed to be researched at the wider societal, organisational field and individual levels, covering an extended period of time, to understand the processes of institutionalisation (Tolbert & Zucker, 1994). The research study was therefore designed to capture the myriad of views and opinions about the national program over a 5-year period to build a rich picture of such processes underpinning large scale IT change.

Three methods of data collection were adopted: (1) a range of academic, government, and industry studies on the healthcare sector were

Table 2. Numbers of interviews conducted

Categories of Interviewees	Year 1		Year 2		Year 3	
	Contacts Made	Persons Interviewed	Contacts Made	Persons Interviewed	Contacts Made	Persons Interviewed
NHS Information Authority	32	5	30	10	10	15
Major IT Service Providers	90	56	60	45	17	12

assembled—both UK and healthcare services in other countries. The materials proved invaluable for understanding the societal, economic, political, cultural, and technical differences in healthcare nationally and internationally; (2) participation in trade fairs, conferences, workshops, and exhibitions on healthcare—focusing on general or more specific healthcare activities. These events also generated many useful research contacts that proved invaluable for targeting interviews. (3) A semi-structured interview (see Table 2) schedule was used to enable interviewees to expand on their answers. While most interviews lasted for about 90 minutes, a limited number lasted just under an hour, with nearly all interviews being tape recorded and subsequently transcribed. Respondents were later contacted with feedback from the interviews and, where necessary, errors were corrected. This method of data collection was critical for allowing interviewees to raise additional themes, issues, and concerns that they felt were important to the research study. As a result of the political contention of some of the interview content, some interviewees asked that names of individuals and hospitals be anonymous.

After the initial 6 months of interviews, the scope of the study had to be extended, as it was important to elicit data and information from a wider range of respondents engaged in the implementation of the national program. These included IT service providers bidding for public sector IT contracts and doctors in general practices around the country. Most IT service providers offered critical insights into the political and procurement processes within the NHS and public sector more generally (Guah & Currie, 2004). General practitioners, on the other hand, offered useful insights about the communication channels underpinning the institutional processes underpinning the national program. Given the range of constituents involved, the resulting data were evaluated and interview schedules refined, ensuring questionnaires be more closely targeted to the professional and personal situation of the individual, as generic questions were less meaningful. The final questionnaire—consisting of

15 questions—was ultimately divided into the following major themes:

- ***Vision*** **for the national program:** overall vision and how it was compatible with individual hospital objectives.
- ***Strategy*** **for the national program:** Who was engaged with and how the strategy was being communicated within different organisations.
- ***Implementation*** **of the national program:** What professional, managerial, and technical skills or capabilities were needed to implement various elements of the national program.
- ***Value delivery*** **for the national program:** The main risks identified by each hospital and how past IT failure could be avoided, as well as looking at the cost/benefit choices and issues for each organisation.
- ***Risk\analysis*** **for the national program:** The value being derived from the national program.

The aim was to get the perspectives of a number of different informants using structured interviewing, by building up intensive longitudinal cases which would, nevertheless, be amenable to statistical analysis. In this method, differences of perception of informants become part of the data, not an inconvenience to be explained away in the search for some objective truth.

DATA ANALYSIS

Content analysis was used to surface themes in the interview data that reflected participants' understandings related to systems implementation. The approach suggested by Weber (1990) was used to code the interview data. A set of codes used to classify the data was developed, based on concepts from the research literature and augmented with major additional concepts discovered by the researchers during the coding. We used a content analysis form where each sentence from the interview transcripts was assigned one or more codes. Each data element was coded with an assessment of the level of agreement in code assignments, involving a certain degree of recoding of data sources. As this was the first study that uses content analysis about modelling of system implementation in the NHS, a certain degree of recoding was considered acceptable.

Table 3 contains a list of the most frequently cited attributes and benefits of the system implementation model. The audiotapes were fully transcribed and individual hospital and service provider summaries were produced before conducting a content analysis of each transcript. After a complete review of all summaries, issues describing IS implementation strategies by iterative examination were identified. Certain themes emerged, which were explored using the competing values framework as an interpretive framework where appropriate (see Table 3). The

trustworthiness of such analysis has been assessed by triangulation between data sources and exploring any differences in the researcher' interpretations during a couple of follow-up meetings with selected interviewees.

During the period of the field study, there was a continuing, vigorous, informal debate within NHS Information Authority as to the merits of establishing a fault proof IS implementation framework in healthcare, particular for the NHS, during this period of healthcare reform. Benefits in terms of improved quality, greater structure, and more discipline were widely accepted.

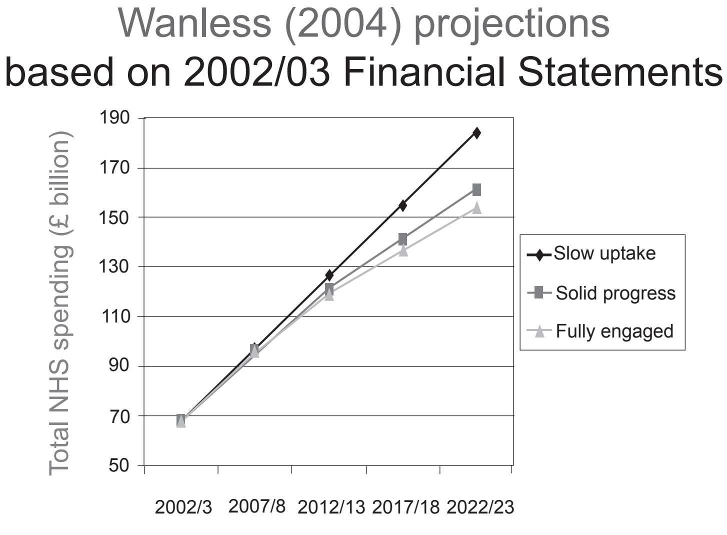
THE NHS CASE STUDY

The NHS is the institution responsible for all healthcare and services in the UK with the goal of undertaking this responsibility at no costs to the public, at the point of delivery. The NHS was created in 1948 by a parliamentary art of the UK government of Mr. Howard Wilson, after a national healthcare review by Mr. Black immediately after World War II. While the NHS operating environment has changed radically within the last six decades, only a few periods of strategic importance to the objective of this article will be revisited by the author.

The period from late 1980s to early 1990s brought in the advent of competitive bidding bringing long-term increase costs to the management of the NHS, as well as a feeling of internal market within the NHS. By the mid-1990s, management of IS in the NHS was division based. Divisions were spread across several sites and medical functions were centrally controlled. Computing services and IS development projects were beginning to be contracted to external private businesses, and staff at the NHS were beginning to feel disgruntled and unappreciated. The increasing influence of global communications, Internet, and other new technologies demanded a response from the NHS.

In the late 1990s the government increasingly recognised the opportunity to use IT to improve the delivery of service within the NHS. After a series of reviews of NHS IT service delivery, a more integrated and seamless IT organisation was recommended (DoH, 2000; Wanless, 2002). The NHS Information Authority embarked on the Integrated Care Report Service (ICRS) project

Figure 1. NHS projected expenditures over two decades (Wanless, 2004)



to provide, among other services, a nationwide electronic patient database. The result was a document called "Information for Health" that specified the need for the complete automation and integration of various patient information databases in the country (DoH, 2000). The system was commissioned to selected IS service providers at a combined price of $10 billion.

In spite of its vision—to transformation IT—the NHS has a history of introducing large-scale IT development projects that have not been overall successes, with some suggesting failure rates of between 60 to 80% (Brown, 2001). Though the UK public sector spent around $3.5 billion annually on IT, the failure of major IT-enabled projects were characterised by delay, overspending, poor performance, and abandonment (National Audit Office [NAO], 2004, p. 3). At the political level, it is argued that "better IT is needed in the NHS because the demand for high-quality healthcare continues to rise and the care now provided is much more complex, both technically and organizationally" (Connecting for Health, 2004, p. 7). About $250 million is spent on management and administration in the NHS, a controversial figure, as many believe more doctors and nurses should be recruited (see Figure 1).

THEORETICAL ANALYSIS OF THE CASE

The NHS case study illustrates the dynamic nature of a national healthcare IS implementation, set within the context of a rapidly changing organisation. As with all large IT-enabled programs, the success or otherwise of the strategic plan is in its implementation (Doolin, 2004; Hendy, Reeves, Fulop, Huchings, & Masseria, 2005; Herzlinger, 1989). The lessons of IT costs versus medical decision making are well documented in the literature and involve the lack of alignment between the business and IT strategy (Luftman, 2000); a lack of ownership and leadership of the IT project among senior decision makers (Brown, 2001); poor risk assessment skills (Heathfield, Pitty, & Hanka, 1998); over-scoping of the functional and technical specification leading to IT projects becoming over-budget and late (NAO, 2004); poor communication between program/project managers and potential users of the system (Guah & Currie, 2005); inadequate resources to deliver/implement IT systems (Currie & Guah, 2006).

The empirical research found that issues of project risk were at the forefront of the minds of clinicians, general practitioners (GPs), hospital managers, and IT staff. Formal project management methods and tools were perceived as offering only part of the solution to mitigate the considerable risks from introducing the national program. The fragmentation was not just about the diversity of IT systems within the NHS, but also about the political geographical, social, organisational, and financial complexity of delivering healthcare.

The overriding view was for the national program to become an integrated IS across and beyond the NHS. The threats to achieving this were perceived by many clinicians to fall within the control of politicians and IT service providers rather than from NHS staff. Project risk mitigation was a complicated issue, compounded by the political and ideological considerations, such as the public-private partnership funding initiative (PFI), which facilitated the increasing use of private sector firms. While the NHS is often characterised as a top-down bureaucracy (Mohan, 2002), past achievements in IT development and implementation had often been initiated at a decentralised (hospital, departmental, unit) level. Although this was now discouraged by the centrist approach of the national program, staff participating in the research expressed concerns that any failures associated with IT project implementation may be labelled *staff resistance* rather than the shortcomings of external constituents, such as politicians, management consultants, or IT suppliers.

The success or failure of IS is inextricably linked with the dynamics of the organisation within which they exist. Miranda and Saunders (2002) have demonstrated the complex interaction of technical, social, cultural, and political elements that result in a failed IS. Equally, IS success depends on more than technical competence. The cultural and political environment of the NHS is difficult to study as it depends not only on the tangible organisational structure but also on the tacit knowledge and the perceptions of the participants (Guah & Currie, 2005). This is in addition to the cultural and political environment of an organisation that is not static but rather in a state of constant flux and dynamic change.

Institutionalism of IS in the NHS is concerned with processes of cultural persistence and change of healthcare processes. The survival of an organisation depends as much on conforming to societal norms of acceptable practice as to achieving high levels of production efficiency and effectiveness (Covaleski, Dirsmith, & Michelman, 1993). Prior work has shown that an organisation's formal structure, policies, and procedures serve to demonstrate conformity with the institutionalised rules and requirements of external constituents (DiMaggio & Powell, 1983; Meyer & Rowan, 1991). In light of these concerns healthcare in the UK showed that the national program was intended to play a high profile role within the heavily institutionalised environment of hospitals (Scott et al., 2000).

The UK healthcare system is infused with institutional logics emanating from various sectors across the organisational field. Healthcare is politically contentious where societal level logics developed by government are embedded into policies and procedures that cascade down to organisations where they are interpreted by various stakeholders including clinicians, managers, administrators, and patients. How these logics are interpreted varies according to the degree to which they affect changes to the perceived or real material resource environment of the institutional actors. The vision for the national program was infused with the institutional logics more commonly associated with the private sector, as an innovation that would contribute to greater productivity, efficiency, cost control, and customer satisfaction in healthcare delivery. Paradoxically, this externally directed institutional logic served to under represent and simplify the vast complexities and contradictions in how it was perceived, and reacted to, by those affected by government-led IT-enabled changed. Within the NHS, staff were increasingly sceptical about the merits of private sector logics, such as the PFI initiative, as their values, norms, and goals invariably placed financial considerations secondary to choices about patient care.

The proliferation of new entrants into the healthcare organisational field was a consequence of changing government policies over six decades. During this era of professional dominance, healthcare workers, particularly clinicians, enjoyed a level of freedom to define and structure their working practices. This extended to choices about the types of technology adopted and diffused across the NHS. As a new era emerged in the 1970s, which embraced managerialism as a way to enhance efficiency and performance, the European healthcare system was increasingly inundated with various managerial fads and panaceas, like BPR and change management (Herzlinger, 1989). An outcome of such interventions was that isomorphic structures across the NHS were increasingly threatened, as NHS managers were keen to demonstrate "best practice" examples through the adoption of the latest management ideas. Implicit in this logic was that NHS organisations that had not embraced "new ideas" ran the risk of being labeled as "against modernisation" or, at worst, "failing institutions."

Moving from an era of managerialism to one which increasingly advocates the use of "market mechanisms" to regulate and monitor healthcare services, efforts to differentiate NHS organisations still needs to be intensified further. The political rhetoric surrounding the right of patients to "choose" between one provider and the next is not likely to be based upon anything more than a crude assessment of the number of "stars" awarded a primary care trust (PCT), with those holding a low number becoming labeled as offering a less than adequate quality of service to patients. This will further fragment the organisational field of healthcare as the status of individual NHS organisations becomes increasingly differentiated on the basis of current and future evaluation criteria to measure performance. The topic of performance measurement was highly contentious, however, as respondents offering both a clinical and technical perspective believed that the emphasis upon target-setting was carefully designed to absolve politicians from responsibility by accentuating the role and accountability of professional groups.

The concepts of the organisational field, institutional logics, and governance systems are central to our understanding of how the healthcare system adopts and adapts to changes in the material-resource environment and the beliefs, rules, and ideas that comprise the value system. How and why these eras have emerged underpins our investigation into the UK NHS and facilitates our understanding of the nature and scope of large-scale change programs, and the extent to which they signal an institutional change within healthcare.

The institutional logics and governance systems must therefore be understood to explain why this type of change has occurred. In our investigation, we are concerned to apply our theoretical framework to help us understand how a large–scale, nation-wide technical change program is being adopted and diffused throughout the healthcare system and, more specifically, the changes in the organisational field, institutional logics, and governance systems that serve to encourage or inhibit such change.

TOWARDS BETTER VALUE IN HEALTHCARE DECISION MAKING

The national program is intended to help the situation healthcare managers presently face—with almost no say over the crucial factors which most managers anywhere else in the Western world and in other industries need to have in order to be effective (Wanless, 2004). The situation was brought about by a mixture of a quasi-medieval system and a control approach to managing patient data. Unlike other industries (i.e., banking and airline industries) where decision making leads to a good outcome, requires adaptation, and matching of the process to the individual customer, the healthcare industry may not necessarily provide a gold standard for a process that guarantees good outcomes for patients (Grabowski & Lee, 1993; Martin, 2003).

The previous is partly a result of humans being biological creatures and biological systems are inherently variable. As individuals we all have our own copies of genetic material—these materials mutate and evolve randomly. Because of the variability, the number of formulas and data points required to document each instantiation of a biological system constantly increases by several folds. Consequently, the number of conditions that need to be handled by uniform data standards is much greater than that required by standards for simpler physical, production or materials handling systems, however large or geographically widespread they may be. It takes into consideration that the patient's state of health is the result of the complex interaction between his/her unique genetics makeup, brain capacity, environment, and habits. Thus explaining why some individuals may be able to carry on fairly normal activities despite severe loss of 80% of their pulmonary capacity, others may be disabled by minor arthritis. Careful reproduction of a healthcare process that results in a good outcome for the former may not help the later.

Such scenarios dictate that the delivery of healthcare is not only unique in variety but also in the range of services and products. This explains why healthcare services are not typically chosen by the patient but by a more professional and knowledgeable representative (although these medics are increasingly being influenced by the pharmaceutical companies and/or government (Stevens et al., 1993). This shows just how the healthcare industry is different from others in the Western economy because the market in most industries is driven by the customer.

Health industry requirements are also exceptionally demanding in a number of areas. Most notable are the implications of violations of personal privacy while involving all those who need to know; dual responsibility for personal and public health; the complexity and expansion of the knowledge base and terminology; the high risk to the providers' livelihood combined with pressures to make critical decisions continuously and rapidly; and poorly defined outcomes. All of this is in the context of a "guild system" of responsibility, accountability, and power (Markus, 1983; Vogel, 2003). The healthcare industry also has to support personal and moral values, which in themselves are very complex. The judgments taken about personal attitudes to risk and potential benefit on interventions are all driven by our unique physical and mental makeup and local context—though our values are constantly changing over time.

The implementation of the national program demonstrates how healthcare services are perhaps the most complex large-scale business of UK's economy. More variability and uncertainty at the point of service, as to causality, processes, and to the outcome of that investment exists in healthcare delivery than in any other public sector. With such "variability and uncertainty" in the healthcare business, it is not surprising that identifying and measuring, let alone valuing, a financial return on investment (ROI) from computers in healthcare presents special challenges.

Value is a much broader concept than "benefits" as it implies the additional gain from one investment as opposed to another (Lucas, 1993; Sambamurthy & Zmud, 1994). The national program, like other IT projects, can generate value in many ways. As well as creating quality and process improvements, data from the system has utility that is much more subjective than that of any other resource (Guah & Currie, 2004). While data may be viewed as a commodity, asset, or resource, information is derived from the qualitative use of data and involves value judgments.

A number of the difficulties in "measuring" the national program's potential value the patients are that (Currie & Guah, 2006; Hendy et al., 2005):

- many infrastructure investments cannot be cost justified on an ROI basis;
- some of its sob-systems are being implemented to change difficult-to-measure NHS staff actions;
- many parts may be strategic systems, thus, eluding measurement;
- much of the new investment does not take into account the prior costs;
- efficiency (doing things right) is easier to measure than effectiveness (doing the right things); and
- since effectiveness (doing the right things) and innovation (doing new things) can not be readily quantified in terms of traditional outputs, improvements are not usually reflected in economic efficiency statistics.

While the effectiveness of a healthcare delivery process can be defined as "the extent to which a desirable outcome is achieved in a timely manner," the efficiency of healthcare delivery process could also be defined as "the extent to which healthcare delivery process is completed with the minimal consumption of resources." Consider the rather complex process of diagnosing and treating certain categories of patients in the NHS, most healthcare delivery processes can be effective (the patient achieves a full recovery and returns to his/her normal activities within 3 months) but relatively inefficient (say the patient had a 15-day inpatient stay, extensive ambulatory services, and consumed $300,000 in healthcare resources). The healthcare delivery process also can be ineffective (the patient has minimal subsequent capacity and never returns to his/her normal activities) but efficient (if the patient had a 3-day inpatient stay, a short post discharge ambulatory regimen, and consumed only $5,000 in healthcare resources). This demonstrates the need for healthcare managers to further strive for high effectiveness in combination with high efficiency and at the lowest possible costs.

Most components of the national program are intended for use in the NHS primarily to capture and manipulate data for improved—both clinical and administrative—decision making. Majeed (2003) suggests that part of the value anticipated from the national program derives from improvements in the effectiveness of the clinical decision-making process. It should enable physicians and nurses to make better, quicker decisions through mechanisms such as online access to evidence-based results for designated disease conditions, assistance in placing orders (detecting a drug-drug interaction before the order for a medication is actually placed), and receiving an alert electronically after a significantly abnormal test result (Keeler & Newman, 2001). Increasing the effectiveness of the clinical decision-making process should also lead to higher efficiency of that process, which should consequently lead to fewer errors being made and fewer resources being consumed. Among many problems highlighted by Majeed (2003), was the fact that necessary information was often difficult to obtain or simply unavailable, and what was available did not always support the clinical decision-making process.

Improved access to records means dramatically improved efficiencies in a variety of areas (Lucas, 1993). With the old paper-based system, the average turn-around time before laboratory and radiology reports reached the physician was several days. With the national program, diagnostic test results are available within seconds of being verified and has the potential of being brought to the physician's attention through their e-mails on the desktop or text message on a mobile (for telemedicine). In addition, the redundant orders that were often triggered by result delays have been virtually eliminated with the faster turnaround time, as well as with duplicate verifications for pharmaceutical orders (Majeed, 2003).

The national program will vastly improve communication between clinicians, particularly between nurses and physicians, and the emergency room and primary care physicians. It will give nurses instant access so that they can communicate with the doctors in the right way; the nurses are less frustrated because they do not have to go through the paper trail like they did before. These intangibles we know can be difficult to value but they are real enough to the participants.

CONCLUSION

The UK NHS is a highly institutionalised and complex system, which exists and operates both as a material-resource environment and a set of beliefs, rules, and ideas. Although these two environmental facets are conceptually distinct, material-resource environments are influenced by the institutional context. The selection of resources and how they are combined and deployed is determined by institutional beliefs and rule systems (Meyer & Rowan, 1991). By looking at the national program, this article has shown that implementing such a large IT project in the healthcare environment involves a supplier base that is seriously diverse, stretching from locally based specialists in particular applications and/or industry sectors to suppliers that are capable of applying a combination of sophisticated management techniques and technology investment to achieve new levels of process performance.

The primary contribution of this article has been to provide a theoretical basis drawing from institutional theory, which was used to analyse the NHS implementation of the national program. The theorisation goes beyond the relatively simplistic types of studies that dominate the IS literature today. Much to the contrary, it has been shown that an implementation strategy can accommodate elements such as the links between culture, contradiction and conflict, an analysis of detailed work patterns, and the dynamic and emergent nature of political involvement at national level.

The theory has been illustrated using limited empirical examples only, with a focus on the NHS systems, but it could be used to analyse any case study involving healthcare systems from any parts of the developed world. Viewed from a more critical perspective, however, any theory illuminates some elements of particular case situations and is relatively silent on others. The NHS has grown within an environmental niche that arose out of a complex interaction between the national healthcare environment, business environment, the organisational environment, and the people within the NHS. Changes within the organisation subsequently rendered the environment hostile to the national program, which was affected by its changing links with organisational structure and people, the changing responses of people within the NHS to the environment around them, and the changing individual and collective mindsets and understanding of those people. While a detailed discussion of ways in which this can be achieved is beyond the scope of this article, some broad approaches have been mentioned.

In the current environment of increasing demands for better quality of healthcare from patient and seemingly reduced amount of funding from national governments, the need for suitable institutional theory is increasingly common and the IS field must increase its understanding of the problematic issues involved and approaches to resolving them. It is hoped that this article makes a modest contribution to these goals.

Informatics Application Challenges for Managed Care Organizations:

The Three Faces of Population Segmentation and a Proposed Classification System

Stephan Kudyba

Independent Scholar, USA

ABSTRACT

Organizations across industry sectors continue to develop data resources and utilize analytic techniques to enhance efficiencies in their operations. One example of this is evident as Managed Care Organizations (MCOs) enhance their care and disease management initiatives through the utilization of population segmentation techniques. This article proposes a classification system for population segmentation techniques for care and disease management and provides an evaluation process for each. The three proposed operational areas for Managed Care Organizations are: 1) Risk Status: early identification of high-risk patients, 2) Treatment Status: compliance with treatment protocols, and 3) Health Status: severity of illness or episodes of care groupings, all of which require particular analytic methodologies to leverage data resources. By applying this classification system an MCO can improve its ability to clarify internal goals for population segmentation, more accurately apply existing analytic methodologies, and produce more appropriate solutions.

INTRODUCTION

Population segmentation is the term broadly applied to technologies used to correctly identify and target the right patients for care and disease management program interventions. Many MCOs are using these technologies, including those containing predictive modeling techniques and quantitative applications, to enhance patient care and optimize available resources. With the rapidly growing use of population segmentation and predictive modeling today, it is essential to understand the relative strengths and weaknesses of different types of population segmentation techniques, including those employing predictive methods. The purpose of this article is to propose a classification system for the different types of population segmentation techniques and their usefulness in addressing the independent and interactive roles of risk status, treatment status, and health status in patient evaluation initiatives.

Organizations across industry sectors have intensified their initiatives to increase operational efficiency through effective resource allocation, and the health care sector is no exception. Given the increased level of competition in today's' digital, information economy, organizations are faced with the task of increasing productivity by more efficiently allocating available resources in producing goods and services to meet the demands of their customers. One of the greatest issues facing the health care industry today is managing patients who suffer from chronic illnesses. Currently, approximately 100 million Americans have at least one chronic condition and this is expected to rise to over 150 million Americans in the next 20 to 30 years (Faughty, 1999; Institute of Medicine, 2001). Furthermore, chronic conditions are the leading cause of death, disability, and illness in the United States, accounting for over 75% of direct medical expenditures (Landro, 2002).

The health care industry has been faced with a number of additional factors that have increased the complexity of managing available resources. Some of these include an increase in the aging population, costs for defensive medicines, optimizing existing health care facility usage (e.g., staffing doctors and nurses along with designated bed utilization rates) and the introduction of new organizations such as HMOs and PPOs (Smith-Daniels, Schweikhart, & Smith-Daniels,1988). One way Managed Care Organizations are attempting to improve their efficiencies in treating illnesses is through the development and management of robust data resources and the utilization of analytic techniques to identify patterns and trends in patient populations. With this information, efficiency can be enhanced by more accurately identifying the sources of resource demand of specific customer segments and initiating strategic health care management policies and better allocating available resources to meet those demands (Heskett, 1983; McLoughlin, Yan, & Van Deirdonck, 1995).

Analytic Methods for Health Care Management

The utilization of analytic techniques in strategic management is increasing (Shook, 2000). More formal analytic techniques such as stochastic trees have been utilized to help increase operational efficiencies by enhancing the decision making process in medical treatment procedures (Hazen, 1992, 2000). Other analytic methodologies involving data mining techniques enable decision makers to identify patterns in clinical-, claims- and activity-based historical data, to better understand explanatory relationships in data and create models to more accurately predict future resource demand (Xiaohua, 2005). Artificial neural networks are computer algorithms that identify relationships in historical data that can be used for classification and prediction (Bishop, 1995; Swingler, 1996). Reducing the uncertainties in process resource requirements through enhanced predictive capabilities is seen to increase efficiency across industry sectors (Kudyba & Hoptroff, 2001).

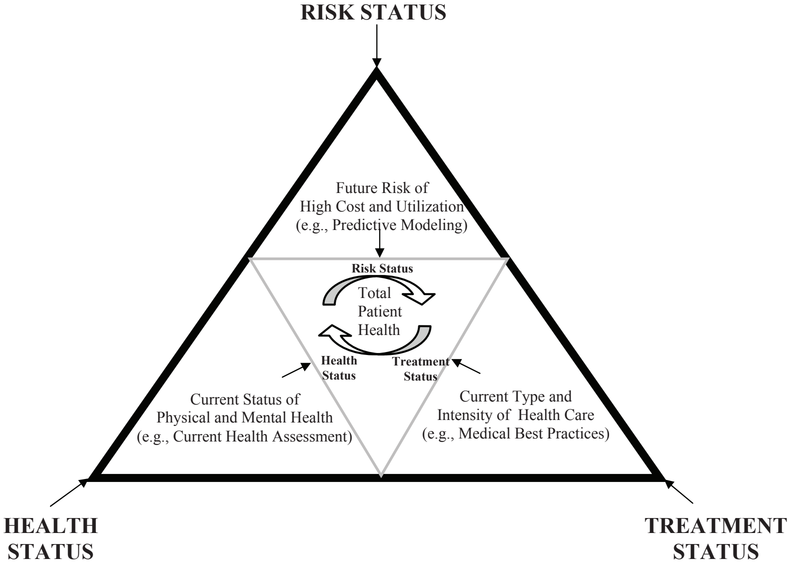
More effective disease management through data analysis can assist our current health care system to fill the ever-increasing gaps in health care service, management, and treatment. Disease management programs utilize both cost-based and health-based rationales for prevention and health promotion, emphasizing medical best practices and evidence-based medicine. Usually, outcomes are evaluated on the basis of clinical/therapeutic improvement or compliance, financial/cost reduction, and behavioral/emotional enrichment (Hunter & Fairfield, 1997; Leider & Krizan, 2001). Ultimately, the success of disease management programs often depends upon the ability to target an appropriate intervention to the appropriate patient, where population segmentation enhances MCOs' ability to accomplish this.

The following section of this article provides more detailed background on the application of population segmentation techniques to enhance health care efficiency and introduces three primary areas where they can be utilized by MCOs. A detailed analysis of the required analytic objective corresponding to three primary health care assessment areas (e.g. Risk Status, Health Status and Treatment Status) is then provided. The criteria for categorizing population segmentation methods according to the three primary assessment areas are then described.

APPROACHES TO POPULATION SEGMENTATION AND PREDICTIVE MODELING AND A PROPOSED CLASSIFICATION SYSTEM

Research addressing the use of quantitative-based decision support systems to enhance efficiency in the health care sector is on the rise given the development of data resources and availability of sophisticated analytic methods (Walchzak, Brimhall, & Lefkowitz, 2006; Raghupathi, 2006). There is great interest today in the application of population segmentation and predictive modeling to enhance care and disease management programs by correctly focusing resources and interventions on the segment of a population who would benefit the most from interventions (Ash, Zhao, Ellis, & Sclein, 2001; Cousins, Shickle, & Bander, 2002; Ridinger & Rice, 2000). While

Figure 1.



A single patient may be looked at from each of the three perspectives.

most analytic approaches share a common goal, to enhance a care or disease management program's ability to improve quality of care while lowering overall cost, they are optimized to address this goal in different ways. We propose a classification system to clarify the objective of the most commonly used population segmentation and predictive modeling approaches.

The proposed classification system divides the methodologies based upon their useful functionality in addressing three primary operational areas for MCOs. The three proposed classifications are Risk Status, Treatment Status, and Health Status (see Figure 1). The benefits of this classification system are to enable MCOs to clarify their primary objective, thereby enabling them to select a methodology that best fits their need and ultimately achieve better disease management solutions.

Disease management programs make use of population segmentation to improve the efficiency and effectiveness of their interventions. Population segmentation approaches often serve different objectives such as early identification of high-risk patients, identifying compliance with treatment protocols, or categorizing patients by severity of illness for payment adjustments or outcomes reporting. It is important to use the appropriate methodology to best meet the information requirements of a specific intervention. Depending upon the MCOs' focus and intervention(s), some disease management programs might use one approach while other programs might use two or more approaches.

For disease management purposes, predictive modeling is defined as utilizing currently available data to prospectively identify an individual's risk of a specific outcome. Thus, one may look at a patient's claims or survey data to determine if the patient has an increased risk of future hospitalization, high cost of care, or some morbidity event (Kudyba, Hamer, & Gandy, 2005). As will be described next, each of the population segmentation applications (i.e., health status, treatment status, and risk status) has a predictive component, but not all are optimized for predicting future risk. The following section will describe the objectives required for each of the three areas of application (assessment) and clarify the appropriateness of corresponding population segmentation approaches.

THREE PRIMARY AREAS OF ASSESSMENT FOR MCOS (RISK STATUS, TREATMENT STATUS AND HEALTH STATUS)

Risk Status

Risk status refers to a patient's likelihood for specific clinical outcomes (e.g., myocardial infarction), financial outcomes (e.g., significant increases in future health care costs), or utilization outcomes (e.g., emergency department or hospital visits). It can also refer to the probability of future risk for developing certain medical conditions, such as obesity or cardiac disease (Perry, 2007). Risk status focuses on the probability of future events, making this classification of population segmentation optimally predictive in nature. Predictive modeling techniques for this area range from simple linear equations to complex neural network forecasting techniques (Grana, Preston, McDermott, & Hanchak, 1997; Kiernan, Kraemer, Winkleby, King, & Tylor, 2001). These may include seasonal adjustment methods and trend lines (Cote & Tucker, 2001), and heuristics including uncomplicated rules-based algorithms to multifaceted decision support techniques (Ferreira et al., 2001). Obviously, the mathematical or logical technique used to assess risk status is highly dependent upon the type of risk being evaluated. Regardless of the methodology, the objective of evaluating a patient's risk status is the same, prediction of an unknown future event.

A recent study conducted by Kiernan et al. (2001) compared two prediction techniques, logistic regression and signal detection, to assess individuals who are at risk for being overweight. This study was based on survey data from 1,635 White and Hispanic men and women. Body mass index (BMI) was used to define "overweight" for this population, and predictor variables used included gender, ethnicity, age, and educational level. Results from the study demonstrate that both methodologies had similar predictive accuracy and identified a similar set of risk predictor variables. Nevertheless, these methods did not classify the same individuals into population subgroups. Notably, a very high risk group (less educated, young Hispanic adults) was hidden by the logistic regression analysis but was revealed by the signal detection analysis. These results demonstrate the importance of selecting the best technique of population segmentation to identify a high-risk population.

Logistic regression was utilized to predict the probability of asthma-related hospital admissions for asthma members in a large HMO (Grana et al., 1997). A predictive model was built from administrative data (e.g., medical, pharmacy, laboratory, and enrolment files) associated with over 54,000 asthma patients. Asthma-specific utilization, pharmacy data, and length of enrolment were found to be the best predictors of future asthma-related admissions. Results were evaluated by the predicted number of admissions compared with the actual number of admissions, broken down into 10 deciles. Analysis of the top three deciles resulted in a sensitivity and specificity score of 0.70 and 0.71, respectively. These results demonstrate how claims data alone can be used to accurately predict future hospitalizations for patients within a population.

Risk status technologies are optimized for predicting future risk. In addition to applications in disease and care management programs, this category of population segmentation, which employs predictive modeling techniques, is also the type of segmentation technology that is currently emerging in underwriting, rating, and payment adjustment. Population segmentation that focuses on Risk Status is best suited for correctly identifying and targeting the highest risk patients and thus is the most predictive of the three classifications. The next operational area which can be addressed by population segmentation methodologies involves Treatment Status for patients.

Treatment Status

Treatment status focuses on the actual care that a patient is receiving, or in other words, the type and intensity of health care delivered. Treatment status encompasses an assessment of medical best practices or evidence-based medicine protocols. It is often evaluated as part of a physician profiling system. Obviously, not all patients are alike; there is variability in both mental and physiological responses to treatment regiments. Likewise, not all physicians are alike; there are differences in education and training as well as in personal attitudes. Nevertheless, evidence-based clinical practice guidelines can help to manage this inevitable variation. Within a disease management framework, treatment status becomes a very important population segmentation application, especially when attempting to manage and coordinate the health care delivery for thousands of chronically ill patients. Often, there is a gap between recommended standards of care and the treatment received by chronically ill patients (Muney, 2002). Only through careful evaluation of a patient's treatment status can these treatment gaps be identified and addressed.

Research on treatment status includes studies such as that conducted by O'Connor, Sperl-Hillen, Pronk, and Murray (2001), to investigate clinical-based practice characteristics related to best practices within chronic disease care. The objective of the study was to identify those features shared by successful primary care clinics. Seven primary care practices managing patients with diabetes, hypertension, lipid disorders, or heart disease were examined. Data from each of these clinics were compiled and treated as individual case studies. Results from this study illustrate that focusing on treatment status of chronically ill patients can facilitate significant improvements in health outcomes within 1 to 2 years in adults with diabetes, hypertension, or lipid disorders. For example, a 20% reduction in risk for a major cardiovascular event (on a population basis) was reported. This study, as well as others (Heller & Arozullah, 2001; Solberg, Reger, & Pearson et al., 1997; Wagner, Austin, & Korff, 1996), illustrates the benefits of improving treatment status in chronically ill patients, which results in better clinical and financial outcomes.

While treatment status has some predictive value and is an important component of care and disease management, it is not optimized for true predictive modeling. For example, we can use a population segmentation methodology to address treatment status to identify two patients that have elevated cholesterol and are not being appropriately treated with antilipidemic medication. Both patients are at increased risk for poor clinical outcomes, so there is some predictive component to this methodology. However, we cannot immediately infer if both patients are at co-equal risk. To add to the example, if one of the patients is 35 years of age with a family history of hyperlipidemia and cardiac disease and the other patient is 85 years of age without any current cardiac disease, then clearly the two patients are not at equal risk for cardiovascular complications in the future. Treatment Status is optimized to identify gaps in treatment, and is therefore not optimized to identify patients' Risk Status or for predictive modeling. One final area of focus for MCOs entails analytic requirements for Health Status applications.

Health Status

Health status refers to the current standing of a patient's clinical, physical, and mental health. Population segmentation techniques to address Health Status are utilized to describe a patient's current health relative to other patients. Health Status technologies generally serve one of two broad purposes: 1) classifying patients by health status for outcomes measurement and comparison purposes, or 2) categorizing patients into similar severity levels for assessing treatment intensity or for payment adjustment design. Other health status methods are utilized to group patients according to their likely treatment needs and resource consumption during a current episode of care (Baker, 2002). Currently, many health care organizations are using proprietary grouper software for patient/provider profiling, utilization/clinical benchmarking, disease/case management activities, and quality improvement initiatives.

There is a relationship between current health status and health outcomes. Goetzel, Anderson, Whitmer et al. (1998) conducted a study of the Health Enhancement Research Organization (HERO) database in order to estimate the impact of modifiable health status factors on health care expenditures. Overall, individuals who had poor health status had significantly higher expenditures than individuals who had a better health status in 7 of the 10 health status categories (depression, high stress, high blood glucose levels, high/low body weight, former tobacco users, current tobacco users, and high blood pressure). Moreover, individuals with poor health status in multiple categories had much higher medical expenditures than those without. For example, those with heart disease, psychosocial, and stroke profiles had 228%, 147%, and 85% higher expenditures, respectively. This study indicates that patients' health status is associated with at least near-term increases in the likelihood of incurring future high medical costs (Anderson, Whitmer, & Goetzel, 2000; Leutzinger, Ozminkowski, Dunn et al., 2000).

Despite the correlation between health status and future health outcomes, general population segmentation technologies that are optimized for Health Status are not optimized for predictive modeling. For example, two patients who are in critical condition may score similarly on a GHA. Both patients are likely to incur substantial costs in the near term and are obviously at short-term risk for poor clinical outcomes. However despite the same GHA score, we cannot immediately infer if both patients are at the same risk for long-term health outcomes or long-term expenditures. To continue the example, if one of the patients is 70 years of age with terminal cancer and the other patient is 25 years of age and was recently in a traumatic accident, then the outcomes may be dramatically different over a 12-month time frame. Health Status is optimized to correctly classify patients vis-à-vis their current health, and is therefore not optimized to identify patients' Risk Status or for predictive modeling.

EVALUATION CRITERIA OF POPULATION SEGMENTATION METHODOLOGIES FOR MCO AREAS OF ASSESMENT

An important first step in evaluating population segmentation and predictive modeling techniques is to define the specific purpose and goal of the modeling initiative. To date, the evaluation process has often been complicated because of a lack of clarity in the specific goal for potential applications. In addition, there is often a lack of clarity within the MCO for what would be done with the information once obtained. For example, the care and disease management departments might envision early identification of at risk patients, the provider network department might envision provider profiling on quality metrics, and the finance department might plan to use the information to enhance underwriting or rating. While all of these are reasonable goals, they may not all be obtainable with a single technology, and it is highly unlikely that a single technology will perform optimally well for all purposes.

The evaluation process should begin with a definition of the purpose and goal of the application, where multiple goals, should be prioritized. This is important when balancing trade-offs in performance. Once this is achieved, the best class of population segmentation technology must be selected to meet this goal. For Risk Status applications, the goal is to apply and evaluate the predictive modeling accuracy. The focus is on accuracy metrics such as positive predictive value, true/false positive rates, true/false negative rates, sensitivity and specificity at various screening thresholds, and ROC or R-squared values. For each metric, it is important to ascertain how the metrics have been validated and if they will generalize to a particular MCO setting. For Treatment Status applications, the goal is to evaluate the comprehensiveness and accuracy of the assessments. The focus is on number of diseases covered, number of evidence-based standards covered, the quality of the algorithms used (i.e., are they disclosed or hidden in "black box" technology?), and the source of the standards (evidence-based, proprietary, etc.). The Treatment Status system's accuracy must also be considered. This typically involves an assessment of the sensitivity and specificity of classification with respect to treatment status. Applications based upon both survey and claims data invariably produce some errors. Consequently, it is important that the assessments produce reasonable information that will be clinically acceptable, providing a sound basis for intervention decisions. For Health Status applications, the evaluation focuses on the system's ability to correctly classify patients into comparable groups or cohorts. For example: (1) What is the accuracy of the system's prediction in categorizing patients into a certain level of health or episode of care? (2) Can the system be generalized and can the results be used to compare to other groups or over time? and (3) Is the system well accepted by the provider community if it is to be included in payment schemes? If a single system purports to provide current health status and also predicted future health outcomes, then it is important to evaluate the accuracy metrics as described above for both the current health status prediction and the future health outcomes prediction.

Existing population management approaches fail to fully utilize information derived from these three statuses. The difficulty in integrating multiple data sources and data types has resulted in the optimization of operational systems based on single sources. Obviously, positive outcomes have certainly been achieved using this type of single source methodology, which focuses interventions vis-à-vis highly specific, singular data sources or assessments (Huffman, 2005; Ropka, 2002). However, as described in this article, when faced with the penultimate operational challenge of population management (i.e., delivering limited resources to the right patients at the right time) it becomes increasingly important to use information derived from multiple sources in order to decrease the probability of incorrect allocation of these resources.

The informatics approach described in this article is not without limitations. This approach requires extensive IT resources and IT system architectural changes. It is also very data intensive and requires the coordination and management of large amounts of data.

CONCLUSION

In this article we have proposed a classification and evaluation method for population segmentation approaches used in care and disease management. Risk Status, Treatment Status, and Health Status assessments each provide useful information to forecast the best allocation of resources and interventions within a population of interest. For example, a disease management company might be interested in managing those patients who are at high risk for future hospitalizations. In this example the disease management company could use information from population segmentation approaches in order to focus resources on the segment of the population with the highest probability of future hospitalizations. However, the analysis of each assessment application is optimized differently: Risk Status is optimized for the prediction of future events, Treatment Status is optimized for the identification of gaps in medical care, and Health Status is optimized for the classification of patients' current state of physical and mental health. Clearly, in order to capitalize on the strengths of population segmentation methodologies, health plans need to understand the primary functionality of a given population segmentation methodology in conjunction with the required objective of the particular assessment application and, subsequently, select the most appropriate modeling approach that best fits their purposes.

As MCOs increasingly rely upon care and disease management programs to fill gaps in health care service and delivery, correctly identifying and targeting patients for program interventions has risen in importance. Though risk status is clearly the application that is optimally predictive in nature, it cannot alone be used to evaluate, assess, and allocate interventions to a given population. Population segmentation methodologies addressing current treatment status and health status, as well as anticipated risk status, are the most effective and logical way to move forward with an overall intervention strategy. Meanwhile, it is important to differentiate between these three approaches, because they have been optimized for different goals. Clarity in purpose and focused evaluation against that purpose will provide MCOs with the best techniques. Consequently, MCO disease management programs that truly integrate/utilize all three approaches will best succeed in accomplishing the main goal of focusing the right resources on the right patients while increasing quality of care and decreasing overall medical expenditures.

Chapter 5.4

Preparing Healthcare Organizations for New IT Systems Adoption:

A Readiness Framework

Robert Breas
National IT Institute for Healthcare (NICTIZ), The Netherlands

Matthew Waritay Guah
Erasmus University, The Netherlands

ABSTRACT

Information systems exist for hospitals but even the most advanced systems concentrate on relatively simple coordination, resource allocation and documentation aspects of healthcare operations. At the same time the need to improve health care performance by means of more sophisticated IT systems is widely felt. In practice, however, the adoption of new IT is usually a difficult and a very slow process. To analyse the underlying reasons, we identified a set of key bottlenecks in the IT adoption process by interviewing large groups of healthcare actors. We conclude that health care organizations should be better prepared in order to facilitate easier IT systems' adoption. To do so, a readiness framework is considered to be helpful, the contours of which are sketched in this article. It is also discussed how, based on clarified clinical pathways, workflow management can assist in framing optimization of resource utilisation, clinical decision-making, staff training and quality improvement in healthcare delivery. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

Recent drive to automate hospital information has focused on the formal implementation of electronic health records. These systems are largely relational databases that focus on transaction-based intra-enterprise applications. Yet only a limited number become fully functional, scalable, distributed systems with interoperability. Based on these observations, it is widely felt that more sophisticated information systems are needed to support health care performance based on the concept of clinical pathway optimisation. The adoption however of such integrated distributed information systems takes place at a very slow rate (Aarts 2005; Stoop 2005). Underlying reasons given in popular literature relate to the misunderstanding of healthcare business processes.

Healthcare processes are very complex and dynamic due to the involvement of clinical and administrative tasks, large data volumes, large numbers of patients and personnel with different tasks requiring specific knowledge. Healthcare is a business where many changes occur (i.e. (new) treatments, drugs, equipment, protocols, and legislation). These changes have their influence on the instantiated processes that need adjustment (Anyanwu et al; 2003).

Observation of the dynamic character of healthcare system and the implementation of IS at Erasmus MC (medical centre) led towards the following research question.

Which internal factors of IS implementation affect healthcare organizations' readiness for new systems?

The following sub-questions assisted in finding answers to the central research question.

- What are the consequences of IS implementation in health care?
- What is the impact of IS implementation on organization?
- What initial choices need to be made before an IS implementation decision in a healthcare organization?

The article is structured as follows. The next section describes the potential workflow management (WfM) and how WfM affects healthcare IS. That will be followed by a brief description of actor network theory (ANT) before a sketch on key bottlenecks related to the introduction of new IT as found in the scientific literature and selected by using criteria taken from change management. The design and results of the empirical research will integrate the content into a coherent view that is used to sketch a readiness framework for new IT adoption in complex healthcare environment. Finally, we discuss the high potential of WfM to provide optimised healthcare, provided that the healthcare organisation at stake has been sufficiently prepared for adopting of WfM systems. We finalize this article by presenting our conclusions.

What is Workflow Management?

In the last couple of years notion was growing about whether data processing in complex organizations should not only be based on integrated data management, but also on integrated process management. Organization processes usually define the order and time of data creation and alteration. Workflow management (WfM), also referred to as structured process management, is an important ingredient for data processing and data management in many cases. Automated support is needed to effectively and efficiently execute process management in complex environments and situations. WfM, from a general perspective, can be seen as administrative logistics. Like physical logistics where the right goods are delivered at the right place and time, WfM takes care of delivering the right information at the right time and by the right person (Grefen, 2001).

Workflow is an abstraction of a business process. Normally a workflow comprises a number of logical steps, known as tasks. These tasks consist of dependencies among tasks, routing rules and participants. A task can require human involvement, or it might be executed automatically by IS applications (Cardoso et Al, 2004). Some well established definitions of WfM in literature are given below.

The ultimate goal of workflow management is to make sure that the right persons execute the proper activities at the right time (Orlikowski, 2000). Although it is possible to do workflow management without using a workflow management system, most people associate WfM with WfM systems.

Cardoso (2002) defines WfM as a workflow model, which is customized to accommodate specific business process structures. Workflows are designed based on business processes. These processes already exist in an organization and need to be improved or managed better. Once the design phase of the model is completed, instances are created to carry the actual steps described in a given workflow. During their execution, the workflow instances can access legacy systems, databases, applications and can interact with users. Workflow systems are flow-independent; they control a data flow among tasks is graphically described during the workflow design phase. This makes applications independent from the underlying workflow system.

Workflow management is a technology supporting the reengineering of business and information processes (Georgakapoulos, 1995). WfM involves:

a. Defining workflows, e.g., describing those aspects of a process that are relevant to controlling and coordinating the execution of its tasks. It will require the skills of individuals or information systems to perform each task.
b. Providing for fast (re)design and (re)implementation of processes such as business needs and information systems change. To effectively support WfM, organizations must evolve their existing computing environments to a new distributed environment that:
    - Is component-oriented, i.e. it supports integration and interoperability among loosely coupled components corresponding to Heterogeneous, Autonomous and Distributed (HAD) legacy, current and new systems;
    - Supports workflow applications corresponding to business or information process implementations accessing multiple HAD systems;
    - Ensures the correctness and reliability of applications in the presence of concurrency and failures;
    - Supports the evolution, replacement, and addition of workflow applications and component systems as processes are reengineered.

The remaining of this section aggregates the above definitions for a more comprehensive one that suits the article's optimal objectives. The above definitions share three factors of importance to our interest in healthcare IS implementation: people, processes, and IS. The other definitions weren't complete on those factors, and lacked at least one of them. Our agreed definition of WfM is the customisation of workflow to accommodate specific business process structures. The goal is to have the right persons execute proper activities at the right time. Workflows are designed based on existing business processes in an organization that need to be improved or managed better. Therefore they support the reengineering of business and information processes. They define aspects of processes that are relevant and necessary for controlling and coordinating the execution of functional tasks. This will require the skills and input of individuals and the usage of Information Systems to perform each task. During the execution of tasks, workflow instances support integration and interoperability among loosely coupled components corresponding to Heterogeneous, Autonomous and Distributed (HAD) legacy and new systems. WfM must also be able to access legacy systems, databases, applications and set-up an interaction with users. It also must ensure the correctness a reliability of applications in the presence of concurrency and failures. Used applications are independent from the underlying workflow system.

The addition of all these factors may not be able to explain why adoption of new IT is so difficult (Guah, 2000). The difficulty is not due to problems related with software or hardware or to limitations of technologies in use. Systems fail because they are built on the wrong assumptions, incorporate problematic models of medical work or implementation is not seen as an organisational change (Berg et al. 2003).

Reflecting these observations, we recognize that organizations might not be well prepared for adopting new IT solutions. This case study on lack of readiness for IS implementation in healthcare organization contains interviews with a set of relevant healthcare actors in Erasmus MC, the largest medical centre in The Netherlands. The main goals of the case study were:

a. to show what we have found as the key bottlenecks in the IT adoption process,
b. based on these key bottlenecks found (and those presented in literature) to sketch the contours of a readiness framework to present in this article, and
c. to illuminate why and how, after having finished the preparation phase, workflow management has great potential to improve quality in complex healthcare delivery (Breas, 2007).

This research shows conflict between the tendency to build internal but somewhat restrictive systems and the need to plan for future interoperability, multi-functionality and scalability by the hospital management to avoid a too limited operational success and acceptance.

Actor Network Theory

Actor-Network Theory (ANT) is a well-known theory from within the field of science and technology studies that has developed conceptual constructs to deal with the processes through which technologies are developed and influence societies. Though ANT has a relatively short history, it is a multi-disciplinary field and unlike the field of information systems, it allows a deeper devotion to theoretical and explanatory studies, without assuming an intellectual responsibility for guiding professional practice (Latour, 1999).

The authors have selected ANT as a framework for analysis due to a number of reasons:

- It is well established with an important hinterland of work explaining, critiquing, developing and applying the theory; including application to information systems in the healthcare sector (Heathfield, Pitty, & Hanka, 1998);
- It has been comparatively stable, with later presentations building on the original theory, probably because the theory is "owned" by a particular group of followers (Latour, 1986);
- It overcomes some important limitations of the "IT as an enabler" perspective of general management science literature that are based on technological determinism and can thus be presented as a complementary approach to information system research.

ANT Concepts

The "actor-network" concept was developed by Michel Callon, Bruno Latour and John Law during the course of the 1980s as a recognition that actors build networks combining technical and social elements and that the elements of these networks, including those entrepreneurs who have engineered the network, are, at the same time, both constituted and shaped within those networks (Law, 1999).

The unique position of technologies in ANT recognizes that IT does not evolve under the impetus of scientific logic unlike common suggestions by technological determinism. IT does not possess an inherent momentum that allows it to do what Latour (1986) describes as passing through a neutral social medium. Bijker and Law (1992) similarly concludes that "technologies mirror societies" considering they are continuously shaped and reshaped by the interplay of a range of heterogeneous forces within the networks. Therefore IT is as much an actor in the networks as are the human parties.

Papers on ANT often develop their arguments in an empirical context (Latour, 1999; Law, 1999) with tales that tend to be heroic. They narrate how actors, within a specified period, manage to constitute themselves and their networks; thus treating the world as a set of related bits and pieces with no social order. There are only endless attempts at ordering through the formation and stabilization of networks (Latour, 1999). By telling stories and tracing histories rather than taking snapshots, ANT proves itself as "a pragmatic, recursive sociology of process with an interest in the uncertain processes that generate power and size" (Law, 1999). By clarifying power relationships in organizational settings, ANT helps us understand how actors are defined, associated and obliged to remain faithful to their alliances.

Bottlenecks

At this moment healthcare organisations are focussing more on the existing processes. Klischewski and Wetzel (2001) proclaim a couple of sticking points that exist in the healthcare environment concerning processes.

- The first sticking point they discuss is the lack of overall responsibility for either the process or it's planning. The process mostly relies on the ability and commitment of individual providers to flexibly shape the service according to their special insights about the patient's case (Klischewski and Wetzel, 2001). A lack of fixed responsibilities seems to be the crux of this problem;
- Secondly, there is a problem relating to the exchange of patient information. Clear rules are needed for documentation of patient records and the exchange of patient information;
- The third point concerns the monitoring of the process status. The healthcare providers involved have little oversight about the complete process, its current status or further development. Healthcare providers often lack information about deviations from tacitly assumed ways to proceed, or are unable to obtain this knowledge (Klischewski and Wetzel, 2001).

What often is forgotten, while implementing an IS related product, is that such an implementation will fundamentally affect the structure and processes in a health care organization. This is a core reason for failure of the implementation (Berg et al. 2003).

What is needed is a mutual transformation of the organization and the (level of) technology. Work tasks and information flows will be affected or changed. This will also affect relationships between (groups of) health care professionals. Discussions about data access among health care professionals will be inevitable and can lead to political and social issues (Berg et al. 2003).

An IS implementation should not be run as only a technical project. Organizational structures, routines and roles should be managed as well. This means that adequate user involvement is extremely important by development and by implementation of IS that must be accepted by the different users. A good fit between work processes, and involved characteristics like roles, and IS is evident. System specifications and implementation plans should be discussed among the different users and IS department. Interdependencies between work tasks should be made clear and less abstract for the users and IT-department during such discussion (Berg et al. 2003).

These identified sticking points by Klischewski and Wetzel result in a set of requirements regarding the software support for inter-organizational services in healthcare, or in other words Workflow Management. They claim four main requirements for the design process:

- **Flexibility support:** The support of the process has to provide flexibility and dynamic selection and configuration of services as the process moves on. The steps in the process also need to be transparent to the parties involved;
- **Interoperability:** Patient information between different physicians and other healthcare providers must be exchangeable and shareable. Therefore software components must be compatible with each other for digital information exchange;
- **Customer Orientation:** Service delivery has to consider the possibly changing customer concern and the subtleties in customer satisfaction. This goes beyond efficiency criteria of underlying processes and has to do with understanding the customer concern and with service customization, e.g. the availability of services;
- **Agreement Process:** The parties involved have to formulate the entire service process, e.g. the kind of service delivery, IS support (Klischewski and Wetzel, 2002).

These requirements are directly related to financial aspects, which also have an important role in healthcare. For this article the financial aspects were considered out of scope.

EMPIRICAL RESEARCH

Three methods of data collection were adopted. First, the researchers assembled a range of academic, government and industry studies on the healthcare sector in The Netherlands. This material proved invaluable for understanding some of the societal, economic, political, cultural and technical differences in today's healthcare delivery and that of the past decades. Second, we attended various meetings, workshops and exhibitions on Duthcare healthcare systems. Some of these events were focused on general topics (i.e. IT in healthcare, patient services, hospital management and professional best practice), with others more focused upon specific activities. These events generated many useful research contacts

We engaged in primary data collection, conducting around 25 open-ended and semi-structured interviews during the nine months period, with a range of actors (i.e. health service professionals and administrators, clinicians, IT researchers, and Erasmus MC IT deparmental staff).

Data Collection

Data was collected using questionnaire in the Obstetrics department and the outpatient clinic. Goal of the case study was to determine the level of efficiency and make measurements for pinpointing where more efficiency could be achieved. Two important aspects of the case study were the process analysis and the time measurement research, were every worker (from secretary till physician) had to register time spent on their tasks. This data was used to find out what and where the primary bottlenecks for IS and healthcare were. Figure 1 demonstrates the bottlenecks observed in the decision structure:

- Decisions are made by people who don't have a clear overview of the work floor;
- Lack of involvement of different actors with different functions during decisions;
- The IS department's primary task is to respond to the requested demand;
- Responsibilities about project tasks are ambiguous.

Lack of Alignment between Existing Processes and IS

Many IS implementations, which were reviewed in this case, weren't based on the workflow of the specific unit. This means that as a result, systems did not have a high compatibility with processes. Other than that, functionalities within implemented systems weren't used to the full capacity. Without a good alignment with processes, IS implementations were not optimal effective and efficient as they could be. A better alignment can result in better patient quality and a reduction in costs.

Involvement of Relevant Actors at Decision Moments

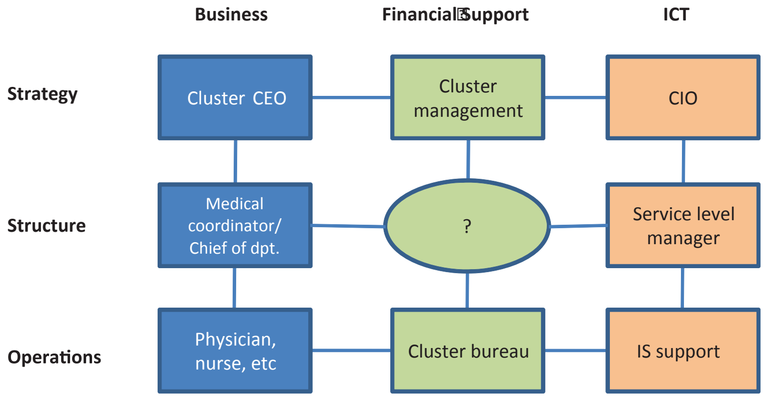
At this moment the medical staffs are the only ones making decisions about which systems to use and what the necessary specifications are needed. The staffs cooperate with the IS department and have information meetings in which decisions are made only from their perspective. Input from other actors, such as physician assistants and nurses, are not taken into consideration. This group are the end users of the specific system because the staff physicians are less involved in the primary care process. Lacking the input of that group is eventually a loss for the workability of the system/application.

Due to staff lack of full knowledge on the level of operational management, their decisions carry a risk of an IS implementation resulting in incomplete fit with the unit. To recapitulate, the people who have to work with the system are very important. They are responsible for the unit to function well. Involvement of more actors is needed to make sure that IS implementations can have a good fit within the unit.

Existence of Inefficient Administration

Across Erasmus MC, most units have high numbers of information systems. E.g. the Obstetric unit uses twenty-three mini-systems just for registering different kinds of patient information. The people who work at the Obstetric unit perceive this high number of used systems as normal. Due the vastness of systems, a lack of communication between them exists. As a result a lot of patient information has to be inputted more than once, which means redundancy. Another danger of redundancy is clarity about where the most recent patient information is registered and whether this information is retrieved. In our opinion this has a negative effect on the quality of patient care. Further research on this topic is necessary.

Figure 1. Business and IT roles, adapted for the Erasmus MC (Adapted Maes, 1999)



Decision Structure

As stated earlier this chapter, many decisions are made by the medical staff. The disadvantage they have is the lack a good oversight of the primary process. Their knowledge is better suited on the tactical and strategic levels of the unit. In combination with the lack of a balanced involvement of actors during the decisions made during development this results in non-optimal decisions about IS. A clear structure for making decisions is necessary. The decision structure must consist of three layers, the strategic, tactical and operational layer. The different actors with their different area of knowledge are categorized in such a way that decisions are optimal knowledge supported.

These four bottlenecks contribute to a low adoption of IS within the hospital with a coherent view in Figure 1.

The horizontal lines, between business and IS, represent common language and understanding. Semantics are of great importance among lines of communication. There is a need for a common discussion between people on the business side and people on the IS side. The horizontal lines represent transfer operational resources and experiences towards sustainable strategic assets (Maes, 1999).

Within the model, all different roles must be fullfilled and anchored. This is needed for a good communication flow between people which have the same semantics. The emphasis must also lay on communication (Gartner 2005). For the case of the Erasmus MC, the important central role as process managers is not fullfilled. Also the roles of physician, nurse etcetera on the operational business side and the service level manager aren't anchored that well. As a result alignment of business and IS is very hard, perhaps impossible, to achieve.

Contours of Readiness Framework

Adjusting the decision structure is necessary to gain efficiency. In the new categorization decisions are made by the actors who have the best knowledge within their layer. The relation of the IS department must be of a more cooperative character instead of a customer/principal relation. The IS department can also act as mediator between the management layer of the unit and with their own project group this way. The result must be a general oversight on the project by the IS department and not just on a split up of the project into the layers. For this to work, the most important change must be made by the people. They are the enabler for change.

Nevertheless, IT is increasingly becoming an important actor based on its changing roles in the delivery of healthcare. As IT becomes "enabler" of necessary organizational change with the Dutch healthcare sector the effect of IT projects will depend on the individual circumstances (Westert and Verkleij, 2006). The mainstream literature has avoided hypotheses of causality between IT innovation and particular organisational or societal effects in critical industries like healthcare (Guah, 2009).

Beside that decisions must be made at the right place: other than the requirements that are described above, Grefen (2001) defines an additional set of criteria for WfM. His criteria set out what kind of data is needed to develop and create a WfM. Grefen (2001) defined the following criteria:

- **Process Specification:** The process specification contains a detailed description of the workflow process. By saving this specification in a database, elements within the specification become accessible;
- **Organization Specification:** The specification of the organization contains the description in which the workflows have to be executed. In this organization model,

descriptions of actors, functions, groups etc. are developed;

- **Information Specification:** The structures of information, which are manipulated by workflows according to the information model of the WfM, are described in this point;
- **Situations in Current Cases:** The situation on "current" cases contains relevant situation and context information for the execution of every case;
- **Historical Information:** Historical information is the information of cases of which the implementation is completed. This information is merely used within the function of an archive. This information can also be aggregated.

These criteria should be used as a guidance principle when developing and arranging WfM.

POTENTIAL FOR WFM IN HEALTHCARE

Uncertainties Faced by Current Decision Structure

The medical staff that may lack a good oversight of the primary process makes many decisions. Their knowledge is better suited on the tactical and strategic levels of the unit. In combination with the lack of a balanced involvement of actors during the decisions made during development this results in non-optimal decisions about IS. A clear structure for making decisions is necessary. The decision structure must consist of three layers, the strategic, tactical and operational layer. The different actors with their different area of knowledge are categorized in such a way that decisions are optimal knowledge supported.

The observed bottlenecks of the decision structure are:

- Decisions are made by people who don't have a clear overview of the work floor;
- Lack of involvement of different actors with different functions during decisions;
- The IS department's primary task is to respond to the requested demand;
- Responsibilities about project tasks are ambiguous.

Adjusting the decision structure is necessary to gain efficiency. In the new categorization the actors who have the best knowledge within their layer make decisions. The relation of the IS department must be of a more cooperative character instead of a customer/principal relation. The IS department can also act as mediator between the management layer of the unit and with their own project groups this way. The result must be a general oversight on the project by the IS department and not just on a split up of the project into the layers. For this to work, the most important change must be made by the people. They are the enablers for change.

The Current Decision Structure must be Adjusted on the Following Points:

- Decisions must be made at the right place: This automatically means that the right persons make the decisions. The knowledge of the medical staff is mostly on the tactical and strategic level. Their knowledge on the operational level is much less. Their interest also differs from the other actors. The primary task of the medical staff is about research and education. These are the factors they will be judged upon at the end of the year. The physician assistants are the ones that are mostly responsible for giving care to the patient. The incentives of the medical staff differ much from the incentives nurses or physician assistants have. Decisions are influenced by the role and incentives of the decision maker. A clear structure for the levels of decisions is therefore necessary.

- IS knowledge is necessary: at this moment the IS department finds themselves solely responsible for the executions of the demand by the customer within the hospital. The relations between the IS department and organizational units, was observed as a principal/customer relation. This relation must be transferred to more of a team relation. This can be reached if one or more representatives from the IS department, depending on the situation, should be present at the different management layers.

What could be another solution is the mediator or middleman. This middleman should give advice on the business level of the unit. The middleman can be seen as an information manager. This function requires that mediation between the different management layers takes place and that the functionalities of the system are specialized.

The result of this structure must be that the quality of consultation and the focus is improved. The advantage is that the execution lines are shorter and results can be achieved sooner. As a result of this, the people will experience more involvement of the IS department. This experience can influence the creation for a good basis for the IS implementation. The shared responsibility for the succeeding of the project will enhance each other. Without reorganizing the decision structure, readiness for the implementation of an IS will be low.

Resolution of Implementation Problem

Healthcare work is a social process. It involves simultaneously dealing with sick individuals, each of which have their own problems and needs, and is connected with other physicians and organizational units. Because of the nature of healthcare work, standard organizational solutions never wholly fit the individual needs of a patient. Healthcare workers are therefore constantly compromising between the problem and solution to give the best care to the patient (Berg et al. 2003). Standardisation of healthcare pathways could provide a possible solution for giving better suited healthcare for the patient and centralizing the patient within the process.

A clinical pathway is the care process that a patient goes through during sickness. It starts with a health complaint and ends after the patient is treated for the health complaint. A clinical pathway displays all the care activities of the treatment that a patient has to follow. Care activities are organized around the patient. This must reduce inter-doctor variation, minimize delays in a treatment and decrease resource use (Lin et al, 2000). A clinical pathway coordinates the treatment procedure and also defines the quality of care that is provided at each activity (Smagghe et al, 2005). The main goal of a clinical pathway is to improve the quality of care while costs are decreased.

The advantage of a clinical pathway overview is the possibility to plan care activities in advance. Most appointments in healthcare are dependent of previous care activities or appointments and of available capacity at other locations within the organization, e.g. an x-ray is needed before the first consult with a physician. The description of the steps within the process helps to make the pathway mutual dependency insightful and offers a better planning. Criteria for quality can also be fixed within the clinical pathway (Bal and Bont, 2005).

When talking about planning up-following care activities in a clinical pathway, it is interesting to take a closer look at Order Management. The goal of clinical pathways is to organize the care activities around the patient. It provides the corresponding ideal sequence and timing of physician and staff actions to achieve the predefined goals with optimal efficiency (Pearson et al 1995). Reasons to use clinical pathways are thus mostly about improving the quality of care and/or reducing costs of a certain product of service. Strongly related is the timely execution of the treatment within the clinical pathway.

Implementation of clinical pathways can be difficult for the following reasons:

- A great deal of time, skill and effort is needed to find and analyse the highest quality evidence available. This quality is essential when making clinical pathways;
- Medical knowledge is changing on a continuous basis. Therefore clinical pathways should also be improved continuously, to be certain that the highest quality is obtained;
- A clinical pathway cannot have all the answers on individual cases;
- Implementation of clinical pathways can face organizational and/or cultural challenges. For example the resistance from physicians against standardisation of medical work (Smagghe et al, 2005).

Order Management (OM) is not about replacing paper forms for electronic versions. OM is about the facilitation of health care workers for initiating and protection of the total sum of health care activities that incorporate the treatment of the patient. OM is the electronic guarding of the healthcare pathway.

The goal of OM is:

- Providing quality on a consistent level;
- Supporting working on a basis of protocols, standardisation;
- Input control and decision support;
- The realisation of time reduction;
- during the application and execution of applications;
- Monitoring the progress of the clinical path.

Examples where OM would prosper are on the area of: medication, radiology, the operating theatre, laboratory, nursing activities, and transport requests. These aspects should always be taken in account when setting up an OM system (Reingoud, 2006).

Functionalities of OM are:

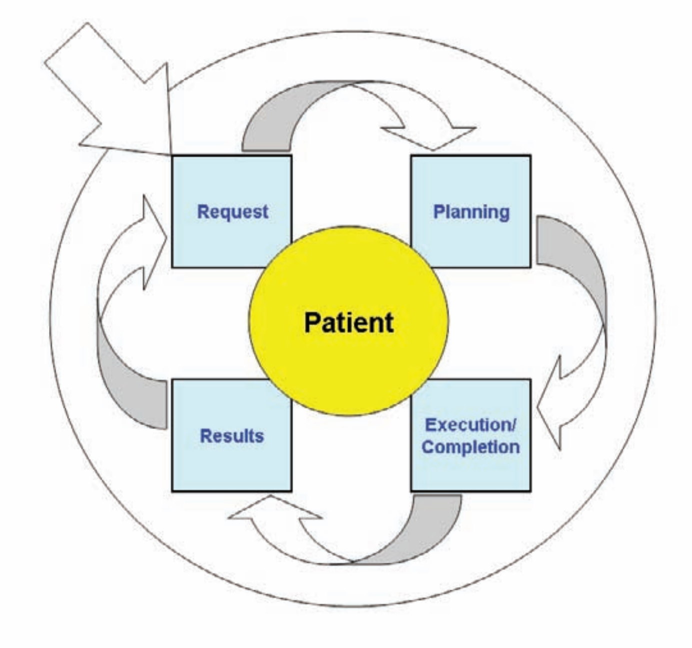
- Monitoring of individual activities in the clinical pathway;
- Giving oversight of individual activities within the clinical pathway;
- Giving oversight in time, for planning purposes;
- Identifying status change and deviations of the predefined norms;
- On clinical paths based access for (lab) results and reports;
- Order application;
- Order planning;
- Order execution;
- General oversight;
- Placing and interfacing the information in the Electronic Patient Record (Reingoud 2006).

For a patient to be treated effectively in a clinical pathway, integration of processes is a key aspect for success. This change can only be achieved when changes in the organisational structures are met. This process includes registering a planned activity (electronically) and the activity being requested, planning of the activity's execution, returning the status of the activity, giving feedback on the activity. Across all of these steps, having the data available electronically can provide opportunities for monitoring of the process.

Order execution comprehends the, administrative, status of the patient in the pathway. Within OM, there is a process of continuous feedback. With this feedback and general oversight of the physician, continuous improvement of the process of the patient is possible. As a result the patient gets the most optimal treatment and unnecessary researches will not be done.

When a patient has an appointment with the physician the physician sends out a request, e.g.

Figure 2. Shows the order management process



a blood test. This request is planned in time with needed resources such as personnel. When the execution of the request takes place the physician who gave the order gets a notification. The next step is that results are returned to the physician and choices about further care activities can be taken.

CONCLUSION

The article has argued why the WfM is important by sketching key issues related to the research problem. The authors have also identified the bottlenecks as suggested in the scientific literature. These bottlenecks are often due to the difficulty in involving physicians during IS implementation, especially if they do not perceive a need to change clinical working practices. Notwithstanding, Erasmus MC has been heralded in The Netherlands as a teaching hospital with technology that would make medical care more cost effective and increase patient safety. Occasionally, there exists perception that making the delivery of care more time and resource efficient is not a clinical necessity. This article has shown that such perception of IS in the healthcare sector is a result of a rather poor understanding of the long-term benefits of improving patient care by changing medical work practices.

The research also showed a rich picture of WfM that includes practical issue of use and implementation and policy issues related to organization strategy and changing healthcare practices in The Netherlands. While the authors acknowledge the complexity of integrating those issues into a comprehensive approach, this article suggest there could be times when less restrictions apply to who can enter orders for the purpose of increasing patient care quality. That's because focussing on subatomic tasks to increase patient safety could occasionally result in decrease in patient safety in the overall process of care. Finally, IS implementation process interacts with an overall healthcare systems that includes healthcare workers at various levels of the healthcare delivery process or patient pathway. The healthcare organization is therefore at the central of any work in this critical sector. Attention must therefore be given to situations when clashes might occur between the rationality of IS that is expressed in technical and functional specifications and the actual use of such system by a healthcare worker. The decision whether to use the system, how to use the system and when to use the systems then becomes more important than just the cost and benefit of implementing a new healthcare information system.

Chapter 5.5

Developments in Modelling Organisational Issues in Healthcare:

Multi Method Modelling

ABSTRACT

Healthcare organisations increasingly use simulation and modelling techniques to analyse their procedures and policies. Modelling activities attempt to help meet the challenges, constraints and requirements for efficiency encountered in the modern healthcare environment. A variety of techniques are used, often applied in different roles and by different functions in the organisation. Recent research has investigated the benefits of considering multiple approaches in the analysis of problems. This chapter briefly introduces the use of simulation and modelling in healthcare and the factors driving the increasingly widespread use of these techniques. Simple examples show how individual methods may be applied to model healthcare problems. The recent emergence of multi method approaches to modelling is examined and, focusing specifically on healthcare, examples of how these new ideas may also be applied in healthcare modelling are presented. Finally the challenges to implementing such new approaches effectively in a healthcare environment are discussed.

DOI: 10.4018/978-1-60566-030-1.ch012

INTRODUCTION

Studies in Healthcare Informatics propose a wide range of new technologies and techniques for use in modern healthcare environments. Many applications of Information and Communications Technology (ICT) in healthcare focus on using information systems, innovative devices, and specialised learning environments for medical practitioners to support the delivery of healthcare services. An area occasionally overlooked in healthcare informatics literature however is the use of computer based modelling to investigate the organisational and policy issues which underlie effective healthcare service delivery. In 2006 the UK organisation the Royal Society produced a report on the future impact of ICT in UK healthcare (The Royal Society 2006). Among the available technologies and changing trends, the report identified simulation and modelling as an effective tool that may be used to predict demand, evaluate costs and improve service overall. This chapter highlights the use of computer based modelling on organisational problems in healthcare and focuses on how a recently proposed approach to developing models, multi method modelling, can enhance the effectiveness of their application.

Until recently the subject of organisational and policy modelling has enjoyed a low profile in healthcare informatics literature. Some older texts such as Sheaff & Peel (1995) and van Bemmel & Musen et al. (1997) make no reference to the topic at all, however, as Eldabi & Paul et al. (2007) indicates, the number of published studies in this area has grown rapidly in recent years. In some health informatics texts, such as Davies & Bensley (2005), modelling is grouped in the wider category of decision support techniques. This has sometimes served to obscure the role of organisational modelling and the particular differences between the methods applied. Some common approaches used in modelling the problems of healthcare organisations include Econometrics, Discrete Event Simulation, System Dynamics and Markov Modelling. While each is individually effective, recent developments in modelling methodology propose that an integrated perspective of the methods may address the challenges of healthcare modelling particularly well.

This chapter provides an introduction to organisational modelling techniques for readers of healthcare informatics literature who are unfamiliar them. By way of illustration, two simple examples of how organisational healthcare issues may be formulated for analysis using simulation techniques are presented. For those familiar with such studies an emerging strand in modelling methodology, multi method modelling, is introduced with a review of key literature and results in this area. The application of multi method modelling to healthcare issues is discussed in detail. Factors which make this approach particularly appropriate for healthcare problems are presented as well as how features of the models may influence their effective deployment. Five examples of recent healthcare studies which have used multi method approaches successfully are briefly reviewed. Finally the future challenges to applying this approach in healthcare modelling are presented. References to key literature are provided throughout to support the reader in further research.

THE CHANGING PROFILE OF MODELLING IN HEALTHCARE

Using abstract models to understand the behaviour of a subject is common in disciplines such as economics and engineering, as a result where these disciplines overlap with healthcare, models are often used. Increasingly however models are also being applied to issues of process, organisation and cost in healthcare using a wide range of techniques. Briggs & Claxton et al. (2006) presents some approaches for evaluating costs including decision trees, Markov modelling and simulation techniques. Morris & Devlin et al. (2007) discusses economic and statistical models.

Fone & Hollinghurst et al. (2003) provides an extensive survey of healthcare modelling studies, particularly where simulation methods are used, and identifies four main areas for their application; hospital scheduling and organisation, infections and communicable diseases, costs and economic evaluation and screening.

Several different influences are reported as making healthcare modelling increasingly attractive. Davies & Bensley (2005) cites the new challenges for healthcare providers driven by changing demographics and social trends. Young & Brailsford et al. (2004) suggests that the high expectations of service expected from healthcare users may interest policy makers in established modelling approaches. Briggs & Claxton et al. (2006) cites the policy of public health bodies in Australia and Canada requiring the systematic evaluation of all new devices, procedures and pharmaceuticals prior to their approval and adoption.

Increasingly institutional factors in healthcare organisations, such as mandatory requirements for data collection and performance reporting, also support the use of modelling. The widespread availability of on site computing capacity, via workstations and an hand held devices and increasing levels of computer literacy in the workforce mean that models can be readily implemented and their findings easily presented to policy makers.

The Varied Role for Modelling in Healthcare

The general benefits of modelling are the ability to investigate the effects of different decisions on a problem or system without committing significant resources or affecting the real situation adversely. As such, using organisational models it is possible to investigate the behaviour of healthcare systems in different circumstances, applying possible policy responses and reviewing the consequences.

Because of the scale of healthcare organisations the financial and resource costs of poor policy or decision making can be significant. The critical role of healthcare in providing medical treatment means that the evaluation of risk is of the upmost importance. The high cost of failure for healthcare organisations also requires that risk is reduced where possible.

Modelling in healthcare therefore is used to support four main areas of interest for policy makers and professionals:

- Planning and design of services
- Investigation of observed behaviour
- Building descriptions of processes
- Evaluation of financial and resource costs

Service organisation and delivery schemes can be planned and tested using modelling techniques. This may be required in the planning of new services; for example new departments or wards. It may be used to plan the reorganisation of existing services. Once represented using an appropriate model the design may be tested with data to ensure that it meets performance targets. Rohleder & Klassen (2002) provide an example of such a modelling study for clinics investigating prospective systems of appointment scheduling.

Healthcare processes and systems may be studied in order to make predictions about their behaviour or investigate unexpected performance. Models may be used to predict outcomes based on a number of relevant factors or possibly suggest areas in the system where improvements may have the most effect. Lane & Monefeldt et al. (2000) provides an example of this kind of study, investigating the dynamic behaviour of an Accident and Emergency Department.

Modelling may also be used to understand or document an existing process or system. In some circumstances healthcare organisations act as complex systems, evolving to solve problems and sometimes producing counterintuitive behaviour. Creating models provides an opportunity to investigate and document how a system works; which may be a valuable training tool for the professionals who must manage the system in future. Conrick & Dunne et al. (1999) describes the use of simulation models in the education of nurses.

Some modelling studies focus specifically on the costs, benefits and resource allocation problems of healthcare processes including the implications of different choices and policies. Briggs & Claxton et al. (2006) describes a number of such studies, including principles and techniques for carrying them out. Briggs & Claxton et al. (2006) also contrasts modelling with use of experimental trials.

SIMULATION MODELLING IN HEALTHCARE STUDIES

Simulation models use software to recreate the activities or structure observed in the problem, in order to generate outcomes which are comparable with the behaviours in the problem. In practice the implementation of most models is computer based, including the Markov models described in Briggs & Claxton et al. (2006). However the relationship between simulation models and computer implementation is different in that, although they may be conceptualised to some extent, they are entirely impractical without, computing resources.

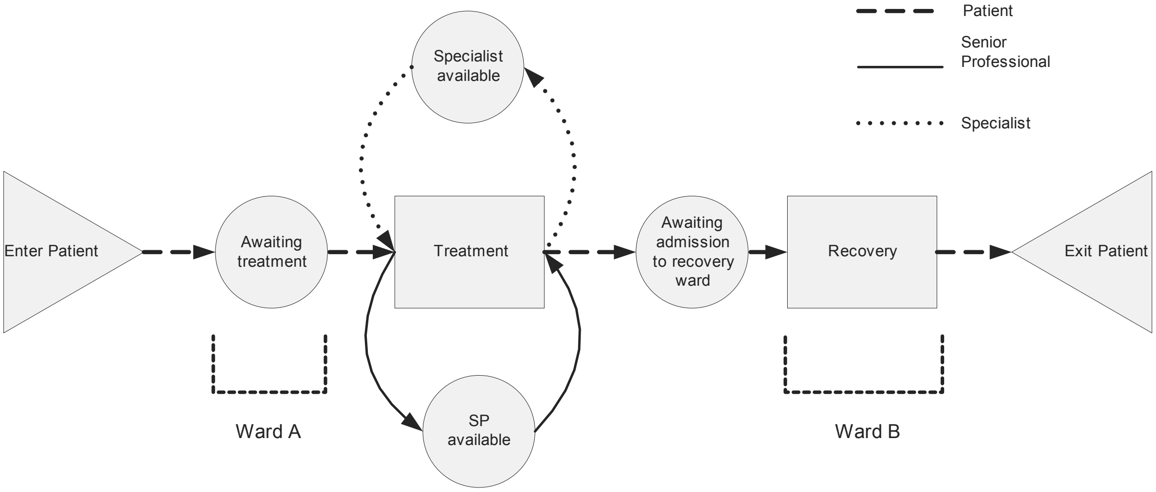
The use of simulation approaches for modelling healthcare issues has received a great deal of attention recently. Eldabi & Paul et al. (2007) describes a dramatic increase in healthcare simulation studies since 2000. Two styles of simulation modelling, System Dynamics (SD) and Discrete Event Simulation (DES), well established in other disciplines have been used widely in healthcare studies. Another emerging form of simulation, Agent Based modelling (ABM), less widespread due to its relative immaturity has also been used in healthcare studies; Kanagarajah & Lindsey et al. (2006) provides an example. This section briefly introduces SD and DES modelling.

Discrete Event Simulation Modelling in Healthcare

Discrete Event Simulation modelling is a technique well established in disciplines such as manufacturing and scheduling. Some key texts include Banks (2001) and Law & Kelton (2000). DES models attempt to imitate the observed behaviour of the problem, typically by using stochastic distributions to generate events and quantities typical for the system. Problems are often conceptualised as networks of queues and servers. The behaviour of the real system is imitated by estimating distributions for the arrival of entities at the queues and the dispatch of entities by the servers. A number of notations may be used to describe their logic including queuing diagrams, flowcharts and Activity Cycle Diagrams (ACDs) described in Paul & Balmer (1993). Consider the example of a treatment ward A with regular patient admissions. Patients wait for treatment, after treatment they enter a recovery ward B until they are ready to leave. The treatment requires one senior professional and two specialists in order to go ahead. An ACD of this problem may be described by Figure 1.

The three entities move between the states defined in the ACD. Service processes require all related entities to be available in order to begin and release them when complete. The simulation reproduces behaviour observed in the real system. An investigation of the problem may proceed by varying factors such as the arrival rate for the patients, the distribution of time required for treatment or recovery and the number of specialists and professionals available. The output of the model is monitored to establish how performance is affected as the variables are changed. Jun & Jacobson et al. (1999) provides an extensive review of some recent healthcare studies using DES.

Figure 1. Simple DES model of a healthcare problem



System Dynamics Modelling in Healthcare

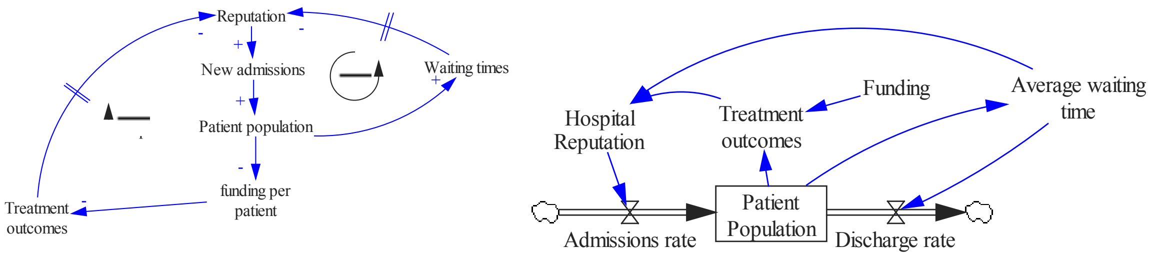
System Dynamics modelling is a technique well established in disciplines such as socio-economic and business modelling. Some key texts include Forrester (1961) and Sterman (2000). SD models attempt to reproduce the causal structure of the problem, identifying components and feedback loops that are the cause the dynamic behaviour observed in the system. Models attempt to focus on the systemic properties of the problem caused by the interaction of flows, interdependencies and delays. They may also include “soft variables”, qualities that are not measured directly yet are proposed to influence behaviour. There are two common forms of notation Causal Loop Diagrams (CLDs), which capture the conceptual relationships in the problem, and Stock-Flow diagrams which describe the structure in the model in more detail. Only Stock-Flow diagrams are implemented as simulations. Both are described in detail by Sterman (2000).

Consider the simple example of a hospital operating on a fixed level of external funding. Patients may chose the hospital due to its reputation based on a combination of the treatment outcomes and waiting times reported. Treatment outcomes are influenced by the level of funding per patient and waiting times by the current size of the population. CLD and stock flow models of this problem may be described by Figure 2.

The description shows how quantities flow through the system in feedback loops and the active mechanisms which may produce interesting dynamic behaviour. The model is intended to provide an impression of the dynamic trends resulting from the system structure rather than reproduce observed behaviour exactly.

An investigation of the problem may vary parameters such as the starting population, the length of the delay in affecting hospital reputation and the effect of the two influences on that factor. The output of the model is used to discuss long term behaviour and the consequences of structural change. Dangerfield (1999) provides an extensive review of some recent healthcare studies using SD.

Figure 2. Simple SD model of a healthcare problem



REALISING EFFECTIVE HEALTHCARE MODELLING

Modelling techniques are usually applied to large or sophisticated problems perhaps containing hundreds of variables. Although the two simulation examples presented are very simple they illustrate the impact models may have in the four areas of interest described previously:

Changes to either service could be planned using the models as prototypes to determine the likely effects. For example the effect on patient throughput of using two recovery wards could be planned using the DES model and then perhaps compared with the effect of adding an extra specialist alternative. The models could be used to recreate unexplained behaviour observed in the problem and investigate their likely causes. For example if an increase in funding leads to an unexpected decline of the hospitals reputation the SD model could be used to investigate whether the effects of delays in the system could provide an explanation and what the long term consequences may be.

The process for providing the service in each case is documented by the models and they may provide an aid to discussion in reviewing the processes which, unlike a written description, is dynamic and pliable. Simulation models can therefore communicate the problem effectively to those familiar with the problem yet uninitiated in any modelling technique. With regard to financial evaluation; as with all models containing quantitative variables cost predictions based on the output are fairly straightforward so long as both overheads and unit costs can be accurately established.

The simple descriptions presented above also illustrate well the role played by those making the model. The individual or team responsible for creating the model must investigate the problem and formulate its detail into an abstract form which can be simulated appropriately. Evidence collected from the primary sources is used to develop the basic structure of the model but also to determine and the refine quantitative aspects of the model too. This may require interacting with personnel, studying key documents, taking measurements first hand and conducting experiments. Through the process of modelling, modellers are able to develop, and perhaps disseminate, a detailed and insightful understanding of the problem. The acquisition of this knowledge is considered to be a powerful indirect benefit of modelling.

Also apparent from the two studies is their difference in approach; The DES model emphasises the effects of the stochastic qualities of a problem, whereas the SD model emphasises the endogenous feedback properties. As a result of these differences, the investigation and analysis required for each of them focuses on different parts of the problem. Each approach is considered to be independently effective and as a result modellers using different systems rarely question the framework of assumptions contained within the approach they are most familiar with.

Considering trends in healthcare modelling, Eldabi & Paul et al. (2007) note an interest among subject experts to combine the different methods in their studies. For example one respondent of the authors, when asked to identify current trends, states the “need for much greater integration between disciplines”. This chapter now considers this idea in more detail by discussing the basic principles requires as well as practical issues and developments.

THE MULTI METHOD APPROACH TO MODELLING

The requirement for modelling techniques to be used combined and used together has caused a new and interesting theme in modelling methodology to emerge. Described simply as Multi Method Modelling, its roots lie in early discussions between groups of modelling practitioners, their search for the fundamental basis of their own method and comparisons with other approaches. Recent developments in this theme have been stimulated by the widespread use of modelling techniques and a new generation software tools offer more flexible modelling solutions.

Distinctions between methods, it is argued, has led to a separation of modelling specialists into method oriented groups which has affected the field to the extent that communication across method boundaries becomes difficult, if not entirely unproductive. Meadows & Robinson (1985) describe this as paradigmatic relationship between practitioners. The multi method research them aims to clarify and evolve the relationship between different modelling methods.

Multi Method Modelling: Background and principles

The key premise of the multi method approach is that understanding more than one method can help improve the practice of modelling. This requires, at least, an understanding of how approaches differ fundamentally, that is often uncommon for subject specialists to posses. Several authors have attempted to address this issue and have included a variety of methods in the discussion. The subject of their work is summarised in Table 1.

Lane (2000) focuses on communication between communities of modellers who use different systems, identifying differences between the two methods and also how different modes of communication can benefit practitioners in areas of common interest. Meadows & Robinson (1985) examine the assumptions underlying different methods and their modelling process using a number of case studies. Morecroft & Robinson (2005) focuses on differences in the features and properties of models created using two different systems. They provide a detailed example of the two methods at work on a single problem by way of illustration. Schieritz & Milling (2003) compare

Table 2. Summary descriptions of five different modelling methods

Modelling Paradigm	Realisation	Description
Agent Based Simulation	Simulation	Imitating the behaviour of a problem using granular entities with encapsulated behaviour
Discrete Event Simulation	Simulation	Imitating the behaviour of a problem using processes and passive entities, based on events
Markov modelling	Stochastic	Using a state based view of a problem and the probability of transition between states to analyse potential behaviour
System Dynamics	Simulation	Identifying flows, stocks, and feedback in a problem in order to analyse systemic behaviour
Econometrics	Statistical	Applying statistical techniques to test relationships between problem data variables or analyse problem variables variation over time.

two different methods and the contrasting ways in which they attempt to achieve similar ends. This list of studies is by no means exhaustive but represents a range of starting points in the comparison of systems that covers a variety of methods. Table 2 briefly describes five different modelling methods that have recently been used to model problems in healthcare.

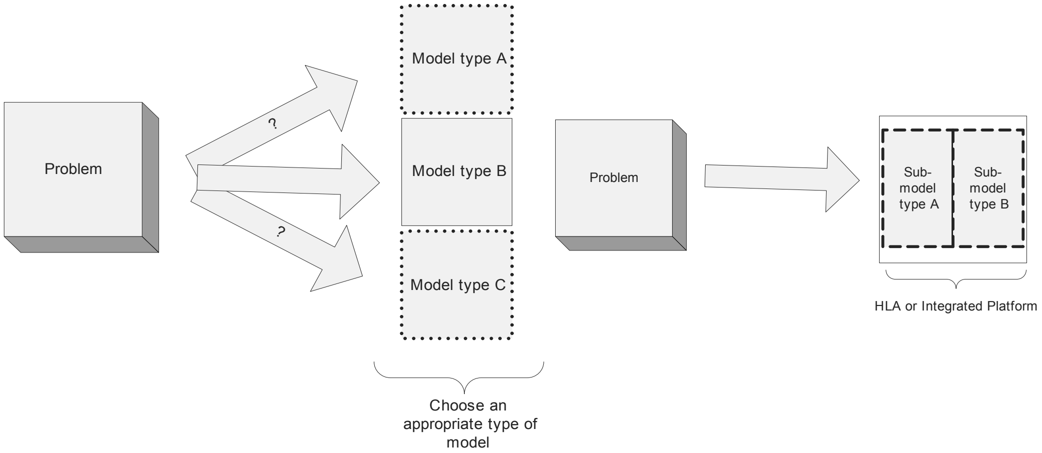
Realisation refers to the mechanism by which implemented models to produce their results. It is often the case that where the same realisation mechanism is used the process may differ significantly. For example Discrete Event Simulation (DES) typically uses stochastic simulation with variable time steps, System Dynamics (SD) uses deterministic simulation with fixed time steps, whereas Agent Based Modelling (ABM) may use either method. In practice computer based modelling is used to implement all five systems.

The comparisons of four studies use a wide range of criteria to isolate distinct properties for different methods, however at present there is no widely agreed definitive list; perhaps because the properties identified are so dependant on what they are compared with. However it is generally recognised that different kinds of models have different properties and the methods propose a different conceptualisation of the problem. Comparisons usually focus on issues such as the use of random variables, the use of data, representing feedback and verification. Some general themes in modelling are also revealed, for example, the role of models in communication, qualitative and quantitative properties of modelling and the benefit of the model as a product compared with modelling as a process. As this strand of research develops it has been proposed that the multi method approach may lead to the development of new integrated forms of modelling where the properties of the model are determined strictly by the properties of the problem.

Practical Applications

A number of studies have been made based on multi method ideas. These range from general developments in for methodology to studies focusing on a particular application area such as manufacturing, supply chain management or healthcare. Themes in these studies may differ considerably; Lorenz & Jost (2006) and Chahal & Eldabi (2008) analyse the choice between different methods, whereas Borshchev & Karpov et al. (2002) discuss the use of an integrated software platform which supports three different modelling methods. However from these and other studies two main practical strands are notable. The first is studies which provide a considered approach to choosing an appropriate modelling method for a given problem. The second are studies which attempt to combine different

Figure 3. Common modes of multi method modelling from literature



kinds of model into a hybrid form either by logical partition of the problem or joining existing models. (see Figure 3)

APPLYING MULTI METHOD MODELLING TO ISSUES IN HEALTHCARE

Considering the developing profile of healthcare modelling and the relative immaturity of multi method approaches it may be expected that each may be of little benefit to the other at their current stages of development. On the contrary, to date, the ideas have aroused considerable interest in healthcare modelling circles. This section discusses some of the reasons that a multi method approach has the potential to deliver significant benefits for modelling in healthcare. Some existing work on multi method modelling in healthcare is also reviewed.

Why Healthcare?

A number of factors account for the interest in using a multi method approach to model healthcare problems and in different organisations the reasons vary. However four reasons it may be especially relevant are listed below and described in turn:

- Variety of healthcare modelling problems
- The benefits of integrating functional views
- Requirements for data and analysis
- Issues of scale and limitations of technology

Healthcare modelling embraces a wide variety of problems. Healthcare organisations are very rich in terms of the types of properties that may usefully be modelled. For example modelling the probabilities of events in one area may be as important as modelling paths through a system or modelling population sizes and costs in another. In each case the nature of the problems differs significantly and an appreciation of several methods equips healthcare modellers to deal with each problem effectively by using an appropriate method.

Healthcare organisations are often complex and contain many different functions focusing on their own targets and goals. An integrated view of problems is often useful but unavailable. The different models functions use, often reflect their different view of the problem. For example an economic policy function may rely on econometric

Figure 4. Composite models combine the views of different functions

modelling, while an operational policy function may use DES modelling. A multi method approach provides a framework for integrating views and exploring how different functions relate to each other, for example by creating a single composite model from those used by two different functions; illustrated in Figure 4.

Different methods have different requirements for the use of formal numerical data and different problems may differ in the amount of formal data available. For example Econometric modelling requires high quantities of formal data in the conceptualisation and construction of models though more moderate quantities are required for validation. SD modelling typically relies on a mixture of formal and informal data in conceptualisation with more formal data used in model construction and validation. Similarly DES may rely on a variety of information sources in conceptualisation with more formal data required in construction, for example in determining appropriate distributions and significantly more, generated by the model, being used in validation. These properties are described in Table 3. The choice of an appropriate modelling method may be based on the alignment of the data available from the problem and the data requirements of the method.

Due to their diversity, issues in healthcare may vary in the scale and level of detail required to analyse them effectively. Problems may be considered over different organisational boundaries. For example models may examine at ward level, department level or hospital level. Problems may be defined in terms of the individuals, generalised behaviour or wider trends. Modelling may cover different time periods such as short, medium and long term scenarios. All these factors determine how actors or entities in the problem are represented. Entities in a healthcare model, for example, may represent beds, patients, ambulances or staff.

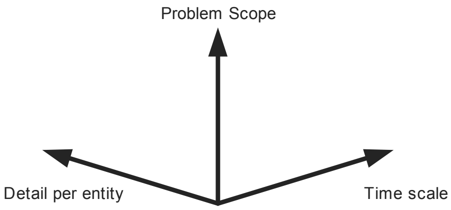
Although different models may require a similar level of effort to conceptualise, in implementation the resources required for the same problem in terms of memory, processor time and mass storage may be significantly different. The factors determining the overall resource requirements for a model are a combination of the level of detail required for each entity, the total number of entities required typically determined by the problem scope and the timescale considered by the model. This relationship is represented in Figure 5.

In this respect different models have different characteristics; ABM typically uses a very high level of resources per entity, modelling the state and processing the actions of each entity in the problem individually. Modelling the same problem

Table 3. Comparing requirements for numerical data at different stages in the modelling process

	Conceptualisation	Construction	Validation
Econometrics	High	High	Moderate
SD	Low	Moderate	Moderate
DES	Low	Moderate	High

Figure 5. Factors determining modelling resource load



in DES would typically use simpler passive entities with behaviour defined in terms the service processes, requiring fewer resources. Even fewer would be required in the SD model where entities typically would be modelled as continuous streams without individual states or behaviour.

One solution to very high resource requirements is to increase the computing resources available until the problem becomes tractable. This is often proposed in healthcare modelling using GRID computing techniques. An alternative solution to applying raw computing power is the use of a multi method approach to conceptualise the problem using a different modelling system. Due to the difference in resource requirements, problems which are intractable using one approach may be tractable by applying another where the overall resource requirement is lower.

Review of Existing Projects

This section briefly reviews some existing and notable multi method studies which focused on healthcare problems. The studies use a variety of methods to achieve range of modelling goals.

Smith, van Ackere (2002) demonstrates an integration of SD and Econometric modelling. The study reviews an NHS problem of understand issues of supply and demand in elective surgery and how behaviour is affected by waiting times and the cost of private treatment. The paper describes how an SD model is developed based on the concepts of the econometric model. The study notes how the difference in approach provides a view of the problem which includes its previously unappreciated dynamic qualities.

Karnon (2003) compares an evaluation of a healthcare treatment using both Markov modelling and DES. Different characteristics of the methods are noted and an example is used to illustrate their different conceptualisation of patient pathways. The problem of evaluating adjunct therapy in the treatment of breast cancer is described. Two models are developed and compared. The conclusions of the paper remark on the differences in their flexibility and resource requirements of the two methods.

Brailsford & Lattimer et al. (2004) describe the analysis of capacity in emergency departments based on SD and DES models. The study describes the problems of resource allocation and capacity facing an emergency unit and explains the choice of SD and its benefits for the main modelling activity, the process and the findings of the study. The paper explains how a DES model was used to examine a particular feature of the problem in more detail which would not have been practical using SD alone.

Cooper & Brailsford et al. (2007) reviews three methods used in the economic evaluation of healthcare problems; DES, decision trees and Markov models. The different properties of the three approaches are described as well as criteria for choosing between them based on the properties of the problem. The study produces a flow chart describing a process for determining which method is most appropriate to a given problem.

Rohleder & Bischak et al. (2007) describes the use of DES in the design for the performance of several patient servicing centres. The study notes that despite the accuracy of the DES modelling on implementation the centres could not sustain the planned capacity. The paper demonstrates how a complementary SD study could have highlighted this issue from the outset.

CONSIDERING FUTURE CHALLENGES

As the use of modelling becomes more widespread in healthcare the potential to adopt a multi method approach increases. This section is concerned with some of the challenges for the successful use of multi method modelling in the future. As work in this area is ongoing it is not possible at this stage to present solutions, simply outline the obstacles to be overcome.

A fundamental challenge to multi method working is overcoming poor communication between subject specialists. Integrated views of modelling require an understanding of the principles and benefits of different approaches. Where this understanding is superficial the resulting studies may be poor and lack validity. This may be addressed though education and the development of guidelines for multi method teams that work to establish the necessary skills.

A key factor in the development of multi method modelling for healthcare applications is the awareness of good practice. It is a challenge to find an effective platform to communicate successes and failures of the approach to the modelling community. An important benefit of recording the practical experiences of applying these methods may be an appreciation of where they are best not applied. It is also a challenge therefore to establish the situations where multiple models can genuinely add value to a study rather than merely cost and complexity.

A practical challenge is the development of integrated tools that support multi method studies. Currently few tools exist which provide a common platform for the development and comparison of multi method models. Specialist tools currently offer superior ease of use in most cases. An important focus for multi method tools may be features for comparing the output of the different models and navigating the modelling structures, in particular mapping between equivalent structures in the different models.

Multi method modelling is occasionally presented as a revolutionary approach that will eventually unify other methods. It has also been proposed that a standard notation for unifying modelling systems may be developed. This position is very much in advance of current state of research and it is questionable whether such a development would either feasible or beneficial. As with all innovative methodological developments, it is a challenge not to inflate the potential benefits of the approach beyond those that can be supported in fact.

CONCLUSION

This chapter has examined the use of modelling to explore the issues that effect healthcare organisations. The application of modelling and simulation to organisational issues in healthcare is sometimes overlooked by healthcare informatics literature. An overview was provided of the role for modelling studies in healthcare and current developments shaping the practice. Some of the principles, applications and key approaches used were reviewed and number of studies and texts are referenced, providing examples of how modelling methods are used in healthcare. The emerging practice of multi method modelling was presented, including some examples of the approach in healthcare. Future challenges to exploit this new approach effectively were also presented.(Explain what went on and th e lessons learned)

The current interest of public health policymakers in measuring performance and evaluating the effectiveness of healthcare processes makes the modelling of organisational issues increasingly relevant. As new projects are undertaken and healthcare models routinely commissioned, familiarity with modelling methods may become a core skill for healthcare managers and model processing a major use of informatics in healthcare. The realisation that the choice of model significantly influences the perspective on the problem is becoming established. Coiera (1997) recognises this to be a basic principle of healthcare informatics and as such devotes to the whole first chapter to basic concepts in models and modelling. As the use of modelling techniques becomes more common throughout healthcare organisations, the benefits of a multi method approach may increase in significance.

KEY TERMS AND DEFINITIONS

Agent Based Modelling: A simulation based modelling approach, where the problem is represented the using software entities with some degree of autonomy. The behaviour observed in the problem is recreated through the interaction of the entities, known as agents, which are typically modelled using data objects with encapsulated behaviour. Models may exhibit complex emergent behaviour even where the rules governing individual behaviour are relatively simple. They are sometimes considered to combine the analytical features of both system dynamics and discrete event modelling.

Discrete Event Simulation: A simulation based form of modelling in which patterns of events in the problem are recreated so that the timing and resource implications can be examined.

The events generated usually include the arrival and departure of entities from the system or one of its sub processes. Timing and quantities in the model are typically generated by implementing appropriate stochastic distributions. Law & Kelton (2000) provides a comprehensive introduction to this form of modelling.

Econometric Modelling: A form of modelling based on the integration of statistical measurements of problem variables with economic theory. Models are based on empirical data collected from the problem and variables may be treated as deterministic or stochastic. A wide variety of statistical techniques are used to measure the quantities in the problem and assess their underlying distributions. These may be used to test hypotheses about the problem and make predictions about future behaviour or the likely effects of policy changes.

Multi Method Modelling: An emerging area in modelling methodology where techniques from different modelling disciples are combined inorder to analyse a single problem. The premise of this approach is that different methods have different features which can, in some cases, be used to support a more effective study. There is particular interest in applying this approach to healthcare problems because of the potential to extend existing model, integrate different stakeholder views and overcome technical limitations in some studies.

Modelling Resource Load: A concept used to compare the relative resource costs of modelling studies using different methods. For small scale studies the difference in resources required may be negligible, however in large studies this factor may be used to determine the most appropriate choice of modelling method. The differences in between methods in problem conceptualisation and model implementation determine the resources necessary to implement the model. In assessing the scale three key factors are relevant; the scope, or size of the problem; the required amount of detail per entity; the time scale considered by the study.

Markov Modelling: A form of modelling based on stochastic processes where the discrete states of a problem and the possible transitions between them are analysed. Systems represented as a network of states with paths between nodes weighted according to their probability of their occurrence. Paths and cycles in the system can be analysed mathematically to determine the likelihood of overall outcomes. The Markov property requires that the probability of transition between two states is dependant only on the current state and the problem must be formulated accordingly.

Organisational Modelling: Modelling undertaken to understand or analyse the effects of the structure, processes, and policies of an organisation. The role of organisational modelling is typically to understand complex observed behaviour, to prototype new policies and configurations or to document existing processes. In healthcare organisations such studies are increasingly used to investigate costs, patient flows and the utilisation of scarce resources. These studies may be contrasted with problems where organisational issues have negligible or no impact; in healthcare these may include anatomical and epidemiological modelling.

System Dynamics Modelling: A systems-oriented simulation based modelling approach first proposed in Forrester (1961). Models are based on the causal structure of the problem including the perceptions of the actors. Two levels of modelling are possible; Qualitative modelling using influence diagrams and causal loop analysis or quantitative modelling using Stock-Flow diagrams and computer simulation.

ABSTRACT

The objective of this chapter is to illustrate a case study of a medical research institute in Malaysia in order to discuss issues pertaining to ICT adoption in healthcare organizations, in particular exploring the culture, challenges, and issues of ICT adoption among medical teams, patients, etc. In this chapter, we examine the question of 'What are the challenges of implementing ICT in healthcare organizations?' Some of the lessons learned from the case study were: ICT was successfully adopted and implemented based on several factors such as supportive organizational culture, competent IT workers, committed IT department and heavy investment on ICT infrastructure. Yet challenges also arise which hinges upon factors like initial deployment of outside IT resources or expertise for ICT implementation, lack of user training and continuous communication between involved parties in the initial stage.

INTRODUCTION

This chapter consists of six sections highlighting issues on information and communication technology (ICT) adoption and implementation. The first section discusses the phenomenon of ICT adoption in healthcare institution. Second, we include literature reviews based on three perspectives that oftentimes pose challenges to the deployment of ICT: (1) organizational, (2) people, and (3) technology. Third, we highlight the methodology of the study in this chapter which is a case study. In this section, we provide the background of a single case study -- a medical research institute in Malaysia -- to illustrate lessons learned and challenges of ICT adoption and implementation. Fourth, we present our findings which is the detailed descriptions of the issues and challenges based on an analytical framework called 5Ws (what, when, why, where, and who) as well as from the three perspectives mentioned above. Fifth, we provide the discussions in light of lessons learned and the contribution of the study. Lastly, the chapter concludes by summarizing the findings for healthcare institutions that intend to adopt and implement ICT in their organizations and presents the directions for future research undertakings.

In the era of globalization and information age, healthcare industries are intensely promoting and adopting ICT to improve patient care. When more and more patients as health consumers seek and prioritize quality in their lives through enhanced healthcare treatments and services, it places great demands on the health care industry's information-handling abilities and infrastructure (Bodenheimer, 1999). As supported by a recent World Bank (2006) report, "Reliable information and effective communication are crucial elements in public health practices. The use of appropriate technologies can increase the quality and the reach of both information and communication."

In line with this, Malaysia as a developing country has invested heavily in ICT with the mission and vision to improve patient care. Malaysia realizes that patients with healthy lives are better able to maintain healthy minds, healthy lifestyles, and a balance between work and family. In a similar vein, healthcare service organizations also seek for optimal strategies and solutions to increase their medical services. When introducing ICT, these organizations need to consider carefully the challenges that arise from it such as whether the organizational culture is supportive towards any ICT adoption and implementation, whether the organization can build ICT infrastructures that are efficiently and effectively, and whether the organization is willing to recruit, select, and employ competent human resources to use ICT as tools.

For example, according to the study by Mass and Eriksson (2006), when ICT was introduced and hospital staff were unprepared for changes because there was no adequate information given by the technology providers, the immediate result was a lack of knowledge of the new clinical requirements, and users who were ignorant of how to use the new technology; the larger consequence, was a slowed process of implementation and adoption. On the other hand, organizations like hospitals have now realized the potential of integrating ICT into their organization. Technology is reshaping organizations by blending their information systems with rapidly advancing telecommunication technology (Frenzel & Frenzel, 2004). In addition, management teams feel that having ICT integrated into their systems will improve and strengthen healthcare systems in the future. Ragam (2007) asserts that successful ICT adoption will lessen errors considerably, if not totally eliminate them. In addition, according to the World Health Organization, technologies form the backbone of services to prevent, diagnose and treat illness and disease. ICTs are only one category of the vast array of technologies that may be of use, but given the right policies, organization, resources and institutions, ICTs can be powerful tools in the hands of those working to improve health (WHO, 2004).

Besides ICT becoming the catalyst factor for economic growth, it serves as an essential medium of communication between patients and medical teams. Studies have shown that in face-to-face encounters, patients often refuse to share or disclose their illness to support groups such as medical teams, family or friends, even when such disclosure can help them cope with terminal illness. Whether ICT will make patients more or less willing to disclose their information to the support group or family members is still unknown. Hence, the main purpose of this chapter is to understand ICT adoption and implementation issues in one case study of a Malaysian hospital as an example of a health-care institution. In this chapter, we will investigate one overarching research question: What are the challenges of implementing ICT in healthcare organizations?

CULTURE AND CHALLENGES OF ICT ADOPTION AND IMPLEMENTATION

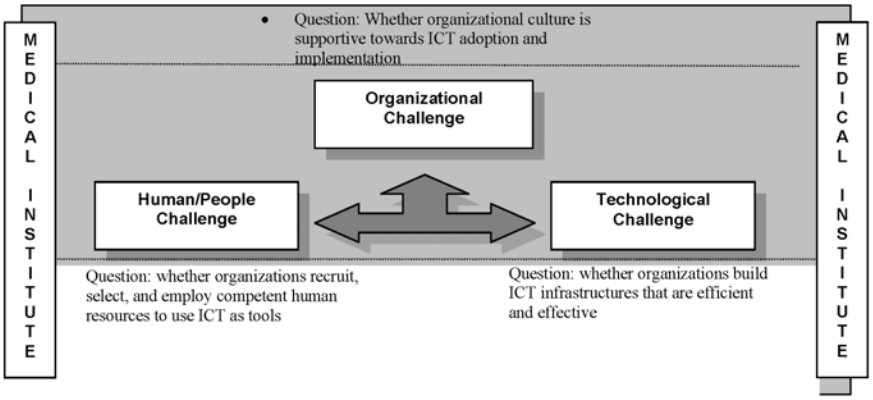
In this section, we first provide some definitions on basic concepts such as culture, organizational culture, and information system culture. We also provide the linkages between these different layers of culture. Second, we also present some literature reviews on ICT adoption and implementation based on the conceptual framework (see Figure 1). In specific, we investigated the culture of ICT adoption among the medical teams and support staff in the hospital environment. Culture can be defined as the way of life or the way things are done. Cultural values are usually associated with nations, though a particular nation may consist of subcultures and even subcultures (Holt & Wigginton, 2002). In addition, Robbins (1996) defines national culture as "the primary values and practices that characterize a particular country" (p.48). Culture differs in many aspects and exists between countries based on cultural dimensions introduced by several theorists. The following paragraphs explore in more detail the three types of culture with which we are concerned: national, organizational, and IS.

A cross-cultural theorist, Geert Hofstede (1980) has conducted hundreds of studies to examine the impact of cultural values on many aspects of organizational behaviors and management practices. His study illustrates national culture based on four dimensions--power distance, uncertainty avoidance, individualism vs. collectivism, and masculinity vs. femininity. Each dimension describes a different area of the cultural impact on management practices. For example, power distance illustrates the willingness of a person to accept the inequality of power in an organization. The second cultural value, individualism vs. collectivism, refers to the 'sense of belonging' a person feels when it comes to job satisfaction and tasks. Third, uncertainty avoidance explains the level of risk and uncertainty that people are willing to accept and undertake. The last dimension, femininity and masculinity, describes the difference between people who are ambitious, hardworking, committed and task oriented as opposed to people who are caring, and relationship-oriented.

Organizational culture comprises the atittudes, experiences, beliefs and values of an organization. According to Schein (1992), organizational culture can be defined as "A pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way you perceive, think, and feel in relation to those problems" (p.34)."Thus the impact of organizational culture is extensive and intense in organizations where it is manifested in concepts such as 'the way we do things around here,' or certain rites and rituals of the company, 'our company climate,' 'our common practices and norms', and 'our core values.' Schein (1985) suggests three levels of culture: artifacts, espoused values, and basic underlying assumptions. These organizational levels definitely overlap with the national background of an individual, which might create conflicts.

Besides organizational culture, another layer of cultural values that need to be emphasized is the information system (IS) culture. What is an IS culture? There is no clear distinction of this type of culture since it overlaps with national and

Figure 1. Conceptual framework of challenges in managing ICT in healthcare organizations



organizational culture. To avoid any confusion with the already multifaceted cultural values in this chapter, we will limit our definition of IS culture to one particular instance, that of the organizational culture of the developer of the ICT and the users who either adopt or reject the technology that he or she uses in an organization. Extending the work of Hofstede, IS culture can be defined as the set of values and practices shared by the members of an organization involved in information activities; this includes people like IT professionals, managers, and end-users. IS culture is thus a subset of an organizational culture, with unique values that are attached to the IT department. IS culture might resist technologies which threaten to change their current status, power, and working habits, especially when they may violate some of the groups' shared values. IS culture may also be more or less compatible with certain forms of IT; when that is the case, the result can be resistance to IT changes, failure in ICT adoption, and lack of implementation. In other words, the way people perceive the usefulness and ease of use of a given ICT will be impacted by the existing national culture – in this case, that of the medical teams as well as the support staff – together with the common practices, artifacts, espoused values and underlying assumptions of the developer(s) in an organization.

On the overall, culture is complex and multifaceted (Fan, 2000). As such, national culture is interrelated to organizational culture, professional culture (e.g. medical teams as doctors and nurses), as well as the IS culture. All these layers of cultural values can affect the way people handle innovation and ICT adoption. For instance, a study by Aggouram & Ingham (2003) found that when an organization attempts to standardize their information system, culture plays an important role as it affects the success of such task. Besides the multifaceted layers of culture, we also need to address the challenges that are confronted by people when a new technology is introduced. The key question is whether or not people are able to adopt the newly introduced ICT and if yes, what is the culture surrounding the ICT adoption and what are the challenges encountered by an organization?

Challenges of ICT Adoption

Based on the following conceptual framework (Figure 1), there are three aspects that we examined pertaining to the issue of ICT adoption in the hospital which are (1) organizations, (2) human, and (3) technology. Without a doubt, ICT has played a significant role in organizations such as hospitals and will continue to play a greater role in the aim of enhancing healthcare services. ICT is no longer just a business tool but an integral part of the organization's strategies. ICT impacts not only the IT department but every area or department in the organization since ICT is responsible for the integration of information across the entire organization. Based on empirical studies, the challenges of ICT arise from three barriers: organization, people and technology (Nambisan & Wang, 1999; Lorenzi & Riley, 2003; Nøhr, 2005; Pare, 2007; Tanriverdi & Iacono, 1999). These challenges and issues must be managed critically and effectively in order for an organization to function successfully via the use of ICT tools and applications.

Organizational Challenges

One of the most widely discussed questions on ICT implementation in hospitals is the cost of ICT investment – that is, the cost of the hardware and software needed to run the healthcare system. This could be actually high depending on the latest cost of software on the market, but it can also be relatively high, for example particularly costly to hospitals located in rural areas where not enough investment is made in updating or changing to new healthcare systems. In addition, organizations must consider costs associated with planning, specifying requirements, customizing and re-customizing systems, training providers, and reengineering the delivery of healthcare systems to accommodate hospitals. Miller and West (2007) suggest that the initial cost of implementing an Electronic Medical Record in a health center may be as high as $US54,000 to $US64,000 per participating physician, with ongoing costs of $US21,000 per physician per year. The key question is thus who will bear the expensive costs of ICT investment?

Another important organizational challenge is the organizational culture. An effective and efficiently managed organization normally ensures that their managers and employees understand the basic beliefs and policies governing behavior both within the organization and in external business relationships. The concept of organizational culture encompasses not only the organization as a whole, but also the individuals who are part of, or interact with it. According to Zakaria and Mohd Yusof (2001), a culture that promotes change is thought to be a more nurturing environment for technology users than a culture that promotes stability and certainty. Resistance towards usage of ICT in healthcare systems will frequently surface unless the culture is receptive towards changes, and unless people are ready to both accept new ideas and, more importantly sustain the changed conditions in the future.

Human/People Challenge

Human resources are the most important assets that contribute to organizational success. With the introduction of complex and rapidly evolving technology, organizations oftentimes are limited by the scarcity of skilled employees and experienced managers needed to operate the newly introduced ICTs. It is recommended that IT managers and their top management have a plan to cope with skill shortages because organizations that fail to manage their present staff stand little chance of obtaining and retaining outstanding individuals. Human resources that are reliable and full of capabilities will also increase the efficiency and effectiveness of the ICT. Therefore, organizations need to ensure they can recruit, train, and retain talented IT experts. This issue is directly related to organizational performance as well as individual performance; significant contributions that materially improve an organization's performance have oftentimes been made by a small number of individuals. Another important aspect is that reliable and competent IT expertise can disseminate operations and services much faster than people who do not know or understand how to use ICTs. Thus user training must be in place in order to bring users up to a tolerable level of competence which in turn increases the user acceptance of technological change. User training must be included in all phases of ICT adoption, from the initial stage up to the implementation stage. As suggested by Johnson (2001), three important tasks need to be included: educating the healthcare professionals, conducting research to understand the importance of ICT to stakeholders, and advocating for ICT use in organizations.

Technological Challenge

Without doubt, ICT is changing the way health care functions. With ICT tools, organizations can enhance healthcare services electronically where barriers like time, distance and space no longer matters. What matters is the quality of services. For instance, health care organizations can offer more efficient and various services for health consumers such as ability to access their own health records, browse the Internet for further information and knowledge about one's illness, communicate freely and speedily between patients and doctors, and reach out to online communities of patients that suffer the same illness for psychological support. However, with the amplified role played by ICT, there are some technological challenges that arise such as ease of use, usability, information security and compatibility of the system with the existing one. All the challenges transpire as a result of the technological change undergone at the organizational as well as individual level. Technological change is defined as "the change period, during which something new is planned and introduced, e.g. the period associated with the introduction of new processes that have major new technological ingredients" (Wild, 1990, p.55). The challenges that stem from such changes need to be managed. According to Benjamin and Levinson (1993), "The greater the functionality of an IT system, the more levels of learning and adjustments are required to use it (p.30)." In support of that, Zakaria and Yusof (2001) suggest that readiness and willingness to learn about the new technology at a greater depth and the customization of each of the processes are key issues that need to be taken into account when planning or undergoing technological change. Only then can the learning and transition processes during ICT adoption and implementation be a success.

METHODOLOGY

A Case Study of a Medical Research Institute in Malaysia

A case study is an ideal methodology when a holistic and in-depth investigation is needed (Feagin, Orum, & Sjoberg, 1991). Following storytelling logic, it seeks a deep understanding of a single organization by analyzing its social context (Dyer & Wilkins, 1991). In order to describe a rich story, case researchers approach the field as closely as possible and apply theoretical constructs in ongoing social settings. The descriptive and interpretive nature of storytelling enables researchers to investigate the process by which an artifact comes to obtain its characteristics (Dyer & Wilkins, 1991). It is a backward tracing of artifact history and an analytical conceptualization of the artifact. In other words, a case study is an act of taking an artifact's history apart and reassembling it within a contextual frame. Through these processes, researchers identify the intricacies of a particular context.

In this study, we use case study as a qualitative method because it is most relevant in exploring ICT adoption in a new setting, in this case--Malaysia. Our case study focuses on one medical research institute (MRI) situated in the northern part of Malaysia. The institute is part of a research university which also has its own teaching hospital located in the eastern part of Malaysia. This research institute's mission is to educate and train more medical and dental professionals in conducting medical research. In addition, the institute also provides outpatient services to the local community. At the same time, the medical research institute is planning to open its own research hospital to be fully operational in the year 2010. They hope to become one of the biggest tertiary and advanced medical centers and to meet the medical demands in the northern part of Malaysia.

In terms of Malaysian healthcare system, there are three types of funding: government, semi-government and private funding. In our case study, the medical research institute is part of a semi-government funding scheme because it is part of a higher learning (university) institution. This means that part of the ICT investment is taken care of by the Ministry of Higher Education, so in our case study, since this is a government run medical institute the medical cost is very minimal. In terms of policy, there is no comprehensive policy in regard to ICT use in hospital or healthcare organizations in Malaysia. In this case, the medical research institute adopts the policies used by the university's teaching hospital. In addition, most clinicians were working with teaching hospitals before they joined the medical research institute and were familiar with the policies.

Using a Malaysian medical institute as a case does not mean that the challenges of medical informatics as illustrated in this chapter are unique to Malaysia. We are more interested in pointing out that implementation and adoption of ICT in hospitals involves challenges and issues that need to be addressed by any organization. Malaysia is just one case in point, and though the case maybe unique to Malaysia it implies that other healthcare organizations may experience the same challenges when implementing and adopting ICT applications.

Data Collection

We began collecting preliminary data with the research objective of exploring the challenges faced by a single healthcare organization during the early stages of ICT adoption and implementation. According to Yin (2003), a case study is a research design that allows a researcher to understand a phenomenon in depth and provides richer insights about the problems being researched. Based on the case study approach, we employed structured interview to elicit as much data as possible pertaining to the phases, challenges, and problems encountered during the technological adoption period.

In order to understand the nature of ICT implementation and adoption in the institute, we had in-depth interviews with two key people in the institute: the clinical director and IT Director. We met the respondents a few times and spent many hours interviewing them to obtain their perspectives on ICT adoption and implementation. The clinical director is responsible for overseeing numerous medical specialties like oncology, psychiatry, dentistry, family health, pediatrics, internal medicine, and obstetrics & gynecology. She is also responsible for providing the space and tools for postgraduate research in the institute. The ICT director oversees all the design, development and implementation of ICT systems within the institute. These include the ICT infrastructure to support information and communication exchange within the institute. In the clinical setting, the IT department is responsible for developing a healthcare information system (HIS) within the institute. The HIS includes patient medical records (e-clinical) linked with the radiology information system (RIS) and laboratory information system (LIS) as well as nurses' station, billing, social work department and inventory. The system was completed and launched on March 2006, the same time as the outpatient clinics began to operate.

Interview Protocol and Validity of Case Study

The process of creating the interview protocol started in a formal researcher's meeting where, we, the researchers brainstormed the main issues pertaining to ICT adoption specifically in Malaysia context. The focus was on the overall picture of ICT adoption that affected different stakeholders in the organization. The researchers then decided that the protocol should be divided into two categories. The first category contained questions related to historical background of the organization. We adopted 5W's type of questioning (what, where, when, how, and why) so that we could explore the organization.

For the second category, we used questions that could address the success and challenges of the organization when adopting ICT. For an example, one of the questions asked the participant to give example of a "success story" during ICT development process. There is also one broad question that deals with "barriers and challenges" faced by the IT department during deployment. The "barriers" question is further expanded by setting probing questions that look into human, technology and organizational issues such as asking *"How, if at all, does the communication between doctors and patients change when ICT is introduced?"*

After the first draft of the protocol was completed, we sent the protocol to several researchers who are expert in the qualitative field. To ensure validity, the panel researchers examine the protocol in terms of clarity, organization, relevancy, accuracy and language-use. Once the protocol was approved, the researcher's team went through a mock interview exercise in order to see the flow of the questions as well to know when to ask the probing questions. We also added some "scenarios" to help the main interviewer understood the meaning of each question in case the interviewer got stuck during the interview. All this exercise had helped the main interviewer to prepare for the interview.

Data Analysis: Content Analysis on the Interviews

Content analysis is an unobstrusive research technique used to explore a phenomenon that yielded rich descriptions (Krippendorf, 2004). Based on the interviews we conducted, we will discuss in detail several challenges surrounding the culture, adoption, design and implementation of Hospital Information Systems in a local context. The transcribed interviews were content analyzed. In the first set of data, since this is a preliminary study attempting to explore and understand the challenges of ICT adoption in a hospital context, we used 5Ws (what, why, when, where and who) analysis to elicit a picture of the overall IT system as well the process of development and deployment of such a system. The 5Ws analysis is a common elicitation tool which enables researchers to get in depth information from research subjects. Then, in the second set, the discussions of the findings center on the three potential barriers: organizational issues, human/people issues and technological issues. The findings are described in the following section.

DISCUSSIONS ON ICT ADOPTION IN HEALTHCARE: A CASE OF A MEDICAL INSTITUTION IN MALAYSIA

Exploring ICT Adoption Using the 5Ws Framework

What is E-Clinical System?

It is crucial to first define the concepts of ICT and electronic healthcare. We suggest using the following definition: *ICTs* are defined as tools that facilitate communication and the processing and transmission of information and the sharing of knowledge by electronic means; this includes the full range of electronic digital and analog ICTs, from radio and television to telephones (fixed and mobile), computers, electronic-based media such as digital text and audio-video recording, and the Internet (Frenzel & Frenzel, 2004). *Electronic healthcare*, or *e-health*, is an emerging field of health informatics that refers to the organization and delivery of health services and information using the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a new way of working, an attitude, and a commitment to networked, global thinking, in order to improve health care locally, regionally, and worldwide by using information and communication technology (World Bank, 2006). For purposes of our case study, we will also talk about the *e-clinical* system which is a healthcare information system (HIS) comprised of seven modules that serve eight clinical subspecialties in the institute. The motivation for creating such a system is to operate a paperless transaction in the medical setting. The development of this software was fully supported by the university's IT department, who provided software and hardware infrastructure as well as manpower for software development.

At this point, e-clinical has five full functioning modules which are registration, patient screening, clinical, laboratories / radiology, and billing / inventory. When patients first enroll in the system, they are entered into the out-patient registration by registration personnel. Next, patients' vital signs are recorded in the patient screening module by nursing staff. During patient-physician interviews, the clinical module is used and the information is dispersed into imaging, laboratory and pharmacy modules for different uses. In each module, all charges are connected with the billing module. The social department reviews cases where patients cannot afford medical care and provides necessary support for those patients. If patients are eligible to receive help, the billing information is sent directly to the social department module. The last module, inventory, is connected to the billing module in order to ensure medications and all other orders are in stock.

Why Develop In-House Electronic Medical Record (EMR)

One of the goals of this medical institution is to operate a paperless hospital. In doing so, the organization planned and developed an in-house EMR by customizing their own system using their local clinical requirements. The initial requirements were generated by the top management of the medical institute followed by a series of user feedbacks after the system was launched. Another motivation for developing the in-house system was to reduce costs. Development was also encouraged by their ability to get technical expertise from the university Information Technology division.

When the Roll-Out Takes Place

The system rollout took place in March 2006. The director of the research institute wanted the system to be available as soon as the outpatient clinic was open. The decision to roll out the system in parallel with the service was quite brave, and was, made even though there were issues in system design at that point. The IT personnel met regularly afterwards and listened attentively to user requests. Changes and modifications to the system were made directly and the IT people took time to sit down and help the users. The local champion participated in the IT daily meeting to report user requests and complaints. In this case, local champions are the first group of people who adopts ICT in this hospital.

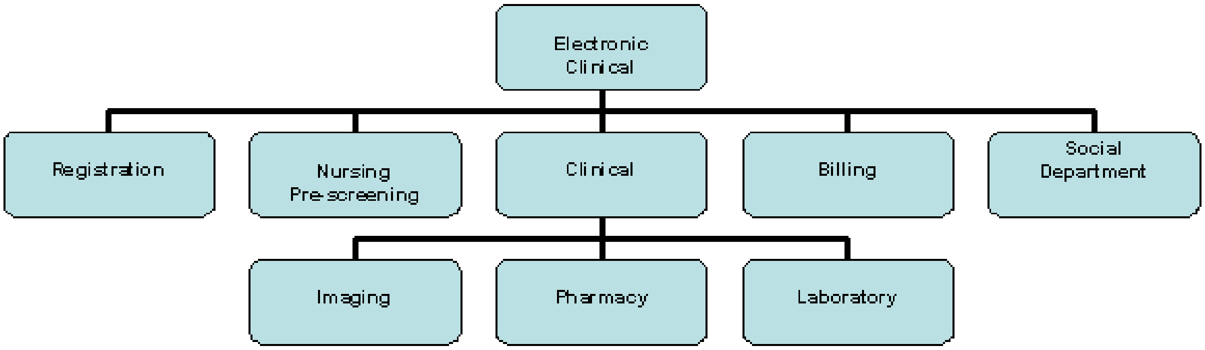
Where the ICTs are Introduced in the Institution

E-clinical operates in the outpatient clinic, laboratory, pharmacy and imaging centers.

Who are the Users

The users of the system include clinicians, nurses, and registration, billing, inventory and social department personnel. However, each user has limited access control as assigned by the IT department. For an example, the registration personnel can only enter and view patient registration and cannot access other modules. Most clinicians

Figure 2. General architecture of e-clinical system



have direct access to all patient information in order for them to track any patients with multiple diseases and get appropriate care from various medical specialties.

ICT Adoption: Issues on Organizations, Human, and Technology

In the context of the medical institute that we researched, we found that people, especially within the top management, were very receptive to and supportive of the organizational change. In other words, organizational change was part of the culture in which people are not only willing to accept changes but also accepted the role of the ICT and recognized the benefits that they would reap from using it. ICT is expected to facilitate the operations and change the way people in the institute work and the way they provide their medical treatments and services. All members of the board of directors, which is comprised mainly of clinicians, are very open towards ICT implementation in their organization. This is evidence that clinicians are actively accepting ICT in their work flow instead of resisting it, as found in many previous research studies. The institute's director himself made sure the e-clinical system was in place in parallel with the outpatient clinic opening because he wanted to make sure that the transitions went hand in hand. In addition to the sophisticated e-clinical system, the clinical director said that the institution has been using e-mail for their interactions with nurses and students.

Based on our case study, the IT director said one important lesson for future in-patient system development is to include all levels of users at the beginning of system development. For example, the IT department should get insights from registration personnel, nurses and clinicians from different specialties, billing officers, social workers, and any other potential users. The users would be able to give ideas on how to make their workflow as smooth possible, and may be able to see if some design would hinder their work process. In addition, they should review the requirements together with decision makers such as the institute's board of directors. All these inputs are important to ensure that ICT facilitates their daily routine and interaction with patients.

The IT director acknowledged the importance of local champion who becomes a liaison to the development team. During the initial roll-out phase, there were daily meetings among the developers and the clinical side on usage issues from the clinical side; the nurse champion was instrumental in gathering feedback from the clinical side and was able to suggest necessary remedies to the problems that occurred. The IT director mentioned that the local champion understood the day to day challenges in using the system because she was herself an avid user and knew the clinical environment well enough to be able to diagnose the problems faced by other users. The IT director also added that the local champion will be included in the early stage of inpatient system development. The advantages of an in-house development team were that it included knowledgeable end users as well as strong technical support from the university's IT department and an in-house developer that understood the system. The programmers were able to interact with the users and make changes instantly because they understand their own system in depth.

The institute only provided a few sessions of user training at the beginning of system deployment. There was no formal training afterwards. The IT director mentioned that most users refer to their own colleagues if they find problems when using the system. However, we feel that this organization should take extra measures to provide user training. The in-house training should be done in a consistent manner whereby training on the overall system and the potential uses of system would be cleared up among the users in the early stage. In a later phase, training should be provided as a continuous learning and improvement tool for the organization.

There were strong collaborative efforts between the IT department and the clinician side. After the system deployment, the IT people met the clinical end users every day to discuss any issues that arose. After a few weeks of daily meeting, the IT top management asked the programmers to work hand in hand with the users. At this point, all the programmers understood the nature of clinical use of the system. It is important to note that the process of cyclical communication is most important at the early stage of ICT adoption. What is even more effective is that the IT top management takes a leading and proactive role to ensure that the technological as well as organizational change transpires smoothly and effectively.

Based on the case study, one of the main questions during the interview was to understand the technology issues surrounding the development. As mentioned earlier, the medical research institute is part of a research university. The university itself has an established IT department that oversees all IT implementation in the university. The e-clinical system template was taken directly from the university's health center, which had been using an electronic medical record system that was designed by the university IT department. When the medical research institute began their own ICT initiative, they immediately adopted the university's electronic medical record system. However, the IT director said they had to do some minimal modifications because the medical research institute handles more medical specialties compared to the university's health center. For the modification process, MRI had to "borrow" the university's IT department programmers. The migration and modification process took several months during which programmers and MRI IT personnel traveled back forth (the university and MRI are 40 minutes away). This back and forth process was not an easy task, and eventually the top management decided to hire their own programmers to handle e-clinical. Finally, they obtained two full-time programmers to operate e-clinical. In addition, MRI also hired an IT manager to lead the development team. Even though MRI now has its own development team, they still rely on the university's IT department for technical advice. Besides the issue of adapting to the university's electronic medical record format, we also found that MRI did not have to spend any money on the software because all licenses are bought by the university. In this case, MRI was able to cut costs in the development system which is an added advantage to the organization.

In terms of infrastructure, there were some issues of physical layout during the initial phase. For example, there was some discussion about where to place the servers; later on they were able to create a separate space just to store the servers. The IT director added that there was no proper planning of where to install the hardware until later on, when they discovered how disorganized it was to have the servers in various places. In other words, when the decision to adopt ICT was made, people were excited at the idea and accepted the decision without taking into consideration many details like space. In future ICT efforts, they have decided to plan hardware space first. She also mentioned that careful planning has been done in the design of the new hospital building. The institute selected one commercial system, which handles the radiological information system; this commercial system is developed in the USA, thus it incorporates standards like DICOM in the system. The IT department has to take into account these standards when incorporating it with the e-clinical system. In addition, the IT department is exploring other suitable standards for their own system.

LESSONS LEARNED FROM THE CASE STUDY

In this section, we first present several key perspectives based on the lessons learned from the above case study to highlight the critical success factors and best practices of healthcare organizations. Subsequently, we present the contributions based on the case study. The following observations were made:

Plan the ICT Investment More Effectively

Since ICT investment is costly and time consuming, for example in getting the right supplier or vendor, top management needs to plan more proactively by taking factors like time, cost, and benefit into consideration. In the case of MRI, the decisions to invest in ICT applications were not solely made by the top management, particularly the IT Director. Instead, the ICT projects were adopted directly from the University with which the medical research institute has a strong affiliation. Thus in the initial planning stage of buying or adopting ICT and the process of making decisions, questions like what types of ICT to invest, what are the cost and benefits of using one particular or several applications, who are involved in decision making, and timeline to adopt the ICT were not discussed at length. Yet, initial planning is as important as any other stage of the ICT adoption. It is crucial that these issues be addressed at the initial stage of decision making processes and as early as possible so that any problems can be identified and solved much quickly. In the case of MRI, it is fortunate that the adoption of the e-clinical system was not much of a problem.

Recruit, Select, and Retain Local IT Experts

By having the in-house experts as gate-keepers, organizations will benefit by continuous improvements and modifications to suit the needs of the organizations. Additionally, IT experts will also become the main advocates for technological changes as well as the liaisons between users and support staff, because they will learn much faster than others. IT experts are expected to be more equipped with knowledge about the information technology systems and applications. Based on the MRI case, the top management strongly felt that when the IT people, e.g. the programmers, were recruited in-house, it was much easier to manage the time allocated for ICT adoption and to educate other users on the ease of use and usability of the new system. With such recruitment, MRI no longer needs to depend on the vendors for help as their own IT people can handle any ‘bugs’ or problems that they encounter. As a result, the ‘layperson’ or non-IT people in the institute have frequently consulted the IT experts for any kinds of problems and difficulties that they encountered not only during the early stage of ICT adoption and implementation, but also on a continuous basis. In essence, IT experts become the main source of reference to help the amateur users in the organizations.

Build a Strong Organizational Culture that Supports Technological Changes

When organizations provide a conducive and supportive environment for ICT, the adoption and implementation process becomes less problematic or challenging. People are more willing to try and use the technology in place. Although in our case study we observed less involvement in decision making and planning in the initial stage of ICT adoption, the organizational culture of the MRI was highly supportive. In fact the IT top management agrees that only with a supportive culture can ICT adoption be successful. As evidence, the processes of adoption and implementation were smooth in the MRI. Personnel at all levels knew that ICT would be part of the normal ways of doing things in the organizations. They welcome such changes because they know that ICT will simplify their work and help them provide their services. Without support, resistance may surface and adoption and implementation will take a longer time.

Involve All Users and Key People in the Organizations

These people can present their needs and provide perspectives on what is desired versus what are the obstacles. By using this strategy, the organization creates an awareness of the change that will take place. When people have first hand information on the changes that will take place, as well as an avenue to voice any grievances, frustrations and anxieties about such changes, they will be more willing and ready to accept such changes. In the end, people will adopt ICT more willingly and become more accountable towards the changes. Our MRI was a unique case because the decision to adopt ICT was not inclusive at the initial planning stage. Rather than "adopt" it was more an issue of "adapt," taking the existing e-clinical system from the other institution -- almost like having a customized system to fit within MRI. But once the e-clinical system was adopted and implemented, the IT director played an active role by ensuring all levels of users participated in the success of the systems. So there are continuous 'loop' feedbacks from end users that provide extensive inputs to programmers on what needs to be done and improved.

Provide Continuous User Training to All Levels of Users

From top management to lower management that will use ICT-- Training is essential at all stages of the transition because educating people on the ICT tools makes them familiar with the new work context, and eventually they become experts in using the tool. Training needs to be given phase by phase, for different people at different times. Top management may take precedence so that they can advocate changes to the subordinates.

Contribution of Study

Without doubt, making investments in ICT can be expensive, for examples in terms of the financial cost, time, and resources. Not only is the infrastructure becomes one of the main concerns for organization, but also the cost of recruiting, training, and sustaining the people as the human resources are as crucial. By looking at the findings based on the lessons learned, there are few implications that can facilitate organizations in managing the rate of ICT adoption among employees. Hence, the contributions of this study come in twofold. First, by looking at the dynamic layers of culture, it helps an organization to fully understand the underlying values of the employees as well as evaluate and improvise the organizational culture, structure, and processes. As such, organizations will incorporate a compatible culture that is consistent with its objectives, vision and mission. Second, organizations can take preventive measurements, proactive plans and strategies to overcome three challenges as previously mentioned (see Figure 1.0). For example, organizations need to invest in training programs for the medical teams and support staffs to use and adopt ICT such administering electronic medical records. Essentially, failure to use and adopt ICT effectively will result in unsuccessful management of patients and its healthcare services.

CONCLUSION AND FUTURE DIRECTIONS

It is obvious that the case study presented in this chapter comprises preliminary data on the practices and lessons learned from an organization that adopts and implements ICT – in this case an e-clinical system. As such, the case provides insights on a Malaysian context in which the effort for ICT adoption is partly supported by the government. In the future, as an emerging healthcare organization, it is expected that the medical research institute will be developing and integrating more ICT applications to support their mission of becoming an excellent medical research center. Although we have presented the issues and challenges surrounding an ICT implementation in the Malaysian health care environment, the challenges can be applied in any other organizational context or in different country-based perspectives. Inherently, there are some important lessons to be learned from this case study as illustrated above. In a nutshell, managing ICT adoption and implementation requires that the organization build effective communication among people who are involved in the technological change processes; create awareness of both the organizational and technological changes that are going to take place; develop continuous and rigorous training to increase familiarity, competency, and knowledge about the ICT to be used; recruit, select, and retain local IT experts to move the ICT adoption processes to success; and promoting supportive organizational culture that supports technological changes. Given these five lessons learned obtained from the case study, we suggest some fruitful questions for future research:

- How, if at all, does ICT change how healthcare delivers its services?
- How has patient care changed, and what are the trends?
- How, if at all, does the work of doctors and nurses change when ICT is introduced in a health care institution?
- How, if at all, does the communication between doctors and patients change when ICT is introduced?
- Does ICT deskill or facilitate doctors and nurses?
- What are the critical success factors for ICT adoption in healthcare organizations?
- How do organizations manage technological changes to ensure effective ICT adoption?

KEY TERMS AND DEFINITIONS

Culture: includes knowledge, belief, art, morals, law, custom, and many other capabilities and habits acquired by a man as a member of a society.

Case study: is defined as a research strategy, an empirical inquiry that investigates a phenomenon within its real-life context. Case study research means single and multiple case studies, can include quantitative evidence, relies on multiple sources of evidence and benefits from the prior development of theoretical propositions.

Electronic medical records (EMRs): are computerized or electronic based health records of a person used by physicians, clinic or hospitals. It is a comprehensive record that combines information across multiple providers.

Information Communication Technology: defined as tools that facilitate communication and the processing and transmission of information and the sharing of knowledge by electronic means which includes the full range of electronic digital and analog ICTs.

Medical informatics: analysis and dissemination of medical data through the application of computers to various aspects of health care and provisions.

Organizational culture: comprises the attitudes, experiences, beliefs and values of an organization. It can also be dfeined as the specific collection of values and norms that are shared by people and groups in an organization and that control the way they interact with each other and with stakeholders outside the organization

Technological change: the change period, during which something new is planned and introduced, e.g. the period associated with the introduction of new processes that have major new technological ingredients.

ABSTRACT

Mobile technologies, such as PDAs, pocket PCs and cell phones, are transforming interpersonal communications, making them independent from a fixed location and then "situated nowhere". The widespread diffusion of mobile technologies combined with the popularity of virtual communities is giving rise to the development of mobile virtual community. Mobile virtual community has the great potential to serve information needs. A relevant application's domain for mobile virtual communities is healthcare, where the need for information is deeply felt and has a long-term nature. Mobile virtual healthcare communities encourage information exchange between patients, between physicians, and between patients and physicians. The exchange of information can be used for detecting patients and physicians that have common objectives in order to establish interaction among them.

DOI: 10.4018/978-1-60566-156-8.ch029

INTRODUCTION

Social relationships are a key component of human life. Whilst in earlier times communities were bound to the limitations of time and space, these restrictions are removed thanks the evolution brought by the Internet (Whitepaper, 2007). In the Web people organize themselves into virtual communities at the same manner they organise themselves in communities in the real word. A Virtual Community can be defined as an information source in which people share interests and information. It consists of tree elements;

- People interacting to satisfy their own needs or play special roles;
- A shared purpose, such as a need, an interest that provides the reason for belonging to the community.
- Communication systems and server architecture that support social interaction and promote a sense of been together.

The popularity of virtual communities, combined with the widespread diffusion of mobile technologies, such as PDA, pocket PC and cell phone, has given rise to the phenomenon of mobile virtual communities. Mobile virtual communities are considered to be the natural evolution of virtual communities. They can be seen as virtual communities to which mobile services are added. Using mobile technologies, users have an anytime-anywhere connection to their community. The use of mobile devices allows members of the community to communicate among them anywhere and anytime and not only if they are in the same physical place. In this way they can constantly have a connection with other members. The communication is both one-to-many and many-to-many. The participants of a mobile virtual community can exchange useful information by communicating and interacting with each other. Mobile virtual communities should be information rich and it should allow information available for many people because they improve and encourage social processes allowing interaction among colleagues, friends etc..

The aim of this chapter is to analyse the social impacts that mobile virtual communities have in the healthcare sector. Belonging to a mobile virtual healthcare community enables patients with diseases to interact in a virtual space with people that have the same experience. This interaction can allow the improvement of knowledge and the decreasing of problems. Moreover mobile virtual healthcare communities offer to physicians an opportunity to improve the awarness of patients' health conditions enhancing their satisfaction. They give the opportunity to increase the involvement of patients in their treatments improving access to health care information and communication possibilities between patients and physicians. The use of discussion forum gives physician the possibility to communicate with patients continuously allowing better information sharing. For patients with chronic illnesses, especially those in rural or outlying areas, consultation with an appropriate specialist can vastly improve the quality and outcome of their healthcare. Finally mobile virtual healthcare communities allow physicians to participate in continuous medical education at a time and location convenient for them, along with useful communication. The use of mobile virtual communities improves possibilities to maintain communication and collaboration with colleagues investigating the same subjects. Here physicians aggregate observations from their daily practice and then challenge or collaborate each others' opinions, accelerating the emergence of trends and new insights on medications, treatments and devices. They can apply the collective knowledge to achieve better outcomes for your patients.

The chapter is organized as follow. After a short introduction, which deals with some issues of categorization and definition of virtual communities, the chapter proceeds to analyse mobile virtual communities. Then the chapter first proceeds to describe mobile virtual communities/communication in healthcare sector and then it analyses three kinds of relationship: between patients, between patient and physicians and between physicians.

VIRTUAL COMMUNITY: A MULTIDISCIPLINARY CONCEPT

The term "virtual community" was even coined long before electronic communication in any form took place. It was a concern of many social theorists and scientists of the 19th and 20th centuries

(Reinhard and Wolkinger, 2003). There are many definitions of virtual community that depend upon the perspective from which they are defined.

From the technology perspective virtual communities are defined according to the software supporting them like newsgroup, list server, bulletin board, Internet Relay Chat (IRC), or Multi-User Dungeon (MUD). These software technologies support the communication within the community, and help in creating the boundaries of the community.

From the sociology perspective virtual communities are defined based on the strength and type of relationship. Etzioni and Etzioni (1999) define a virtual community as "a Web of affect-laden relationships encompassing group of individuals (bonding) and commitment to a set of shared values, mores, meanings and a shared historical identity (culture)". Romm, Pliskin and Clarke (1997) define a virtual community "as a group of people who communicate with each other via electronic media, such as the Internet and share common interests unconstrained by their geographical location, physical interaction or ethnic origin". Ridings et al. (2002) define virtual Communities as "groups of people with common interests and practices that communicate regularly and for some duration in an organized way over the Internet through a common location or mechanism".

Ferguson,et al. (2004) define virtual Communities as "groups of people drawn together by an opportunity to share a sense of community with like-minded strangers having common interest".

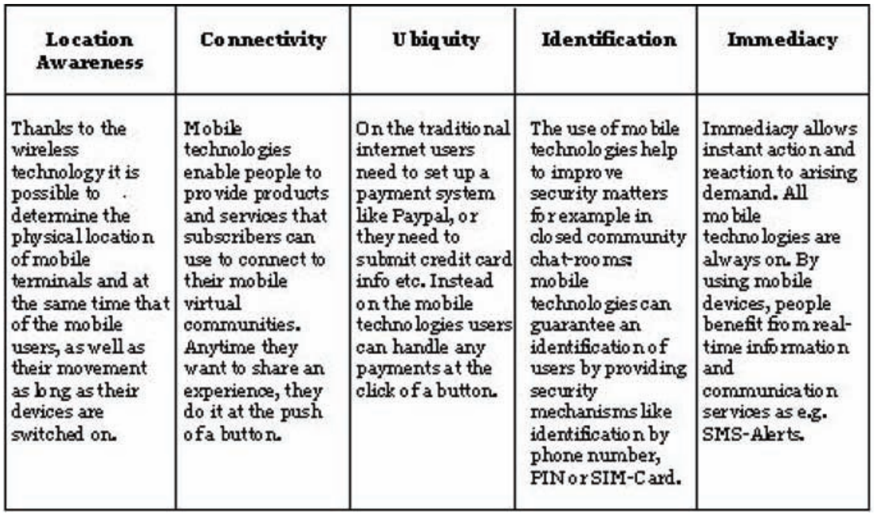
On the contrary Balasubramanian and Mahajan (2001) take an economic perspective and define a virtual community "as an aggregation of people, who is rational utility-maximizes, who interact without physical collocation, in a social exchange process, with a shared objective".

In all of these definitions virtual communities are described as social entities comprised of individuals who share information or other bases for social interaction.

The notion of information refers to the possibility to access to specific information regarding areas of interest. The exchanging of a lot of information in a virtual community, allows users to discuss about different questions and problems by creating a global vision about them. Within virtual community individuals can give information (by posting conversations) or get information (browsing information by posting questions). These information resources are socially helpful because they allow people to easily establish contact among them. A virtual community can be used also to improve the knowledge-sharing process using the experiences of the participants. The most effective way for allowing knowledge-sharing is the conversation. It is through conversation that we learn how to learn together. In a virtual community conversations can occur using a shared space where people can interact, creating new knowledge and, mainly, sharing knowledge. Therefore, common functionalities, provided by virtual community and aimed at sharing resources within the community, contain discussion boards, that provide individuals with the ability to post and reply to messages in a common area, whiteboard, that allows individuals to brainstorm together, draw graphical objects into a shared window etc, video/audio conferencing, that allows making virtual face-to-face meeting, and shared notepad, that provides community's members with the ability for cooperative writing and documents. Other functionalities concern the scheduling of common events and activities, the organization and retrieval of knowledge and the broadcast of shared documents on the Web.

Whilst the notion ofinteraction refers to the search of relationship during which individuals can share, with others, interests and experiences that can facilitate to overcome difficulties and to solve problems. Community is the process of bringing those who have interest in specific domain and

Figure 1. Mobile characteristics



Location Awareness	Connectivity	Ubiquity	Identification	Immediacy
Thanks to the wireless technology it is possible to determine the physical location of mobile terminals and at the same time that of the mobile users, as well as their movement as long as their devices are switched on.	Mobile technologies enable people to provide products and services that subscribers can use to connect to their mobile virtual communities. Anytime they want to share an experience, they do it at the push of a button.	On the traditional internet users need to set up a payment system like Paypal, or they need to submit credit card info etc. Instead on the mobile technologies users can handle any payments at the click of a button.	The use of mobile technologies help to improve security matters for example in closed community chat-rooms: mobile technologies can guarantee an identification of users by providing security mechanisms like identification by phone number, PIN or SIM-Card.	Immediacy allows instant action and reaction to arising demand. All mobile technologies are always on. By using mobile devices, people benefit from real-time information and communication services as e.g. SMS-Alerts.

remove interaction barriers, to build trust and relationships among the members of the community. In the created community each member develops his/her own identity in relation to the community (Bouras, Igglesis, Kapoulas, and Tsiatsos, 2005). The members' interactions over time help members in creating a network of trustees, composed of those who feel confident and comfortable with. This in return creates a reference source to ask for help when it's needed. An important factor in a community is the mutual engagement among community's members. Members whether joined the community voluntarily or were obliged to join and they can not be forced to contribute to it. Virtual community members should underline not only the content but also promote the social aspects as well if they wish to increase the success of their virtual community.

People have the need to be affiliated with others, because groups give individuals with a source of information and help in attaining goals and receiving social support. Social support plays a major role in influencing the well being of individuals. According to Turner, et al. (2001), the support received through virtual communities is perceived as helpful as support provided by real-world contact persons. Positive effects of online support are also mentioned by Gustafson and Maloney-Krichmar (2001). Both these studies report that members of online self-help groups superiorly cope with information about their disease due to the received support; furthermore, their emotional situation improves. A study conducted by Loader et al. (2002) identifies emotional as well as informational support as types of support provided by virtual relationships.

MOBILE VIRTUAL COMMUNITIES

Today we live in a mobile-devices-focused society. Mobile technologies, such as PDA, pocket PC and cell phone, transform interpersonal communications, which are independent from the fixed location, and result in the phenomenon of "situated nowhere," in which communication occurs everywhere. The ubiquitous form of communication allows people to micro-coordinate activities without prearranging an agreed-upon time and space. (Chih, 2007). Mobile technologies provide all the services that the traditional PC based Internet can offer. Even though the screen is smaller, it is not an obstacle. Everything is available on the Web, including its interactivity, can be avail-

Figure 2. Mobile virtual community application

able on mobile virtual communities. In order to analyse mobile virtual communities, it is useful to firstly illustrate mobile characteristics. Several studies specify mobile characteristics as classified by the chronology of their realization while others studies do not suggest any systematic order. On analysing the literature, we classify mobile characteristics into the following classes: location awareness, connectivity, ubiquity, identification and immediacy (Figure 1).

Mobile technologies are very useful to support people communication and interaction. Using the standard functions of mobile technologies people can communicate with others by sending photos, videos, etc. from a mobile device equipped with Internet functions. The Internet presents new opportunities for one to many and many to many interactions, creating a proliferation of virtual community. The popularity of virtual communities, combined with the widespread diffusion of mobile technologies has given rise to the phenomenon of mobile virtual community (Figure 2).

Rheingold (2006) asserts that a mobile virtual community "is characterized by blending the features of virtual communities and mobile communication, which are characteristic of affinity-based and local-acquaintance-based social communication". More specifically, mobile virtual communities are known as a platform for many-to-many communication, a platform for coordinating activities in geographic space, and an arena for socializing.

Mobile technologies extend computing and Internet into the wireless medium, and provide flexibility in communication and information sharing. By using mobile technologies, people can get an anytime-anywhere connection to their community und benefit from real-time information and communication services (Siew, 2001) Anytime/anywhere computing remove time and space constraints enhancing capabilities for communication, coordination, collaboration, and knowledge exchange. Users of mobile technology can access to the Internet and mobile applications whenever the need arises, such as when "travelling, wandering, and visiting". Examples of mobile virtual communities are Myspace and Facebook.

MySpace is a social networking Website offering an interactive, user-submitted network of friends, blogs, personal profiles, groups, music, videos and photos. MySpace is the world's sixth most popular English-language Website and the sixth most popular Website in any language, and the third most popular Website in the United States, though it has topped the chart on various weeks. It has become an increasingly influential part of contemporary popular culture.

Facebook is a social networking Website that allows people to communicate with their friends and exchange information. In Facebook users can select to join one or more participating networks, such as a high school, workplace, or geographic region.

MySpace and Facebook redefine the notion of community and encourage friends, family, colleagues and strangers to interact and exchange information.

MOBILE VIRTUAL HEALTHCARE COMMUNITIES

In this section we introduce the mobile virtual community concept for healthcare sector. The literature indicates a virtual community in healthcare sector as “a group of people using telecommunication with the purposes of delivering health care and education, and/or providing support, covers a wide range of clinical specialties, technologies and stakeholders” (http://www.ncbi.nlm.nih.gov/pubmed/16406472)..In respect of this definition, we can describe mobile healthcare virtual community as “a group of people using mobile technologies with the purposes of delivering health care and education, and/or providing support, covers a wide range of clinical specialties and people with the same medical problems”. An example of mobile virtual healthcare community is krebsgemeinschaft.de (see Figure 3).

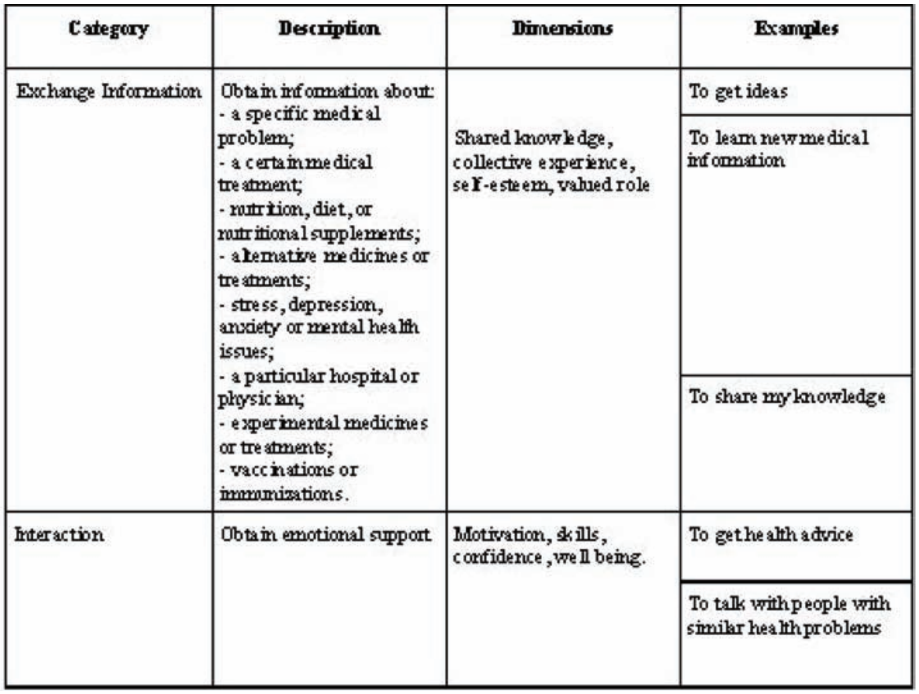
Krebsgemeinschaft.de has the potential to serve ubiquitous needs (Leimeister & Krcmar, 2003). Such an omnipresent problem situation exists in healthcare when patients develop a need for information and interaction, which exceeds the offer of physicians. Several studies demonstrate that there are different kinds of health information that people exchange in krebsgemeinschaft.de (Figure 4).

These kinds of information underline that usually patients want to become well informed about healthcare. Krebsgemeinschaft.de represents an unprecedented opportunity for patient self-education. This is due to the simplicity of use and to the fact that access and age barriers are rapidly disappearing and patients express their needs in using the krebsgemeinschaft.de to develop:

- Consumer-oriented health care models;
- The increase of health information;
- Actions that increase the possibility to access to best care.

For this reason patients see it as an important information source. This is particularly relevant for illness such as cancer. Also interaction and social support play a relevant role in positively influencing the well being of cancer patients (Leimeister & Krcmar, 2006). In krebsgemeinschaft.de people with particular health problems have the possibility to share information and potential solutions with other people; this can facilitate to overcome

Figure 4. Social aspects of krebsgemeinschaft.de

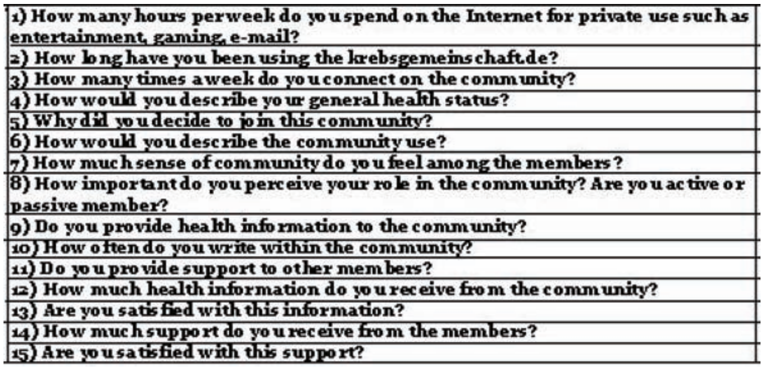


Category	Description	Dimensions	Examples
Exchange Information	Obtain information about: - a specific medical problem; - a certain medical treatment; - nutrition, diet, or nutritional supplements; - alternative medicines or treatments; - stress, depression, anxiety or mental health issues; - a particular hospital or physician; - experimental medicines or treatments; - vaccinations or immunizations.	Shared knowledge, collective experience, self-esteem, valued role	To get ideas
			To learn new medical information
			To share my knowledge
Interaction	Obtain emotional support	Motivation, skills, confidence, well being.	To get health advice
			To talk with people with similar health problems

difficulties and to solve that problems. In order to analyse how people use medical information and how they interact on krebsgemeinschaft.de we carried out an interview (Figure 5). The interview is short and it was designed to be less intrusive as possible. Twenty people, members of the mobile virtual community, were involved in the interview. The interview aims to analyse the frequency of community connections, the average time of each connection and the motivations that stimulate users to join community. Moreover, the interview aims to identify the level of satisfaction that users achieve in belonging to the community.

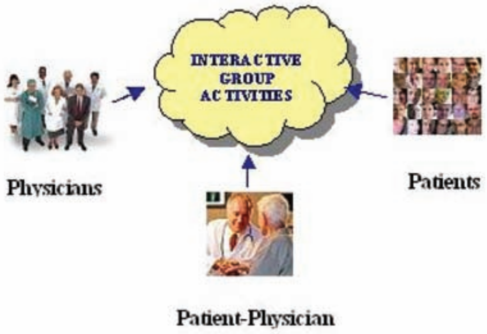
The results of the interview underline that members are interested in using information provided by other members and disclose personal experiences within the community. They demonstrate trust that information provided by other

Figure 5. Interview



1) How many hours per week do you spend on the Internet for private use such as entertainment, gaming, e-mail?
2) How long have you been using the krebsgemeinschaft.de?
3) How many times a week do you connect on the community?
4) How would you describe your general health status?
5) Why did you decide to join this community?
6) How would you describe the community use?
7) How much sense of community do you feel among the members?
8) How important do you perceive your role in the community? Are you active or passive member?
9) Do you provide health information to the community?
10) How often do you write within the community?
11) Do you provide support to other members?
12) How much health information do you receive from the community?
13) Are you satisfied with this information?
14) How much support do you receive from the members?
15) Are you satisfied with this support?

Figure 6. Interactive group activities



members is trustworthy and correct. As proof of this, interviewed people indicated that they have based their real-life actions on information gathered in the community.

INTERACTIVE GROUP ACTIVITIES

The mobile virtual healthcare communities are formed by people organised according to three major groups of activities (Figure 6):

The first is a group of professionals who actively seeks each other and share authentic information. Professionals from one part of the world with expertise in one particular field can share their experience with people from other parts of the world. Interaction can be purely unilateral (e.g. expert review of pathology slides and X-rays of cancer patients), or it can be bilateral (e.g. group of intensivists discussing the practices at their institutes). These groups also provide a cheap, fast and reliable mode of sharing relevant information or knowledge for the clinicians who often find it difficult to spare enough time from their busy schedules to attend conferences or courses in order to keep themselves up to date. Not to mention the cost of these events.

The second is a group of people that share common health problems (e.g. cancer, infertility etc). Mobile virtual healthcare communities mainly provide information and mutual support for users. They provide information concerning treatments, health insurance or particular medical problems. Mobile virtual communities are socially helpful because they allow people to easily establish contact among them and to have a mutual knowledge that is much more sound. People with particular problems have the possibility to share their problems with other people or with physicians that can facilitate to overcome difficulties and to solve problems. Emotional support in mobile virtual healthcare communities benefits from the absence of traditional barriers to access and the possiblity to assure online anonymity thath can be helpful for those who have stigmatizing or embarrassing conditions.

Third are a group of professionals and a group of patients. Patients see mobile virtual healthcare communities as a convenient way to interact with physician who is important to them. With the continued increased development of Internet, mobile virtual communities can be a simple, valid, convenient and inexpensive mechanism for interact. They can support the health care distribution

Figure 7. Traditional community vs mobile virtual community

	Traditional community	Mobile virtual community
Knowledge	Localized	Distributed
Boundaries	Fixed	Dynamics
Membership	Sometime forced	Volunteer and explicit
Feature	Oriented to consolidate the accumulated knowledge	Oriented to innovation and knowledge creation

process by allowing written follow-up clues, test results, as well as, a means for patients to easily contact their physician. The evolution of patient-physician communication shows that mobile virtual communities have a relevant impact on the way in which patients and doctors interact. Mobile virtual communities allow patients and physicians to share opinions and medical information every time and everywhere. Mobile virtual communities offer to physicians an opportunity to improve the awarness of patient's health conditions and enhance their satisfaction.

THE RELATIONSHIP BETWEEN PHYSICIANS

Regarding the relationships between physicians, mobile virtual healthcare communities allow them to participate in continuous medical education at a time and location convenient for them, along with:

- Useful communication and collaboration
- Knowledge sharing.

The use of mobile virtual healthcare communities improves possibilities to maintain communication and collaboration between physicians. In a virtual space physicians aggregate observations from their daily practice and then challenge or collaborate each others' opinions, accelerating the emergence of trends and new insights on medications, treatments and devices (Ebner, Leimeister & Krcmar 2004). Technology is an essential requirement of any mobile virtual healthcare communities to ensure an effective and rapid communications among physicians, especially distant ones. Technology used in mobile virtual healthcare communities allows transmitting, extending, saving and managing knowledge shared among community members. The most common technologies used in mobile virtual healthcare communities are the asynchronous tools, such as discussion boards, that provide physicians with the ability to post and reply to messages in a common area, whiteboard, that allows physicians to brainstorm together, draw graphical objects into a shared window etc, video/audio conferencing, that allows making virtual face-to-face meeting, and shared notepad, that provides community's members with the ability to create a document together (Malkary, 2005). Other functionalities concern the scheduling of common events and activities, the organization and retrieval of knowledge and the broadcast of shared documents to the Web.

Although technology cannot completely substitute face-to-face interactions, mobile virtual healthcare communities can foster the growth of knowledge sharing between physicians. In this sense mobile virtual communities will supplement, not supplant, traditional communities (Figure 7).

As Tab. 4 shows, virtual community supplements traditional community in creating a more dynamic environment oriented to innovation and knowledge sharing. In healthcare sector mobile virtual communities allow the enhancing of "meeting opportunities" between physicians. As consequence, emerge the increasing number of skills, competencies and "knowledge profiles" of each physician involved into the mobile virtual community. In this perspective, a mobile virtual community amplifies openness, interoperability, scalability, and extensibility of a traditional community. In the same time, this does not mean that in a mobile virtual community of creation face-to-face interactions are substituted by electronic communications. On the contrary, face-to-face interactions are enabled and supported by electronic communications that try to make easier, more immediate and less expensive the knowledge relations, amplifying their efficacy.

THE PATIENT-PATIENT RELATIONSHIP

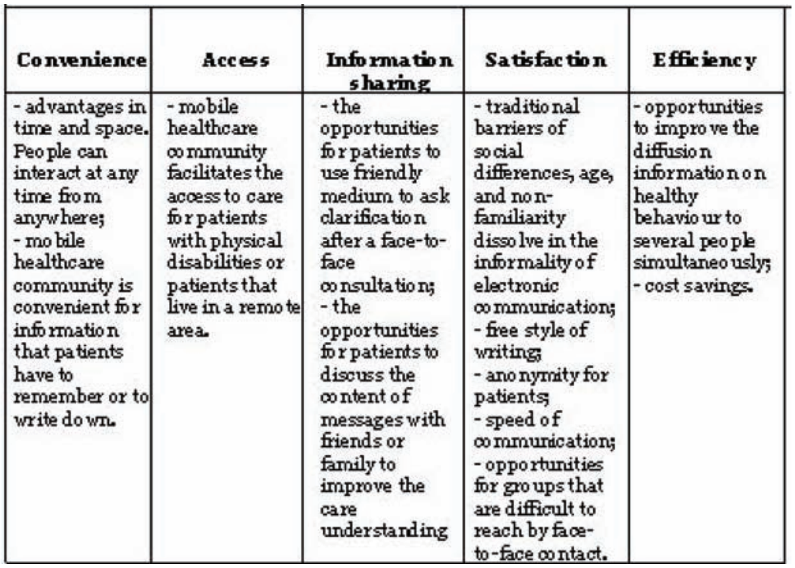
Patients' demands for information often increase after a diagnosis of a disease or during medical treatment. Patients may seek information to help them make sense of a diagnosis. Recent research on patients' information needs (Leimeister Arnold Y., Krcmar H. 2006) demonstrates a strong information interest in the following areas:

1. Side effects.
2. Explanation of disease and prognosis.
3. Treatment options and explanations of therapy.
4. Logistical issues (transportation, work, etc.).
5. Lifestyle issues (exercise, diet, sexuality, smoking).
6. Follow up/what happens after therapy finishes.
7. Support or self help groups, alternative medicine.

Besides demands for information, there is a desire to seek emotional support with other patients (Leimeister & Krcmar 2005). Several studies have identified five, interrelated forms of emotional support common to face-to-face and virtual mutual aid groups. These forms of emotional support help to reduce members isolation and empathy to enhance self-esteem and sustain hope. People join mobile virtual communities to experience a sense of community with others like themselves. To obtain this benefit, members must stay involved long enough to feel a sense of connection with other members. They are more likely to have this experience if they begin exchanging messages with other members. Researchers have found that when members write longer posts and ask questions, they are more likely to post again. There are various types of technologies used by patients to form and facilitate interactions within a mobile healthcare community. Some of these include:

- **E-mails:** the exchange of electronic messages between peers via e-mail is widespread. However, it is often a clumsy tool to be used to converse with other community members and it lacks security due to the high probability of deleting or misplacing mistakenly a document or a message.
- **Instant messaging:** exchanging messages simultaneously is a real-time approach used for immediate correspondence among individuals. Nevertheless, excessive instant messaging and/or many members participating in the same conversation can be annoying to users. In addition, it takes extra effort to save these conversations.
- **Newsgroup:** represents a repository of messages posted by many users from different locations. It can be considered as a virtual space where physicians exchange

Figure 8. Advantages of mobile virtual healthcare communities



Convenience	Access	Information sharing	Satisfaction	Efficiency
- advantages in time and space. People can interact at any time from anywhere; - mobile healthcare community is convenient for information that patients have to remember or to write down.	- mobile healthcare community facilitates the access to care for patients with physical disabilities or patients that live in a remote area.	- the opportunities for patients to use friendly medium to ask clarification after a face-to-face consultation; - the opportunities for patients to discuss the content of messages with friends or family to improve the care understanding	- traditional barriers of social differences, age, and non-familiarity dissolve in the informality of electronic communication; - free style of writing; - anonymity for patients; - speed of communication; - opportunities for groups that are difficult to reach by face-to-face contact.	- opportunities to improve the diffusion information on healthy behaviour to several people simultaneously; - cost savings.

ideas, discuss, communicate and even make friends.

- **Web conferencing:** refers to synchronous (live) meetings, Web seminars and applications sharing over the Web. In a Web conference participants can see whatever is on the presenter's screen, and simultaneously share applications (ex: spread sheet) and discuss matters of common concern.
- **Blogs:** is a cooperation environment that contains reverse chronologically order posts that are contained in a common Web page.
- **Wikis:** provide an effective virtual forum that allows physicians to add content and also to edit content supporting collaborative writing, opening discussions, interaction and Web-authoring. They also provide an asynchronous platform for virtual community, and with their capacity to archive different page versions can act as repositories, thereby enabling effective knowledge management. It is sure that the use of mobile virtual healthcare communities presents very clear advantages in different area (Figure 8).

THE PATIENT-PHYSICIAN RELATIONSHIP

Mobile virtual communities are rapidly changing the physician-patient relationship. They allow patients and physicians to share opinions and medical information every time and everywhere. Moreover, they offer to physicians an opportunity to improve the awarness of patient's health conditions and enhance their satisfaction. They also give the opportunity to increase the involvement of patients in their treatments and they improve access to health care information and communication possibilities between patients and physicians. Through the use of mobile virtual communities physician have the possibility to communicate with patients continuously allowing better data collection. (Leimeister & Krcmar 2003). For patients with chronic illnesses, especially those in rural or outlying areas, consultation with an appropriate specialist can vastly improve the quality and outcome of their healthcare. Mobile virtual communities can be used by doctors to send instant messages to patients reminding them when they need to take their medication. This serves to eliminate certain administrative costs that are associated with hospitalisations that result from not taking the prescribed medication at the correct time. People and doctors could also have a mutual knowledge that is much more sound *and mobile technologies*.

There are many potential benefits for patients and physicians who communicate in mobile virtual communities:

- patients may feel more comfortable in addressing sensitive, complex or personal issues;
- mobile virtual communities can solve problems related to large distances or patients' disability;
- patients can influence physician prescribing decisions by presenting product information they find online.

Mobile virtual communities have the potential to educate health consumer, by giving information on health and health services, supporting patient choice, guaranteeing convenience, anonymity, and quantity of information (Kane & Sands, 1998).

For incorporating virtual consultations into routine medical practice it is necessary to proceed on the basis of secure evidence.

It is important to understand the following aspects related to the communication between physicians and patients: how the communication by mobile virtual communities can be integrated with other modes to communicate the patient and physician preferences in the use of mobile virtual communities and identify people that most likely can benefit from virtual communication.

However mobile virtual community does not have the capability to reproduce the traditional relationship because of the impossibility of the physical presence. In fact medical practice includes complex processes as diagnosis, treatment, prognosis and these processes require the presence of the patient for several activities. Therefore, in conclusion we can observe that mobile virtual communities can modify and integrate the traditional physician-patient relationship but, at the moment, cannot replace this relationship.

CONCLUSION

Mobile technologies represent a familiar part of the lives of many people today. They give virtual words a new character, with the simultaneosly information exchange. On the virtual space, mobile virtual communities are accessible by mobile devices. Mobile virtual communities have the great potential to serve ubiquitous information and communication needs. This applies especially to the healthcare sector where the need for information and communication is deeply felt and of a long-term nature.

In this chapter we analysed the social impacts that mobile virtual healthcare communities have on relationships between: 1. patient and physician; 2. patients; and 3. physicians has been shown.

With respect to the first relationship the evolution of patient-physician communication shows that mobile virtual communities have a relevant impact on the way in which patients and physician interact. Mobile virtual communities allow patients and physicians to share opinions and medical information every time and everywhere and offer to physicians an opportunity to improve the awarness of patient's health conditions and enhance their satisfaction. They also give the opportunity to increase the involvement of patients in their treatments and they improve access to health care information and communication possibilities between patients and physicians. Through the use of mobile virtual healthcare communities physician have the possibility to communicate with patients continuously allowing better data collection. For patients with complicated cases or chronic illnesses, especially those in rural or outlying areas, consultation with an appropriate specialist can vastly improve the quality and outcome of their healthcare. Moreover mobile virtual communities can be used by doctors to send instant messages to patients reminding them when they need to take their medication. This serves to eliminate certain administrative costs that are associated with hospitalisations that result from not taking the prescribed medication at the correct time.

Concerning the patient-patient relationship, the use of mobile virtual communities enables patients with long-term chronic diseases to interact with people that have the same experience (Ferguson, 1998). This interaction can allow a decrease of the problem. Online anonymity can be helpful for those who feel embarrassment discussing their health conditions. Mobile virtual communities mainly provide information and mutual support for users. They provide information concerning treatments, health insurance or particular medical problems. Information shared between users includes reports on how the disease was contracted and how it affects daily life.

Regarding the relationships between physicians, mobile virtual communities allow them to participate in continuous medical education at a time and location convenient for them, along with useful communication. The use of mobile virtual communities improves possibilities to maintain communication and collaboration with colleagues investigating the same subjects. In a virtual space physicians aggregate observations from their daily practice and then challenge or collaborate each others' opinions, accelerating the emergence of trends and new insights on medications, treatments and devices. They can apply the collective knowledge to achieve better outcomes for your patients.

In sum on discussing the social impacts of mobile virtual communities on the traditional physician-patient relationship, patient-patient relationship and physician-physician relationship, we emphasize that they are transforming these relationships. One of the most important advantages of mobile virtual communities is that they promote the opportunity for users to interact with more people than in the past. Is it clear that these communities don't have the capability to reproduce the traditional relationship because of the impossibility of the physical presence. This is mainly valid for medical practice that includes complex processes such as diagnosis, treatment and prognosis. These processes require the presence of the patient for several activities. However the information exchange can be used for detecting patients and physicians that have common objectives and share common interests in order to establish communication and interaction among them.

KEY TERMS

Collaboration: A structured, recursive process where two or more people work together toward a common goal.

Electronic Communication: The assisted transmission of signals over a distance for the purpose of communication.

Healthcare: The prevention, treatment, and management of illness and the preservation of mental and physical well being through the services offered by the medical and allied health professions.

Mobile Services: A radiocommunication service between mobile and land stations, or between mobile stations.

Mobile Technologies: A combination of hardware, operating system, networking, and software.

Social Network: A social structuremade of nodes that are tied by one or more specific types of interdependency, such as visions, idea, friends etc.

Virtual Communities: A group of people that primarily interact via communication media such Usenet rather than face to face.

This work was previously published in Handbook of Research in Mobile Business: Technical, Methodological and Social Perspecives, Second Edition, edited by B. Unhelkar, pp. 316-327, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 5.8

Understanding Computerised Information Systems Usage in Community Health

Farideh Yaghmaei
Shadeed Behesthi University of Medical Science and Health Services, Iran

ABSTRACT

This chapter introduces factors that affect computer usage. Discussions of computer systems effectiveness or system success frequently focus on questions of which factors provide better system usage. As there are many factors that affect computer system usage, measuring the influence of the factors is necessary. The objective of the current study was to gain a further understanding of some factors that affect the use of computerised information systems. Most studies have been in business and few studies have been conducted in the health sector and specifically in community health. The study measured the role of external variables on computer attitude, subjective norms, and intention to use computers based on the theory of reasoned action (TRA) (1). These external factors included: demographic characteristics, users' characteristics (computer experience), organisational support, and involvement.

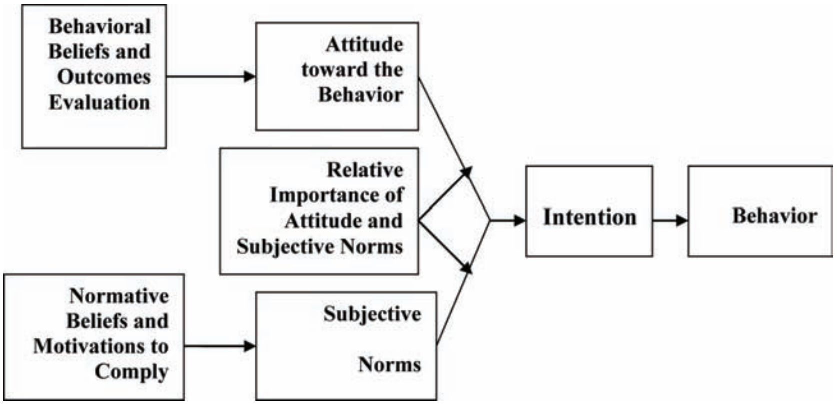
DOI: 10.4018/978-1-60566-356-2.ch030

THEORY OF REASONED ACTION (TRA)

The Theory of Reasoned Action (TRA) was developed by Fishbein and Ajzen (1975) (Figure 1). The foundation of this theory rests on the distinctions between beliefs, attitudes, intentions and behaviour. The theory shows the relationship between beliefs and behaviour through attitudes, subjective norms and behavioural intentions.

- **Beliefs:** Beliefs are formed by direct observation, outside information, or the way a person learns about an object. For example, new information from any source (such as; environment) may influence a person's beliefs.
- **Attitude:** An individual's attitude towards any object is a response to beliefs about the object so beliefs are important in determining attitude. It can be stated that attitudes are based on a person's beliefs. Attitudes may influence the formation of new beliefs about objects.

Figure 1. Theory of Reasoned Action (TRA). Source: Ajzen & Fishbein (1980)



- **Subjective norms:**Fishbein and Ajzen (1975) proposed that the formation of intention depends on the previous formation of attitude and normative beliefs.
- **Intention:** The effects of attitude (A) and subjective norms (SN) on behaviour are mediated by the behavioural intention (BI). According to the TRA, intention is the immediate determinant of behaviour and can lead to actual behaviour.

EXTERNAL VARIABLES

The external variables can influence in three ways; 1) influence on attitudes and significant amount of weight on intention, 2) influence on the subjective norms and significant amount of weight on intention and 3) influence on the relative weights of the two components (attitudes and subjective norms).

Methods

For the purpose of the present study the following hypotheses were defined (see Figure 2).

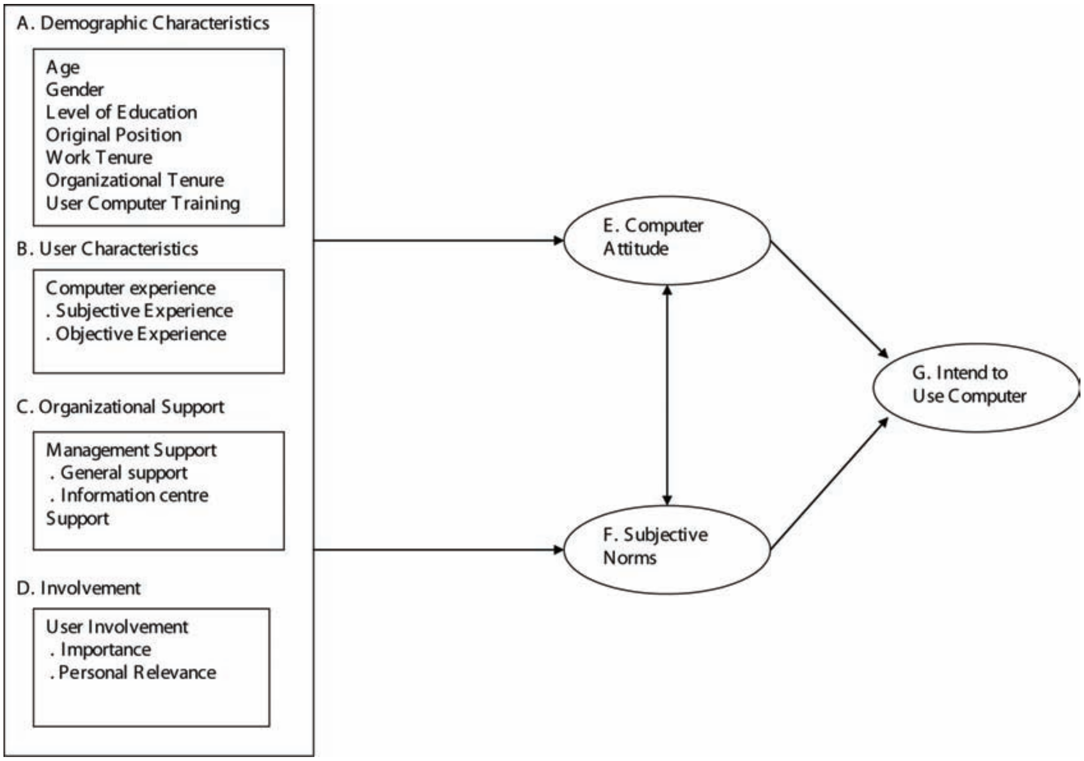
After a thorough search of the literature the researcher found valid and reliable scales for measuring the above variables. A questionnaire that consisting of 62 questions that covered users' characteristics (positive and negative subjective computer experience) (Yaghnaie 2007), management support, (general support and information centre support) (Igbaria and Chakrabarti 1990), users' involvement (importance and personal relevance) (Barki and Hartwick 1994), computer attitude (Jayasuria and Caputi 1996), subjective norms (Hebert 1994) and intention to use computers (Hebert 1994) was used.

Then study was conducted in the Community Health Services of one Area Health Service in New South Wales, Australia. The questionnaires were mailed to 430 staff (nurses and health workers) in 51 Community Health Centres in the Illawarra Area Health Service. A response rate of 70% (302) was achieved. The data was analysed using a statistical computer program (SPSS). Structural equation modelling was used to test the measurement model and the structural model. Overall, high support was found for the structural model in this study.

Results

The measurement statistics were substantially improved from the first model. The results of the revised model showed a good fit of the data, as evidence by Goodness-of-Fit (GFI = 0.9927), and the root mean square residual (RMSR = 0.0144), GFI adjusted for degree of freedom

Figure 2. The research model



(AGFI = 0.9600), and the likelihood-ratio chi-square statistic, X^2 (12, N = 302) = 12.2395, P = 0.4266. The final model accounts for the 57% of the variance in computer attitude, 26% of the variance in subjective norms, and 51% variance in intend to use computers.

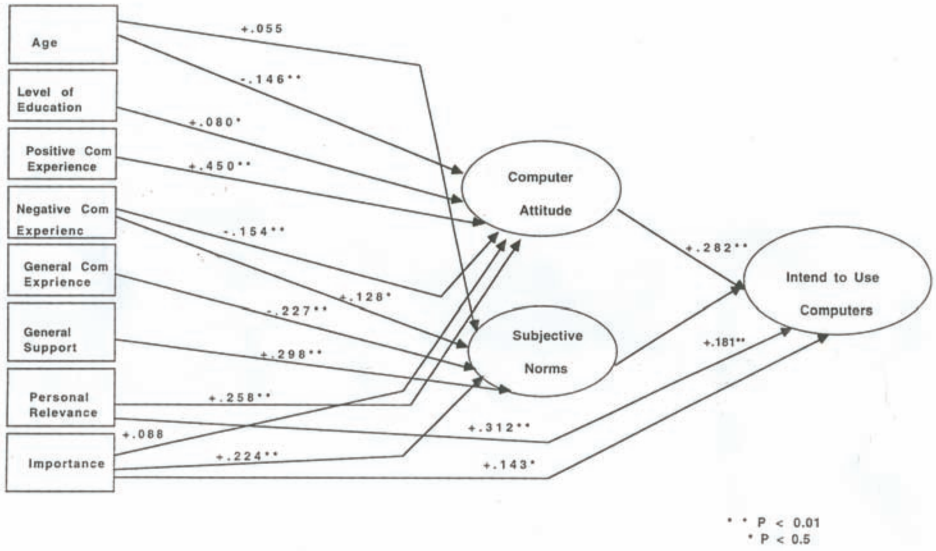
The results of the multivariate test of the structural model showed a significant direct and positive effect of level of education (ß = 0.0801, P < 0.05), positive computer experience (ß = 0.4497, P < 0.01), and personal relevance (ß = 0.2580, P < 0.01) on computer attitude. As expected, age (ß = -0.1458, P < 0.01) and negative computer experience (ß = -0.1543, P < 0.01) had significant negative and direct effect on computer attitude.

Moreover, the results showed that negative computer experience (ß = 0.1279, P < 0.05), general support (ß = 0.2980, P < 0.01) and importance (ß = 0.2241, P < 0.01) had significant positive and direct effect on subjective norms to use computers. On the other hand, general computer experience had significant negative and direct effect on subjective norms to use computers (ß = -0.2275, P < 0.01). In addition, age had a non-significant positive and direct effect on subjective norms to use computers (ß = 0.0547). The results also indicated a significant positive and direct effect of computer attitude (ß = 0.2822, P < 0.01) and subjective norms (ß = 0.1812, P < 0.01) on intention to use computers (Figure 3).

NEW FINDINGS

This study showed additional factors that predicted the intention to use computers. The results of the modified model showed that dimensions of user involvement (personal relevance and importance) affected the intention to use directly and indirectly through computer attitude and subjective norms.

Figure 3. Final model for predicting intention to use computers



While other external variables had an indirect effect on intention to use through attitude and subjective norms, personal relevance (ß = 0.3115, P < 0.01), and importance (ß = 0.1426, P < 0.01), had a significant positive and direct effect on intention to use computers. The direct effect of personal relevance was found to be stronger than importance on behavioural intention to use computers.

In total, the model explained 57 percent of the variance in computer attitude, 26 percent of the variance in subjective norms to use computers, and 51 percent of the variance in intention to use computers. Since the objective of this study was the understanding of behavioural intention, the model was acceptable in terms of explanatory power.

DISCUSSION OF RESULTS OF STRUCTURAL MODEL

The research model was found to fit the data from a sample of 300 observations. The present study investigated the specification search based on the initial model. This result provided a parsimonious model with its relationships. In general, the results showed that of the 30 direct paths tested in the structural model for the hypothesised model, 13 were found to be statistically significant in the revised model (Figure 3). The strongest effects on computer attitude were positive computer experience and weakest (but significant) was the level of education on computer attitude. Among the demographic variables, age was negatively related to computer attitude. The results also showed that the strongest significant effect on subjective norms was general support and weakest and significant was negative computer experience.

Moreover, the effect of computer attitude on intent to use was stronger than subjective norms toward intention on it.

The results of the structural model and its pattern in relation to the hypotheses of the study are as follows. Paths marked (S) are supported; paths marked (NS) are not supported; paths marked with (S√) are supported, but in the opposite direction; paths marked (SX) are supported, but were not in the hypotheses:

- **H1a:** Age will have a positive direct effect on computer attitude (S√).
- **H1b:** Gender will have a positive direct effect on computer attitude (NS).
- **H2a:** Age will have a positive direct effect on subjective norms (NS).
- **H2b:** Gender will have a positive direct effect on subjective norms (NS).
- **H3:** Demographic characteristics (organisational position, organisational tenure and work tenure) of user will have a positive direct effect on computer attitude (NS).
- **H4:** Demographic characteristics (organisational position, organisational tenure and work tenure) of user will have a positive direct effect on subjective norms (NS).
- **H5:** Level of education will have a positive direct effect on computer attitude (S).
- **H6:** Level of education will have a positive direct effect on subjective norms (NS).
- **H7a:** Positive computer experience will have a positive direct effect on computer attitude (S).
- **H7b:** Negative computer experience will have a negative direct effect on computer attitude (S).
- **H7c:** General computer experience will have a positive direct effect on computer attitude (NS).
- **H8a:** Positive computer experience will have a positive direct effect on subjective norms (NS).
- **H8b:** Negative computer experience will have a positive direct effect on subjective norms (S).
- **H8c:** General computer experience will have a positive direct effect on subjective norms (S√).
- **H9a:** General support will have a positive direct effect on computer attitude (NS)
- **H9b:** Information centre support will have a positive direct effect on computer attitude (NS).
- **H10a:** General support will have a positive direct effect on subjective norms (S).
- **H10b:** Information centre support will have a positive direct effect on subjective norms (NS).
- **H11a:** Personal relevance will have a positive direct effect on computer attitude (S).
- **H11b:** Importance will have a positive direct effect on computer attitude (NS).
- **H12a:** Personal relevance will have a positive direct effect on subjective norms (NS).
- **H12b:** Importance will have a positive direct effect on subjective norms (S).
- **H12c:** Personal relevance will have a positive direct effect on intention to use computers (SX).
- **H12d:** Importance will have a positive direct effect on intention to use computers (SX).
- **H13:** Computer attitude will have a positive direct effect on intention to use computers (S)
- **H13:** Subjective norms will have a positive direct effect on intention to use computers (S)

The most important result of this study was the finding of the strong direct and significant effect of positive computer experience on computer attitude. It seems that in the formation of computer attitude, positive computer experience has an important role. This study showed the effect of positive computer experience on computer attitude. On the other hand, as expected, negative computer experience had a negative effect on computer attitude. Thus, computer attitude can be changed by positive or negative experiences of the users with computer systems. An interesting result was that negative computer experience had positive direct effect on subjective norms to use computers. These results confirm the important role of both organisational policies and a climate to use computers, especially for users with negative experience.

A new finding of this study was that involvement not only affected intention to use indirectly but also directly. Thus, the importance of the role of involvement was confirmed in this study. It seems that user involvement is an important factor in system usage and there is a need to expand the theory in order to better understand factors that potentially influence system usage.

Future research is needed to refine the latter model (Figure 3) and improve it by removing non-significant relationships. Moreover, a study is needed into the use of some parameters that were deleted in this study, due to the insufficient sample (such as; computer training and task characteristics). In sum, it is important that research continues in this area.

DISCUSSION OF THE STUDY

There are various views toward acceptance and use of computer technology in different fields. For example, health information systems offer automated systems to assist personnel to administer patient care by increasing access to large volumes of information, improving delivery of care and decision making.

One of the interesting results of the present study was the negative effect of age on computer attitude. The result was similar that of Igbaria (1993) when he reported that older managers expressed more unfavourable attitudes towards computers than younger. Other studies also showed that younger personnel in hospitals had more positive computer attitudes than older personnel (Grann, 1984; Zoltan-Ford, 1984). The results reinforce the notion that age is a factor that can influence computer attitude. In addition, the examination of age on subjective norms indicated that there was a positive effect of age on subjective norms to use computers. It means that older users pay more attention to the policies of organisations and their peers' perspectives for using computers than younger users.

The result also showed direct positive and significant effect of the level of education on computer attitude. It seems that level of education is a factor that can affect computer attitude. This result is consistent with the study by Rapko and Adaskin (1993) who reported that nurses with high levels of educational qualification had positive attitudes toward computer systems because the level of education influenced their understanding of the systems. Moreover, Lucas (1978) argues that users' with a high level of education accept computer systems, but users with a low level of education may resist them. Therefore, the level of education influences the understanding of computer systems (Brodt and Stronge, 1986).

An important hypothesis of this study was to test whether positive computer experience affects computer attitude. The results showed a strong positive and significant effect of positive **c**omputer experience on computer attitude. This indicates that the provision of opportunities to gain positive experience, especially for new or inexperienced users would be useful for effective system usage. Furthermore, positive computer experience may help users in increasing favourable perceptions about the impact of computers on their life (Yelland, 1995). The importance of prior computer experience in promoting computer attitude and usage was highlighted by the finding of other studies. For example, Igbaria (1990) reported strong correlations between computer experience and computer attitude. The results confirm that increasing computer experience is vital for providing favourable attitude and ultimately system usage (Igbaria, 1990; Kleintop et al., 1996).

The results also indicated a direct negative and significant effect of negative computer experience on computer attitude. This finding emphasises the importance of negative computer experience as a real problem and its effects on computer attitude. Negative computer experience may cause negative perception about using computers and it can cause difficulties is being able to use computer systems. Thus, attempting to provide positive experience will help users to accept and use computer systems.

In contrast, negative computer experience had a direct, positive and significant effect on subjective norms. In those situations in which users have negative experience with computers, the role of organisational policies about information systems and their usage could assist users to accept computers in their workplaces. However, computer system usage with users who have negative computer experience is not guaranteed because usage may be ineffective or insufficient. Therefore, the needs of participants with negative computer experience should be takes into account, especially when system usage is compulsory. In this regard, managers should assess users with negative feelings about computer and help them to change their negative feelings to positive. From the results it can be concluded that the role of information system (IS) managers is crucial in providing positive computer experience or changing negative experience. Moreover, managers should be aware that psychological and subjective feelings can influence physical and mental ability. Very little experimental research has been conducted in this area and future studies are needed.

The results also showed that general support had direct, positive and significant effect on subjective norms. The participants with support from the management system paid more attention to others' expectations (managers or friends to use computer system) than those without support. The organisation with a supportive management will have a co-operative climate (Songer-Nocks, 1976). This study confirms the importance of the need for users support regarding acceptance and performance of computers.

The understanding involvement factor and its role in systems usage require examination as a factor on users' perceptions. This study examined the influence of users' involvement (importance and personal relevance) on computer attitude and subjective norms. The results showed that personal relevance and importance had directly positive effect on computer attitude, however, the effect of the importance on computer attitude was not significant. The results also indicated that importance had direct positive and significant effect on subjective norms to use computers. The participants also believed that the importance of the system can influence their attention to organisational policies and others' expectations to use systems. If the users' involvement is considered they would be satisfied with the information systems policies, consequently, the organisation would have a high quality of performance.

The results of the present study showed additional factors that influenced intention to use. Importance and personal relevance (dimensions of involvement), directly and indirectly, (through attitude and subjective norms), affected intention to use computers. In the Theory Acceptance Model (TAM), the role of perceived usefulness is similar to important and personal relevance in this study. However, these two constructs, usefulness and involvement, are different. A system may be useful but not necessary importance or personally relevant (Barki and Hartwick, 1994). Thus, this study found a different connection between importance and personal relevance to intention to use. It seems that user involvement is an important factor in system usage. Therefore, user involvement as a psychological belief (Barki and Hartwick, 1994) can increase the system's value and consequently, system usage. The study suggests that involvement of health staff can be useful for developing and implementing a new computer system. During system development, users should have a sense of perceived involvement that leads to system acceptance and usage. As mentioned earlier, involvement is a perceptual issue so if users believe that they are actively involved in system development and their inputs are valuable and worthwhile, they will be more satisfied. From the results of this study, it is indicated that an appropriate level of a user's involvement will result in a better management information system (MIS).

It seems that users' involvement is an important responsibility for managers to provide positive and open communication between users and other key groups to support the important role of users in processes of development and usage. In addition, managers should be aware of the nature of users' involvement because from these results it can be concluded that users need to have a sense of active psychological involvement.

The finding showed that computer attitude had a strong direct positive and significant effect on intention to use computers. The participants, with favourable computer attitudes, were willing to manage difficulties related to systems and were capable of improving their performance. This study confirms the results of another study in health area (Hebert, 1994). Therefore, computer attitude may affect the actual success or failure of system implementation.

By focusing on subjective norms in this study, the effects of peers, superiors, subordinates, and organisational climate on systems usage was studied (Moore, 1987). The result also showed that the users' subjective norms influenced directly and positively the intention to use computers. Hebert (1994) reported that the users' subjective norms influenced their intention to use computers and use of technology was based on the policy of the organisation. In a different study, Nederhof (1989) reported similar results: that there was a strong relationship between the participants' subjective norms and their intentions. In addition, other studies, Bentler and Speckart (1981); Igbaria et al. (1996) had similar findings. Therefore, the role of the subjective norms in information system studies is crucial for making policies in organisations. Information system (IS) managers should convey to users the purpose and the policies of computerised technology because if users accept the IS policies the organisations will have a co-operative condition (Songer-Nocks, 1976). Communication of users with their peers and also understanding the information policies can enhance computer systems usage. Therefore, in some situations behaviour of persons may be influenced by subjective norms, rather than attitude. The important findings related to subjective norms in this study suggest that more research, focusing on system usage is necessary and would be useful.

The results showed the influence of positive computer experience on computer attitude, the effect of negative computer experience negatively on attitude. The results also showed that negative experience had positive and direct affect on subjective norms. The other new finding of this study was the direct effect of importance and personal relevance on intention to use computers. The results also supported other studies on the importance of organisational support regarding intention to use systems. Moreover, computer attitude and subjective norms were also found to mediate relationships between external variables and intention to use computers. In general, the study was able to explain the variables that affected the intention to use computers directly and indirectly (Figure 3).

STRENGTHS OF THE STUDY

Method and the Research Model

This study with its multi-method approach contributes to the body of knowledge on management information system (MIS) and established a foundation for further studies.

It serves a number of purposes. It provides a tested theoretical framework for increasing and understanding factors related to use of computerised systems. Integration of the different personal and work factors in this study could be helpful for different organisations in more effective implementation of MIS.

The present findings provide evidence of the utility of the Theory of Reasoned Action (TRA), its application for understanding and predicting computerised information system usage. To the researcher's knowledge, there are only a few published studies demonstrating the applicability of the TRA (Fishbein and Ajzen, 1975) for system usage in the health area, especially in community health centres.

The model presented in this study holds important implications for practising information system managers in organisations attempting to manage system usage. It will provide guidance concerning those factors that need to be managed well in terms of system usage. Understanding how the differences in personal and organisational characteristics impacts on system usage in the model and it provides a basis for further research in this area. The framework of analysis presented in the model, will be useful for practitioners as well as researchers. Therefore, the search for other relevant factors can be facilitated in future studies. The result of this study showed factors that are important in a global environment; however, the result cannot be extended to all fields.

Furthermore, subjective norms play an important role in development process of information systems. In the early stage of implementing a new system subjective norms are important for determining acceptance of a computerised system and in later process attitude are the crucial determinant. Therefore, it is critical important for users to understand that organisational policies are in place to ensure that the computerised systems are used effectively and efficiently. Many of the findings and arguments regarding social pressure or others' expectation that developed in this study are appropriate for organisations in general.

The other strong point of this study is the number of factors as external variables in the research model that can provide more and more precise results especially in health area. In general, the findings of the current study revealed the strength of the external validity of the TRA.

From a practical stand point, the research model, as a general model of computer usage and the scales that were introduced in this study could be useful for system development and system usage.

SUGGESTIONS FOR FUTURE STUDY

Computer Experience Scale

Additional research is needed on a number of fronts. The Subjective Computer Experience Scale (SCES) that was developed for measuring computer experience should undergo further testing. Multiple studies would lead to refinement and increased generalability of this scale. The researchers might add more items (perhaps including some omitted from the original instrument), measure the reliability of those items and discard the unreliable ones. In this process any organisation could be targeted for in-depth analysis of the scale.

Due to the importance of subjective computer experience, the SCES could be used in a longitudinal study to determine; 1) how and to what extent initial computer experience influences judgement of people about their positive or negative experience? 2) how, under what conditions, what kinds of computer experience could be provided? 3) how subjective computer experience changes over time? 4) what is the characteristic of users who have positive or negative computer experience? and 5) what is the similarity and differences in their characteristics? Longitudinal studies can determine result more explicitly. This information will give new knowledge about computer experience because by more attention to human factors, usage of computer systems would be enhanced (Staggers, 1991).

Based on the previous study of Songer-Nocks (1976), some factors such as; previous experience may affect behaviour directly. It would be interesting to determine in future studies, whether factors such as; high levels of positive computer experience, lessens the moderating influence of computer attitude that found in this study.

Moreover, research could move toward clarifying under what conditions subjective norms can be effective and useful in reducing users' negative experience. This will answer many questions regarding organisational policies that most managers face today with regard to user resistance to computer systems.

As result of the training-related findings, this study suggests that computer training can reduce negative computer experience. Type of training in this regard, is an important factor (Harrington et al., 1990). Therefore, additional research on negative computer experience is needed to find how training can reduce the duration (temporary and permanent) or intensity of negative computer experience.

User Involvement

These findings suggest that future studies in this area should be careful in assessing user involvement because the perception of involvement may influence the subsequent system success or failure after implementation. One approach to minimising the impact of bias may be to use longitudinal designs.

This study measured the effects of user involvement on participants' attitude and subjective norms. Based on the involvement-related results in this study, it is suggested that the effect of involvement on computer attitude and subjective norms may be due to some user characteristics. It would be interesting to examine whether the relationship of perceived users' involvement to system success is moderated by variables such as; demographic and personality characteristics. The findings will have important implications. Organisations that follow general recommendations to obtain high levels of users' involvement may not obtain the anticipated benefits due to individuals' differences among users.

In addition, the difference of nurses' and health workers' task characteristic highlights the question of: when and who should be involved? In the process of information systems whose judgement and under what condition should it be accepted? These are important issues and require further exploration.

Other Variables in the Research Model

Since computer systems use depends on the many factors related to task environment and system characteristics, it is important to expand the model in future research to explore other potential factors which influence system usage. These factors include: organisational size, organisational age, length of computerisation of organisation, work environment variables, quality of systems, availability and accessibility of system, user participation, career opportunities, salary, job autonomy and task uncertainty.

Furthermore, a number of specific variables and their roles were discussed in the current research study (see chapter 4), such as; user self-efficacy, confidence and satisfaction. Studies regarding to satisfaction, computer experience and computer usage have shown that there are positive relationship among these variables (Rivard and Huff, 1988; Igbaria, 1990; Igbaria and Nachman, 1990). Thus, these can be examined as external variables on computer attitude and subjective norms in future study.

Moreover, based on the studies of Hill et al., (1987); Compeau and Higgins (1995), self-efficacy can influence computing skills of users and system usage. Studies in the health sector emphasised the effect of computer experience on computer self-efficacy, outcome expectancy and consequently, job performance (Henry and Stone, 1995). Mills and McQueen (1997) studied effects of self-efficacy on computer use in the health sector. The findings suggested that self-efficacy and confidence affected computer usage. The authors point out that confidence of users could assist them to use computer systems effectively and successfully. These finding indicate that to assist users in developing performance with respect to computer systems, developing positive perception and confidence for their ability are useful. The relationship between self-efficacy, computer experience and system usage requires more investigation to give more information for management of computer systems.

Extend the Research Model

This study provides a model of computer usage which further research may modify. In order to explain usage and the value of the information systems more broadly, future research is needed to explore additional issues. For instance, a research model that integrates the TRA and the TAM will provide greater insights of both the theoretical model and better understandings of the factors that influence systems usage. The ultimate model will be able to broadly predict system usage and acceptance of technology in organisations. Continued research will greatly enhance our understanding of the determinants of system usage.

Chapter 5.9

Managing E-Procurement in Public Healthcare:

A Knowledge Management Perspective

Tommaso Federici
University of Tuscia, Italy

Andrea Resca
LUISS 'Guido Carli' University, Italy

ABSTRACT

In large parts of Europe, the development of healthcare is subject to contrasting forces: explosion in spending, while governments are faced with budget constraints, and pressures to be innovative, technologically advanced in order to improve the services' quality. Even though e-procurement initatives can be seen as a solution to the first issue in this dilemma, such initiatives have not been widely deployed and have not delivered the expected benefits so far. In this perspective, as case study of an e-procurement implementation of an Italian local healthcare agency has been examined because of the comprehensive design of the e-procurement system, the differentiation of tools adopted and the multiple solutions already implemented or in progress. The aim of this work is to reconstruct, by following a knowledge management approach, the steps that led to the introduction of e-procurement as a new operating practice, by redesigning supply purchasing, supply chain and logistic processes.

INTRODUCTION

In large parts of Europe, the development of healthcare is subject to contrasting forces. On the one hand, there has been an explosion in spending and, at the same time, governments are faced with strict budget constraints. On the other hand, public healthcare is under pressure to be innovative, technologically advanced and to provide increasingly better quality of services. In this context, e-procurement can be seen as an instrument for providing solutions to the first issue of this dilemma. Two recent European directives 2004/18/EC and 2004/17/EC, according to the i2010 eGovernment Action Plan, promote e-procurement to achieve significant efficiency improvements – also in public healthcare – by reducing at the same time purchasing and administrative costs.

However, e-procurement initiatives in such area have not been widely deployed, and most of them have not fully delivered the anticipated benefits, so far. The main reason for the lack of tangible results is the traditional resistance of public institutions to IT-based process innovation and the complexity of healthcare procurement – in terms of the variety of goods, specificity, and of suppliers' numbers – that requires different supply processes and diverse competences.

In order to investigate this scenario in more detail, the case study of a large e-procurement implementation at an Italian public Local Healthcare Agency (LHA – Azienda Sanitaria Locale, ASL), considered one of the most advanced by the Central Procurement Agency (CONSIP), was explored. This case study is remarkable because of the comprehensive design of the e-procurement system, the differentiation in adopted tools, the robust testing (since 2000) and the multiple solutions already implemented and in process within the Agency. The decision to examine this case study is also due to the fact that the use of e-procurement tools is seen as only one aspect of a more profound reorganization of the entire supply process.

The purpose of this work is to reconstruct - by performing interviews with some of the most representative players and examining documents and previous studies on this case - the managerial interventions that made this innovation possible and in particular how knowledge has been managed in this innovative programme. From this perspective, it was presumed that the introduction of e-procurement and the reorganization of purchasing, supply chain and logistical processes, had required diverse knowledge which has been investigated at the cognitive level, the organizational level and the social and institutional level of knowledge, proposed by Lam (2000).

Distinguishing between individual knowledge and knowledge related to a specific social context, this approach gives a comprehensive picture of the concept of knowledge. Furthermore, this perspective is helpful to examine the realities of Public Administrations (PAs) like LHAs, which are characterized by the importance of rules and procedures and by hierarchical organizational structures. Lam's extensive references to Mintzberg's classic studies (1979) is important in this point, as the organizational forms singled out by Mintzberg fit very well in the PA area, reinforcing the accurateness of this analysis.

RESEARCH STRATEGY

The research question of this work concerns the dissemination of innovation and primarily its adoption. The focus is on the ability of a specific organization to adopt an innovation and on the elements that facilitate or hamper such adoption. In other words, the issue is the impact, at an organizational level, that the introduction of innovation produces, and its possibility to be absorbed and managed.

At the basis of this investigation there is the concept of knowledge, as the element that characterizes an organization, both before the innovation introduction and after it. Therefore, a specific aspect to take into consideration is the meeting of established knowledge and the new one enabled by innovation.

The research strategy adopted to study the dynamics between established and new knowledge is based on a case study, which concerns innovation related to the introduction of a widespread e-procurement at Viterbo's Local public Healthcare Agency. Because of its tendency towards innovation, as seen by the implementation of several e-procurement projects in recent years, the LHA of Viterbo can be considered to be an explanatory case study (Yin, 2003). The analysis of such a case study provides answers which throw light on how and why innovation dissemination has taken place, on the basis of the organizational interventions that have been introduced.

The objective of this case study is also to throw light on the effects of these interventions in order to outline the dynamics at play by the introduction of e-procurement. These dynamics will be analysed looking at a knowledge management approach and in particular Lam's model (2000). As it will be later detailed, this approach seems to be apt to investigate knowledge and its management alongside the innovation process. Actually, Lam's perspective succeeds, to a certain degree, to highlight diverse types of knowledge which arise through the introduction of innovation. Therefore, using Yin's words (2003), it is possible to draw a pattern out of the connection between this perspective and the dynamics present in the case study.

In addition, as it is detailed below, the theoretical framework based on Lam's model leads to causes of difficulty in interpreting the dissemination of adopting e-procurement and the suggestions in overcoming them. However, these results should not be generalized.

Regarding data collection, Federici's research (2005, 2006) informs the basis of this research project. It has examined, step by step, both the several projects that have led e-procurement to the present state of the art and the organizational changes introduced at Viterbo's LHA. However, this is not only a bibliographic research, further internal documents were analyzed and semi-structured interviews conducted with some of the key representative managers in charge of procurement, both operating in the traditional and more innovative areas.

THEORETICAL FRAMEWORK

The issue of e-procurement in the public sector has been, so far, a rarely discussed topic. Studies are mostly concerned with the analysis of policies and behaviour of Public Administrations (PAs) and Procurement Authorities at a national and centralized level (Hardy & Williams 2005, Somasundaram & Damsgaard 2005, Somasundaram 2004, Devadoss *et al.* 2002). Even less frequent is research on the healthcare sector, particularly at a local operating level, where e-procurement solutions must be implemented, which impacts on the structures and the knowledge already existing within the organizations, which require different approaches of intervention.

Procurement Within the Healthcare Sector

Firstly, it is necessary to take into consideration that healthcare structures deliver critical and specialized services (vs. the rest of the PA): more than in other sectors, it is paramount to safeguard high quality standards for the purchasing of goods and services (and their impact on service quality), together with the economy and timeliness of purchases, the transparency of activities in an environment in which companies are subject to market competition and its governing principles. Healthcare spending for goods and services can be classified into three sections:

- *common* for the whole PA, independent from the type of buying Administration (e.g.: phone services, office materials);
- *common-but-differentiated*, existing for all Administrations but highly differentiated through the buying sector (e.g. in the healthcare sector: maintenance and cleaning of hospital buildings);
- *healthcare-specific*, composed of drugs and medical devices (appliances and materials that, separately or jointly, are used in instances of injury, disease or surgical operation).

This diversity must be taken into account when devising innovative ways to manage procurement before choosing the most appropriate solutions, in order to improve quality and efficiency of supplies, whilst at the same time rationalizing and reducing spending. The large difference among the three spending categories indicated above and the availability of diverse electronic tools ask for a deep reflection on which solutions suit each type of good / service. This requires a segmented approach (Federici 2006).

Secondly, the term "procurement" is often used in a narrow sense, being associated with the sole purchasing phase, as can be seen in Panayioutou *et al.* (2004) or in Kim & Shunk (2004). Consequently, the term "e-procurement" becomes a synonym for a class of electronic tool that directly link buyers and suppliers on the same network to make a deal. According to other studies (Somasundaram 2004, MacManus 2002), and with the typical operation of a healthcare agency, in this work "procurement" indicates a broader process, which begins with the need for a good or service and ends with its use and the payment for its supply. It involves: purchase programming, the sourcing choice, the purchasing act, incoming material handling, warehouse logistics, inventory control and invoice processing.

An e-procurement system deals with the whole procurement process, and not just with its purchasing phase. The term "e-procurement" here consistently indicates that organizational solutions supported by ICT-based tools, which allow electronic forms of procurement and are potentially more effective and efficient than traditional ones. Such solutions involve a more or less wide-reaching and thorough redesign process to take into account the entire life-time of a product or service.

E-procurement solutions include process redesign and the use of appropriate tools in two main areas, which have to be used in a complementary way to streamline the whole procurement process:

- *e-purchasing*, includes very different tools which allows the purchasing phase to be entirely managed, from finding a product to invoicing and payment, through on-line tenders (*e-tendering*) and the use of *marketplaces* and *electronic catalogues* (*e-requisitioning*), electronic invoice exchange and processing (*e-invoice*) and liquidation activity (*e-payment*);
- *e-logistics*: which aims to optimize the management of inventories (in healthcare structures: pharmacy and the supply office) and internal goods flows, based on Intranet/Extranet technologies, integrating Supply Chain Management (SCM) solutions, linking both internal and external players.

Knowledge Management: Lam's Perspective

The knowledge management approach and, especially, Lam's (2000) interpretation of it, considers three levels (the cognitive level, the organizational level and the societal-institutional level) that could outline the e-procurement phenomenon in a comprehensive manner. The present issue is to build a bridge between an abstract concept like knowledge and an organizational process supported electronically, such as e-procurement in the Health sector. In other words, the question is how this process can be represented in terms of the concept of knowledge.

According to Lam's model, any organizational form, if seen through the lenses of the concept of knowledge, characterizes itself in terms of the three levels mentioned above. In particular, any individual, in a single or collective dimension, interacts with others on the basis of his/her background (the cognitive level of knowledge). The same individual operates in an organizational context with a low degree of autonomy, in the case of an organizational environment characterized by rigid procedures and routines, or a high degree of autonomy in case of an organizational environment loosely coupled (organizational level of knowledge). Furthermore, he/she is part of a specific labour market that rewards some profiles, but not others; moreover he/she has formed a background on the basis of a particular educational or training institution (social-institutional level of knowledge). Of course, these three levels overlap with each other and knowledge characterizing a specific organization is something unique that emerges from such an overlap. Nevertheless, Lam's approach leads to a wide-ranging perspective to investigate organizational life, and the introduction of an important innovation such as an e-procurement system.

To thoroughly examine Lam's work, it requires a detailed study of each level. The double entrance matrix is the methodological instrument used in order to analyse any level of knowledge. This matrix surveys relationships between two variables but in this case they are represented by dichotomies leading to a four cell matrix. For instance, the cognitive level is exemplified by the relationship between the ontological dimension of knowledge, presented in terms of the individual-collective dichotomy, and the epistemological dimension of knowledge, explicit-tacit dichotomy (see Figure 1). The same methodology has been used to examine the remaining two levels. So, each of the three levels of analysis generates a four cell matrix each with different content.

Opposing the explicit-tacit dichotomy and the individual-collective one at the cognitive level of knowledge, four categories emerge (Collins 1993, Blackler 1995):

- Embrained knowledge (individual-explicit) can be exemplified by what is learnt at school. It is abstract, theoretical and used to solve conceptual problems such as calculations and speculations;
- Embodied knowledge (individual-tacit) is based on practical experience. It does not depend on the activity of reasoning but on action alone. The "learning-by-doing" method represents this kind of knowledge and learning to ride a bicycle is a prime demonstration of it;
- Encoded knowledge (collective-explicit) is codified and stored into rules and procedures. Therefore, it is readily transmitted through language, signs and symbols (information). Scientific management principles, for example, are an attempt to codify workers' skills and 'know-how';
- Embedded knowledge (collective-tacit) represents the shared values and beliefs that define informal rules and norms of a specific social context which contributes to govern the interaction and communication among members of a society.

Lam's work looks for organizational forms that can support the type of knowledge mentioned above. In her understanding of this point, this result can be achieved by opposing 'knowledge agent' and 'standardization of knowledge and work' in the double enter matrix. 'Knowledge agent'

Figure 1. Cognitive level: knowledge types (source: Lam, 2000)

		Ontological Dimension	
		individual	collective
Epistemological Dimension	explicit	**Embrained** Knowledge *(abstract and theoretical)*	**Encoded** Knowledge *(information)*
	tacit	**Embodied** Knowledge *(action oriented)*	**Embedded** Knowledge *(values and beliefs sharing)*

is characterized by the individual-organization dichotomy and 'standardization of knowledge and work' by the dichotomy high-low. If the 'knowledge agent' is individual, there is the possibility to enjoy a certain degree of autonomy and subjects can develop their own know-how and practical problem-solving. If the 'knowledge agent' is the organization, the managerial hierarchy becomes the engine of organizational activities transforming individual knowledge in rules and procedures. A high 'standardization of knowledge and work' suggests a scenario in which each role is strictly coordinated with others in an environment characterized by hierarchical controls. On the other hand, a low standardization outlines an organizational environment in which coordination is achieved via direct interaction and mutual adjustment and not on the basis of comprehensive design. The combination of these dichotomies results in four organizational ideal-types (see Figure 2):

- 'Professional bureaucracy' (embrained knowledge) experiences a reduced role at senior management level. Organizational activities are based on individual expertise which relates to specific professional bodies. Nevertheless, coordination and control are governed centrally through standardized and bureaucratic means. Hospitals are a typical example of this organizational form;
- in the 'machine bureaucracy' type (encoded knowledge), coordination and control are also centrally governed. Moreover, the entire organization is subject to a continuous process of formalization and codification of knowledge in which the top management tier is at the head of formulating strategies and directives;
- the 'operating adhocracy' form (embodied knowledge) sees the loss of importance of the organizational chart and coordination and control is not based on rules and procedures. In this instance, mutual adjustments among organizational actors prevail and activities are not managed vertically but left to the subjects' undertaking;
- the 'J form' (embedded knowledge) idealized characteristics in Japanese companies (Aoki 1988). Coordination is not loosely coupled as in adhocracies because of a strong corporate culture rather than hierarchical control. At the same time, horizontal coordination prevails giving rise to shared work experiences and joint problem solving amongst organizational members.

Lam maintains that knowledge outlined through organizational forms is not sufficient for investigating the entire knowledge configuration operating in organizations as they are part of a larger social context. Education and training systems (Maurice *et al.* 1986) and the nature of labour market organization (Marsden 1986) are the two elements believed to be able to enrich

Figure 2. Organizational level: organizational forms (source: Lam, 2000)

		Knowledge agent	
		individual	**organization**
Standardization of knowledge and work	**high**	Professional Bureaucracy	Machine Bureaucracy
	low	Adhocracy	J-form organization

Figure 3. Social-institutional level: education and labour market (source: Lam, 2000)

		Labour Markets *(career and mobility)*	
		OLM *(market)*	**ILM** *(firm)*
Education and training *(degree of formalization and academic bias)*	**high**	Professional model	Bureaucratic model
	low	Occupational community model	Oganizational community model

the understanding of knowledge at work in any organization leading, in this way, to the social and institutional level.

Labour market organization is interpreted according to the dichotomy occupation based labour market (OLM) and firm-based internal labour market (ILM). The former sketches a situation in which market forces govern personal careers and areas of learning. In the latter instance, expertise is internally controlled by firms causing a lower level of standardization and, thus, the difficulty of being governed by market forces. Regarding education and training systems, they can be studied according to the high or low degree of formalization and academic bias.

Again, a double entrance matrix can be built (see Figure 3): the opposition of ILM and OLM, in one dimension, and low and high degree of formalization and academic bias, in the other one, suggests four institutional configurations:

- the 'professional model' (embrained knowledge and 'professional bureaucracy') arises from a situation in which a high degree of formalization and academic bias, on the one hand, and OLM, on the other hand prevail. Here, certified expertise enables access into professional bodies and, on this basis, market forces can operate as personal careers are transparent and subject to continuous evaluation.
- in the 'bureaucratic model' (encoded knowledge and 'machine bureaucracy') there exists a high degree of formalization and academic bias. Expertise is far removed from problem-solving practices and is based upon a deductive method of reasoning. ILM characterizes this model and a narrow on-the-job training, in which careers are based on hierarchies of jobs with tiered boundaries, can contribute to establish a bureaucratic work model.
- even though the 'occupational community model' (embodied knowledge and 'operating adhocracy') characterizes itself because of OLM, inter-firm mobility is not based on certified expertise but on the 'know who' of member networks which consist of a cluster of interdependent occupations and firms. It is insides these communities that practical expertise and problem-solving can be maintained.
- the 'organizational community model' (embedded knowledge and 'J-form' organization) distinguishes itself because of a broad-based education and training system. Learning by doing and problem-solving capabilities are encouraged to the detriment of abstract theoretical knowledge in a context in which team working is seen as an instrument for connecting different workforce layers. An ILM based on a broad on-the-job training and not linked to tiered

boundaries but a common ranking system can contribute to build this community.

To sum up, a theoretical approach has been built up, with at its core the cognitive level, which constitutes the background for the organizational level that, in turn, constitutes the background for the societal-institutional level. The sum of these three levels (see Figure 4) enables a cumulative process of knowledge to be employed in organizational analysis. Nevertheless, to represent a variable through a dichotomy has some limits: on the one hand, it streamlines the analysis of a phenomenon and, on the other hand, leads to a simplified representation of reality.

E-PROCUREMENT INTRODUCTION AT THE LHA OF VITERBO

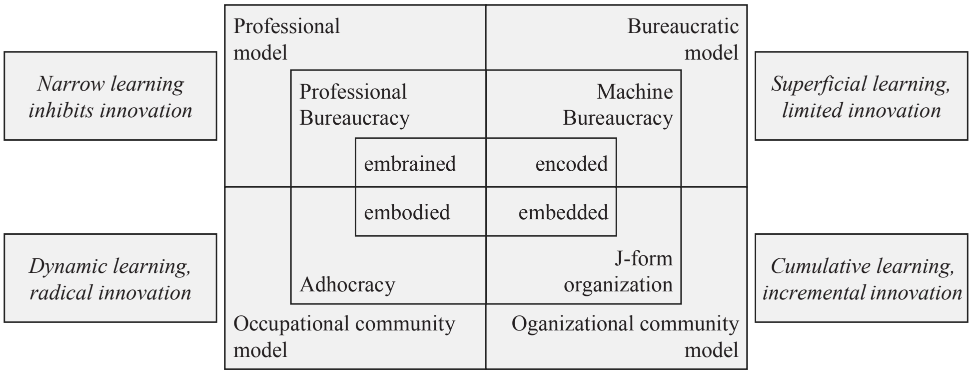
Context and E-Procurement Experiences

The Viterbo's LHA – like similar organisations (Cicchetti 2004) – is divided into three distinct areas: hospital services, territory services, administration services. With about 3.200 administrative and healthcare employees, it provides healthcare to the province of Viterbo (859 hospital beds), with a production value of about 350 €m, which is determined according to the individual spending allocated for each citizen (a total of 297,686 people since December 31, 2001).

With the aim of increasing efficiency and reducing the spending for goods and services procurement, Viterbo's LHA, since 2000, has conducted several experimental projects on e-procurement, in partnership with the Italian public as well private players (Federici 2005):

- the first initiative, in 2000, was a trial of a marketplace promoted by a private merchant: despite some positive results, this experiment ended prematurely, when the marketplace platform failed because of the low volume of transactions;
- in 2002 – when these tools were still under construction and not yet targeted to the healthcare sector – the LHA started to use the *Public Electronic Catalogue* of goods and services, which could be purchased at pre-defined conditions established in the Framework Contracts previously negotiated by the Central Procurement Agency (CONSIP 2003), and the *Marketplace for the Public Administration* (MEPA), also created and managed by CONSIP (Viterbo's LHA was one of 20 Italian PAs to take an active part in the implementation of MEPA);
- in 2003 the first platform for e-tenders was tested, which was later dismissed because of its lack of functionality; recently it has

Figure 4. Knowledge, organizations and institutions: three interlocking levels (source: Lam, 2000)



been replaced by a new one, that manages a tender electronically, providing either a complete or partial solution (this latter leaves the offer evaluation off-line);
- the LHA also carried out two distinct projects on e-logistics, both of them were promoted by private companies and based on extensive outsourcing solutions supported by extranet platforms. The first one (e-Logistics) involved central and departmental warehouse logistics for managing common goods and non specific devices used routinely in hospital wards (e.g.: gauzes, disinfectants etc.). The second project (Operating room e-procurement) coupled the supply of specific medical devices used in operating rooms to their overall logistical management: its driver was the innovative 'intervention-based' concept of linking procurement to the surgical operations performed, instead of the traditional 'stock-based' approach to purely managing the inventory levels.

These pilot projects were all driven by the Procurement and Logistics (P&L) Department of the LHA. Results were remarkable, even though they were different in nature and dimension, also taking into consideration the obstacles met (technological, organizational and also normative), as in any innovation.

Post 2004, after these pilot projects were concluded, Viterbo's LHA launched an extensive programme. Its purpose was to innovate the end-to-end procurement process (as seen above), through the adoption of diverse solutions which were coherently linked to different and specific requirements. The first step was the implementation of multiple e-procurement solutions in two segments of the broad procurement process: namely the purchasing and invoicing phases.

At present, while traditional procurement procedures are still largely used, the state-of-art of the e-procurement at Viterbo's LHA is:

- the Marketplace for PA is frequently used to buy common goods, and also some non specific medical devices (such as gauzes and alcohol etc.), but not for large orders;
- the platform for e-tenders is sometime used, also for tenders over the EU threshold, but its application is limited because the specificity of some goods, the suppliers' unreadiness in some sector and the changes introduced by recent legislation;
- the full deployment in all hospitals of the Operating room e-procurement solution is currently ending;
- the implementation of the e-Logistics outsourcing solution for common goods and non specific devices, after some difficulties caused by the suppliers, started only a few months ago and is still ongoing.

Managerial Interventions to Promote E-Procurement

Prior to starting the e-procurement introduction, the purchasing activities were divided among four Offices, on the basis of the typology of goods or services, as they are highly differentiated and specialized in healthcare. This requires the adoption of diverse procedures and connections to diverse suppliers. The subject of the four Offices is respectively: products (drugs, medical devices, consumables like paper and ink etc), general equipment (furniture, cars and elevators etc), electronic equipment (medical appliances and computers etc) and services. This division is still in existence, as such specialization is considered useful.

The traditional purchasing Office, which already existed before the e-procurement initiatives, are characterized by a knowledge oriented towards correctly applying the rigid external laws (settled by national or regional government, or by the EU) and procedures (determined by the same LHA), that regulate purchasing in a Public Administration. This sort of knowledge is strictly coded in rules and is shared within the Agency by means of official documents; for this reason, it can easily be transferred. Another important piece of knowledge concerns information about distinguishing characteristics of the product typology. To properly examine this issue, it is necessary to acquire more experience in the field, whilst the standard of education previously acquired for a position in this field had little or no relevance (actually, none of the interviewed Office supervisors had a degree, even fewer employees in law, as could be expected before). The training is entirely performed within the organization and the acquired expertise can only be used in the same Office. For this reason, career advancements and mobility are very limited. Moreover, it is important to notice that, in this context, collaborations with purchasing Offices of similar structures (e.g.: others LHAs) are occasional, hampering the development of a professional network.

The four traditional Offices – each of them, as stated above, operate separately from the others – have an average staff consisting of a supervisor and three clerks. Each role requires standardized tasks to be performed, which are typically: the sourcing of information about the product to be purchased (price, characteristics and suppliers), the writing, revising and issuing of the tender, support of the evaluation process and award notification. Despite knowledge being shared among staff in the same office, interchangeability is extremely difficult because of the tendency for staff to stay for long periods of time doing the same role. In this context the role of IT systems is to automate the traditional procedures: with office automation tools (word processing and occasionally spreadsheets) or legacy systems (accounting systems, to check fund availability and to reserve them). Consequently, a high IT literacy amongst personnel staff is not required to operate such systems. The traditional purchasing Offices have a typical form of bureaucracy: because of their culture and organizational form, they are not very flexible and not so much disposed to change. Moreover, even though they are effective in managing their duties, their activity is not efficient, as the result of the above quoted research largely demonstrates.

As the general manager of the LHA and the director of P&L Dept explored new ways to gain efficiency and to produce savings (both in terms of cost and time), they promoted a programme to introduce e-procurement. Bearing in mind the diverse issues at stake, they considered the four Offices unfit to test this innovation and decided to set up a project team, composed of new resources. To achieve this, two young economic graduates were brought in to constitute the staff that jointly operated with other private or public partners involved in the above mentioned pilot projects. The above described scenario for the development of e-procurement is the result of a series of managerial decisions made by two senior managers, which was based on the assumption that the characteristics of the two sides – the traditional and the innovative – are quite different in terms of the knowledge requested, the means of operating and the staff profiles.

The work of this team was highly experimental (because this was one of the very first attempts at e-procurement in a healthcare sector), and adopted a trial-and-error approach, whereby knowledge increased through a learning-by-doing approach.

The level of education was quite high amongst those staff involved, nevertheless it was directly spent only in some parts of the work (such as analysis of the outcomes, auditing on costs …) In addition, they were selected also because their high IT education (although they weren't IT experts) and their willingness to innovate, in comparison to workers in traditional office environment.

As parts of the constitutive platform for e-procurement, many diverse IT systems (office automation, marketplaces, platform for e-tenders, and e-logistics extranet solutions etc.) were tested in real operations over a planned period of time. The aim of each test was to model a new organizational solution, in order to provide streamlined and effective process and to employ human resources in more value-added tasks.

The Team experienced a high level of individual autonomy in an environment where informal managerial controls have prevailed, the procurement sector to test has continuously changed jointly with the related IT and organizational solutions. Team members with time have increased their knowledge about the Agency structures, ways of operating, suppliers' characteristics, purchasing rules, and so on. But they conclude that they never perceived the initial lack of knowledge to be problematic, since they turned to an 'internal expert' on a specific topic, when they needed more detailed information in that field.

As regards the use of IT tools, they were trained in some of them, particularly the more structured ones, such as MEPA or e-tender platforms. Finally, they were used to collaborate with people operating on e-procurement in other LHAs and throughout the CONSIP (Central Procurement Agency), thus creating a professional network of e-procurement experts.

At the end of the testing phase, when it was decided to promote the widespread adoption of e-procurement, two more graduates were selected, and the former informal Team became a Unit called Innovative Projects (IP) devoted to the all e-procurement processing. This Unit was integrated, with two other offices which had already moved to total paperless activity, in charge of order and invoice processing, and came under the coordination of the Director of P&L Dept. Despite this formal change, the IP Unit still works as a project team, with a high degree of delegation and informal controls. Expertise highly shared among the Unit workers, and they are fully interchangeable. They consider their knowledge easy to employ in a similar position in other administrations, but hardly worth it in other areas of the LHA. For this reason they judge their experience as exciting, but not so useful for career advancement (also because of Agency budget constraints).

The Unit in charge of e-procurement is different from the traditional purchasing office, it manages supplies regardless of the nature of the goods. In addition, even though innovative e-purchasing solutions have already been fully implemented and frequently used, this Unit is still separate from other offices, that continue to run the purchasing activity in a traditional way. Furthermore, while the traditional Offices manage the sole purchasing phase, the e-procurement Unit not only operates as a buyer (through on-line tenders or direct purchases on MEPA), but also supervises the entire procurement process (including: supply chain and logistics) being directly linked to: external providers, warehouses (for common goods and for medical devices and drugs) and internal departments who receive the supplied goods.

After being set up, the IP Unit took the lead in implementing projects to deliver new purchasing solutions and operating room e-procurement. Presently, it is leading the e-Logistics project introduction, managing the on-line purchases and supervising the go-live phase of the Operating room e-procurement.

The current goal of the P&L Dept. director is to substitute the traditional purchasing procedures with more innovative ones which are nowadays the norm at the Agency, at least at the IP Unit. The P&L Department Director wants to transfer to the four traditional purchasing offices the use of the e-purchasing tools in all of their operations: to reach this target, there must be a transferral of new knowledge solutions, and the Department Director assigned this task to the IP Unit, who will achieve this by undertaking brief courses and by having a strong supporting structure in place.

As an interesting result of the changes outlined above, the expert role, which had previously been played by the four offices, will now be played by the IP Unit. At the end of this process, the IP Unit will lose its 'buyer' role and will be responsible for controlling and auditing the broad e-procurement process and for conducting tests on other innovative solutions which sit alongside it.

KNOWLEDGE MANAGEMENT AT THE LHA ACCORDING TO LAM'S MODEL

As stated above, the objective is to study the introduction of e-procurement in the LHA using Lam's model. In other words, can this perspective interpret and evaluate the dynamics caused by this technological system in the organizational life of the Agency? In order to investigate these dynamics, the organizational setting at the LHA is investigated prior to the introduction of e-procurement.

The LHA is a typical PA and, if Lam's model is applied, this organization has a knowledge configuration which is characterized by the dominance of encoded knowledge. The reason for this is based on the prevalence of the collective-explicit dimension of knowledge at the cognitive level. Moving on to the organizational level, the 'machine bureaucracy' characterises the organizational form which represents this administration and the 'bureaucratic model' outlines the social and institutional level with references to the labour market and the education and training system.

The analysis of the e-procurement narrative at the LHA is marked by a significant number of projects, and since 2000 a project instrument has been used in order to introduce such innovation. The first question then concerns the impact of these projects. Here, it is important to notice that not only is the Agency under examination, but also a range of other actors – private IT vendors, public bodies like CNIPA (National Centre for the development of IT into the Public Administration) and CONSIP – were involved in these projects, thus affecting the knowledge configuration of the LHA.

These projects can be considered an organization in itself as, according to Daft (2003), organizations are: 1) social entities; 2) guided by objectives; 3) deliberately envisaged as coordinated and structured systems that 4) interact with an environment. E-procurement projects can surely be included in this definition. The issue is then to study if these organizational structures (pilot projects) share the same knowledge configuration as that of the LHA.

Starting with the cognitive level, in this instance encoded knowledge is of little importance. The collective dimension, in particular, seems not an appropriate to represent a context frequented by application vendors, Central Procurement Authority, university researchers and an atypical administrative unit solely dedicated to the introduction of e-procurement (IP Unit). From this perspective the individual dimension of knowledge rather than the collective dimension seems to prevail. But the cognitive level also characterizes itself because of the explicit-tacit dichotomy. At first glance, there does not seem to exist the conditions for developing tacit knowledge. However, this cannot be entirely ruled out as in specific contexts, this type of knowledge can be produced. In such conditions, embrained knowledge (individual-explicit) prevails.

Turning towards the organizational level, a 'professional bureaucracy' could represent organizational forms within e-procurement projects. This is because the 'knowledge agent' is the individual and his/her professionalism rather than the organization as in typical PAs. Civil servants, engineers, lawyers, economists etc. with their specific expertise collaborate to manage pilot projects. 'Professional bureaucracies' also distinguish themselves, because of a high 'standardization of knowledge and work'. The varied nature of actors participating in these projects renders it plausible control and coordination based on a high 'standardization of knowledge and work' although mutual adjustments and team working cannot be ruled out.

Taking into consideration the social and institutional level of knowledge, the 'professional model' emerges as the dominant model. Members seem to be in the circle of the occupation-based market (OLM) professionals with a transparent and valuable career which is subject to market forces. Concerning education and training, a high degree of formalization and academic bias seem to emerge because of the disparate figures involved; even in this case, however, forms of learning-by-doing and team building are not a remote possibility.

The comparison between knowledge configuration of the LHA and innovative projects introduced to implement e-procurement systems highlights two diverse scenarios. The LHA distinguishes itself because of encoded knowledge, the 'machine bureaucracy' and the 'bureaucratic model'. Innovative projects distinguish themselves differently because of embrained knowledge, the 'professional bureaucracy' and the 'professional model'.

A further analytical step leads us to the reshaping of knowledge configuration of the LHA due to the introduction of e-procurement projects. From an analysis of this case study, it can be seen that only part of the LHA (the e-procurement Team that later will become the IP Unit) has been deeply involved in these projects. The IP Unit is a relative small Unit in comparison with the four Offices in charge of the traditional purchasing and logistical element, even though they have recently been enlarged. So, the point, now, is to investigate the impact of this Unit on the entire P&L Dept.

In order to examine this point, it is necessary to analyse the role of the IP Unit in the P&L Dept. Interestingly, a dual role comes to the fore: that of the agent in innovative projects and that of a unit in large bureaucracies like the LHA. This ambivalence is reflected in its specific knowledge configuration. A configuration in which, as time passes by, has developed embodied knowledge (individual-tacit): individual because, as has been stressed, of the personal backgrounds of Unit members, and tacit because of the possibility of developing specific operational skills and know-how. Moving from the cognitive level to the organizational level, a situation arises in which the 'knowledge agent' becomes the individual member rather than the organization, and in such situations members are not subject to or bound by to specific rules and procedures that would ordinarily affect the rest of the LHA. As far as it concerns issues of coordination and control, mutual adjustment prevails suggesting a low 'standardization of knowledge and work'. Therefore, the IP Unit turns to adhocracy as organizational form, rather than distinguishing itself because of the 'machine bureaucracy' as seen in the rest of the LHA.

Regarding the social and institutional level, it can be noticed the establishment of a low degree of formalization and academic bias, due to the importance of problem-solving and practical expertise, on the one hand, and of the occupation based labour market (OLM), on the other hand. Members of the IP Unit are not only employees of a large bureaucracy but are, at the same time, part of an inter-firm network formed by project partners. Therefore, it is the 'occupational community model' that defines the social-institutional level due to the connections established and the shared experiences of members.

Results of the cohabitation between the IP Unit and the P&L Dept. were taken into consideration, principally, in section 4.2. However, drawing further conclusions, the organizational solution to constitute a specific unit like the IP one to introduce e-procurement can considered successful, since the organizational forms like adhocracies lend themselves extremely well to innovative projects. Knowledge configuration mobilized in this way adapts itself in order to cooperate in a context where various actors exist. The good results reached by pilot projects bear witness to this fact. However, more problematic is the dissemination of innovation to the rest of the P&L Dept. Here, a knowledge configuration characterized by embodied knowledge, operating adhocracy and the 'occupational community model' is highly inadequate. This knowledge configuration responds to the idiosyncratic situations and tasks that exist in turbulent environments. On the other hand, this knowledge is inherently instable. Consequently, the organizational chart loses its importance, roles are no longer designed in order to establish a comprehensive system and coordination and organizational members are no longer part of a general design that predetermines organizational objectives and the execution of task standards. The IP Unit can be considered, in some sense, isolated from the rest of the organization hampering the possibility of spreading an innovation like e-procurement to the entire P&L Dept.

CONCLUSION

In conclusion, it is evident that the configuration of knowledge mobilized by the IP Unit is not entirely effective in supporting the introduction of e-procurement. This innovation is, on the one hand, so pervasive and complex to adopt but on the other hand, the normal configuration of knowledge in PAs (such as the LHA) are able to support only superficial learning and limited innovation. Consequently, diverse dissemination solutions are required.

From this perspective, we can question whether Lam's model is helpful to envisage possible interventions for extending e-procurement adoption. It is believed that knowledge configuration characterized by embedded knowledge, a 'J-form' organization and an 'organizational community model' could be a point of reference to follow. For example, as far as it concerns the organizational level, the 'knowledge agent' organization seems more appropriate than the individual one which exists in an adhocracy. However, the solution proposed is not the same as the 'machine bureaucracy' perspective, in which everything is centralized and in the hands of senior management which governs through standardized and bureaucratic means. Instead, the solution emphasizes the role of working teams and, in particular, of cross-functional teams. Due to their positions, they are at the junction of knowledge flows and act as a nexus among teams.

Actually, the P&L Dept.'s senior management is moving in this direction, and it has not been ruled out that the IP Unit will play this role in future organizational charts. Finally, concerning the social and institutional levels, the 'organizational community model' could represent a solution for overcoming limitations concerning the high degree of formalization and academic bias that typifies public administration careers, and the risk of focusing excessively on the so-called 'on-the-job' training that tends to neglect practical experiences and problem solving exercises.

ACKNOWLEDGMENT

The authors wish to acknowledge the correspondent persons of the LHA of Viterbo, whose willingness and contributions have been considerable and decisive for this research: Andrea Bianchini (Director of P&L Dept.), Silvia Dari and Tania Morano (in charge of IP Unit).

ABSTRACT

E-business today has moved focus to information sharing and integration across organisational boundaries in an effort to transform business processes throughout the value chain and standardize collaboration among communicating entities. Healthcare comprises a strongly collaborative distributed business environment in which information value plays a strategic role and informational privacy comprises a great concern. This new era in e-business, however, is followed by a series of issues that need to be addressed both at application and infrastructural level, such as information heterogeneity, system interoperability, security and privacy. The Grid as a technology enables sharing, selection, and aggregation of a wide variety of distributed resources comes to fill these gaps. In this chapter, the communication of information among healthcare organisations operating over a Grid infrastructure will be presented and analysed both from a technical and a business perspective.

INTRODUCTION

Healthcare provision organisations (hospitals, clinics, etc), pharmacies as well as insurance organisations typically perform their operations from keeping and tracking patients' records and billing records to exchanging and retrieving e-health information through various computer systems. The efficient, reliable and effective operation of these intra- and inter-organisational collaborations requires the communication of these trusted systems. In fact, in such a strongly collaborative distributed business environment information comprises a valuable resource that requires cost-effective and efficient management. Yet, the variety of the systems and the data and message formats involved in such collaborations lead to serious interoperability and standardisation problems concerning the exchange, integration, sharing and retrieval of e-health information. Moreover, great differences are met across these entities in terms of data collected, database and file structures, software systems, politics, payment structures, business models; in other words each entity and even each department of theirs (such as doctor's office, out-patient clinics, imaging center, microbiological laboratories and so on) has specific requirements related to data queried and collected and interaction with patients. These issues combined with the reluctance of organisations to share their data due to lack of trust and/or security concerns lead to limitations to the successful operation of the collaborations. Moreover, given the nature of the data exchanged crucial privacy issues rise that pose even stricter requirements for prudent management of information flows, access and storage within the collaborations.

From a technical point of view these interoperability and performance issues in the healthcare environment can be distinguished into infrastructure-related and application-related. In the infrastructural level, organisations in the extended healthcare environment, including not only hospitals, clinics and doctors but also insurance organisations and pharmacies among others, use a variety of computers, networks, topologies, operating systems, configurations and data management systems offering and supporting various levels of reliability, performance, availability and security depending on their needs, budget and management policies. The existing systems improve internal processes of organisations but are not robust and secure enough to efficiently support the load of information and transactions and enable the efficient and effective cooperation, communication and sharing of information across organisational borders among the participating entities in the collaborative healthcare environment from start to finish.

At the application level, current limitations of health information systems to a specific department or healthcare organisation in the environment comprise an important obstacle to the interoperability of these systems beyond organisational boundaries. The lack of a universally accepted encoding for representing information about drugs, diseases and Electronic Health Records (EHRs) and a globally adopted message protocol for the exchange and sharing of information among the different entities in the collaborative healthcare environment pose serious restrictions to the interoperability of their systems and the efficient communication of information among them. Significant delays of information communication, when the latter is required, are posed and more importantly great inconsistencies in the EHR of the patient across healthcare providers are met leading to significant implications in care provisioning, quality of treatment and related costs.

BACKGROUND

There are several ongoing development efforts on health care standards globally aiming at information sharing and processing among healthcare stakeholders in a uniform and consistent manner. An important effort towards the treatment of the interoperability and standardisation issues mentioned above is HL7 (Health Level Seven) (HL7 Organisation, 2009), which provides messaging standards that improve care delivery, optimize workflow, reduce ambiguity and enhance knowledge transfer among stakeholders and collaborates with other standards development organisations both in the healthcare and the information systems domain so that compatible standards are produced and promoted. However, the financial cost and the great technical effort related to the transition of the currently used message mechanisms to HL7-based ones, as well as the rather slow adoption rate which stems from the reluctance of the various entities in adopting new technology and changing their perennially followed processes pose tremendous obstacles towards the adoption of the standard.

In the meanwhile, as mentioned in the previous paragraphs, the distributed nature of the intra- and inter- organisational collaborations in healthcare and the strategic role of information in these environments pose strict infrastructural requirements as well. In fact, in many cases real or 'near' real-time data integration and delivery across heterogeneous data sources as well as real-time analysis of business data and fast end-user access to key business data for decision-making acceleration are required. And what is more, issues of data consistency and privacy as well as system flexibility and robustness need to be dealt with in a cost-effective way – with security, reliability, interoperability and scalability climbing the higher stairs in the hierarchy. Such advanced infrastructural requirements combined with the innate business goal for lowering costs have driven key business sectors such as healthcare towards adopting Grid solutions into their business.

Although initially designed to cover the computational needs of high performance applications, Grid (Foster, 2002) technology of nowadays aims at providing the infrastructure for the general business domain. In fact, Data Grids (Chervenak, Foster, Kesselman, Salisbury, & Tuecke, 2001) – as a specialisation and extension of the Grid - are regarded to be the next generation inter-organisational data management systems for coordinated sharing and exchange of data as well as distributed, heterogeneous storage resources among organisations. Thus, a well-defined Grid-based solution combined with evolving international standardization efforts in healthcare comprises a new approach to information economics and can eliminate the myth of most weaknesses mentioned above and this will be the main focus of the respective paragraph.

THE MEDICAL INFORMATICS BUSINESS ENVIRONMENT

E-Health Scenario

Overview

Nowadays, e-health management and administration systems are mainly tailored to the needs and focus of the healthcare institution and the insurance organisation they serve. However, recent advances in infrastructure technologies combined with the general tendency of the population for mobility and the need for and the proven value of minimisation of communication overhead among collaborating entities within the broad healthcare domain bring to front a new era; *collaborative e-health*. A scenario of a futuristic collaborative e-health environment will be presented in this section aiming to provide the basis for analysing the technical requirements of such an environment in which inter-organisational communication is supported.

Entities and Roles

In this collaborative e-health scenario the main entities and roles involved include:

- Healthcare Provider: the term encapsulates hospitals, clinics, private doctors registered to the collaboration. Provision of healthcare services may be offered by public, private and non-public health care institutions. The roles interacting with this collaborative environment include doctors, nurses, the logistics department, among others.
- Health Insurance Organisation: it may be a government-sponsored social insurance organisation or a private insurance company. The covered individual pays (directly themselves or through stoppages) premiums or taxes to the Health Insurance Organisation it has registered to in order to help avoid high or unexpected healthcare expenses. Health Insurance Organisations closely cooperate with the Healthcare Providers in order to proceed with transaction clearing of the healthcare-related expenses of the covered individual. Quite often this process does not only involve the communication of the receipts and the appropriate supporting documents but also a negotiation process between the two parties due to their conflicting interests, leading to slow cycles of information exchange.
- Pharmacy: it provides the prescribed medication to the patient and based on the Health Insurance Organisation the patient is registered to as well as the related policies requests for a specific percentage of the total amount of money or even the whole sum.
- Patient: it involved every insured person visiting a Healthcare Provider. The individual may be covered by a public or a private health insurance, whereas it is not unusual that the person may have both types of health insurance and thus be registered to more than one Health Insurance Organisations (one public and one private).

Scenario Description

Patient X insured at Insurance Organisation A in Greece is traveling quite often in his country for business purposes. After a long meeting at his enterprise headquarters in Salonica he felt intense discomfort and took his heart pills. However, the pills didn't manage to ease his pain and based on his doctor's advice he took after calling him, he went to Hospital B that his insurance organisation cooperates with in Salonica to be examined. The doctor at Hospital B requests for the patient's e-health record (EHR) from the system. He gets information about his medical history, examination reports and list of medication he receives or has taken in the past as well as his allergy list. After examining him, he decides to proceed with the admission of the patient to the hospital for one day in order to monitor carefully the status of the patient.

After the patient is officially admitted to the hospital, his e-health record is updated with the admission information (hour, hospital section, floor, room, supervising doctor, cause for admission, expected duration of staying). After the results of the cardiogram, the doctor decides to increase for a few days the dosage of his medication and orders the nurse to give him another pill that will relax him and ease the pain on his chest. The next day the patient is ready to leave the hospital. The doctor prescribes him another set of pills, while he advices him not to forget to increase for a few days the dosage of his previous medication. The doctor proceeds with updating the patient's e-health record with the examination performed and the results as well as the temporary change in the patient's medication. Patient X goes to the accounting department where they access his e-health record to proceed with the final billing of his exams. The employee is able to view the list of examinations the patient took only that day at the specific Healthcare Provider as well as the related cost. The information displayed concerns the patient's exams performed within

Hospital B followed by their cost. Patient X is worried about his health status after this episode and decides to visit his personal doctor in Athens. For this reason, he calls him and arranges an appointment with him for the following day. The doctor's secretary updates the patient EHR with the upcoming appointment.

The patient gets a receipt for these exams and pays 20% of the total cost based on his insurance organisation policy. The list of pending operations for Insurance organisation A that patient X is insured at is updated with the current examinations the patient took. The insurance organisation accesses the billing record and the list of examinations the patient took as well as the patient's demographic information and the Hospital B information. In the meanwhile, patient X will be soon out of pills after the increase in his medication dosage and thus goes to a pharmacy the doctor at Hospital B suggested based on the list of cooperating pharmacies with his insurance organisation. The patient pays 25% of the total cost of the pills while his EHR is updated with this information. The insurance organisation receives the request through the system and is displayed with the medication the patient bought followed by the justification and the related billing information as well as the pharmacy's details. In the meanwhile, the Statistics company S is performing an anonymous resource management survey on European Hospitals and requests data from the EHR system including examination records per hospital and city.

Technical Requirements

Based on the scenario described above a set of technical requirements can be identified:

- As the information managed through such a system contains *sensitive data*, enhanced *data protection mechanisms* need to be established. In fact, *dataprivacy* and *security* constitute important issues that need to be carefully dealt with. Different levels of access to e-health medical records need to be defined and developed, secure data storage and transfer must be offered, advanced identity management needs to be supported, traceability, end-to-end message security and message integrity checks must be offered, identity theft occurrences need to be predicted and eliminated, whereas the content of the e-health medical record must be relevant, accurate but not excessive.
- Given that information comprises the most valuable resource within a collaborative e-health environment, the cost deriving from information loss (due to system attacks or network, application or hardware problems or even due to the human factor) can have great impact on the proper and successful operation of the system as well as the relations among collaborating parties (e.g., loss of medical subscription or patient history medical data) and thus a reliable and robust infrastructure is required. For this reason, *fault-tolerant mechanisms* need to be integrated to the system with the main priority being on *data reliability*.
- *Scalability* comprises an important non-functional requirement as the system must be able to serve a continuously growing number of users who are geographically dispersed.
- It should be noted that fluctuating factors affect the e-health environment, such as epidemic and a new flue among others. Hence, *efficient load balancing* techniques are required combined with enhanced dynamic data replication mechanisms must be supported by the underlying infrastructure so that the system is able to operate efficiently during rush hours and increased seasonal demand.
- In such a collaborative data-oriented system, strong needs for *efficient and real-time data management* are posed. Information is continuously updated, data

may be heterogeneous, distributed to many sites and each requiring different levels of authorisation.

- Given the current state in the e-health sector, information exchange focusing not only on e-health medical records but also on financial and billing information is required in order for non-affiliated healthcare organisations to be able to interact and exchange information. In other words, *interoperability* comprises one of the most important issues that need extensive work to be done. The IEEE (Institute of Electrical and Electronics Engineers, 1990) defines interoperability as follows: the ability of two or more systems or components to exchange information and to use the information that has been exchanged. In other words, interoperability is a term that refers both to the functional level regarding the exchange of messages and information, i.e., the physical communication among components and systems and to semantic level, i.e., interpreting operations, messages and information with a common language. In this example, interoperability issues rise due to the different encodings each healthcare actor may have adopted (regarding encoding for drugs, diseases, EHR, etc) as well the messages exchanged (e.g., different versions of HL7, etc) as it can be easily seen in figure 1.
- As already mentioned security, privacy and trust are of paramount importance. Moreover, as it can be easily deduced from the scenario described in the previous section, *effective and flexible SLA (Service Level Agreement) mechanisms* need to be established among the collaborating parties within the e-health environment monitoring and evaluating different SLAs established between the varying parties in the collaboration and handling unexpected occurrences during operation.

TECHNICAL ANALYSIS OF THE MEDICAL INFORMATICS BUSINESS ENVIRONMENT

As it can be easily deduced from the analysis of the technical requirements of an e-health collaborative environment presented above, secure, dynamic, privacy-preserving, *efficient and reliable information management* as well as interoperability comprise two of the major challenges and poses string infrastructural requirements. In the following paragraphs, it is presented how Grid technologies and the HL-7 initiative aim at addressing these issues respectively.

Information Management and the Grid

The Grid infrastructure comes to offer dynamic, on-demand provisioning of resources (storage, data, applications, processing units, bandwidth, etc) and interoperability. For this reason the use of Grid technology in this environment for sharing and integrating heterogeneous resources seems more than beneficial and gives the opportunity for meeting the demands of such a dynamic and complex collaborative environment.

As it has been mentioned, Data Grids comprise an extension of the Grid and aim to be the next generation inter-organisational data management systems for coordinated sharing and exchange of data as well as distributed, heterogeneous storage resources among organisations. Chervenak et al (2001) identify four main principles for the Data Grid architecture: mechanism, neutrality, policy neutrality, compatibility with Grid infrastructure and uniformity of information infrastructure. Mechanism neutrality refers to the independence of the architecture from the underlying low-level mechanisms which are used for data management, such as storing, transfering, etc. With the term policy neutrality they point out that apart from the basic operations, the implementation of the policies should be via high-level procedures so that the end user can adjust them to their needs. The third principle denotes that Data Grid must be an extension of the Grid inheriting the mechanisms relating to authentication, resource management, and so on. Uniformity of information infrastructure refers to using a common data model and interface to the data.

Based on this brief analysis of the Data Grid concept, applying the Data Grid mechanisms within the e-healthcare collaborative environment (i.e., *Grid-enabling*) can enable the sharing of information across organisational boundaries through an extended list of operations and services it offers. Among others, data state information including audit trails, file versions, validation data (size, checksum, validation date), locks, can be managed as well as interactions with storage systems, metadata can be assigned, efficient data replication techniques can be applied, owners to data and access controls can be assigned. Thus, what the Data Grid infrastructure offers is a set of mechanisms and technologies that provide efficient and reliable data management.

In an effort to enable trust among collaborating parties Service Level Agreements (SLAs) are established between them. An SLA (Wustenhoff, 2002) helps in the definition of the relationship between two parties by allowing the setting of the expectations between the *consumer* and the *provider*. In the case of the healthcare collaborative environment the main aim is to ensure that the overall need for timely, secure, efficient and reliable information communication is offered according to predefined Quality of Service (QoS) parameters. Thus, an SLA in this environment would for example include terms such as, the message broker service technical team will respond to service unavailability during rush hours (Monday to Friday) within 5 minutes and resolve the problem within 30 minutes or response time of 99% of drug database transactions from clinic A will be less than 1 second, with response time being the time interval between the time the user from clinic A sends the transaction request and the time he receives confirmation of successful transaction completion, whereas any deviation from these figures comprises a *violation*.

However, an SLA itself does not offer much to the participating parties if not managed appropriately. For this reason feverish research is taking place in Service Level Agreement Management (SLAM). In (Rosenberg and Juan, 2009), the authors present the SLA lifecycle including (i) SLA template specification, (ii) publication and discovery, (iii) negotiation, (iv) optimisation of resource selection, (v) monitoring, (vi) evaluation, (vii) re-negotiation and (viii) accounting. This way, after an SLA is defined and accepted by both parties (steps i-iv), the metrics (e.g., memory and disk space, transaction response time, network bandwidth, etc) related to the terms in the agreed-upon SLA are being monitored (v). The evaluation step (vi) includes the comparison of these terms with the metrics being monitored so that violations are detected and the respective pre-agreed action is taken by the system and upcoming violations of the term are prevented. Hence, for example, if more than 1% of the drug database transactions take more than 1 second, then this comprises a violation and specific action needs to be taken according to the pre-agreed policy (e.g., the technical support team needs to take action or requests are redirected automatically to another replica of the database).

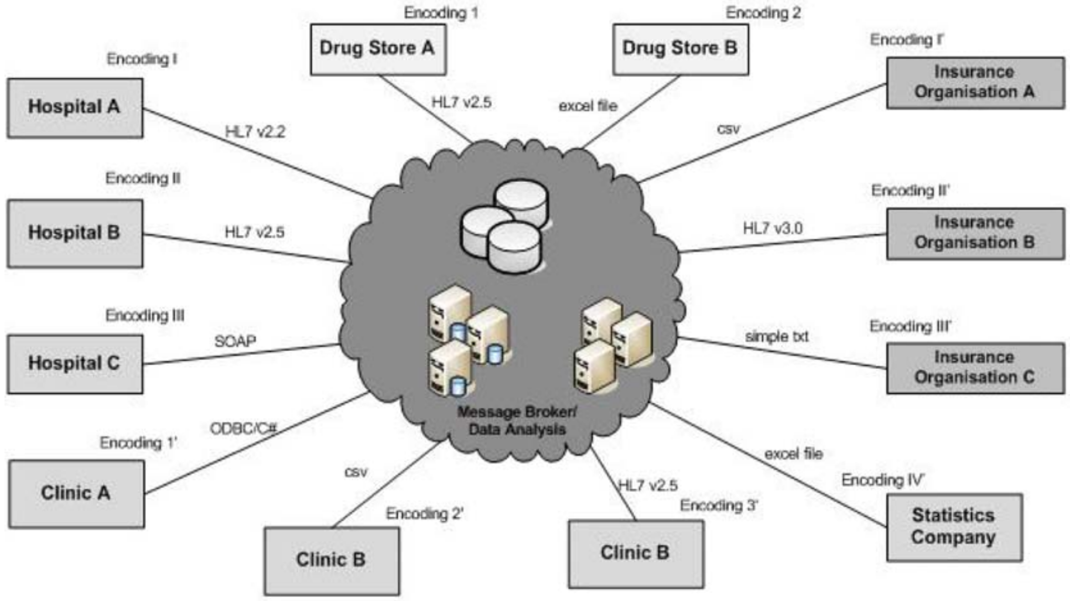
The reliability aspects of data management within a Grid environment are mainly dealt with through data replication techniques. The major topics that the task of data replication covers include the replica creation, placement, relocation and retirement, replica consistency and replica access (Venugopal, Buyya, & Ramamohanarao, 2006). In real-world environments, constraints that the system imposes need to be taken into account such as available storage space, computational resources, network bandwidth, maintenance, access and storage costs, energy consumption, etc.

The Grid provides an environment suitable for solving the problem of storage and most importantly management of such data sets and for making them available over wide geographical areas. Data replication techniques that can be employed by the Grid imply the creation of exact copies of data sets. In other words a data set or just a part of it can be located at many different storage nodes at the same time, thus making possible the redirection of requests made for the data set by a client application to the most ‘appropriate’ storage node. When developing a data replication management set of services within the e-healthcare environment, certain features of the environment must be taken into account; the *great volume of information exchanged* on a daily basis, the *variety of roles* and the *various levels of authorization*, the *significant number of users* of the e-healthcare services, the *geographical dispersion* of the entities and resources in the e-healthcare environment, the need for *real-time operations* (especially related to the synchronization of the e-health records).

An important decision to make in such an environment is the number of replicas to be created as well as the location of these new replicas in order to meet a performance goal. In the e-healthcare environment, this decision strongly depends on the Quality of Service (QoS) requested (e.g., level of reliability the participating entity is willing to pay for or the law poses), whereas minimal infrastructure cost is targeted for from the Service Provider’s side. In fact, in the case of the e-healthcare environment in which a significant portion of the data exchanged and stored comprises sensitive data, a perfect balance between achieving the desired QoS and reducing the number of instances of the data to the minimum so that the possibility of data abuse, disclosure and attack is reduced is required. Based on the replication scheme followed a replica persists until the authorised entity deletes it based on a predefined policy or its lifetime expires (static replication), or replicas are automatically created and deleted based on system or entity-related parameters (dynamic replication), such as current workload, network bandwidth, cost, expected demand. Though the latter incurs additional costs and network overhead, it allows for workload balancing, fault-tolerance and more efficient handling of the dynamicity of the Grid environment.

Concerning the user management and the authorisation assignment and monitoring aspects, Role-Based Access Control (RBAC) (Chakrabarti et al, 2008) and/or Process-Based Access Control (PBAC) mechanisms (GRIA, 2009) are used. The first one requires accurate directories of the healthcare provider’s and health insurance organisation’s staff based on their position in the respective organisations as well as careful listing and description of the different roles having access to the information and their authorisation levels. This process will actually form the privacy levels of the information in the environment. Thus, doctors will be granted access to different pieces of information (including historical data, medication, examinations, surgeries, allergies, symptoms, signs) of a patient’s e-health record than the nurses or the logistic department within the same healthcare Organisation, whereas the information exposed to different roles in a health insurance organisation will involve a different perspective focusing on pending payments and thus including billing information linked to the specific healthcare provider’s details as well as supporting documents related to the billing data. PBAC 2 comprises a dynamic access control mechanism. In brief, each web service has a list of operations that it can perform and PBAC determines which user can perform which actions in which context. The core component is a Policy Decision Point (PDP), which responds to the question “Can <this user> perform <this operation> on <this resource>?”. The response depends on the roles the user belongs to that are bound with the resource and policy related to the resource. Although these mechanisms are met individually on various systems serving from healthcare to surveillance and defence, hybrid models also exist.

Figure 1. Conceptual View of Interoperability among healthcare domains



Application Interoperability: The HL7

Apart from the infrastructural demands at resource level, current limitations of health information systems to a specific department or healthcare organisation in the environment comprise an important obstacle to the interoperability of these systems beyond organisational boundaries. These interoperability issues mainly stem from the various encodings used by each healthcare organisation for describing information about drugs, diseases, EHR as well as the different messaging mechanisms used for the communication of information, including different versions of HL7, simple text files, CSV (Comma Separated Values) and so on (see Figure 1). This results in significant delays of communication when required and more importantly in great inconsistencies in the EHR of the patient across healthcare providers leading to significant implications in care provisioning, quality of treatment and related costs. Hence, application interoperability is also required; a need that is tightly coupled with standardisation of the terms and the interaction in the healthcare environment while maintaining flexibility and cost-effectiveness. The "Health Level-7" initiative aims at producing specifications for bringing these gaps, just like a common language gives the opportunity to people of different native tongues to communicate with each other.

What is unique about HL7 (HL7 Organisation, 2009) is the fact that it deals with specifying flexible standards and guidelines of the entire healthcare organisation and is not limited to specific departments and is continuously adjusted and extended in an effort to support the varying requirements and needs of the different users, roles and entities within the e-healthcare domain. By defining a set of rules allowing for information exchange and processing while achieving uniformity and consistency, HL-7 specification aims at enabling interoperability among different healthcare entities and thus minimising delays in the information flow as well as geographical isolation and great variations in medical care. Healthcare providers are thus given the opportunity to standardise their daily operations and procedures. Based on common events taking place in healthcare organisations with clear focus among others in the patient administration domain, the HL-7 initiative has been developing message structures, Web services among others, able to carry HL7 messages. An example comprises the HL7 ADT (Admission, Discharge and Transfer) set of messages for exchanging information about the patient's state and status of their demographic data (Spronk, 2008). Thus, using the patient data (e.g., demographic data, next of kin, diagnosis, insurance information and so on) collected by the ADT application and transmitted via the related messages, the healthcare providers' Patient Billing System (PBS) will then create a billing record for this patient. The analysis of the HL-7 specification goes beyond the scope of this book chapter.

The implementation of the e-healthcare collaborative environment can, thus, be realised in two ways: either through the wide adoption of an HL7-based messaging architecture able to use different messaging and transports, including web services over a Grid infrastructure or through the integration of a *message broker* able to "translate" the exchanged messages to the standard each organisation is currently using. There are ongoing efforts for achieving the wide adoption of HL7 as a messaging standard for communicating information within and across the various entities in the healthcare environment. According to Rowland (2007) until 2007 HL7 had already 27 recognised International Affiliates with negotiations with 5 other countries in process, whereas the latest list of HL7 Affiliates includes more than 30 countries worldwide (HL7Australia, 2009).

As already mentioned however, the realisation of these standards in the healthcare environment comprises a time-consuming process requiring tremendous effort. For this reason, during this transitional stage the incorporation of a message broker responsible for translating the messages from one entity using a specific messaging protocol to another entity using a different one can enable the interoperability among the various systems. As a prerequisite each collaborating entity should have registered in advance the message protocol as well as the encodings for drugs, diseases and EHR it is currently using to the message broker, whereas a mapping from one messaging protocol to other and from one encoding to the other will be required. Thus, for example if clinic A is using X-based messages for communication of information, Y-based encoding for EHR and Z-based encoding for drugs and wants to communicate with clinic B using H-based messages for information communication, T-based encoding for EHR and W-based encoding for drugs, then, when receiving a request from clinic A to clinic B, the message broker should "translate" the messages from clinic A to clinic B based on the pre-defined mapping { X ↔ H, Y ↔ T, Z ↔ W).

Use of standard web services makes the incorporation of the services into the different entities in the domain relatively easy and cost-efficient, whereas the Grid infrastructure, as a standard-based infrastructure offering security, reliability, policy definition and monitoring and efficient content management, proves to be the proper enabling technology. Currently efforts on Grid-enabling application within the healthcare domain have mainly focused on exploiting the computational capabilities of the Grid or Data Grid within the healthcare providers' domain. Jin et al (2006) presented MIGP (*Medical Image Grid Platform*) which performed information retrieval and integration in distributed medical information systems focusing on combining HL7 and Grid infrastructure into the WSRF-compliant HL7 (Health Level 7) Grid middleware to enable medical data and image retrieval within Healthcare Providers. Another approach for the medical information integration as well as content-based image diagnosis of emphysema disease based on the Grid infrastructure was presented by Zheng et al (2008). However, the presented medical informatics collaborative environment goes beyond the organisational boundaries integrating healthcare providers', health insurance organisations' and pharmacies' systems through the introduction of *a reliable and robust Grid infrastructure* enabling *message brokering*, *encoding mapping* and *data analysis and aggregation*.

BUSINESS ANALYSIS OF THE E-HEALTH BUSINESS ENVIRONMENT

The healthcare domain comprises one of the strongest business environments as it is tightly coupled with "inevitability" in people's life; health problems. During the latest national conference held some months ago in Florida USA, Senator Tom Coburn mentioned that "*administrative costs in account for $700 billion of the $2.3 trillion spent on health care annually in the U.S.",* indicating that about 30% of the healthcare budget is actually put on non-healthcare provision tasks. These figures lead to great cost concerns which make ICT-enabled information management and communication as well as interoperability and general infrastructural changes a crying need.

The presented scenario indicates the frequency of the interactions with the system as well as the complexity of the information flow. Currently however, it is quite often that even within a healthcare provider specialized systems serving different departments are not integrated, forcing staff in search of a patient's medical or administrative data to enter another department's system in order to obtain a full clinical picture. Given the lack of standardization and the resource-poor infrastructures which are unable to meet the overwhelming demands of these information flows ICT solutions climb the highest stairs of the next steps hierarchy within the e-healthcare collaborative environment. Through the integration of Grid technologies in the resource infrastructure level and the implementation of the HL7 specifications in the application infrastructure level significant steps towards the efficient and privacy-aware information management and exchange will be made. Taking a closer look to this collaborative environment these infrastructural changes allow for a set of benefits to be realized.

In the technical analysis of the proposed e-health collaborative environment HL7 is presented as a set of specifications working towards enabling interoperability in the healthcare domain through developing standards for the management and integration of e-healthcare information. Standards comprise the most efficient path towards enabling interoperability between systems in a cost-effective manner, allowing for the sharing of health-related information among healthcare providers as well as healthcare providers and pharmacies with health insurance organisations. In fact, through standardization waiting times across the transaction cycle within the full healthcare environment (including not only healthcare providers but also pharmacies and public and private health insurance organisations) are minimized, errors mainly due to the human factor are significantly reduced and the road to large-scale e-health realization can finally open. In other words, the quality of healthcare provision can improve significantly while the overall costs within the healthcare domain can in fact be lowered and/or transferred for the improvement of the healthcare services offered to the patients, such as better medical devices, lower queues to doctor's office and timely management and communication of information to the interested parties.

As it has been quite obvious from the previous analysis of the e-health collaborative environment information comprises the most valuable resource. Within this domain information can be distinguished between medical information and administrative data. Medical information includes symptoms, signs, medication, diagnoses, family history, surgeries, examinations (from blood measurement to amniocentesis and cervical smear test), whereas patient demographic information, health insurance, billing information, health plan are regarded administrative data. It is quite evident that within a large-scale e-healthcare collaborative environment constant updating of information is required in order to achieve information synchronization, the size of the information collected and continuously being updated is tremendous whereas the nature of much of this information requires proper handling and management since it encapsulates sensitive data.

Efficient organisation of information and timely communication of administrative data not only between the medical departments and the logistic department of a healthcare provider but also between healthcare providers and health insurance organisations (public or private) offers a significant reduction in the billing process. Nowadays, especially the lack of standardization in the communication between healthcare providers and health insurance organisations and of integration of the various systems (medical system, record system, billing system, etc) causes tremendous delays in the billing cycle. Many records are still in paper format whereas those electronically kept are still incompatible across systems – even within the same organisation. Before the finalisation of the process health insurance organisations quite often request for additional supporting documents from the healthcare providers and a negotiation process begins in order for both parties to meet their interests. More specifically, the first ones want to ensure that the amount of money claimed by the healthcare provider is not greater than the expected cost of the medical examinations, the treatment and facilities use due to possible admission, the medication provided and the equipment of materials used. At the same time, the second ones want to reassure the full settlement of their patient's billing. For this reason, it is a common phenomenon that people or healthcare providers – based on the policy of the health insurance organisation – experience long delays before the final financial settlement.

Efficient information sharing and communica-

Table 1. E-health collaborative environment SWOT analysis

Strengths	Weaknesses
• Reduced operating expenses • Operations performance improvement • Increased efficiency, availability and reliability of the offered services • Interoperability among the players within the e-health environment • More timely communication of information both among healthcare providers as well as between healthcare providers and health insurance organisations • Reduction of the delays related to the fulfillment of the transactions cycle among the involved entities and thus of the finalization of the payment procedure • Access to important, quite often critical information related to their e-health medical record by the healthcare provider serving them	• The different players are unfamiliar with Grid technology • Unwillingness of patients as well as healthcare providers and health insurance organisations to share their data externally • Ownership of e-health medical records • Aggregation of massive data requiring long-term preservation and maintenance
Opportunities	**Threats**
• Increasing market maturity • Generally accepted need for standardization and interoperability of e-health systems • International market • Growing and improved networks • Continuously advancing information technologies	• Security, profiling and privacy concerns for individual's confidential as well as sensitive data being exposed through an extended network of collaboration. • Reluctance of healthcare providers and health insurance organisations to proceed with the adoption of new technology • Vague presence of Grid applications in large-scale collaborative environments

tion along with interoperability among systems of these entities comes to make the billing process a less tedious task and a more accurate and cost-effective process.

Efficient privacy-aware information management through a scalable and interoperable infrastructure based on Grid technologies and HL7 specification leads the way towards the implementation of a large-scale multi-institutional international platform offering consistent and secure linking of e-health records and providing privacy-preserving access to the latter to different departments and organisations at the same time. Such an implementation offers a helping hand to doctors who frequently lack access to updated and complete patient medical information allowing for the improvement of the quality of patient treatment as well as the reduction of the duplication of examinations occurrences. In fact enabling inter-linked e-health records can accelerate the diagnosis and treatment processes and thus through its wealth of important – often critical - information proves to provide valuable input during the doctor's decision making process. However, apart from the personal treatment of patients, e-health records implemented and exposed within a large-scale e-healthcare collaborative environment, it also offers great benefits related to clinical trials. In fact, the collection and processing of medical information from e-health records while ensuring the anonymity of the patients, allows for researchers to exploit this informational wealth for examining the effects of medication on a certain disease, the relation of demographic data to a specific health problem, the regular progress of a certain illness and so on.

ISSUES, CONTROVERSIES, PROBLEMS

Following the business-technical analysis of the e-health collaborative environment this section presents the related concerns and challenges of the proposed Grid- and HL7-enabled environment as well the expected future trends. Initially a common SWOT (Strengths, Weaknesses, Opportunities and Threats) analysis for the proposed environment is presented in the following table.

Businesses are slow at and quite reluctant in adopting new ICT solutions. Especially when it comes to the healthcare domain in which traditional processes are more than commonly rooted within, the barriers for integrating new ICT solutions become greater. For this reason a significant transition period will be required starting from intra-organisational changes and followed by inter-organisations ICT-enabled collaborations establishment. The lack of successful implementation and operation of large-scale collaborative environments with quantifiable benefits poses even greater obstacles towards this direction.

Data privacy comprises also an important issue. Entities within the e-healthcare collaboration are really concerned about the exposure of the medical and administrative data to other parties over the network or even their disclosure to other parties. The Electronic Privacy Information Centre (EPIC) identifies 4 main concepts of privacy (Electronic Privacy Information Center, 2002): (1) bodily privacy, (2) territorial privacy, (3) information privacy and (4) informational privacy. Informational privacy which incorporates a more descriptive definition and constitutes the main privacy aspect within an e-healthcare collaborative environment, comprises the establishment of rules governing the collection and handling of personal data such as credit information, medical and government records (also known as "data protection") with any secondary uses of that information constituting violation of the person's right to control it (Banisar, 2000). In the e-healthcare domain, informational privacy is almost equal to medical privacy, with the latter referring to the right of the person to manage their medical records at their desire. Common concerns include disposal of medical information to their insurance company, their employer, the media or even their acquaintances for different reasons per occasion, such as financial, social or even personal ones.

From the legal perspective, apart from informational privacy, ownership of the e-health records comprises an important issue. In such a large-scale distributed medical informatics environment the most potential scenario would include a company serving e-health record preservation and maintenance. In this case, trust establishment through legal means as well as close watch by an appointed authority would be required to ensure proper data handling according to predefined policies and standards avoiding data disclosure or illegal processing, as well as provision in case of company closing down.

From the technological aspect, information within the e-healthcare collaborative environment currently is stored and exchanged in many different forms; printed, written on paper, electronically stored in different formats (such as files, databases), displayed with slides or films, spoken, sent by mail or through electronic means. In order for a Grid- and HL7-enabled solution to be applicable within this environment however the transformation of this information initially into an interoperable electronic form is required, which is a time-consuming and tedious task.

FUTURE RESEARCH DIRECTIONS

Grid technologies – although a set of technologies feverishly researched for years – still retain open issues that need to be tackled with. In fact, as they were initially inspired from and designed for enabling and improving computationally intensive applications, support for large-scale collaborative environments and their resulting shifting of non-functional requirements priorities from performance to reliability, scalability, trust and security poses stricter requirements related to efficient and cost-effective data management, informational privacy, dynamic SLA establishment and flexible user management. Taking into consideration the e-healthcare – and more specifically the medical informatics - sector-specific features, developing reliable, cost-effective, robust, privacy-aware data management techniques which address the heterogeneity, the dynamicity and the great volume of information is of great importance. When it comes to the privacy preservation aspect of the data management techniques, it should be noted that its successful development satisfying the strict requirement for informational privacy requires a *multidisciplinary* approach integrating considerations and joint effort from the legal, medical, technical and social domain. Hence, when implementing such a collaborative environment, the legal framework covering data protection (leading to data minimization and requiring special handling of *sensitive data*) along with the specific informational needs from each entity (doctors, hospital's billing department, different departments in insurance organization, etc) should be taken into account.

A great challenge also met concerns the maintenance of the Electronic Health Records. As the vision for the e-healthcare collaborative environment incorporates their long-term preservation, special provision needs to be made on the lifetime of the information stored so that information included is not out-dated while no obsolete or unnecessary information is kept in the system.

Aiming at providing an evolvable and flexible platform for the e-healthcare collaborative environment, mobility should also be taken into account. According to Litke et al (2004) Mobile Grid comprises a full inheritor of Grid with its additional trait being its ability to support mobile resources (with the latter serving either as a service provider or a service consumer) in a seamless, transparent, secure and efficient way. Hence, our environment can be extended providing m-health services through allowing for real-time access and update of the e-health record of a patient could by using 3G-enabled PDA devices in cases that the doctors perform examinations out of the healthcare providers premises, e.g., medical visit at the patients' home, if required. Moreover, mobile telemedicine can be integrated to the system allowing for real-time monitoring of patients health status, communication of information to their personal doctors and automatic updating of their e-health records.

CONCLUSIONS

This book chapter showed that it will not be long before e-healthcare collaborative environments become commonplace for the broader healthcare domain, including healthcare professionals, health insurance organisations, pharmacies, patients and citizens. Medical informatics comprises a rising interdisciplinary field that promises substantial benefits within the healthcare provision area. In this book chapter we analysed the technical and business requirements of the e-healthcare collaborative environment. Given the nature, the variety, the volume and the importance of the information in the e-healthcare collaborative environment as well as the complexity of the information flows current techniques applied within this domain prove to be obsolete or inadequate. With efficient, reliable and privacy-aware data management and interoperability climbing the highest stairs in the hierarchy of the technical and business requirements, the integration of Grid technologies followed by the implementation of the HL-7 specifications paves the way towards the successful realization of a large-scale international e-healthcare collaborative environment allowing for the continuous, timely and reliable communication of medical and administrative information across organisational boundaries. The SWOT analysis presented showed that the potential of this integration is promising although quite a few barriers need to be overcome; reluctance in the adoption of new technology and the transformation of the currently followed operations, data privacy concerns, current technological insufficiency in meeting the strict requirements for efficient, reliable, privacy-aware data management and interoperability. However, these deterring factors can be translated into interesting research fields that require feverish work and a multidisciplinary approach.

Chapter 5.11

Projecting Health Care Factors into Future Outcomes with Agent-Based Modeling

Georgiy Bobashev

Andrei Borshchev
XJ Technologies, Russia

ABSTRACT

Human behavior is dynamic; it changes and adapts. In this chapter, we describe modeling approaches that consider human behavior as it relates to health care. We present examples the demonstrate how accounting for the social network structure changes the dynamics of infectious disease, how social hierarchy affects the chances of getting HIV, how the use of low dead-space syringe reduces the risk of HIV transmission, and how emergency departments could function more efficiently when real-time activities are simulated. The examples we use build from simple to more complex models and illustrate how agent-based modeling opens new horizons for providing descriptions of complex phenomena that were not possible with traditional statistical or even system dynamics methods. Agent-based modeling can use behavioral data from a cross-sectional representative study and project the behavior into the future so that the risks can be studied in a dynamical/temporal sense, thus combining the advantages of representative cross-sectional and longitudinal studies for the price of increased uncertainty. The authors also discuss data needs and potential future applications for this method.

INTRODUCTION

Risk Factors and Predicted Dynamic Risks

Predicting the future of health outcomes is always a challenge. Almost all specific health outcomes can depend on hard-to-predict factors. For example, the number of new influenza cases in a town depends on the random contacts among its residents. At the same time, some stable causal dependencies can provide robust background for ballpark estimates, qualitative analysis, and often quantitative assessment of relative risks. In the same example, children at school have a much higher chance of getting the flu than a single adult working on a construction site. The challenge of modeling is to differentiate between the actual critical factors that shape the outcome and the uncertainty surrounding the prediction. In a few instances it is possible to combine the two approaches (Bobashev et al., 2000) so that a mathematical model part captures the robust dynamics and a statistical part accounts for the unexplained variation.

Naturally, modeling strategy depends on the objectives. Beyond that, a clear understanding of the scales on which the outcome resides drives the modeling approach such as system dynamics, agent-based, process (Colizza, 2007 Riley, 2007).

Often global patterns and relationships are the results of the interactions of many local behaviors and decisions (Epstein, 2007). Thus, the description of these local factors becomes critical for understanding how interventions should be structured and which sub-population is the most responsive to an intervention.

Stable and reliable global patterns of the spread of communicable disease could arise dynamically from local and seemingly unpredictable behavior; for example, random network contacts could lead to exponential growth of HIV prevalence. Thus, the studies of local behavior and contact structure could be critical for the description of global outcomes.

In order to project the outcome into the future, one usually needs the following:

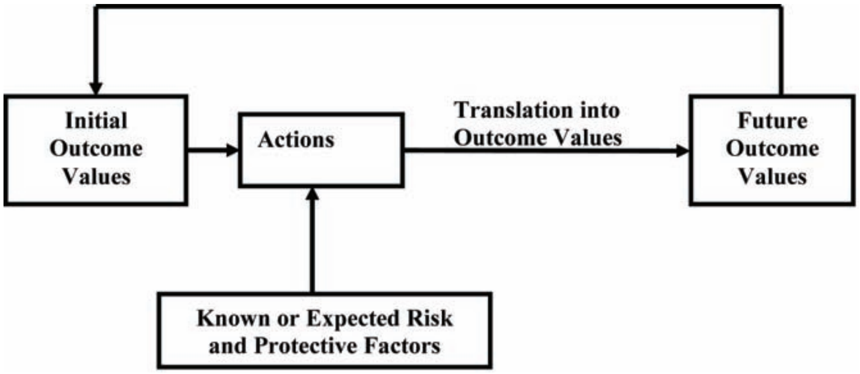
- A clear definition of the initial outcome values and risk factors (i.e., the values of the outcomes at the starting (initial) time point. For example, an individual at the baseline could be either HIV positive or negative;
- A description of the actions that individuals may take in the future (e.g., attending a ball game during a flu epidemic season);
- The collection of factors determining the actions, which could relate to a number of independent variables as well as the past actions or past states simultaneously (e.g., mixing matrices, which probabilistically describe a choice of a sexual partner, reflect that individuals are more likely to seek partners with some similar and dissimilar qualities to themselves so that, as some studies have shown, individuals who have many sexual partners are likely to have sex with those who themselves have many sexual partners [Turner et al., 2006]); and
- The translator of the behaviors into the outcomes (e.g., HIV is transmitted per direct syringe-sharing with a certain probability, which is lower if the syringe is rinsed in bleach).

Simulation models put the ingredients together and, by iterating behavior over time, provide updated outcome values as the events occur (see Figure 1).

Agent-Based Models as Tools for Projecting Behavior into the Future

Agent-based modeling is a method of developing simulation models that suggests that the modeler focuses on describing the behavior of individual entities (e.g., patients, staff, households, companies). Such entities—agents—are put into a certain environment where they interact, change their state, move, or are created or destroyed. The system level (aggregate) behavior emerges as a result of simulation of multiple individual behaviors (Borshchev & Filippov, 2004). Agents in agent-based models (ABMs) are typically acting under control of a simulation engine on a computer and in virtual (model) time. The agent-based approach is particularly helpful when a researcher

Figure 1. A process diagram of the iterative behavior projecting into the future



considers interaction between the individuals and emerging behavioral patterns.

In many health care applications, ABMs can capture reality in a more natural way and often are easier to develop than models based on differential or difference equations, which require aggregated parameter estimates. Because of recent developments in computational hardware and software, realistic agent-based modeling has become quite feasible and thus its popularity has grown in many areas of application.

In this chapter, we consider applications of agent-based modeling in two different health care areas: containment strategies in the spread of infectious diseases and interaction of staff and patients in a hospital.

Examples of Problems that Agent-Based Models can Solve

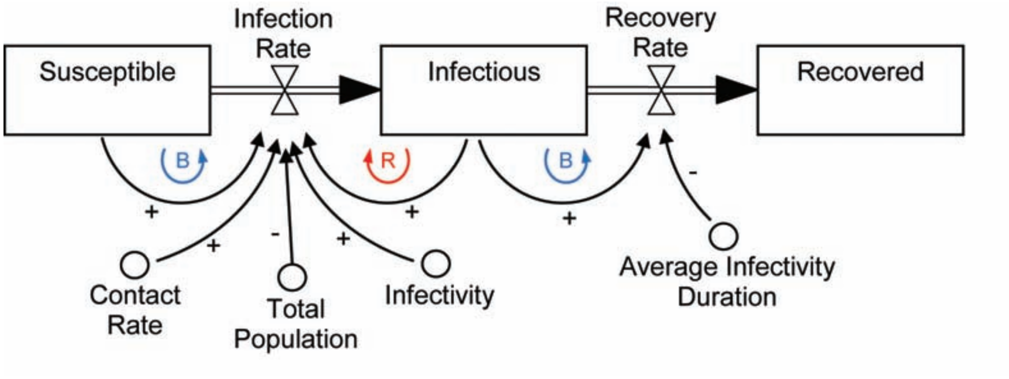
We start with the system dynamics (differential equations) description of a simple Susceptible-Infectious-Recovered (SIR) model of disease diffusion and show the limitations of such an approach in realistic populations. We then re-conceptualize the model using the agent-based method and demonstrate the basic patterns for specifying behavior of individuals (agents). We then compare the simulation results of system dynamics and agent-based models.

Next we extend an ABM to capture the social network contact structure and illustrate how different network types and parameters affect the results. The further enhancements of the model can include households, working environments, travel, and health interventions such as self-isolation and quarantine.

Another application of network-related behavior is a model of HIV diffusion in a network of drug users with a hierarchy of syringe-sharing and the use of different syringe types. We show which groups of individuals have the highest chance of being infected in the future and thus need the most attention of the public health interventions. We show that even a small percentage of high dead-space syringes could be enough to sustain a high level of HIV in the population.

The last model in this chapter is a model of an emergency department (ED) where patients and staff interact with one another. We use a process modeling method for this model, which can be considered as intermediate between system dynamics and agent ABM. We show that such a model allows ED administrators to optimize the use of the staff and the utilization of other ED resources, and outline how ABMs can help to further enhance the model.

Figure 2. The stock and flow diagram of the SIR model



The Modeling Language

Throughout the chapter we use the modeling language of AnyLogic (a software tool for agent-based and mixed-method simulation modeling), which includes several commonly adopted visual notations: stock and flow diagrams, statecharts, and process flow diagrams. All models described in this chapter are available as runnable applets at the AnyLogic Web site (AnyLogic 2008).

How Do Social Networks Affect the Disease Dynamics?

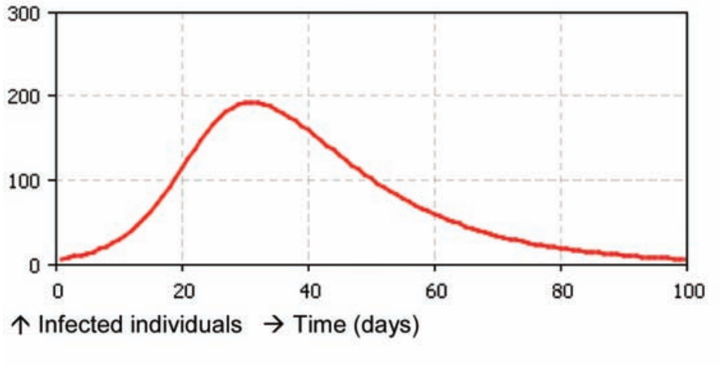
When one gets the flu during a winter epidemic, does one always know who has given them the disease? Probably not. Most people would say that they picked it up "randomly" from "someone" at work, in school, etc. Of course, most people don't want to get sick and do not specifically target a hazardous contact, so there might be an impression that infectious disease are spreading "randomly." However, when it comes to a sexual encounter, could it be considered "random"? Do people randomly pick a sexual partner, or drug-injecting partner, or even a person with whom to socialize at work? A recent study has shown that sexual partnerships are quite different among teenagers than among mature adults, and these structures can dramatically affect the spread of sexually transmitted diseases among these sub-populations. Similarly, among drug injectors, some networks have almost no HIV, while in others the prevalence can reach 80%.

One of the answers is hidden in the network structure of social, sexual, and drug-injecting contacts. In the next section, we show how to explore the impact of such a structure on the disease dynamics using ABMs. Because different diseases have different infectivity, course of disease, mortality, etc., we illustrate the impact of the networks on a generic disease where individuals can be susceptible to, infected with, or recovered from the disease.

A System Dynamics Model

In a "classic" system dynamics model of a disease diffusion (Anderson and May, 1991; Sterman, 2000) we divide the total population into three compartments (categories) with respect to their disease status: Susceptible to the disease, Infectious, and Recovered, hence the three compartments that could be modeled as stocks in the stock and flow diagram used in system dynamics science (see Figure 2). As people are infected they move from the Susceptible category to the Infectious category, and then, as they recover, to the Recovered category. The disease spreads as those who are infectious contact and pass the

Figure 3. The dynamics of infectious population (disease prevalence) in the system dynamics SIR model



disease to those who are Susceptible (the positive feedback loop) while at the same time depleting the pool of susceptible (the negative loop). The recovery from the disease creates another negative feedback loop.

Mathematically, the system dynamics model is a system of differential and algebraic equations, in the case of SIR they are:

Initially a fraction of the total population (PercentInitiallyInfected) are Infectious and the rest are Susceptible.

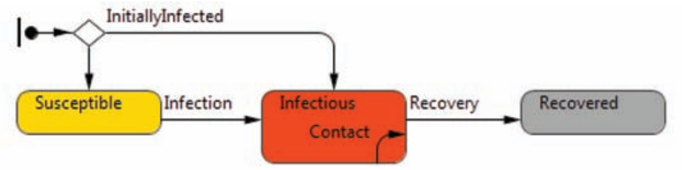
The simulation of the system dynamics SIR model produces a bell-shaped curve of the Infectious population (see Figure 3). However, this model makes a number of simplifying assumptions. One of the strongest assumptions is the homogeneity and perfect mixing of individuals in each compartment (stock): for example, all infectious people are assumed to behave in exactly the same way regardless of their individual history, properties, etc. This assumption implies that any person in the population can contact anyone else with the same probability. This simplification could sometimes be justified when the disease of interest is spread through airborne particles like influenza and the population of interest resides in a large well-connected metropolitan area such as New York or London. However, for structured populations and diseases where the transmission depends on the type of contact, such simplification could be misleading. In the ABM of the same problem, such an assumption can be dropped completely.

An Agent-Based Model

In a completely disaggregated ABM, each person is modeled as a separate object with his own parameters, state variables, and behavior rules. The agent's behavior may be continuous over time, discrete (based on events), or hybrid. In this particular model, we distinguish between three different states of a person (Susceptible, Infectious, and Recovered) and assume that state transitions are instantaneous and there are no continuous changes.

A statechart with a sequence of three states naturally describes this behavior. Note that the states of an agent mirror the three stocks in the system dynamics model; however, here the states are mutually exclusive: the agent can be in only one state at a time (see Figure 4). To reflect the fact that some people are already infected at the beginning of the simulation, the statechart entry point has a branch InitiallyInfected. The choice of the initial state can be probabilistic (e.g., based on a global model parameter PercentInitiallyInfected) or deterministic (e.g., with infected people placed

Figure 4. The statechart of a person in the agent-based SIR model



in particular locations).

The transition to the Infectious state models the event of a disease being passed to the agent from a sick person. In the model terms, the trigger of that transition is the message "Infection." Once in the Infectious state, the agent is able to pass the disease to others; thus, we are interested in his contacts. We assume that ContactRate (a global parameter) is constant while in the Infectious state, and we can use internal transition Contact that will be repeatedly taken until the agent recovers. In the action of that transition, the agent will choose another agent from the people that he knows (this is defined by the social network, which we consider below) and send him the message "Infection." However, we know that not every contact results in infection being passed, so the message should be sent with the probability InfectionProbability, which is yet another global parameter. If the message reaches an agent who is already Infectious or Recovered, it is ignored because there is no transition from those states triggered by such a message. Finally, the transition Recovery is a timeout that defines the illness duration. In the system dynamics model, the timeout is often modeled as exponentially distributed with the mean AverageIllnessDuration. Here we can use the same assumption for the sake of comparison; however, the more realistic approach would be to use a real distribution of the length of the infectious period as was done in Rvachev and Longini (1985) to compare the simulation results with the output of the system dynamics model. However, the ABM gives you absolute freedom in modeling durations of agent states: for example, you can easily use a uniform distribution between 5 and 15 days.

At the top level of the model, we define the population, the social network type, and the global parameters, which are the same as in the system dynamics model. In this particular model, the agents are homogeneous, i.e., they share the same parameter values and have identical behavior. Again, one is free to add any degree of heterogeneity to agent-based models: from individual parameters with different values to different behavior patterns (e.g., different ContactRate of different people).

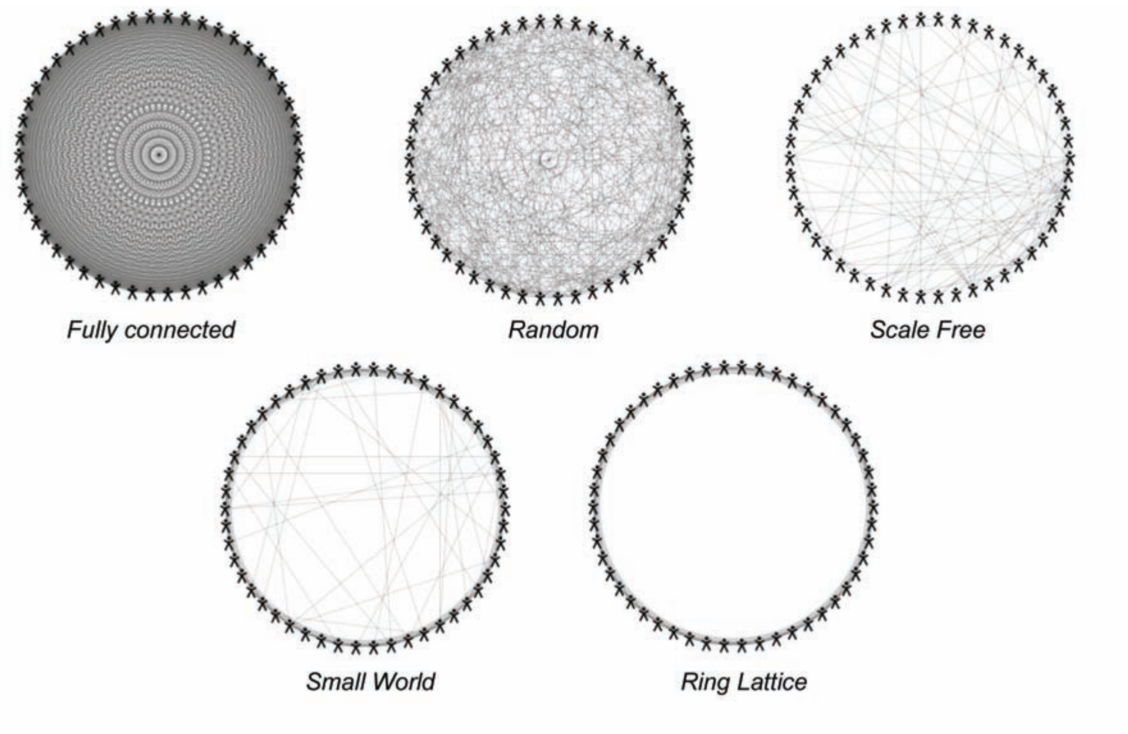
We also need to define simulation outcome variables on which to collect the statistics of interest such as the maximum size of the infectious population and the time from initial exposure to the maximum size of the infectious population.

The Network Types

The experiment design for this model follows the pattern suggested in Rahmandad and Sterman (2008). We explore the dynamics of disease diffusion in the following types of networks:

- Fully Connected: Anybody can contact anybody else. This network type fully corresponds to the perfect mixing assumption of the system dynamics model.
- Random: An agent is linked to a random subset of the agent population.
- Scale Free (Barabasi & Albert, 1999): Some people are "hubs" with lots of connections and some are "hermits" with few connections. This type of network is built using a preferential attachment algorithm where the probability of a new person

Figure 5. Schematic diagrams of different network structures



linking to the existing people is proportional to the number of links those people already have.

- Small World (Watts, 1999): Most agents are linked to their close neighbors, but there is a certain percentage of long-range links, i.e., links to distant agents. One of the ways to describe such arrangement is to arrange the agents in a circle (ring structure) and define neighbors as agents closest to the left and to the right.
- Ring Lattice: Each person is linked to a fixed number of his closest neighbors on a ring. This type of network is most distant from the fully connected network.

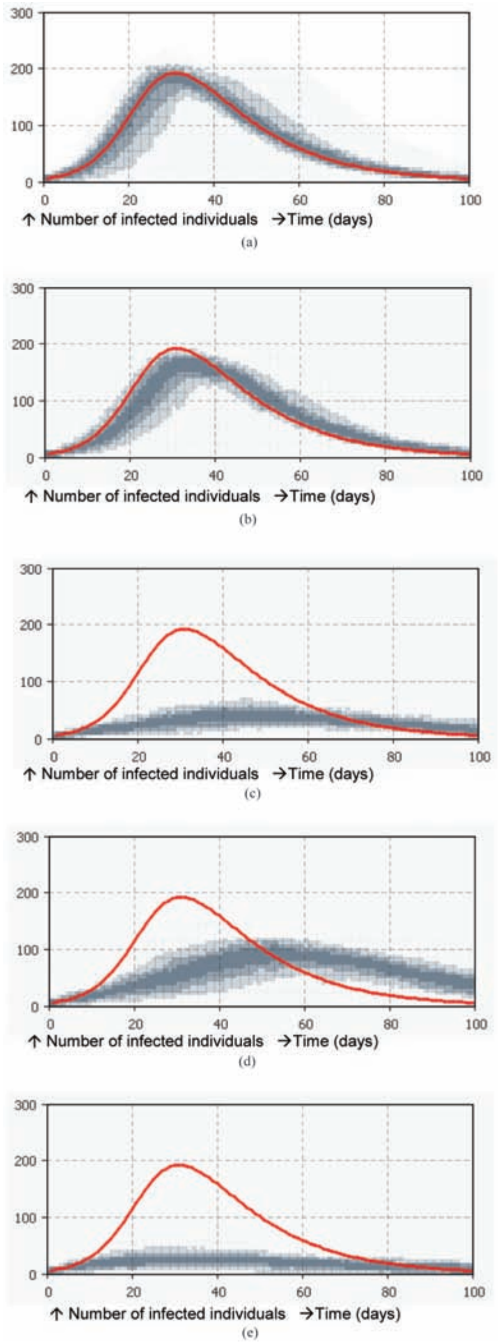
The network structures are illustrated in Figure 5 for a population of 50 agents.

The Simulation Results

Unlike the system dynamics model, which is deterministic and generates a single trajectory, the ABM is stochastic (in this case due to the contact occurrences, the probability of infection being passed during a contact, the illness duration, and the network structure). Therefore, each simulation run will give different results. We will perform a number of runs for each network structure and assemble the distribution of results in a two-dimensional histogram with highlighted envelopes to indicate the mean realization and variation around it. The solid curve is the number of infected individuals calculated from the base case system dynamics model. The results are qualitatively the same as in Rahmandad and Sterman (2008).

As one can see from the plots in Figure 6, the less a network resembles a well mixed structure, the stronger the discrepancy in the disease dynam-

Figure 6. (a) Disease diffusion in a fully connected network. (b) Disease diffusion in a random network with 10 links per node. (c) Disease diffusion in a scale free network with parameter = 2. (d) Disease diffusion in a small world network with 10 links per node and 5% of long distant links. (e) Disease diffusion in a ring lattice with 10 links per node.



(a)

(b)

(c)

(d)

(e)

ics on the networks. This effect is best explained by looking at the extreme setting. When all people are completely connected (Figure 6a), the ABM performs the same as the homogeneously mixed system dynamics model by construction. The epidemic quickly rises and then tails out. Not all people get infected. A percentage of individuals remain susceptible. When the subjects are connected randomly, the epidemic is smaller and spreads more slowly than the completely connected case, because each individual has only a limited number of connections. When all subjects are arranged in a circle, the disease is spread only to the nearest neighbors, and thus the speed of the transmission is much slower, and the epidemic could last for a much longer time and eventually produce an even greater number of infected individuals than under the random mixing case. Small world epidemic shapes could be viewed as a combination of the random mixing and the ring lattice cases, because the small world populations are structured as nearest neighbors with random connections to the rest of the population. One of the main features of the scale free populations is that they have potential "superspreaders" who, if they become infectious, can quickly infect large numbers of people. Although these networks may appear somewhat artificial, they have a direct application to disease prevention programs. Not long ago, Bearman et al. (2004) showed that sexual networks in adolescents and young adults are very different from those among older adults. Most older adults have stable monogamous partnerships, with a small fraction of very active individuals who have a large number of partners concurrently (i.e., network structure with superspreaders). If a sexually transmitted disease enters the population, it could cause a large outbreak (or outbreaks) when people connected to the superspreaders get infected in a short period of time. The rest of the population remains protected because of their monogamous relationships. While the structure of adolescent sexual network is mostly monogamous with no concurrency, the rate of partner change is relatively high. If a sexually transmitted disease enters such a population, it would not cause a quick outburst but would travel slowly from one partnership to another similar to a ring lattice or a small world network with sparse links across the population.

In these examples, we have illustrated the advantage of the ABMs in capturing the network structure. The further enhancements of the agent-based SIR model may include introduction of households, working environments, travel, and self-quarantine.

However, in the SIR example the agents are homogeneous, that is, they do not differ from each other by any specific features. In our next example, we increase the complexity of the agents to illustrate how individual features make a difference in disease dynamics.

How can Being on the Top of Social Hierarchy among Drug Injectors Protect One from HIV?

At the beginning of the HIV epidemic in the United States, heroin users who had been injecting for a longer period of time had a lower prevalence of HIV than drug users with a shorter history of injecting. The answer was unexpectedly simple. Those who had used heroin longer were likely to be higher on the social hierarchy of users and were more likely to procure heroin. Thus they were more likely to inject before others, and an infected syringe would be less likely to reach them (Bourgois, 1998, 2004). Such an effect is difficult to model using conventional methods, but agent-based modeling allows us to incorporate such a modification easily. Below we describe how this could be done in a model of injecting drug users in a single U.S. county.

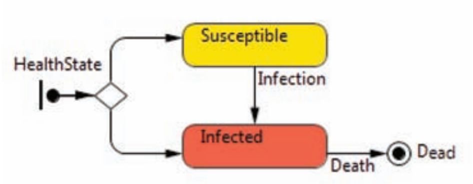
A Model of HIV Transmission among Injecting Drug Users

An ABM consists of two major structural components: the agents who are performing all the action and the top-level "container" object that defines the structure of the networks, describes the distribution of buddies, prior experiences, etc. In other words, the top-level defines the initial conditions and the global structure for the model.

We first consider a model of a drug user (an agent). To distinguish between the Susceptible and Infected states of the drug user, we use a statechart with two states (note that, in contrast with the previous SIR model, there is no Recovered state for HIV). A certain percentage of drug users are initially HIV infected; they start in the Infected state. Otherwise, the drug user begins in the Susceptible state and transitions to Infected in the event of using an infected syringe during an InjectingActivity with a certain probability. The corresponding transition Infection is triggered by the message "Infection" coming from the InjectingActivity organizer (the injection behavior is described below). If we plan to run the model for a longer period of time, we can also model the reduced life duration of an infected user. This can be done by adding a transition from Infected to a final state: Dead, triggered by a timeout. The timeout is a draw from the (known) distribution of life duration of an HIV-infected person, and the action of the transition is deleting this user from the model.

The central part of the drug user model is the injection behavior. Each user has a number of "buddies" who periodically get together to use drugs. The number of buddies is defined by the network. Occasionally, an injector would use with a "stranger" who is a random person from the entire population of injectors (Blower et al., 1991). We use a statechart with two states—Idle and InjectingActivity—to model the drug usage behavior. There are two ways to get to the InjectingActivity state: organize an activity or be invited. We assume that anybody can organize an InjectingActivity and invite others. The transition Organize from the Idle state to the InjectingActivity state occurs after a period of inactivity (in the Idle state) that can be between 1 and 3 days. When this transition is taken, the organizer of the InjectingActivity invites his buddies with a certain probability (FractionInvited) by sending them the message "Invitation." If the user being invited is in the Idle state, he will take the transition Invitation, confirm participation (by sending back the "Confirm" message) and proceed to the InjectingActivity state. The other possibility is that the invited drug user is already at another InjectingActivity, in which case the invitation will be ignored.

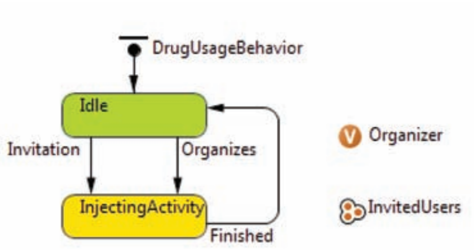
Figure 7. The HealthState statechart for an injecting agent



The duration of the InjectingActivity itself is not relevant here (we only need to know the participants), but we can set it to 1 hour deterministically for animation purposes. Therefore, the transition InjectingActivityIsOver that brings the drug user back to the Idle state has a constant timeout of 1 hour. The actual injection sequence is modeled in the exit action of the state InjectingActivity of the organizer. The organizer iterates through the list of participants (sorted by the experience, most experienced users at the beginning), starting with the clean syringe. If a user is already infected, the syringe is marked as infected and the subsequent users will get infected with the probability InfectionProbability (in the model terms, the message "Infection" is sent to the user).

An agent can receive three types of messages: "Invitation," "Confirm," and "Infection." The

Figure 8. The DrugUsageBehavior statechart and the related drug InjectingActivity data for an injecting agent



"Invitation" message is forwarded to the DrugUsageBehavior statechart, the "Infection" message is forwarded to the HealthState statechart, and the "Confirm" message causes its sender to be added to the collection InvitedUsers according to his experience. Experience is a parameter that indicates how long the user has been injecting and defines his rank in the social hierarchy of users. The initial value of Experience for a particular user can be set up as a draw from the distribution of experience throughout the drug user population (which, in this case, is the required input data for the model) or deterministically. Note that Experience is the only source of agent heterogeneity in this model.

The Top Level of the Model

At the top level of the model, we need to define the population of injecting drug users, their network of contacts, and some global parameters, namely the following:

- InitialNumberOfUsers: the initial number of agents in the model;
- PercentInitiallyInfected: the percentage of users who are initially HIV positive (for simplicity, we can assume this is not correlated with Experience);
- FractionInvited: the probability that a drug user who is known to the InjectingActivity organizer will be invited;
- InfectionProbability: the probability of getting infected after injection with an infected syringe; and
- ExperiencePDF: the distribution of experience among the drug user population used to initialize the Experience parameter of individual drug users.

For illustration purposes, here we use a small world network; however, in practical models of HIV transmission, the network structure should be estimated from the data or at least by using a mixing matrix (who injects with whom) as described in the data section below.

Note that if we wish to model the new drug users that join the network during the model runtime, we need to dynamically connect them to the existing users while preserving the network parameters.

The other important model elements that are defined at the top level are various statistics, output visualization, and animation. The following outputs are important in our case:

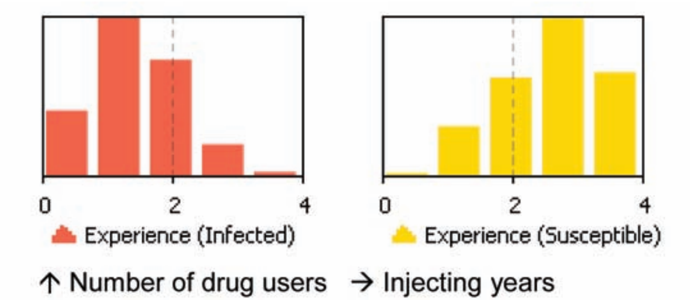
- the dynamics of the drug user population (if we do not add new users during the simulation),
- the dynamics of the fraction of HIV-infected drug users, and
- the distribution of experience among the users who are infected and not infected at the end of the simulation.

After the model is set up, one can use it to answer important policy and research questions.

The Simulation Results

One of the first illustrations of model application results is estimation of the effects that the drug-using experience has on the chances of HIV infection. Because we can track each individual agent in the model, we can make comparisons based on their behavior. After using the simulations

Figure 9. Distribution of Experience among Susceptible and Infected users at the end of simulation.



to project the behavior over the 3 years ahead, we can compare the distribution of experience among users who are HIV positive and HIV negative (see Figure 9). By running the model many times (e.g., 100) we can collect the necessary statistics and estimate the difference in survival from HIV between those who had more than 2 years of drug-using experience and those who had less (see Figure 10). As both figures show, the survival is indeed better among those who had used drug for a longer period of time. One could use a variety of statistical methods to estimate odds ratios, relative risk, hazard, etc., by applying appropriate statistical methods to the simulated data in the same manner as it would be applied to the real data. However, the main difference is in the interpretation of the variation. In simulation modes, the variation is composed of two sources: uncertainty in the parameters and variation due to the stochasticity of the simulation. We discuss these sources in the discussion section.

This model could be expanded to represent a number of comparisons when agents are supplied with individual characteristics such as demography, disease status, behavior, etc. The next example illustrates how such models can help evaluate the impact of high dead-space syringes on HIV transmission.

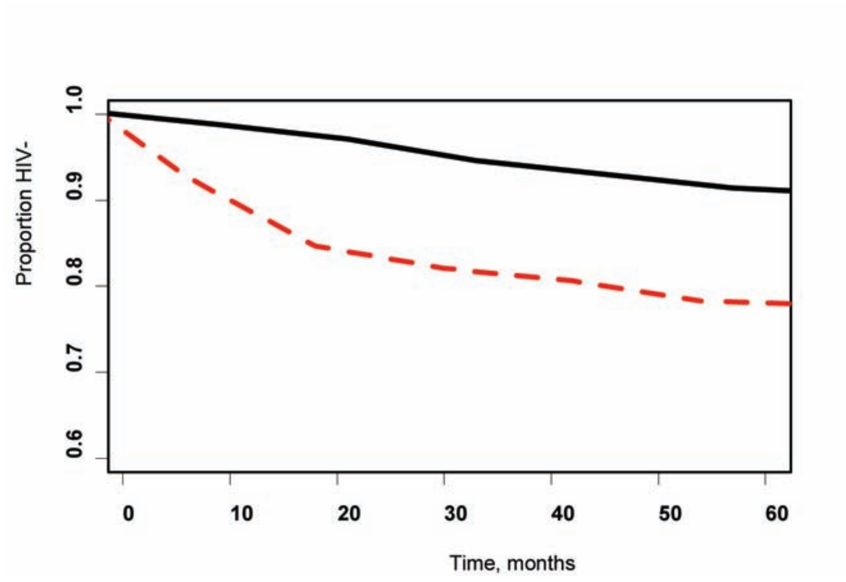
Do All Syringes Pose Equal Risk for HIV Transmission?

William Zule and his coauthors have pointed out the fact that different syringes have different amounts of so-called "dead space," which is a small space in a syringe barrel between the fully depressed piston and the needle (Zule & Bobashev, 2008). This dead space in syringes with detachable needles can retain 50 times more blood after the injection than insulin syringes with built-in needles. While injecting the drug, a user often draws back some blood to fill up the barrel and then injects the drug back into the vein. The syringe could then be passed to the next user, with some blood retained in the barrel. After a couple of rinses, which the injector usually does to prevent the needle from clogging and to reduce the risk of HIV, the relative amount of the virus in the dead space becomes more than 1,000 times higher in the detachable needle syringes compared to insulin syringes. If the concentration of the virus has an impact on the probability of HIV infection, then switching to insulin syringes could reduce the incidence and consequently the prevalence of HIV. But what percentage of injectors would need to switch to more expensive insulin syringes in order to reverse the course of HIV epidemic? Below we demonstrate how to incorporate the use of different syringes into the model of injectors.

Changes to the Injection Drug Users Model

We assume each drug user always uses a particular type of syringe (safe or unsafe), so we add a Boolean parameter UsesSafeSyringe to the model of the drug user. At the top level of the model we add SafeSyringeUsersFraction—a probability

Figure 10. Survival curves among the highly experienced (solid line) and low experienced (dashed line) injectors



needed to initialize UsesSafeSyringe for each user. We also need another top-level parameter InfectionProbabilitySafe—the probability of getting infected after injection with an infected safe syringe, which is obviously lower than InfectionProbability for a regular (unsafe) syringe.

Another assumption we make is about injection behavior. We assume that if at least one user at the InjectingActivity uses a safe syringe, then that syringe will be used by everyone. Therefore, in the model of the injection sequence in the exit action of the state InjectingActivity of the organizer, we should first check if anyone has a safe syringe and, if so, use InfectionProbabilitySafe instead of InfectionProbability.

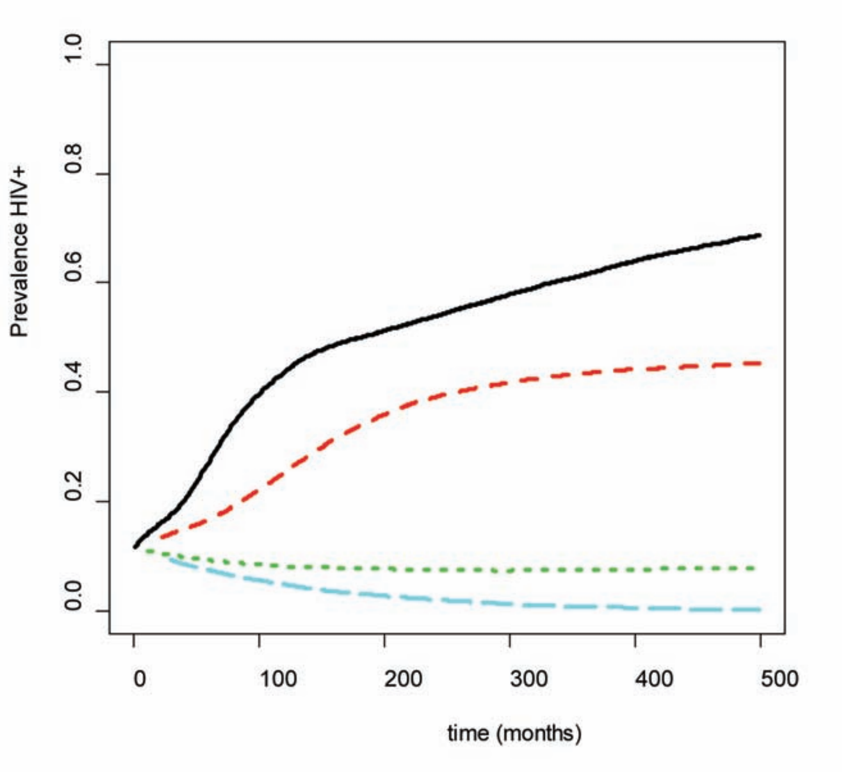
The Simulation Results

Once again, when the model is run a number of times (e.g., 100) we can accumulate the data about the outcomes and summarize it in a form of a statistical analysis or a graph.

Figure 11 shows that even a small percentage of high dead-space syringes can lead to a high prevalence of HIV, which implies that in order for the intervention to be successful, it is necessary to replace the vast majority (>90%) of high dead–space syringes.

By giving the researcher the possibility to track an individual agent, ABMs have the advantage of adding an explicit spatial component. Knowing the location of the individual, it is possible to place them on a Geographical Information System (GIS) map; conduct spatial statistics; and assign various environmental information such as poverty, crime, and education indexes (see Figure 12). This option could have the risk of producing potentially identifiable personal information. However, there are a number of safeguards to protect individual privacy. Some common methods include perturbing the actual location by random spatial noise, aggregating spatial locations up to large spatial areas (from individual addresses to a block group), and using synthetic populations, which are populations of virtual agents that have comparable demographic characteristics to the census at some aggregate level such as county or census tract (Wheaton et

Figure 11. Dynamics of HIV prevalence in a population of injecting drug users. Solid line corresponds to 100% of high dead-space syringes, dashed line to 50%, dotted line to 10%, and long dashed line to 0%.



al., 2006). The use of virtual populations is thus advantageous because the agents' characteristics are not the characteristics of real people, but at the statistically aggregated level the results of the analysis are similar to what they would be for the real population.

Can ABMs Help to Efficiently Manage the Emergency Department?

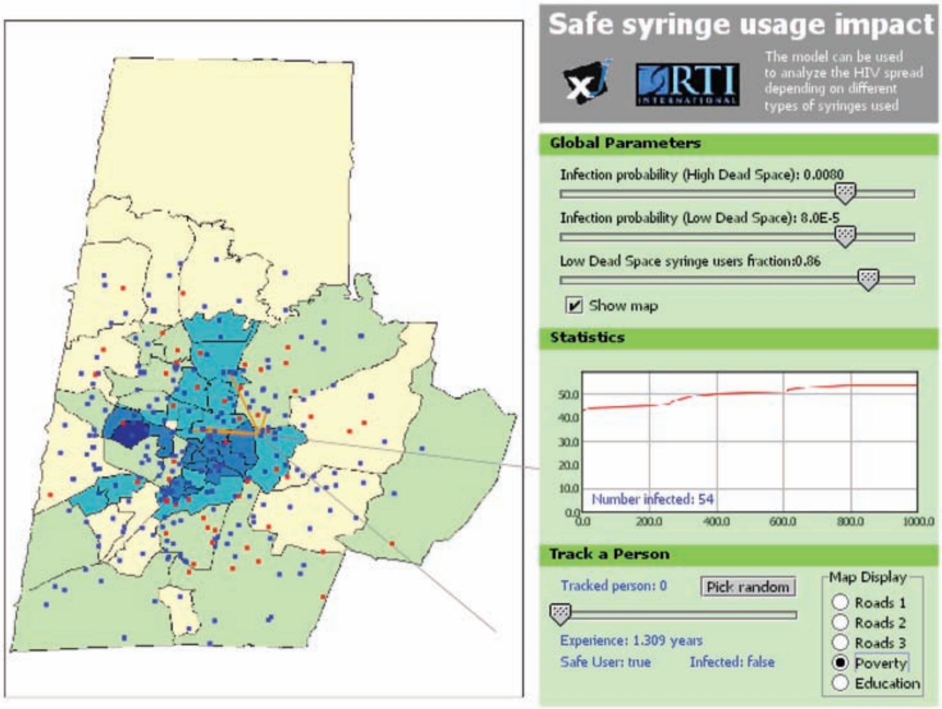
The workload in emergency departments is notorious for being extremely high at times. "Physician patient load patterns and ED demand patterns should be taken into consideration when physician shift times are scheduled so that patient load may be balanced among a team. Real-time monitoring of physician patient load may reduce stress and prevent physicians from exceeding their safe capacity for workload" (Levin et al., 2007). The same is true for a number of health care departments that are not EDs.

Because the functioning of an ED is quite complex and the patient cases range widely in the type of care they need, it is often difficult for the management to process the bulk of the information needed for optimization. A strategy to ease workload in one place can create a bottleneck elsewhere in the process (Miró et al., 2004). Below we demonstrate how ABMs allow one to summarize the processes in the ED and evaluate different strategies to ease the workload.

The Model

Compared to other parts of a hospital, the ED has more clearly defined sequences of operations.

Figure 12. Example of using GIS to map the poverty index and the locations of the injecting drug users in Durham County, North Carolina. The actual locations of the responders have been stochastically scrambled.



Safe syringe usage impact

The model can be used to analyze the HIV spread depending on different types of syringes used

Infection probability (High Dead Space): 0.0080

Infection probability (Low Dead Space): 8.0E-5

Low Dead Space syringe users fraction:0.86

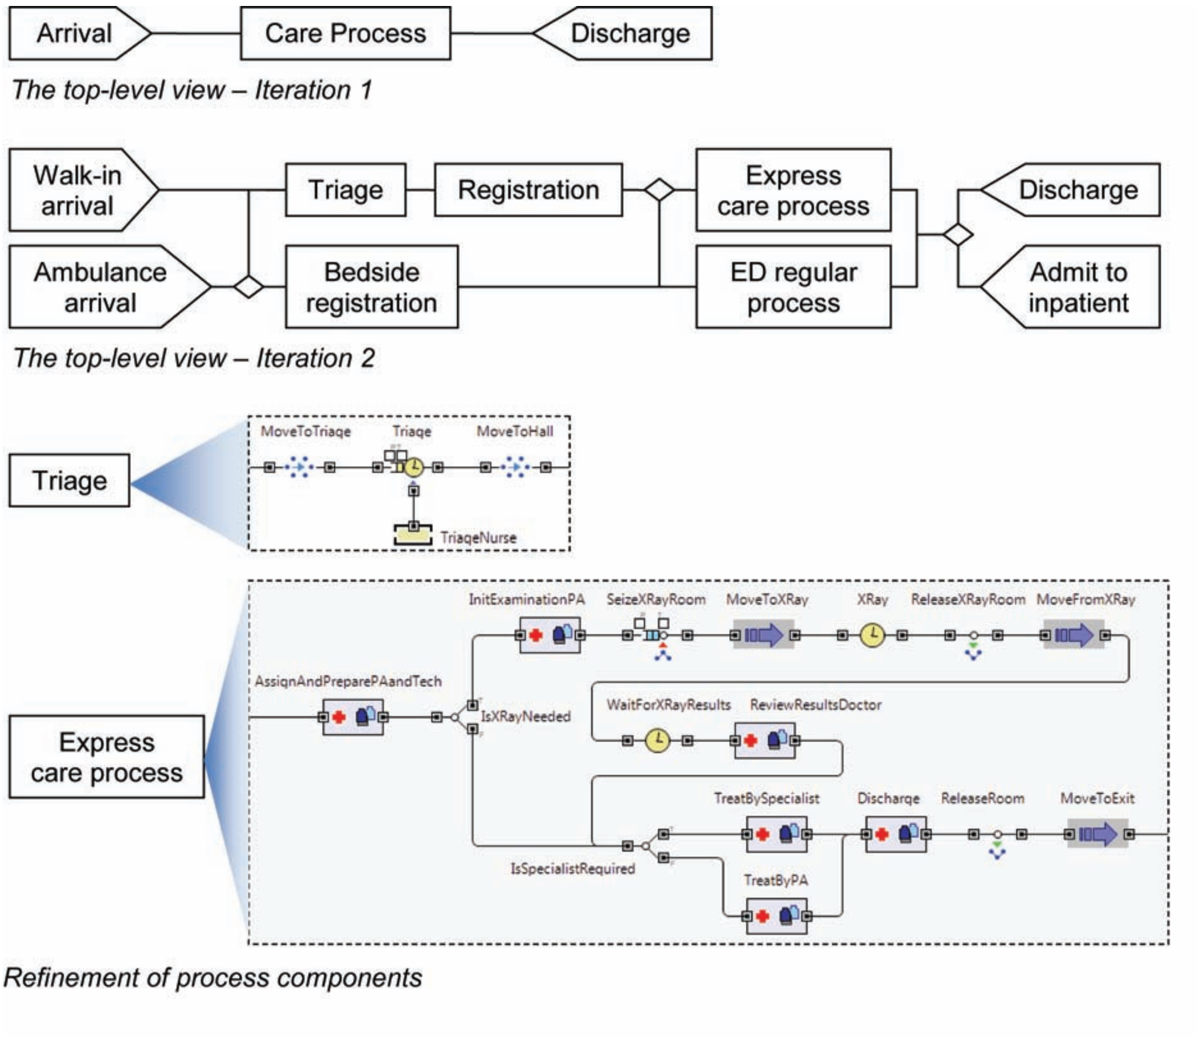
○ Education

Therefore, we can start with a modeling technique that can be considered to be intermediate between system dynamics and agent-based modeling: process modeling, also known as “discrete event” modeling. This modeling method has been known for decades; is well developed; and is widely used in manufacturing, business processes, the service sector, etc. Process modeling suggests that the modeler view the system as a process—a sequence of operations, perhaps with branches and loops—where entities (in this case patients) interact with (and compete for) resources (staff, rooms, equipment). The entities and resource units are modeled as individual objects and may have individual parameter values. Therefore, process models are disaggregated like agent-based ones. However, these objects are passive. They have no independent behavior and thus are completely controlled by the process; and here the process models are fundamentally different from ABMs. We begin by modeling the operations of the ED as a process and then we outline how the model can be extended by adding the agents.

Process models can be designed both bottom up and top down. For this example, we chose the top-down method. The top level of the ED operation model is a sequence of patient admittance, care process, and discharge (see Figure 13). In the next design iteration, we distinguish between walk-in patients and patients brought by ambulance. The walk-in patients go through triage and registration and are then placed into an emergency care room. The ambulance patients are put into a room first and are then registered. There are two types of care process in our ED model: Express Care (open 11AM–11PM) and Regular Care (open 24 hours). These two types have different steps and require different resources. The internals of the

Figure 13. The process model of an emergency department



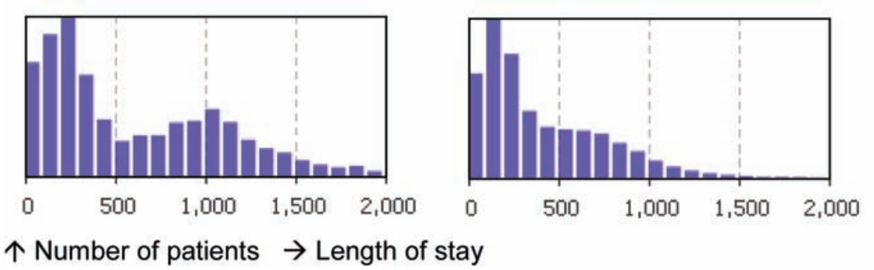
Express Care process are shown at the bottom of Figure 13. First, a personal assistant and technician examine and prepare the patient. Then, if X-rays are needed, they are taken and the results are reviewed by a doctor. After that (or directly after initial examination if X-rays are not needed), a specialist may be needed to treat the patient. After treatment, the express care room is released and the patient is discharged, or, alternatively, admitted to inpatient.

At the bottom level, the process components are built of primitive library objects such as Seize, Delay, Release, MoveTo, ResourcePool, Decision, etc. The properties of patients that flow through the process may affect the branches taken, the duration of operations, the type of resources needed, etc.

The Simulation Results

During the simulation of the process model, we are able to collect various kinds of statistics related to patients, staff, rooms, and equipment. Typically, we are interested in the following:

Figure 14. Distribution of patients' length of stay in the emergency room for two different working hours options of Express Care process



- the length of stay of patients in the ED;
- staff, room, and equipment utilization; and
- locations of bottlenecks in the process, particularly the sizes of queues.

These outputs are used to compare different process improvement strategies, to choose optimal staff levels, and to set working hours. Figure 14 shows the distribution of patients' length of stay in the ED for two different working hours options of the Express Care process.

Another kind of output is animation of the ED operation. Animation can be used to verify the model behavior and to perform rapid what-if experiments. For example, the animation of the ED model could be viewed on a floor plan of the actual ED (applet is available for viewing at the Web site: http://www.xjtek.com/anylogic/demo_models/healthcare/).

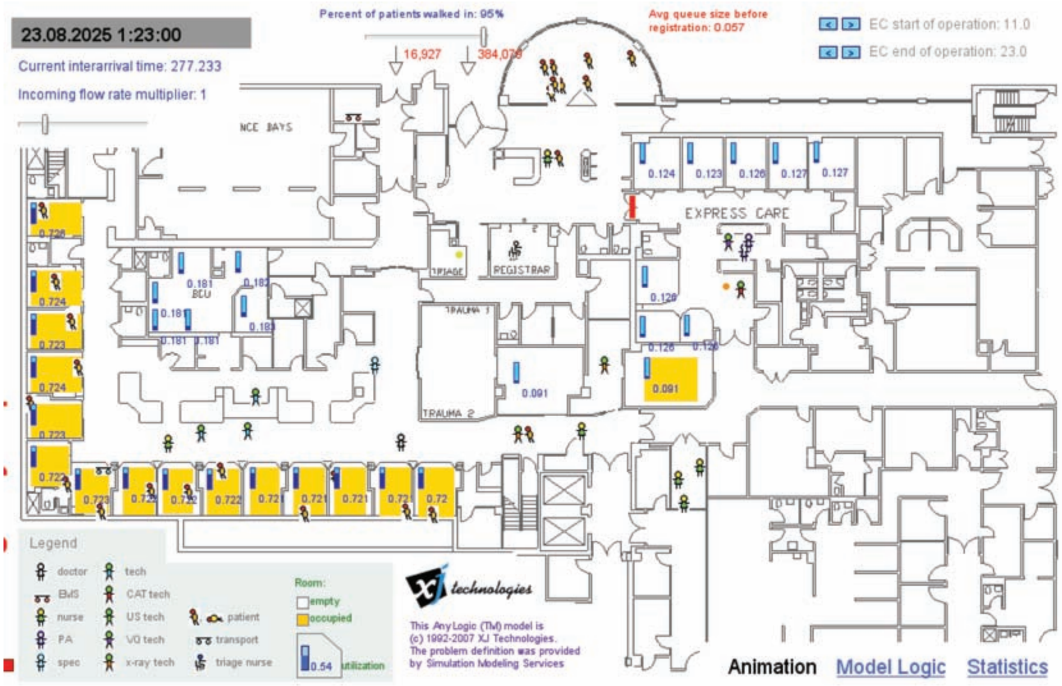
Extending the Model with Agents

Although process models are capable of capturing diversity in individual parameters of both entities and resources, the inability to define individual behavior puts a natural restriction on how far the model can go in reflecting reality. In particular, ABMs can help in modeling the longer-term behavior of ED staff. We can associate an agent with each staff resource unit in the process model (a specialist, a technician, a nurse, etc.) and make it persistent throughout the model run, so that the agent exists even when the corresponding resource is not present in the process model. We can then efficiently model the staff knowledge development, trainings, vacations, and even interaction of individual staff members at work, which can affect the ED process. For example, the staff performance and error rates when treating patients may depend on the individual states and properties of the corresponding agents.

FUTURE TRENDS IN DATA COLLECTION

One of the main challenges in the construction of ABMs is obtaining the right data to calibrate and validate the model. It is often *the* main challenge. When conducting health surveys, the focus of the sampling is usually to collect a representative sample of the studied population. The cornerstone of sampling methods and the resulting models is an assumption of independent and identically distributed subjects where one subject could well be a representative of many other similar subjects. Is this assumption true in the case of sexually transmitted diseases? If sexual partners are seldom picked at random, does the selected partner represent hundreds or thousands of other potential partners? Could a number of partners be averaged for the sake of simplified assumptions? If, over the past month, one person had one sexual partner and another had 9, does that mean that between

Figure 15. Animation of the emergency department model



them they had on average five sexual partners? Similar questions could be asked about a number of other types of contacts, such as injecting drug use contacts and contacts within hospitals and workplaces.

Most often, survey data focused on static and individual estimates is not suitable for the estimations of transition probabilities and network interactions, which are at the center of ABMs. Instead, the surveys for ABMs should focus on collecting data for dynamic and network estimates. Of course, such data pose very serious challenges.

Obtaining network information carries with it the issue of privacy. For example, in order to collect accurate data on sexual networks, one has to ask for identifiable information about sexual partners, which many respondents are reluctant to provide and sometimes do not even have. One compromise between the ease of data collection under the representativeness assumption and the need to obtain partnership information is to collect information about the *types* of partners. For example, sexual partners could be classified into long-term and short-term; their demographics could include age, race, gender, education, and socioeconomic status; and their behavior could include drug use and number of sexual partners as assessed by the respondent. Such information could be then be used to construct a mixing matrix, indicating the probabilities of having a sexual partnership between the representatives of particular categories (Morris, 2004).

Another challenge in obtaining network information is the adequate type of sampling design. Probability surveys are not helpful in identifying target populations, especially if part of the population of interest can be "hidden," such as in the case of injecting drug users. There is no practical way to enumerate all the users to develop a sampling frame. On the other hand, respondent-driven sampling (Heckathorn, 2002) allow one to obtain a representative sample of connected individuals. In this sense, respondent-driven sampling sample links rather than individuals, and following the links combined with the information on the mixing matrices could potentially allow one to reconstruct the network structure.

One critical component that distinguishes ABMs from other types of models is a dynamic scheduling of the events. After the respondents are enrolled, they are usually asked questions regarding their behavior. Some of the typical survey questions deal with the initiation of the behavior ("When was the first time you…?"), recency ("When was the last time you …?"), and frequency ("How often do you…?"). Although these questions somewhat help to schedule the events by estimating the periodicity of particular behavior, they do not help to establish transitions between the types of behavior and its consistency. ABMs often require questions of the type "For how long have you been… ?" or "In what other activities were you involved while…?" Concurrency and the rate of partner change are critical for the transmission of many sexually transmitted diseases. However, such questions are seldom asked in the surveys. For example, knowing how many sexual partners a person had over the last 6 month does not help a researcher to establish how many are stable partners and how many are short-term or occasional.

Nevertheless, a number of tools have been used to collect important behavior data suitable for ABMs. One is a "timeline fall back" where a subject is asked retrospectively about particular events. Prospective ethnographic tools have also been developed to follow-up with respondents and collect information on the scheduling of events (Vahabzadeh et al., 2007). However, these tools were not developed specifically for use in ABMs, and some adaptation might be needed. The use of blogs became very useful in collecting scheduling information. For example, a very sophisticated model of influenza spread in a city, EpiSims (Eubank et al., 2004), used blogs to validate individual movements and contact information.

Additional information that impacts transitions and interactions requires even more detailed ethnographic description. That is why development of ABMs highlights the need for close collaboration with ethnographers and for adapting the old ways of data collection to the new levels of formalizing and using them to project dynamic risk factors into the future.

DISCUSSION

We have presented several simple examples of the uses of ABMs and showed how they could be useful for understanding and projecting risk factors into the future. These models, although quite simplistic, uncover some of the relationships that should be considered when developing health services policy. Because the actual behavior and health-related outcomes could be very complex (detailed, nonlinear, evolutionary, and multiscale), the modes focusing on any specific areas of research are likely to be of a much higher complexity level. In the discussion, we reexamine the utility of agent-based modeling, and modeling in general, to provide some means of safeguarding against misuse and misinterpretation of the models.

Agent-based modeling is a fast-developing area of research, and while numerous models have been developed and utilized, there is not much theory for evaluating ABMs as rigorously as can be done for most system dynamics models. ABMs have a larger number of parameters, each of which has to be evaluated; the stochastic nature of micro-simulation often leads to a broad variety of solutions. Reality, in turn, could be viewed within a similar paradigm: the observed events and behavior are only a single realization of what could have happened out of millions of potential outcomes. The function of ABMs is thus not to reproduce actual observations but rather to capture more general features of the phenomenon. Thus, we would like to warn about a temptation to treat the outcome of an ABM as an imitation of an observed real-life situation. Another application of ABMs is identification of the results that could be rare or unusual. These applications are especially important in risk management, when the objective is to estimate the risks of rare but potentially damaging outcomes. Before the conclusions can be made about ABMs, the outcomes from a large number of realizations should first be processed to reveal the trends and relationships that are general enough to guide future decisions. The same argument applies to modeling in general; however, system dynamics models are often already operating in terms of the aggregated measures such as rates, odds ratios, and risk factors, while ABMs evaluate individual trajectories and thus require an additional aggregation step.

What makes ABMs advantageous in specific cases is the ability to describe local non-linearity and self-organization resulting from a sequence of local events. There is one more important utility of ABMs that makes them attractive to modern modeling: the natural manner in which events are described. ABMs allow the description of events without using sophisticated mathematical apparatus. While system dynamics models require that the aggregated dynamic equations are developed first and then the solution of these equations projects the outcome into the future, in ABMs the behavior is project into the future first and then the results are aggregated. This process is often easier and more natural to formalize and thus more appealing to a researcher. For example, when describing health-related processes in a complex world, one might start with a simple equation-based model and then increase the description of disease transmission by adding more and more compartments corresponding to various population subgroups. For a simple system of four differential equations described here it is possible to derive important analytical solutions that have a strong impact on health policy (Bailey, 1975; Anderson & May, 1991). When the number of equations becomes too high, the model loses its analytic appeal but becomes more useful as a numeric simulator. An ABM is designed as an efficient numeric simulator from the very beginning. By design, ABMs are naturally expandable to accommodate increasing levels of complexity such as heterogeneity in contacts, variations between individuals, and combinations of processes across physical scales such as molecular, cellular, organ, individual, group, and population.

ABMs also have a number of specific challenges, including the following:

- *Challenge to populate the model with parameter values.* Populating an ABM often requires knowledge of detailed individual decision-making and/or scheduling patterns. For example, in a model of different types of syringes, we did not consider the fact that many drug users change their behavior after they learn about their seroconversion. It takes different lengths of time for different categories of people to admit to the testing clinic and then change the behavior (often depending on the local intervention programs and insurance status). Also, knowledge of the actual network structure would change the actual numerical values of the results. However, the qualitative assessment might remain very similar. Depending on the purpose of the models and the results of sensitivity analysis, one should make decisions about spending large amounts of money to improve the model's numerical values, as opposed to conducting inexpensive qualitative assessment of a simple model.
- *Challenge to validate the model.* Validating ABMs is a topic of numerous discussions. With the large amounts of data that would be available in the industrial setting with repeated processes, validation is not as big a challenge as in the health care environment. The lack of validation data that was discussed in the data collection section prohibits the models from being fully validated. In the presented models we used simplified parameterization when the

values of parameters were obtained from published literature and educated guesses. This was done to illustrate that even simple models can provide additional insight into important health-related problems. There is a large body of models and peer-reviewed literature that describes more detailed models that have been calibrated and validated to different degrees (Law, 2007), but the assessment of these much more complex models is not the purpose of this chapter.
- *Challenge to obtain an analytical solution.* Although for equation-based models it is possible in many cases to obtain an analytical solution or an approximation, little has been done yet to obtain an analytical solution for an ABM that could be used instead of numerical simulations. Few exceptions occur when agents are simple, i.e., when they are not involved in complex interactions and do not evolve during the course of the simulation. In such simplified case, the model is reduced to the analysis of the networks that have a more advanced theory behind them (Snijders et al., 2007, Newman, 2002).
- *Computational challenge*. The advantage of system dynamics models is that they deal with aggregated populations and thus do not depend as dramatically on the population size they describe. Conversely, ABMs increase computational demands as the population size increases. The more complex are the agents the stronger becomes the limitation. For example, when agents are organized in a large network, each agent contains information about the individuals that they are likely to meet in the households, workplace, common areas, etc. Advanced computational methods are needed to program such arrangements in an efficient way. The options for conducting large simulation experiments are to use large computational facilities such as supercomputers, distributed computational clusters, and computational networks such as TeraGrid. However, for the purposes of evaluating the impact of policies in smaller locations such as hospitals and health care facilities, user-friendly software packages, such as AnyLogic, which create manageable models, are often sufficient.

Finally, we would like to bring clarity into the "explanatory" and "predictive" sides of modeling. In different subject areas, these terms would have different meanings. For example, in economics, a "predictive" model would produce a predicted value for disease prevalence with a confidence interval, and the same would apply for the estimated forecast of monetary burden. In behavioral and neuroscience, predictive would often indicate a more qualitative way of uncovering a mechanism that governs behavior. Regardless of definitions, we argue that explanatory and predictive are not necessarily conflicting objectives, but rather parts of a larger logical process. For example, the prediction of the national level of HIV prevalence for the next year might be based on a statistical regression trend model. It would probably be the same as this year with small variation that could be explained by the amount of funding spent on prevention and treatment. The linkage between cost and effectiveness could be done with some empirical algebraic equation. What such a model would not be able to tell is why some regions, communities, and individuals are at a higher risk and what would be a better way to change people's behavior. In this sense, a dynamical model powered by ethnographic knowledge may describe the phenomenon qualitatively and thus could be considered "explanatory" or "educational." However, the result of such models would be a qualitative "prediction" aimed at making a suggestion to public health as to which intervention direction is more promising for societal well-being. Thus, explanatory models become useful when their intent and focus is future practical prediction and application. Otherwise, purely explanatory models would have little practical value beyond the casual appeal of computer games.

ACKNOWLEDGMENT

The authors would like to thank Dr. Joshua Epstein for his valuable discussions.

Chapter 5.12

Practical Action and Mindfulness in Health Information Security

Jeff Collmann
Georgetown University Medical Center, USA

Ted Cooper
Stanford University Medical Center, USA

ABSTRACT

Although it is sometimes tempting to treat information security as a domain of its own, this approach will inevitably yield failures of information security and failures for the organization. This occurs because serious breaches may originate from organizational conditions not obviously related to information security policies, procedures or practices and because information security practices operate in, and are affected by the context of their parent organization. For these reasons, healthcare leaders must comply with but look beyond good industry practices alone while planning, implementing, and evaluating information security programs. In this chapter, we demonstrate that a consensus exists on key good information security measures that all healthcare leaders should, and often do use in designing their information security programs. We follow this analysis with two case studies that demonstrate the limitations of focusing only on good information security practices. These case studies help explain the mutual interaction between health information security programs and their wider organizational context by introducing key concepts about organizational performance, including "practical action," "practical resistance," "sponsored social movement," and "mindfulness" and examining them at the individual, group, organizational, and cross domain levels of organizational life.

DOI: 10.4018/978-1-60566-356-2.ch022

INTRODUCTION

Health care leaders and staff members have spent several years now designing, implementing and evaluating programs for complying with the privacy and security regulations of the Health Insurance Portability and Accountability Act (HIPAA) of 1996 (Department of Health and Human Services

[HHS], 2000, 2003; Gostin, Turekbrezina, Powers et al 1993; Mandl, Kohane and Brandt 1993). This work typically entails deploying traditional safeguards for information privacy and security on which wide consensus exists. As health care leaders reflect upon their work, however, they should begin looking beyond the boundaries of the traditional information security domain to include insights from the social science literature on High Reliability Organizations (HROs) and organizational failure. Two concepts, practical action and mindfulness may offer particular help in better understanding and trying to learn from their experiences with HIPAA compliance. Scott Snook introduces the concept of "practical action" in his explanation of the friendly fire shoot down of two American helicopters by two American F-15 jets over Northern Iraq during Operation Provide Comfort. According to Snook (2000), "practical action" operates as a ubiquitous feature of organizational life and refers to "behavior that is locally efficient, acquired in practice and legitimized through unremarkable repetition" (p. 182). Weick and Sutcliffe (2001) describe mindfulness in their analysis of avoiding failure in complex organizations faced with the high possibility of unexpected, catastrophic events. From the perspective of Weick, Sutcliffe and Obstefeld (1999), organizations that develop and sustain a state of collective mindfulness create "a rich awareness of discriminatory detail and (facilitate) the discovery and correction of errors capable of escalation into catastrophe." (p.81) Expanding their focus beyond the domain of information security alone will help healthcare executives identify potential vulnerabilities and sources of failure that standard approaches to information protection ignore.

RESEARCH DESIGN AND METHODS

We designed this project to illustrate the necessity for evaluating broad organizational conditions as well as industrial guidelines for good practice in information security planning. Thus, we begin by analyzing current surveys in English of information security practice and comparing them with two important information security initiatives of the United States (US), the Federal Information Security Management Act (FISMA) of 2002 and Security Standard of the Health Insurance Portability and Accountability Act (HIPAA)of 1996 (HHS 2003). This analysis demonstrates that a consensus exists on key good information security measures that all healthcare leaders should, and often do use in designing their information security programs. We follow this analysis with two case studies in the design and implementation of good information security practices across two large organizations, the United Kingdom National Health Service and the US Military Health System. These case studies introduce concepts for and demonstrate the importance of understanding the organizational context for implementing good information security practice. Drawing from the work of Scott Snook (2000), we consider efforts to reform healthcare information security practice at the individual, group and organizational levels of action as well as across levels in the case studies.

TRADITIONAL INFORMATION PROTECTION SAFEGUARDS

With the wide-spread use and integration of information technology into the operations of most organizations, failures in information security have commonly compromised operations, resulted in financial losses and besmirched reputations. To improve information technology security, a body of knowledge has developed that includes policies, procedures, best practices and administrative, physical and technical controls. This body of knowledge has been codified in a number of places including: 1. *An Introduction to Computer Security: The NIST Handbook* (National Institute of Technology and Standards [NIST] 1995), 2.

ISO/IEC 27002 *Information technology - Security techniques - Code of practice for information security management* (2005), 3. Information Security Forum *The Standard for Good Practice for Information Security* (2007) and in Federal regulations such as the Federal Information Security Management Act (FISMA) (2002) and HIPAA Security Standard (HHS 2003).

To improve the performance of information technology security, it is essential to understand what impacts performance in this area. A search of the World Wide Web and information technology literature yields surveys that attempt to identify and assess issues of information security. Prominent surveys in English include:

a. UK Department of Trade and Industry (2006) Information Security Breaches Survey 2006 – PWC
b. National Association of States (2006) Chief Information Officers Strategic Cyber Security Survey 2006
c. Information Technology Association (2006) Survey of American Federal Chief Information Officers 2006
d. Deloitte (2006) Global Security Survey of Global Financial Services Industry 2006
e. Computer Security Institute (2002, 2003, 2004, 2005, 2006, and 2007) Annual Computer Crime and Security Survey 2002-2007

These surveys asked questions about implementing technology, best practices, physical security, security controls, security training and awareness, adequacy of budgets, staff skills and the attitudes of corporate senior management towards information security. While each survey varied considerably in its level of detail, all asked questions in certain areas of information security. None of the surveys appeared to have been designed to be comprehensive or to cover the complete set of practices as codified in any of the cited bodies of knowledge. Rather, they tended to be based on a limited set of categories and often focused on those areas commonly reported in the media with a sensational impact. They often sought to determine the most commonly experienced types and costs incurred with exploited vulnerabilities rather than elucidating their root causes. (See Table 1)

The categories of survey question can be separated into three groups that represent a rough rank order of consensus about concern: Group I (High Consensus) - topics investigated by four or five of the surveys; Group II (Medium Consensus) – topics investigated by three of the surveys, and; Group III (Low Consensus) – topics investigated by only one or two of the surveys.

High consensus of concern was found in the surveys that organizations must allocate resources for security as a necessary business expense. Organizations must develop plans to protect and recover from damage to their information and information management systems using administrative, physical and technical safeguards. At the operational level, organizational staff must learn about their information security roles and responsibilities. The IT program must monitor, interpret, document and report on the flow of events in their systems as the first line of enforcement defense. These activities all require staff, time, money and, thus, an information security budget.

Medium consensus of concern was found in the surveys that organizations should implement three types of good information security practice: Risk Assessment, Incident Management, and Technical Control Mechanisms. All organizations should examine threats to the privacy and security of information, vulnerabilities in information security defenses, and the consequences of an information security breach for customers and business. They should identify what administrative and technical mechanisms exist to prevent security breaches as well as how organizations recognize, document, report and manage incidents. The surveys also express moderate consensus about Compliance with Laws and Insurance Policies, two areas of traditional and important corporate risk manage-

Table 1. Question asked by prominent surveys in English

Question Categories	Surveys				
High Consensus	**A**	**B**	**C**	**D**	**E**
Security Budget	X	X	X	X	X
Training & Awareness	X	X	X	X	X
Security Plans	X	X	X	X	
Business Continuity Plans	X	X	X	X	
Audits	X		X	X	X
Physical Controls	X	X	X		X
Medium Consensus					
Compliance with Laws	X	X			X
Insurance Policies	X		X		X
Incident Management	X	X			X
Risk Assessment & Management	X	X		X	
Technical Controls	X	X			X
Low Consensus					
Security in IT Architecture		X	X		
Plan Supports Organization Mission		X	X		
Effectiveness Evaluations		X		X	
Inventory of Systems				X	
Security Standards	X				

ment. Relative to the other ten topics: Security in IT Architecture, Evaluation of Effectiveness Security Standards, Maintaining Inventory of IT Systems and Plans Support the Organizational Mission warranted low consensus of concern.

The HIPAA security rules include thirteen of the sixteen topics meriting investigation by any of these surveys, including all of the topics in Group I (Security Budget, Training and Awareness, Security Plans, Business Continuity Plans, Audits and Physical Security); four of the five topics in Group II (Compliance with Laws, Incident Management, Risk Assessment, Control Mechanisms) and three of five topics in Group III (Effectiveness Evaluations, Inventory of Systems, and Security Standards). HIPAA does not reference insurance policies, security in IT architecture or plan supports organizational mission. HIPAA does impose several requirements not included in these surveys, including most critically, requirements about sharing patient information with third parties (a "privacy-related" topic). HIPAA also assigns a higher priority than the survey consensus of concern rankings to risk assessment and risk management, two standards that constitute the foundation of overall HIPAA security compliance and health information protection.

Under FISMA, agencies of the United States Federal government must annually report their performance according to a set of criteria released by the Office of Management and Budget (OMB). Although OMB issues specific reporting instructions each year, a core set of criteria has emerged with updates to reflect current issues such as the physical security of laptops. For FISMA, the reports have included eleven of the sixteen survey topics, including four of the five topics in Group I (Security Budget, Training and

Awareness, Security Plans, and Business Continuity Plans); three of the five topics in Group II (Incident Management, Risk Assessment, Control Mechanisms) and four of five topics in Group III (IT Architecture, Effectiveness Evaluations, Inventory of Systems, and Security Standards). During the five years of reporting, FISMA has not requested measures of Auditing, Compliance with Laws, Insurance Policies or Plan Supports the Mission. FISMA does require agencies to report on their Plans of Action and Milestones, a document meant to guide and mark correction of deficiencies in their security plan implementation as well as security of contractors' operations, Privacy Reports and agency plans for emerging technologies and threats. FISMA requires all non-security systems in US agencies to comply with Federal Information Processing Standards and to use as guides for program development the special publications on information security of the National Institute of Standards and Technology (see http://csrc.nist.gov/).

Taken as a group, these surveys indicate an overall consensus on topics of concern with more than half of all surveys as well as HIPAA and FISMA agreeing on ten of the sixteen topics. Most of the survey questions derive from regulatory requirements or authoritative guidance about the actual performance of information security in various commercial or governmental domains. Although highly relevant to their purpose of surveying compliance with specific regulations or good information security practice, these surveys ignore a range of questions about the organizational context of information security practice. They also take for granted how organizations mobilize to implement reforms. Yet, from the perspective of healthcare leaders, these issues are critical for successful performance. On the one hand, organizational conditions outside the narrow domain of information security potentially threaten the confidentiality, integrity or availability of information. On the other hand, reforming established practices of information security to comply with new mandates requires vibrant leadership and extensive work at all levels of an organization. How should we think about these two issues?

BEYOND TRADITIONAL INFORMATION PRIVACY AND SECURITY SAFEGUARDS

Since Charles Perrow's (1999) classic study of "normal accidents", social scientists have been debating the feasibility and methods for designing and safely operating complex technological systems. While acknowledging the structural difficulties of managing complex systems, "High Reliability" or "High Resiliency" theorists (HRT) argue that strong leadership, continuous training and practice, redundant safety mechanisms, and organizational mindfulness create cultures of safety that prevent catastrophic accidents and allow organizations to learn from their mistakes (Wildavsky 1988; Weick and Sutcliffe 2001; Collmann and Cooper 2007; Cooper, Collmann and Niedermeyer, in press). Normal Accident Theorists (NAT) argues that complex, tightly coupled systems inevitably produce system accidents that are difficult if not impossible for human operators to manage (Sagan 1993; Rochlin 1997; Snook 2000). Complex systems include many diverse components interconnected in multiple ways. Tightly coupled systems exhibit few gaps enabling rapid system operation and process flow, and, in the event of error, allowing local human and technical failures to escalate into larger-scale accidents with implications for the system as a whole. Thus, complex, tightly coupled systems often preclude even well-trained operators from effectively tracking and preventing system accidents with catastrophic consequences. These analyses converge in recognizing our contemporary dependence on complex technological systems and the need for great care in their management. Scott Snook (2001), who has drawn extensively from both approaches, recasts the problem in the form of an important question: "What are the critical design features of a hyper-complex, multi-level, multi-task, organizational system that will increase the likelihood of accomplishing the "total task" consistently?" (p. 235). All these questions may be asked of electronic healthcare record systems because they function as complex and tightly coupled technological systems and require highly reliable management systems to avoid and recover from accidents (Collmann, Alaoui, Nguyen, and Lindisch 2005; Collmann and Cooper 2007; Cooper, Collmann and Neidermeyer, in press).

Much guidance has emerged for healthcare organizations about what new policies, procedures and practices they should adopt (Cooper, Collmann and Demster 2007). From a strategic perspective, however, this guidance does not address how healthcare organizations should envision the mobilization effort itself. For this question, the literature on social movements provides some guidance, particularly its focus on fostering novel or reformed activities, knowledge and social relationships. Sociologists typically describe "social movements" as activities that seek to create new ways of behaving and new relationships, including such examples as the American Civil Rights Movement or the global environmental movement. Although they may create new organizations to help accomplish their aims, people engaging in social movement action typically work "in the street" and outside the boundaries of the specific organizations they seek to change. From a sociological perspective, social movements represent examples of "collective behavior" rather than "formal organization". In contrast to much of the social movement literature, analyzing health information security reform requires describing the conditions under which formal organizations with established routines, bodies of knowledge and organizational relationships intentionally and effectively change in response to new mandates. Although a minority of thought leaders in healthcare recognized the need for effective health information security programs as part of computerizing patient records, many others required the motivation of Federal regulations as embodied in the privacy and security rules of the HIPAA to act. Thus, once the HIPAA regulations were published and compliance dates set, many healthcare organizations faced the problem of mobilizing their compliance effort and, beyond that, achieving genuine changes in the activities, knowledge and social relationships through which they protected the privacy and security of patient information. We have developed the concept of "sponsored social movement" to aid in interpreting this paradoxical situation that seems to require "top-down" as well as "grassroots" action.

Case 1: Group Logon with a Smartcard in the UK EHR

Scott Snook (2000) developed a set of core concepts about organizational performance in his analysis of the incident in which two US Army Blackhawk helicopters were shot down by US Air Force jets during Operation Provide Comfort (OPC) over northern Iraq on 14 April 1994. After analyzing specific reasons for this incident at the individual, group and organizational level, Snook introduces the core concept of "practical action" to describe a process that operated across all levels of OPC. By practical action, Snook (2001) means "behavior that is locally efficient, acquired in practice and legitimized through unremarkable repetition" (p. 182). This concept helps explain how the original design of OPC changed from its inception in the Pentagon through three years of implementation in Iraq to the day the helicopters were shot down. As the American service personnel attempted to do their jobs in OPC, they gradually adapted the policies and procedures required by the multi-layered OPC plan to "life in the real world". For example, the OPC plan required Air Force jets to enter the protected air space over northern Iraq in the morning before any other allied aircraft. It also required all aircraft entering the airspace to file a flight plan indicating their schedule as well as points of origin and destination. An Air Force Airborne Warning and Control Systems plane (AWAC) was supposed to track all these events and maintain situational awareness of the airspace. Army helicopters functioned as airborne taxicabs for high profile customers such as the United Nations personnel killed during the shoot down. In order to meet their customers' needs, the helicopters came and went as they pleased without regard for the policies and procedures of the OPC plan. Indeed, by the time of the accident, several generations of Army helicopter pilots had cycled through northern Iraq. Over the generations they developed their "customer-focus", trained new pilots in their adapted procedures and satisfied their customers without incident, at least until 14 April 1994. Snook (2001) coins the term "practical drift" to refer to this "slow steady uncoupling of practice from written procedure" (p. 194). Instead of being tightly-coupled and rule-driven as specified in the OPC plan, daily life in Northern Iraq became loosely-coupled and task-driven. The shoot down occurred on a day when certain personnel invoked a design rule (jets first in protected space) at the expense of personnel who were acting according to locally efficient practices (take care of your customers) under the gaze of a distracted AWAC crew.

Snook's case study refers to an event that occurred in a social system that was designed and implemented from scratch, Operation Provide Comfort. In such circumstances, change occurs with reference to a formal design and clear implementation starting point. Organizational leaders attempting to implement a reform in current practice face a different situation: "behavior that is locally efficient, acquired in practice and legitimized through unremarkable repetition" (Snook 2001, p. 182) already exists and dominates the reform target area. In Snook's terms, they are attempting to modify institutionalized task-driven, loosely-coupled activities to comply with a new design. The reform designs often envision a developmental cycle of events with the intention of reconfiguring daily practice in line with explicit new laws, rules or regulations such as HIPAA. "Compliance" means following the designed rules and, often, abandoning "behavior that is locally efficient, acquired in practice and legitimized through unremarkable repetition." (Snook 2001, p. 182) We have developed two concepts to help interpret the dynamics of this confrontation between the reform design and existing, locally-efficient behaviors, "practical resistance" and "sponsored social movement".

"Practical resistance" or the unwillingness to change established task-based, loosely coupled practices in response to reform programs potentially emerges when a reform design encounters the practical action already dominating the target area. Adapting Snook's explanation of practical action to this different context, we observe that practical resistance may emerge as local actors resist changing locally efficient practices developed with experience, potentially subvert compliance efforts in daily practice, and tacitly or explicitly protest against proposed changes. We observe such practical resistance widely in attempts to improve information security policies, including but not limited to the healthcare industry.

The House of Commons (2007) 2007 Report on the Electronic Health Record (EHR) of the British National Health System (NHS) describes a clear example of practical resistance in the implementation of smartcard access. The South Warwickshire General Hospitals NHS Trust (2007) decided to permit its staff in the Accident and Emergency (A&E) Department to logon to the hospital's EHR as a unit for an entire shift using a single smartcard. Although officially permitted by the hospital leadership, it violated the NHS EHR principle of a unique smart card for each user. From the perspective of practical resistance, the hospital justified its decision on the fact that logging on with the smartcard required 60-90 seconds per logon, an unacceptable delay in the context of a busy emergency room. The EHR

Report (House of Commons 2007) presents the terms of the debate nicely in report paragraphs 217-219 as follows:

217. The Assistant Information Commissioner acknowledged that local security breaches of this type had occurred and stated clearly that the sharing of smartcards represented an unacceptable breach of operational security systems: …there have been some graphic examples where perhaps security precautions have been circumvented by people logging on for a whole shift, using one card rather than their own cards. That must be stamped out; there cannot be any of that.

218. But other witnesses argued that the misuse of smartcards would prove inevitable unless they could provide immediate access to systems. Dr Paul Cundy commented that unless "instantaneous" access to DCR systems could be achieved, smartcards would inevitably be seen as an "obstacle" to clinical processes, particularly in a busy, multidisciplinary environment such as A&E. It is notable that the justification given for sharing smartcards by the acute trust board in Warwickshire was that access to the new PAS application could take between 60 and 90 seconds.

219. CSC (Computer Sciences Corporation), the LSP (local service provider) for the West Midlands area, acknowledged that smartcard sharing had resulted from slow access times. Guy Hains commented: The sharing of smart cards was really about the fact that the system did not provide a sufficiently immediate log on for people who wanted to use the system quickly…we recognize the need for a smart card log on procedure of 10 seconds. (p. 75)

A better example of the issues at stake in practical resistance does not exist. Throughout the world, smartcards are accepted as an effective, relatively easy-to-use means for controlling access to electronic information systems. Yet, in this context, because of the extended time necessary to logon, the smartcard obviously interfered with "behavior that is locally efficient, acquired in practice and legitimized through unremarkable repetition" (Snook 2001, p. 182); that is, rapid access to the computer workstation for processing high volumes of patients in an emergency room. This case appears particularly interesting because the practical resistance to the formal procedure occurred at all levels of the hospital from the Board that approved the policy to the A&E staff who had to use the smartcards to the IT staff who helped install the new system. In spite of this evident consensus at the local level, the Assistant Information Commissioner, a high official in the NHS far removed from the scene, highly disapproved and insisted that such practices "must be stamped out; there cannot be any of that." (House of Commons, 2007, p.75)

Case 2: Lessons Learned from HIPAA in the American Military Health System

The concept of bureaucratic reform as "sponsored social movement" seems paradoxical. In some respects, it implies "top down" reform with senior leadership attempting to mobilize change from within. In other respects, it implies "grassroots" activity with local groups organizing demands and means for organizational change. For example, many healthcare organizations experienced the HIPAA privacy and security rules as unfunded mandates. In an already tight financial situation, the Federal government imposed new requirements that necessitated assigning people, time and money to work for which nobody necessarily planned or budgeted. Moreover, HIPAA compliance work could not easily be assigned to existing organizational structures such as the information technology department because it entailed changes in policy and procedures as well as technology, changes that required review and discussion by the many different constituencies composing modern healthcare organizations, including patients and vendors as well as employees and consultants. Thus, organizations had to "sponsor" HIPAA.

Mobilizing such efforts, however, bear many of the hallmarks of "social movements." Social movements generally press for changes in ways of thinking, social practices and social structures but emanate from the grassroots. For example, the American Civil Rights Movement attempted, among other things, to undermine racial prejudice, promote racial integration in public institutions, and eliminate all forms of legal segregation. Demand for these changes emerged from multiple sources within both the black and white communities, including churches, labor unions and other forms of formal organization. The Civil Rights Movement produced national, regional and local champions who targeted certain social practices and institutions for focused attention and mobilized new social groupings through which they sought a generalized change in the American way of life. Social conflict emerged, often in brutally physical forms, and over a long period, major changes occurred in relations among black and white Americans. In the context of bureaucratic change, even "sponsored" reforms require champions working at all levels of the organization to translate the requirements into practice and overcome practical resistance. HIPAA compliance encounters practical resistance because it competes with the routine business of healthcare, engenders conflict, and thus, fights for its bureaucratic life. Without concerted "grassroots" effort by champions at many levels of the organization, the HIPAA reforms cannot survive or may become mere compliance efforts that change little in the structure or practice of health information security.

In large, complex organizations, bureaucratic reforms such as HIPAA depend upon changes at multiple levels of the organization including individual, group and organizational levels. The concepts of practical resistance and sponsored social movement apply across the levels, to each level and to segments within levels as well as the organization as a whole. In a fundamental sense, practical resistance to bureaucratic reforms necessitates mobilizing reforms through sponsored social movements. The interaction of practical resistance and sponsored social movement yields a complex political field marked by reform sponsors, reform resisters, reformed practices, and residual, now deviant practices. The long term fate of specific reforms depends on how the interaction of practical resistance and sponsored social movement among all these different activities, actors, interests and organizational levels evolves over time.

We observe this complexity in the successful effort to change health information security policies, procedures and practices for the US Department of Defense (DoD) Military Health System (MHS) to comply with the HIPAA privacy and security regulations. (US Air Force Medical Service 2003)

Organizational Level

The MHS officially sponsored and coordinated the defense HIPAA reforms using a common format known as the HIPAA Integrated Project Team or HIPAA IPT. (Kelly 2002) The HIPAA IPT received an official charter with requirements and formally appointed members representing key stakeholders, including the Army, Navy and Air Force Surgeons General and key components of the Office of the Assistant Secretary of Defense (Health Affairs). As each set of rules under the HIPAA Administrative Simplification provisions emerged, the HIPAA IPT spawned Working IPTs (WIPTs) to devote specialized attention to each one, including transactions and code sets, privacy and security. Again the WIPTs included a charter with requirements and officially appointed members representing key stakeholders, many of whom served on all four teams. These teams met monthly.

In addition to the officially appointed members, supporting staff and consultants attended the monthly meetings and performed much of the background work. Occasionally, representatives of stakeholders potentially affected by but not directly implicated in HIPAA would also attend. The HIPAA IPT and three WIPTs established the strategic direction as well as specific lines of work in sponsoring the MHS HIPAA compliance effort, such as drafting and coordinating HIPAA-related DoD policies, implementation guides and training materials. The HIPAA IPT coordinated major investments in enterprise capabilities such as computerized HIPAA training and compliance management systems. The HIPAA IPT funneled centrally-provided funds to MHS and service HIPAA efforts. The HIPAA IPT and the three WIPTs also functioned as platforms for presenting, discussing and sponsoring tools, meetings, and educational efforts funded by other MHS or service agencies. As the primary forums for addressing strategic compliance efforts, the HIPAA IPT and WIPT meetings created conditions and opportunities for conflict among participating constituencies but, from a global perspective, accomplished their objectives in planning and implementing the MHS HIPAA compliance effort.

As a Federally-mandated requirement, none of the military medical services could ignore HIPAA. Thus, each service formulated its own HIPAA-compliance effort that included sending representatives to the HIPAA IPT and WIPT meetings. Yet, depending on the specific HIPAA rule set, to different degrees they did or did not follow the lead of the HIPAA IPT and WIPTS. Each was subject to dynamic service-specific conditions that affected both their approach to HIPAA in general and their manner of participation in the various HIPAA WIPTs. These service-specific conditions produced differences in their individual interpretations of HIPAA, the new efforts they thought necessary and, thus, the extent of their "sponsorship" of HIPAA reforms within their own services. For the HIPAA Transaction and Code Set rule, the MHS and services shared common interests given the complete novelty of the requirements and its limited impact on daily operations beyond the billing operation. The HIPAA Privacy regulation built on the experience of the MHS with the Privacy Act but instituted new practices some of whose implementation could be centrally-funded and broadly shared such as posting of the Notice of Privacy Practices and training. Points of contention and practical resistance emerged where the HIPAA privacy regulations required extensive new effort at the local level as with disclosure tracking. Because it potentially required investment of new resources of time, effort and funds at the local MTF level, HIPAA Security provoked the greatest variation and controversy, particularly the requirement to conduct a local information security risk assessment.

With the engagement of MTF resources, organizational "sponsorship" required concurrence of regional and local as well as headquarters leadership. For one service, regional and local "pushback" produced a judgment that existing procedures sufficed and, thus, HIPAA security warranted no new investment of local resources. This delayed progress on implementing key HIPAA Security WIPT-approved programs in that particular service for many months. For the other services, the majority of regions and MTFs eventually concurred but at varying rates, with varying degrees of enthusiasm and with varying degrees of effectiveness. Working these new tasks into the local work routine required making adjustments in local priorities and resource allocation as well as fostering new groups. Thus, practical resistance expressed as regional and local priorities conditioned the distributed impact of strong central sponsorship from MHS and service senior leadership.

Group Level

The DoD HIPAA Security campaign required creating new groups at the MTF level, known as the Medical Information Security Readiness Teams (MISRT) (Jenkins 2002; Randolph 2004; department of the Army 2003). Envisioned as an interdisciplinary team of clinicians, medical records managers and information technologists, the MISRT were intended to function as local facilitators, staff and advocates for the MHS HIPAA security campaign. Their primary responsibilities included executing the MTF information security risk assessments, developing and implementing the plan to close gaps in the MTF's HIPAA security compliance, and securing command support for the results of their work. They brought the HIPAA security social movement to the local MTF level. Many conditions affected their ability to accomplish their tasks and mobilize HIPAA security at their MTFs.

First, by virtue of being interdisciplinary with only one of three constituencies avowedly "expert" in computerized information systems, the MISRT required training in HIPAA security and the information security risk assessment method (Jenkins 2002; Randolph 2004). Multiple rounds of training accomplished this task for over 1500 individuals from all MTFs around the globe. Second, given that the MISRTs work required adding new tasks to already full workdays, a strong mandate had to exist in order to justify diverting them from their primary tasks. When the training started in January, 2001, release of the final HIPAA security regulations seemed imminent and a strong sense of urgency existed at all levels of MHS and service leadership. Upon repeated delay of the security regulations' release, the sense of urgency and accompanying mandate waned. When the Department of Health and Human Services (DHHS) ultimately released the privacy regulations before the security regulations, the mandate shifted from security to privacy. Because HIPAA required established security controls in support of privacy, training in risk assessment continued but the actual privacy work took precedence and preempted almost all effort on risk assessment. Third, service personnel in the US military do not stay long in one post, least of all officers. With the emergence of privacy and subsequent delay in security-oriented work, many of the trained MISRT individuals transferred to new assignments. In some cases, trained individuals assumed new positions that permitted them to be reassigned to the MISRT. In many cases, however, the military mandate to diversify officers' work experience shifted trained MISRT individuals away from the HIPAA effort entirely. Fourth, thanks to the attacks on 11 September 2001, the United States went to war. Thus, in addition to experiencing turnover from the normal process of reassignment, many MTFs lost trained MISRT to deployment in support of the wars in Afghanistan and Iraq. Thus, during the period 2001-2004, conditions did not favor effectively establishing the MISRT at the MTF level.

Individual Level

The concept of "career" helps link individuals to the HIPAA security social movement. With the possible exception of local military IT staff, HIPAA tasks of whatever sort constituted an extra duty for military personnel not recognized in their job descriptions or necessarily acknowledged in considerations for promotion. Indeed, observations suggest that failures in activities like HIPAA compliance work can hurt but successes have little or no effect on chances for advancement. Consequently, service personnel have little personal or professional interest in diverting their attention from their regular assigned to new HIPAA-related duties. As a result, they seek others who can execute most of the work while they adopt a supervisory role. Consultants or government workers frequently fill this role. Thus, "sponsoring the social movement" at the local level often included providing consultants who could perform or, at least, facilitate performance of the new tasks. Because conducting the risk assessment required soliciting, interpreting and acting upon local funds of knowledge held primarily by military personnel, a conflict existed between the requirements of the task and the career requirements of military personnel participating in the MISRT. Moreover, responsibility for fostering the social movement shifted from members of the organization to outsiders with minimal authority or respect. These conditions sometimes produced what experienced military personnel know as "pencil whipping", performing the least work necessary to be said to have accomplished the task. Where military or consultant champions existed, local MTFs accomplished much beyond the minimum necessary compliance work.

To its credit, the MHS achieved its mission and compliance for all three elements of the HIPAA Administrative Simplification section on time. In the transition from achieving initial compliance to sustaining HIPAA, the MHS formed and fully staffed the TMA Privacy Office in order to continue sponsoring the HIPAA privacy and security reforms (see http://www.tricare.mil/tmaprivacy/default.cfm). This office continues to sponsor monthly meetings of HIPAA service representatives and a variety of activities in support of central, service and MTF compliance. Snook's analysis would lead us to begin checking for "practical drift" or the "slow steady uncoupling of practice from written procedure" as services and MTFs adapt their HIPAA practices to work with locally practical actions, at least until some incident occurs that highlights the differences between design and implementation some place across the MHS.

Interpreting sponsored social movement and practical resistance as paired concepts helps us recognize the fundamentally political character of bureaucratic reform. For every sponsor or grassroots champion of a reform, we find many practical resisters. From the perspective of sponsors, grassroots champions, oversight officers, and reformers, practical resisters seem like recalcitrant impediments to achieving the desired end state. From the perspective of practical resisters, however, the reforms may pose new and unnecessary barriers to accomplishing their primary obligations such as patient care in a locally efficient manner. In the case of HIPAA, FISMA and similar information security reforms, few people quarrel with the desire to protect the privacy and ensure the security of personal health information. Yet, some procedures developed as part of the reform effort interfere with the work that the overall system exists to accomplish, at least from the worker's point of view. "Compliance" with the requirements of bureaucratic reform, thus, unfolds as the emergent result of these ongoing negotiations.

TRANSCENDING THE LIMITS OF TRADITIONAL INFORMATION SECURITY

Healthcare organizations take confidence that, by implementing common good information security practices such as risk management, staff training, technical and physical controls, they adequately protect patient health information. However, deep-rooted relationships among organizational culture, information system design, and health information security generate both unexpected threats and resistance to reform in the practice of information security. An organization may assess issues that originate outside the bounds of traditional information security concerns by evaluating its operations and culture from a sociological perspective.

Karl Weick and Kathleen Sutcliffe (2001) attribute the success of High Reliability Organizations (HROs) in managing the unexpected to their "determined efforts to act mindfully." (p.3) They caution that, in all cases, failures are inevitable but should not necessarily be disabling. For an organization to recover from failure, however, it must be "mindful" of, and interrupt failure's emergence in their everyday operations. HROs "organize themselves in such a way that they are better able to notice the unexpected in the making and halting development. If they have difficulty halting the development of the unexpected, they focus on containing it. And if some of the unexpected breaks through the containment, they focus on resilience and swift restoration of system functioning." (p. 3) Weick and Sutcliffe (2001) identify five specific features that characterize mindful HROs, including:

1. **Preoccupation with failure:** HROs recognize that any lapse could be a symptom that something is wrong with the system and, if other small errors happen to coincide, severe consequences could result. To avoid this situation, they encourage reporting of errors, determining lessons learned from near misses, being wary of complacency, reducing margins of safety and drifting into automatic processing.
2. **Reluctance to simplify interpretations:** HROs take deliberate steps to simplify less and see more. They encourage those with diverse experience to cross boundaries, express skepticism toward received wisdom and to use negotiating tactics that reconcile differences in opinion yet preserve the nuances that diverse skills and knowledge detect.
3. **Sensitivity to operations:** HROs recognize that latent failures exist in the system's defenses, barriers and safeguards and that they may become manifest in inconsequential ways prior to a major accident. HROs expect normal operations to reveal such deficiencies as "free lessons" and incorporate them into their organizational safety program. Encouraging well-developed situational awareness permits continuous adjustments and prevents such errors from accumulating and enlarging.
4. **Commitment to resilience:** HROs experience but are not disabled by errors. In addition to encouraging experts to develop skills that cross domains and participate in frequent training, HROs formally assess worst case scenarios and use the equivalent of fire drills to test their ability to address these scenarios.
5. **Deference to expertise:** To prevent the deadly scenario where errors at higher levels combine with errors at lower levels of an organization to make problems catastrophic, HROs seek out the front line individuals with specific knowledge of the situation and the individuals with the most expertise, regardless of experience or rank. Decisions are made on the front line with authority coming from the experts.

Weick and Sutcliffe (2001) propose that organizations assess themselves for mindfulness by the use of an audit. We applied this approach by identifying behaviors in health information management and health information security indicative of mindfulness. To formulate our mindfulness questions, we used as guides the audit questions for the five areas of resiliency presented in Weick and Sutcliffe (p. 85-115). We suggest that health care executives use these questions as guides to evaluating their health information security programs in terms beyond the narrow orthodoxy illustrated by the previously discussed surveys The more frequently an organization answers "Yes" to these questions, the more mindfully they operate in the domain of information security. Yet, if taken in the proper spirit, answering these questions will help identify areas of relative mindlessness and, thus, of concern. At one extreme, we raise the possibility of organizations who address information security from a mere "compliance" perspective. Indifferent to the actual protection of their patient data, they only want to "pass the test". At the other extreme, we envision organizations that recognize the possibility of information security as a part of the "total task". Such organizations will mindfully attempt to reconcile the demands of information security and clinical care and, thus, minimize practical resistance such as witnessed with smartcards in the UK NHS EHR.

The audit's five section headings refer to the five characteristics of mindfulness explained above (for example, I. Assessing Your Firm's Preoccupation with Failure). The numbered statements (for example, "1. People in this organization expect, and look for a major information security breach to occur eventually.") originate from the self-audit of Weick and Sutcliffe. We have revised their questions related to mindfulness to refer specifically to information security practice. After completing the survey and developing a general picture of its information security mindfulness profile, an organization should select key issues for more detailed review, particularly but not exclusively questions that receive "No" for an answer. Areas in which an organization feels it displays strong qualities of mindfulness might offer lessons to less well-developed areas and, thus, also warrant detailed review.

MINDFULNESS IN INFORMATION SECURITY AUDIT

Please answer "Yes" or "No" for each question.

- Assessing Your Firm's Preoccupation with Failure.
    1. We focus more on information security outcomes than compliance with regulations?
    2. We treat near misses and errors as information about the health of our information security program and try to learn from them?
    3. We make it hard for security violations to go unnoticed?
    4. Managers seek out and encourage bad news about our information security program?
    5. People feel free to talk to superiors about problems with our information security program, including how it disrupts clinical practice?
    6. People are rewarded if they spot problems, mistakes, errors, or failures in our information security program?
- Assessing Your Firm's Reluctance to Simplify.
    1. People in this organization seek and expect major information security breaches to occur?
    2. Our leadership regularly queries the staff about possible deficiencies in our information security program?
    3. We actively seek opportunities to improve information security policies, procedures and practices?
    4. People in this organization feel free to bring up problems and tough issues in our information security program?
    5. Our organization thoroughly investigates actual and near miss security breaches?
    6. People are encouraged to express different views of the impact and effectiveness of the information security program?
    7. People listen carefully to all perspectives on the information security program?
    8. People are not punished for surfacing information security issues that could interrupt operations?
    9. When an information security incident occurs, people are more concerned with listening and conducting a complete analysis of the situation than with advocating for their view?
    10. We appreciate skeptics of the design and implementation of the information security program?
    11. People demonstrate trust in each other during discussions of information security issues and incidents?
    12. People show a great deal of mutual respect for each other when discuss-

ing information security issues and incidents?

- Assessing Your Firm's Sensitivity to Operations.
    1. Someone pays attention daily to information security and remains readily available for consultation if something unexpected arises?
    2. Should an information security incident occur, someone with the authority to act is always accessible and available, especially to people on the front lines?
    3. Supervisors readily engage in managing information security incidents?
    4. People openly discuss information security issues during their day-to-day activities?
    5. People are always looking for feedback about things that do not go as expected with the information security program?
    6. People are familiar with information security operations beyond their own job?
    7. We have access to resources if unexpected information security surprises emerge?
    8. Managers constantly monitor workloads and obtain additional resources if an information security issue requires extra attention and work?
- Assessing Your Firm's Commitment to Resilience.
    1. We devote great attention to assessing and analyzing information security risks?
    2. We devote resources continually to training and retraining people on the properties of the information security technical system?
    3. People have more than enough training and experience in information security?
    4. This organization actively develops staff members' skills and knowledge in information security?
    5. This organization encourages challenging stretch assignments when promoting people through the security ranks?
    6. People are known for their ability to use knowledge in novel ways when addressing information security issues, incidents and problems?
    7. This organization builds staff member competence and response repertoires in the domain of information security?
    8. People draw upon informal contacts to help solve information security problems?
    9. People learn from their information security mistakes, breaches and incidents?
    10. People are able to rely on others when attempting to solve information security problems?
- Assessing the Deference to Expertise in Your Firm.
    1. People are committed to doing information security well?
    2. People respect the information security dimension of each other's job activities?
    3. If an information security incident occurs, people know who has the expertise to respond competently?
    4. People in this organization value expertise and experience over hierarchical rank when addressing mistakes, breaches and incidents in information security?
    5. In this organization, the people most qualified to make decisions about information security make them?
    6. If an information security incident occurs, the most highly qualified

people, regardless of rank, make the decisions?

7. People typically "own" an information security problem until it is resolved?
8. It is generally easy for us to obtain expert information security assistance when something comes up that we don't know how to handle?

CONCLUSION

In this chapter, we offer a broad perspective on information security that links traditional, widely-accepted practices with the sociological literature on organizational performance. Our experience suggests two reasons for adopting a broader perspective. First, serious information security breaches may originate from organizational conditions not obviously related to traditional information security policies, procedures or practices (Collmann and Cooper 2006). For example, the failure to integrate new application development and implementation into an organization's overall information management program may inadvertently yield security breaches. Second, information security practices operate in, and are affected by the context of their parent organization (Cooper and Collmann, in press). Although it is sometimes tempting to treat information security as a domain of its own, this approach will inevitably yield failures of information security and failures for the organization. For these reasons, we offer in the chapter a survey to help health care executives link the domain of traditional information security good practice to its organizational context while planning, developing and evaluating efforts to protect the privacy and security of their patient and business health information.

We began our study with references to High Reliability Theory. In recent years, the Software Engineering Institute (SEI) has conducted an important series of studies designed to improve the resiliency of organizational information security programs through engineering design. With origins in efforts to develop self-directed information security risk assessments and understand network survivability, the SEI Resiliency Engineering Framework Team recently issued a preview version of the *CERT® Resiliency Engineering Framework* (2008). In many important ways, this work supports and converges with the approach outlined in this chapter, particularly in its attempt to integrate SEI's deep knowledge and long experience in computer science engineering in information protection with an organizational perspective. All healthcare executives should become aware of this body of work (see http://www.cert.org/resiliency_engineering). While not yet reduced to an implementable planning and design tool, the CERT Resiliency Framework should at least orient healthcare executives to specific issues in linking information protection programs to their organizational context. As a formal protocol for analysis and potential organizational change, the CERT Resiliency Framework goes beyond the objectives of this chapter. We are currently exploring the points of convergence and divergence between our approach and the CERT Resiliency Framework, particularly those rooted in differing images of "organizational context" and differing emphases on anticipation and response in the information protection developmental cycle. A middle ground must exist that enables formal protocols and meticulous examination of the flow of events to yield better methods for protecting sensitive personal and business information in complex organizations.

KEY TERMS AND DEFINITIONS

Information Security: An established body of good practices developed to protect the confidentiality, integrity and availability of information.

Information Security Breach: A violation of organizational policies, procedures and established practices for protecting the confidentiality, integrity and availability of information.

Mindfulness: An organizational process that attends to small deviations from expected behavior and, thus, prevents small errors or failures from escalating into major catastrophes.

Normal Accident: A component or system failure that occurs because of the design and routine operation of the system itself rather than poor performance of individual operators.

Practical Action: Behavior that enables people to accomplish their tasks efficiently, is learned on the job and goes unquestioned because it generally works without incident.

Practical Resistance: Behavior through which people resist changing locally efficient practices developed with experience, potentially subvert compliance efforts in daily practice, and tacitly or explicitly protest against proposed changes to their standard way of doing business.

Sponsored Social Movement: A reform process that combines "top down" with "grassroots" efforts to change an existing organizational system.

Chapter 5.13

Demographic Differences in Telehealth Policy Outcomes

Mary Schmeida
The Cleveland Clinic, USA

Ramona McNeal
University of Northern Iowa, USA

ABSTRACT

This chapter is an analysis of demographic variables influencing policy outcomes with online health information searches in the general U.S. public. This study is based on The Internet and American Life Daily Tracking Survey, August 2006 from the Pew Research Center for the People and the Press. Multivariate regression statistical technique is used to explore changes in individual level behavior following the search for online medical information. The data show individuals in most need of healthcare services (poor, less educated, and minority groups) and those with a recent demand for services, are more likely to make changes to improve their health after accessing online medical information.

INTRODUCTION

The public sector in the U.S. is increasingly using the Internet to provide information, deliver services, and interact with citizens, businesses, and other government agencies (West, 2003, 2004). There are numerous reasons for the government adoption of electronic government (e-government) practices that "refer to the delivery of information and services via the Internet or other digital means" (West, 2004, pp 2). E-government is expected to deliver services and information around the clock, making government more efficient and transparent to the public (Tolbert and Mossberger, 2006; West, 2003). The adoption of these practices may make government more responsive through its ability to provide communication options that are quicker and more convenient for users (Thomas and Streib, 2003).

Telehealth is an important example of e-government that takes on many forms. Although there is no consensus on its definition, the United States Congress defines telehealth as the use of electronic information and telecommunication technology to support long-distance clinical healthcare; patient and professional health-related education; public healthcare and administration (U.S. House of Representatives 2157, 2001). In practice, telehealth is understood as the inclusion of telemedicine plus other on-line social services.

DOI: 10.4018/978-1-60566-002-8.ch036

Regardless of how telehealth is defined, this new medium for delivering medical services has been adopted with the goal to improve the accessibility of public and private healthcare, service quality and clinical outcomes. It is often implemented as a way to provide cost-effective healthcare. However, if we examine all the different aspects of telehealth in the U.S.—technology-enabled delivery, regulation and enabling legislation (state policies), and healthcare information available online, we find a unifying theme of broadening healthcare access. Telehealth practices may act to expand healthcare services through improving the dissemination of health information by Internet to the public, facilitating Internet based second opinions on disease management, improving consultative services to rural facilities and has the potential to reduce medical errors (Schmeida, 2005).

Despite the hopes for telehealth (as well as other forms of e-government), there is also a literature suggesting that these service delivery advancements will not live up to expectation. One barrier to the Internet for expanding healthcare access is the Internet cleavages that exist among United States citizens---people who do and do not use the Internet. These differences in Internet usage are based on a number of socioeconomic factors including age, income, education and race. The variation in Internet practices attributed to these socioeconomic factors has been linked to underlying inequalities in Internet access and technological skills, along with psychological barriers (Mossberger, Tolbert and Stansbury, 2003; Stanley, 2003). This suggests that e-government will only act to widen the gap between those that do and do not benefit from telehealth services.

Supporting this literature on Internet inequalities is research examining the differences in online health information searches among the various socioeconomic groups in the U.S. (Schmeida and McNeal, 2007). In exploring differences among socioeconomic groups in searching for Medicare and Medicaid information online, Schmeida and McNeal (2007; 2006) find some disparities are narrowing as the elderly and poor in need of these publicly subsidized health insurance programs are online searching for information at the U.S. Centers for Medicare & Medicaid Services Web site. Services and information obtainable at this Web site include eligibility criteria, enrollment procedures, Medicare plan options, local physicians and medical suppliers, pharmacy directory and healthcare chat rooms. In addition, beneficiaries can obtain personal information on their benefits and services. However, people without Internet access and experience, remain disadvantaged in accessing this critical information that can link them to needed healthcare services, suggesting that e-government service delivery advancements may not be living up to expectation.

This current research on Internet healthcare information and government services only represents an initial step in exploring the impact of online health searches and does not discuss the policy implication of these findings. To minimally understand the healthcare consequences of disparities in Internet usage in the U.S., one needs to examine if telehealth is changing how citizens take care of themselves and others. This chapter discusses these behavioral outcomes and the policy implications. In exploring this issue, this chapter will first examine the literature on barriers to the promises of e-government with a focus on the digital divide. Next, it will outline government policy toward eliminating barriers to Internet use. Finally, multivariate regression analysis will be used to empirically test the impact of one example of telehealth (seeking medical information online) and behavior directed toward improving and maintaining health.

THE REALITIES OF INTERNET USAGE IN THE UNITED STATES

Despite the promises of e-government, there is a literature suggesting there are barriers to realizing its possibilities in the United States. One reason is cleavages that exist between those who have and do not have access to this technology. These differences in access are referred to as the "digital divide." There is an extensive body of literature finding that Internet access is not distributed equally in the U.S. based on socioeconomic factors (Pew Internet & American Life Project, 2003; Mossberger, Tolbert and Stansbury, 2003).

Mossberger, Tolbert and Stansbury's (2003) research found gaps based on income, education, age and race/ ethnicity that continue to exist even after strides toward digital inclusion. The study indicated that Asian Americans had the highest predicted probability of access followed by whites with Latinos and African Americans significantly trailing behind. Furthermore, Internet access has not been adopted equally based on region and geography. West and Miller (2006) find U.S. regional disparities in Internet accessibility, privacy and security with southern states having lower levels of Internet connectivity.

Another barrier to widespread e-government is lack of technological skill. The use of e-government requires skills, such as being able to use a computer mouse and knowing how to find Internet information. Younger individuals are more likely to carry these skills because of Internet exposure in school. Respondents to the Pew Internet and American Life Project 2003 survey, *Ever-Shifting Internet Population*, were asked why they do not go online. Forty-six percent of respondents indicated they lack the technological ability to navigate the Web because of its complexity.

Mossberger, Tolbert and Stansbury (2003) find that computer technology skills can be summarized into two broad categories. The first category (technical competencies) includes the necessary skills to use hardware and software such as typing and using a mouse. The second (information or basic literacy) concerns the ability to determine what information is obtained from the Internet for specific tasks (Mossberger, Tolbert, and Stansbury, 2003: pp. 38). Their study shows the individuals lacking the technology skills necessary for Internet use includes those older, less educated, less affluent, Latino, and African American. Since these factors are the same as those associated with the "digital divide," they may work to exacerbate the gaps in usage based on access.

While the findings from the Mossberger, Tolbert and Stansbury (2003) study point to socioeconomic factors as predictors of the skill divide, other research adds psychosocial variables to the list of barriers to developing technological skills. Stanley's (2003) research found motivation as a significant element of digital skill development. Her research examined "new computer users," or individuals with limited experience and "non-computer users," those with minimal or no computer ability to determine what factors acted as a barrier in developing computer skills. The individuals in her study were primarily low income and had resisted obtaining computer skills until economic motives (finding a job, gaining a promotion, or getting a better job) led them to seek training. The findings revealed that psychological barriers (such as computer fear and poor self-concept) were more important than education in preventing computer skill development (Stanley, 2003: pp. 410-13). All of these study findings suggest there are potential barriers to the development of e-government use in the U.S., despite its promises.

U.S. GOVERNMENT POLICY ADDRESSING UNEVEN INTERNET USAGE

Although the federal government has pushed for adoption of e-government practices, its policies for eliminating Internet use disparities has been fragmented and piecemeal. Policy with the Clinton administration stressed public access strategies, emphasizing connectivity in libraries and schools with funding authorized by the Telecommunications Act of 1996. Two of these programs which provided more flexible funding were largely eliminated under the Bush administration.. The Technology Opportunities Program (TOP), offered grants for public Internet access and technology projects to solve social problems (Edutopia News, 2004). The Community Technology Centers Program provides matching grants for state-local, and nonprofit sectors providing public access in the community. Program funding fell from $32 billion to only $5 million in the 2005 budget (Edutopia News, 2004).

The government is addressing regional disparities to Internet use by mandating private-sector telephone companies to improve access and affordability of Internet to rural America. The Telecommunications Act of 1996, for example, keeps rural policy on the same trajectory as urban policy by requiring that companies provide affordable telehealth utilities in rural America as they do to urban counterparts in the same state (Schmeida, 2005). Recent Congressional hearings also target reform in the Federal Communications Commission universal service fund subsidizing rural Internet services for elementary and secondary schools public libraries and not-for-profit rural healthcare providers (U.S. House of Representatives, 2006).

Under the Clinton administration, libraries provided public access for computers and the Internet and a source for Internet training. Studies conducted by the University of Washington revealed that 30% of library patrons have no other Internet access. Job search is especially important for low-income library users, and medical information searches are prevalent in rural areas (Gates Foundation, 2004).

Under the Bush administration, policy for eliminating Internet use disparities switched from providing public access to improving Internet skills through the requirements of "The No Child Left Behind Act." Since implementing this policy, there has been progress in providing more technology in the schools (Kleiner and Lewis, 2003). Yet, schools face shortages in funding for computer maintenance and support staff and in some districts partly rely on students for technical support.

The review of the current U.S. policies regarding e-government and unequal Internet usage reveals contradictory policies. On the one hand, the federal government has strongly encouraged government units to adopt e-government practices for providing information and services. Yet, there are gaps in Internet usage based on a number of demographic factors limiting individual citizens who can benefit from the practices. This is coupled with policies addressing the disparities in Internet use that can at best be described as fragmented and piecemeal. What are the consequences of such conflicting policies with regard to telehealth? Is telehealth practice aiding those in greatest need of healthcare services, or resulting in greater inequality of service delivery?

DATA AND MEASUREMENT

In an attempt to address these questions, this chapter utilizes *The Internet and American Life Daily Tracking Survey, August 2006*; conducted for the Pew Research Center for the People and the Press, by the Princeton Survey Research Associates. The Pew survey is a random digit dial national telephone survey conducted in August 2006 and has a sample size of 2,928. In this study, we limit our exploration to the 1,594 respondents who reported searching for healthcare information online. Our dependent variable is represented by a count of the number of 6 healthcare activities an individual performed following a health information search online, see Table 1.

Since the current literature (Schmeida and McNeal, 2007; 2006; Mossberger et al, 2003) suggests that demographic and region factors are important in determining searches for online health information, variables are included for age, gender, education, income, full-time employment, part-time employment, African American, Asian American, Latino, Northeast, Midwest and the West regions. Age is in years and gender is mea-

Table 1. Dependent variable- searching for health information online (Pew Internet and American Life Project, 2006)

Did the information you found online affect a decision about how to treat an illness or condition?
Did the information you found online change your overall approach to maintaining your health or the health of someone you help take care of?
Did the information you found online change the way you cope with a chronic condition or manage pain?
Did the information you found online affect a decision about whether to see a doctor?
Did the information you found online lead you to ask a doctor new questions, or to get a second opinion from another doctor?
Did the information you found online change the way you think about diet, exercise, or stress management?

sured using a binary variable coded 1 for male and 0 for females. Education is measured using a 7-point scale, ranging from less than a grade-eight education to a Ph.D. education. The income measure is based on an 8-point scale where 1 indicates that family income ranges from \$0 to \$10,000 and 8 signifies a family income of \$100,000 or more.[1] A binary variable is used for full-time employment coded 1 for full-time and 0 other wise, a similar variable is used for part-time employment. To control for race and ethnicity, dummy variables are included for African Americans, Asian Americans, and Latinos with non-Hispanic whites as the reference group. Three variables are used to measure region---Northeast, Midwest and West with South as the reference group. Measures for need/ demand were also added including recent medical care experience, recent medical diagnosis and recent medical emergency. Each is binary coded 1 for yes and 0 for otherwise.[2]

FINDINGS

Since the dependent variable represents a count of different behavioral health outcomes/ action to online health information searches, a Poisson regression model in Table 2 is reported. A number of demographic factors were found to statistically predict policy outcomes. Contrary to expectation, many demographic groups who are least likely to have Internet access at home are most likely to have taken health-related action to the health information they searched on the Internet. Our model shows the less-educated, poor, African Americans, Latinos and those living in the south were more likely to have taken action after reading online healthcare information. Additionally, people with a recent new medical diagnosis and recent medical emergency experience were also more likely to have taken action. Table 2 shows the coefficient for education is statistically significant and negative. As education decreases, the probability of behavioral outcomes increases even after controlling for age, gender, income, employment, race, ethnicity, geography, and demand. The less educated are not only less likely to have Internet use at home (Mossberger et al., 2003) but those who do have access and searched for health information online are more likely to take some health-related action after their searches.

The coefficient for income is also significant and negative. The poor are more likely to take health-related steps after an online health information search than the wealthy. Our model also indicates that minority groups (African American and Latino) were statistically more likely than Caucasians to take action after online searches. Region is also a significant predictor in our model. The coefficient for *Midwest Region* was significant and negative. This suggests that residents of the South searching for health information online have a greater chance of taking action following their search than those living in the Midwest.

Two demand variables were important predictors in our model. We find the online health searchers who have had some type of recent interface with the health system are more likely to take some type of health-related action after their online information searches. The variable for *Recent Medical Diagnosis* was significant

Table 2. Poisson regression models- health behavior outcomes to online health searches

VARIABLES	β (se)	p>|z|
Age	.001(.002)	.727
Male	-.039(.049)	.428
Education	**-.053(.017)**	**.002**
Income	**-.028(.013)**	**.032**
Full-time Employment	-.025(.058)	.664
Part-time Employment	-.129(.085)	.127
African American	**.288(.075)**	**.000**
Asian American	.162(.176)	.359

Poisson regression estimates with standard errors in parentheses. Unstandardized coefficients reported. Reported probabilities are based on two-tailed tests. Statistically significant coefficients at .10 or less in bold (Pew Internet and American Life Project, 2006).

and positive. Individuals who either personally or had someone close recently diagnosed with a chronic medical condition (such as asthma, diabetes, heart disease, or high blood pressure) and then searched for health information online had a greater chance for taking some type of action after the search. The factor *Recent Medical Emergency* was also significant and positive. Individuals (or someone close) who had faced a serious medical emergency or crisis and then searched for information online had a greater chance for taking a health-related action.

DISCUSSION

Our chapter attempts to explore the differences in policy outcomes with online health information searches in the general U.S. public. It goes beyond the current research exploring differences based on demographic factors in the use of telehealth without exploring the consequences of these inequalities. The outcomes under study are the health behaviors that occur as an effect to online health information searches at home---seeking a second opinion from another doctor, changing self-care practices, changing one's way of pain management, among other.

We find that certain demographic variables are statistically associated with behavioral outcomes of online health information searches. The demographic groups found in this study (less educated, poor, African American, Latino) to act on online healthcare information are surprisingly the same groups found least likely to have Internet access and Internet literacy skills for the U.S. In other words, those least likely to use the Internet are most likely to take steps toward improving their health if they do access healthcare information online. We also find that severity of need/ demand to online searches (individual facing medical crisis and new medical diagnosis) is important in influencing the health-related behaviors that occur after online health information searches are made.

How do we settle the contradiction in our findings? Why are those individuals who are least likely to have Internet access and the necessary skills to use it, most likely to benefit from healthcare searches online? To answer this question, we turn to previous work by Mossberger, Tolbert and Stansbury (2003). They found that even though African Americans and Latinos were less likely than similarly-situated whites to have home computers or home Internet access, to use the Internet as frequently, to report sufficient skills, or to use the Internet at all, they were more likely than whites to express positive attitudes about technology. Additionally, they found that

African Americans were statistically more likely than whites to use the Internet for activities, such as job search and online classes. Mossberger and Tolbert (2005) resolved the contradiction in their earlier findings through using hierarchical linear modeling to illustrate that factors, such as concentrated poverty and racial segregation are responsible for what seem like racial differences in Internet usage. Their research indicated that factors, such as community educational attainment and median income, explained more of the variation in frequency of Internet use than individual characteristics.

The findings of this chapter and the research by Mossberger and Tolbert (2005) are somewhat reassuring. Despite fears that those individuals most likely to benefit from e-government would be left out, they appear to be using the Internet to access services, such as healthcare, education and job searches. Furthermore, this chapter shows those most in need of healthcare services are more likely to take measures to improve their health after reading health/ medical information online. However, there is also indication that the policies enacted in the U.S. to alleviate gaps in Internet use are insufficient and under stress. Libraries have become the temporary solution for inequalities in Internet access and skill. Nevertheless, they are showing the strain of this responsibility as funding of public libraries is insufficient to keep up with Internet access demand (Bertot, McClure, Jaeger, and Ryan, 2006; Gates Foundation, 2005). Given the potential for telehealth and other forms of e-government to help deliver services and information to citizens, there is a significant need for a holistic policy for closing the gap between those who do and do not access the Internet.

KEY TERMS

Demographics: Population statistics about socioeconomic factors such as gender, age, education, income, marital status, ethnicity, etc.

Electronic Government (E-Government): The delivery of information and services online through the Internet or other digital means (West, D.M., 2000; p. 2)

Internet: A worldwide computer network that is capable of linking all network users.

Poisson Regression: A linear model, Poisson regression analysis is used when the response variable represents counts.

Telehealth: The term is often interchanged with telemedicine. There is no consensus on its definition. However, the United States Congress defines it as the use of electronic information and telecommunications technologies to support public health and health administration,long-distance clinical healthcare, patient and professional health-related education (H.R. 2157, 2001). An example of e-government.

Telehealth Policy: An electronic government policy that uses the Internet to improve accessibility of public and private and non-profit healthcare services in rural and urban areas, while improving the quality of services at lower service costs.

Technological Skill: Skills, such as being able to use a computer mouse and knowing how to find Internet information. Younger individuals are more likely to have developed these skills because of Internet exposure in school. A barrier to widespread e-government is lack of technological skill.

U.S. Internet Cleavages: Internet cleavages that exist among United States citizens---people who do and do not use the Internet, and can be based on a number of socioeconomic and psychological factors.

ENDNOTES

[1] This variable is further defined as the total 2005 family income from all sources, before taxes (Pew Internet and American Life Project, 2006).

[2] The variable *Recent Medical Care Experience* asks: "In the last 12 months have you visited a doctor or medical clinic for any reason, including check-ups or visits to the emergency room or hospital outpatient department?" The variable *Recent Medical Diagnosis* asks: "In the last 12 months have you or has someone close to you been diagnosed with a chronic medical condition, such as asthma, diabetes, heart disease, or high blood pressure?" *Recent Medical Emergency* asks: "In the last 12 months have you or has someone close to you faced a serious medical emergency or crisis?" (Pew Internet and American Life Project, 2006).

Chapter 5.14

Developing Global Competitiveness in Healthcare:

A Thai Healthcare Organization's Perspective

William P. Wall
Shinawatra University, Thailand

ABSTRACT

Healthcare is a competitive business in its own right. Global competition in healthcare adds yet another complex dimension to the success of a healthcare organization. Providing state of the art technology along with the manpower and management skills to bridge boundaries and cultures, confronts today's healthcare organizations with challenges that, while on the surface may appear simple, may also prove to be a bigger challenge to their success and survival than the medical care they are actually providing. This case study explores one major healthcare organization in Thailand posing the question of what it sees as critical to the success of healthcare competition in the global community. An inductive approach was utilized for a method of determining competitiveness. The resulting qualitative analysis of that data addresses issues of seeking and maintaining global competitiveness, providing superior quality care with competitive and reasonable pricing of sub-specialty and high acuity services and work effectively through strategic alliances. In the case of the healthcare organization in this study, global competitiveness is maintained through what they term "Thainess". That "Thainess" or ability to provide comfort and hospitality at the same time as providing excellent medical care and facilities give them both economy of scale to provide reasonable pricing and a uniqueness in the medical care provided. Uniqueness and quality in service attracts strategic alliances of similar quality and allows for expansion into global communities that were not possible in the past.

INTRODUCTION

As global economics change, the competitive pressure on companies and organizations becomes more intense. This is never more evident that in the current economic environment that is seen today. To that end, the main question to be answered today is what does the healthcare organization in this case study see from their perspective as critical to the success of healthcare competition in the global community? The private healthcare organization in this case study is one of a total of 344 hospitals with 35,086 beds in Thailand. Of these hospitals, 102 are private hospitals with a total of 15,000 beds located in Bangkok. 43% of the entire country's facilities are concentrated mainly in Bangkok (Kasikorn Research, 2007). Thailand as a destination for medical treatment has rocketed in recent years. As an example, over 60,000 United Arab Emirates citizens a year come to Thailand to avail treatment (Tourism Authority of Thailand, 2007). Over the past three years, the number of foreign patients has grown at a rate of 12.4% and is expected to reach 1.54 million this year. Medical tourism is quickly becoming one of Asia's fastest growing industries. It is projected by 2012 to be worth a minimum of $4 billion USD. Why? 1.3 million Tourists get the promise of low cost quality healthcare in countries like Thailand where the average medical tourist spends on average $362 USD per day, compared to the average traveler spending $144 USD. In addition those costs are five to ten times less expensive than in Europe and the US as in the following examples:

- **Cardiac surgery:** India $4,000 vs. United States $30,000 (Stokes, 2007)
- **Hip replacement:** Thailand, Singapore $13,000-$13,500 vs. United States $44,500 - (Global Doctor Options Guide, 2008)
- **Knee replacement:** India $7,000 vs. United States $45,000 (Wockhardt Hospitals, 2008)

The main reasons for this influx of medical travelers are lack of health insurance and the high cost of healthcare (Bernheim, 2008).

Private hospitals have also expanded their presence in regions where there are many foreign tourists and residents and increased business is also predicted from wealthy citizens of neighboring countries such as Vietnam, Laos, Cambodia and Burma.

Can management, technology and medicine be combined to provide a solution to healthcare that is both beneficial as well as affordable? What are the challenges facing hospitals today and in the coming years? How will they overcome those challenges? These questions must be continually addressed if today's healthcare system is to be effectively and efficiently competitive on a global scale (Cortez, 2008).

If an organization is to be profitable it needs to focus on three major areas of operation: quality service, competitive/reasonable pricing and the effective and efficient delivery of that service. Today's hospital must also be a strong financial institution.

METHODOLOGY

The research was conducted by way of a survey. To gather the required data to address the research questions, the main survey technique used was a questionnaire. While other instruments may be used to collect this data, it was found that the questionnaire is relatively inexpensive to administer and reasonably easy to analyze the data collected.

The construction of the questionnaire was accomplished by reviewing prior examples (Bowling, 2005). The procedure of the questionnaire construction is explained here addressing the subjects, the development of the questionnaire, components of the questionnaire, administration, collection and validity and reliability.

The objective of this research was to determine what major factor contributed to global competitiveness of this healthcare organization.

At this major healthcare organization, fifty subjects were investigated in this study: Senior Management (4); Administrators (8); Medical Personnel (21); and, Staff (17). These 50 subjects were chosen because it was believed that they represented the most significant subjects working in their respective divisions at the present time. The highest level of education among the subjects was a Doctor degree (33%) followed by a Master degree (57%) and all with Bachelor degrees with 23 subjects being male and 27 being female.

The questionnaire used in this research consisted of 17 questions written in English and was given to all 50 subjects. Closed-end and open-ended questions were used and the questionnaire was designed to relate to the purpose of the research and obtain relevant information from subjects (Appendix A). The administration of this questionnaire and the resulting clarification interviews were conducted by the researcher. Of the subjects given questionnaires, 40 were interviewed. These interviews were used as a means to expand and allow subjects to discuss openly and freely some of their responses to the questionnaire. From the data collected and from the information obtained, some irrelevant items were excluded and some ambiguities were clarified.

Questionnaire construction and subsequent interviews were conducted with no predetermined outcome in an effort to avoid any type of bias. Bias may arise in quantitative analysis, where quantitative researchers sometimes use it, for example in discussions of significance levels (Levine, 1993). It may also be used by qualitative researchers. Becker argued that sociological analysis is always from someone's point of view, and is therefore partisan (Becker, 1967). In this qualitative research, every effort was made to avoid biases and therefore, as stated in the previous paragraph, subjects were allowed to discuss their responses in the interviews openly and freely. The researcher also had no predetermined agenda or result in mind in the construction of the questionnaire or the resulting information derived from the questionnaire or the subsequent interviews.

Every effort was made to assure the validity of the research instrument. Development and construction of the questionnaire was based on literature and research reviews and preliminary discussions with subjects used in this research. Comments and suggestions were then incorporated into the final instrument to reflect a reasonable claim of face validity as justification of the questionnaire produced. The reliability value of the questionnaire was calculated using Cronbach's Alpha Method revealing the reliability coefficient of the questionnaire was .9693

The questionnaire (Appendix A) used in this study included 'open' questions that resembled interview scripts. Written responses were more likely to be one of conscious effort and not repetitive, while in an interview interesting responses could be explored interactively in great depth. Categories derived from the questionnaire responses were combined with categories derived from interviews in grounded theory analysis.

Grounded Theory (Strauss & Corbin, 1998) and Porter's Diamond (Porter, 1990) was used in the qualitative analysis (Ezzy, 2002) of this study to discover patterns, aspects and importance of global competitiveness as well as the interrelationship of those factors from the data collected. Qualitative analysis was used also since it was not the objective of this study to compile the data collected numerically (Miles, 1994). The field of inquiry was limited to areas, subjects, people and questions that would directly relate to data necessary to be analyzed (Wolcott, 1994). Qualitative conclusions also lent themselves to communicating the vision, mission and support of the organization's current plans and those of the future.

Porter's Diamond (Porter, 1990) was used to identify key areas of competitiveness utilized by the healthcare organization in this study addressing four broad attributes - factor conditions, demand conditions, related and supporting industries and firm strategy, structure and rivalry - of an organization that shape the environment in which firms compete and either promote or impede the creation of competitive advantage. Porter's Model for Competitive Advantage was utilized addressing cost leadership, differentiation and focus (Porter, 1998).

With cost leadership through economies of scale, the company has a better ability to manage growth and hold off competition. For instance, by establishing a hospital facility where little or no hospital services or medical care exist, distributed fixed costs can remain fairly stable and services can be priced to be more profitable (Bushe, 1995).

Differentiation is achieved by concentrating on specific specialties or sub-specialties creating a service that is perceived as unique by the patient. This is perceived as superior value by the patients and therefore, since the patient sees the service as unrivaled unequaled, the price value can be adjusted to be more flexible. This also tends to develop more brand loyalty and helps insulate the organization against the competition.

The focus is important because the organization seeks to be more competitive by being more effective than efficient. Hence the focus to specialty and sub-specialty practice to set the organization apart as being the best in a certain segment of the business within a group of businesses.

This competitive advantage is key for organizations such as the one studied here to perform well and survive in today's highly globalized and intensely competitive healthcare market.

An inductive approach (Thomas, 2006) for analysis of data was initially used to consolidate and refine that data followed by a more concise triangulation of information as a qualitative process to specifically determine conclusions of this study.

Background of the Healthcare Organization

Established in 1972, started by a group of doctors and pharmacists with five specialists and 30 full time nurses, this healthcare organization became the largest hospital in Thailand with more than 400 fulltime consultant physicians and 600 nurses. One hospital has now turned into 12 hospitals, 16 specialty centers and 15 clinics at home and eight other facilities in Cambodia, Vietnam, Burma and Bangladesh.

Specialized centers come completely equipped with the latest treatment and diagnostic methods and tools that cover a range of services from pediatrics to geriatrics, neurology, cardiology and ophthalmology and treatments for sports related injuries.

Patient's requirements for different cultural and personal needs are attended to through specially designed outpatient clinics. Each clinic has unique facilities such as International, Japanese and Arabic services and is broken into four groups: Internal medicine; Surgery; Obstetric and Gynecology; and, a special clinic to deal with psychiatric disorders such as insomnia, depression and behavioral problems of children.

Investment is made in the latest technology, medical expertise and support facilities and is in continuous development contributing to the hospital's reputation and current status as one of the top medical organizations in Southeast Asia. A state-of the-art videoconferencing system links all of its hospitals, clinics and medical professionals in Thailand enabling the sharing of medical images while minimizing time for treatment administration and discussion of cases by specialists and physicians in different centers throughout the country. This allows the group to operate its branches as a single entity and is currently being developed for Southeast Asian inclusion.

This organization is dedicated to maintaining the highest international standards of medical practice by delivering quality patient care to each and every patient. Their vision statement tells it all – "our patients' complete satisfaction."

Seeking and Maintaining Global Competitiveness

One of the big questions for healthcare is why even be globally competitive in the first place?

One reason is that the healthcare market in Thailand will eventually saturate. To maintain growth, this Thai healthcare organization needs to look outside the country. Another reason is that healthcare today is being transformed in part from medical travelers from those wealthy patients from developing countries traveling to seek high quality medical care at affordable prices. In the case of this Thai healthcare organization, their market is expanding to Abu Dhabi. Due to the increasing cost of travel, eventually foreigners, especially in the Middle East, will not be able to afford to travel. The main reason for this is in examples found of long term care. Traditionally in the Middle East relatives typically accompany the patient. Not just the cost of health care, but accommodation, plane ticket, extra expenses and pocket money are increasing to the point of making a trip abroad prohibitive. The Middle East is also trying to discourage people from seeking health care outside the country. For instance, there is only one hospital in Saudi Arabia that has long term care. Rich people can still afford to travel, but the poor may not be able to afford the care outside the country.

The "why" of global expansion for competitiveness for this healthcare organization is answered by addressing location and planning. Being a pioneer in healthcare in Thailand, this organization has served both local and foreign patients and their communities with prompt professionalism in world-class facilities at reasonable prices for more than 26 years making it difficult for its closest competitors to follow.

It has positioned itself as a convenient, integrated solution to often complex healthcare. This is due largely to a well established differentiation in its infrastructure where Positioning (convenient and integrated healthcare solutions), Differentiation (wide network, wide range of services) and Brand working in conjunction with Brand Integrity, Image and Identity all work together to create a winning situation for both patient and healthcare organization (Porter, 2006).

This healthcare organization is currently building a hospital in Abu Dhabi. Abu Dhabi is a wealthy country and still underdeveloped in the areas of medical care and their economy. Conversely, Dubai is saturated with medical facilities and a multitude of hospitals, the population growth is slowing down. Abu Dhabi is now working on a plan to catch up with Dubai. There has been a population explosion in Abu Dhabi and they currently have produced a 22 year plan regarding growth and population planning.

Abu Dhabi is a modern society shaped by an ancient culture. The strategic policies in this Urban Structure Framework Plan, "Plan Abu Dhabi 2030", provide a way of reversing sometimes inappropriate development trends and of satisfying the needs of a growing population (Abu Dhabi Plan 2003, 2007). These policies are grounded by the three basic elements of sustainability: the natural environment, economic development and cultural heritage. Abu Dhabi is only the beginning of this active search for expandable locations. Doha, Qatar and Saudi Arabia are the next areas that may be looked at. Saudi Arabia has a population of more than 30 million people and the healthcare structure there is still underdeveloped.

Investment is not the only answer. Establishing and maintaining that global competitiveness can be focused into three main areas:

1. Expanding the reach as a healthcare provider into key strategic locations such as urban and industrial areas where patients reside as well as specific tourist destinations.
2. Providing quality with sub-specialty and high acuity services with global and national patient care quality standards together with state-of-the-art medical technologies.
3. Efficiency of shared services among network hospitals, sharing resources, consolidating back offices and decreasing monitoring and administrative work.

In addition, by utilizing this network approach the duplication of services can be avoided while concentrating on providing the best possible service to the customer at a reasonable cost.

Superior Quality Care, Reasonable Cost

Of all of these issues the biggest factor in determining global competitiveness is assurance to the patient of quality care. The organizational growth and improvement of the quality of services is clearly linked to an organization's commitment to improvement (Spulber, 2007). How this improvement process is driven, the use of performance measurement, external verification and the difficulties in accessing relevant data is a constant challenge. In healthcare today the pursuit of excellence is no longer an option (Asch, et al., 2006). It is essential.

Encouraged by the government's drive to make Thailand a regional hub for healthcare, this organization raised its bed capacity and looked beyond the local market, currently serving over 10,000 outpatients and 1,000 in-patients per day. The International division is now staffed with an international team who is culturally aware of the needs of patients and the need to provide those patients with a comfortable and reassuring environment and ambiance to make their stay as pleasant as possible. Hotel-style rooms and specially catered meals suiting every dietary requirement are provided to patients as well as access to the hospital's language translation service covering 26 different languages to help patients in making inquires and to explain medical conditions as well as instructions for treatment and maintenance. In-patient care is prompt and professional with care taken for consideration of special cultural, personal and religious needs and the tension of medical treatments is eased by specially selected services like Thai massage or personal grooming.

What standards are provided to assure the patient of safety and reliability in treatment? In the case of this health care organization, quality care is determined based on American standard practices of medicine as well as accreditation by the Joint Commission International (JCI).

JCI's mission is to continuously improve the safety and quality of care in the international community through the provision of education and consultation services and international accreditation. As the largest accrediting agency of health care organizations in the United States, it surveys nearly 20,000 health care programs through a voluntary accreditation process. (Joint Commission International, 2007).

Specific services for sub-specialty and high acuity services are not only targeted demographically, but are coordinated with state of the art technology to provide a standard of quality that patients can rely on time after time. Customer relationship management (CRM) (Buttle, 2003) helps to develop and improve Key Performance Indicators (KPI) (Shahin, 2007). Key Performance Indicators help a healthcare organization to define and measure progress toward organizational goals. Once the healthcare organization has analyzed their mission, identified all their stakeholders and defined their goals, they need a way to measure progress toward those goals. Key Performance Indicators are those measurements.

Faster availability of data is beginning to becoming more and more a concern. Delays of a month or two may provide unreliable information as demographics change. So technology is needed to blend with organizational goals.

Cost efficiency is accomplished through a network of shared services among network hospitals sharing services and resources, consolidating back offices and decreasing monitoring and administrative work and Key Performance Indicators (KPI) are watched closely and once the network has been established a number of issues are addressed. The main areas of analyses are:

1. Volume numbers related to patients (new patients, existing status and patient attrition).
2. Patient turnover by market segment (demographic studies).
3. Analysis of individuals demographically who may be potential patients.
4. Profitability by demographic segments and segmentation of customers by profitability.

This combination of cost control to provide reasonably priced health services in areas that are lacking not only in the quality but availability of healthcare allows this healthcare organization to be competitive in the market outside Thailand. It is important to note that a company must be explicit about its choice of strategy with regard to value creation (differentiation) and low cost (Porter, 1996).

Strategic Alliances

Alliances and contractual relations between collaborating partners in the healthcare market are shifting rapidly, therefore the need to be adaptive to the changing environment and be competitive both domestically and internationally are critical. Strategic alliances have allowed this healthcare organization to have revenue with a diversified base with a different environment, currency, nationality and behavior. The challenge is to manage those factors and get a positive result.

Today's healthcare industry is characterized by new and often problematic, opportunities and challenges in greatly expanding markets that can change overnight by research findings, a financial report, new legislation, new regulations, or the introduction of new technology. The healthcare industry is a "turbulent environment where companies worldwide and across many industries are turning to alliances as a cooperative, inter-organizational mechanism for adaptation" (Zuckerman, 2002). Strategic alliances enable participating organizations to extend their operations and expand toward desirable strategic goals. They can help to be more than a convenient arrangement to help healthcare providers to get through a tough period or resolve a major problem. Strategic alliances are now used in the healthcare field as a viable operational and strategic consideration. In today's environment of continual change and unpredictable developments, organizations may many times face circumstances where strategic alliance is necessary to stay timely and competitive. Strategic alliances are designed to achieve strategic purposes not attainable by one single organization. They provide flexibility and the ability to be responsive while retaining the basic structure of participating organizations (Lieberman, 1987).

The rationale to form these alliances is to recognize their value in engendering flexibility and allow them to access to a broadening array of resources and markets. These are essential considerations of any corporation that hopes to continue to remain relevant and vibrant (Stein, 1992). In the case of this Thai healthcare organization, a strategic alliance in Abu Dhabi tends to be particularly important in an unfamiliar market. While this provider has dealt with the Middle Eastern client base for a number of years, trying to enter the local market through a strategic alliance was a sound practice to build local alliances since local knowledge and connections are extremely valuable. It also enabled them to network ties outside their traditional boundaries and to possibly expand global resources of materials, capital, and/or expertise.

More enhanced operational capabilities and higher strategic goals are not achieved automatically. Management issues can be continual and difficult to resolve. These issues must be met by experienced, capable businesspersons, if an alliance is to be workable, productive and beneficial. Some alliances come apart; and some do not fulfill their purposes. Management complexities are enormous. To justify all the short term, extra costs, the rewards to both the hospital as well as the community must be enormous (Size, 1995).

Strategic alliances currently have been formed by this healthcare organization in Cambodia and presently in Abu Dhabi and the 30 bed facility currently in progress at Abu Dhabi is in negotiation to expand to a 60 bed facility. Abu Dhabi, however, presents a diverse challenge.

Issues such as cross-cultural communication present reoccurring problems that must be resolved on a daily basis. The Health Authority in Abu Dhabi (HAAD) has mandated that all health care facilities' staff need to be culturally sensitive and deliver culturally competent health care for the population residing in the Emirate of Abu Dhabi (Health Authority - Abu Dhabi, 2007). They have also identified five specific elements that are expected if the staffing and service delivery system is to become more culturally competent:

1. Value diversity
2. Have the capacity for cultural self-assessment
3. Be conscious of the dynamics inherent when cultures interact
4. Institutionalize cultural knowledge
5. Develop programs and services that reflect an understanding of diversity between and within cultures

A strong source of competitive advantage can come from understanding and proactively managing these cultural differences. If the management is poor, it can create a source of poor team performance and divided patient/provider relationships. Cultural norms in one country can differ greatly from those of another country making a seemingly minor incident into something of extraordinary proportion.

Being an effective and trusted global healthcare services provider requires not only a network of competent healthcare professionals, but a genuine understanding by all key administrators, doctors, nurses and support staff of the cultural issues that affect the core of the healthcare process in another country. This healthcare organization has addressed active steps to generate value from the diversity of their internal talent to help them be best placed to compete in the increasingly international healthcare environment.

CONCLUSION

Competitive strategy has been experiencing a dramatic transformation from a situation where one competitor gains at the expense of another, to one that is a mutually beneficial collaborative effort, where that joint effort creates more economic value for all parties. This new competition involves looking forward and positioning oneself in future and possibly still undefined markets and developing these markets with collaborative efforts. In today's competitive global economy with its intensively interconnected business environment, a major challenge faced by healthcare organizations is how to maximize shareholder value and sustain growth, while at the same time creating economic value for all. Two necessary strategic ingredients are needed to achieve these long range organizational objectives:

1. To set up and be the central focal point of a cluster of partners with whom a new and continuous stream of attractive and innovative services with value are developed and offered to customers, and
2. Identifying unique combinations of these services by actively engaging customers in the development of those customized services to meet their continuously unique and changing needs.

The conclusion drawn from this research is that if a company wants to attain a competitive advantage and remain profitable, the strategy, operations and organization must be consistent with each other coupled with unique service.

Markets must be sought out that lack sufficient medical care to service their population. The most often sited reason for the global competitiveness of this healthcare provider using triangulation of data received was the ability to provide comfort and hospitality or “Thainess” (90% response) at the same time as providing excellent specialty and sub-specialty medical care and facilities (82% response) giving the organization both economy of scale to provide reasonable pricing and uniqueness in the medical care provided. In turn, that uniqueness and quality in service has attracted strategic alliances that provide further inroads to a wider base of patients in the global community.

It is in this venue that this Thai healthcare organization competes not to maximize their market share, but to maximize the value of service offered to the customer, those providing them with a stable position in the competitive global healthcare industry.

Further study will be done on how cross-cultural management affects the strategy, operations and organization of the company in additional research. That data will ultimately be combined with this study to conclude additional research.

ACKNOWLEDGMENT

The author acknowledges the Editor-in-Chief of the Journal, Professor John Wang, and the anonymous reviewers for their indispensible input that improved the paper significantly.

Chapter 5.15

Physician Characteristics and EMR Attitudes

David Meinert
Missouri State University, USA

Dane K. Peterson
Missouri State University, USA

ABSTRACT

Despite the numerous purported benefits of Electronic Medical Records (EMR), the medical profession has been extremely reluctant to embrace the technology. One of the barriers believed to be responsible for the slow adoption of EMR technology is resistance by many physicians who are not convinced of the advantages of using EMR systems. This study examined potential characteristics of physicians that might help identify those individuals that are most likely to pose a threat to the successful implementation of an EMR system in a multi-specialty clinic. The results demonstrated that older physicians and physicians with only minimal computer skills are more likely to have negative attitudes regarding EMR technology. Medical specialists were most likely to have positive attitudes with respects to the use of EMR systems, while primary care physicians were most likely to have doubts regarding the purported benefits of EMR technology.

PHYSICIAN CHARACTERISTICS AND EMR ATTITUDES

An Electronic Medical Record (EMR) is a computerized system that contains a patient's long-term legal health record generated by encounters at one particular medical practice. Thus an EMR electronically stores such items as x-rays, prescriptions, physician's notes, structured data, diagnostic images, wave forms, scanned images of paper documents, and other types of medical documentation. EMR technology offers a number of potential benefits, including improved quality of patient care, more efficient healthcare workflows, and reduced costs (Thompson, Osheroff, Classen, & Sittig, 2007). Improvement in the quality of patient care can be credited to several attributes of an EMR system including superior documentation, flexible data organization, integrated systems, and assisted clinical decision making (Shekelle, Morton, & Keeler, 2006).

Because of the many potential benefits associated with EMR technology, a number of experts believe the market for EMR systems will grow rapidly over the next decade. A recent study projected a13.5 percent growth rate for EMR technology in the U.S. over the next four years (Pizzi, 2007). This study estimated that the 2005 EMR market of $1 billion will grow to more than $4 billion by the year 2015. The prospects for market growth in the EMR industry are further enhanced by evidence suggesting that the U.S. represents only a small proportion of the market potential for EMR technology. Enormous growth is also anticipated on the global level, making EMR software an exceptional opportunity not only for the current market players, but also for new entrants into the market.

Despite the numerous benefits associated with EMR systems, there is extensive documentation indicating that the healthcare industry in the United States has been extremely reluctant to embrace the technology (Fonkych & Taylor, 2005). As a whole, the healthcare industry is almost 20 years behind the rest of the nation's industries in the adoption of information technology (Ilie, Courtney, & Slyke, 2007). The financial service industry for example spends nearly $200 billion a year on information technology, while the healthcare industry spends only about one-tenth of that amount ("From clipboards to keyboards," 2007). Estimates of the number of hospitals in the U.S. that have adopted the technology range from about 30 to 56 percent depending largely on how EMR systems are defined (Fonkych & Taylor, 2005). The slow growth rate has prompted possible intervention by the U.S. government to facilitate the implementation of EMR systems. In 2004, the U.S. federal government announced a framework to accelerate the adoption of health information technology, with the goal of having electronically stored medical records for most Americans within the next decade (Health IT Strategic Framework, 2004).

The slow adoption pace for EMR systems has been attributed to a number of barriers, such as privacy concerns and interoperability. In hospital settings, one of the key obstacles to successful EMR implementation is resistance among physicians. Physicians may be reluctant to accept EMR technology for a number of reasons, including the perception that the use of an EMR system requires extensive training and interferes with the quality of physician-patient interaction. Many physicians are skeptical about claims that EMR systems reduce errors, increase productivity and the overall assertion that the benefits of EMR technology outweigh the costs (Handy, Whiddett, & Hunter, 2001). While the validity of these issues have been addressed in a number of previous studies, it is important to note that physician acceptance of EMR technology is dependent on the physicians' perceptions and not necessarily the actual value of EMR technology.

Since physicians must use EMR systems in their day to day work, physician acceptance is crucial to widespread adoption of EMR technology (Mazzoleni et al., 1996). Many unsuccessful attempts to implement EMR technology have been attributed to the physicians' dissatisfaction with the EMR system (Van Der Meijden, Tange, Troost, & Hasman, 2003; Wager, Lee, & White, 2002). This is exemplified by several highly publicized EMR implementation fiascos, including the Cedars Sinai Medical Center in Los Angeles, in which physicians revolted and forced the administration to scrap a $34 million computer system (Connolly, 2005).

On the other hand, instances in which physicians approached the adoption of EMR technology with a positive attitude were often associated with successful implementations (Darr, Harrison, Shakked, & Shalom, 2003). Thus, a better understanding of the factors that are associated with physicians' attitudes toward the adoption of EMR systems is a key to achieving the substantial benefits associated with EMR technology (Reardon & Davidson, 2007). Therefore, this study examined the perceptions of physicians associated with a multi-purpose clinic to identify potential barriers to the acceptance of EMR technology. Such information may be useful in developing EMR training programs to enhance the prospects for successful EMR implementation.

PHYSICIANS' PERCEPTIONS REGARDING EMR TECHNOLOGY

One concern for many physicians is the amount of training time required to become proficient users of EMR technology. Although most EMR vendors claim extensive training is not required, adequate training appears to be crucial for the successful implementation of EMR systems (Miller & Sim, 2004). The exact amount of training required to become a proficient user of EMR technology is difficult to ascertain, since the necessary training time appears to be dependent on a number of factors (Bergeron, 2006; Ovretveit, Scott, Rundall, Shortell, & Brommels, 2007; Vanmeerbeek, 2004). For instance, it appears the specific type of EMR system being implemented, the training method employed, and the general computer proficiency of the physicians influence the required amount of training time (Aaronson, Murphy-Cullen, Chop & Frey, 2001; Kirshner, Solomon, & Chin, 2004). Thus, it appears that in some instances, the empirical evidence supports the concerns of many physicians that extensive training time may be necessary. Consequently, the present study examined physicians' views regarding the willingness of their colleagues to expend the time necessary to become proficient EMR users.

Quality of care, particularly the significance of physician-patient interaction, has been a primary concern among many physicians (Russell & Spooner, 2004). At issue is whether incorporating computers in the examination room detracts from the quality of communication between the physician and the patient (Aaronson et al., 2001). The results from empirical investigations appear to be mixed. For instance, one study reported that gazing at the computer monitor was inversely related to physician engagement in psychosocial questioning, emotional responsiveness to the patient, and overall psychosocial exchange during patient visits (Margalit, Roter, Dunevant, Larson, & Reis, 2006). In addition, keyboarding activity (physician order entry) has been reported to adversely influence the medical dialogue between physicians and patients. On the other hand, other investigations have not observed any negative consequences associated with the use of computers in the examination room (McGrath, Arar, & Pugh, 2007). In fact, some evidence suggests equipping examination rooms with computers may a positive effect on physician-patient interactions (Hsu, Huang, Fung, Robertson, & Jimison, 2005).

The conflicting results regarding use of EMR systems and physician-patient interaction may be the result of differences in the level of EMR experience among the physicians. That is, use of computers in the exam room may be less likely to interfere with physician-patient interaction as physician become more experienced with EMR systems (Rouf, Whittle, Lu, & Schwartz, 2007). This conclusion is based on objective methods of investigating physician-patient interaction, such as eye contact with the patient. However, the successful implementation of EMR systems may be more influenced by physicians' attitudes than such factors as amount of eye contact. Thus, the present investigation examined physicians' perceptions regarding the influence of EMR systems on quality of patient care.

One of the many claims made by vendors is that the use of EMR systems can result in a reduction of medical errors. Certainly, medical errors in hospital settings are both prevalent and costly (Crane & Crane, 2006), and there is some empirical evidence that the use of EMR technology can reduce medical errors. For instance, one study reported that use of EMR technology reduced documentation errors by over five percent (Gearing et al.2006). However, a review of the literature suggested that using EMR technology does not always result in a reduction of errors (Sidorov, 2006). One comprehensive investigation examined 17 measures regarding the quality of care in ambulatory settings. The results credited EMR technology with improvement for two outcome measures, but EMR technology resulted in a worse outcome for one measure, and no differences on the remaining 14 measures (Linder, Bates, Middleton, & Stafford, 2007). Thus, there would appear to be some valid reasons why physicians may not perceive EMR technology as a useful means for reducing medical errors. The present investigation provides a current examination of how physicians' view the effectiveness of EMR technology to reduce medical errors.

Increased productivity, or the number of patients seen per day, is another benefit often touted by EMR vendors (Joos, Chen, Jirjis, & Johnson, 2006). Although increased productivity is widely claimed as one of the benefits of EMR technology, there is only a modest amount of evidence to support the proposition and much of the evidence is anecdotal (Gonzales & Puri, 2008; Thakkar & Davis, 2006). Thus it is quite reasonable to expect physicians to be skeptical about the claimed benefits associated with increased productivity (Handy, Whiddett, & Hunter, 2001). Given the conflicting evidence, it would seem beneficial in this study to examine the current perceptions of physicians regarding the usefulness of EMR technology for increasing physician productivity.

A number of studies have attempted to assess the overall cost/benefits of EMR technology (Gearing et al., 2006). Developing an effective and valid assessment procedure has proven to be a difficult task (Thompson et al. 2007). However, the majority of the evidence suggests that the benefits of EMR technology outweigh the considerable costs of the technology (Hillestad et al., 2005; Simon & Simon, 2006). Even in instances in which physicians were initially skeptical about cost/benefits of EMR technology, the objective evidence indicated a substantial return on investment (Mullen, & Donnelly, 2006). To ascertain how the empirical evidence has influenced physicians' perceptions of EMR technology, this study examined physicians' views on the cost/benefits of EMR systems.

Finally, this study asked physicians if they believe their colleagues were aware of the benefits of EMR technology, whether the clinic should adopt EMR technology, and if EMR technology is adopted, will it be necessary for administration to mandate the use of the system in order to achieve successful implementation.

Attitudes and Physician Characteristics

Most theories on the diffusion of information technology suggest that the attitudes and perceptions of users is a key to successful implementation (Bagozzi, Davis & Warshaw, 1992). Thus, a number of studies have examined potential relationships between characteristics of physicians and attitudes regarding EMR technology with the hope of identifying the physicians most likely to resist EMR implementation. The goal is to determine which physicians represent the greatest obstacle to successful EMR implementation and thus, the physicians who would benefit the most from EMR training programs. Some of the primary factors investigated include the physician's age, computer sophistication, and medical specialty.

With respect to age, most studies have found that younger physicians are more likely to use EMR technology (Burt, Hing, & Woodwell, 2005; Terry, 2005). However, while younger physicians may be more likely to use EMR technology, some studies have reported that younger physicians are also more likely to have negative attitudes regarding the EMR system they are currently using (Darr et al., 2003; Terry, 2005).

Several researchers have suggested that a lack of computer sophistication among physicians may impede the implementation of EMR technology (Anderson, Asher, & Wilson, 2007; Rabinovitch, 2007: McGowan, Passiment, & Hoffman, 2007). Although there appears to be a substantial need for improvement in the computer skills among some physicians, studies examining the relationship between computing skills and EMR acceptance has produced contradictory results. Some studies have found a positive association between level of computer sophistication among physicians and use of EMR technology, while other studies did not observe a significant relationship between these variables (Joos et al. 2006).

Studies examining EMR adoption by medical specialty have also failed to produce consistent results. While some studies have found primary care physicians are most likely to use EMR technology (Terry, 2005), other studies have reported medical specialist are more likely to adopt to EMR systems (Audet et al., 2004; Burt et al., 2005; Corey & Grossman, 2007).

Study Objectives

To date, most studies examining EMR adoptions have reported general findings in terms of system "availability" or "usage." Unfortunately, such studies provide minimal understanding of what drives physician acceptance or resistance of EMR systems. While global measures such as "availability" and "usage" provide information regarding the rate of adoption of EMR systems they fall short of providing detailed insight into variables relevant to their successful widespread implementation.

The objective of the present investigation was to examine the attitudes of physicians at one large multi-specialty hospital regarding EMR technology. In addition, the study examined how perceptions regarding EMR technology were related to age, computer sophistication, and medical specialty of the physicians. Identifying which physicians are likely to have positive attitudes regarding EMR technology could assist hospital administrators and technology managers identify potential "innovators". Innovators, or early adopters, can play an important role as "opinion leaders" in the diffusion of information technology (Andrews, Pearce, Sydney, Ireson, & Love, 2004). Similarly, identifying physicians that are most likely to be resistant to EMR technology may provide administrators with information on who may benefit the most from technology training. Studies have shown that proper training improves attitudes toward EMR technology, even among physicians who were initially resisted the adoption of EMR systems (Kirshner, Salomon, & Chin, 2004).

METHODOLOGY

Sample

To examine physicians' attitudes regarding EMR systems, a mail survey of 358 physicians affiliated with a large, multi-specialty clinic in the Midwest was conducted. The clinic is a physician-led, professionally managed group practice in an integrated health-care system. Although some of the physicians had prior experience using EMR technology in other settings, the survey was conducted before the clinic had implemented an EMR system.

Targeting physicians at one multi-specialty clinic made it possible to obtain a high response rate to the questionnaire, avoiding a common problem encountered by many similar studies. In addition, the clinic was only in the preparation stage for adopting EMR technology. Thus most of the physicians had only read about EMR technology, but had little experience with specific EMR systems. Hence, their opinions were not likely to be overly influenced by use of one specific EMR system.

Questionnaires were mailed to physician homes, with follow-up mailings to non-respondent's homes (3 weeks later) and offices (5 weeks later). Preaddressed, postage-paid return envelopes were provided. A total of 266, or 74 percent, of the questionnaire were returned. Five of the questionnaires (1.4%) were excluded because at least half of the items were not completed. Thus, useable data was obtained from 261 (73%) respondents. The high response rate and percentage of usable questionnaires was a result of reminders by administrators and physician-executives to participate in the research. These reminders were conveyed via email, weekly newsletters and staff meetings.

Questionnaire

The questionnaire asked respondents to rate their degree of agreement regarding eight items on a forced Likert scale (no neutral point) ranging from 1 - strongly agree to 6 - strongly disagree. The eight items are listed in Table 1. These items were derived through an examination of the literature, discussions with administrators at the multi-specialty clinic and physicians in other clinics. The questionnaire also contained items to assess the physician's age, computer sophistication, and medical specialty. As in previous studies (Audit et al., 2004; Burt et al., 2005), physician age was classified as under 35, 35 to 44, 45 to 54, and over 54. Based on the same reasoning, medical specialty was classified as Primary Care, Surgical, and Medical Specialist. It was determined that computer sophistication was best assessed by a single item that asked respondents to rate their "Knowledge/experience working with Windows based applications (e.g., Word, PowerpPoint, Excel)" on a scale from 1 – "Proficient" to 4 – "Non-existent". Due to the small number of respondents indicating non-existent computer skills (n = 22), the last two categories were combined (i.e., minimal and non-existent computer skills).

RESULTS

The percent of physicians agreeing with each statement (respondents checking 1, 2, or 3 on the Likert scale) is displayed in Table 1. The physicians generally agreed that EMR technology would be beneficial. That is, nearly 80 percent of the

Table 1. Percent of physicians agreeing with each item

Concerns	Percent Agreeing
1. Physicians will devote the time necessary to be trained using an EMR	68.3
2. An EMR will improve the quality of patient care	76.6
3. An EMR will reduce the number of errors	82.6
4. An EMR will increase a physician's productivity	60.2
5. The benefits of an EMR system will outweigh the costs	72.0
6. The clinic's physicians are familiar with EMR functions and benefits	43.8
7. The clinic should implement an EMR system	79.6
8. EMR usage will have to be mandated	71.5

Table 2. Attitudes and physicians' age

	Under 35	35 to 44	45 to 54	Over 54	F
Sample Size	23	97	91	44	
1. Physicians will devote necessary time to training	3.31	2.81	3.17	3.41	2.70*
2. EMRs improves quality of patient care	1.95	2.49	2.79	3.20	4.27**
3. EMRs reduce errors	1.82	2.27	2.54	2.86	3.76*
4. EMRs increase physicians' productivity	2.19	2.99	3.53	3.59	6.35**
5. EMR benefits outweigh costs	2.24	2.46	2.84	3.39	4.82**
6. Clinic should implement EMR systems	2.04	2.29	2.49	3.21	4.18**
7. EMR usage will have to be Mandated	2.86	2.57	2.80	3.07	1.10
8. Familiar with EMR functionsand benefits	3.62	3.72	3.71	3.98	0.61

** P < .05, ** p < .01*

physicians agreed that the clinic should implement an EMR system and 72 percent agreed the benefits will outweigh the costs. However, the physicians were somewhat pessimistic regarding the acceptance of EMR technology by their colleagues. Only 43.8 percent of the physicians believe that their colleagues are familiar with the benefits of EMR technology and 79.6 percent believe the clinic will need to mandate the use of EMR systems in order to achieve widespread use of the technology.

Only 55 of the 261 respondents were females. Statistical tests indicated no gender differences on any of the eight dependent measures. Thus, all subsequent analyses were based on all 261 respondents without including gender as a separate factor. A separate ANOVA was performed on each of the eight dependent measures. Of the three independent variables, a chi-square test indicated that only physician age and computer proficiency were significantly related. That is, younger physicians were more likely to rate themselves as proficient computer users and less likely to have minimal or non-existent computer skills (chi-square = 20.36, p = .002). Chi-square tests on the relationship between physician age and medical specialty and between computer proficiency and medical specialty were not significant.

The ANOVA results for physician's age are summarized in Table 2. The analysis indicated the difference between the age groups was significant for all items except mandated use of EMR systems and familiarity with EMR benefits. For each item in which significant age differences were observed, younger physicians had a more positive attitude regarding EMR technology.

The results for physician's computer knowledge are summarized in Table 3. As expected,

Table 3. Attitudes and physicians' computer proficiency

	Proficient	Adequate	Minimal/ Non-existent	F
Sample Size	68	112	72	
1. Physicians will devote necessary time to training	2.74	2.93	3.63	11.62**
2. EMRs improves the quality of patient care	2.18	2.34	3.67	26.99**
3. EMRs reduce errors	1.94	2.21	3.20	20.90**
4. EMRs increase physicians' productivity	2.64	2.95	4.17	24.51**
5. EMR benefits outweigh costs	2.18	2.45	3.69	24.69**
6. Familiar with EMR functions and benefits	3.23	3.68	4.29	14.84**

Table 4. Attitudes and physicians' specialty

	Primary Care	Surgical Specialist	Medical Specialist	F
Sample Size	106	35	107	
1. Physicians will devote necessary time to training	3.15	3.11	2.99	0.50
2. EMRs improves the quality of patient care	3.03	2.60	2.32	6.52**
3. EMRs reduce errors	2.72	2.29	2.16	5.10**
4. EMRs increase physicians' productivity	3.48	3.18	2.96	3.21*
5. EMR benefits outweigh costs	2.87	2.85	2.54	1.38
6. Familiar with EMR functions and benefits	4.00	4.00	3.39	8.28**
7. Clinic should implement an EMR system	2.72	2.47	2.25	2.40
8. EMR systems will have to be mandated	2.71	2.83	2.80	0.13

** P < .05, ** p < .01*

physicians who were more proficient with computers were more likely to agree with the items. The difference between the groups was significant on all eight items.

Table 4 summarizes the results for physician specialty. The differences between physician specialties were significant for four of the items, namely quality of patient care, reduced errors, physician productivity, and familiarity with EMR benefits. Although the results were significant on only four of the eight items, the pattern of results were the same for all questions. That is, medical specialists were most likely to agree with the statements indicating a more positive attitude with respect to EMR technology. Primary care physicians were least likely to agree with the items.

CONCLUSION

One of the strengths of the present study was the high response rate (74%) which overcomes a limitation in some previous studies in which the results might be biased because the physicians completing the surveys may be those with the most interest in EMR technology. With the high response rate in this study, the results should be highly representative of the views of physicians working in multi-specialty clinics.

In general, the results suggest that physicians agree that EMR technology can be beneficial. The majority believed EMR technology can improve the quality of patient care, reduce errors, increase physician productivity, and believe the benefits of EMR technology outweigh the costs of implementing an EMR system. Consequently, nearly 80 percent of the physicians agreed that the clinic should implement an EMR system. However, only 43.8 of the physicians agreed that their colleagues were familiar with EMR functions/benefits and only 68.3 physicians believed their colleagues would be willing to devote the time necessary to be trained in using EMR technology. Thus, it is not be surprising that 71.5 percent of the physicians believe that in order to achieve successful implementation of an EMR system, the clinic will need to mandate the use of the technology.

The results overwhelmingly demonstrate that younger physicians have a more positive attitudes regarding EMR technology. Younger physicians were more likely to agree that EMR technology improves patient care, reduces errors, increases productivity, and that the benefits outweigh the costs. They are also more likely to agree the clinic should implement EMR technology. Similar results were found for computer proficiency. That is, physicians who rated themselves as proficient computer users had more positive attitudes regarding EMR technology than those with minimal or non-existent computer skills. As observed in many previous studies outside the medical profession, age and computer proficiency were highly related (Marquie, Jourdan-Boddaert, & Huet, 2002). Thus it is difficult to independently assess the importance of physician age and computer proficiency on physician attitudes.

The results of the present study also show that medical specialists are more likely to have a positive attitudes regarding EMR technology than surgeons, and surgeons are more likely to have a positive attitude with respect to EMR technology than primary care specialists. Thus the results are consistent with most previous investigation examining medical specialty (Audet et al., 2004; Burt et al., 2005; Corey & Grossman, 2007), but contradicts the of one recent investigation (Terry, 2005). The conflicting results of the latter study may be attributed to the classification categories used for medical specialty. Studies such as the current investigation that have classified physicians as primary care, surgeons, or medical specialist have generally produced consistent results.

LIMITATIONS AND CONCLUSION

There are limitations to all research and it is important to note those that may affect the implications of the present study. An obvious limitation is that all physicians were affiliated with the same multi-specialty clinic. While this approach provided several advantages such as a high response rate and more control over physician experience with specific EMR systems, it limits the generalizations that can be made from the study. Clearly, replications with different subject population would add significantly to the literature. A second issue pertains to the classification of medical specialties. While the division into three medical specialties was based on procedures used in several previous studies, there are other classification schemes that have could be used (e.g., see Corey and Grossman, 2007). It may be useful in future studies to examine potential differences in perceived importance of EMR functions using alternative methods of classifying medical specialty. A third concern pertains to controlling for the degree of previous EMR experience. Thorough information on physicians' previous experience with EMR technology and the types of information physicians used to form their perceptions regarding EMR technology would be helpful to understanding differences in perceived usefulness of EMR technology. Future investigation may examine how perceptions change depending on specific sources of information available to physicians and their personal experiences with specific EMR systems.

In conclusion, the results indicate that resistance to EMR implementation may be most likely to occur among older, less computer proficient physicians, particularly among primary care physicians. The fact that younger physicians are more computer proficient may suggest medical schools are taking the advice of researchers who have been advocating a curriculum that devotes more time to teaching computer skills (McGowan et al., 2007). Thus, it may be expected that resistance to implementing EMR technology may diminish over time as younger physicians with greater computer skills enter the profession.

Chapter 5.16

Physician Characteristics Associated with Early Adoption of Electronic Medical Records in Smaller Group Practices

Liam O'Neill
University of North Texas, USA

Jeffery Talbert
University of Kentucky, USA

William Klepack
Dryden Family Medicine, USA

ABSTRACT

To examine physician characteristics and practice patterns associated with the adoption of electronic medical records (EMRs) in smaller group practices. Primary care physicians in Kentucky were surveyed regarding their use of EMRs. Respondents were asked if their practice had fully implemented, partially implemented, or not implemented EMRs. Of the 482 physicians surveyed, the rate of EMR adoption was 28%, with 14% full implementation and 14% partial implementation. Younger physicians were significantly more likely to use EMRs ($p = 0.00$). For those in their thirties, 45% had fully or partially implemented EMRs compared with 15% of physicians aged 60 and above. In logistic regression analyses that controlled for practice characteristics, age, male gender, and rural location predicted EMR adoption. Younger physicians in smaller group practices are more likely to adopt EMRs than older physicians. EMRs were also associated with an increased use of chronic disease management. INTRODUCTION

Electronic medical records (EMRs) have the potential to transform health care in the United States. Achieving the goal of a standardized, interoperable EMR would offer significant economic and social benefits. An EMR-based health care system would shift the balance away from acute care and specialists and toward primary care and prevention. The experience of the Veterans Affairs (VA) system over the last decade offers some important lessons in this area. In the mid-1990s, the VA invested in a system-wide EMR, eliminated excess hospital beds, and shifted its focus toward health promotion, prevention, and outpatient care. The result has been the transformation into a "full-service" integrated delivery system (Greenfield and Kaplan 2004). One recent study found that VA patients received higher quality care than Medicare patients for 11 out of 11 measures, including preventive services and treatment of chronic diseases, such as diabetes and hypertension (Jha et al., 2003).

A target date of 2014 has been established by President Bush to achieve the widespread adoption of an inter-operable EMR. Yet progress to date has been slow. According to a recent study from the Centers for Disease Control (CDC), only 12.4 percent of physicians nationwide reported using a comprehensive, fully-functional EMR (Hing, Burt and Woodwell 2007). Adoption rates tend to be higher in large academic medical centers and lower in smaller, primary care practices (Rosenthal and Layman, 2008; Hing et al., 2007). Among the reasons given for not adopting EMRs were the following: lack of capital; difficulty finding a system to meet needs; uncertain that EMR investment would produce an economic return; concern that the system would become obsolete; and apprehension over loss of productivity (Conn, 2007).

Historically, some physicians have viewed clinical information technology with skepticism and as a threat to their professional autonomy (Shortliffe, 2005). And whereas some physicians have embraced IT in the clinical setting, others are concerned that IT might interfere with the physician-patient relationship and promote a "cookie cutter" approach to medicine. In a recent editorial, Hartzband and Groopman (2008) warned of the "clinical plagiarism" that occurs when physicians cut and paste each other's notes into the patient's record. They also argued that EMRs would constrain creative thinking and promote a rigid, unreflective approach that they termed "automatization."

Numerous studies have examined the economic aspects of EMR adoption. These include the estimated total savings from a nationwide EMR (Hillestad et al 2005), and the "business case" for adopting EMRs at the practice level (Wang et al. 2003; Miller et al., 2005). Yet the business case alone has proven to be insufficient to bring about widespread adoption (Kleinke, 2005). Smaller practices may lack the resources to implement EMRs, and most of the benefits tend to accrue to other stakeholders, such as insurers, patients, and society.

In smaller practices, physicians are the primary decision-makers on IT investments. Without physician acceptance, a clinical information system will have little chance of success. Yet the role of physicians in EMR adoption decisions and the characteristics of "early adopters" has not been adequately studied and is poorly understood. Our purpose is to address this gap in the literature.

BACKGROUND AND CONCEPTUAL FRAMEWORK

Compared to other OECD countries, the US lags 5-10 years behind in public investment for health information networks. For example, the United Kingdom (UK) has invested $11.5 billion in an enterprise-wide EMR, as compared with $125 million U.S. Federal spending on Health Information Technology (HIT) over a comparable period (Anderson et al. 2006). Hence these countries have moved beyond the planning stage and toward implementation. Patients in the UK can now choose hospitals and make appointments through a national, on-line scheduling system.

Canada expects to have EMRs for half its population by 2009.

Policy measures have attempted to address this problem by encouraging EMR adoption through changes in reimbursement. "Pay-for-performance" systems, now being used by both private and public payers, offer bonus payments for reporting and meeting quality targets (Rosenthal et al. 2007). These incentives encourage IT adoption, since the data management and reporting required would be difficult to implement without robust information systems (Shortliffe, 2005). For example, it would be extremely costly and time-consuming for a practice with paper records to report on the immunization status of its patient panel. However, the typical bonus payment is small at only 2 - 3 percent of total reimbursement. Thus it is debatable how much these financial incentives would actually change provider behavior (Berwick 2005). Other policy initiatives include the "Wired for Health Care Quality Act" that would require most providers to adopt EMRs within three years. This bill is currently under consideration in the U.S. Senate, although it is unlikely to be enacted.

Everett Rogers (1995) developed a well-known framework to describe the social process of technology diffusion. Assuming that "innovativeness" follows a normal distribution, then potential adopters can be grouped into five categories, based on how quickly they adopt an innovation (Figure 1). These five categories are the following: Innovators (2.5%), Early Adopters (13.5%), Early Majority (34%), Late Majority (34%), and Laggards (16%). Innovators are the first to adopt and are characterized by their venturesomeness and tolerance of risk. They have the resources to absorb the economic loss of a failed innovation. However, they are often socially disconnected and are rarely opinion leaders. In contrast, Early Adopters are frequently opinion leaders and serve as role models for other members of the social system. The Early Majority are more deliberate and cautious than Early Adopters and more local in their perspectives. They are more likely to adopt an innovation because it meets an immediate need than because it is an interesting idea. The Late Majority adopts only when the innovation has become the norm. They wait until the uncertainty has been removed and the price of adopting has dropped. The choice to adopt may also be the result of network pressure from peers. Laggards are the last to adopt an innovation; they tend to be isolated and localized in their social networks. This group has also been called "traditionalists" in that they swear by the tried and true (Berwick 2003).

Using the framework developed by Rogers (1995), we will, in the first stage, examine the physician characteristics associated with early adoption of EMRs. We will restrict our focus to group practices with five or fewer physicians, since individual physician characteristics are of lesser importance in larger practices, where decisions on IT adoption tend to be more bureaucratic and "top-down." Organizational variables that may influence EMR adoption are also included in the model, such as size of the practice, urban/rural location, and the percentage of Medicaid patients treated (Menachemi et al. 2007). In the second stage, we examine the impact of EMR adoption on disease management and preventive services.

In practice, the conversion to EMRs takes place in stages and over many months or even years (O'Neill and Klepack, 2007). The first stage involves the use of EMRs for internal operations, such as billing, scheduling, patient progress notes, internal communications, and organizing electronic information (Figure 2). The second and third stages involve using EMRs to communicate with clinical partners and for advanced functions, such as preventive services and disease management. Thus we define "Partial EMR Adoption" as Stage 1 implementation and "Full EMR Adoption" as those who have reached Stages 2 and 3. In practice, there is often significant overlap among these stages.

SURVEY DATA AND METHODS

We used a cross-sectional design to survey primary care physicians regarding their practice's use of information technology and practice patterns, in terms of prevention and disease management. The survey was administered in conjunction with the Kentucky Department for Medicaid Services. The initial panel consisted of a statewide random sample of 2,000 providers with at least one Medicaid patient visit in the previous year. The survey methodology followed the Dillman design process (Dillman 2000), with four overall mailings (a pre-survey letter, a survey packet, follow-up postcard, and a final survey packet). After eliminating 62 providers due to bad addresses, 1,928 providers remained in the final sample. The survey process began with mailings in April, 2006, with the final survey coding completed in June, 2006. There were 533 surveys returned for a response rate of 27.6%.

Only 50 out of 533 respondents (9.3%) were in medium-sized or large group practices (those with six or more physicians), and these were excluded from further analysis. Providers were asked if their practice had fully implemented, partially implemented, or not implemented EMRs. Physicians were asked what percentage of their patients received preventive services and disease management in a typical week.

A county was considered "urban" if it was located in a metropolitan area, with the largest city having a population of 50,000 or greater. Six of Kentucky's 120 counties met this criterion; the rest were considered "rural."

Statistical Analysis

Significant differences between EMR adopters (full or partial) and non-adopters were identified using χ^2 tests for dichotomous variables. For ordinal variables, the Mann-Whitney (non-parametric) test was used.

Two separate logistic regression models were used to predict the likelihood of 1) full EMR adoption and 2) full or partial EMR adoption. Candidate variables for the logistic regression models included physician characteristics (age, gender, board certified) and practice characteristics (solo, rural, percentage of Medicaid patients, percentage of managed care patients, and number of physicians in the practice). Variables were selected for the final logistic regression model using the SPSS stepwise procedure (SPSS for Windows, 13.0) and significance was considered at the $p < 0.05$ level.

RESULTS

Of the 482 physicians surveyed, the rate of EMR adoption reported was 28%, with 14% full implementation and 14% partial implementation. This result is consistent with a 2006 nationwide survey of 3,350 office-based physicians conducted by the CDC. In that survey, 29.2% of physicians reported using "any EMR" and 12.4% reported using a "comprehensive EMR", as defined by functionality (Hing et al., 2007).

Physicians who had fully or partially implemented EMRs differed from non-adopters in several important respects (Table 1.) EMR adopters were 5.9 years younger than non-adopters (47.5 vs. 53.4; $p<0.01$). They were also less likely to be in solo practice (65.1% vs. 75.8%; $p<0.01$), more likely to practice in a rural area (79.9% vs. 69.3%; $p<0.05$), and had fewer managed care enrollees (12.5% vs. 17.8%; $p<0.01$).

In terms of practice patterns, physicians who had fully or partially implemented EMRs provided more chronic disease management than non-adopters (49.6% vs. 40.6%; $p<0.01$). Physicians who had fully implemented EMRs provided more preventive services than those who had not adopted or partially adopted EMRs (34.1% vs. 25.5%; $p=0.07$). Further investigation revealed that preventive services differed by

Table 1. Physician and practice characteristics associated with use of electronic medical records

Physician Characteristics	Full or Partial EMRs	Non-Adopters	Difference
Sample size	134	348	--
Age (MD)	47.5	53.4	-5.90 **
Male	84.8%	80.1%	4.7%
Board Certified	88.0%	83.9%	4.1%
Disease Management	49.6%	40.6%	9.1% **
Preventive Services	30.1%	25.5%	4.6%
Practice Characteristics			
Solo Practice	65.1%	75.8%	-10.7% *
Size (Number of MDs)	1.67	1.54	0.13 *
Rural	79.9%	69.3%	10.6% *
Medicaid Patients (%)	25.7%	24.4%	1.3%
Managed Care (%)	12.5%	17.8%	-5.3% **

** P-value<0.01
* P-value<0.05.

specialty ($p<0.001$). For physicians with a specialty of internal medicine or family medicine (n = 109), those with full EMR adoption provided significantly more preventive services than practices with partial or no EMR adoption (46.7% vs. 29.4%; $p = 0.027$).

Two separate multivariate logistic regression models were used to predict full EMR adoption and full or partial EMR adoption, based on physician and practice characteristics (Table 2). Physician age ($p<0.001$), male gender ($p<0.05$), and rural location ($p<0.05$) were significant predictors of EMR adoption. Other physician and organizational characteristics, such as board certified, solo practice, percentage of Medicaid and managed care patients, and the practice size (number of physicians) were not significant.

The relationship between EMR adoption and physician age is clearly shown in Figure 3 and Table 2. For physicians in their thirties, 45% had fully or partially implemented EMRs as compared to less than 15% of those physicians aged 60 or above. The rate of full EMR adoption was 30% for physicians in their thirties and less than 5% for physicians age 60 and older.

This study has several limitations. By design, survey data depend on the ability of participants to give accurate responses. Further, surveys with

Rural	0.607	0.263	1.834	0.021

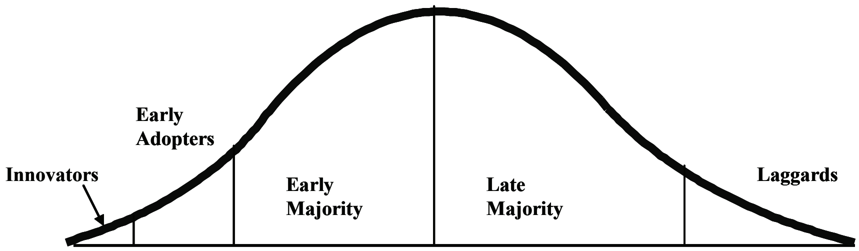
less than a perfect response rate are subject to response bias. Because the data come from one state, care should also be taken in generalizing the findings to other geographic areas. Overall, EMR adoption was found to be highest in the West and Midwest regions, as compared to the Northeast and South regions (Hing et al., 2007).

DISCUSSIONS AND CONCLUSION

Numerous studies have examined the economic aspects of EMR adoption. Yet few studies have examined the crucial role of physicians in the "social process" of EMR diffusion. This study found that early adopters of EMRs were younger on average than non-adopters and that the likelihood of adopting decreased with increasing age. Previous studies across different industries have found an inconsistent relationship between age and innovativeness (Rogers, 1995). In a survey of office-based physicians, Burt and Sisk (2005) found that physician age was not a significant predictor of EMR adoption. In an e-mail survey of 2,145 primary care physicians, Anderson and Balas (2006) did not find a significant relationship between physician age and clinical IT usage.

Our survey response rate was 27.6%, which is consistent with other published studies with a similar design. For example, three studies on the physician adoption of IT had response rates that ranged from 21 to 28 percent (Gans, Kralewski et al., 2005; Brooks and Menachemi, 2006; Rosenthal and Layman, 2008). For the smaller practices studied, physician rather than organizational characteristics were found to be primary determinants of EMR adoption. Previous studies had found that organizational characteristics, such as the percentage of Medicaid patients, to be significant predictors of EMR adoption (Menachemi et

Figure 1. Categories of EMR adopters



Adapted from Rogers, 1995

al., 2007). Our study found EMR adoption to be higher in rural areas. A previous study of North Carolina physicians found lower EMR adoption in poorer, rural counties (Rosenthal and Layman, 2008).

According to Rogers (1995), early adopters also serve as opinion leaders who are influential in persuading their peers to adopt the innovation. The advocacy of opinion leaders is often needed to achieve a "critical mass," that is, the tipping point where the process becomes self-sustaining and is typically reached at adoption levels of 10 - 20 percent. Here the diffusion process follows the S-shaped curve, also known as the "epidemic model." According to the CDC, the nation-wide adoption of "comprehensive EMRs" increased from 9.3% in 2005 to 12.4% in 2006. Thus, we appear to be entering Stage 2 of the process in Figure 1. This is a critical phase in that it can determine whether the innovation spreads throughout the population or stagnates. During this phase, Early Adopters can play a pivotal role in facilitating the diffusion of this technology. For example, they can demonstrate to those in the Early Majority how EMRs meet an immediate, practical need.

This approach of enlisting early adopters has been used successfully in other countries. In Australia, "enthusiastic adopters" were identified, and these became local clinical champions and volunteer advocates for Health*Connect,* the country's national health network (Anderson et al., 2006). The NHS in the United Kingdom has also used "pull marketing" techniques to encourage and then leverage these EMR early adopters. Due to its significant ($11 billion) public investment, the UK currently has a national health network for on-line appointment scheduling and electronic prescribing. It plans to achieve full EMR adoption by 2014.

As with other information technologies, such as fax and e-mail, EMRs have significant network effects, in that their utility increases in proportion to the number of other users in the network. In Kentucky, the level of inter-connectivity of health networks remains low. For example, only 27 percent of the physicians in this study who used EMRs reported filing prescriptions electronically. Concerned with this lack of connectivity and the problem of rising Medicaid costs, the Kentucky state government has recently launched an "E-Health Action Plan" that consists of a consortium of purchasers, payors, providers, and practitioners (ehealth.ky.gov). It mission is to increase provider connectivity and lower costs by investing in health information networks. This state initiative can assist the "partial adopters" who are currently in Stage 1 (see Figure 2) to become "full adopters" by establishing electronic linkages with pharmacies, insurers, and hospitals.

We hypothesized that physicians who use EMRs provide more chronic disease management for such conditions as asthma, congestive heart

Figure 2. Stages of EMR implementation

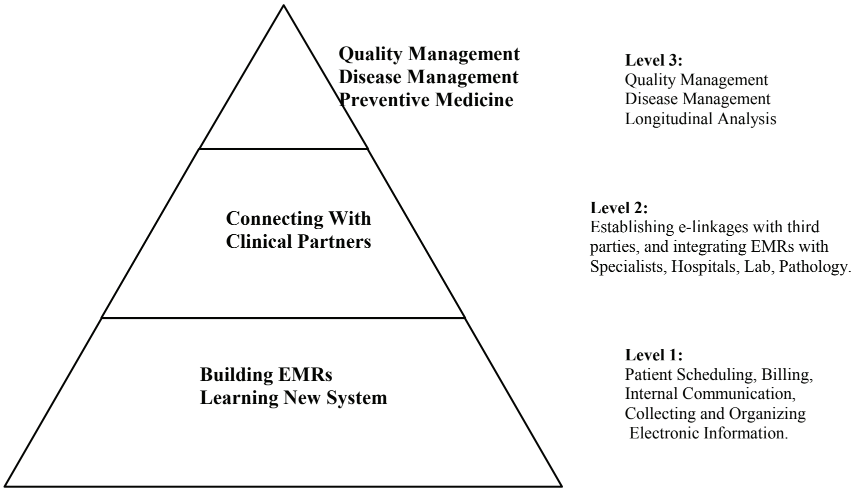


Figure 3. Relationship between EMR adoption and physician age

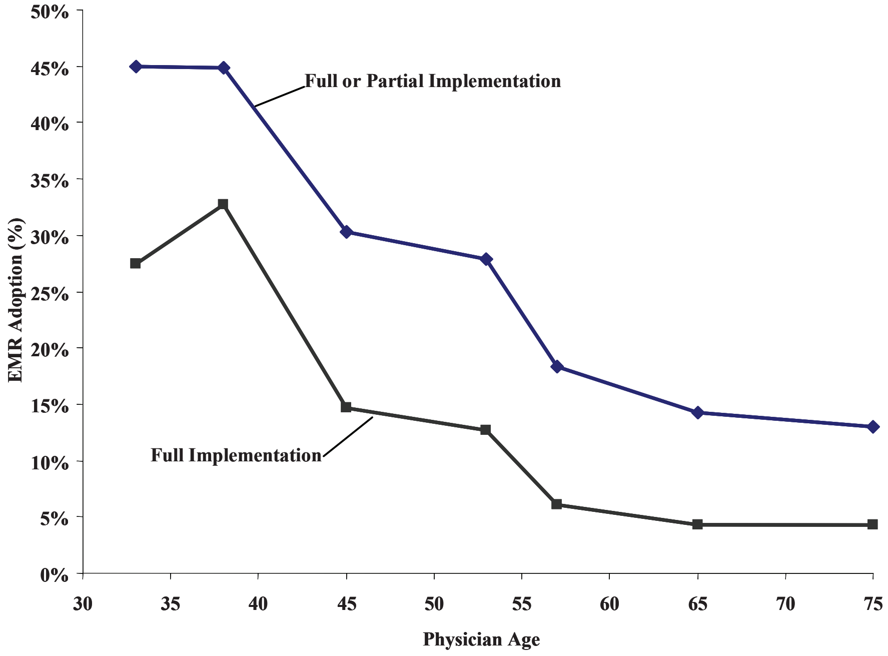

Adapted from O'Neill and Klepack (2007)

failure, diabetes, HIV, and hypertension, and our results support this hypothesis. Physicians who used EMRs and with a specialty of internal medicine or family medicine also provided more preventive services. In order to check for possible confounding, a two-stage regression analysis was performed, and a propensity score to adopt EMRs was calculated using logistic regression in the first stage, as shown in Table 2. The predicted values from this model were used as a predictor variable in the second stage. "Propensity to adopt EMRs" was not a significant predictor of physician practice patterns, whereas "EMR usage" was significant (p=0.026). This finding further supports the hypothesis by ruling out potential confounders. But whereas these early results are encouraging, they should be interpreted with caution. The learning curve associated with EMRs is long, and the impact of EMRs on these higher level functions (prevention and disease management) may take a year or more to measure (O'Neill and Klepack 2007). Moreover, they require viable "health information networks," that include hospitals, pharmacists, and other providers. Thus the "partial adopters", that is, those in Stage 1 (See Figure 2) cannot expect to realize the full benefits of EMRs.

The impact of EMRs on health care quality as measured by prevention and disease management has significant policy implications. Over the long term, an investment in preventive medicine today can be expected to yield lower costs tomorrow, in the form of fewer hospitalizations and a lower disease burden. Thus, previous studies on "EMR economics" may have underestimated these long-run benefits. Much more research is needed in this area, especially regarding the impact of EMRs on pharmaceutical usage for chronic conditions, such as diabetes and high cholesterol, and their impact on spending for hospital (inpatient) care.

Whereas the costs of EMR adoption in primary care are mostly borne by small group practices, the benefits often accrue to other stakeholders, such as consumers or society. Physicians are not currently reimbursed based on cancer deaths prevented or hospitalizations avoided. Other countries, such as Canada, England, and Australia, have recognized EMRs as a public good that requires substantial public investment (Anderson et al. 2006). "Pay-for-performance" attempts to re-align incentives toward prevention and quality, thereby encouraging EMR adoption.

The identification of early adopters and opinion leaders presents an alternative policy response that could accelerate the uptake of EMRs. Future research could extend this study by examining the needs, attitudes, and beliefs of physicians about the role of clinical information technology in their practice, especially those in the "Early Majority" and "Late Majority" categories.

Chapter 5.17

An Exploratory Study of Patient Acceptance of Walk-In Telemedicine Services for Minor Conditions

Christina I. Serrano
University of Georgia, USA

Elena Karahanna
University of Georgia, USA

ABSTRACT

Though healthcare costs continue to soar, the healthcare industry lags other service industries in applying information technology to improve customer (i.e., patient) service, improve access to healthcare services, and reduce costs. One particular area of concern is overuse and overcrowding of emergency departments for nonurgent care. Telemedicine is one potentially important application of information technology in this realm. The objective of this study is to examine the antecedents of patient acceptance of walk-in telemedicine services for minor ailments. Drawing upon theoretical models in the healthcare and technology acceptance literatures and based on salient beliefs elicited during interviews with 29 potential adopters, the authors develop a conceptual model of antecedents of patient acceptance of walk-in telemedicine services for minor conditions. While relative advantage, informational influences, and relationship with one's physician emerged as important predictors of acceptance, media richness and e-consultation diagnosticity emerged as central concerns for potential adopters. They discuss the study's implications for research and practice and offer suggestions for future empirical studies.

INTRODUCTION

In the United States (U.S.), the healthcare industry lags other service industries in applying information technology to business practices. Healthcare spending in the U.S. continues to outpace gross domestic product (GDP), comprising nearly $1.9 trillion, or 16 percent, of GDP in 2004 and is projected to rise to 20 percent of GDP by 2015 (Borger et al., 2006). With the healthcare economy rapidly growing but suffering from pervasive organizational inefficiencies, there is vast opportunity for implementing technological innovations to meet the demands of both industry and consumers, reduce overall costs, and provide widespread access to healthcare at affordable rates.

One particular area of concern is patients' increased use of emergency departments for non-urgent conditions. While this trend contributes to the rising costs of healthcare, patients often choose this option because their primary care physician is not readily accessible or because they do not have a usual source of care (Afilalo et al., 2004; Howard et al., 2005). Proposed solutions to this problem include walk-in urgent care clinics and emergency department fast tracks, often staffed by nurse practitioners and physician assistants (Howard et al., 2005). Another potential solution is a walk-in clinic for minor conditions that uses telemedicine (telecommunication systems to facilitate healthcare consultations between individuals remotely) to connect patients to healthcare providers. Advantages of a telemedicine walk-in clinic include fewer required staffing resources compared to a traditional walk-in clinic and the potential to provide patients, particularly those in rural areas, greater access to routine healthcare services.

Thus, the current study investigates this new application of telemedicine[1] that provides healthcare services for minor ailments to walk-in patients via a teleconferencing e-health center. The first facility of this kind in the U.S., the Health e-Station (HES), opened in 2006 in Georgia. Designed primarily to promote patient empowerment and improve access to healthcare during off-hours, HES is open weekdays from 4:00 p.m. to 8:30 a.m. and for 24 hours on weekends—i.e., during times when primary care providers are generally unavailable. Proponents of HES argue that its main advantages over emergency rooms are its lower cost for services and quicker access to healthcare providers (Health e-Station, 2006).

A typical HES visit involves patient interaction with a trained technician, who connects the patient to an available physician via videoconferencing and operates the instruments to perform the patient examination. The videoconferencing technology transmits images and sounds taken from the patient examination to the physician and permits real-time interaction, via video and audio, between the physician and patient. Moreover, the patient is able to view the transmitted images on a display monitor in the examination room.

Though research on adoption of other telemedicine technologies exists, our understanding of the antecedents leading to patient adoption of telemedicine services that are readily offered to a broad population to diagnose minor conditions is limited. With this type of health services model, the choice to seek health services originates from the patient, as opposed to other types of telemedicine (e.g., telepsychiatry or teledermatology), which typically involve a provider referral to the telemedicine service. Further, it differs from telemedicine use for telemonitoring of chronic conditions since this service is used for diagnosing minor conditions and not for recurrent monitoring of an existing condition. As such, the determinants of patient acceptance of walk-in telemedicine services for minor conditions are likely to differ from other applications of telemedicine and warrant new investigation. Thus, the research question for this study is: *"What are the antecedents of patient adoption of walk-in telemedicine services for minor conditions?"* In this study, patient perspectives concerning walk-in telemedicine services (WITS) for minor conditions are assessed by eliciting potential adopter beliefs concerning use of HES. Using qualitative methods, the study identifies the salient factors that influence patient acceptance, builds a theoretical model, and derives propositions that can be investigated empirically in future studies.

BACKGROUND

A growing body of literature focuses on patient satisfaction with telemedicine, and a few researchers have published extensive literature reviews in this area. These reviews suggest that most patient satisfaction studies have been published since 1995, conducted in the U.S., and focused on a particular medical specialty, with telepsychiatry and teledermatology being some of the most prominent (Mair & Whitten, 2000; Williams et al., 2001). Given many studies' focus on a particular specialty, generalizations across studies may not be appropriate. Different conditions involve different costs, different types of sensory requirements (e.g., psychiatry versus dermatology), and different degrees of severity and risk—all factors that influence patient adoption and satisfaction beliefs. Moreover, patient adoption choices will likely be influenced differently by periodic minor conditions versus ongoing or more serious conditions, by diagnostic versus monitoring care, and by synchronous versus asynchronous interaction.

Furthermore, many studies were descriptive, comparing patient experiences between telemedicine and face-to-face consultations. Some authors caution that patients' perceptions may be skewed when they receive both telemedicine and face-to-face care for the same health condition, calling for further investigation of telemedicine being used as a replacement for, rather than an adjunct to, face-to-face care (Mair & Whitten, 2000; Williams, et al., 2001). These authors also report on the dearth of qualitative studies concerning patient acceptance of telemedicine.

Though some theory-driven studies have been conducted regarding *physician* perspectives on telemedicine (e.g., Gagnon et al., 2003; Lehoux, Sicotte, Denis, Berg, & Lacroix, 2002), few studies apply theory to explore *patient* perspectives on telemedicine (Whitten & Love, 2005). Further, while some studies have applied theory to investigate telemedicine adoption or use from a multiple-adopter perspective (e.g., LeRouge, Hevner, & Collins, 2007; Menachemi, Burke, & Ayers, 2004) and provide some insights into theoretical frameworks underlying patient acceptance of telemedicine, the studies focused on a general range of telemedicine services and did not always specify the type of telemedicine applications, making generalizations to the current setting unclear. Wilson and Lankton (2004) developed a model of patient acceptance of provider-delivered e-health based on technology acceptance theories. However, the antecedents leading to patient use of a Web-based health application at home and those leading to patient use of a *telemedicine clinic* that delivers health services (which is the focus of the current study) likely differ because the latter focuses specifically on synchronous clinical care within the structural boundaries of a healthcare facility.

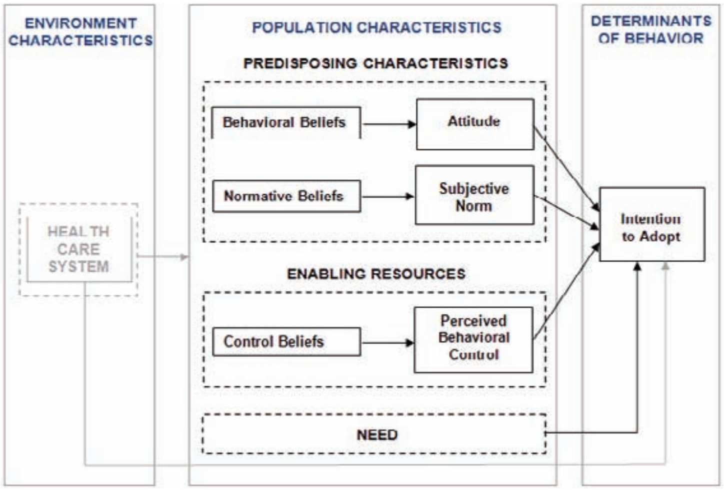
THEORETICAL FRAMEWORK

Theoretically, the study lies at the intersection of technology acceptance and healthcare services use. As such, two broad theories, the Behavioral Model of Health Services Use (BMHSU) and the Theory of Planned Behavior (TPB), were combined in an overarching framework that guides the research.

BEHAVIORAL MODEL OF HEALTH SERVICES USE

In the health services literature, the BMHSU has been a widely accepted and used model to explain access to and use of healthcare services (Andersen, 1995; Andersen & Newman, 1973). According to this model, the use of health services is dependent on people's predisposing characteristics, enabling resources, need for medical care, and external environmental factors. Predisposing characteristics include individuals' attitudes, beliefs, knowledge, values, demographic characteristics, and social structure. Enabling resources are the barriers or facilitating conditions that influence decisions

Figure 1. Combined BMHSU and TPB framework adapted from Ajzen (1991) and Andersen (1995)



to use healthcare services. Perceived need takes into account people's perceptions of their own general health, how they experience illness and anxiety symptoms related to their health, and whether their health state sufficiently warrants need of professional assistance. Aside from population characteristics, BMHSU posits that environmental factors—primarily the healthcare system—affect health services use. Inclusion of the healthcare system concept acknowledges that national healthcare policy and resources play a significant role in determining the population's use of healthcare services. However, because this study focuses on individual perceptions, an assessment of the national healthcare system is beyond the scope of evaluation.

Consistently, research has shown that perceived need is the prime determinant of healthcare use. The two remaining determinants of use, predisposing characteristics and enabling resources, are conceptually similar to determinants of behavioral intention in the TPB. An integration of these two models forms the underlying framework used in this study (Figure 1).

THEORY OF PLANNED BEHAVIOR

TPB (Ajzen, 1991) has been used to predict behavior in multiple contexts, including the technology acceptance domain (e.g., Pavlou & Fygenson, 2006; Taylor & Todd, 1995). According to TPB, behavior is a function of individuals' intention to engage in a behavior and their perceived behavioral control in achieving the target behavior. Behavioral intention is determined by individuals' attitudes, subjective norm, and perceived behavioral control.

Attitude is an overall evaluation of the pros and cons of engaging in a behavior. It is determined by salient behavioral beliefs regarding the consequences of engaging in a behavior and the evaluation of these consequences. Attitude and the corresponding behavioral beliefs are conceptually similar to the notions of attitudes, beliefs, and values included in the construct of predisposing characteristics of the BMHSU.

Subjective norm (SN) represents the social element of TPB and suggests that people decide to enact behaviors, in part, due to their perceptions of referent others' opinions about how they should behave. SN is determined by an individual's salient normative beliefs, or perceived expectations of

Table 1. Sample demographics

Demographics	Frequency (%)		Demographics	Frequency (%)	
Gender	16	(55%)	**Income**	1	(3.4%)
Female	13	(45%)	Less than $9,999	1	(3.4%)
Male			$10,000-14,999	5	(17.2%)
Age	2	(6.9%)	$15,000-24,999	3	(10.3%)
18-24	10	(34.5%)	$25,000-34,999	8	(27.6%)
25-34	8	(27.6%)	$35,000-49,999	7	(24.1%)
35-44	5	(17.2%)	$50,000-74,999	2	(6.9%)
45-54	3	(10.3%)	$75,000-99,999	1	(3.4%)
55-64	1	(3.4%)	$100,000-149,999	1	(3.4%)
65+			$200,000 and above		
Race	15	(51.7%)	**Highest Education**	1	(3.4%)
White	5	(17.2%)	Less than high school	16	(55.2%)
Black/African American	3	(10.3%)	High school	8	(27.6%)
Asian	3	(10.3%)	Bachelor's degree	2	(6.9%)
Hispanic	3	(10.3%)	Master's degree	2	(6.9%)
Multiracial			Doctorate degree		

referent others, and motivation to comply with these expectations. SN is conceptually similar to the notion of social structure included in the construct of predisposing characteristics of the BMHSU.

Perceived Behavioral Control (PBC) refers to one's perceptions of the level of ease or difficulty in engaging in a behavior. Thus, even if an individual has strong intentions to engage in a behavior, if he/she does not perceive the existence of resources and opportunities to achieve this goal, then there is less likelihood that he/she will realize the target behavior. The determinants of PBC are an individual's salient control beliefs and perceived power of these beliefs to facilitate or inhibit the behavior. PBC is conceptually similar to the enabling resources construct of the BMHSU.

According to TPB, all other constructs influence behavior through their effects on beliefs, attitudes, SN, and PBC. Therefore, demographic characteristics and other individual differences that are part of BMHSU's predisposing characteristics will influence behavior through their effect on beliefs, attitudes, SN, and PBC. Though the model specifies the relationships across the constructs, it is silent in terms of the specific behavioral, normative, and control beliefs that are salient in the context of patient acceptance of telemedicine services. In order to determine these, a process of belief elicitation was undertaken (Ajzen & Fishbein, 1980).

METHODS

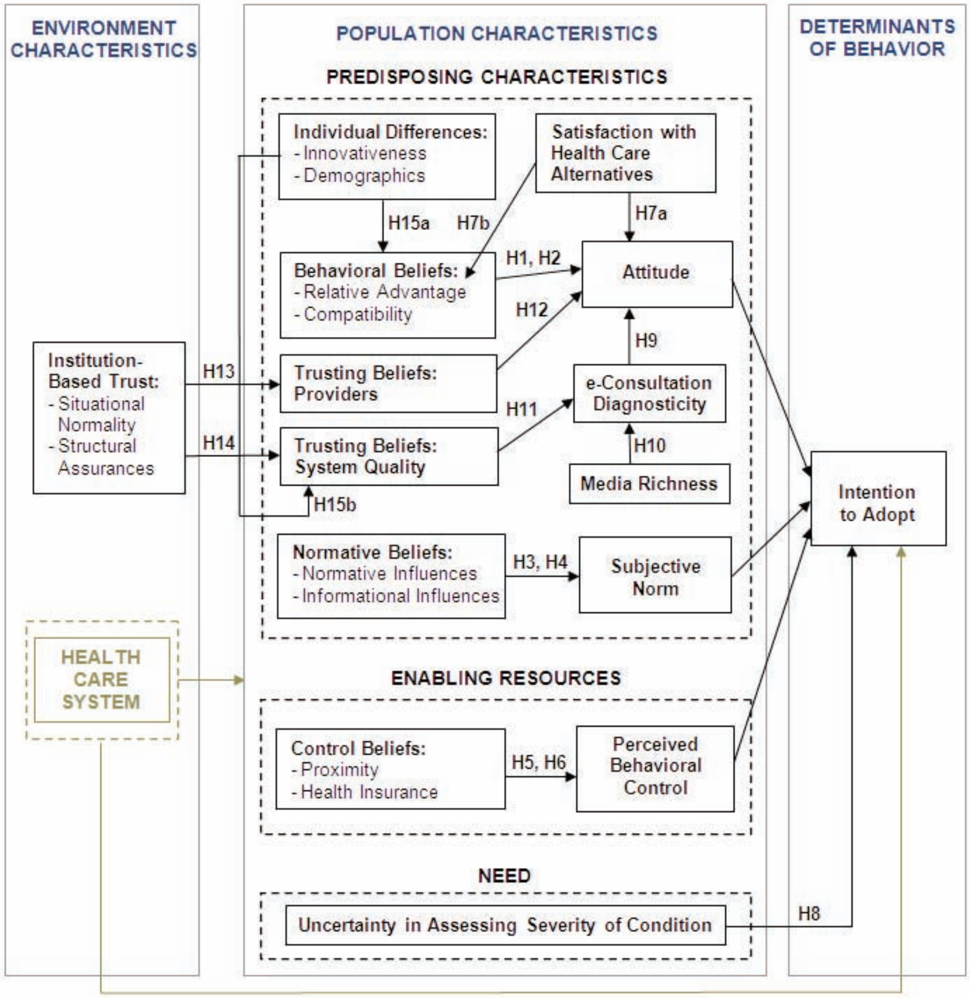
A total of 29 individuals were interviewed in 2007. All respondents were adults capable of making decisions concerning their own healthcare. Respondents varied in age, gender, race, education, and socio-economic status (see Table 1 for demographic data). For each interview, the respondent first watched an online video that describes HES, an example of a WITS clinic for minor ailments, by demonstrating a patient examination and discussing potential pros and cons of using the telemedicine services at this facility. The video can be viewed online (A Doctor's Visit, 2006), and a complete transcript of the video can be requested of the researchers. Showing the video was necessary since none of the respondents were familiar with WITS for minor conditions. After watching the video, respondents were asked structured interview questions based on the belief elicitation guidelines suggested by Ajzen and Fishbein (1980). While the interview questions were pre-specified, we allowed

Table 2. Frequency of elicited salient beliefs

Salient Beliefs	Description	Frequency (%)	
Behavioral Beliefs	Relative Advantage – Wait Time	25	(86%)
	Relative Advantage – After-Hours Availability	17	(59%)
	Media Richness	16	(55%)
	e-Consultation Diagnosticity	15	(52%)
	Relative Advantage – Convenience	14	(48%)
	Relative Advantage – Cost	11	(38%)
	Compatibility – Values	9	(31%)
	Compatibility – Personal Lifestyle	6	(21%)
	Complexity	2	(7%)
	Relative Advantage – Advantage over Alternatives	2	(7%)
	Relative Advantage – Less Exposure to Germs	1	(3%)
	Relative Advantage – Patient Empowerment	1	(3%)
Normative Beliefs – Normative Influence	Family Members	12	(41%)
	Healthcare Providers (Physicians and Nurses)	8	(28%)
	Health Insurance Companies	5	(17%)
	Friends	3	(10%)
	Employer/Employer-related	2	(7%)
	Other	2	(7%)
Normative Beliefs – Informational Influence	Interpersonal Network	9	(31%)
	News Media/Expert Opinions	7	(24%)
Control Beliefs	Proximity	21	(72%)
	Health Insurance	14	(48%)
	Public Transportation (on Bus Route)	3	(10%)
Trusting Beliefs – System Quality	Functionality, Reliability, Data Integration	7	(24%)
Trusting Beliefs – Providers	Technicians	6	(21%)
	Physicians	2	(7%)
Institution-Based Trust	Structural Assurances	11	(38%)
	Situational Normality	10	(34%)
Individual Differences	Demographics	15	(52%)
	Innovativeness	9	(31%)
Satisfaction with Healthcare Alternatives	Satisfaction with Healthcare Alternatives	14	(48%)
Nature of Condition	Uncertainty in Assessing Severity	8	(28%)
	Personal/Private	3	(10%)
	Telemedicine Technology Fit-to-Condition	2	(7%)
	Pain	2	(7%)
Reinvention*	Use Other Than Intended Use	6	(21%)
Relationship with WITS Provider	Familiarity with WITS Provider	3	(10%)
Facility Characteristics	Cleanliness	3	(10%)
Friendliness of Office Staff	Receptionists and Administrative Staff	2	(7%)

*Because we are interested in acceptance of WITS *as is*, we excluded the concept of reinvention from the model.

Figure 2. Emergent model - factors influencing patient adoption of walk-in telemedicine services for minor conditions



respondents to freely discuss their opinions of WITS for minor conditions and added questions as new concepts developed. Hence, there was an iterative process between the data gathering and conceptual development.

Twenty-three interviews were conducted in person, three via phone and three via email. We stopped collecting data when theoretical saturation (Glaser & Strauss, 1967) was achieved and no new concepts were emerging. Interviews were transcribed, and concepts were coded and sorted into conceptually similar categories. Both researchers separately coded all transcribed interviews and subsequently met to resolve disagreements. After four rounds of coding, there was 100% inter-rater agreement.

RESULTS

Table 2 contains the constructs (beliefs) that emerged through the interviews and their corresponding frequencies and Figure 2 shows the resulting theoretical model. To identify *salient* beliefs, we used Ajzen's and Fishbein's recommendation of including those beliefs mentioned by at least 20 percent of respondents. Then these beliefs were mapped on the TPB behavioral, normative, and control beliefs based on whether they referred to beliefs about consequences of adopting or not adopting the service (behavioral beliefs), important referent opinions as to whether the respondent should or should not adopt (normative beliefs), and perceptions of obstacles or facilitators to adopting (control beliefs). In addition to the salient belief categories of TPB, other concepts emerged and were added to the resulting theoretical model. Below we discuss the constructs and relationships that emerged from our analysis and present these in hypotheses format. The resulting model and hypotheses can be further tested in future research.

BEHAVIORAL BELIEFS

Two concepts from Rogers' (1995) Innovation Diffusion Theory (IDT) emerged as salient beliefs about the consequences of adopting WITS for minor conditions: *relative advantage* and *compatibility.* Relative advantage is the degree to which using an innovation is perceived as being better than its precursor while compatibility is the degree to which using an innovation is perceived as consistent with the existing values, practices, and experiences of potential adopters (Rogers, 1995). Empirical studies in technology acceptance (Karahanna, Straub, & Chervany, 1999; Moore & Benbasat, 1991) and a meta-analysis by Tornatzky and Klein (1982) suggest that these two constructs have been consistent significant predictors of innovation adoption behaviors.

Relative Advantage

According to IDT, relative advantage is a multi-dimensional construct that captures the benefits of an innovation in comparison to the practice it supersedes (Rogers, 1995). Rogers (1995) provides some possible dimensions to this construct, such as lower costs, savings in time and effort, and social prestige. Clearly, the specific benefits to be derived from an innovation vis-à-vis its precursor will be context-specific. In fact, Rogers (1995) states, "The nature of the innovation determines what specific type of relative advantage (such as economic, social, and the like) is important to adopters" (p. 212). Thus, there is no universal *a-priori* list of relative advantage dimensions and the dimensions need to be determined for each specific context.

The most significant relative advantage dimensions that emerged in our study were wait time, hours of availability, convenience and cost. In fact, all respondents mentioned that reduced wait time, or quick service, is one of the main advantages of using HES. Many individuals also perceived benefits in service availability during after-hours periods when physician offices are closed. Some indicated that after-hours availability was also attractive because it enabled them or their children to receive healthcare services without having to miss work or school:

You can go here at a more convenient time. There would be times when I didn't want to take off work or adjust my schedule just to get to the doctor by 4 p.m.

You'll get help late at night. For kids, if they have a rash or something, you can get a prescription real fast, so they don't miss school.

Further, many individuals indicated that this is a more *convenient* service than the emergency room or their physician's offices.

I would use a Health e-Station because it would be a fast and convenient alternative to visiting the emergency room.

Finally, the perceived lower cost of service relative to an emergency room visit was another commonly cited advantage.

I would use this over an emergency room because it's cheaper.

The health services literature also has revealed that these factors have been identified empirically as some of the most significant factors driving patient satisfaction with health services (Andersen, 1995). As such, we propose the following:

H1a-H1d: *Beliefs concerning the relative advantage of wait time, availability, convenience, and cost will positively affect attitude toward adoption of WITS for minor conditions.*

Compatibility

Based on Rogers' definition of compatibility, Karahanna, Agarwal, and Angst (2006) define compatibility as a multi-dimensional construct comprised of four dimensions: compatibility with values, compatibility with existing practices, compatibility with preferred work style, and compatibility with prior experience. The first two dimensions emerged as salient beliefs in our study.

In regards to healthcare, some respondents expressed strong values as to how healthcare should be delivered. Therefore, *compatibility with their values* about healthcare delivery became an important factor in determining their attitude toward the service. For instance, a few respondents indicated that they subscribe to holistic healing teachings. As such, they perceived WITS-provided care to be incompatible with their holistic healing values. Other respondents said that they associate use of WITS with the perpetuation of hasty, profit-driven healthcare.

There's a clear separation, where people can not be seen in a holistic way. I think it's driving medicine further and further from real interaction with the patient.

It's a more of an assembly line approach to healthcare…get the patient in and out, no rapport with the doctor. [The] patient may feel cheated, impersonal, violated.

On the other hand, some respondents made it clear that they had a preference for quick care and viewed this type of care as *compatible with their lifestyles*. Typically, these respondents noted that they have very busy schedules and, in some cases, travel routinely and find it difficult to establish connections with primary care practitioners.

For me, it's cool because I don't have a regular doctor; I move around a lot. For simple situations like an ear infection or strep throat, and you just need a prescription, it's really useful.

Hence, regarding compatibility, we propose that the higher the compatibility of WITS with existing values and lifestyle, the more positive the attitude towards using this facility:

H2a-H2b: *Beliefs about the compatibility of telemedicine use with healthcare values and beliefs about compatibility with lifestyle will positively affect attitude toward adoption of WITS for minor conditions.*

NORMATIVE BELIEFS

Two types of social influence emerged: normative influences that refer to influences that motivate individuals to comply with the expectations of others, and informational influences (Bearden, Calcich, Netemeyer, & Teel, 1986; Burnkrant & Cousineau, 1975; Karahanna et al., 1999) that refer to accepting information from others as evidence of reality.

Normative Influence

Two main referent groups emerged as sources of normative influences for the adoption of WITS: family members and healthcare professionals.

Seventy-three percent of respondents mentioned that their family members' opinions regarding the respondents' adoption of WITS would be important considerations. Respondents also indicated that their healthcare provider's opinion (approval or disapproval) would influence their adoption decision.

H3a: *Beliefs about family members' opinions will positively impact the subjective norm of adoption of WITS for minor conditions.*

H3b: *Beliefs about healthcare professionals' opinions will positively impact the subjective norm of adoption of WITS for minor conditions.*

Informational Influence

Adopting an innovation is high in uncertainty about the characteristics of the innovation and the consequences of adopting (Rogers, 1995). Thus, potential adopters examine two kinds of uncertainty reducing information: (a) information to determine what the innovation is, what it does, and why it works (principles knowledge) and (b) innovation-evaluation information about the innovation's advantages and disadvantages. Once such information-seeking activities have reduced the uncertainty about the innovation's expected consequences to a tolerable level, a decision concerning adoption or rejection will be made.

Therefore, communication channels are highly influential in providing information about WITS and its potential advantages and disadvantages. Mass media channels have a greater impact in gathering information about the innovation (WITS), while interpersonal channels more strongly influence the decision making process of whether or not to adopt (Agarwal & Prasad, 1998; Brancheau & Wetherbe, 1990; Rai, 1995; Rogers, 1995). Overall, respondents have indicated that communication from both channels would be influential in their decision to adopt WITS for minor ailments. Word-of-mouth influences through interpersonal networks, especially from individuals who will have used WITS, were cited as important sources of evaluative information and influential in the adoption decision. Additionally, media sources, such as news channels and the expert opinions of health professionals, were influential informational sources.

People who I know who have used this clinic before would influence me. That's the only way I would use this clinic, if people I know gave me favorable feedback about the clinic.

If it becomes a consensus in the medical field that this is adequate and if media report positive aspects of it…that would influence me to use it.

H4a: *Word-of-mouth communications will positively impact the subjective norm of adoption of WITS for minor conditions.*

H4b: *Media communications from news and expert sources will positively impact the subjective norm of adoption of WITS for minor conditions.*

CONTROL BELIEFS

Two salient control beliefs were identified: proximity and health insurance acceptance. Respondents mentioned that the closer in proximity a WITS clinic is to their location, the easier it would be to visit this facility. Furthermore, the facility's acceptance of the respondents' health insurance would be instrumental in determining whether they adopt the service. Though the latter represents an aspect of the Healthcare System environment in BMHSU, it is a control belief in our model since it will inhibit patient adoption despite otherwise positive beliefs on advantages.

H5: *The proximity of a WITS facility is positively related to perceived behavioral control over adoption of WITS for minor conditions.*

H6: *The acceptance of a patient's health insurance policy will positively affect perceived behavioral control over adoption of WITS for minor conditions.*

SATISFACTION WITH HEALTHCARE ALTERNATIVES

Adoption of WITS for minor conditions occurs in the context of other alternatives. As such, perceptions of relative advantage will be influenced by one's satisfaction with these alternatives. Specifically, respondents who were satisfied with and had a good relationship with their primary physician saw fewer advantages and were less likely to adopt WITS:

With your own physician, you build up a rapport. I would rather wait and make an appointment with my doctor.

H7a: *Satisfaction with healthcare alternatives will have a negative influence on attitude toward adoption of WITS for minor conditions.*
H7b: *Satisfaction with healthcare alternatives will have a negative influence on the relative advantage of WITS for minor conditions.*

UNCERTAINTY IN ASSESSING SEVERITY OF CONDITION

Several respondents indicated that the nature of their health condition would influence their decision to use WITS. While we framed the research questions within the context of minor health conditions, some respondents still expressed concern that they would not be able to assess whether their condition is minor or severe. These respondents indicated that they would use WITS for minor conditions only when they are confident in their assessment of the severity of their health condition.

I would use it only if I could self-diagnose myself or if my condition is simple.

H8: *Uncertainty in assessing the severity of one's own health condition will be negatively associated with adoption of WITS for minor conditions.*

Technology and Trust Factors

Though technology applications can be very promising and useful, technology is not infallible; inevitably, there will be system failures, power outages, glitches in software, and so forth. Further, in telemedicine, the technology limits the extent of communication cues between the patient and physician; hence, there is less richness in telecommunication versus face-to-face communication (Daft & Lengel, 1986). Many respondents noted that, by its very nature, telemedicine-based care can not be as comprehensive as in-person healthcare because the physician can not utilize all senses in assessing the condition of the patient. In other words, when utilizing telemedicine, the physician is limited to visual and auditory senses and can not take advantage of tactile and olfactory senses in deciding on a proper diagnosis. We discuss this group of factors next.

Perceived E-Consultation Diagnosticity

We introduce a new construct, perceived e-consultation diagnosticity, which is defined as the perceived ability of the telemedicine technology and users to convey to physicians sufficient patient diagnostic information that helps physicians in accurately understanding and evaluating the health conditions of remote patients. This concept is adapted from the marketing literature, in which the concept of perceived product diagnosticity has been studied. Perceived product diagnosticity involves consumer judgments of product trials—the extent to which consumers perceive that the product trial process is helpful in allowing them to evaluate products and their specific attributes (Kempf & Smith, 1998). In the context of e-consultation diagnosticity, physicians evaluate the specific symptoms and health conditions of patients without being present to "touch and feel" the patients; rather, they rely on images and sounds transmitted through technology. Respondents in this study shared concerns as to whether physicians can provide a thorough evaluation of patients via telemedicine's inherent indirect means and, thus, correctly diagnose their condition.

> *You still need the human touch when you're dealing with doctors…Even though you can see the person, sometimes you actually have to touch the person to see if something is swollen.*

> *A doctor may not be able to make a 100% accurate diagnosis every time because he is limited to only video images and audio to diagnose a problem.*

> *It's not a full, proper exam, even though you can still see and hear… Using the technology would not bring across the symptoms, secondary symptoms, and underlying symptoms associated with your health problem.*

In the words of one of the respondents, "*The diagnosis is the most important part of the visit.*" As such, perceived e-consultation diagnosticity and related media richness concerns were the fourth and third most frequently mentioned factors influencing adoption of the telemedicine service. Patients visit WITS to receive diagnoses for minor health conditions. If patients perceive that they can receive accurate diagnoses, then they will have more favorable evaluations of adopting WITS. In contrast, patients who doubt that they will receive accurate diagnoses will have more negative overall attitudes toward adopting WITS.

H9: *Perceived e-consultation diagnosticity will have a positive impact on attitude toward adoption of WITS for minor conditions.*

Media Richness

Media richness is a medium's ability to convey rich information (Daft & Lengel, 1986; Daft, Lengel, & Trevino, 1987) and is based on the ability of the medium to provide instantaneous feedback; to convey multiple cues, such as social presence, voice inflection, body gestures, words, and graphic symbols; to provide language variety (e.g., numbers and natural language); and to enable conveyance of personal feelings and emotions. Though media have an "objective" level of richness, this may be perceived differently across individuals and, thus, our focus is on perceived media richness (e.g., Carlson & Zmud, 1999).

The telemedicine technology enables instantaneous feedback as well as language variety to the same extent as a face-to-face encounter. Therefore, it is not surprising that respondents only identified multiple cues and ability to convey emotions as salient factors. Specifically, social presence, the availability of all sensory cues, and personal interaction with the physician were commonly cited as limitations of the telemedicine technology and sources of concern.

> *The doctor may not see subtle things that he/she may see in person…the way the patients talk or other things.*

> *The doctor can't see how the patient actually feels. One-on-one contact is different.*

The extent of telemedicine media richness perceived by patients will influence their perceptions of e-consultation diagnosticity because the technology limits the cues available for diagnosis:

> *A doctor may not be able to make a 100% accurate diagnosis every time because he is limited to only video images and audio to diagnose a problem, as opposed to visual, auditory, olfactory, and tactile methods.*

H10: *Perceptions of media richness will positively influence perceived e-consultation diagnosticity.*

TRUST IN TECHNOLOGY BELIEFS: SYSTEM QUALITY

Since diagnosis is mediated through technology, the quality of the telemedicine system is paramount in facilitating an effective exchange between the patient and physician and diagnosis of the condition. As such, system quality concerns were an important consideration by respondents. Though the literature suggests various dimensions of system quality (DeLone & McLean, 1992), our respondents focused on reliability, dependability, accuracy, and functionality of the technology.

Just because you're depending on technology, that stuff can break sometimes or not show a good picture or get good reception.

There's all this room for error when you deal with technology. I don't think the technology would work right.

When expressing system quality concerns, respondents said they do not "trust the technology."

I don't trust those machines…You're taking a risk by relying on the machines and the technicians. What if the images are different – the image isn't high quality, or it doesn't transmit exactly the same?

Trust in technology has been defined as the extent to which a user is confident in and willing to depend on the technology (Lankton & McKnight, 2008; Madsen & Gregor, 2000) and is based on trusting beliefs of competence, benevolence, integrity (Wang & Benbasat, 2005), predictability, dependability, faith, competence, responsibility, and reliability (Muir & Moray, 1996). These trusting beliefs are similar to the dimensions of system quality identified by our respondents (e.g., accuracy, reliability, dependability, and functionality). In some comments, beliefs on system quality were inextricably linked with comments on trusting the technology. Therefore, in the context of telemedicine, trusting beliefs in technology refer to beliefs about the quality of the system. Further, as respondents indicate, their beliefs about system reliability, accuracy, and functionality influence their perceptions of e-consultation diagnosticity:

The technology limits the extent of diagnoses and tests they can do from a distance.

This center, being more tech-inclined, may have more of the latest technologies, diagnosis tools, information…that might mean better care.

H11: *Beliefs concerning system quality will positively impact perceived e-consultation diagnosticity.*

TRUSTING BELIEFS: PROVIDERS

Concern for one's own physical well-being is likely to influence potential adopters' perceived risk of using WITS and ultimately make trust a salient consideration in the adoption of WITS. Trust has been defined as one's trusting beliefs of ability, benevolence, and integrity concerning the trustee, or the object of trust (Mayer, Davis, & Schoorman, 1995). Ability refers to the competence that the trustee possesses to perform the task. Benevolence reflects the goodwill of the trustee—i.e., the extent to which the trustee will not take advantage of the trustor or otherwise act opportunistically. Integrity refers to the belief that the trustee will adhere to the principles perceived to be acceptable by the trustor.

Respondents indicated three categories of healthcare providers associated with a WITS facility: physicians, office staff, and technicians. However, only beliefs concerning *technicians' ability* surfaced as salient beliefs. Because the technician is the one interacting with the patient face-to-face and coordinating the communication between the patient and physician, patients are more concerned with trust issues with regard to technicians. Without the technicians' expertise, the interaction between the patient and physician can not properly take place. It is interesting to note that respondents expressed no concerns about the ability, benevolence, or integrity of the physicians or benevolence and integrity of the technician.

You're basically at the mercy of your technician, so they would need to be properly trained and motivated.

What if the technician measured you wrong or missed something? Do they know what they're doing?

H12: *Trusting beliefs in the technician's ability will positively influence attitude toward adoption of WITS for minor conditions.*

INSTITUTION-BASED TRUST

Institution-based trust (IBT) is defined as the perception that impersonal structures are in place to protect individuals (Shapiro, 1987) and is an antecedent of trusting beliefs (McKnight, Cummings, & Chervany, 1998). There are two types of IBT: situational normality and structural assurances (McKnight et al., 1998). Situational normality refers to the sense that the situation is customary and as expected and as such it instills a confidence that the transaction will be a success (Baier 1986; Lewis & Weigert, 1985). This assures people that everything in the setting is as it ought to be and that a shared understanding of what is happening exists (McKnight et al., 1998; Zucker, 1986). Structural assurances refer to the safety nets (e.g., regulations, guarantees, legal recourse, and contracts) an institution puts in place in order to protect individuals (McKnight et al., 1998; Shapiro, 1987; Zucker, 1986). Perceptions of institutional safeguards at a WITS facility will emanate trust in both the healthcare providers and the technology.

Situational Normality

Respondents favorably inclined to adopt WITS specifically noted that a WITS visit did not appear to be too different from a regular physician's visit or an emergency room visit. In contrast, respondents skeptical of the efficacy of WITS observed low situational normality.

I would just use it because it doesn't seem too different than a regular doctor's visit. The only difference is that the doctor is not there with you. But if you talk to the doctor on camera, or on TV, the doctor would still be able to diagnose what's going on with you.

If the person operating the telemedicine equipment is just a technical person rather than trained in medicine, I would be more hesitant to think it's the same as seeing a doctor.

Thus, to the extent that patients perceive that WITS are similar to other models of healthcare delivery, they will show increased trust in both the providers and telemedicine system.

H13a: *Situational normality will positively influence trusting beliefs toward the providers.*

H13b: *Situational normality will positively influence trusting beliefs concerning system quality.*

Structural Assurances

Some respondents referred to various structural assurances issues. For example, because HES does not have nurses or physicians on staff, nor the wide range of medical technology resources that a hospital has to treat serious conditions, some respondents suggested that patients' misdiagnoses of the severity of their own symptoms may result in dire consequences. Hence, respondents indicated that they would put more trust in WITS for minor conditions if appropriate resources or safeguards were available to protect patients who have unexpected serious health conditions. Other examples of structural assurances that were mentioned include concerns regarding information security and physical security. Some respondents expressed skepticism that the network-based technology would be a secure channel for protecting their patient confidentiality.

It's wide open for fraud with insurance companies. How easy is it to hack into the Internet? What's the proof that somebody went to the clinic and saw a doctor?

People may be wary of privacy issues... because information is traveling through networked technology, the information is not private.

With structural assurances in place, patients will exhibit higher levels of trust in the providers and telemedicine system. Regarding providers, for example, if quality assurance guarantees exist, patients are more likely to believe that the providers possess competence, benevolence, and integrity. Likewise, if safeguards and procedures are in place to prevent system hacks and downtime, patients will put more faith in the quality of the telemedicine system.

H14a: *Structural assurances will positively affect trusting beliefs toward the providers.*

H14b: *Structural assurances will positively affect trusting beliefs concerning system quality.*

INDIVIDUAL DIFFERENCES

Two groups of relevant individual differences emerged through the interviews: demographic characteristics and the personality trait of innovativeness. Respondents indicated that younger individuals may be more likely to adopt, likely because they are more open to technological innovations (Morris & Venkatesh, 2000). In addition, people in rural areas and of lower income may find the enhanced access to healthcare and the lower costs more attractive than people who have better access (geographic and financial) to alternative services. Finally, respondents who viewed themselves as innovative were excited about the possibility of at least trying WITS. Personal innovativeness with respect to information technology (the willingness of an individual to try out any new information technology) has been shown to be an important factor in technology acceptance decisions by influencing salient beliefs (Agarwal & Prasad, 1998).

I wouldn't go to a Health e-Station. It's too new. The first try is so risky that I wouldn't do it, unless it's proven.

The technology is pretty interesting, the fact that you can see the scope of your throat or eardrum… that's pretty innovative. Right now, I'm not sick very often. I probably would just go out of curiosity.

H15a: *Personal innovativeness with respect to technology will positively influence behavioral beliefs toward adopting WITS for minor conditions.*

H15b: *Personal innovativeness with respect to technology will positively influence trusting beliefs towards system quality.*

Though we do not posit hypotheses with respect to demographic variables, we include it in the model to highlight the fact that demographic variables such as age, geography, and socio-economic status are likely influential factors in the nomological network leading to patient acceptance of telemedicine services.

LIMITATIONS

Like all research, the current study has limitations. Though our sample is diverse in age, gender, race, education, and socio-economic status, it may not be entirely representative and, as such, generalizability of findings should be interpreted with care. For example, our sample did not include many individuals with lower socio-economic status, without health insurance, and over the age of 65; additional perceptions and challenges may emerge for these groups.

While most of the data were collected in face-to-face interviews, email and phone were used for six respondents. Though inspection of responses showed no differences in the types of beliefs elicited, method differences in responses cannot be conclusively ruled out. However, since the objective was to elicit salient beliefs, the use of multiple methods is not a threat to the validity of the results. Additionally, our focal telemedicine service is HES. To the extent that other telemedicine services differ significantly from HES, results of the study may not generalize to patient acceptance of other telemedicine services.

Furthermore, our methodology involves showing potential adopters a video of HES, which relays expert opinions (pros and cons) of this telemedicine service. Though this was necessary given the newness of the application and given that none of the respondents were familiar with walk-in telemedicine services, these expert opinions may have introduced bias in the respondents' reported beliefs concerning WITS for minor conditions. It is possible that the respondents may have been influenced in the beliefs elicited not only by the description of the facility and illustration of how it works to diagnose a minor medical condition, but also by the experts who were presenting their opinions (one pro and one against) regarding WITS (HES, specifically). Thus, certain beliefs, such as wait time, cost, and uncertainty in assessing the severity of the condition, may have become more salient in this study and, thus, may be over-represented in frequency. Though this is not unlike how beliefs are formed prior to adoption—i.e., mass media and interpersonal networks play an important role in shaping beliefs (Rogers, 1995)—the model developed in this study should be tested empirically with potential adopters who become aware of WITS via other means. The model should also be tested with users of WITS for minor conditions who have *first-hand* experience with the service since antecedents of adoption and repeated use may not be the same necessarily (Karahanna et al., 1999).

DISCUSSION AND DIRECTIONS FOR FUTURE RESEARCH

The study has provided insights into the antecedents of patient acceptance of WITS for minor conditions. While the majority of the respondents (n=15, 52%) reported that they would use WITS, there were a few (n=4, 14%) who indicated that they would never use WITS. Furthermore, there were several respondents (n=10, 35%) who specified that they would only use WITS under certain conditions (e.g., if the WITS facility would accept their health insurance plan, if they could self-diagnose their condition, if they could not see their own physician within a reasonable amount of time, etc.), indicating that many respondents are not ready to embrace e-consultations as a replacement for face-to-face consultations if the face-to-face option is readily available.

Specifically, perceived e-consultation diagnosticity, perceptions of relative advantage and compatibility, trust in technology and in the providers, and institutional guarantees all emerged as important salient behavioral beliefs. Proximity and health insurance acceptance emerged as salient control beliefs while both informational and normative influences emerged as important sources of social influence. Other antecedents that were identified include individual differences in age, socio-economic status, and geographic location as well as the personality trait of innovativeness and one's satisfaction with his/her local healthcare provider.

Extant studies on technology acceptance suggest that perceived usefulness (or relative advantage in terms of efficiency and effectiveness), ease of use, compatibility with work style, and social influence are key determinants of user acceptance of technology (see Venkatesh, Morris, Davis, & Davis, 2003 for a synthesis). Results of the study highlight that while some commonalities exist, patient acceptance of telemedicine technology entails some unique antecedents. Specifically, perceived e-consultation diagnosticity emerged as a central concern for potential adopters. Given the possible personal risk entailed in healthcare decisions, and the technology-mediated nature of the interaction with the physician, potential adopters raised concerns about the efficacy of the technology in enabling diagnoses of their health condition. These concerns emanated from perceptions that the technology was not rich enough to permit "touch and feel" cues that are important in diagnosing as well as questions about trusting the technology to be reliable and accurate. As more technology-mediated healthcare services become available and given the dire potential risks of misdiagnoses, the concept of perceived e-consultation diagnosticity will likely continue to be a central concern for patient acceptance. As such, future research should focus on developing measures of this construct as well as additional antecedents and consequents.

In addition, the potential higher personal risk involved in healthcare decisions manifested in the emergence of additional trust-based antecedents of patient acceptance. Both types of institution-based trust, structural assurances and situational normality, as well as trust in the provider beliefs were identified as significant factors. Thus, to instill trust, at least initially, telemedicine services should resemble other professional health services and use similar procedures. Salient structural assurances included guarantees about the security and privacy of information and safeguards to assure proper treatment of more serious medical conditions. The existence of guarantees, legal recourse, and safeguards appears to be a focal trust-building mechanism and an important way in which to reduce perceptions of risk. Future research should identify other specific structural assurances that can instill trust in telemedicine services.

Further, while innovation diffusion theory posits relative advantage as an important determinant of adoption (Rogers, 1995; Tornatzky & Klein, 1982), it does not specify the relevant dimensions of relative advantage that are salient in each context. Our study suggests that potential adopters perceive benefits in wait times, hours of availability, convenience, and cost. The advantages are reflective of current patient frustrations with extant alternatives in the U.S. Additional or different dimensions may emerge in other countries where physicians' office hours, for example, are more convenient for the patients or where physicians make home visits. As such, though the model suggests that relative advantage is an important determinant of adoption, it is likely that its specific dimensions will be country-specific. Identifying these dimensions and determining their generalizability across countries is a fruitful direction for future research.

The study makes three important theoretical and practical contributions. First, using both belief elicitation and guided by theory, we develop a model of patient acceptance of WITS for minor conditions. Future research should empirically test the emergent research model to validate and further develop and refine the nomological network. The current research focused on identifying pre-adoption beliefs. Future research should examine how patient beliefs change over time and determine beliefs that lead to continued WITS usage. Second, we develop perceived e-consultation diagnosticity as an important construct in the nomological network leading to patient acceptance and we identify its antecedents. Perceived e-consultation diagnosticity emerges due to the technology-mediated nature of telemedicine diagnoses. As telemedicine services grow, we expect the construct to be of interest to academics and practitioners in health informatics. Finally, from a practical perspective, the factors identified in the model provide leverage to practitioners in designing and implementing telemedicine systems and in deploying marketing efforts to enhance acceptance of telemedicine services.

ACKNOWLEDGMENT

The research was supported by a Terry-Sanford grant from the Terry College of Business, University of Georgia.

Chapter 5.18

Disability Determinations and Personal Health Records

Elaine A. Blechman
University of Colorado at Boulder, USA

ABSTRACT

Newly disabled workers are often unemployed, uninsured, and indigent. They are in desperate need of Social Security OASDI monthly benefits, and the Medicare health insurance that follows 24 months after benefits begin. Applicants must prove that their medical conditions (excluding drug and alcohol abuse) have resulted in severe functional limitations that prevent them from any gainful employment. Delays and denials of benefits result when applicants cannot find or retrieve medical records from providers familiar with their medical history, health status, and functional limitations. The disability application workflow is complex, particularly for applicants with cognitive and mental health impairments. Health information technology (HIT) has been used to automate care delivery workflow through provider-controlled, electronic health record systems (EHRs). Disability applicants' workflow could, just as well, be automated through consumer-controlled, unbound, and intelligent personal electronic health record systems (PHRs), which are not tethered to a health plan or employer network, and which automatically exchange information updates with authorized providers' EHRs. Applicants' PHRs may later prove helpful with self-management of chronic conditions prior to Medicare coverage and with periodic reevaluations of their medical status.

INTRODUCTION

"A 20-year-old worker has a 3 in 10 chance of becoming disabled before reaching retirement age" (http://www.socialsecurity.gov) by a condition that prevents work or that limits the kind or amount of possible work (Burkhauser & Houtenville, 2006). In 2004, an estimated 7.9% (or about one in 13) civilian noninstitutionalized, men and women, aged 18-64 in the United States reported a disability that limits work; about one in four people with disabilities lived in families with incomes below the poverty line (Houtenville, Erickson, & Lee, 2005).

DOI: 10.4018/978-1-60566-016-5.ch005

About 46.6 million people or 15.9 percent of the U.S. population have no health insurance (Hadley, 2007). Approximately 18,000 Americans die prematurely each year because they lack health insurance (DeNavas-Walt, Proctor, & Lee, 2006). A telephone survey of people with disabilities found that those who were uninsured were more likely than others to do without or delay necessary care, including prescription drugs and preventive healthcare services that would reduce their future need for healthcare (Hanson, Neuman, Dutwin, & Kasper, 2003). Newly disabled and unemployed workers who no longer have private health insurance coverage are exceptionally vulnerable to deteriorating health and untimely death. If they qualify for Social Security disability benefits, they get a modest income for themselves and their dependents and, after 24 months, Medicare Part A (http://www.socialsecurity.gov/disability/3368).

Disability benefits have expanded and contracted since their institution during the Great Depression (http://www.ssa.gov/history/briefhistory3.html). In 1935, President Roosevelt signed the Social Security Act (SSA), creating a contributory system in which workers prepared for their retirement through taxes that they paid while employed. In 1956, an amendment to the Act provided benefits to disabled workers aged 50-64 and disabled adult children. In 1960, President Eisenhower signed an amendment permitting SSA disability benefits for disabled workers of any age and their dependents. In 1996, President Clinton signed a bill (P.L. 104-121) that changed eligibility for SSA disability benefits from a medical condition that prevents work, to a medical condition other than drug addiction or alcoholism that prevents work.

About 48.4 million people received Old Age, Survivors, and Disability Insurance (OASDI) monthly benefits in December 2005. Disabled workers and their dependents were 17% of OASDI beneficiaries, their average monthly benefits were $938. In 2005, OASDI payments exceeded $44 billion a month, approached $521 billion for the year, and represented 4.2% of the U.S. gross domestic product. At the same time, employees, self-employed workers, and employers contributed $593 billion to the OASDI trust funds (SSA, 2007).

Two recent studies indirectly suggest the importance of SSA disability benefits. In Sweden, 197 individuals granted disability pensions reported less illness, larger social networks, and less work and family role limitations than 96 individuals who did not receive disability pensions (Ydreborg, Ekberg, & Nordlund, 2006). In the U.S., a survey of 4,918 veterans found that their odds of impoverishment were reduced considerably if they applied for and received VA benefits for posttraumatic stress disorder (Murdoch, van Ryn, Hodges, & Cowper, 2005).

The findings of a third study (McWilliams, Meara, Zaslasvky, & Ayanian, 2007) are directly relevant to the impact of Medicare coverage following (by 24 months) qualification for SSA disability benefits. McWilliams et al. (2007) used longitudinal data from the nationally representative Health and Retirement Study to assess self-reported healthcare use and expenditures from 1992 through 2004 among 5,158 adults who were privately insured or uninsured before age 65 and of Medicare eligibility. Previously uninsured Medicare beneficiaries with hypertension, diabetes, heart disease, or stroke required more intensive and costly healthcare, and died earlier than previously insured Medicare beneficiaries with these same chronic conditions. There were no differences in morbidity or mortality between previously uninsured and insured Medicare beneficiaries without chronic conditions.

Chapter Overview

Newly disabled workers are often unemployed, uninsured, and indigent. They are in desperate need of Social Security OASDI monthly benefits and the Medicare health insurance that follows 24 months after benefits begin. Applicants must prove that their medical conditions (excluding drug and alcohol abuse) have resulted in severe functional limitations that prevent them from any gainful employment. Delays and denials of benefits result when applicants cannot find or retrieve medical records from providers familiar with their medical history, health status, and functional limitations. The disability application workflow is complex and obscure (Pransky & Dempsey, 2004), particularly for applicants with cognitive and mental health impairments (Banks & Lawrence, 2005).

Health information technology (HIT) has been used to automate care delivery workflow through provider-controlled, electronic health record systems (EHRs). For example, providers can use capabilities of their EHR systems to automate scheduling of patient encounters, e-prescribing, ordering of laboratory tests and import of laboratory results, and production and export of health insurance claims for reimbursement of their services.

Disability applicants' workflow could, just as well, be automated through consumer-controlled, unbound, and intelligent personal electronic health record systems (PHRs), which are not tethered to a health plan or employer network and which automatically exchange information with authorized providers' EHRs. For example, consumers could use their PHRs to automate transmission of requests for medical records, autofilling of SSA forms, importing of requested data and documents from providers' EHRs, and exporting of the completed application portfolio to SSA interviewers and evaluators in formats they require. Applicants' PHRs may later prove helpful with self-management of chronic conditions prior to Medicare coverage, and with periodic reevaluations of their medical status.

In the remainder of this chapter, I suggest how newly disabled workers could use PHRs to ease the disability benefits application process. First, I describe some of the workflow requirements confronting newly disabled workers applying for SSA benefits. Next, I present the conventional assumption that a National Health Information Network (NHIN), scheduled for rollout in 2014, should be composed of provider-controlled EHRs networked in regional health information exchanges (HIEs) with limited consumer access via tethered PHRs.

A provider-controlled NHIN simply cannot satisfy the workflow requirements of low-income, unemployed consumers with chronic conditions, such as applicants for SSA benefits. And so, I recommend that the NHIN architecture make room for consumer-controlled, unbound, intelligent personal electronic health record systems (PHRs), which are capable of automating data exchange across the NHIN with provider-controlled EHRs, are not tethered to employer or health plan networks, and automate the workflow required to compile, update, and selectively share an electronic disability benefits application portfolio.

PROBLEM: APPLYING FOR SSA DISABILITY BENEFITS

The applicant for SSA disability benefits must satisfy SSA's five-step disability application process. Applicants must meet an earnings requirement including a duration-of-work test to show sufficient length of work under Social Security. And, they must prove that they are unable to work due to limitations associated with medical conditions other than drug addiction or alcoholism. Decisions about eligibility, according to various SSA documents, can take from three months (for applicants with confirmed disabilities on the SSA list) to five years (for applicants who contest denial of their initial application and await the ruling of an administrative law judge). The application process, with its various permutations, is depicted on the SSA Web site in a 15-page-long flow chart.

SSA deems applicants eligible for benefits if they:

1. Are not working or have monthly earning in an acceptably low range;
2. Have a severe medical condition that "significantly limits your ability to do basic work activities—such as walking and remembering—for at least one year";
3. Have medical conditions on the SSA list of impairments (http://www.ssa.gov/disability/professionals/bluebook/AdultListings.htm) that are automatically considered disabilities as defined by law; or
4. Have medical conditions that the state agency decides prevents applicants from being able to do the work they did before; and
5. Are judged by a state agency unable to do other work than before.

SSA 3368: The process usually begins at the applicant's local Social Security office where the applicant, assisted by an SSA interviewer, completes SSA Disability Application 3368, Adult Disability and Work History Report (http://www.socialsecurity.gov/disability/3368). SSA 3368 includes 275 data fields covering illnesses, injuries, conditions; work; medical records; medications; tests; education and training; vocational rehabilitation; and employment. SSA 3368 is available online so that applicants can print it out and use it to prepare for the interview at the local SSA office. (Although the SSA Web site indicates that online submission is an option, my several attempts to initiate an online submission failed).

Other applicant forms: In addition to the basic SSA 3368 application form, applicants must complete other forms which describe their medical conditions and explain how it affects their ability to work, and which give permission to doctors, hospitals, and other healthcare professionals to release applicant information and records to the SSA. (These forms are mentioned on the SSA Web site, but my repeated attempts to find these forms failed).

Supporting documents and medical records: SSA requires applicants to supply documents and medical records that support claims made in SSA 3368 forms including:

- The Social Security number and birth certificate or other proof of age for each person applying for benefits (including your spouse and children, if they are applying for benefits);
- Names, addresses, and telephone numbers of doctors, hospitals, clinics, and institutions that treated you and dates of treatment;
- Names and prescribed dosage of all medications you are taking;
- Medical records from your doctors, therapists, hospitals, clinics, and caseworkers;
- Laboratory and test results;
- A summary of where you worked in the past 16 years (company names, addresses, supervisors' telephone numbers) and the kind of work you did;
- A copy of your W-2 Form (Wage and Tax Statement), or if you are self-employed, your federal tax return for the past year; and
- Dates of your current and any prior marriages, if applicable

The SSA Blue Book (SSA, 2006a) recommends that applicants request medical records documenting their medical condition (including prescribed medications and lab test results) from healthcare providers who are familiar with them and able to provide *a detailed longitudinal picture of the claimant's impairments.* Many applicants cannot retrieve medical records from the healthcare providers who diagnosed and treated them in the past. Their past providers may be unresponsive to requests for medical records. Or, they may not be able to recall the identity or location of the many past providers with whom they have had diagnostic and treatment encounters. Applicants who are unable to retrieve sufficient documentation from their own healthcare providers must submit to a one-time examination by an SSA-appointed examiner. SSA examiners are unfamiliar with applicants' medical history and health status; and, they are probably less inclined than applicants' own physicians to find in the applicant's favor.

If an applicant's claim is denied by the state agency, the applicant may request a hearing before an administrative law judge involving reconsideration of application evidence by a vocational or medical expert. The waiting time for hearings ranges from 90 days to 18 months. When a judge issues a partially favorable or unfavorable decision, the claimant may appeal to Social Security's Appeals Council, whose response time ranges from 12 weeks to three years.

The SSA disability application process requires applicants to procure, store, and share a comprehensive and up to date portfolio of medical records, lab tests, and evaluation reports. Applicants must make copies of items in this portfolio available to any number of SSA employees and subcontractors involved in the applicant's case for as many as five years from start to finish of the application process. Most applicants who are awarded benefits must be prepared for periodic re-evaluations of their status by continuously updating their medical records portfolios.

The SSA publishes annual statistical reports (e.g., SSA, 2007) enumerating the proportion of applicants who are denied benefits and the reasons for denial such as "Impairment is not severe." An unknown number of applicants pay doctors and lawyers to prepare, submit, and appeal their applications. It is not clear how many applicants are improperly denied benefits, because they lack the human or financial resources required for continuous, long-term exchange of records and information with providers, vocational and medical experts, lawyers, administrative law judges, and appeals councils. Nor, is it clear how many applicants make substantial investments in this process, but die before they become eligible for benefits.

It seems likely that a substantial number of genuinely eligible applicants cannot find and supply the required data and supporting documents, due to the presence of medical conditions (such as traumatic brain injury) and associated cognitive and mental health disabilities (such as dementia and PTSD), and due to the absence of capable, informed family caregivers. Many beneficiaries, similarly unprepared for SSA reevaluation of their status, may lose their benefits.

Controversy: A Provider-Centered National Health Information Network

For about two decades, health information technology (HIT) has been employed to automate healthcare providers' workflow, including records management, scheduling of patient encounters, and submission of claims to health insurance payers. No noticeable attention has been directed to automation of workflow of consumers with chronic conditions and their family caregivers who spend hours each week managing health-care records, scheduling appointments with providers, and contending with healthcare financing problems. Lessons learned from automation of providers' workflow could readily be applied to consumers such as SSA disability benefits applicants or SSA beneficiaries undergoing reevaluation of status. HIT might just as well be used to automate the SSA disability application workflow, making it easier for deserving applicants to speedily and successfully submit applications and qualify for benefits.

Health Information Technology Policy Recommendations

The Institute of Medicine (IOM) of the National Academies of Science is a nongovernmental body established to advise the U.S. Congress about healthcare policy. The IOM has repeatedly recommended the use of HIT to automate the workflow of healthcare providers with the expectation that the results would benefit consumers, particularly those with chronic illnesses and disabilities.

In 1991, the IOM proposed, "The Computer-Based Patient Record," as an essential technology solution for inadequacies in U.S. healthcare (IOM, 1991). In 2000, the IOM reported that, "More people die in a given year as a result of medical errors than from motor vehicle accidents (43,458), breast cancer (42,297), or AIDS (16,516)" (IOM, 2000, pp. 1), and in 2001, recommended the use of HIT to make healthcare more safe, effective, patient-centered, timely, efficient, and equitable (IOM, 2001). In 2003, the IOM described the key care delivery functions with which an electronic health record system or EHR could promote patient safety in hospitals, ambulatory care settings, nursing homes, and the community (IOM, 2003). In 2006, the IOM recommended the use of HIT to improve the coordination of care for cancer survivors (IOM, 2006). In 2007, the IOM recommended e-prescribing in order to prevent an estimated 1.5 million adverse drug events each year (IOM, 2007).

Building a National Health Information Network

The U.S. is a decade or so behind other economically developed countries in the design and deployment of a nationwide health information network and in network inclusion of disabled, uninsured, and indigent individuals (Anderson, Frogner, Johns, & Reinhardt, 2006).

With bipartisan support, President Bush, in 2004, ordered nationwide implementation of an interoperable health information technology infrastructure to improve the quality and efficiency of healthcare by 2014. David Brailer (2005), the first national health information technology coordinator, predicted that a National Health Information Network (NHIN) composed of interoperable electronic health records (EHRs) would "not only transform but become healthcare," with regional health information organizations (now called health information exchanges or HIEs) as likely local NHIN hubs (Halamka, Aranow, Ascenzo, Bates, Debor, Glaser, Goroll, Stowe, Tripathi, & Vineyard, 2005).

Kaushal, Blumenthal, Poon, Jha, Franz, Middleton, Glaser, Kuperman, Christino, Fernandopulle, Newhouse, Bates, and the Cost of National Health Information Working Group (2005) estimated NHIN roll out over five years would cost $156 billion, assuming that physicians, hospitals, skilled nursing facilities, home health agencies, laboratories, payers, and pharmacies acquire interoperable EHRs. Walker, Pan, Johnston, Adler-Milstein, Bates, and Middleton (2005) estimated the costs of interoperability between physicians, hospitals, laboratories, radiology centers, pharmacies, payers, and public health departments at $320 billion if nonstandardized (i.e., dependent on customized adapters to translate data between EHRs), and at $276 billion if standardized (i.e., based on common standards for data exchange).

Efforts are underway to build sustainable business models (e.g., Yasnoff, Humphreys, Overhage, Detmer, Brennan, Morris, Middleton, Bates, & Fanning, 2004) that would leverage private healthcare enterprise funding for the NHIN with federal contributions for research and development but not for ongoing operations. Private funding for the NHIN would come from providers who adopt interoperable EHRs and from regional HIEs, which provide the infrastructure for data exchange among EHRs across the NHIN. How a private enterprise NHIN business model would impact uninsured, unemployed, and indigent consumers has been given little consideration to date.

So far, only 9-15% of physician offices have adopted EHRs (Kaushal et al., 2005). To motivate provider adoptions, vendors are enhancing EHRs in ways presumed to build patient loyalty and simplify practice workflow. One such EHR enhancement gives consumers limited views of their records through patient portals or tethered personal electronic health record (PHRs). Tethered PHRs ease the workflow of providers and office staff by encouraging consumers to report information (e.g., allergies, family medical history, complaints), schedule appointments, and otherwise self-manage their healthcare—online. For healthy, employed, and insured consumers, who encounter their primary care providers perhaps once a year, tethered PHR are a pleasant convenience.

For disabled, unemployed, and uninsured consumers, who frequently visit many providers, tethered PHRs are not particularly convenient because they display partial views of fragments of consumer information and do not permit aggregation of data across tethered PHRs or exchange of aggregate data with other EHR systems. Applicants for disability benefits need both options. Regardless of the capabilities of tethered PHRs, disabled workers are unlikely to encounter many publicly funded providers who are equipped with EHRs and associated tethered PHRs.

Efforts are underway to select and harmonize technical standards (Hammond, 2005) for information exchange across the NHIN. The search for interoperability standards is largely focused on the exchange of patient information among provider-controlled EHRs within and across regional HIEs. The expected result is that the NHIN will be implemented as a network of networks that joins national technical interoperability standards to state or local control and funding.

In order to implement the NHIN, the Office of the National Coordinator of Health information technology (ONC), in the U.S. Department of Health and Human Services, established the American Health Information Community (AHIC) and the Health information technology Standards Panels (HITSP). AHIC's role is to develop high-level use cases related to information exchange across the NHIN. The role of HITSP's four technical committees—public health, care delivery (EHRs), consumer empowerment (PHRs), and security and privacy—is to develop interoperability standard specifications for the AHIC use cases.

How the architecture of the NHIN will impact uninsured, unemployed, and indigent consumers, who are not profitable customers of privately financed healthcare, has been given little consideration to date.

Recommendation: Room at the NHIN for Consumers with Disabilities

There needs to be room at the NHIN for consumers without primary-care provider advocates. Newly disabled workers exemplify the consumers who most need NHIN data-exchange capabilities but who are least able to get what they need for their disability benefits applications from provider-controlled EHRs.

Delays and denials of benefits result when applicants cannot find or retrieve medical records from providers familiar with their medical history, health status, and functional limitations. The disability benefit application workflow is complex, particularly for applicants with cognitive and mental health impairments. Health information technology (HIT), which is routinely used to automate care delivery workflow through provider-controlled EHRs might just as well be used to automate the workflow of benefit applicants through consumer-controlled PHRs. For this purpose, applicants would need unbound, intelligent PHRs.

Unbound PHR systems are not tethered to a health plan or employer network; they supply the utility infrastructure services required for current point-to-point exchange with diverse providers' EHRs and for future participation in the NHIN. Intelligent PHRs automate the workflow of applicants including the automated exchange of new and updated information with authorized providers' EHRs, eliminating the necessity for manual data entry, without reimbursement, by providers' office staff.

Tethered PHRs, which give consumers selected glimpses into providers' EHRs, represent the first generation of PHRs. Consumer-controlled and unbound PHRs, which enable consumers to control the exchange of data with providers' EHRs represent the second generation of PHRs. Consumer-controlled, unbound, and intelligent PHRs (or smart PHRs), which automate consumers' healthcare workflow such as applying for SSA disability benefits, represent the third-generation of PHRs (see for example, http://www.thesmartphr.com).

For disability applicants, smart PHRs would seem to offer several advantages including facilitation of the initial benefits application and of periodic reevaluations of their medical status, self-management of chronic conditions prior to Medicare coverage, and ongoing preparedness for medical emergencies and Hurricane Katrina-like disasters.

Instead of prolonged speculation about potential advantages, we need randomized field trials with large samples of disability applicants. The first research step would be to examine usage rates, and self- and provider-perceived utility for various PHR types with and without assistance from patient navigators. (What type of PHR with what kind and amount of assistance is used most and perceived as most useful by all or some applicants?) The next step would be to examine impact on the disability application process of a frequently used, and apparently useful PHR. (Are PHR-equipped applicants more successful at getting benefits than PHR-unequipped applicants?) A third, and particularly important, research step would be to examine the impact of PHR usage on perceived and objective measures of applicant health. (Do beneficiaries with high rates of PHR usage evidence better health in the two years before Medicare coverage than beneficiaries with lower rates of PHR usage, controlling for pre-existing differences between high-usage and low-usage beneficiaries?)

FUTURE TRENDS

Due to Google, consumers expect to have information about every imaginable topic immediately available. Yet, consumers' own medical records are inaccessible, locked away in providers' paper and electronic files. Educated and affluent consumers, aware of the fallibility of the healthcare establishment, are primed for advances in information technology that give them increased control over the healthcare workflow. The purchasing decisions of these opinion leaders may make consumer-controlled PHRs as ubiquitous as cell phones and affordable even to newly disabled workers applying for SSA benefits.

CONCLUSION

A National Health Information Network can be accessible to providers via interoperable EHRs supported by regional HIE networks and to consumers via interoperable, unbound, and intelligent PHRs with HIE infrastructure inside. Disabled workers applying for SSA benefits or undergoing periodic reevaluations of their status could use this consumer-centered information technology to avoid delays and denials of essential income and Medicare coverage. Evaluations of adoptions, usage, and consequences of this technology among SSA applicants and beneficiaries are in order. At the end of the day, health information technology has value only if it benefits the disabled consumers who "pay the price for America's healthcare crisis" (Cohn, 2007).

INTRODUCTION

The healing process can be viewed as a partnership between doctors and patients, nurses and physicians or, more generally, a partnership of health professionals and health care users (Anonymous, 2008, Graham, 2007). A patient-centered approach that empowers patients to participate in decisions about their treatment and health care options asks for active participation of patients themselves, specifically, in health information gathering and exchange of this information with their health or medical records (Bachman, 2007; Stolyar, Lober, Drozd, & Sibley, 2005).

DOI: 10.4018/978-1-60566-026-4.ch003

BACKGROUND

Medical or Health Record

Every physician has a number of patients in his or her care. Many patients also have a number of specialists taking care of their health. It is almost impossible for physicians to keep in mind all the information about even a single patient, let alone all patients in their care. Similarly, patients need to remember and comply with many recommendations communicated to them by their doctors. Recording patients' data is, today, a necessity, especially considering a large number of available diagnostic procedures and instruments producing information relevant for making medical decisions. One implication of such recording is the creation of medical records in health institutions; they are created and accessed by health professionals. According to the National Library of Medicine, the MeSH (medical subject heading) term "medical record" considers "recording of pertinent information concerning patient's illness or illnesses" (http://www.PubMed.com).

However, the medical data gathered by health professionals are not enough for making good medical decisions. Information that is not strictly medical can be added to medical data. We therefore usually talk about a *health record*, consisting of data and information that affect or could affect the patient's health status, or simply describe it. A health record is a more general term than a medical record, nursing record, or dental record, and should be used as an immediate superior term to them. Keeping all the information pertaining to a particular patient in one place, and making it accessible at any time to authorized professionals, is a challenge. In seeking solutions, the information and communication technology should be consulted.

Personal Health Record

In trying to encourage people to take an active interest in their own health, patients are supported to manage their own personal health records. A personal health record can contain copies of data from the health record, which is created by health professionals, and also information entered by patients themselves (for example, subjective information such as description of symptoms, and objective information such as values of self-measured blood pressure or blood glucose levels, etc., recorded in a personal health diary).

Thus far, the literature does not give an adequate definition of a personal health record. Wikipedia defines it as "a health record that is initiated and maintained by an individual," but it is unclear who the individual is, the health professional or the patient. According to Tang (2006), a personal health record includes health information managed by the *individual*, who is not necessarily a *patient,* an ill person. This distinction emphasizes that the personal health record is a tool used to care for health and wellness, not only illness.

CURRENT STATUS

Electronic Health Record and Personal Health Record

There are several definitions of the electronic health record and many descriptions of its characteristics and demands (Hayrinnen, 2007). According to ISO (2004), "the EHR means a repository of patient data in digital form, stored and exchanged securely, and accessible by multiple authorized users. It contains retrospective, concurrent, and prospective information and its primary purpose is to support continuing, efficient and quality integrated health care." One of the most exhaustive descriptions of electronic health records is given by the Advisory Committee on Health Infostructure of Canada (2001). According to the description in their Tactical Plan for a pan-Canadian Health Infostructure, an electronic health record is "a longitudinal collection of personal health information of a single individual, entered or accepted by health care providers, and stored electronically. The record may be made available at any time to providers, who have been authorized by the individual, as a tool in the provision of health care service. The individual has access to the record and can request changes to its content. The transmission and storage of the record is under strict security." This means that an electronic *health* record also incorporates electronic *medical* records, including digital medical images (computer tomography or similar) and biomedical signals (electrocardiography or similar), laboratory findings, the interpretation of all such findings, and physicians' recommendations to patients. Hospital records, nursing records, dental records, and other similar records can also be parts of an electronic health record.

It is generally agreed that patients have the right to know who is collecting, storing, accessing, communicating, or processing the data in their electronic health records, for what purpose, where the data will be kept, to whom they will be communicated, and for what purpose (Kluge, 2004).

The definition of electronic personal health records as "electronic summaries of a patient's medical record that are often portable and easily accessed by the patient" (Endsley, Kibbe, Linares, & Colorafi, 2006) is not adequate, for it does not distinguish from electronic medical records. A better description of an electronic personal health record was given as "an electronic application through which individuals can access, manage and share their health information" (Pagliari, Detmer, & Singleton, 2007). We propose the most appropriate description of an electronic personal health record would be "a digitally (electronically) saved health information, created and accessible by both health professionals and the individual, respecting privacy, security and confidentiality."

Content of the Electronic Health Record

Today, electronic health records are used in many hospitals, primary care offices, and other health institutions. Each of these sites collects specific patient data particularly relevant to the type of health care received at the site, but all the data could, and should, be mutually communicated. Pulling together health data from different sources should help doctors make better diagnostic and therapeutic decisions. However, pulling information from several different sources will require a unique identifier (Mayor, 2007). This is the first demand on electronic health records.

Patient Identifier

Health systems of different countries define patient identifiers in different ways. Sometimes patients are identified by their health insurance number, other times by the social security number, and sometimes by biometric characteristics of a patient. As a general rule, all of these identifiers are unique (i.e., any two patients have different identifiers) and should have a check digit calculated by a defined algorithm. Table 1 shows an example of creating such an identifier.

Health and Medical Data

Structured electronic medical records can result in quicker data entry, improved quality of care, and improved usefulness of records for daily clinical practice (Kruger, 2007). Doctors and nurses prefer structured data entry; electronic nursing records are better, and databases with structured electronic patient records can be used on a large scale to develop treatment regimes and support quality assurance (Kruger, 2007). Integration of clinical decision support systems into electronic medical records holds a promise for more efficacious and cost-effective solutions in daily medical practice. However, designing and structuring the electronic health (or medical) record is a daunting task.

The starting point of the electronic health record should be *patient history*. Patient history is produced during a conversation between the patient and the health care professional. It is not a final product made by, for example, a general practitioner at the first appointment, but it should be resummarised, recontextualised, and recreated in the light of new information, possibilities, and changing priorities during patient care. Some of these data can be structured, but some should also be written as free text.

Laboratory data are mostly structured. Some are measured and recorded as numeric values (e.g., blood glucose 5.3 mmol/L), while some laboratory data are qualitative and usually coded (e.g.,

Table 1. Creating a patient identifier (algorithm: module 11)

Starting with: 10000001
Add ponders to each digit: 7 6 5 4 3 2 7 6
Calculate: 7*1+6*0+5*0+4*0+3*0+2*0+7*0*6*1=13
Calculate: 13∧:∧11∧=∧1, remnant∧=∧2*
Calculate: 11∧–∧2∧=∧9
Conclusion: 9 is a check digit and the created identification number is: 100000019
* in case of remnant∧=∧0 the 8 digit number should be omitted; in case of remnant∧=∧1 the check digit shoudl be 0
Following the same algorithm the next identifiers will be:
100000024
100000038
100000043
100000057
....#

blood groups: A, B, O, AB; proteins in urine: -, +, ++, +++).

Radiological data (medical images) and *biomedical signals* can be recorded digitally, and described (interpreted) by a radiologist or another appropriate specialist in the form of free text.

Diagnoses are coded according to an adequate coding system (International Classification of Diseases – ICD-10, SNOMED-CT, etc.), and *drugs* usually by the ATC classification.

Procedures are also coded, usually by using a specific coding system, depending on the country, health sector (hospitals, primary health care, etc.), and the purpose of such data. A diagnosis-related group (DRG) is based on the major diagnosis, length of stay, secondary diagnosis, surgical procedure, age, and types of services required. It is internationally accepted for acute cases in hospitals in order to determine the fixed payment per case (Hammond & Cimino, 2001), but it can be locally adjusted.

Patient *discharge letter* could be partially structured (parts including numeric and coded data), but it also includes some descriptions (free text).

Other Data

The electronic health record can contain other data such as personal data, socio-demographic and administrative data (e.g., name of the individual, date of birth, gender, education, insurance data, etc.).

Characteristics of an Electronic Health Record

Electronic health records should support the delivery of good quality patient care and improve decision making in all daily clinical situations. It should be standardized (e.g., EN 13606). In particular, an electronic health record should improve the management of chronic conditions and help maintain immunization records.

Specific characteristics of digitally recorded data are:

- They can be viewed from a variety of locations (general practice office, specialist practice, laboratory, hospital, etc.) at any moment, when needed,
- For viewing the data as a specific output (e.g., tables or graphs), a specific software is needed; viewing is not static and final, but is instead continuously modifiable,
- Users' authorization levels determine which parts of electronic health record they can access and which actions they can perform (security and protection),
- It is possible to trace who entered the data and who has seen the data, and when (any action can be recorded for the sake

of patient safety and responsibility of the health professional),

- Periods of nonavailability of electronic health record data can be known (criterion for usability of the particular system).

Opposite to this, paper-based medical data can be viewed from only one location, they can be seen unconditionally, there is no possibility to specify which part of the document can be read (all or nothing), it is not possible to know who has seen the data and when (it is not recorded), and periods of nonavailability are unknown.

An electronic health record can be used not only for patient management, but also for reporting, quality assurance processes, research, and administrative processes, such as scheduling and billing. A standardised electronic health record is a prerequisite for good communication in the health care system (examples of standards relevant for electronic health record and communication are EN 13606, DICOM, LOINC and HL7).

Benefits of the Electronic Health Record

Electronic health records increase patients' confidence in their health care providers. They save patients and health care providers the repetition of various information (such as personal information – name, address, etc., previous course of the disease, test results) in different health institutions. At the same time, patients are assured that all health professionals caring for them have access to all the relevant parts of their health history. Also, online communication between health care providers in different institutions speeds up health service. There is no need to wait for discharge letters or test results, and the number of lost test results is markedly reduced. Quality of care is improved as the electronic health record (and data in it) makes the communication with experts much easier. Consequently, another benefit of an electronic health record can be a reduction in the number of medical errors.

Content of the Electronic Personal Health Record

Individual patients have their own documents about their health, their own personal health records. These could be copies of medical documents in paper or in electronic format, for example, laboratory findings or x-ray images (Fig. 1), or even hospital discharge letters. These could also be data on drugs, herbal medications, diet, or

results of home testing (blood pressure, medication, etc.) (Fig. 2). Some patients can analyze their health data (e.g., visualization of time series of blood pressure) (Fig. 3) and change their behavior accordingly. Personal health record can also contain various administrative data, such as the name of the person's physician or data related to health insurance.

Characteristics of the Electronic Personal Health Record

There is no standard for electronic personal health record, but there are many electronic applications offered for this purpose (MyPHR, iHealthRecord, etc).

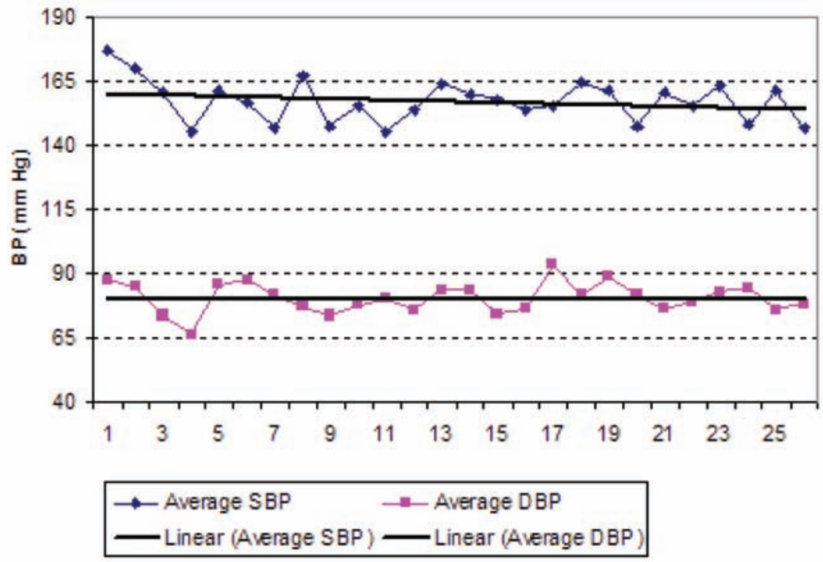
Benefits of the Personal Health Record

Without doubt, the two leading benefits of personal health records are patients' empowerment and promotion of active partnership between patients and caregivers.

FUTURE TRENDS

Electronic health records have been successfully implemented in many settings. Still, they all need further development and improvement, usually linked to rapidly changing technologies. Other aspects of improvement deal with the contents

Figure 3. Example of visualization of blood pressure measurements as a part of an electronic personal health record



and the way in which the data are recorded (such as classifications or coding systems).

Electronic personal health records are emerging and have much room for further growth. Simpler models of personal health records include passive access to data written on a compact disc or a smart card, or possibly at a Web site. Interactive systems of personal health records demand the integration of a personal health record with health providers' record systems (i.e., electronic health records). Ensuring the security of such systems remains a challenge. According to Pagliari (2007), views on values vs. risks of electronic records are highly polarized. Still, as all new initiatives take time to become fully developed and accepted by its users, this polarization is likely to be only temporary.

CONCLUSION

Electronic health records are the present and the future of contemporary health care systems. Electronic personal health records should be developed in accordance to the needs of all the participants in the health care (health care providers and health care users). It could be expected that the electronic personal health record and electronic health record will interact while not threatening privacy, security, and confidentiality. Both types of records are only parts of the same system, and both need more development and improvement. The ultimate goal of high interactivity, accuracy, and safety can be assured by the information and communication technologies, but both health care professionals and health care users need to accept such a system and become partners in using it, in order to benefit from it.

KEY TERMS

Active Patient: is an emerging term describing patients' active participation in the management of their health and wellness.

Electronic Health Record (EHR): A health record stored electronically.

Electronic Medical Record (EMR): A medical record stored electronically.

Electronic Personal Health Record (EPHR): A personal health record stored electronically.

Health Record (HR): A longitudinal collection of personal health information of a single individual, entered or accepted by health care providers.

Medical Record (MR): A longitudinal collection of personal data concerning patient's illness or illnesses.

Personal Health Record (PHR): A longitudinal collection of personal health information of a single individual containing copies of parts of health records, health related data measured and/or noticed by the individual, and administrative data.

Chapter 5.20

Using Stakeholder Analysis to Identify Users in Healthcare Information Systems Research:

Who is the Real User?

Alexander J. McLeod Jr.
University of Nevada, USA

Jan Guynes Clark
The University of Texas at San Antonio, USA

ABSTRACT

Applying IS research to the healthcare context is an important endeavor. However, IS researchers must be cautious about identifying individual roles, the context of the setting, and postulating generalizability. Much of IS theory is rooted in organizations, their business processes, and stakeholders. It is not a simple matter to generalize healthcare IS research, assuming that it is equivalent to organizational IS research. Hospitals, emergency rooms, and laboratories are different from the "business environment", and "healthcare users" vary considerably in their roles. Therefore, IS researchers need to understand the healthcare setting before they can appropriately apply IS theory. Obviously, if we are studying the wrong person, or group of people, we cannot expect to get relevant results. In order to alleviate confusion regarding "who is the user?" in healthcare IS research, we provide examples of healthcare scenarios, perform simplified stakeholder analysis for each scenario, and identify the stakeholders.

INTRODUCTION

Information systems continue to make inroads into the healthcare industry as more of those in medicine adopt computer technologies (Goldschmidt, 2005; Huston & Huston, 2000; Khoumbati, Themistocleous, & Irani, 2006). Innovative technologies support healthcare by maintaining or reducing costs, distributing care to geographically distant patients, and providing consulting specialists where expertise is limited or not available (Field, 1996; LeRouge, Hevner, & Collins, 2007; Login & Areas, 2007). Emphasizing the needs and abilities of those who are using the technology improves the quality of health information systems research.

Crafting Information Systems (IS) research for the healthcare context is an important endeavor. However, IS researchers must be accurate when identifying individual roles (Kling, 2003; Reponen, 1994), the setting context, and postulating generalizability (Avgerou, 2001; DeLone & McLean, 2003; Rawstorne, Jayasuriya, & Caputi, 2000). One of the most important principles for IS researchers is "know your user" (Norman, 2005). This principle should also apply to those performing healthcare information systems research. However, this is often not the case.

Much of IS theory is rooted within the organization, its business processes, and stakeholders (Ginsberg & Venkatraman, 1985; Magni & Pennarola, 2008; Massa & Testa, 2008; Van de Ven, 2005). One well accepted definition of a stakeholder is "Any group or individual who can affect or is affected by the achievement of the organization's objectives" (Freeman, 1984). In order to understand "who really counts", we need to systematically evaluate stakeholder relationships (Mitchell, Agle, & Wood, 1997). IS stakeholders within a business context generally fall within one of three groups – users, managers, and IS professionals. Although this distinction is fairly clear in healthcare administration (the business side of healthcare), it is not nearly as clear-cut in patient healthcare.

Hospitals, emergency rooms, and laboratories are very different from the normal "business" environment, and healthcare stakeholders vary considerably in the role they play (patient, attending physician, specialist, intern, resident, nurse, clinician, administrator, etc.). Depending upon the situation, any or all of these stakeholders can be users of a healthcare IS system. Therefore, definitions originating from the business environment involving business users and processes may not apply in the healthcare setting. For example, attempting to apply an IS theory such as the Technology Acceptance Model (TAM) to telemedicine requires that the investigator realize the differences in stakeholders. All stakeholders are not users. A physician who reads a report generated by a clinician that operated some technology is not the "user" of the technology. It would therefore be inappropriate to survey the physician's user acceptance or usability of the technology. The clinician, not the physician, is the "user". In addition, a patient who obligingly reports for an examination and passively participates in a televideo consultation is not a "user". The technician who operates the equipment is the user, and the technician's acceptance of the technology is important to IS researchers.

We contend that IS researchers should understand the healthcare setting and the role of its stakeholders before applying IS theory. In addition, networks of patients and practitioners using information technology create very different interrelated user and interorganizational processes. Healthcare processes are considerably different. These processes may involve life and death situations that depend on extremely important and often time sensitive data and information. Most patients facing illness or injury are sick and stressed. Ignoring these contextual differences in favor of generalizability simply dilutes or negates the effects of human computer interactions in the unique healthcare environment.

A recent meta-analysis of patient satisfaction revealed that a) few studies adequately defined terms, b) most studies lack explanation of interaction effects of the physician-patient relationship, and c) in general, studies lack data correctly examining the perceptions of the users (Mair & Whitten, 2000). These studies were performed by medical and/or information systems researchers. The very division of healthcare into medical/clinical and socio/technical entities begs for a duality of understanding when applying theoretical constructs.

Conceptualization of the user is fundamental to healthcare and IS research (Lamb & Kling, 2003). Those researching the "IS user" in healthcare must have insight into the triad of physician, clinician, and patient in order to correctly apply IS theory in the healthcare setting. Arguably, inadequate definitions, missing relationships, and erroneous perceptions cast doubt over the generalizability of healthcare information systems research.

Some readers may view this as "simply stating the obvious". However, as former healthcare professionals, we have identified several IS/healthcare research articles in which the user was not properly defined. The researchers, as well as the reviewers of their research, simply did not understand the complexity of healthcare and IT. It is not our intent to embarrass any healthcare researchers or publishers. Therefore, we will discuss known errors in a generic fashion. The vast majority of healthcare IT user research focuses on either the patient or the primary physician. In many cases, neither the patient nor the primary physician was the actual user of the technology. For example, one recent IS healthcare article surveyed patients on user satisfaction. However, the patients did not use the technology. Instead, they provided medical data input to a system that was used by either clinicians or physicians. Although patient satisfaction is important, it does not always equate to IS user satisfaction. In other prior research, physicians were surveyed to determine ease of use of a medical technology that rarely, if ever, is actually "used" by a physician. Instead, clinicians "use" the technology and send reports to the physician. Other researchers have studied the wrong physician, focusing on primary physicians, rather than the medical specialist, such as a cardiologist, who actually used the IS healthcare technology. Obviously if researchers do not properly define the user, the validity of the research is in question.

In order to facilitate "IS user" research in healthcare, we propose performing a simplified stakeholder analysis of the decision or implementation in order to better define the users of the technology. The next section provides a brief review of research that focuses on the "IS user". This is followed by a discussion of stakeholder analysis as it applies to information systems research in the patient healthcare setting.

IS USER LITERATURE

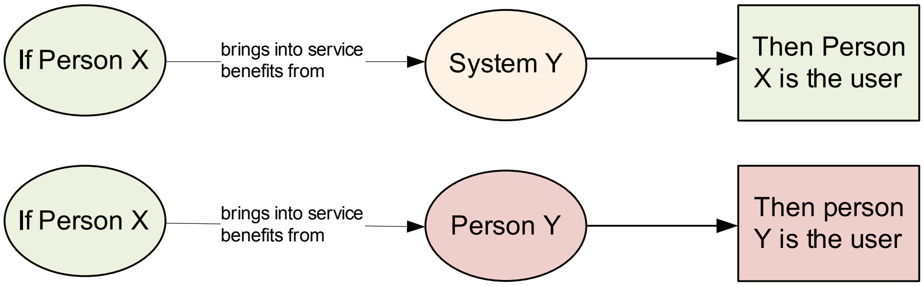
To understand the user concept, it is necessary to first define the user within the context of IS research. Historically, user definitions are scarce, and even fewer definitions exist within specific contexts. Davies (2002) conceptualizes the user from four theoretical perspectives: distributed cognition, situated action, activity theory and as social actors. In defining the user via these perspectives, Davies suggests the following relationships.

1. X causes Y to act or serve a purpose.
2. X brings Y into service.
3. X avails himself of Y.

If X brings Y into service, then X benefits from Y. One could assume that if X benefits from Y, then X is automatically the user. However, that is dependent upon whether Y is a person or an object. For example, assume data is needed. Someone can retrieve the data for you, or you can retrieve it yourself, from an online database. If you ask Person Y to provide you with the data, then Person Y is the user. You are the data recipient and a stakeholder but not the user. However, assume that Y is a system. You bring System Y into service by entering the commands to retrieve the data. In this situation, you are a stakeholder, the user and the data recipient. Figure 1 details the User Definition. If Person X brings Person Y into service, Person X benefits (indirectly) from Person Y. Therefore, Person Y is the User. If Person X brings System Y into service Person X benefits (directly) from System Y. Therefore, Person X is the User.

Note that these definitions are presented in the simplest form. As complexity increases, the

Figure 1. User definition diagram



true definition of the user becomes blurred. For example, if Person X requests data from Person Y, who then passes on the request to Person Z, Person Z becomes the user. In other situations, Person X may receive data indirectly, but still be a user of the system. For example, assume an EKG technician performs an EKG on a patient and transmits results electronically to a physician. If the physician signs on to the system and retrieves and analyzes the EKG data, the physician is also a user of the technology. However, if the physician simply receives a hard copy of the EKG, the physician is only a data recipient. Therefore, for the purpose of this paper, a user is anyone who manipulates a system in order to perform a given task.

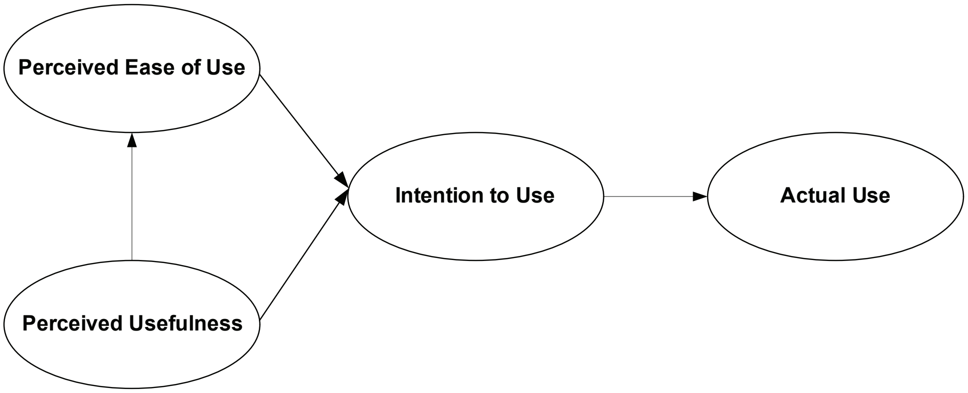
As would be expected, there is an abundance of research related to the user construct in IS literature. A review of the top five ranked journals listed on IS World revealed over 350 "user" titled articles (ISWorld, 2006). This exemplary review was not exhaustive but did supply an adequate number of articles with which to classify the user construct for further analysis. The primary user concepts in these articles included user acceptance, user participation, user satisfaction, user training, user performance, user interfaces, and end user computing. We examined the user construct in each of these areas to see how IS researchers conceptualized the user.

User Acceptance

User acceptance is one of the most studied areas of information systems research (Hu, Chau, Sheng, & Tam, 1999; Ma & Liu, 2004). In this area, IS research examines how and why people adopt and use information technology (Venkatesh, 2000). The importance of user acceptance is its potential relationship to system success. System success in IS research is often dependent upon many independent variables, one of which is user acceptance (DeLone & McLean, 1992). Often, user unwillingness to accept technology obstructs implementation and use. In IS research, the user's perceived ease of use and perceived usefulness provided the starting point for measuring acceptance (Davis, 1989). Figure 2 shows the user acceptance model as originally proposed and its relationship to use.

Many researchers extended and modified this model adding mediating and moderating variables, resulting in a variety of possible user acceptance conceptualizations. Venkatesh et al. (2003) attempted to unify this diverse topic by discussing, empirically comparing and consolidating eight prominent models of user acceptance. The unified model maintains the dependent variable as originally conceived. The basic concept underlying the user acceptance model is the individual's "**Actual Use**" of information technology. Actual use can be seen in the model as suggested by Venkatesh (2003) in Figure 3. As

Figure 2. User acceptance model (Davis 1989)



conceptualized, "Actual Use" conforms to the Davies (2002) user definition test. The individual causes the computer to act or serve a purpose, brings the computer into service, and benefits from using the system. Obviously, "Actual Use" of the information technology is a requirement in IS research involving user acceptance theory. Those performing healthcare related acceptance research need to ascertain if the participants are "actually using" the information system.

User Participation

User participation is another important area of IS research. System analysis and design has been the primary context for studying user participation (Ives & Olson, 1984). Many authors use the term 'user involvement" interchangeably with "user participation" (McKeen, Guimaraes, & Wetherbe, 1994). This led to confusion in user participation research, causing Barki and Hartwick (1989) to define user participation as taking part or playing a role in the development of a system. They also refined the term "user involvement" to mean the psychological state in which the user considers a system important and personally relevant. Thereafter, a distinction in "user involvement" and "user participation" existed for IS researchers.

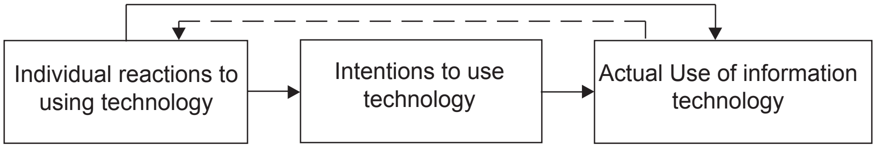
User participation deals with the primary users of the system, or those who use the output of the system (Ives & Olson, 1984). This is supported by Powers and Dickson (1973) who suggest that the actual users are those who receive and use the products of a project rather than the development personnel. From this, it can be seen that IS user participation theory is concerned with the primary users of the information technology product.

In an analysis of user participation, McKeen, Guimaraes and Wetherbe (1994) looked at 19 articles. They examined the nature and role of user participation, concluding that IS development requires the appropriate user's participation at a stage and in a manner that supports significant contribution. These concepts support the Davies (2002) definition. The appropriate user participates and contributes by bringing knowledge concerning how the system must act or serve a purpose, be brought into service, or be available for use. Therefore, actual use of the product and output rather than development of the system is a requirement in IS research involving user participation theory.

User Satisfaction

User satisfaction is another concept widely explored by IS researchers. DeLone and McLean

Figure 3. Actual use concept of technology acceptance (Venkatesh, Morris et al. 2003)



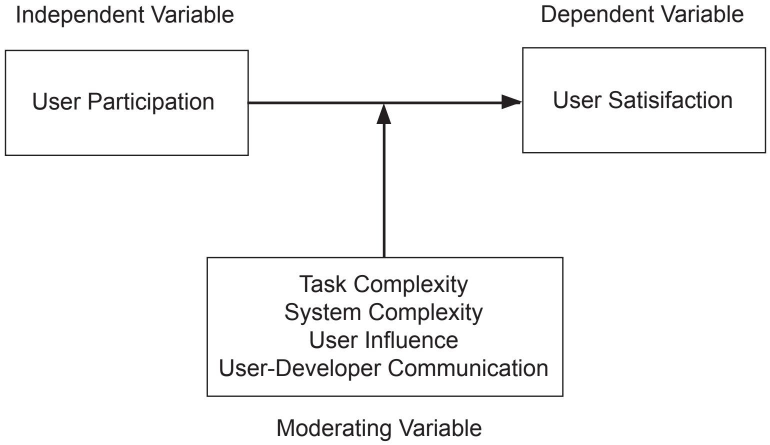
(1992) theorize that system success variables include system quality, information quality, use, user satisfaction, individual impact, organizational impact. User satisfaction is often a surrogate for system success. Successful implementation leads to greater user satisfaction and in this line of research, user satisfaction is the dependent variable. Participation has been postulated to be a predictor of user satisfaction (McKeen et al., 1994). Figure 4 shows these relationships. Unfortunately, user satisfaction weakly predicts system usage (Wixom & Todd, 2005). This is understandable. Some people use a technology because it is a requirement of their job, rather than because they like it and want to use it. There is little "voluntariness" for most health care systems users who are employees performing professional tasks (Agarwal & Prasad, 1997). We would argue that there is also little "voluntariness" for patients using health care systems in their medical treatment.

The system use literature takes a different view of user satisfaction. For example, Shneiderman (1987) believes that interface design makes a substantial difference in user satisfaction. In this line of research, system interaction affects the attitude of the user (Hiltz & Johnson, 1990). Satisfaction is derived from the person's feelings or attitudes about system characteristics (Wixom & Todd, 2005). Thus, healthcare information system researchers working with user satisfaction should take note that stakeholders who do not actively interact with the system should not be considered users. In most situations, patients are data providers and stakeholders, but not users. However, if they are required to manipulate the system in some manner, they are users.

Users in Healthcare

Early technology adoption took place in business settings with employees using mainframe systems to accomplish major business processes such as accounting, payroll, and budgeting. Users were typically employees using transaction-processing systems to accomplish routine business operations. Although healthcare delivery systems vary considerably from traditional business settings, many of the traditional IS theories are making their way into healthcare information systems research (Chiasson & Davidson, 2004). Unfortunately, many researchers simply fail to provide enough detail to ascertain the true users of the system. For example, research in telemedicine involves user satisfaction, cost and acceptance (Huston & Burton, 1997; Huston & Huston, 2000). The focus of some telemedicine research involves the perceptions of the patient, although the patient is not using the technology. In most cases, the physician and/or the clinician are the users during telemedicine. If the focus is user satisfaction or acceptance of a given technology, it is more appropriate to survey the clinician or physician, not the patient. Often, patients are surveyed for their acceptance of tele-video systems when they are non-using medical participants or simply social actors (Lamb & Kling, 2003; Wong, Hui, & Woo, 2005). Other researchers have studied patients as users when their intent was to determine the accuracy of a given technology (Baba, Seckin, & Kapdagli, 2005). In most cases, the patients would have no knowledge of the accuracy of the technology. Instead, they are simply the data source. Healthcare IS researchers must bear in

Figure 4. User Participation Model (McKeen, Guimaraes et al. 1994)



mind that not all stakeholders are users. Some may participate in a given act or action, but they are not necessarily users within that given context or time period.

Another common research topic in telemedicine research is user involvement. In an examination of tele-radiology, Chau (1996) argues that user acceptance is highly dependent on user involvement. In his study, physicians were correctly identified as users of the technology. There was little mention of patients except from the standpoint of patient care, patient management, and patient images. Clearly, the patient's role was that of stakeholder and data source, not user.

USING STAKEHOLDER ANALYSIS TO IMPROVE USER IDENTIFICATION

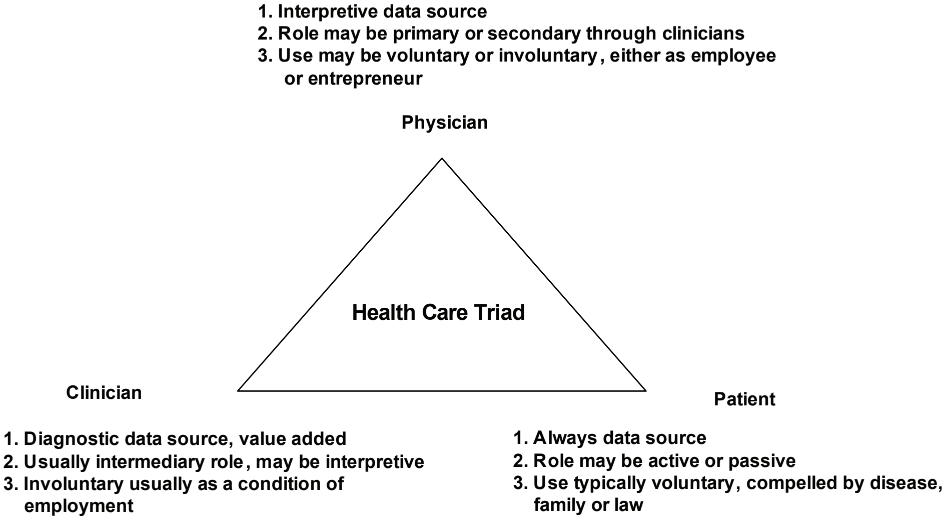
We contend that those conducting IS-related research in the healthcare setting should undertake a comprehensive study of stakeholders. Stakeholder analysis is an approach used to improve understanding of the "behaviour, intentions, interrelations and interests" (Varvasovszky & Brugha, 2000) of individuals and/or organizations as they relate to a given decision or implementation. This information will satisfy a variety of needs. For example, it could be used to develop objectives, strategies, or policies, or to aid in evaluating or implementing a given technology. Our primary intent for utilizing stakeholder analysis is to determine the actual healthcare user in IS related research. For example, in patient treatment, the three primary stakeholders are physicians, clinicians, and patients. Depending upon the situation, the user can consist of one or more individuals from any or all of these categories. Obviously, if we are researching the wrong person, or group of people, we cannot expect to get relevant or valid results.

When applying stakeholder analysis, it is useful to view the triad of patient, clinician, and physician to establish their individual roles. Figure 5 depicts the relationships between these actors, as well as possible roles.

Pouloudi (1999) proposed the following principles of stakeholder behavior, suggesting that these fundamentals can assist in identifying inter-organizational stakeholders within a given context:

1. The group and number of stakeholders are time and context dependent.
2. Stakeholders should not be isolated from others when determining their role.

Figure 5. Health care triad



3. The role of a given stakeholder may change with time.
4. A stakeholder may have multiple roles within a given context or time period.
5. Stakeholders do not have the same perspectives or wishes.
6. Stakeholders may change their perspectives or wishes over time.
7. Stakeholders may not be able to satisfy their needs or desires.

When conducting IS-related research in the healthcare setting, all participating stakeholders need to be evaluated. The technology, what the group is trying to achieve, and how they interact with each other dictates their activities and aid in determining if they are, in fact, users of the technology. For example, a physician providing a cardiac consult might enlist several clinicians to evaluate a patient. One clinician may perform an echocardiogram, another electro-cardiogram. The results of both of these procedures may feed data into an information system. The consulting physician may in turn interact with an aggregating software package that combines several data inputs in order to diagnose the patient. This situation involves a minimum of four stakeholders: the consulting physician, two clinicians, and the patient. However, they are not all users. If the physician actually utilizes the software to aid in diagnosing, or if the diagnostic results are presented in a format, or time basis different than if the system were not available, the physician is considered a user. However, if there is no difference in regard to time or context, the physician is not a user. If the clinicians need to perform some task in order to move the data from the medical equipment to the information system, they are users. For example, technicians may have to physically move data from the EKG monitor to the Information System. If this is done transparently, (i.e. with no clinician intervention), the clinicians are not considered users. In each of these situations, the patient is a data source, and not a user.

Researchers also need to be aware of which physician they are researching. In the above example, the cardiac consult physician may, or may not, be a user. However, the patient's primary physician is most likely a recipient of the data, and has very little knowledge of the technology used to obtain and/or diagnose the data from the patients.

At different time periods, a patient may play the role of both data source and user. Take the case of a diabetic patient recently diagnosed. Initially, a technician will draw some blood from the patient (data source) and insert the sample into a blood glucose analysis system to analyze the patient's blood glucose level. In this situation, the clinician (or maybe the physician) is the user, and the patient is the data source. Eventually, the patient may learn to monitor his or her own glucose levels. The patient may draw the blood, use the glucose analyzer, and enter the reading into an information system. In this situation, the patient is both a data source and the user. Varvasovszky and Brugha (2000) suggest the following be reviewed before performing a stakeholder analysis:

1. Purpose and time dimension (past, present, or future) of the stakeholder analysis
2. Time frame and available resources
3. Culture and context
4. Level (local, regional, national, international) of the analysis

Depending upon time and resource constraints, the stakeholder analysis can be performed by an individual, or group. Data related to the decision or implementation is collected. The analysts can learn not only more about the process at hand, but also more information related to potential stakeholder conflict and/or alliances.

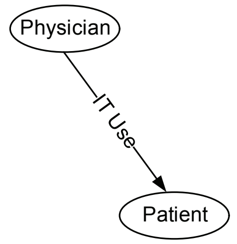
Patient Healthcare Examples for Identifying the User(s)

Utilizing Varvasovszky and Brugha's (2000) suggestions for stakeholder analysis, we provide examples of situations in which the patient, clinician, and/or the physician are users in healthcare information systems (Figures 6-11). The researcher must also be aware of Pouloudi's (1999) principles, remembering that purpose, time, context and level of analysis are important. In essence, before conducting user research, the researcher must first answer the questions of who, what, where, when, and how. Who are the stakeholders? What role do they play? Are there any circumstances in which their role (user, data provider, data recipient, etc.) may change? If so, what are these circumstances? Where are the stakeholders located (local, regional, global)? Does their stakeholder role change if their location changes? When are they doing this? Are all stakeholders involved in real-time? How do the stakeholders interact with each other? How does the stakeholder role change with changes in technology?

Stakeholder Analysis 1: Two Stakeholders: One User

Figure 6 is an example of two stakeholders, the physician and the patient, but only one user, the physician. In this case, the physician uses telemedi-

Figure 6. Physical Exam via Tele-Technology: Two Stakeholders - One User



Purpose: Perform a physical exam via tele-technology.
Time dimension: Present.
Time frame: Short term.
Available resources: The technology used for telemedicine.
Culture and context: Physician-patient relationship. Physician needs to extract information from the patient.
Level of analysis: Not local. Could be regional, national or international.
Stakeholders: Physician and patient.
User: Physician.

cine technology in the present (real time) to extract information from a patient. The remote physician might be regional, national or international but not in the same location as the patient. According to Pouloudi's (1999) principles, both the remote physician and the local patient are stakeholders. Applying the Davies (2002) definition, the physician is the only valid user for IS research. The patient is the data source.

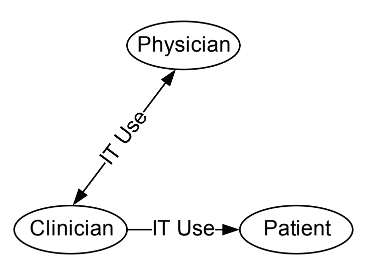
Stakeholder Analysis 2:
Three Stakeholders: One or Two Users

Another example might be the physician who diagnoses a cardiac arrhythmia over the Internet. This could occur in either real time or a store-and-forward time dimension. The clinician would use technology to obtain an electro-cardiogram (EKG) from the patient and transmit it to the physician. The patient would merely be a data source for the exam. In this example, three stakeholders interact with one another and the technology to provide healthcare delivery. The patient is the data source and the physician is a user. The clinician may, or may not, be a user. If there is no change in the manner in which the EKG is conducted, and it is transparently sent to the physician, the clinician is not a user. However, if the clinician needs to perform a different function in order to transmit the EKG, he is also a user. The IS researcher must know more about both the technology and procedure in order to determine the user(s).

Stakeholder Analysis 3:
Three Stakeholders: Up to Three Users

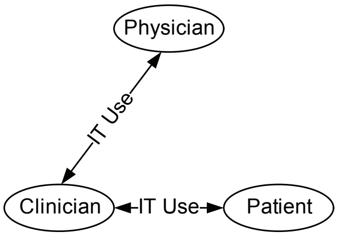
Assume the diabetic patient is now hooked up to a wireless blood glucose continuous monitoring device that transmits data to the clinician over the Internet, who aggregates results and transmits them along with clinical interpretation to the physician. As shown in Figure 8, all three members of the healthcare triad are stakeholders and may be users. The patient's role occurs in the present, while the clinician and physician's roles occur in the present and/or future. The patient is local, but the clinician and physician might be regional, national, or international. All three are considered stakeholders. In this scenario, all three are also considered users for IS research. As previously discussed, time could change the relationship of the users. Initially, the clinician and physician may be users, with the patient only being a data source. Over time, the patient may actually self-monitor and adjust medication accordingly. In this case, all three stakeholders are users. Later, there may be no need for the clinician, or the patient may not be healthy enough to play the role of user. As shown, IS researchers need to be aware of Pouloudi's principles (1999).

Figure 7. Diagnosis via Internet: Three Stakeholders – One or Two Users



Purpose: Diagnose a cardiac arrhythmia via the internet.
Time Dimension: Present or past.
Time Frame: Intermediate term.
Available Resources: Cardiac monitor, web interface.
Culture and Context: Physician-clinician, clinician-patient relationships, Clinician needs to extract EKG, Physician needs to diagnose arrhythmia.
Level of Analysis: Physician not local. Could be regional, national, or international. Clinician local.
Stakeholders: Physician, clinician, patient.
Users: Physician and clinician.

Figure 8. Wireless Continuous Blood Glucose Monitoring: Three Stakeholders – Up to Three Users



Purpose: Check and report blood glucose level.
Time Dimension: Present and/or future.
Time Frame: Short term.
Available Resources: Wireless glucose monitor, online access to reporting facility, web interface.
Culture and Context: Physician-clinician, clinician-patient relationships, Physician and Clinician need access to patient's glucose level, Patient needs to adjust meds.
Level of Analysis: Physician and Clinician not local. Could be regional, national, or international. Patient local.
Stakeholders: Physician, clinician, patient.
Users: Physician, clinician and patient.

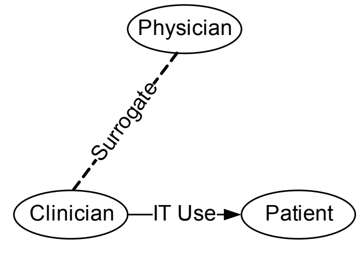
Stakeholder Analyses 4 and 5: Physician as Stakeholder, but not User

Physicians often employ specialists to serve their clinical needs. In Figures 9 and 10, the physician serves the role of manager or employer using a surrogate clinician to deliver healthcare services. In both of these scenarios, the physician is a stakeholder, but not a user. In Figure 9, the clinician secures a medical history from the patient, inputting the information into a wireless tablet PC. This medical history is acquired for the physician, the employer. The patient is the data source. All three are stakeholders in this system. However, the clinician is the sole user.

In Figure 10, a similar surrogate relationship exists. An outpatient is required to perform pulmonary function tests twice daily. The pulmonary function monitor is wirelessly connected to technology which creates graphs of the patient's pulmonary functions and transmits results to a remote location in real-time. Both the clinician and the patient interact with the diagnostic technology. The clinician is an employee of the physician, and only contacts the physician if pulmonary function results are not within expected limits.

In this example, it would be inappropriate to apply IS user theories to the physician. All three are stakeholders, but only the clinician and the patient are users.

Figure 9. Obtain Patient History: Three Stakeholders - One User



Purpose: Obtain patient history for electronic record.
Time Dimension: Present.
Time Frame: Short term.
Available Resources: Wireless tablet PC, secured wireless network, health care information system.
Culture and Context: Physician-clinician, clinician-patient relationships, Physician surrogates clinician to obtain patient's medical history.
Level of Analysis: Physician not local. Could be regional, national, or international. Clinician and patient local.
Stakeholders: Physician, clinician, patient.
User: Clinician.

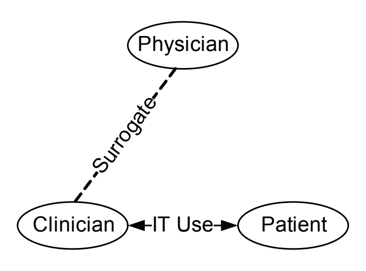
Stakeholder Analysis 6: Network of Stakeholders

While all of these examples are potentially real, in many cases healthcare delivery requires a network of stakeholders. Figure 11 represents such a setting. In this example, a seriously injured patient is admitted to an emergency room (ER) after an accident. The patient is immediately seen by an ER triage nurse and ER physician to evaluate the degree of injury. X-rays are ordered and while the patient is waiting, an admitting clerk obtains needed identification and insurance information using a wireless tablet PC. The ER nurse enters the initial signs and symptoms of the patient into the system that aggregates medical history and personal information. The patient's primary physician is notified and an orthopedic physician evaluates the patient's musculoskeletal injuries prior to the X-ray. The X-ray technician arrives and shoots a set of ordered X-rays that are then transmitted to a radiologist who diagnoses a fracture. The patient uses none of the technologies involved in triage, diagnosis, treatment or documentation. Instead, the patient is merely the data source. The patient, ER nurse, admitting clerk, X-ray technician, ER physician, and orthopedic physician are local. The radiologist is remotely located regionally, nationally or internationally. Most processes are in real time. It is possible that the orthopedic physician will diagnose the fracture and store-and-forward the X-rays to the radiologist for evaluation in the near future. In this scenario, there are eight stakeholders, and only four of which are users - the radiologist, emergency room nurse, the x-ray technician and the admitting clerk. The patient, ER, Orthopedic and primary physicians are data sources – and in most cases data recipients, but they are not users of any of the technologies.

The network example is more representative of a "real world" case, where multiple stakeholders share the responsibility of healthcare, play a variety of interacting roles, and function in a particular setting over time.

Note that the environment in which the technology is utilized may also influence user definition. Hospital policy may dictate how technology is used, and therefore how the user is to be identified. We have provided examples related primarily to telemedicine. The general assumption is that the two environments involve two hospitals or a hospital and a physician's office. However, it is often more complex. Technology may cross boundaries such as emergency medical care, extended care, and specialty clinics. The stakeholders and users of each of these facilities must be properly identified and considered.

Figure 10 . Three Stakeholders - Two Users



Purpose: Pulmonary function test.
Time Dimension: Present.
Time Frame: Short term.
Available Resources: internet access, information system
Culture and Context: Physician-clinician-patient relationships, Physician surrogates clinician to analyze test and inputs results. Patient reads.
Level of Analysis: Physician not local. Could be regional, national, or international. Clinician local. Patient local and regional, national or international.
Stakeholders: Physician, clinician, patient.
Users: Clinician and patient

CONCLUSION

Major problems associated with applying IS-related research to healthcare include the lack of understanding of the nuances of the healthcare concept and its context. One of the most important principles for those doing research in information systems is “know your user”. This principle should apply to those doing research in healthcare as well. However, this is often not the case, leading to unrealistic assumptions associated with user identification. We presented how a simplified stakeholder analysis can aid the IS healthcare researcher in identifying the appropriate user or users.

It was not our intention to identify prior research in which the user was inaccurately defined. Instead, we propose a way in which future research may be improved. As shown, not all stakeholders are users, and a user in one situation is not necessarily a user when time dimensions, resources, and/or the levels of analysis differ. This is especially evident in healthcare. Some physicians are actual users of technology, whereas other physicians rely upon technicians to use the technology. This varies among both physicians and procedures.

Each of the healthcare stakeholders plays an important role. It is our responsibility to assure that we properly identify that role and conduct research accordingly. Another important area of research in healthcare is client acceptance or satisfaction. The client generally will not manipulate the system, but may be heavily impacted by the system. Therefore, we encourage IS researchers both in healthcare and healthcare administration to develop instruments that focus on client acceptance and satisfaction.

The healthcare industry is becoming increasingly dependent upon technology, and it is imperative that research in IS/healthcare be conducted properly. Prior studies (Shah & Robinson, 2007) have shown conflicting results regarding the importance of user involvement when evaluating and developing medical devices. Perhaps these results could be attributed to improperly defining the true user of the technology.

Chapter 5.21

Economic Efficiency and the Canadian Healthcare System

Asha B. Sadanand
University of Guelph, Canada

ABSTRACT

In this chapter the authors examine the compatibility of the objectives of universality and public funding which are two important pillars of the Canadian healthcare system, with the objectives of cost effectiveness and more generally economic efficiency. The authors note that under some very innocuous conditions, markets and other economic based mechanisms such as second price auctions are characterized by economic efficiency and cost effectiveness. For the particular case of healthcare, some additional features that must be considered in the design of the mechanism are that healthcare services and products are valuable if, when taken together they constitute the components of a needed procedure, and otherwise they are worthless to the individual; and timely completion of procedures is what is valued, delays and waiting not only prolong suffering but may eventually prove to be more costly to the system if the condition worsens. They recommend a market-based mechanism, encompassing these features, that utilizes mobile agents representing patients and their medical needs. In order to incorporate the basic goals of universality and public funding, the agents will participate in virtual auctions using a needs based ranking as the currency for making bids.

DOI: 10.4018/978-1-60566-772-0.ch002

INTRODUCTION

A universal, publicly funded healthcare system, such as the one in Canada, has many attractive features that have general appeal. The belief that healthcare is a basic necessity, which must be provided by the state for all the citizens, is the underlying principle for universality. Public funding ensures that all people, no matter how wealthy or poor, can rely on the government for their healthcare needs.

The system has been a source of great pride for Canadians, and a reason for envy by other nations.

For decades, it has served the Canadian people well in taking care of their health needs in a timely fashion and without a large financial burden. However, recent times have witnessed some dissatisfaction as the Canadian population is beginning to age and health costs have burgeoned. The costs, that have throughout been creeping upward, have now threatened to overtake the budget and the system has responded by lengthening waiting lists. In the case of some procedures the waiting lists have reached such proportions that patients are needlessly suffering by prolonged waiting, during the course of which, their conditions have often worsened, at times to the point where they must be treated on an emergency basis. Indeed, many patients have contracted further complications in addition to their original illness, and in rare cases died from the complications. Allowing the patient to worsen generally has irreversible implications on treatment, and ultimately on outcomes; quite perversely, it can also increase the total cost of treatment for the patient, further aggravating the budget problem of healthcare provision. This escalation of both cost and suffering for the patient could have been prevented had the patient been treated in a timely fashion.

In effect, the much touted public healthcare system is now forcing Canadians to accept a compromised level of service by requiring protracted waiting followed by late treatment, and possibly at higher cost. This is certainly not fitting of a world class standard of care, and it is certainly not what was envisioned by the founders that first drafted this policy.

In trying to find solutions, three main strategies arise, and ideally, all three strategies should be used in forming and maintaining the best healthcare programs. The first and most obvious is to increase the budget. This has proven to be quite difficult when taxpayers are already burdened with fairly high taxes. Nevertheless, a somewhat higher budget does seem inevitable in the present situation. Indeed, it should be expected that supplying healthcare for an aging population, should cost more. However, in the future, such demographics should be anticipated. A scheme should be instituted whereby rather than burdening the current work force of younger individuals with the large healthcare costs of the top heavy aging cohort, the healthcare system avoids periods of crisis and recovery as the population demographics swing from aging to youthful populations. To achieve this steady cost for healthcare, a fund must be developed which would accumulate a total for each person summing to the average expected lifetime healthcare costs. An important part of developing such a system would be to have access to accurate data on average lifetime health costs, and to be able to make accurate predictions of future average lifetime health costs.

Another direction is to reduce the demand for healthcare by urging the public to adopt healthier lifestyles. There are certainly many initiatives being taken in this direction by both private individuals and organizations, as well as through Canadian public policy. There is currently greater awareness in the general public about maintaining a healthy active lifestyle than ever before. The government has also been promoting healthy living through massive advertising campaigns and economic incentives, such as preferential tax treatment or deductions for the cost of children's fitness participation. However, these are long horizon initiatives, and the benefits of these efforts in terms of improved health and lower medical costs will only be realized much farther in the future.

Finally, there is the strategy of ensuring that, given the limited budget that does exist for healthcare, it is allocated in a manner that achieves the maximum benefit at the lowest possible cost. In this chapter we will focus on this last strategy. This is not to say that the other two directions are not worthwhile, but rather that we do not expect to see much immediate relief by utilizing them, although they definitely have a necessary role in the proper long term functioning of a carefully crafted healthcare program.

The concept of a universal publicly funded healthcare system is very idealistic, and as such there are some inherent difficulties that must be overcome in order that the scheme works smoothly. The first and foremost issue has to do with the limited budget. The reality, of a budget that is limited, is that we are immediately confronted with the difficult questions of choices: Which treatments are to have a priority, which procedures are covered and which ones are not; among all the different needy patients, which shall we treat first and which patients will be treated later, all become very relevant questions.

These difficult questions that must be answered, are not exclusively encountered in the healthcare sector, but are issues that arise for most goods and services. We are accustomed to resolving these questions (in the other contexts) by allowing markets to determine the allocation of who gets how much of each good. Individuals decide whether to buy a certain good based on the price and whether, given the price, it is worthwhile to buy the good as compared to the next best alternative purchase. Suppliers are willing to provide quantities of the goods at different prices based on their costs; generally prices cover cost and more because suppliers who may be providing specialized goods or services often have incurred some set-up costs that must be covered in the long run. It is competition that keeps in check the suppliers' motivation to obtain prices that exceed their costs. The price for a good adjusts depending on demand until the amount demanded is exactly equal to the amount that can be supplied at that price. At that point the market is said to be in equilibrium. Once the market is in equilibrium, the people that end up buying are those that value the good more than the price, and those who do not buy, value the good less. Thus, the market achieves an allocation where the people are neatly divided into two groups; the high valuation people who consume the good, and the low valuation people who do not; and we notice that this maximizes the sum over all people, of the value of having this good. Further, if we extend the market to all goods, then the overall value to all people for all goods is maximized.

We are interested in knowing whether the market allocation is a good allocation: that is, whether the right people end up with the right amounts of goods or whether one could redistribute to achieve a better allocation. Economists have explored this issue and come up with the notion of economic efficiency.[1] The idea here is that an allocation is good (efficient) if it is impossible to alter the allocation and find that all people are at least as happy with their situation as before, and some strictly happier. This is called allocative efficiency. Starting with an arbitrary allocation, if we had to go from person to person, asking about alternative allocations, to verify allocative efficiency of the initial allocation, it would be an almost impossible undertaking, particularly if the number of people were large: the sheer volume of people that must be consulted and the number of questions that must be asked about all the possible alternative allocations will be endless.

Happily there is another way to verify efficiency. Economic theory shows that given certain conditions[2] market equilibrium is always efficient.[3] To see this intuitively, suppose that initially the market determined the allocation of all goods. Now suppose one attempted to reallocate by taking a unit of a good away from a person and returning the price to them, and at the same time allowing another person who did not initially buy, to buy the one unit of the good at the market price. The first person would be able to spend the money on something else if they liked. But since they did not originally buy any alternative good, it must have been that their value for the alternative good was not as high as that for the good they actually bought, leaving them worse off as compared to how they were before the reallocation. Similarly, the new person to whom the good is being reassigned would not find it worthwhile to pay the price for the good, since, if instead they had found it worthwhile they would have bought it in the first place. We can see how the second person is also worse off from our reallocation. Any other attempt to reallocate will suffer the same fate. It can then be concluded that markets must achieve allocative efficiency.

In addition to allocative efficiency, one might be interested in productive efficiency: whether, for a given cost of production, the maximum amount of goods has been produced. Here, again, economic theory indicates that markets result in productive efficiency,[4] since producers wish to make the highest possible profit. If production were not efficient, producers could simply modify their choices of inputs, produce more, earn more revenue, while throughout, keeping their cost the same.

Finally, even if all existing products are allocated efficiently, and all production of these products is efficient, there can still be room for improvement. If our economy was producing the wrong sorts of goods that people didn't particularly want, for example, this would be an area for improvement. In very simplistic terms, if a list of goods was being produced, but the consumers would be willing to pay more if only there was a different mix of goods available, it will improve things to change to the different output mix. Now, in a market economy where firms are motivated to earn profit, if there could be more profit made by modifying the line up of products offered, then naturally firms would change their product lines to avail themselves of the higher profit.

Thus, we see that under certain required conditions[5] the market (price system) does result in allocations that satisfy all the different aspects of efficiency. And this maximization of efficiency as it turns out, is equivalent to the notion that markets maximize the sum of the value to all individuals of all the goods in the market.

Why can we not apply this approach to healthcare? The greatest stumbling block in utilizing the efficiency properties of the market for healthcare is that we would lose the claim to universality. Some people would not be receiving even basic healthcare because they cannot afford it. While we can enjoy the benefits of the market system, namely the efficiency, we see that simultaneously we must accept the vagaries of the market.

However, as it happens, the market system outcome leads us to only one of many possible economically efficient outcomes. To see what extreme situations are admitted as efficient, consider a situation where we allocate all the goods and services available in an economy to a single individual. This one individual has everything and all the others have nothing. We notice that this satisfies the definition of economic efficiency and indeed would be economically efficient, because there would be no possible reallocation that would improve or leave *everyone* as well off, since if we change anything, the one person that had everything will become worse off. Once we see that this is efficient, we can also see that all the other allocations where we give everything to another of the people and nothing for the rest would also all be efficient. And then we can imagine that there will be all the possibilities in between that gradually distribute more among all people in the economy, but at the same time maintain economic efficiency. How can we choose between all these different efficient allocations?

We know that the market system chooses one particular allocation from all of these possible efficient outcomes, and that allocation depends on the wealth distribution of the people. The drawback of such an allocation is that, although it would be efficient, the wealthy can afford much healthcare, and the poor, very little. Universal healthcare instead requires that all people have equal access to healthcare, whenever the need arises.

The main question that this chapter addresses is whether the efficiency qualities of the market can be harnessed while at the same time preserving the universality of healthcare. This will be a measure of how well we are able to achieve the maximum benefit for the greatest number of people, with a fixed healthcare budget.

A number of schemes have been proposed to utilize the market system in the context of healthcare. One such plan gives each person an equal sum of healthcare dollars annually that can be saved to form a fund, from which they can draw as a health need arises. Being market based it does have potential for being efficient. However, the argument against such a plan is that it *equalizes spending* rather than equalizing access to treatment. In particular then, if an individual was very unlucky in their health problems, through no fault of their own, they may risk running out of funds; while another person who is relatively healthy may have a surplus in their account. Therefore, this plan in biased in favor of individuals with a good genetic endowment in health factors and as well as individuals that have been lucky in their health outcomes. Another similar possible approach is to allow individuals to save tax-free in order build a fund to be used for health needs, much like an RRSP. Individuals who know that they are predisposed to certain conditions would have the ability to prepare for such a contingency and would benefit form the tax-free treatment of these funds. However, like the open market, this has the problem that wealthier individuals will be able to save more, and afford more healthcare than the less wealthy. Moreover, in our current fluctuating financial climate, bad luck or unwise investment decisions may render an entire lifetime of saving earmarked for healthcare completely worthless. Thus, in addition to the inherent uncertainty about health outcomes, we may end up imposing even more uncertainty on individuals with this scheme.

In addition, both of these policies have the problem that if individuals are not farsighted enough they may have long spent their budgets on negligible health issues, and underestimate their future healthcare needs. There are a few other variations on these basic themes, but the general conclusion about the market based policies that have been proposed is that they have some important drawbacks with regard to universality as well as farsightedness, but in their favour, they do have the efficiency properties gained by utilizing the market system.

In this chapter we propose an entirely new market based mechanism. The plan proposed here uses the efficiency of the market system and simultaneously allows the system to be needs based. In order to have a market based system, we need to have a virtual market working in the background that signals the cost and the value of each procedure. At the same time if we want the system to be needs based, we need to establish a priority of medical procedures, and also have a needs based sense of which patients should be treated first, and the order in which the rest would receive treatment.

For the system to be truly needs based, patients must be ranked according to which ones have the more serious need. In the Canadian system there is some rudimentary ranking of the patients belonging to a single specialist, and this is the waiting list. Patients are mostly ordered according to their arrival into the system. The specialist has some discretion in modifying rankings based on his/her own reassessment of the changing of urgency of the patients. However, there is no sense in how one physician's patients compare with another physician's patients. For a market type system to work, there must be something akin to a "master" waiting list that ranks patients nationwide (or at least within a region that is served by a geographic cluster of medical care facilities) for urgency and priority of treatment. Compiling such a list itself is a major undertaking, and approaches to how this can be effectively achieved will be discussed further and in greater detail in a later section.

Once the ranking has been established, it will influence how patients will propagate through the system. The actual scheduling will be done with mobile agents, each representing a patient in the system. The agents will participate in a mechanism that is similar to a market, which will allow the system to realize the efficiency properties of markets. Moreover, because need alone govern the capability of the agents to secure treatment in the schedule, there is no connection between the timing, or quality of treatment, and the patient's wealth. The allocation is not based on ability to pay, but rather on need, thus satisfying the goal of universality.

THE MECHANISM

The mechanism for scheduling elective procedures that we propose here will be achieved by representing each patient by a mobile agent. The agent will have assigned to it the detailed description of the patient's malady, and will be updated as there are changes in the patient's information. Based on the description of the patient's case, physicians will have some input in arriving at a ranking between 1 and 100, indicating the urgency for treatment of this patient. The mobile agent will be given this ranking and it will also be given information about the treatment the patient needs, including all the hospital and medical equipment and types of personnel necessary for the treatment. With the treatment information and the rankings the computer agent will search and obtain treatment for the patient as early as possible. The agent will essentially participate in a mechanism that is very similar to a market or auction. We will discuss in depth both the ranking process and the auction.

The system will have information about the availability of all the hospital facilities and staff at each point in time. These are the items that are being auctioned in our fabricated market. Each agent will have a list of items that are needed to complete their procedure. For example the procedure may be a hip replacement. In that case the agent needs to secure adequate surgery time in an operating room, find an orthopedic surgeon that is available at that time, enough nurses to assist, an anesthetist and any specialized equipment and medical supplies that will be needed. The ranking, which reflects the urgency of its case, will be the amount that the agent has to spend to secure all the items on its list. How this ranking, or budget, is determined will be discussed in a later section; for the present we will simply assume that the budget gives a true representation of the urgency of the case.

The agent will bid on each needed item in virtual auctions that will be conducted on an ongoing basis, competing with other agents representing other patients who may seek different procedures and place bids for a somewhat different list of needs. The actual method for determining which agents will obtain the items is quite involved. The agents participating in our large-scale auction will together form an economic game. In designing the game, the objective will be for the equilibrium to be characterized by all items going to the agents that have the highest willingness to pay. A simplified version of the mechanism to be used is the second price or English auction[6]. In this setting, for any particular item, the agent with the highest bid will receive the item, and pay the second highest bid price. Since each agent's valuation for the items on his list depends on the urgency of his own situation, this is called a private values auction.[7]

There is a large literature on second price private values auctions. Essentially it is an economic game; a situation where a number of people are all taking actions and everyone's action affects each person's outcome. Here, the agents are acting in the place of people. The outcome is generally thought to be a Nash equilibrium for the game: a stable set of choices where, if we fix what everyone else is choosing, each agent will not want to change their choice. Another way to state the Nash conditions is that no agent will unilaterally want to change its choice, given the choices of all the other agents.

To understand the Nash equilibrium for second price private values auctions, we initially simplify by supposing that all bidders know each others' valuations. In such a situation, economists have established that although there can be many equilibria, the most compelling one[8] is where the each agent bids his true value. The agent with the highest valuation wins and pays the second highest valuation. In the case of private information, that is, a situation where the agents do not know each others' valuations, the case for truthful bidding by each bidder is even stronger. With unknown valuations, agents will not want to bid a lower price than their own valuation, for fear that there might be another agent with a valuation that is between the amount bid and the agent's valuation, that could outbid it. The agent will not want to bid any higher than what it is worth because of the negative payoff earned it the agent wins the auction. Thus, in the private or unknown values situation, each agent will bid his true value and the highest valuation agent will win.[9]

In the auctions, agents are trying to buy all the components needed for the treatment, and they try to schedule the treatment for the earliest date possible. Consequently, the same procedure at an early date will have a higher price than for a later date. Since all agents are searching at once, only the most urgent cases—where the representing agent can bid higher than anyone else—will succeed in obtaining all the necessary items at an early date.

Just as we have found with markets, it has been shown that private values second price auctions are also always economically efficient. Economic efficiency requires that the object should go to the bidder with the highest valuation. Since in the most compelling Nash equilibrium all agents will bid truthfully, we find that the agents representing the patients with the highest needs (as determined by physicians) are served first, which is the efficient outcome.

Economic literature has established the basic result of the efficiency of private values second price auctions in allocating a single item that is being auctioned by a seller. Things become a little more complicated when there are several items, and multiple units. Further, the literature distinguishes between situations where buyers are interested in purchasing only a single item and where each buyer buys a set of items. Situations where each buyer eventually buys something, are referred to as the assignment problem. A distinction is also made for situations when the value of acquiring one item maybe affected by the entire set of items acquired. This is clearly the case in our setting, since the items are only valuable to the patient if all the necessary ingredients for the required procedure are obtained. Distilling all this literature[10], it seems that an efficiency preserving mechanism that generalizes the second price auction in all these various dimensions can be created. Such a mechanism would constitute our virtual market where the mobile agents would interact, and economic efficiency would be attained.

Ranking by Colleagues

Finding the best way to rank patients is quite a major undertaking. In the Canadian system, a physician maintains his own waiting list by using his/her assessment of his/her patients. Occasionally physicians working in a group may request their colleagues to accommodate early treatment for a particularly serious patient if they will not fit in their own schedules. However, for the most part the waiting lists are not integrated across physicians.

As a result there is no proper ranking across lists to determine the absolute urgency for a patient. This integrated waiting list is a very important aspect of our mechanism. One way to achieve integration is to have a system of multiple ranking. Each physician will periodically be given anonymous information about a list of patients and be asked to rank them impartially. The lists will include not only some of the physician's own patients, but also some patients belonging to other physicians that are also in the system. The list of patients to be ranked by a particular physician will be randomly generated by the computer with the specification that a fraction, such as say at least a three quarters, will be another physicians' patients, and we can also require that every patient is ranked by at least by a certain number of physicians, say a minimum of four.[11] The actual ranking that each patient is assigned will be an average of all the various physicians' rankings, and this will serve as the currency, utilized by the agents representing the patients, in obtaining from the virtual market the various scarce resources required for the needed procedure.

One sentiment raised by the medical profession in our current world of very scarce resources, is that patients also have a role in affecting their health outcomes. In keeping with this line of thinking, patients that have been following prescribed lifestyles and taken all the preventative measures but have nevertheless contracted some illness that needs medical attention should be more deserving of higher rankings[12] than others who may not have been as conscientious. If there was a strong consensus that these factors were to be taken into consideration, such information could also be contained in the anonymous patient profiles.

To the extent that some resources will be common across many procedures, patients from each of these areas would all need to be in a common auction. This will mean that each physician will be ranking patients not only from his own speciality, but also some from other specialities. There may be some apprehension among doctors about having to rank cases outside their respective areas, but if we consider the alternatives, there is no one better qualified to rank than impartial (and unbiased by speciality) physicians themselves; without such a fully universal ranking, we cannot guarantee efficient use of resources that are common to several specialities.

Clearly, the universal ranking that will be produced using this method may initially be somewhat contentious, and perhaps there can be a built in adjustment procedure to allow for over riding corrections of any result that is too anomalous. However, in time we expect that this procedure will provide generally acceptable results. Perhaps over time there will be some adjustment of approaches to ranking as the doctors see how their own choices are connected to the final ranking. If there is a worry that doctors may recognize their own patients from the anonymous profiles that they are asked to rank, and may inadvertently be motivated to rank their own patient higher, the ranking protocol can be adjusted to accommodate such issues by having a lower fraction of the profiles to be ranked be the doctor's own patients, diluting the impact of the own patient ranking. In the end, if this continues to be a serious problem, we can even have that no patients to be ranked will be the doctor's own patients.

Economists have studied incentives in making choices. It is known that there are many incentive compatible mechanisms and they mostly rely on achieving truth telling by not allowing an individual's choices to affect matters that are important to the individual. Thus, a situation where the ranking involves only the patients belonging to other doctors, the outcome will not be biased by any incentive to alter the rankings.

THE DYNAMICS AND PRACTICAL ISSUES OF SCHEDULING

What we have described so far will work for allocating resources at a single moment in time. However, we know that healthcare allocation is an ongoing process. Therefore we need to discuss how the auctions will be held in a dynamic time setting.

It is quite reasonable to think that schedules will be fixed a certain amount of time in advance of the actual date of the procedure; this will be for the convenience of all involved. Such a lead-time may be a couple of weeks or perhaps a month, or it could also be dependent on the specific procedure. All bidding would be finished in advance of this time, and the participants (both patients and medical practitioners) would be informed of the schedule; all people will stick to the schedule unless something completely unexpected happens that forces them to cancel.

If, after the schedule is fixed, an even more urgent patient arrives, they would have to be dealt with as either on an emergency basis or may be able to be accommodated in the regular schedule, if someone has cancelled at the last minute. Until the point at which the schedules are fixed, new agents could be joining the auction. Agents, who could not afford to purchase their treatment requirements at a particular point in time, will automatically start making bids on components for procedures scheduled for a later time. In the meantime, having waited the extra time, their ranking will be higher, and so, all other things being equal, they will have a greater chance of securing the requirements for their procedure. Instead of having to re-rank a continuing patient, perhaps (if the medical profession endorses it) there can be an automatic inflation factor in the ranking of patients that do not secure treatment in a week and must be carried over to another week. The automatic ranking adjustment can be overridden if there is some important change in the patient's health status that requires physicians to revisit the needs ranking of the patient.

The agents can also be given extra information of a non-medical nature such as the patient's scheduling preferences (availability of dates and times, possibility of travelling to nearby locations, and any other relevant aspects for scheduling). An issue that we find in the current system, which can be easily addressed, is that of surgeons and other specialists working and or being on call continuously for extended periods of time, that may be deemed as excessively long. With the agent system, we can easily include system checks that record the duration of work for the various specialists, and we can easily institute regulations such as mandatory breaks after a certain duration of work. This might ensure that specialists performing critical procedures are well rested, and best able to exercise the care and precision needed for good results.

Shadow Prices and Other Incidental Benefits

Besides giving us economically efficient outcomes, there are further advantages associated with our mechanism. The mechanism and the prices therein provide us with some much needed, valuable information.

The prices, at which all the various medical facilities trade, are very significant. They represent the current relative value to the system of each medical component. In situations where there is an opportunity to expand the available facilities these shadow prices will specify which facilities are most in need, as indicated by the highest auction price. Specifically, if more money becomes available and there is a plan to expand the healthcare facilities in the locality, the most efficient use of the funds at the margin is to invest in the particular items that have the highest difference between relative prices and relative real dollar cost. For example if a new hospital bed costs $100 per night and new MRI equipment costs $400 per use[13], say, we compare that to the shadow prices for the same amount of use for each equipment coming from our auction. Suppose the auction prices were 12 and 20, respectively, say, then it would be better to spend on more beds, since the cost ratio of beds to MRI is 1/4, but the ratio of valuations of hospital beds to MRI equipment is 3/5. The beds are valued relatively higher in the auction than their relative dollar cost. Of course, this type of analysis is valid only at the margin. If there is a large infusion of funds, the relative shadow prices will no longer be accurate.

In addition, the whole aspect of being able to computerize all use of the medical system in a constellation of hospitals and medical facilities allows the generation of valuable data about many issues. Of primary importance to the whole business of healthcare provision is that the data from this mechanism will allow us to estimate the lifetime real medical costs of an individual, controlling for any number of characteristics that could be relevant. This would allow for precise and sophisticated forecasting of future healthcare costs for the system as whole, allowing for demographic trends and any other trends that could be relevant.

There will be a huge wealth of other data (of course respecting the understood rules of patient anonymity[14]) that could be useful for medical research; such as in the success rate of various procedures in the treatment of different conditions, the incidence of certain conditions in different populations, better documentation of past treatments of a given patient (instead of relying on the patient's memory) that might be significant for their current ailment. This could lead to a better level of service for the patient, as well as a better understanding of the success of treatments and thus greater progress in development of appropriate treatments.

CONCLUSION

Economists have been pivotal in devising many currently adopted mechanisms for allocation, where the goal is to find the best match, or in other words maximize the economic efficiency of the allocation. An example of such a mechanism is the matching system for medical residents to hospitals.[15] Markets and also auctions are known to maintain economic efficiency, but have the problem that the efficient outcomes are tied to individual wealth, and do not result in an equitable allocation. We have devised a mechanism here to overcome his drawback, by allowing representative agents to be traders in markets for healthcare products and services utilizing a fictitious currency that is equitably distributed according to the medical need of the patient, as determined by physicians. The mechanism further has the potential to provide valuable information about many aspects of healthcare provision, such as trends, estimation of costs, utilization rates of various equipment, and these data can be employed to give precise projections of the future based on demographics, and other relevant information about the population. Also of importance is the feature that the shadow prices arising form the mechanism will point to the areas that have the most benefit from investment and expansion of facilities. Thus, we have the means to develop a mechanism that maintains all the principles underlying a universal publicly funded healthcare system.

ENDNOTES

[1] This idea of efficiency was first introduced by Pareto, and it is called Pareto efficiency. It includes many components of efficiency, such as allocative efficiency, production efficiency and efficiency of product mix, which are discussed later.

[2] There are several conditions necessary to guarantee efficiency of markets. First all participants must be competitive, and this is typically assured if there are large enough numbers so that the choices of any one agent alone do not affect prices. Next all participants must have full information about the available choices. Now in this auction all that they really need to know is which components they need. Lastly, there are no externalities, which means that one agent's benefit from obtaining a particular item is unaffected by what items other agents have obtained.

[3] This idea was first developed by Adam Smith in 1776 in his famous book, *The Wealth of Nations*.

[4] Markets result in productive efficiency under the same conditions as required for allocative efficiency.

[5] See footnote 2.

[6] The English auction is the one with which we are the most familiar. Bidding begins at a starting or reserve level, set by the seller. Buyers will sequentially offer higher and higher bids until finally no one bids any higher. The winner is the highest bidder, and he pays his winning bid price. As it turns out this formulation can be shown to be identical (in terms of the underlying game and its Nash equilibrium) to the second price (or Vickrey) auction where players simultaneously submit sealed bids; the agent with the highest wins and pays the next highest bid price.

[7] Private values refer to a situation where each agent can have a different valuation for the item being auctioned. This is in contrast to the alternative scenario, termed common values, where all participants have the same value for the item being auctioned. The latter best describes auctions where an asset is being auctioned, all participants value it the

same, since their main purpose in buying it, is for investment; the critical issue in such auctions is whether all participants are fully informed about the what the common value is. In our setting the agents are buying the item for the patient's personal use, and so it is very plausible that different agents have different valuations.

[8] The dominant strategy, as it is called, is to always bid truthfully when playing this game. This is because for each possible choices that the other people make, agent will be no worse off by being truthful, as compared to any other action.

[9] The reader, who may not be familiar with the economics literature, may wonder why we use second price instead of first price auctions. We note that the actual price paid is not important since no real currency is spent; of greater importance is who wins the auction, and whether the allocation was efficient. Since the highest valuation agent wins the second price auction, efficiency is achieved. It turns out that the first price auction can also be efficient, but the argument is more involved.

To provide just a rough idea of the argument, in a Nash equilibrium of the first price auction, there must be an agent that bids just below the winning bid, to prevent the agent with the winning bid to shade his bid lower. Thus, the highest valuation agent can bid anywhere between his own valuation and the next highest valuation and win. In particular, then, he could bid just above the second highest valuation, giving a result which is not too different from the second price auction. Indeed there is a technical result known as the revenue equivalence theorem, which states that the expected social surplus from first and second price auctions is the same.

[10] The early economics literature is on the Clarke-Groves mechanism, where is purpose is to elicit truthful information about individuals' valuation. See Clarke (1971), Groves (1973), Groves and Ledyard (1975), and Leonard (1983). This is not a main concern in this application, since the valuations are known as the rankings are actually assigned by groups of physicians. Instead our focus is on whether the assignment can be implemented by a decentralized process where participants (the agents representing the patients) can arrive at the scene whenever their condition presents itself, and expect to join a process that has already begun with earlier participants. Examples of the literature examining various decentralized mechanisms begin with the simple auctions and branch out to multi item auctions, assignment problems, and package assignment problems. See Milgrom (1985), Demange, Gale and Sotomayor (1986), Bansal and Garg (2001), Amoros, Corcheon and Moreno (2002),Bikhchandani and Ostroy (2002),. Some of the literature is due to computer scientists and is particularly focused on automatic bidding, or agents bidding. See Sandholm (1996) and Sandholm and Lessor (1997), Anderson and Sandholm (1999), and Sandholm and Gilpin (2007). One important idea discussed in some of the recent literature, is the notion that agents may want to renege their contracts with a penalty (cost) if they are not able to obtain all the remaining items needed to complete their list.

[11] The precise values to be used here are not known at this stage. Fine-tuning of the system will be necessary and possible as more experience is gained.

[12] The question of whether a patient's illness is due their own neglect of health or whether it arises through no fault of their own is a very slippery surface. Recently some medical practitioners have advocated that a healthy lifestyle naturally resulting in healthy outcomes should be rewarded, while illness

arising from unhealthy lifestyles should not be as readily treated, particularly for repeat offenders. Of course the worry is that in many instances there cannot be definitive proof that a particular lifestyle choice lead to a particular illness. We suppose that the medical profession is best informed in these matters, and if such consideration is included in rankings all necessary precautions to avoid unfair rankings would be taken.

[13] These numbers are completely hypothetical and do not in any way represent the real costs of any of the medical equipment discussed. Similarly the auction prices are purely fictional and in particular have not been produced from any simulation of the mechanism.

[14] Computer systems are generally very good for maintaining anonymity of data, as it can simply be programmed into the system that all names and other identifying references be dropped when information is being used for purposes other than the patient's own treatment.

[15] The combined work of many economists such as Starr, Ludmerer, Gale and Sahpley, and Roth and Sotomayer has shaped the current system of resident matching programs. See Roth (2003) for a survey of this topic.

ABSTRACT

In the healthcare and public health community, information technology and data management tools are indispensable in preventing, preparing for, responding to, and recovering from public health emergencies, both natural and manmade. This chapter is divided into three sections. The first section discusses various uses of health technology and data systems in disaster preparedness and response. The second section expounds on technological applications to train healthcare staff for their roles and responsibilities in delivering critical health services during a disaster, as well as to integrate healthcare organizations and providers into the broader community planning and response processes. The chapter concludes with a model that has been implemented to integrate and train the broader group of community stakeholders, including healthcare organizations and providers, in disaster preparedness and response.

INTRODUCTION

In the healthcare and public health community, information technology and data management tools are indispensable in preventing, preparing for, responding to and recovering from public health emergencies, both natural and man-made. This

chapter is divided into three sections. The first section discusses various uses of health technology and data systems in disaster preparedness and response. The second section expounds on technological applications to train healthcare staff for their roles and responsibilities in delivering critical health services during a disaster, as well as to integrate healthcare organizations and providers into the broader community planning and response processes. The chapter concludes with a model that has been implemented to integrate and train the broader group of community stakeholders, including healthcare organizations and providers, in disaster preparedness and response.

USING TECHNOLOGY AND DATA TOOLS IN DISASTER PREPAREDNESS

Information technology and data management systems are invaluable in preventing, preparing for, responding to and recovering from emergencies. According to Mathew (2005):

> *preparedness functions, including "prevention strategies, research and epidemiologic studies, education programs, rapid mobility and deployment of resources and services, community preparation, remote area planning, medical incident management, disaster site arrangements, communication network from the disaster site to casualty treatment post, training, disposal of dead, vector control, hygiene and sanitation, and psychological interventions," can be made more effective through the use of technology and data systems. (p. 56)*

A United States federal government report, Bioterrorism Preparedness and Response: Use of Information Technologies and Decision Support Systems, identifies potential technology uses by clinicians and public health officials in the event of a bioterrorist attack (Agency for Healthcare Research and Quality [AHRQ], 2002; Bravata, 2004). To conduct a review of the literature, researchers classified five broad systems categories: detection systems; diagnostic, management, and prevention decision support systems; surveillance systems; reporting and communication systems; and integrated systems. According to another AHRQ report, information technology supports bioterrorism preparedness in the following ways:

- Detection and monitoring systems support disease and threat surveillance and collect national health status indicators.
- Analytical systems facilitate real-time evaluation of live data feeds and turn data into information to identify disease outbreaks.
- Information resources and knowledge management systems provide reference information, distance learning, and decision support.
- Alerting and communications technologies transmit emergency alerts, facilitate routine professional discussions, and support collaborative activities.
- Response systems help manage vaccine distributions, track side effects, and disseminate public health information (Agency for Healthcare Research and Quality [AHRQ], 2005a, p. 3).

This first section describes various existing and emerging uses of information technology and data management systems in the health arena for disaster preparedness and response. The uses addressed here are surveillance, to include disease tracking, detection, diagnosis and reporting; communication; volunteers; electronic health records; modeling and simulation; telehealth; continuity of operations; and education and training.

Surveillance Systems

Surveillance entails the ongoing systematic collection, analysis, and dissemination of data about disease (Teich, Wagner, Mackenzie, & Schafer, 2002). Federal, state and local health departments and private healthcare providers must all work together to effectively detect, manage, communicate, and respond to health threats (Trust for Americas Health, 2007). Information technologies and decision support systems are a vital asset for public health practitioners and healthcare providers during disease outbreaks or in disasters (AHRQ, 2002; Bravata, 2004). Many surveillance systems are integrated systems. This section will briefly discuss disease tracking systems, rapid detection systems, diagnostic systems, and reporting/data sharing systems and provide examples of these integrated systems.

Surveillance systems include surveillance networks of sentinel clinicians, influenza surveillance, laboratory surveillance, foodborne and zoonotic disease surveillance, and sydromic surveillance, such as drug store sales for over-the-counter medications, and hospital-based surveillance, including emergency department data (AHRQ, 2002; Bravata, 2004). Management and prevention systems are designed to make recommendations to clinicians by abstracting clinical information from electronic medical records to make patient-specific recommendations (AHRQ, 2002; Bravata, 2004). Electronic health records will be discussed in greater detail later in this section. According to an AHRQ report (2005a):

> *Disease detection and diagnosis once relied solely on the astute clinician. Now, with advances in information technology, disease monitoring can be done electronically using "real-time" or instantaneous data analysis. While the astute clinician remains critical to early detection, this technology reduces the burden on clinicians to identify an unusual disease occurrence. Automated decision-support systems also offer an important tool to clinicians who are likely to be on the frontlines of detecting a disease outbreak or bioterrorist event. These systems enable the clinician to use computer programs to make a faster diagnosis. (p. 2)*

Disease diagnosis and reporting technology is also used in laboratories. Electronic Laboratory Reporting (ELR) increases the volume of tests reported to surveillance programs and improves the timeliness and completeness of reports (Nguyen, Thorpe, Makki, & Mostashari, 2007). Overall, some ELR system issues and concerns exist such as technology compatibility and interoperability and maintaining security and confidentiality.

Several surveillance systems are effectively being developed and utilized as part of the Public Health Information Network (PHIN). PHIN is a national initiative in the United States to implement a multi-organizational business and technical architecture for public health information systems. It was first funded in 2004 by the U.S. Department of Health and Human Services (DHHS) and the Centers for Disease Control and Prevention (CDC) through Public Health Response and Preparedness Cooperative Agreements. The goal of PHIN is to implement a unified national network of preparedness systems. PHIN's functional requirements include early event detection, outbreak management, laboratory systems linkages, countermeasure and response administration, partner communication and alert, and cross functional components (Loonsk, McGarvey, Conn & Johnson, 2006). PHIN provides national standards that serve as the basis for developing and implementing information technology projects for various CDC-funded programs, including BioSense, the National Electronic Disease Surveillance System (NEDSS), Health Alert Network (HAN), and others, which promote the use of data and information system standards to advance the development of efficient, integrated, and interoperable surveillance and communication systems at federal, state, and local levels (Yale Center for Public Health Preparedness, 2006; Centers for Disease Control and Prevention [CDC], n.d.).

Communication and information sharing, with staff in the healthcare facility, public health officials, emergency responders, and other healthcare institutions, is critical in a disaster. Integrated surveillance systems assist in data reporting and information sharing, as well as performing several other functions. An integrated system in New York, Health Emergency Response Data System (HERDS), has been used in regional and local drills and exercises, in ongoing surveillance and event detection, statewide asset and capacity inventory, and in actual health events. Specifically, this data system has been utilized to:

- Improve usability of the system in drills.
- Test planning and response activities for SNS activation, influenza outbreak, U.S. Postal Service Biohazard Detection System alerts, hypothetical subway bombings, and a SARS outbreak scenario in full-scale exercises.
- Collect and maintain statewide inventories of healthcare staff, assets, and capacities, which are periodically updated and audited.
- Provide advance preparedness for hospital resource planning and event patient management.
- Continually survey bed and equipment availability, blood supply, Emergency Department traffic and symptoms, and hospitalizations, particularly during flu season.

In actual events, this system has enabled detection and response for staff and health resource shortages; response to elevated national threat levels and imminent and actual natural disasters; and identification of, communication with and deployment of medical volunteers. HERDS is a collaboration effort between the healthcare community, local health departments, and response partners resulting from information sharing gaps that emerged during the World Trade Center attacks in September 2001 (Gotham et al, 2007).

Another integrated surveillance and communication system was piloted by the City of Milwaukee Health Department during a time period that coincided with several events expected to attract 1.2 million visitors. The Public Health Dashboard, which linked 13 hospital Emergency Departments (EDs) with local public health agencies, used existing, secure regional Internet infrastructure to gather voluntary and active syndromic cases reported by EDs, clinical laboratory reports of communicable disease, sentinel physicians' offices, hospital emergency room diversions, ambulance runs, medical examiner reports of unusual / suspicious deaths, poison control and nursing hotline call volumes, and pharmacy over-the-counter sales. This information, collected primarily by electronic means, was collated and reviewed by the Milwaukee Health Department's epidemiology unit for unusual trends and then aggregated into the "surveillance dashboard." Baselines were established that would trigger further investigation at a threshold of 2 standard deviations above baseline. Communications regarding potential mass casualty events were piloted during the project period using the Website. E-mail and text pager alerts related to extreme heat conditions and the region's first 2002 occurrence of avian West Nile Virus were sent to and received by all participating EDs. Potential benefits of an early warning surveillance/communication system include both managed healthcare capacity and more effective response in the community. Efficiencies in patient management could result from early alert messaging of a community threat leading to substantial subsequent cost reduction associated with advanced preparation, predetermined therapy, and predefined treatment (Foldy et al, 2004).

Satellites for Epidemiology (SAFE) is an early health warning system that incorporates satellite, radio, wireless networks, Geographic Information Systems (GIS), integrated technology, and data mining to promptly identify and respond to a disease outbreak. The SAFE technology is composed of a pre-hospital mobile coordination center and has the ability to analyze biological samples, monitor resources, and simulate the development of an incident using GIS. SAFE also utilizes electronic health record systems and data mining techniques to provide early health alerts, provide a foundation for evidence-based medical decision-making, support collaboration for second opinions on simulation cases, and utilize video conferencing for coordination of mobile teams (Chronaki et al, 2007).

Communication and Information Sharing

Information technology assists in communication and information sharing prior to, during and after disasters. Communication prior to an emergency may entail using technology systems to raise awareness and provide information to patients and the community. It may also involve communicating with staff and others with emergency response roles, so that they understand their responsibilities and make necessary preparations to ensure readiness. Communication during emergencies includes communication between responders, with appropriate agencies and partners, and with the public. Information sharing might include providing instruction to the public or reporting vital information from the disaster site to healthcare facilities. Post-disaster communication is necessary to assist healthcare organizations, public agencies and other businesses in returning to operations as quickly as possible.

Informatics improves the speed and quality of information shared between partners. It is particularly important to connect field responders to hospitals and healthcare providers (Weiner & Trangenstein, 2007). In a U.S. federal government report identifying existing communication systems, only eight of twenty-six systems were designed for communication among pubic health officials at the local, State and Federal levels. No single system was found that effectively linked members of the public health community at national, State and local levels, although efforts are ongoing to integrate communication of public health information both horizontally and vertically within the U.S. public health system. Five systems were designed for the automated communication of information from hospital-based electronic medical records to clinicians and three systems facilitated communication between emergency departments and first-line emergency response personnel (AHRQ, 2002; Bravata, 2004). Examples of existing communication systems include:

- Maryland's communication network, *Trauma Line*, which enables pre-hospital field care providers to communicate directly with physicians in trauma centers and other referral centers.
- *MobiDoc*, an entirely mobile telecommunication system using wireless technology, which allows teams to perform multiple charting, vital sign monitoring, image collection, and other data acquisition tasks for multiple patients. Data are sent securely to the hospital's intranet and allow for more efficient care and use of limited resources.
- Bar code system technology, developed in St. Louis, to log and track victims of a mass casualty incident and enable family members to locate victims more easily. This system also allows medics to log patients and their belongings using Personal Digital Assistants (PDAs) (Weiner & Trangenstein, 2007).

A RAND report found that communication failures during Hurricane Katrina were due more to "a lack of coordination between the relevant parties…" and not so much to "technical failure on the part of the communications infrastructure" (Ringel et al, 2007, p. v). Technology should be used as a centralized method to share resources, connect local jurisdictions with state and federal officials to request supply needs and inventory, determine if needs were met, by whom and how long it took to deliver (Weiner & Trangenstein, 2007). Information technology also enables secure communication methods with the media by providing interface to the public-at-large and ensuring that information is accurate, timely, and from the designated authority (Weiner & Trangenstein, 2007).

Volunteers

According to testimony given to the United States Congress, U.S. Senate Subcommittee on Bioterrorism and Public Health Preparedness on April 5, 2006, "planning for a medical response to mass casualties remains the most neglected component of public health preparedness and homeland security." Recruiting, training and organizing volunteers to work in their own localities and states should be a top priority (Roundtable on All Hazards Medical Preparedness and Response, 2006). Healthcare volunteers are a necessary component of disaster and emergency response, but they also create challenges. While technology may help solve issues related to registration and credentialing, political and liability issues still exist (Weiner & Trangenstein, 2007).

Technology and databases are being utilized for healthcare volunteer registration and credentialing. The Emergency System for Advance Registration of Volunteer Health Professionals (ESAR-VHP) System is an electronic database of healthcare volunteers that are able to provide assistance in an emergency. "An ESAR-VHP System must 1) register health volunteers, 2) apply emergency credentialing standards to registered volunteers, and 3) allow for the verification of the identity, credentials, and qualifications of registered volunteers in an emergency" (Health Resources and Services Administration [HRSA], 2005, p. 13). This registry aims to discourage and restrict spontaneous volunteers that may not be prepared for a successful response effort (Weiner & Trangenstein, 2007).

Electronic Health Records

According to Brown et al (2007, p. S136), benefits of electronic health records include "improved access, formatting, legibility, and organization of patient data," as well as "timely decision making, improved communication and coordination of care, cost control, public health surveillance, population health planning and clerical task reduction." Electronic health records also aid residents that are forced to evacuate in disasters that leave important documents, such as health records, behind and are unable to locate or reach their primary care provider. Electronic health record systems grant public health and healthcare providers access to patient medical, prescription and immunization records. In the case of Hurricane Katrina, paper medical records faired poorly against the water and mold, and few healthcare providers remained in or returned to the area to retrieve records (Choi, 2006).

In New Orleans alone, tens of thousands of evacuees required immediate medical care and over 200,000 had chronic conditions that required ongoing management (Brown et al, 2007). While problems, such as ownership of records and interoperability of systems, exist, these systems have been used post-disaster with some success. After Hurricane Katrina, an online service for authorized health professionals, www.Katrinahealth.org, was created to provide access to evacuees' medical history and medication information in order to renew prescriptions, prescribe new medication, and coordinate care. The database was a compilation of government and commercial sources including community pharmacies, government health insurance programs, such as Medicaid, private insurers, and pharmacy benefits managers in affected states (Weiner & Trangenstein, 2007).

Due to the Department of Veterans Affairs ongoing efforts to "maintain appropriate and un-interrupted care" through nationally accessible, standardized, comprehensive electronic health records, the experience of VA patients and providers was entirely different than other evacuees (Brown et al, 2007, p. S137). Existing health records, which included patient demographic data, inpatient and outpatient medications, visits and diagnoses, laboratory results and vital signs, were made available through a national call center, a web-based interface, and by rehosting the New Orleans data systems to a physical computer system in Houston, Texas. After Hurricane Katrina, records were accessed for thirty-eight percent of New Orleans VA patients or a total of 14,941 (Brown et al, 2007).

Information systems were also utilized for immunizations after Hurricane Katrina to make these records available to healthcare providers for hurricane evacuees. Use of immunization records provided benefits to patients, parents, and immunization providers and saved money and the inconvenience of revaccinating displaced children. According to estimates, electronic records were located for 18,900 to 21,000 children and provided an estimated cost savings of $3.04 million to $4.6 million in revaccination expenses (Boom, Dragsbaek & Nelson, 2007; Urquhart, Williams, Tobias & Welch, 2007).

After Hurricane Katrina, the Markle Foundation, an information and communication technologies firm, convened experts to improve the use of electronic health records in disasters. They identified the following needs:

- Foster immediate discussions regionally and nationally among government health leaders, insurers, healthcare providers, and information technology companies to determine what, how, and when patient medical information can be shared securely and quickly in the event of a disaster.
- Create electronic health information systems that are based on simple, open web standards, so that data can be provided in different formats from different users and still be accessible to all.
- Agree upon a method to authenticate the identities of doctors, pharmacists, other health professionals, and patients using the web site, so that they can quickly and securely access private health information needed for their ongoing treatment.
- Make electronic health information records accessible to nurse practitioners, physician assistants, and nurses who will likely be working with physicians and clinics in a disaster's aftermath, rather than just by physicians.
- Examine federal and state public policies governing privacy and medical records-such as the Health Insurance Portability and Accountability Act of 1996 and existing state privacy laws-to be sure they do not hinder the delivery of medical care for displaced persons post-disaster (Weiner & Trangenstein, 2007).

Modeling and Simulation Programs

When a disaster occurs, local jurisdictions may go unaided for up to 72 hours. Modeling programs, using existing technology, databases, and software, help decision-makers forecast and plan local response efforts, make informed decisions, and utilize training tools. Modeling programs provide information through situational analysis, spatial modeling, and disaster mapping, and simulate disasters by evaluating the history of disasters, risks and vulnerabilities in communities, and associated health effects (Mathew, 2005). Modeling programs aid community leaders in making decisions regarding priorities, resources, and next steps, developing and implementing policy, and making more efficient decisions to decrease time and save lives (Weiner & Trangenstein, 2007).

Similar to modeling programs, companies and institutions like Sandia National Laboratories, Noblis, and the University of Illinois School of

Public Health Center for the Advancement of Distance Education are creating video games to simulate health-related emergencies and biological, chemical, radiological and natural disasters. According to Breslin, McGowan, Pecheux, and Sudol (2007):

> *Although healthcare delivery is often divided into organizational silos–ambulatory care, acute care hospitals, emergency rooms, critical care, post-acute care, public health services, etc.–the need to plan, train and prepare for new situations that require the coordinated interactions of many healthcare organizations grows every day. These needs are even greater when looking outside the modes of delivery to include other areas of the healthcare continuum such as prevention and disaster response. (para. 4)*

These video games are designed to cross-train healthcare workers, public health and emergency response personnel, decision-makers, volunteers, and others in multiple responder tasks and roles, as well as assist in collaborative preparedness planning and asses the effectiveness of alternate response strategies (Sandia National Laboratories, 2007; Christopher, 2005; Breslin, McGowan, Pecheux, & Sudol, 2007).

Telehealth Applications

As technology has improved, opportunities for telehealth application have increased and expanded. In the event of a disaster, telehealth technology provides disaster-site expertise and support; remote management of trauma patients for remote guidance of procedures; specialty consults and information services to remote areas in a more effective and timely manner; and distance learning and continuing education for community health providers and other responders who are located away from urban training centers or not able to leave their community due to staffing shortages (Weiner & Trangenstein, 2007; Mathew, 2005). Telehealth applications depend on having an existing infrastructure that may be unreliable or even destroyed in a disaster (Weiner & Trangenstein, 2007).

Continuity of Operations

A special report in the Journal of Homeland Defense addresses the importance of technology for continuing workplace operations in the event of a pandemic or other major disaster. “Access to communications, applications, data and even other people” will allow employees to work from home or designated government centers and provide means to coordinate and communicate with a mobile or remote workforce. Utilizing technology to continue operations supports sustainable programs and processes if the workplace closes down due to fires, hurricanes, and power outages or when employees cannot or should not come into the office because of a flu pandemic, transit strike, or blizzard (Philpott, 2007, p. 2).

Telecommuting, or teleworking, is vital to the continuity of operations because the ability to communicate and exchange information in a disaster is critical. According to Philpott (2007), “a telework program creates an emergency communications system during a crisis and a resource to keep key employees engaged and in touch during an emergency. It also enables employees to remain close to their family during a crisis, reduces reliance on transportation and other infrastructure which may be seriously overstretched during an emergency, and it provides the basis for a speedier path to resumption of normal operations (p. 2).” However, systems have to be in place to allow staff to train and exercise before they have to respond to an actual crisis. Further, many of the critical resources necessary to provide continuous patient care, such as MRI, telecommunications, electrical systems, databases, data encryption, server virtualization and disk-to-disk backup, are technology dependent (Rozek & Groth, 2008).

Education and Training

Internet technology develops knowledge bases, decision support systems, and expert systems to provide necessary information and data to responders and decision-makers, who can then evaluate and analyze options and rapidly make appropriate decisions for disaster management (Mathew, 2005). Technology prepares healthcare provider and other responders through competency-based education, training and exercises. In 2001, the Agency for Healthcare Research and Quality released the report, *Training of Clinicians for Public Health Events Relevant to Bioterrorism Preparedness*. This report found that satellite conferences improved knowledge, enhanced print-based materials and appeared to be as effective as classroom training (Agency for Healthcare Research and Quality [AHRQ], 2001). In the past years, U.S. Centers for Disease Control and Prevention (CDC) -funded Centers for Public Health Preparedness (CPHP) have taken a lead in training multiple disciplines in an all-hazards response. Primarily located at Schools of Public Health, CPHPs "are a national network of academic institutions working in collaboration with state and local public health departments and other community partners to provide life-long learning opportunities to the public health workforce, in order to handle the next public health crisis" (ASPH, n.d.).

The New York eClinician Project provided Personal Digital Assistants (PDAs) and wireless internet to clinicians working in Community Health Centers to:

> *1) Increase awareness and encourage adoption of information technology among providers in Community Health Center by providing PDAs as first line strategy towards achieving this goal, 2) enhance access to information on emergency preparedness, 3) improve patient outcomes by providing PDA-based clinical decision-support tool, 4) encourage chronic care management and health promotion/disease prevention activities, and 5) increase productivity and efficiency. (Adusumilli et al, 2006, p. 839)*

Other IT systems, such as one developed and implemented at the Marburg University Medical Center in Germany, have been used to improve clinician compliance and performance through computer-based decision support, reminder systems, guidelines to reduce undesirable practice variability, and patient-specific advice at the time and place of consultation (Blaser et al, 2005; Lenz et al, 2006; Blaser et al, 2007). These systems, which improve quality of care and reduce costs, could also provide guidance and assess and improve capabilities, compliance, and performance by clinicians and other responders in disasters.

USING TECHNOLOGY TO TRAIN AND INTEGRATE HEALTHCARE STAFF INTO THE BROADER COMMUNITY PLANNING AND RESPONSE

One technology application for the healthcare population previously mentioned is education and training. It is essential to train and prepare healthcare staff for their roles and responsibilities in delivering critical services during a disaster. As technology has improved and expanded, it has increasingly been used to educate clinicians and improve clinical performance, efficiency and decision-making (AHRQ, 2001; Mathew, 2005; Adusumilli et al, 2006; Blaser et al, 2005; Lenzet et al, 2006; Blaser et al, 2007).

Training healthcare staff increases their capacity to respond to an emergency within the hospital walls, but it does not facilitate an integrated, community-wide response. Existing technological infrastructure can incorporate multiple disciplines into emergency preparedness planning and response through integrated systems and collectively increase knowledge, skills and abilities to prevent disasters from occurring, protect the public, and respond to and recover from disasters. Multidisciplinary collaboration provides an opportunity for healthcare organizations and other partners to share resources, learn from one another, leverage best practices, and combine forces to achieve together what they could not do alone (PricewaterhouseCooper's Health Research Institute, 2007). To announce the 2007 report, *Improving Health System Preparedness for Terrorism and Mass Casualty Events*, published jointly by the American Medical Association (AMA) and the American Public Health Association (APHA), Georges Benjamin, MD, FACP, FACEP(E), Executive Director of the APHA, said:

> *For too long public health and medicine have responded to emergencies in separate silos. Today's report represents our attempt to bridge the gap so that our health care and public health systems are fully integrated and interoperable in ways that allow for a rapid and efficient disaster response. (American Medical Association [AMA], 2007, para. 3)*

The Health Center Emergency Preparedness Guide, *Working With Your Community: Preparing for Emergency Response,* emphasizes the necessity for healthcare organizations to convene community stakeholder, establish good working relationships, be aware of available resources, develop and practice a comprehensive community-wide emergency response plan in advance of an emergency, and effectively mobilize resources when a disaster takes place (Community Health Care Association of New York State, n.d.).

Local healthcare providers are essential in detecting the first signs of an outbreak and are key resources for responding to a potential outbreak event. These providers need better linkages to the public health infrastructure, including local health departments, State laboratories, and emergency departments. Strengthening these ties to public health is important as well as enhancing and reinforcing information technology connectivity between the health care system and the public health infrastructure (Agency for Healthcare Research and Quality [AHRQ], 2005b). Coordinated and integrated planning efforts involve both vertical and horizontal coordination and integration, with private healthcare practitioners, local clinics and hospitals, larger health systems, and regional, state and federal agencies and associations working together, as well as local healthcare providers and organizations working with the multiple stakeholders at the local level, including government, emergency management, public health, law enforcement, other first responders, and mental health personnel. Thus, in addition to training, technology can be used to incorporate healthcare organizations and providers into the broader, integrated community planning and response processes to assist local community stakeholders in all phases of emergency management.

AN APPLIED TRAINING AND INTEGRATION MODEL

Recognizing the need to prepare the broader workforce of responders to plan and respond to the consequences of public health emergencies, the Texas A&M Health Science Center School of Rural Public Health (SRPH) launched a self-supporting, continuing education initiative in March 2003, designed to offer training to individuals throughout Texas with responsibility for emergency planning, preparedness, and response. The Texas Training Initiative for Emergency Response (T-TIER), developed using the U.S. Centers for Disease Control and Prevention-identified competencies by focus area, is a three-module training initiative that builds upon the knowledge, skills, and abilities that participants acquire in each preceding module. To address the need to change the traditional emergency response model, T-TIER assembles a broader audience of public health, healthcare, emergency management, and other professionals responsible for emergency planning and response. Within this collaborative environment, participants exercise and roleplay their own job roles, as well as the roles of other key stakeholders within their local jurisdictions, thus ensuring a more effective multidisciplinary response. Due to national attention and the need for this type of training initiative beyond Texas, T-TIER was expanded nationally into USA-TIER and offered in other primarily rural states and rural sections of the country. USA-TIER fosters the integration and collaboration of key disciplines and organizations, including healthcare institutions, and enhances the multiple roles and skills needed to increase the capacity and effectiveness of local planning and response to bioterrorism, emerging health threats, or other public health emergencies (Quiram, Carpender, & Pennel, 2005).

To increase efficacy, USA-TIER uses multiple training methodologies and modalities, including live presentations, hands-on practical activities, tabletop exercises, satellite broadcasts and archived video streaming, CD-ROM tool-kits, and a combination of interactive video-conferencing, connecting multiple sites with on-site professional support. This unique, multidisciplinary approach enhances respect and collaboration among the various disciplines, limiting unilateral emergency preparedness planning and response at the national, state, and local levels. The final section of the chapter describes the four elements of this initiative: Rural Preparedness Roundtables, Module I (Didactic Training), Module II (Tabletop Exercise), and Module III (Technical Assistance Team Visits). It will further examine USA-TIER as a model for clinician training and integration and explain the uses of technology in its application to healthcare and the broader community.

Rural Preparedness Roundtables

The mission of the SRPH is to improve the health of communities, with emphasis on rural and underserved populations, through education, research, service, outreach and creative partnerships. Although applicable to urban, rural and suburban areas, USA-TIER, in practice, has a particular emphasis on primarily rural states and rural sections of the country. According to Dobalian, Tsao, Putzer, and Menendez (2007), there is a need to assess resources and response mechanisms in rural and neighboring urban communities to meet anticipated post-event health needs. Rural Preparedness Roundtables (RPR) are a strategy that have proven effective in engaging a target audience in a rural community or communities; identifying local strengths and resources, existing relationships and gaps within the current system; distinguishing the broader, non-traditional rural public health system and additional stakeholders; identifying and educating local decision makers; and working together to address a specific rural health issue. This strategy has been used successfully in a number of venues to elicit a wide variety of outcomes including improving local emergency preparedness and bioterrorism planning; developing networks of interested health professionals working in the HIV/AIDS arena; initiating local infrastructure building processes; facilitating dialog to identify local resources and access issues; and identifying coalition building, obesity prevention and rural disaster planning best practices and success stories (Pennel, Carpender, & Quiram, 2008).

The purpose of the RPR is to engage local stakeholders in a face-to-face discussion about a particular public health issue. This informal, facilitated discussion endeavors to create a local network between the participants, facilitate a broader and more inclusive dialogue, enhance communications to evolve the local network that will continue once the facilitating organization leaves and empower local groups to take ownership, plan and problem solve with existing assets. The Roundtable focuses upon relationship building and serves as a catalyst for rural communities to work together to initiate and make changes based on the issues discussed and the assets available (Pennel, Carpender, & Quiram, 2008).

With a concentration on rural communities, which frequently lack the strong technology infrastructure found in urban areas, fostering these linkages during the planning process is integral. A tool that has provided personal connections between stakeholders, when face-to-face discussions are not feasible, is an internet-based message board. When using Distance Education (DE) modalities, the message board serves as a means for participants to ask questions, obtain information, resources, or technical assistance, communicate with experts, communicate with one another, and share issues and proposed solutions.

Module I: Didactic Training

The objectives for Module I address competencies that parallel the Critical Capacities and Critical Benchmarks for Focus Areas in the CDC Continuation Guidance for Cooperative Agreement on Public Health Preparedness and Response for Bioterrorism. While there is flexibility depending on the needs of the audience, Module I is typically a 4 ½ -day training module. The curriculum for this module consists of didactic classroom activities and interactive training components. Guest speakers with real-world expertise conduct presentations in core areas of emergency planning and response. These presentations typically include Historical Preparedness Perspective; The Threat Factor and a Viable Response; Biological Agents; Infectious Disease Control Practices; Chemical Agents; Agroterrorism; Communication and Information Technology; Disaster Preparedness in Hospitals and Clinics; Strategic National Stockpile; Syndromic Surveillance; Epidemiology/Outbreak Investigation; National and International Perspectives on Preparedness; Risk Communication and Information Dissemination; Law Enforcement and Public Health: Federal Bureau of Investigation Perspective; Department of Emergency Management Structure; and Incident Command System/National Incident Management System.

Module I participants actively take part in lectures, discussions, team projects, and role-playing scenarios. Participants benefit from practicing their work-related roles, as well as having the opportunity to assume the roles of other key stakeholders with responsibility at the local, regional, or state level. In addition, they profit from shared experiences and lessons learned from colleagues in jurisdictions from across the state. A culminating tabletop experience, led in partnership with the National Emergency Response and Rescue Training Center, allows demonstration of knowledge, skills, and abilities through participation in a simulated emergency response situation that considers multidisciplinary approaches to planning and preparedness. Certificates of USA-TIER completion are awarded, in addition to 36 contact hours or 3.6 hours of Continuing Education Units, upon successful completion of this module. Much of the didactic classroom work for this program has been converted to a significantly web-based training to support broader participation throughout the United States.

Module II: Tabletop Exercise

Module II consists of components that address those competencies related to education and training (Focus Area G in the CDC Continuation Guidance): the design, implementation, and evaluation of disaster training activities and an integrated, 1-day functional exercise in a training center facility that requires participants to apply and demonstrate the knowledge and skills acquired within a structured, role-playing scenario. While there is flexibility depending on the needs of the audience, Module II is typically presented over a 2 ½-day period. Participation in Module I, or a training equivalent, is required prior to undertaking this module. Certificates of completion are awarded, in addition to 20 contact hours or 2.0 hours of Continuing Education Units, upon successful completion of this module. Module II exercises are frequently provided through a combination of interactive technologies, such as video-conferencing, telephone, and fax machine, connecting multiple sites with on-site professional support.

Module III: Technical Assistance Team

Module III are designed to make available Technical Assistance Team visits to geographically dispersed sites to observe and provide specific assistance to local officials who have attended Modules I and II of USA-TIER. This module consists of a 2-day, on-site visit, staffed by professionals with expertise in areas specified by the jurisdiction. The teams travel to regional and community public health headquarters or other locations within a jurisdiction to meet in groups with USA-TIER participants, as well as other local stakeholders. At these meetings, the Technical Assistance Team is prepared to review and provide technical advice on plans for (and possibly observe) local/regional response exercises. If requested, these site visits can also be conducted via teleconference technology. Whether by site visit or by teleconference, the Technical Assistance Team provides participants with a wide range of technical assistance related to emergency preparedness planning and response to public health emergencies.

CONCLUSION

Information technology and data systems are vital components to disaster preparedness and response. As technology advances, its utilization in disasters will expand exponentially. Current uses include disease tracking, detection, diagnosis and reporting; communication and information sharing; volunteers; electronic health records; modeling; telehealth; continuity of operations; and education and training. Technology also helps integrate the many stakeholders and disciplines at the local, regional, state and national levels required to prepare for and respond to disasters. The Texas A&M Health Science Center School of Rural Public Health has implemented such a training and exercise initiative in several states through the Texas Training Initiative for Emergency Response (T-TIER) and USA-TIER to assemble and train the broader audience of public health, healthcare, emergency management, and other professionals and to ensure a more effective multidisciplinary response. This initiative has been adapted to various technology applications and continues to expand and investigate new, innovative methods to reach, train and fully integrate multiple disciplines into coordinated emergency planning and response efforts.

KEY TERMS AND DEFINITIONS

Continuity of Operations: Business planning that accounts for how quickly workplaces can recover from a disaster to quickly resume or restore operations or to continue or maintain work operations away from traditional worksites before, during or after a disaster.

Disaster Communication: Using multiple methods of sharing information with, as well as receiving information from hospital and healthcare staff, first responders, appropriate agencies and partners, media, public, and patients and their families before, during, and after a disaster.

Disaster Education and Training: Increasing knowledge, skills, and abilities to prepare healthcare, public health and first responder personnel to plan and respond to public health emergencies and other disasters.

Electronic Health Records: Documentation of patient health data in shared systems that can be utilized by healthcare and public health providers in disasters when paper records are lost, destroyed or otherwise unavailable.

Healthcare Volunteers: A necessary component of disaster response that will be needed to supplement the healthcare workforce.

Integration: Interdisciplinary training, planning, and exercising in preparation for and responding to disasters, both horizontally and vertically, within and outside of the healthcare system and at the local, state and national level.

Modeling: Electronic programs and tools that can aid decision-makers and other stakeholders in disaster forecasting, simulation, training and education, and planning.

Surveillance: The ongoing systematic collection, analysis, and dissemination of data about disease.

Telehealth: Utilizing an existing technological infrastructure to provide on-site disaster expertise and support; remote management of trauma patients; specialty consults and information services to remote areas; and distance learning and continuing education for community health providers and other responders who are located away from urban training centers or not able to leave their community due to staffing shortages.

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of health information systems. Particular contributions address the implantation of an enterprise system in a healthcare network and applications of a case management software system in non-profit organization. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how health information systems can inform their practices and behavior.

Chapter 6.1

A Process Architecture Approach to Manage Health Process Reforms

Christine Stephenson
Emirates Airlines, Dubai, UAE

Wasana Bandara
Queensland University of Technology, Brisbane, Australia

ABSTRACT

Business Process Management (BPM) is often perceived as a top priority concern in organisations; both in public and private sectors. This has been clearly noticed in the Australian health care sector, evidenced by the Australian Government's commitment to pursuing a reform agenda that reflects a new approach to improving health and aged care services. The adoption of a business process management approach can be a key tool to facilitate health reform in the public and private sectors. This approach provides a structured and hence rigorous approach to ensure that health processes are reviewed, improved and implemented consistently throughout the organisation, especially where public health services are provided from multiple service points. Process modeling is an embedded component of most BPM initiatives, yet a resource intensive task. How process models can be derived efficiently (i.e. with less resources and time) and effectively (at a high quality to meet the specific needs) is an integral element of interest to most organisations, however, this area of research is still in its infancy. This paper aims to address this gap by proposing a 'process-pattern' based approach to process modeling where models are created and managed within a 'process architecture'. The process pattern approach is explained with evidence from a large state based health organisation using an integrated risk management process for health care service management as an example. The study employed an action research approach and the chapter unfolds its findings around the main phases of the research method. The contributions from this work are two-fold. From the perspective of practice, it offers a validated high level example of a process pattern for an Integrated Risk Management Program for health. From an academic perspective: it presents a validated Risk Management process pattern for

DOI: 10.4018/978-1-60566-030-1.ch018

delivering health services which can be used as or a benchmark in further research.

INTRODUCTION

Australia's growing health demands are creating new challenges for governments at the national, state, territory and local levels (Minister of Ageing, 2008). The Australian Federal Health Department intends to spend $51.8 Billion dollars on National Health initiatives in 2008-2009 through the National Health and Hospitals Reform Plan. The aim is to improve the capacity of the states and territories to deliver health services when and where the citizens (in particular, working families) need them. The current Australian Health Care Agreements will be extended for 12 months with an extra $1 billion in provided funding. New agreements will be finalised by the end of 2007, with opportunities for major reform (Department of Health and Ageing, 2007). One of the major challenges to implement the intended reforms relates to how Hospitals are currently organized using logical groupings (functions) of clinical specialties instead of being grouped according to process groupings. Taking a process-oriented approach to improving processes can be challenging as these processes need to cross the traditional functional boundaries in order to realize process efficiencies (Vera, A. & Kuntz, L. 2007).

The adoption of a Business Process Management (BPM) approach can be a key tool to facilitate health reform in the public and private sectors. Business Process Management (BPM) provides a structured and consequently a rigorous approach to ensure that health processes are reviewed, improved and implemented consistently throughout the organisation, especially where public health services are provided from multiple service points.

BPM in general, includes methods, techniques, and tools to support the design, enactment, management and analysis of business processes (van der Aalst et al., 2003). One of the key concerns and challenges when applying BPM is the lack of accepted methodologies, and resources to guide these initiatives (Larsen and Myers, 1998; Murphy and Staples 1998; Amoroso, 1998; Indulska et al., 2006). A common BPM methodology that can be utilised and catered for all specific contexts is yet to be derived; and may not be feasible due to the complexities that each individual context brings in. However, a common aspect of all BPM approaches is the orientation towards understanding the current-processes and aim towards an improved better-process. Business process articulation in the form of high-level and detailed process models is a common component of most process improvement projects (Indulska et al., 2006; Bandara 2005). Process Modeling provides a structured and consequently a rigorous approach to ensure that all required aspects of processes are reviewed, improved and implemented consistently. However, detailed process modeling can be an expensive exercise (Becker et al, 2003), and also complex in terms of managing all the different types and levels of processes (and their models), their relationships and interdependencies. While Process Architectures are highly recommended for this (Davis and Bradander, 2007), there is a dearth of examples and information on how to implement such an approach. Addressing this gap is the main aim of this chapter.

In this chapter, we propose a Process Architecture approach where Process Patterns are used at different levels to capture and deploy s for health processes. A risk management process in the health arena is selected to demonstrate the design and application of the proposed Process Architecture concept. This research combines diverse concepts in the area of risk management, business process analysis and health treatments services. The remainder of the chapter commences by first briefly introducing these concepts. The chapter then introduces the Organisation in which this research was designed and implemented at. The paper then proceeds to provide a detailed example which demonstrates how a Process Architecture is designed and implemented (by using process patterns). The details are presented in the form of empirical evidence gathered through an action research approach Finally, the chapter concludes with a discussion of the limitations, of this work as well as a preview of future activities.

INTRODUCING KEY CONCEPTS

This section is dedicated to describing the many terms and concepts used later in the chapter during the overall research process and findings discussions that are followed.

The term 'best practice' is used to describe the process of developing and following a standard way of doing things that can be used (i.e. for management, policy, and especially software systems development) multiple times. Even though the term 'best practice' has now become a buzz word within organizations, it is not a new notion. For example, Frederick Taylor (1911) stated that *"Among the various methods and implements used in each element of each trade there is always one method and one implement which is quicker and better than any of the rest*" (Taylor, 1911). Best practice is ideally, defining ways that can be used to get things done based on past experience. Organizations benefit by adapting these, as they assure quality results and consistency when the process is followed. Today, 'best practices' are documented in various forms, such as in reference models and information libraries (i.e. SCOR, ITIL, PMBOK, ETOM etc) and are accepted more as 'better-practice' that can assist organizations to define, design, implement and monitor business process improvement initiatives. These documented s often use graphical models to illustrate the methods to follow.

Process Modeling

Process modeling is an approach for visually depicting how businesses conduct their operations by defining the entities, activities, enablers and further relationships along control flows (Curtis et al., 1988; Gill, 1999). It is widely used to increase awareness and knowledge of business processes, and to deconstruct organizational complexity (Davenport, 1993; Hammer and Champy 1993; Smith and Fingar 2003). The visualization of business processes in the form of process models has increased in popularity and importance (Bandara et al., 2005). Process modeling is an embedded component of most BPM initiatives, yet a resource intensive task (Becker et al., 2003). "*The importance of business processes has been amplified by being in the centre of late technological inputs in the form of ERP and workflow systems that aim at increasing productivity and functional interconnectivity by automating internal and external transactions*" (Adamides and Karacapilidis, 2006). Thus, how process models can be derived efficiently (i.e. with less resources and time) and effectively (at a high quality to meet the specific needs) is an integral element of interest to most organisations. This area of research is still in its infancy, with only a few studies conducted on critical success factors of process modeling (e.g. Bandara et al, 2005). Even these, (while they depict what the critical success factors are with empirical evidence) do not provide procedural guidelines on how to achieve these success factors, to improve the efficiency and effectiveness of process modeling initiatives.

Process Pattern

A pattern in general is "*an abstraction from a concrete form which keeps recurring in specific non-arbitary contexts*" (Riehle and Zullighoven, 1995). Patterns have been usefully applied across different disciplines in the past. Alexander et al., (1977) describes how patterns can be used for building architectural designs. Patterns have been widely applied in the Software development arena since the "Gang of Four" (GoF) patterns were introduced by Gamma et al., (1995), they have also been widely applied in the workflow management arena[1]. Recent research (i.e. Van der Aalst et al, 2003) has proposed the use of patterns for the description and evaluation of workflow management technologies. Forster (2006) describes potential business process improvement options across different layers of an organisation using a pattern approach. Literature predicts the high proliferation of patterns within the BPM arena (Harmon, 2003).

The basic benefit of a pattern is that the fundamental elements can be reused and hence better knowledge management, efficiency and effectiveness reached, when they are applied within projects. Patterns can be seen as *building blocks*, which when put together form a meaningful entity with minimal effort. However, the knowledge (held by the person applying the patterns) of how to, and when to bring them together, plays a critical role for its success. Patterns can also be perceived as *standard recipes*, where the basic fundamental concepts can be adapted and catered for to meet specific needs.

Within a BPM context, a pattern is "*an idea that has been useful in one practical context and will probably be useful in others*" (adopted from Fowler, 1997, p.8). Hence patterns are not invented, rather discovered by observing its success over a number of applications. In other words, a process-pattern is a common approach to solve problems that are proven to work in practice (adapted from Ambler, 2000). Process patterns are different to reference models (such as SCOR, ITIL, PMBOK etc) – which have been applied widely for process improvement projects. "*A reference model is an abstracted depiction of reality that serves as a standardised or suggestive conceptual basis for the design of enterprise specific models, usually within a like domain*" (Taylor, 2003, p. ii). A pattern has a much smaller focus, and can be a part of a reference model. While process patterns may inherent some features of reference models, they do not provide 'enterprise' solutions, rather provide process specific solutions, which are much smaller in scope. Process patterns can be usefully applied across the various phases of a BPM project.

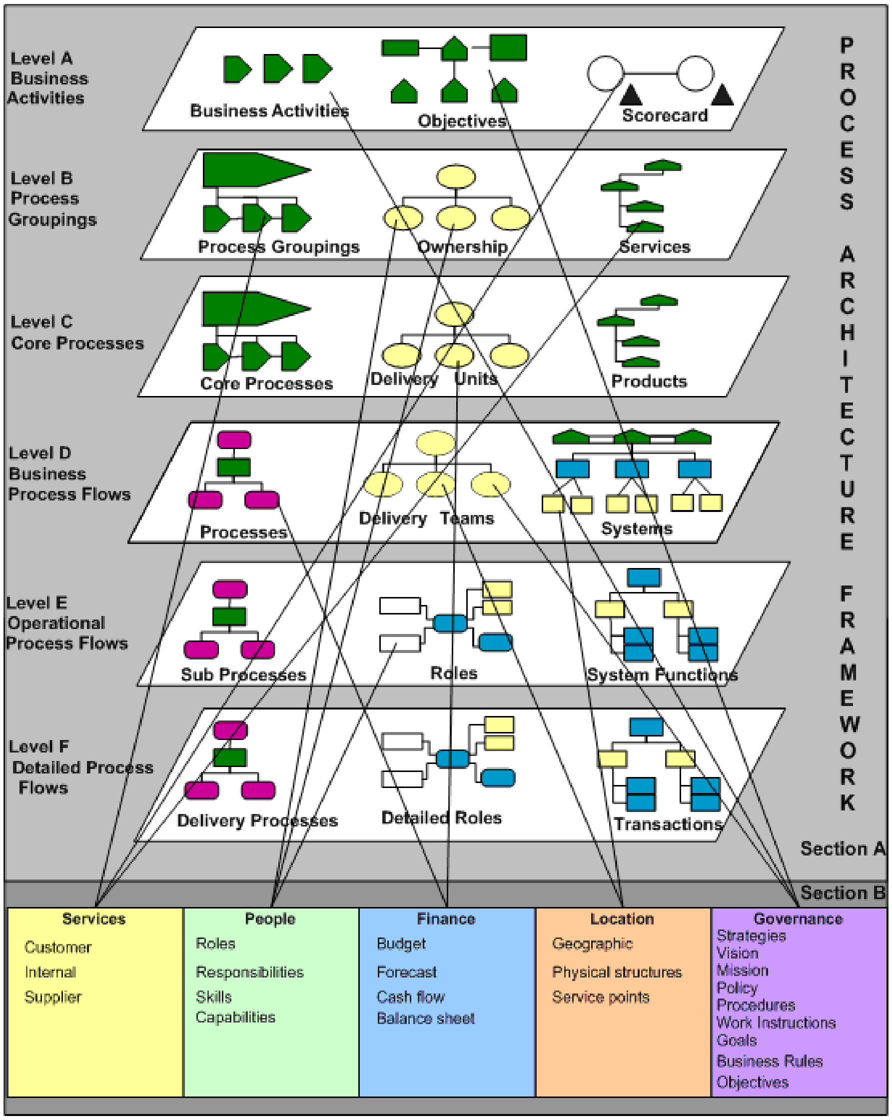
Enterprise Business Architecture and Process Architecture

An Architecture illustrates the relationships between parts that create a whole; however, they do not illustrate flow, sequence or timing of events (Whittle and Myrick, 2005). Therefore, an Enterprise Business Architecture provides the guiding framework that describes the relationship between all the parts of the organisation from the strategy to implementation[2]. The Enterprise Business Architecture is made of a number of facets of the organisation as shown in Figure 1.

The Zachman framework for Enterprise Architecture developed by John Zachman, provides a guide for how information about an Enterprise should be organised. The purpose of Zachman's framework was to provide a simple structure that supports the enterprise to access, interpret, develop, manage and change descriptions of the organisation (The Open Group, 2007). The framework proposed above in Figure 1 aligns well with the Zachman approach by providing multiple perspectives of the organization from the contextual, conceptual, logical and physical layers of the enterprise (Figure 1- section A) which also describes the what, how, where, who, when and why in the Zachman model (Figure 1- section B) for each perspective outlined in the figure below.

The process architecture is one of the facets of the Enterprise Business Architecture, where it provides the framework by which the organisation's processes can be structured. The process architecture more importantly provides the relationship between the processes to the other facets

Figure 1. Facets of enterprise business architecture



of the Enterprise Business architecture such as the People, Finance, Location, Governance etc. In general terms, process architecture is the structural design of general process systems.

“A business process architecture is a hierarchical structure of process description levels and directly related views covering the whole organisation from a business process point of view. It starts with high-level process maps representing a conceptual business view down to the detailed process flow descriptions describing specific tasks and their relation to roles, organisation, data and IT systems.” (Davis and Brabander, 2007, p.50). This process architecture defines a framework for organising, deriving, managing and maintaining the process pattern.

A process architecture organises the processes so that staff can easily adopt a pattern based approach to their work as this provides them with a structure to manage their business analysis and improvement projects. The process architecture model adopted in this study is shown in Figure 1 Section A. This is the architectural process modeling approach proposed by Davis (2006) which is also applied across British Telecom. This model provides a top down approach using six layers from A to F (see Figure 1 section A and Table 1 for details on each layer) where the level of detail represented by the process models increases from top to bottom. Process patterns can be identified at each level of the model which is actually the 'design' of the organisation and how it is meant to operate.

THE CASE ORGANIZATION

A major Australian Health organization[3] provides public health treatment services to a geographically dispersed population of nearly 4 million people. These services are provided through a number of tertiary hospitals, clinics, aged care facilities and community health centers in metropolitan, rural and remote regions. Table 2 provides a brief overview of the case organization under investigation.

This large state-wide Health Services organization has introduced a major program of improvement and transformation which is supported by funding provided under the Australian Health Care Agreement 2003 – 2008 (Department of Health

Table 1. Process architecture hierarchy descriptions (adapted from Davis and Brabander, 2007)

Process Architecture Framework Levels	Definitions
Level A: Enterprise Map	This may be represented as three fundamental activities that are carried out to run the organisation's business: • Direct the Business; • Manage the Business; and • Operate the Business. It distinguishes operational customer oriented processes from management and strategic processes.
Level B: Process Groupings	The level defines different views of how the processes are structured to deliver the three business activities at Level A, which are to Direct, Manage and Operate the Business. These Processes may be structured from: • A process execution perspective showing standard end-to-end processes (e.g. Service Fulfilment); or • A functional perspective (e.g. Value Domains such as Emergency Services, Health Services).
Level C: Core processes	These are recognisable sub-processes of end-to-end Processes. They can generally be carried out by a Business Unit or a Line of Business functional area. These types of models define those activities that deliver services that are unique to an organisation and that no other organisation delivers, as distinct from supporting processes. Level C Process Models are normally modelled as Value Chains and are comprised of tasks that are defined in detail in the Business Process Flows at Level D.
Level D: Business Process Flows	This level defines the process flows of the core processes defined at Level C and are comprised of tasks. They are normally defined generically (i.e. not specific to a particular product, service, customer, geographical operation, etc). It often will only show the 'Happy Case' (the most common) scenario and exclude the detail of alternative actions, failures and error recovery. Tasks can be decomposed into more detail if required in Level E Operational Process Flows.
Level E: Operational Process Flows	These process models define in more detail the Business Process Flows defined at Level D. It is comprised of steps, normally specific to an operational environment and will be characterised by the Application Systems and Organisational Units or Positions that support and execute them. These types of models typically will include the 'Sad Case' scenario showing the detail of alternative actions, failures and error recovery. The 'Happy Case' and 'Sad Case' scenarios comprise the Business Rules of the organisation. These steps can be decomposed into more detail if required in Level F; Detailed Process Flows.
Level F: Detailed Process Flows	This level defines in more detail the Operational Process Flows defined at Level E. It is comprised of operations and may be used to generate workflows or be used as detailed requirements for systems development. An example of an operation is to describe program logic using pseudo code which can then be coded in the specific programming language. This is embedding the operation logic into the software.

Table 2. Brief overview of the of the case organization

Population Serviced	**3.9 Million[4]**
Annual Budget (as of 2007)	Approximately $8.3 Billion
Hospitals	38
Number of Public Health Service Centers including hospitals	Approximately 160
Number of Beds	Approximately 10,000
Key Stakeholders	• Members of the Public – Health Service Consumers • Primary Health Care Providers • Specialists • Non-Government Organizations • Health Service Industry Partners such as Diagnostic Service Providers
Number of employees (including full-time, part-time and contractors)	• Approximately 75, 000
Types of services provided	• Public Health Services • In-Patient and Outpatient Clinical and Non-Clinical Health Services • Aged Care • Community Health
Number of IT Systems	Approximately 45 Statewide systems with over 25, 000 localized systems
Number of IT Staff, full-time, part-time and contractors	Approximately 900

and Ageing, 2008). As a result of this initiative, a business unit was established – its focus being on innovation and reform in the workplace. The objective of the new business unit was to develop a culture of safety and standardize systems and clinical practice to ensure . These goals align well with the concept of using a pattern-based approach to achieve . The Integrated Risk Management (IRM) program was identified as a key strategic initiative that would ensure that a approach was taken to ensure patient safety and support a culture of risk management where staff are encouraged to report clinical incidents and ensure that risk management strategies are implemented to minimize risk. The overarching goal of the Integrated Risk Management program was to document a set of Business Requirements to review the current business processes and define a set of Functional Requirements for an ICT solution to facilitate the capture and management of risk information.

A number of projects commenced as a result of this IRM program which was to define an enterprise-wide Risk Management policy, standards, guidelines and the implementation of an IT system within all Health Service Centers from hospitals to clinics and other health facilities. The IRM Program consisted of three major projects; (i) to define an IRM Framework for the enterprise, (ii) define business requirements for a Complaints Management system, and (iii) define business requirements for a Clinical Incident Management system. Each of the three projects required a detailed review of the current (As-Is) business processes where workshops were conducted with key stakeholders.

The Clinical Incident Management project commenced first due to critical strategic and political pressure resulting from negative press reports in the local paper reporting stories of negligence by clinical staff. The objective of the project was to improve the management of clinical incident reporting at health service centers and restore confidence in the public. The Complaints Management project commenced shortly after, followed by the Integrated Risk Management framework which was meant to integrate the risk areas across the Enterprise.

Table 3. Brief descriptions of the three risk management projects

Projects	Description
Clinical Incident Management	The proactive identification and treatment of hazards before they can lead to patient harm. This also includes the minimization of harm when it does occur and corrective action to minimise the risk of the incident occurring again.
Complaints Management	The management of complaints made by members of the public. This process identifies the incident(s) which lead to the complaint and ensures that an investigation is conducted ending in feedback being provided to the complainant on the corrective action taken.
Integrated Risk Management	The integration of risk management at each level of management into all business activities including strategic planning and decision-making processes

These three projects, in the Integrated Risk Management Program, were implemented sequentially where the intention was to incrementally build on the lessons learnt from each implementation phase. At the time of commencement, similarities between each project were not clear and the objective was to leverage any synergies identified between them.

PROJECT DESIGN AND FINDINGS

An action research method was chosen for this project, which was conducted as a combined consulting and research project, with the goal of producing immediate practical and academic outcomes. Action research is proposed as a useful methodology when the goal is the inquiry into a particular situation and the development of a solution to a problem. It is a form of research that is not a separate, specialised technical activity but one which is closely linked to practice and which can be comfortably undertaken by practitioners. This is particularly valid for the nature of research conducted in the health services sector (Winter and Munn-Giddings, 2001).

The principal researcher led the proposed Process Architecture design and pattern design and played an integral role within the project settings. "*Action research aims to contribute both to the practical concerns of people in an immediate problematic situation and to the goals of social science by joint collaboration within a mutually acceptable ethical framework*" (Rapoport, 1970, p.499). It also assists to "*develop self-help competencies of people facing problems*" (Susman, and Evered, 1978, p.588). It is a scientific research method that has its roots and methods well established since Kurt Lewin (1946) first introduced the term 'action research' as the pioneering approach towards social research (cited in Susman, and Evered, 1978, p. 586).

While different studies classify action research in various ways, most action research follows the traditional 'plan-do-check' approach (Chein et al., 1948). We have adapted the Susman, and Evered (1978) five phased action research model, following an 'experimental action research' approach (Chein et al, 1948; Susman, and Evered, 1978). The five core phases are; (i) diagnosing, (ii) action planning, (iii) action taking, (iv) evaluating, and (v) specifying learning. The next sections will describe each of these phases in detail.

Diagnosing

This phase primarily identifies and defines and problem. Health administrations are increasingly experiencing the need for disclosing their processes and proving the efficiency of their occupation. Process modeling methods have proven to be an adequate mechanism in order to achieve transparency, but process modeling projects can be very expensive and time consuming, often with many external consultants involved (Becker et al, 2003). Thus, a high level framework (pattern) to depict the major process tasks and flows is proposed as a useful way to get started (Davis and Bradander, 2007).

Aligning organisation strategy and the implementation of the strategy is a challenge faced by all organisations (Smith, 2007). The public sector in Australia is faced with an increase in demand for health services, combined with an ageing population and an acute skills shortage[5]. Overseas trained specialist skills are being sourced to fill this gap, but with such a strategy come complications in terms of culture, language etc[6]. It is critical that processes are put in place to ensure that health services are delivered safely and patient care is optimal. In order to implement an Integrated Risk Management strategy, it is therefore important to ensure the implementation of the strategy is structured and closely aligned to achieving the right outcome.

Many organisations in Australia and New Zealand adopt the ASNZS4360:2004 standard as the framework to manage risk which can be applied to a wide variety and wide range of activities from the public, private or community organisations and by groups and individuals (ASNZS4360:2004). The risk management framework consists of a number of steps which is shown in summary through Figure 2. Appendix 1 provides an overview of the standard and its core steps. This framework has been adopted by the case study organisation as the standard approach to managing risk in clinical and non-clinical areas. Subsequent policies, procedures and governance processes have been implemented by hospitals, clinics and other health treatment service centres to ensure compliance.

It is expected that the implementation of the Risk Management Framework would provide a systematic process to ensure that all internal systems promote evidence-based strategies to minimizing risk across the entire organization increasing patient safety and reducing the risk of harm.

Action Planning

Alternative courses of action for solving a problem are considered in this phase. The Program Manager provided the Program Management Steering Committee, as the Governance Authority, with two alternative approaches to implement the Integrated Risk Management Program. The alternatives endorsed by the Steering Committee were two fold:

Approach 1: Establish a Risk Management Policy and Allow Each Business Unit to Implement the Policy Independently

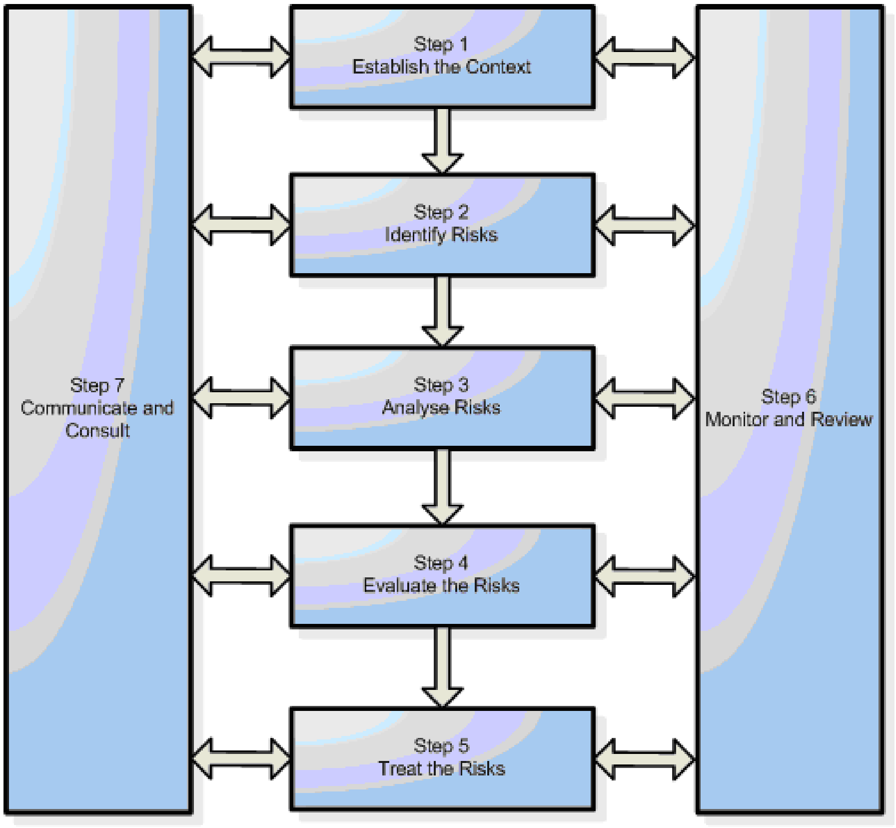
This would be a typical approach adopted in a large federated organisation where the head of each federated unit is accountable for implementing the policy. Such an approach would require each jurisdiction to report their alignment with the policy but manage risk independently within their area. The problem with such an approach is that it becomes difficult to manage risk consistently across the organisation with varying levels of maturity, budget pressures, skills etc. The policy is open to interpretation and hence implementation becomes inconsistent.

This approach has been used in the past in the Case Study organisation and was the current approach before the IRM Program was proposed. During the development of the Business Case for the IRM Program a significant issue observed was the inconsistent interpretation of the current State-wide policy across the Health Service Centres.

Approach 2: Implement a Process Architecture Approach

A process architecture approach will provide the structure required to ensure that there is clear alignment between the policy, procedures, work instructions, business and system requirements definition. This approach will use process pat-

Figure 2. Risk management framework (Adopted from the Australian and New Zealand Standard on Risk Management ASNZS 4360:2004)



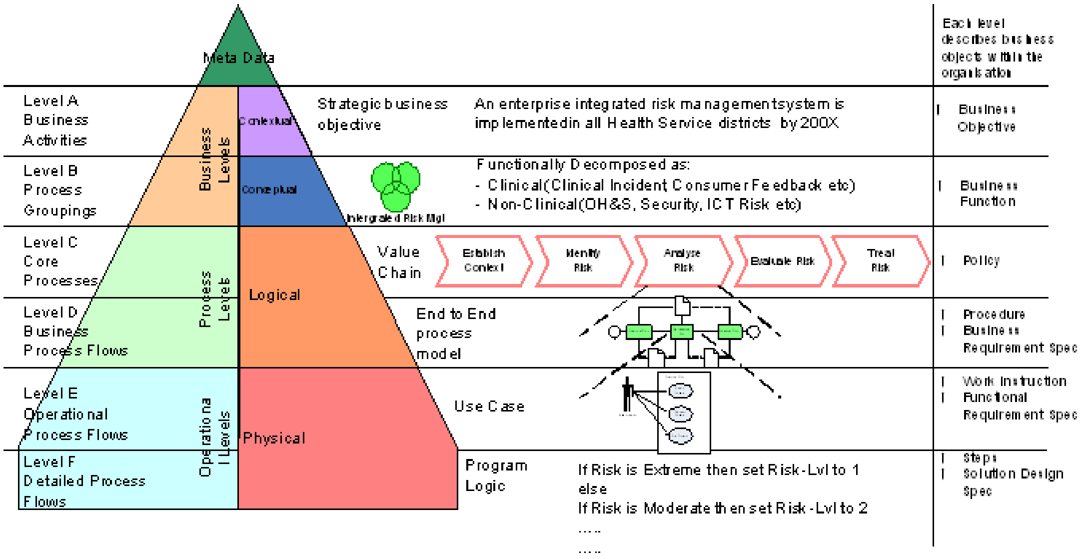
terns to facilitate the implementation of the IRM framework independent of business context areas of Clinical Incidents, Complaints Management and Risk Management.

The contexts for each of the three projects was observed by the business to be very different processes and not related to each other. Clinical Incident staff such as Nurses and Doctors believed that they were responsible for ensuring that clinical incidents did not occur while treating patients. Patient Liaison staff responsible for managing complaints made by members of the public (including patients), felt their objective was to investigate complaints and provide feedback in a timely manner. The only similarities observed by these staff were when it came to assessing the risk of each clinical incident or customer complaint, the investigator identified process patterns for each business context area to demonstrate that by using a process pattern approach, it was possible to identify other areas of process synergy and view all three contexts from the same process pattern. These demonstrations lead to an increased understanding of all the stakeholders of how the overarching Risk Management Policy applied equally to Clinical Incident, Complaints and Risk Management.

Action Taking

This phase deals with the selection of some form of action and the actual implementation of it. Reforming and aligning the organisation's services, processes, people, budgets, location to

Figure 3. Applied six level process hierarchy (adopted from Davis and Bradander, 2007)



the new Integrated Risk Management Policy required a Process Architecture approach to ensure alignment from the Conceptual to the Physical Implementation level in the organisation.

Given that it is challenging to align policy and outcomes, the process pattern approach taken will allow for the effective implementation of strategic policy and operational outcomes. This approach involved a detailed review of the different business context areas within the organisation and a top-down approach was designed for this purpose. Figure 3 (accompanied with Table 4) depicts the overall approach taken in graphical form.

The researcher reviewed the Health organisation's strategic information to firstly understand how the organisation currently implemented Risk Management Policy. Standards, procedures, work instructions, information system solutions relevant to risk management were examined to get an understanding of how the staff within the organisation enacted the processes which manage risk within the organisation constraints (business rules). It soon became apparent that managing risk was a high level corporate goal to provide safe and quality health services to the public. Each federated health service centre was responsible for interpreting the enterprise risk management policy to define internal risk management standards, policies, procedures and work instruction. Federated information systems were also built within each area to support the capture of incident data for analysis and reporting. Appendix 2 depicts in detail the business objects that were looked at each main level of the Process Architecture, demonstrating the artefacts that were reviewed and the model types that were use to depict these (within the Process Architecture). Appendices 3 to 8[8] contain example models used to document each of the Process Architecture levels.

The levels depicted above in the Process Architecture hierarchy in Figure 3, provides levels of abstraction (the ability to decompose a concept, in a structured way to manage the complexity more effectively) in this case within the Risk Management pattern. Enterprise Architects frequently use these levels of abstraction to develop and use models of the organization (Aitken, 2007). In this case study, business process models have been used to provide these levels of abstraction within the Clinical Incident, Complaints and Integrated

Table 4. Levels of abstraction of the process architecture (Aitken, 2007)

Model type7	Purpose	Alignment attribute type	Description
Contextual	Provides a description of the goal or purpose of the process	Goal Requirements	Consists of the Business Vision, Mission, Goals, Objectives etc. that describe the motivation of the organisation
Conceptual	Describes what the process must achieve in order to satisfy the high level goal	Objectives Constructs	The way the organisation is structured to support the strategic objectives
Logical	Describes the implementation criteria for the process - the logic for implementing the processes in a particular manner	Design principles and assertions Logical components and implementation criteria	The Policies and Procedures provide the guiding logic for who is responsible for enacting a process and how it should be enacted.
Physical	An exact description of what is to be implemented	Measures Physical components	The instantiation of the processes which are guided by the work instructions. Detailed business rules provide guidance on what should be done to complete a process.

Risk Management business context areas. Each of these levels of abstraction are described in the Table 4.

The Risk Management process pattern is embedded from the strategy, policy and procedure levels right down through to the lowest program logic level to transparently align the organization from the top to the bottom. The statewide IRM policy (Level C in Figure 3) and procedures (Level D in Figure 3) are issued as corporate governance documents to every Health Service Centre. Alignment with the policy is monitored through planned audits of each Health Service Centre's implementation of the corporate policy. The IRM policy is also used to articulate a set of business requirements for ICT solutions to support Clinical and Non-Clinical Risk Management areas. The business processes are embedded in these business requirement specifications to communicate how the Risk Management policy and procedures are to be implemented by other business solutions providers such as trainers, change managers etc.

Based on the preliminary research conducted at the early stages of this phase (refer to Appendix 2 for details), a process pattern was documented, that described the 'Integrated Risk Management Framework' that describes the essential steps involved in managing risk in the organisation (see Appendix 5) . Although the research was a time consuming exercise, the development of the pattern was relatively quick as a Risk Management expert was approached to support the documentation and validation of the pattern. As mentioned earlier, Appendix 2 provides a list of documents that were provided by the Risk Management expert and reviewed through out the exercise. The pattern was then tested during the phased implementation of the Clinical Incident and Complaints Management projects assigned to the researcher with the various stakeholder groups identified in the process pattern, who came from an a variety of service areas within the business.

It was important to ensure that this process architecture and pattern approach could be applied independent of the context of the risk being managed. The areas reviewed as part of the exercise were from within hospital administration, clinical service, occupational health and safety, fire safety and building management.

Instead of drawing separate process models for each of the three areas reviewed, the risk management process pattern was used to validate the process within each risk context area. Typically such projects take life between three to six months (as evidence from archived past project documentation), however, the process pattern approach enabled the researcher complete the project in one month. Adopting a pattern-based approach allowed one model (pattern) to be used to validate the process at each area with the analysis focusing on the similarities and differences between them.

Evaluating

This phase is dedicated to studying the consequences of the action(s) taken. As discussed earlier, the pattern based approach was very effective to meet with accelerated time frames and provide quality process models.

Figure 4 (together with Table 5) below describes the high level approach taken to implement and evaluate the three projects. Things were implemented in 6 core role-out phases, each phase having an evaluation and feedback loop (as described in column 3 of Table 5).

However, this is not to say that the approach is without its limitations. Some of the limitations identified through reflection and observation were as follows:

- **Low level of process architecture maturity:** The non existence of a process architecture meant that the researcher had to develop the process architecture as the project evolved. The process of discovering and developing patterns would have been more efficient if an architecture and hence, a structure, defined for discovering and developing patterns was already in place.
- **Organizational cultural hindrances:** Typically in large organisations, stakeholders believe that their process is 'different' or unique and thus, do not lend itself to things that may seem 'generic'. Patterns on the other hand are generic forms of information (derived through the extraction on what keeps on recurring within certain contexts). A process pattern is a successful tool to initially focus on the similarities in the process (and not the differences). When the pattern based approach was applied with each risk context areas stakeholders, the idea of being too unique hindered its acceptability and created resistance. However, once it was shown that only the terms used to describe incidents and risk were different, but the process was essentially the same, the pattern based approach was accepted and adapted. In addition to self reflection and observations, evaluative data were gathered through formal feedback through a series of interviews. Clients were asked to provide feedback on the approach taken during the project and post-project. Clinical and non-clinical staff positively commented on the reduction in time taken to complete workshops without

Figure 4. Project implementation steps

Table 5. The project implementation approach

Step	Description of each step	Evaluation Technique(s) used
Project Scope	Project scope was defined with key stakeholders such as the Project Sponsor, Steering Committee and Subject Matter Experts. Three health service centres were identified as representative sites from which to gather data.	Face-to-face meetings Scoping Workshops Review of Strategic Documents, standards, external legislation
Define Business Baseline	The As-Is business processes were defined and issues identified based on input from subject matter experts at each of the three sites. Process Pattern for Risk Management Documented.	Workshops Interviews with frontline staff On the Job observations Review of Policies, Procedures and Work Instructions Review of current Information Systems used
Analyse Process Synergies	The As-Is processes at each site were compared against the Process Pattern to identify process synergies.	Workshops with Subject Matter Experts.
Document Target Business Processes	Target business processes were defined for each business context area highlighting the processes that were in common – Risk Identification, Risk Analysis, Risk Evaluation, Risk Treatment and Monitoring and Review	Workshops with Subject Matter Experts
Design New Business Solution	The Target business processes provided the functional business requirements which were described using Use Cases and the Solution Requirement Specification which used UML models to describe the interactions of the user with the software system	Workshops and documentation of the functional requirements by the business analyst Joint Application Development workshops with the Super User, Business Analyst and Systems Analyst Development and User Acceptance testing of the software system
Implement the New Business Solution	The new system was rolled out across the organisation and is current in use today. Change management techniques were used to train staff to use the new system.	State wide Training sessions Communication of the updated policy, procedures and work instructions through the Intranet website Link to the web-enabled software system with a User Manual

the need to consume significant amounts of Subject Matter Expert time. Remarks were made on the quality of the business analysis artefacts, mainly due to the fact that the researcher could spend more time on reviewing the process models, conducting detailed analysis and providing recommendations for improving the business. A range of specific organisational benefits of using a pattern approach were stated during these interviews. They are briefly summarised below.

- ***Better control on how things are done:*** An organisation can reduce overhead costs by analysing the most efficient and effective way to implement a business process to ensure alignment of the business with the strategic objectives. This process pattern can then be implemented right across the organisation to conduct business in a consistent way.
- ***Clearer requirements definitions for Enterprise solutions:*** An organisation should first document the current business process for the ideal scenario (in a pattern) and use this model (the pattern) to examine the differences between business areas to the pattern/ideal scenario. Significant differences can then be analysed and decisions made to standardise the processes (to-be pattern) and define requirements for the Enterprise solution.

-***Audit for Compliance*:** Quality management systems typically use policy, procedures and work instructions to conduct audits. Audits consist of checks to see if a process has been implemented the way it is supposed to. A pattern repository can enable the organisation to assign benchmarks to the pattern and assist audit the business area based on the benchmark.

- ***Communication and transparency on how things are done*:** Training staff consistently to do the same thing the same way can be challenging, especially in large organisations. A pattern based approach can be adopted where the process pattern is used to develop training material.

Specifying Learning

The goal of this phase is to use a process architecture to implement process patterns so that these patterns may be used as a solution to realise an organisation's strategic objectives using a structured top-down approach. Eight main issues were identified as major areas to be addressed when applying a pattern based approach. They were classified as Process Architecture requirements and high and low level project requirements. *Process Architecture requirements* related to (i) Defining a process architecture framework, (ii) establishing standard terms and definitions. *High level project requirements* related to the elements that were important at a project level when implementing a pattern based approach and included (iii) the creation of a pattern repository, and (iv) the documentation of pattern governance and ownership. The *low level project requirements* were those elements that related to the individual patterns and consisted of; (v) having different levels of abstraction, (vi) fragmentation, (vii) embedded flexibility and (viii) context specification.

Process Architecture Requirements

- ***Defining a process architecture framework:*** In the absence of literature or empirical evidence, there is very little guidance on what a good process architecture framework looks like, leave alone what a process architecture framework should be. It is critical however to define such a framework in order to represent the different levels of abstraction in the organization and the relationships between the variety of process perspectives.
- ***Establishing standard terms and definitions:*** There is a significant amount of ambiguity in the Business Process Management domain where terms and definitions are confusing. It is important therefore, for an organization to establish a standard set of terms and definitions to reduce ambiguity and establish a common language prior to proceeding with projects as these.

High Level Project Requirements

- **The creation of a pattern repository:** The processes and the frameworks have to be stored somewhere in order for people to access them. These repositories should store the pattern models, the meta models and the processes on how to use the meta models.
- **Pattern governance and ownership:** Governance processes should dictate who the pattern owners are and ensure that the patterns are reviewed regularly, so that they don't end up becoming shelfware. Changes in the business environments are inevitable, the impact of these changes on the process patterns should be evaluated periodically to ensure the pattens continue to be ".

Low Level Project Requirements

- **Maintain different levels of abstractions:** Every process pattern has to fit with the process architecture, otherwise its applicability within the organisation becomes vague. Thus, each pattern must be within the layers of the process architecture, with clear meta-data on which perspectives it captures and the degree of detail it entails.
- **Maintain fragmentation (for reuse):** Large scale process modeling projects are often conducted in a piece mental manner (Green and Ould, 2004). End to end processes can be broken down to fragments, where each fragment can be depicted by a process pattern, which can be adapted separately. While fragmentation, and structured layering of process patterns is important, an overarching structure (a high level pattern) to depict how these fragments fit together is very important.
- **Allow flexibility and context specification:** Flexibility has to be maintained within the patterns to allow minor changes to fit the process/ context . Issues related to flexibility has to be integrated into the guidelines on how to use the patterns (i.e. *'how can one expand and edit the models*?' has to be described within the pattern deployment guidelines). What is a detailed pattern within a certain context can be extracted at a higher level, which can be then used as a pattern at a higher level across any context (e.g. delivering a treatment in health vs a generic delivery of service). The higher the pattern sits in the Process Architecture (refer to figure 2, Level (i.e. A, B C) compared to lower levels (i.e. D, E, F), the more context free it is and hence the more flexible it should be.

FUTURE TRENDS

There are numerous opportunities for organizations to adopt a business process management approach that includes process architecture to enable the successful implementation of organization strategy that is aligned from the top level to the implementation level. Organizations using a process architecture approach to link the various facets of the business to processes will provide the linkage required to align strategy with outcomes. This approach can also be used to provide a common platform to lead valuable discussions between various functional areas of the organisation and to identify how each functional area relates and their contribution to the common goals and objectives.

Further research could be conducted to populate process repositories consisting of process models at each level in the organization where these patterns could then become 'free ware' and re-usable in the truest sense of a pattern in any organization. The identification of these process patterns is worthy of research as business context patterns such as health, manufacturing, research etc could be shared amongst organizations especially in areas where there is a high degree of commonality in business processes (e.g. Governance, HR, Finance, Quality Management etc).

CONCLUSION

This chapter proposed a pattern based modeling approach for health services to enhance related business processes. It depicted an example of deploying an Integrated Risk Management Program within a large health organisation. The study followed an action research approach within a reputed public heath organisation, in Australia. It first presented an introduction to the research context, with an overview on the key concepts applied and a brief introduction to the case organization. The research design and findings within each phase were then presented unfolding the story of how the research conclusions were obtained.

The study's findings are of benefit to both the research and practicing communities. In particular, the paper depicted how process patterns can be implemented using Process Architecture framework to (i) align organisations strategies to the actual implementation of these strategies, and (ii) derive a 'standard' to the services across federated organizational units.

The study is not without its limitations. Process patterns are presented here as '' (or 'better practice'); as a possible 'standard' that can be followed within a particular setting or context. Past evidence has shown that the adoption of such standards is hindered by lack of stakeholder awareness and lack of perceived usefulness. Furthermore, process patterns are relevant only to document a certain limited high-level process flow, and there is a fair amount of skill that is required by the adoptee of the patterns to usefully apply it in a given context. Process patterns can have embedded constraints based on organisational policies, legislations, culture and varying structures. The notion of 's' does not commit people or companies to one inflexible, unchanging practice, instead, s is a philosophical approach based around continuous learning and continual improvement, hence the process patterns need to be continuously reviewed and updated.

The results reported in this paper are the first steps towards depicting the value of a pattern based approach for better process management and reform within the health context, and further improvements to the reported findings are underway. Means of increasing the awareness of the benefits and buy-in for process patterns (to increase their adoption and proliferation) has to be conducted. More empirical data can to be collected for triangulation purposes in the evaluation phase of the study design. 'Usability' testing (in the form of extended empirical tests) to identify what further details can be provided to support the adoption of these patterns within specific contexts needs to be addressed. In particular, the integration of context specific information within the process patterns (Rosemann, 2006) will be useful to support the adoption of these high-level process patterns within the specific, detailed processes of an organization. While the process patterns provide a useful body of knowledge, this should be owned and managed by a process-pattern-owner in order to sustain its currency and usefulness in this ever - changing environment.

For Health Reform Managers, there is an opportunity to take a holistic approach to reform by identifying process patterns before embarking on a reform project. Process patterns can help manage behavior and enforce compliance by demonstrating similarities between seemingly disparate groups to encourage the organisation and staff adopt the process pattern as a tried and tested method to achieve an objective. Managers can sell their business case for reform more effectively by being able to identify areas of synergy through the use of the pattern and demonstrating the cost effectiveness of using a uniform approach to manage the reform. The added advantage, of course, is being able to demonstrate the linkage between reform in practice to the overall organisation goals and objectives.

KEY TERMS AND DEFINITIONS

'Best Practice': The term 'best practice' is used to describe the process of developing and following a standard way of doing things that can be used (i.e. for management, policy, and especially software systems development) by multiple times.

Business Process: A business process is a collection of tasks that produce something of value to the organisation, its stakeholders or its customers.

Business process architecture: A business process architecture is a hierarchical structure of process descriptions levels and directly related views covering the whole organization from a business process point of view. It starts with high-level process maps representing a conceptual business view down to the detailed process flow descriptions describing specific tasks and their relation to roles, organization, data and IT systems. (Davis and Brabander, 2007).

Business Process Management: Refers to aligning processes with the organization's strategic goals, designing and implementing process architectures, establishing process measurement systems that align with organizational goals, and educating and organizing managers so that they will manage processes effectively. (http://www.bptrends.com/resources_glossary) last accessed 9/7/2008

Business Process Modeling: Business process modeling includes techniques and activities used as part of the larger business process management discipline. Business process modeling is an activity performed by business analysts within an organisation. Analysts use modeling tools to depict both the current state of the business and the desired future state.

Business Requirement: A method of describing in business terms of what an organisation does and how it does it in order to achieve a business objective.

Enterprise Business Architecture: Enterprise Business Architecture provides the guiding framework that describes the relationship between all the parts of the organisation from the strategy to implementation[9].

Pattern: A pattern in general is "an abstraction from a concrete form which keeps recurring in specific non-arbitrary contexts" (Riehle and Zullighoven, 1995).

Policy: A policy is a deliberate plan of action to guide decisions in order to achieve an organisation's objective.

Process Architecture: The process architecture is one of the facets of the Enterprise Business Architecture, where it provides the framework by which the organisation's processes are structured. The process architecture more importantly provides the relationship between the processes to the other facets of the Enterprise Business architecture such as the People, Finance, Location, Governance etc.

Process Modeling: Process modeling is an approach for visually depicting how businesses conduct their operations by defining the entities, activities, enablers and further relationships along control flows (Curtis et al., 1988; Gill, 1999).

Risk Management: Is the culture, processes and structures that are directed towards realizing potential opportunities whilst managing adverse effects.

Work Instruction: The detailed description of the steps person, robot or a computer system must complete in order to fulfill a task.

Value Chain: A value chain is a sequence of activities that is initiated by a firm's customer and ends when that customer receives an outcome (service or product).

Task: A task is an atomic activity that is included within a process.

Business Rules: Business rules describe how an organisation operates and the constraints under which the operations are performed.

Operations: Operations are ongoing recurring activity that a business is involved in. Business operations deliver direct or indirect value to the organisations customers.

APPENDIX A: EXTRACT FROM THE ASNZS:4360:2004 RISK MANAGEMENT STANDARD

Risk management involves managing to achieve an appropriate balance between realizing opportunities for gains while minimizing losses. It is an integral part of good management practice and an essential element of good corporate governance. It is an iterative process consisting of steps that, when undertaken in sequence, enable continuous improvement in decision-making and facilitate continuous improvement in performance.

Risk management involves establishing an appropriate infrastructure and culture and applying a logical and systematic method of establishing the context, identifying, analysing, evaluating, treating, monitoring and communicating risks associated with any activity, function or process in a way that will enable organizations to minimize losses and maximize gains.

To be most effective, risk management should become part of an organization's culture. It should be embedded into the organization's philosophy, practices and business processes rather than be viewed or practiced as separate activity. When this is achieved, everyone in the organization becomes involved in the management of risk.

Although the concept of risk is often interpreted in terms of hazards or negative impacts, this Standard is concerned with risk as exposure to the consequences of uncertainty, or potential deviations from what is planned or expected. The process described here applies to the management of both potential gains and potential losses.

Organizations that manage risk effectively and efficiently are more likely to achieve their objectives and do so at lower overall cost.

The Main Elements of Risk Management are as follows:

- **Establish the context:** Establish the external, internal and risk management context in which the rest of the process will take place. Criteria against which risk will be evaluated should be established and the structure of the analysis defined.
- **Identify Risks:** Identify where, when, why and how events could prevent, degrade, delay or enhance the achievement of the objectives.
- **Analyse Risks:** Identify and evaluate existing controls. Determine consequences and likelihood and hence the level of risk. This analysis should consider the range of potential consequences and how these could occur.
- **Evaluate Risks:** Compare estimated levels of risk against the pre-established criteria and consider the balance between potential benefits and adverse outcomes. This enables decisions to be made about the extent and nature of treatments required and about priorities.
- **Treat Risks:** Develop and implement specific cost-effective strategies and action plans for increasing potential benefits and reducing potential costs.
- **Monitor and Review:** It is necessary to monitor the effectiveness of all steps of the risk management process. This is important for continuous improvement. Risks and the effectiveness of treatment

measures need to be monitored to ensure changing circumstances do not alter priorities.

- **Communicate and Consult:** Communicate and consult with internal and external stakeholders as appropriate at each stage of the risk management process and concerning the process as a whole.

The Risk Management Standard provides a generic guide for managing risk in any organisation context whether it is public, private, community, enterprise or individual. It is thus a scalable framework that can be applied quite successfully independent of industry or economic sector.

APPENDIX B: CASE STUDY SAMPLE DOCUMENTS

The table below catalogs the documents that were reviewed as part of the research project. When conducting a document review, each document was categorized into the relevant Process Architecture Levels to identify what type of business object needed to be identified and reviewed. The principal researcher then selected the appropriate model type to be used to capture the relevant information about the business object. Adopting this approach provided a structured method for gathering and analysing information that is relevant to the exercise and supports the implementation of a Process Architecture approach.

Process Architecture Levels	Business Objects	Artifact Reviews – Content Extracted	Model Type
A	Business Objective	Strategic Plan - Provide safe and sustainable services	• Contextual Model drawn using blocks, arrows, triangles • Organisation function chart
B	Business Functions	Function Groupings from Organisation Charts: Clinical Incident Management Complaints Management Integrated Risk Management	• Service groupings • Functional perspective • Conceptual models
C	Policy	Review of Policy Document to extract Value Chains and IDEF0 models: Clinical Governance Policy Consumer Complaints Management Policy Integrated Risk Management Policy	• Value Chains • End-to-end processes using BPMN or IDEF0 • Logical models
D	Procedure Business Requirement Specifications	For each Business Context Area IDEF0 models were drawn: - Implementation Standards and Procedures e.g. Management of Clinical Adverse Events Procedure, Consumer Feedback Management Procedure - Business Requirements Specification consisting of AS-IS process models	BPMN Process Model, IDEF0 or IDEF3, UML Workflow
E	Work Instructions	For each Business Context Area at each Health Service Centre an example of the Work Instruction artifacts observed to define Use Cases: - Incident Reporting using the Central Information System Database - Receiving a Complaint Work Instruction - Pressure Area Care Work Instruction As part of the Business Analysis activities, Functional Requirements Specifications were created for each of the three Business Context Areas.	BPMN Activity Model, Use Cases

Process Architecture Levels	Business Objects	Artifact Reviews – Content Extracted	Model Type
F	Steps	UML Workflow models were used to depict workflow: The Corporate Integrated Risk Management Solution was built based on detailed Solution Requirement Specifications defined for each of the three Business Context Areas.	Flowcharts, System Flow Chart, Data Flow Diagram

APPENDIX C: LEVEL A CONTEXTUAL MODEL: INTEGRATED RISK MANAGEMENT

The Model shown in Figure 5 was used to show conceptually how the Integrated Risk Management function collectively supports the achievement of the case study organisation's strategic objective. The model also shows how the Integrated Risk Management function is structured within the organisation.

APPENDIX D: LEVEL B CONCEPTUAL MODEL: COMPLAINTS MANAGEMENT

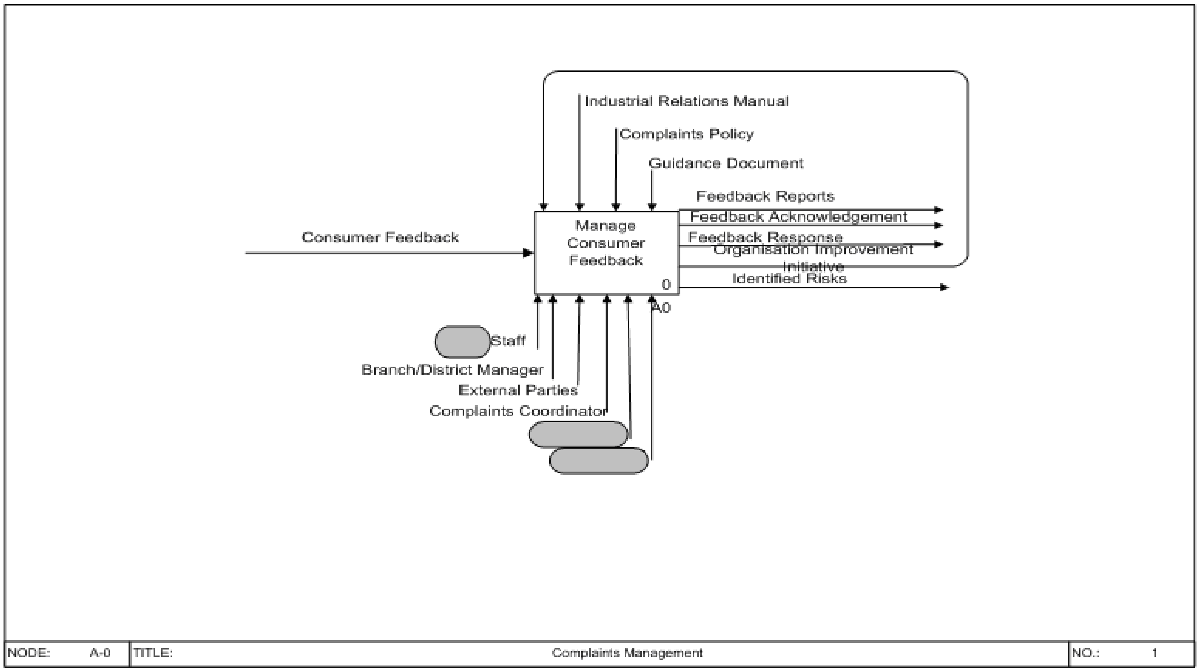
The IDEF0 High-Level A0 model (see Figure 6) was used to define the scope of the Complaints Management function. The same approach was taken to identify the scope of the Clinical Incident and Integrated Risk Management functions.

APPENDIX E: LEVEL C PROCESS MODELS – INTEGRATED RISK MANAGEMENT

IDEF0 was used as the notation to document the end-to-end process (value chain) for all three projects. Figure 7 is an example of the IDEF0 model which shows the application of the ASNZS4360:2004 Risk Management framework as it is implemented in the case study organisation. The same pattern was used to document the Clinical Incident and Complaint Management Processes.

Figure 5.

Figure 6.



APPENDIX F: LEVEL D BUSINESS PROCESS FLOW MODEL – TREAT RISKS

The IDEF0 business process flow model shown in Figure 8 was used to document how Risk is treated within the case study organisation. This pattern was used to validate that risk is treated the same way in Clinical Incident, Complaints and Risk Management.

APPENDIX G: LEVEL E USE CASE – COMPLAINTS MANAGEMENT – ASSESSING RISK

Figure 9 is an example of the UML Use Case that was used to document how Risks are assessed. This Use Case is meant to show how business rules are applied and cause branches in logical flow. Use Case provided the Solution Requirement specifications to the IT software development group on how a solution is required to interact with the User/Actor.

APPENDIX H: LEVEL F OPERATIONAL PROCESS FLOW MODEL

Figure 10 is an example of a detailed Operational Process Flow Model. Typically, Systems Analysts use these types of model to document how a software developer will convert the business logic and business rule into software syntax. The human-computer interaction is also depicted in these models to clearly demonstrate when the user is required to interact with the software system.

Figure 7.

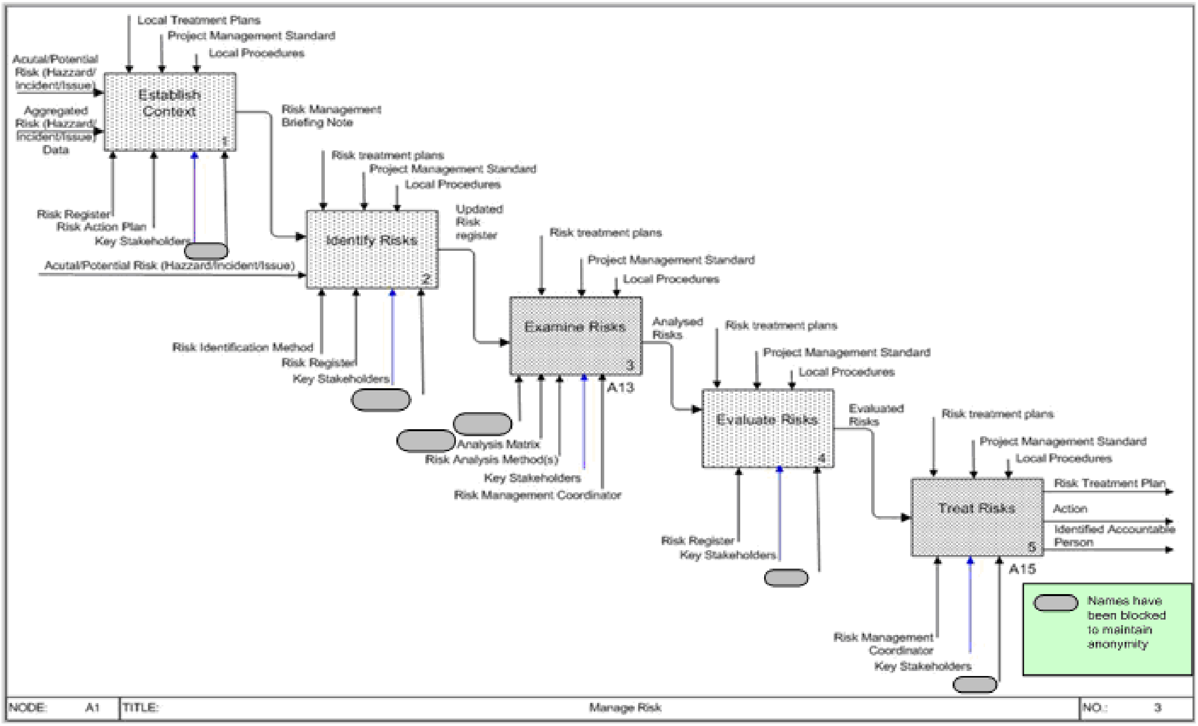


Figure 8.

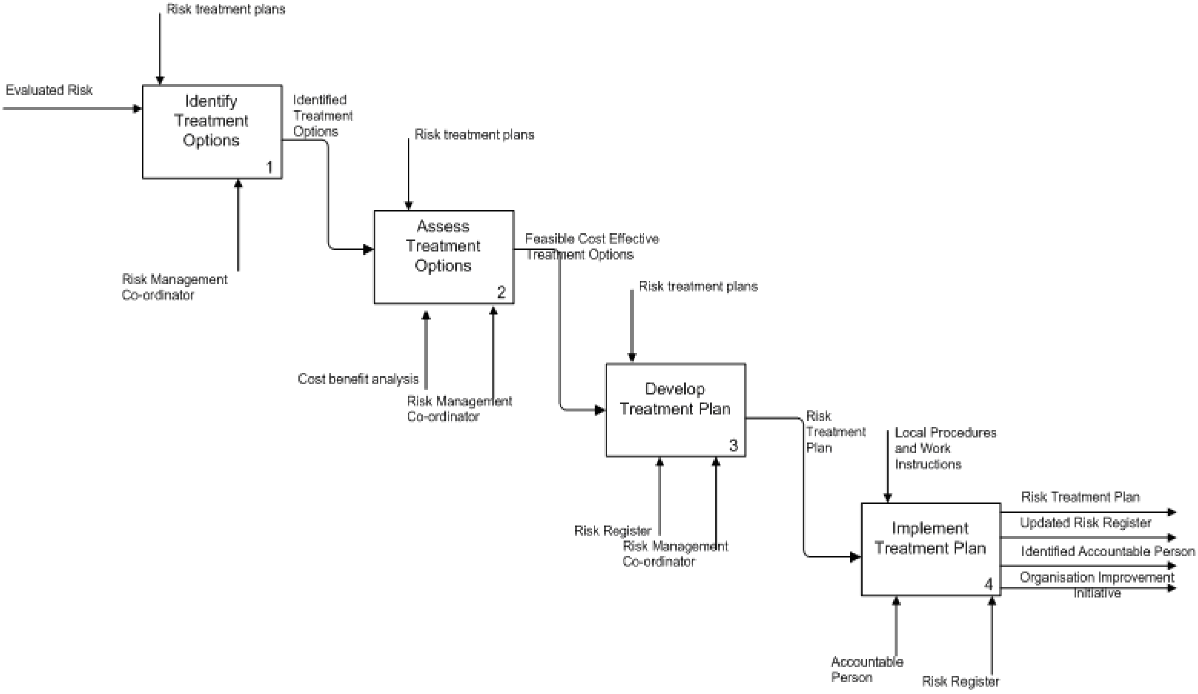

Figure 9.

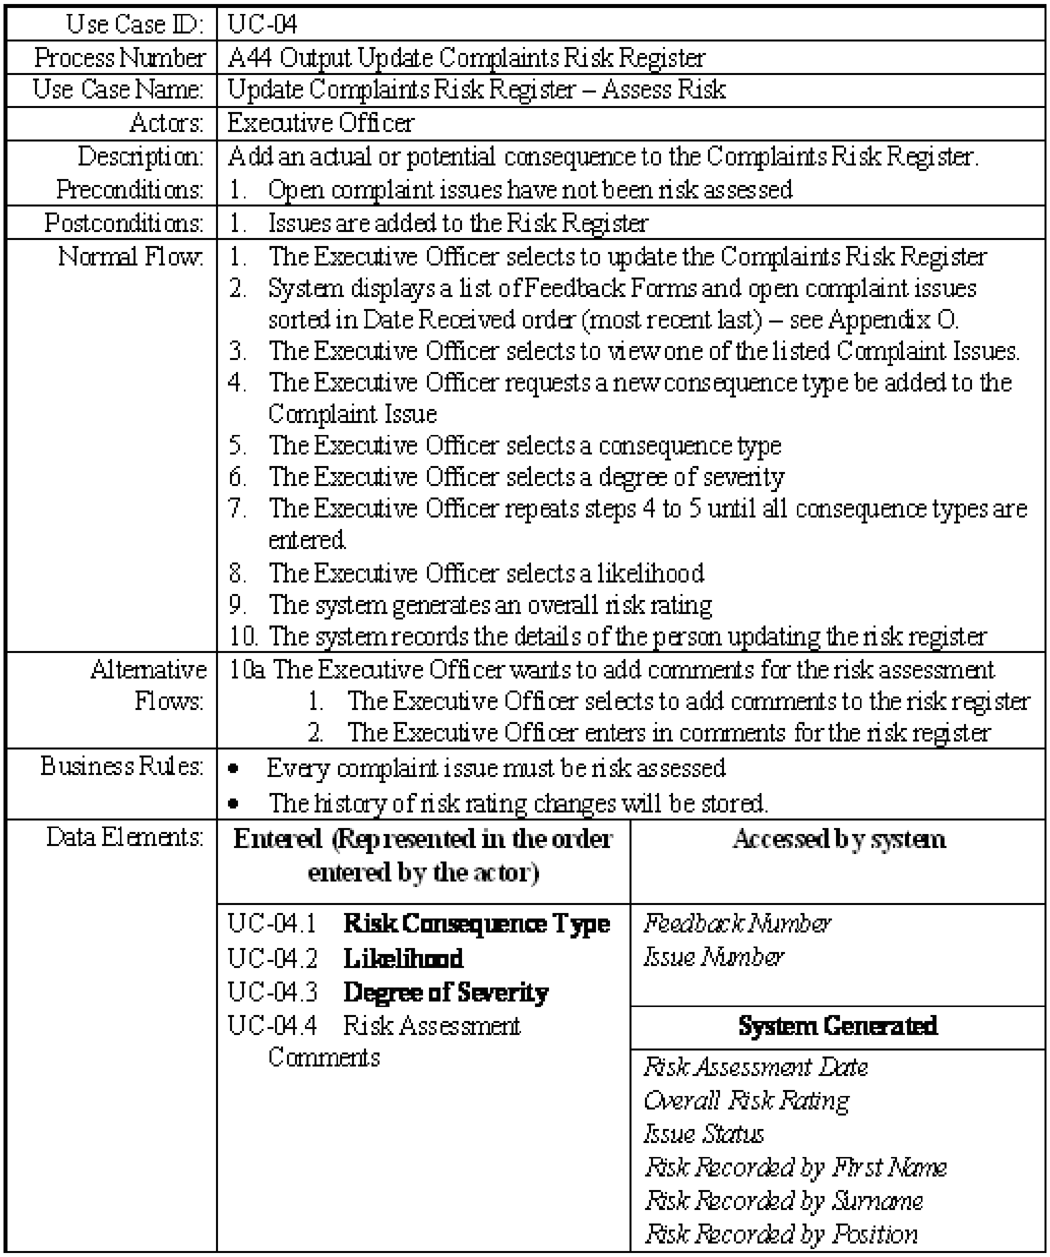

Use Case ID:	UC-04	
Process Number	A44 Output Update Complaints Risk Register	
Use Case Name:	Update Complaints Risk Register – Assess Risk	
Actors:	Executive Officer	
Description: Preconditions:	Add an actual or potential consequence to the Complaints Risk Register. 1. Open complaint issues have not been risk assessed	
Postconditions:	1. Issues are added to the Risk Register	
Normal Flow:	1. The Executive Officer selects to update the Complaints Risk Register 2. System displays a list of Feedback Forms and open complaint issues sorted in Date Received order (most recent last) – see Appendix O. 3. The Executive Officer selects to view one of the listed Complaint Issues. 4. The Executive Officer requests a new consequence type be added to the Complaint Issue 5. The Executive Officer selects a consequence type 6. The Executive Officer selects a degree of severity 7. The Executive Officer repeats steps 4 to 5 until all consequence types are entered. 8. The Executive Officer selects a likelihood 9. The system generates an overall risk rating 10. The system records the details of the person updating the risk register	
Alternative Flows:	10a The Executive Officer wants to add comments for the risk assessment 1. The Executive Officer selects to add comments to the risk register 2. The Executive Officer enters in comments for the risk register	
Business Rules:	• Every complaint issue must be risk assessed • The history of risk rating changes will be stored.	
Data Elements:	**Entered (Represented in the order entered by the actor)**	**Accessed by system**

Chapter 6.2

Difficulties in Accepting Telemedicine

María José Crisóstomo-Acevedo
Jerez Hospital, Spain

José Aurelio Medina-Garrido
University of Cadiz, Spain

ABSTRACT

Telemedicine requires a new type of worker: the health care teleworker. Nevertheless, physicians remain wary of adopting telemedicine. This work examines the sources of the resistance to incorporating telemedicine. We adopt a focus centering on the difficulties that human factors have in accepting the practice of telemedicine. Employees' resistance to change comes mainly from the inertia that perpetuates traditional routines and methods of working. The success of telemedicine projects will be determined by these human factors as well as by an adequate use of information technology and an appropriate organizational management. This work also offers some practical implications in human resource management for managers of telemedicine projects to consider.

INTRODUCTION

Information technology (IT) can improve aspects of both medical care and of the underlying administrative infrastructure. Thus, as in any other industry, we are seeing a proliferation of specialist applications and systems such as hospital information systems (HIS), medical decision support systems, interpretation of biomedical signals and medical images, integration of knowledge-based systems with HIS, and telemedicine.

Telemedicine enables the provision of health care services or the exchange of health care information across geographic, temporal, social, and cultural barriers (Chau & Hu, 2004). Telemedicine makes use of a wide range of technologies to overcome distances, such as radio, analog landlines, e-mail, the Internet, ISDN, satellites, telesensors, and so forth, for the transmission of medical information (data, voice, and video) and provision of medical services from a distance.

Thanks to telemedicine, health care centers can offer diverse specialty services to other centers, to other physicians, or directly to the patient, such as, for example, telecardiology, teledermatology, teleendoscopy, telemedicine, telemonitoring, telenursing, telepathology, teleradiology, and telesurgery (Tachakra, 2003).

The concept of telemedicine does not actually require the use of information technologies. Indeed, it was common in the past to exchange medical opinions and prescribe treatments using mail, the radio, or even visual signals. People living in remote areas of Australia at the beginning of the 20th Century used radio to communicate with the Royal Flying Doctor Service of Australia. At this time, physicians on dry land also used the radio to communicate with ships suffering from medical emergencies (Wootton, 2001). Some African villages used smoke signals to warn outsiders not to approach the village during an epidemic. Similarly, ships used flags to warn that they were in quarantine (Darkins & Cary, 2000). Nevertheless, modern IT has given new meaning to the practice of telemedicine (Bladwin, Clarke, & Jones, 2002).

Telemedicine requires a new type of worker: the health care teleworker. Indeed, telemedicine can be seen as a pioneering activity in the field of teleworking. But unlike in other types of telework, the human factor is much more important for the success of projects in telemedicine. Nevertheless, physicians remain wary of adopting telemedicine. Most experts agree that the major barriers to implementing telemedicine are known but that the solutions are complex and require cooperative efforts.

This chapter examines the sources of the resistance to incorporate telemedicine. We adopt a focus centering on the difficulties that human factors have in accepting the practice of telemedicine. Employees' resistance to change comes mainly from the inertia that perpetuates traditional routines and methods of working (Pardo & Martinez, 2003; Rumelt, 1995). The success of telemedicine projects will be determined by these human factors, as well as by an adequate use of IT and an appropriate organizational management (Bruque-Cámara, Vargas-Sánchez, & Hernández-Ortiz, 2004; Khatri, 2006; Melville, Kraemer & Gurbaxani, 2004; Powell & Dent-Micallef, 1997).

The rest of this chapter is organized as follows. The second section discusses the relationship between telemedicine and human resource management. The third section tries to identify the obstacles in the way of an adequate acceptance and development of telemedicine. This section also offers some practical implications in human resource management for managers of telemedicine projects to consider. Section four suggests some future research opportunities within the domain of the telemedicine and human resource management topics.

BACKGROUND

There has been a considerable amount of work on telemedicine in the scientific literature (Demiris & Tao, 2005; Roine, Ohinmaa, & Hailey, 2001), but academics have focused mainly on technical questions—to do with what technologies are available for the practice of telemedicine (Rao, 2001)—or on health care issues: to what medical fields telemedicine can be applied (Fishman, 1997; Tachakra, 2003).

Researchers have shown rather less interest, however, in questions concerning the organization and management in the adoption and implementation of telemedicine projects. In particular, few studies analyze the impact of telemedicine projects on the management of the human resources participating in such projects (Croteau & Vieru, 2002; Hu & Chau, 1999; Hu, Chau, Sheng, & Tam, 1999).

Health care staff's reluctance to accept the new technology or collaborate on it is one of the main causes of the failure of such projects, these professionals being the proposed end-users of the system (Gagnon, Lamothe, Fortin, & Cloutier, 2005). The rejection of telemedicine by the health care workers involved is often a result of the resistance to change generated by inertias in the existing organizational routines (Pardo & Martinez, 2003; Rumelt, 1995). These routines are threatened by the need to redefine traditional professional roles and by the professionals' loss of status, since IT blurs the functional and hierarchical boundaries in health care organizations (Aas, 2001; May, Gask, Atkinson, Ellis, Mair, & Esmail, 2001).

Apart from the problem of acceptance, there are problems due to the fact that the staff involved are not only teleworkers—their work is also based on the possession, application, and exchange of knowledge. In this sense, telemedicine collaborations can be mutually beneficial exchanges of knowledge to develop partner absorptive capacity and access to unique learning experiences and data (Robinson, Savage, & Campbell, 2003).

There is a common misconception that investing in IT leads to a reduction in costs and enhanced efficiency in the production or services delivered. This belief led to what some have called the productivity paradox, or technology paradox, whereby productivity is negatively associated with investment in IT. As in other sectors, investment in telemedicine and its advantages have been exaggerated. Clearly, not all investments in telemedicine projects satisfy initial expectations, and some even fail. Explanations for the productivity paradox include (Bruque & Medina, 2002): organizations need to learn how to use new technologies efficiently, which takes time; the strategic necessity hypothesis, whereby organizations invest in IT to match other companies competitively rather than to achieve advantages over them; savings in production and transaction costs are achieved, but they are outweighed by the investment made in IT; and when the social and technical systems do not have the same interests, format, or structure. With regard to the latter, a mere change in the information systems is not enough to change the culture of the organization. Technology cannot transform a company by its mere presence. The necessary transformation requires a fundamental change in habits, attitudes, values, expectations, and incentives relating to information management.

DIFFICULTIES IN ACCEPTING TELEMEDICINE

There is no doubt that telemedicine offers considerable advantages. Physicians can gain by accessing digital information that can help them in their diagnoses and treatments, as well as use the technology to exchange opinions with expert colleagues. Nevertheless, the use of telemedicine is advancing only slowly, and health care professionals have shown some reluctance to embrace it (Audet, Doty, Peugh, Shamasdin, Zpaert, & Schoenbaum, 2004; Parente, 2000; Sands, 2004; Wilson, 2005).

This section analyzes the main factors that may explain practitioners' resistance to accept telemedicine. The most important obstacles to the development of telemedicine are as follows: inertias in the existing organizational routines, problems inherent to telework, lack of time, opposition from professional organizations, limitations of the technologies, difficulty in using the technologies and understanding their utility, lack of training, and lack of trust.

The most common inertias, or obstacles to change, in the specific case of telemedicine projects, are those that arise either from the management of the telemedicine project or from organization members' resistance to change (Arjonilla-Domínguez & Medina-Garrido, 2002). Project managers may fail due to lack of leadership, lack of top management support, lack of adequate training, the failure to adapt the project to the organization's strategy or to the available organizational resources, or the failure to adapt the structure of the organization to the proposed changes.

Employees' resistance to change may be a result of their lack of participation in the project, the failure to consider their interests or needs, the fear that their jobs or status are under threat, lack of training and information, fear of uncertainty of what will happen when the new system is launched, the perception that change is unnecessary, the tendency to concentrate on short-run problems, the refusal to believe that past successes may end unless things change, group pressure on the individual to continue with what has been normal up to now, the risk of failure, the effort required when adopting something new, a lack of strategic vision throwing doubt on whether the right path has been taken, a lack of consensus with regard to the decisions taken, the difficulty in breaking with the established routines, and waiting for others to act so as not to run the risk of changing unilaterally.

The essence of telemedicine is to move the medical knowledge and experience rather than move the patient physically. For this, telemedicine involves rather more than just taking medical services to where they did not exist before. It has also become a practice of transmitting and handling knowledge. It enables medical practitioners to exchange their knowledge (Robinson et al., 2003) so that others can apply it in specific situations.

Health care professionals who practice telemedicine can therefore be said to be knowledge teleworkers. Nevertheless, the nature of the work of a knowledge worker is inconsistent with the flexibility associated with telework (Bentley & Yoong, 2000). In this respect, there are various problems with the development of telemedicine with regard to its consideration as telework (Arjonilla-Domínguez & Medina-Garrido, 2002):

- Telework is mainly an after-hours' activity, and thereby extends the normal working day (Bentley & Yoong, 2000). But this activity tends to be measured by results rather than by the time dedicated, so it frequently leads to overworking.
- The figure of teleworker is not as legislated in most countries as other contractual labor figures. This can generate some labor and economic insecurity, as well as fewer social security benefits.
- Teleworkers, depending on where they are located, can feel isolated from their firm or from their profession and may perceive a lack of status. Their location may often provide an inadequate working environment.
- Often, not of the technical resources necessary to do the work are available due to insufficient planning. A telemedicine project is often validated by implementing a small-scale pilot project, only for the full-scale project to be denied the equivalent resources when it is launched.
- Telemedicine teleworkers, being knowledge workers, can easily feel isolated, making it difficult for them to work in a team and resolve operational problems.

Some possible solutions to the above problems include:

- Establish areas and timetables requiring teleworkers' presence. Mix telework with presential work. Create telework centers and networks of teleworkers. Develop contact mechanisms (meetings, discussion forums, etc.).
- Offer clear contractual conditions, and conditions for promotion and training. Offer competitive economic incentives (Ahern, Kreslake, & Phalen, 2006).
- Offer continuing support from the firm, and provide the necessary resources.
- Communicate a feeling of being in a team,

and develop group training.

In addition, these problems of health care teleworkers make it necessary to develop the right human resource policies to retain valuable personnel in the telemedicine projects. Such policies include notably: offer telemedicine as a flexible working environment, that is, as a chance to reconcile working life with family life; retain valuable personnel who wish to retire or work part time; offer recognition and status visible to others; and since the work processes are not always observable in telemedicine, it is useful to link incentives with the measurable results obtained (Ahern et al., 2006; Arjonilla-Domínguez & Medina-Garrido, 2002; Bentley & Yoong, 2000).

Physicians often argue that they do not have time to attend to patients remotely, as they are too busy with the consultations and medical services they provide to the patients who see them in person. This is a shortsighted view from the strategic perspective, since they would be able to attend to more patients if they saved time on traveling and if they automated medical services wherever possible. By using technology to automate existing routine tasks, performance can be optimized (Kirsch, 2002). Better efficiency is driven by better use of information, and this is where telemedicine can be utilized. In this respect, many of the services provided to patients are routine and repetitive, and by definition, are capable of being automated. For example, it is possible to automate the process of dispensing prescriptions to patients, if the physicians establish the treatment requiring them in the computer system, or if they have diagnosed a chronic illness. But automating this process would lead to a loss of power on the part of these professionals.

The power that professional colleges hold over health care professionals is well known. This is particularly true in the case of the medical colleges. Telemedicine projects need broad institutional support to gain legitimacy. This institutional environment is made up of the public authorities, legislators, labor unions, the population, and the above-mentioned professional colleges. Nevertheless, some medical colleges are drawing up ethical codes of conduct that make it difficult to do telemedicine properly. Such colleges have even criticized the practice of medicine realized exclusively by mail, telephone, radio, press, or the Internet (Ferrer-Roca, 2001).

One of the arguments used by the organizations of health care professionals to reject telemedicine concerns privacy. Although this is a legitimate concern, patient data can be more vulnerable in physical files in a medical filing room than in electronic records in a well-designed information system. Despite this, many interest groups resist change in the name of the right to privacy (Kirsch, 2002).

One of the most reasonable concerns of telemedicine professionals is the doubt about whether telemedicine can really substitute properly for face-to-face care. For example, in a videoconference-based telemedicine project involving Hope Hospital, in Salford (UK), and the University of Salford, nurses tried to monitor the neonatal intensive care unit from a distance. Many participants complained that the image quality made it impossible to detect the subtle color changes in the infants' pallor, and that the sound quality made it impossible to correctly hear their breathing (Qavi, Corley, & Kay, 2001). On the other hand, physicians' acceptance of telemedicine is strongly influenced by psychological and perceptual factors. Thus, physicians' acceptance of telemedicine depends on: their attitude towards the use of technologies in general, their previous experience in using technologies (Qavi et al., 2001), and their perception that the technologies are easy to use, and that they will prove useful in their work (Hu et al., 1999).

These psychological factors suggest some useful conclusions for the management of human resources in telemedicine projects. Managers need to cultivate a favorable attitude towards the general use of technologies among health care staff (Hu et al., 1999). To achieve this objective, the health care organization that is promoting the telemedicine project should communicate clearly and to all concerned the utility of the technologies in medical work. Technical and informational sessions need to be organized to communicate their utility for medical practice. It will not always be possible to reduce the perception that some technologies are difficult to use, but this problem can be alleviated through intensive training courses. To encourage acceptance of change, these courses should focus on how the new technologies can make patient care and the services provided to patients more efficient, rather than on how they should support the already existing organizational routines.

The need for training and preparation in the use of the technologies supporting telemedicine is not reflected in the syllabuses of university medical departments (Ferrer-Roca, 2001). This is why many health care professionals fail to see the connection between their work and the technical issues (use of applications and databases, electronic interchange of data and image files, standards to use, etc.) or legal issues (IT security, data protection and privacy, international practice of telemedicine, etc.) that concern telemedicine.

Trust plays a key role in all collaboration relationships (Gefen, 2000), and this is particularly true in virtual relationships. Telemedicine projects that do not inspire trust among the physicians do not tend to encourage team working (Paul & McDaniel, 2004). Nevertheless, telemedicine brings its own additional problems in creating and maintaining trust. This is because telemedicine involves the participation of multidisciplinary teams, and in virtual processes that are different from the ones health care professionals are used to. Launching a telemedicine project can also be seen as a threat—as the first step in the replacement of the health care professionals by other professionals delocated geographically, even in other countries.

From the practical perspective, managers need to foster confidence in the telemedicine projects they are implementing if they wish the professionals to work together successfully in teams (Paul & McDaniel, 2004). For this, they should be aware that telemedicine depends on a social context in which the professionals may be reluctant to work together and may distrust the management's intentions. The most practical way of improving this confidence is by training, information sessions and meetings involving the participating professionals. At the same time, the management of the health care institution needs to make it clear that the intention is not to substitute the staff participating in the project, and offer incentives (salary, social, status, professional, quality of working life, etc.) to the participants (Ahern et al., 2006). Managers also need to emphasize the professional advantages possible from using telemedicine, and the improved service quality it can provide.

The most significant advantages of telemedicine for health care professionals are (Robinson et al., 2003; Wilson, 2005): quick access to information anytime, anywhere; real-time access to specialty consultations; access to continuing training; platform for learning specific medical techniques; fast diffusion of information, knowledge, and skills; generation of professional contact networks, useful for collaboration in work and in research; better communication and coordination between physicians; specialist support for primary care physicians treating patients; less traveling and loss of time spent reaching remote areas, working in teams, receiving training or learning specific techniques, and so forth.

Health care professionals also need to be informed about the benefits telemedicine can bring to their patients. These benefits include: fast access to health care services; specialty care under the supervision, or not, of the family physician; freedom to choose or switch hospitals and physicians; staying close to home and to relatives whenever possible; convenience for the patient; continuous improvement in the health care services; more information about the illness suffered and the prescribed treatment; less traveling and concomitant time wasted; prescription of over-the-counter (OTC) medicines, and so forth.

Some authors ask why some companies encounter difficulties and yet others prosper when using the same IT, and why IT-based advantages dissipate so quickly. Their response is that integration should be produced between the IT, complementary human resources, and business capabilities (Bruque-Cámara et al., 2004; Khatri, 2006; Melville et al., 2004; Powell & Dent-Micallef, 1997). The integrated management of IT and complementary resources and capabilities can be regarded as the most feasible path towards attaining IT advantages. A list of these complementary resources and capabilities is shown in Table 1.

The benefits of IT lie in its capacity to free up information throughout the organization. An artificial culture or structural constraints devalue the technologies. The philosophy of having an open organization and an open communication permits access to operational information and promotes informal and frequent communication across functional and project boundaries.

Consensus is not necessarily always positive for performance in a technological project—a low level of conflict enriches and enables innovation—but a high level of conflict is dysfunctional. Consensus reinforces the capacity of IT to expand communications and disseminate information. Conflicts rooted in territorial disputes or between health care professionals frustrate this consensus and inhibit the functionality of the technologies.

Management commitment increases the success of telemedicine projects, making resources available for their implementation, integrating IT into the organization's strategies and processes, and ensuring that the investment in IT will continue over time.

Another requirement for the adequate implementation of a telemedicine project is organizational flexibility. Implementing a telemedicine project provokes significant changes in the organization's structure, communication models, and power relationships. But individuals tend to show resistance to change (Pardo & Martinez, 2003; Rumelt, 1995). This resistance is even stronger if the changes imply the need to acquire new knowledge or to modify work routines.

The management capabilities listed in Table 1 include the need to take investment decisions regarding the technologies for telemedicine that are consistent with the organization's strategic planning. The technologies used in telemedicine cannot be chosen to meet operational health care needs in an improvised way; they must be adequately planned. At the same time, managers need to integrate the choice of the most appropriate technologies for the telemedicine projects being implemented into the strategic planning of the entire organization.

The technologies used to connect with the health care service providers and suppliers, although not regarded as telemedicine, are contained within the concept of e-health. As in other industries, specific standards of electronic data

Table 1. Complementary human resources and business capabilities (Source: Adapted from Powell and Dent-Micallef (1997))

interchange (EDI) systems are put in place to facilitate electronic interaction with the providers. But such a system is of little use unless there is a relationship of open communication and trust with the provider. Thus, connecting electronically with the providers should be preceded by the establishment of mutual trust that creates a favorable environment for making investments in specialist technologies. This trust is essential because these specialist investments cannot always be used for interchanges with other providers. All this, of course, does not preclude the necessary contractual guarantees.

Implementing any technology is sure to fail if the individuals that are to use it do not have sufficient technical training. But the majority of university courses in the health care area do not include this training in their syllabuses. Although extrapolating traditional health care practice to the electronic universe may seemingly be immediate, in fact this is generally not the case. Some authors estimate that it takes about 2 years for health care staff to be trained to use telemedicine properly in medical practice (Ferrer-Roca, 2001). They need to relearn how to manipulate and interpret patient information (for example, from their electronic medical records), images (such as radiographs, high-resolution medical images, computer tomography scans, magnetic resonance imaging pictures, ultrasound images, electrocardiograms or echocardiograms, video images of endoscopic cameras, etc.), or sounds (for example, from electronic stethoscopes) (Rao, 2001).

Supporters of process reengineering argue that the traditional functional structure of organizations can mask the best way of conducting some processes at work. The organization's management should not invest in IT that immortalizes its current processes, but should instead find a new, more rational design for the processes. Indeed, the access to information and the support IT provides to communication dissolve traditional hierarchical and departmental boundaries, and enable work processes crossing these boundaries to be designed. In the case of telemedicine, it is essential to design new processes that meet the technical and health care needs of each telemedicine service (telenursing, teleradiology, telepathology, teledermatology, telecardiology, telesurgery, etc.), eliminating or automating many of the bureaucratic and administrative activities that clog up the process without adding any value to the traditional health care services.

One of the most important uses of IT lies in the support it offers for working in teams. Technologies such as e-mail, voice mail, conference by computer and videoconference make it possible to coordinate the asynchronous and geographically-separated tasks that normally hinder team working. Telemedicine frequently implies that there is an exchange of health information, without personal contact, between two physicians. Thanks to telecommunications technologies, telemedicine enables the exchange of health care information across geographic, temporal, social, and cultural barriers (Chau & Hu, 2004).

In telemedicine, as in other innovative applications of IT, benchmarking the best practices of other health care organizations is a fundamental tool. This procedure allows managers to precisely evaluate the characteristics, functionalities, benefits, applications, and costs of the technology. All telemedicine projects should avoid the mistake of "reinventing the wheel." Thus, when planning the telemedicine project the strategic analysis stage should carry out an in-depth study of the characteristics of other, similar telemedicine projects carried out in other organizations and countries.

FUTURE TRENDS

Implementing and managing IT cannot be undertaken independently of the management of other elements in the organization. The human resources and business capabilities of the managers are two vital factors for the success of any technological project, and, by extension, of any telemedicine project. In this respect, managers of telemedicine projects would be recommended to develop human resource management practices centering on: (1) the existence of a fluid communication between technical staff and the management; (2) the absence of any organizational conflict; (3) flexibility in the procedures and decision-making; (4) the use of inter-departmental working groups; (5) the explicit leadership of the top management in the process of technological renovation; (6) the dedication of efforts in training for the new technologies; (7) an inclination towards change of the organization members; and (8) the fit between the technology used and the socio-economic system of the organization (Bruque-Cámara et al., 2004).

Future research should examine whether these human resource practices have the same positive impact on the performance of IT-based projects in the health care sector as in other industries. In this respect, some particular characteristics of health care professionals should be considered, such as their feeling of professional autonomy, perception of a high social and professional status, and strong professional corporatism, the existence of protocols and organizational work routines that are difficult to change, the fact that the results of the work are not always easily observable, and the possession of knowledge that is difficult to structure and automate.

CONCLUSION

Now in its early years, telemedicine will have to overcome the same legal, financial, personal, and cultural obstacles that have confronted every other technological change in the history of medicine (Jarudi, 2000).

In this chapter we have analyzed various factors leading health care staff to reject telemedicine. Chief among these have been the obstacles to change generated by inertias in the current organizational routines, problems inherent to their nature as teleworkers, the irrational excuse of lack of time, the influence of the professional organizations' opposition, the impossibility of these technologies substituting for personal contact with the patient, the perception of the ease of use and utility of the technologies to be applied, the lack of training and preparation in the use of the technologies, and problems of trust for working in virtual teams.

Analysis of these obstacles to acceptance allows us to offer some practical implications for managers of the human resources involved in telemedicine projects. They would be advised to promote the trust of the participants, inform professionals about the benefits of telemedicine both for the professional and for the patient, and correctly manage the complementary human resources and business capabilities of the managers.

Many authors have forecast the rapid diffusion of telemedicine for supporting health care services provision, but in fact the new markets being created by these technologies are growing very slowly, rather like the acceptance of such technologies by health care professionals. The first thing that really needs to be done to ensure that a telemedicine project will work—and be accepted by the health care staff—is to combine the real and current needs with user-friendly technologies, so that current processes can work better, more quickly, and more cheaply (Kirsch, 2002).

KEY TERMS

E-Health: The provision of any health care service that is supported by electronic processes and communications.

Electronic Medical Records: Computer-based patient medical records. Patient medical records are a systematic documentation of a patient's medical history and care.

Over-the-Counter (OTC) Medicine: A medicine that can be bought without a doctor's prescription, such as some analgesics.

Telecardiology: The digital transmission between health care professionals of information relating to electrocardiograms, echocardiograms, angioplasty, and cardiac pacemaker monitoring.

Teledermatology: The digital transmission between health care professionals of images of the skin using a dermascope.

Teleendoscopy: The digital transmission between health care professionals of the results of endoscopic examinations.

Telemedicine: The use of information and communications technologies to exchange information between practitioners, or to deliver medical services to a patient remotely.

Telemonitoring: The remote monitoring of patients' state of health. It is fundamentally used to control and treat chronic patients.

Telenursing: Health care services provided by nurses remotely, such as monitoring patients in their homes or referring patients to the appropriate medical services through the processing of patient data.

Telepathology: The digital transmission between health care professionals of high-resolution images of, for example, microscope slides, photographs of injuries or smears, and so forth.

Teleradiology: The digital transmission between health care professionals of electronic radiology images such as X-rays, computerized axial tomography scans, or magnetic resonance images.

Telesurgery: Remote surgery using robotics and audio/video devices.

Virtual Health Care Teams: Teams made up of health care professionals that share information about patients electronically in order to improve their knowledge and decision-making.

Chapter 6.3

Investigating Trust Relationships in a Healthcare Network[1]

Stefanie Kethers

David Sier
CSIRO Mathematical and Information Sciences, Australia

ABSTRACT

Public hospitals currently face an ever increasing demand on their resources, and there are many attempts at streamlining processes and patient flows. However, in many cases, optimizing processes is not enough, as 'soft' factors such as the relationships between hospital wards influence how efficiently the resources needed to treat patients are utilized. These factors are often ignored when attempting to improve patient flows. In this chapter, the authors describe a case study investigating the relationships between an acute stroke ward and a specialist stroke rehabilitation ward of a large metropolitan health service. The motivation for this study was the hospital management's interest in improving communication and collaboration across wards as a means to optimize hospital processes, and thus, patient care. To assess the relationships between the two wards, the authors examined the patient handover process that links the wards' activities and applied the Trust-Confidence-Distrust (TCD) framework of Gans et al. (2003), which was developed to model trust relationships in social networks, to examine the trust relationships between the wards.

INTRODUCTION

Public hospitals are under a lot of pressure to improve both their efficiency and service quality, and many hospitals have therefore been spending time and effort to optimize their processes. For example, Ramakrishnan et al. (2005) note that attempts to reduce the lengths of waiting lists for elective procedures and long stays in emergency departments often focus on policy setting, clinical process mapping, or capacity models of patient flows. However, perfectly well-designed processes can run less than smoothly if they fail to address the human side of patient movement through a hospital. In many cases 'soft' factors such as the relationships between hospital staff in different wards along a clinical pathway will determine how efficiently the resources needed to treat patients are utilized. In many situations these factors are ignored when attempting to improve patient flows.

In this paper, we describe the application of the Trust-Confidence-Distrust (TCD) framework defined by Gans et al. (2003) to the investigation of trust relationships between two hospital wards engaged in a patient handover process. This case study represents one of the first applications of the TCD framework to a real-life situation with real-life data. Given that the two wards were part of a large metropolitan health service which is more similar to an organization than to the social network described by Gans et al. (2003), we were particularly interested to see which aspects of the framework were still applicable, and which ones were not.

This paper is structured as follows: In the subsequent section, we outline the background of our study. Then, we briefly describe the TCD framework for analyzing trust relationships. Afterwards we give an overview of the case study we performed, including the setting. Having introduced the research methodology, especially the data capture process, we describe our analysis of the trust relationships using the TCD framework. Eventually, we evaluate the applicability of the TCD framework to the context of our case study and briefly sketch future trends.

BACKGROUND

In health informatics, clinical, organizational processes are mainly investigated in regard to how they can be supported or improved by information technology. Even though this is not the focus of our contribution, such analyses presuppose means to describe and model these processes. Due to the focus on information systems, typical process modelling notations such as event-driven process chains (Scheer, 1994), Petri net based workflow notations (van der Aalst and van Hee, 1996), or languages like the business process modelling notation BPMN (www.bpmn.org) are commonly used. In (Framinan et al., 2005) some have been investigated in the context of business process reengineering of clinical processes. They allow capturing the timely relation of activities and the assignment of resources and responsibilities of involved actors. Also Saboor et al. (2007) propose a method, named MedFlow, to support the systematic assessment of clinical processes focusing on the quality of information logistics. They derived relevant quality criteria from literature, developed an extended process modelling notation based on UML activity diagrams, and evaluated the method in a preliminary case study. Their analysis distinguishes four different process aspects, i.e. control flow, data flow, tool usage, and organizational information. For each of them, a rule-set that represents a "pattern of critical cross-points" was used, to detect weak points within these views. A shortcoming of these modelling means is that the human side of the process, the social interaction of the people that carry out these processes and for example, trust issues that are involved, are neglected. When trust is investigated in the context of health informatics, mostly three fields are considered: how to build up trust in online communities or health information on the web (Luo and Najdawi, 2004; Song and Zahedi, 2007), trust issues in the context of electronic health records (Smit et al., 2005), or regarding the physician-patient relationship.

Networked organizations in health care have already been explored by Peterson et al. (2000). They focused on the foundational constitution and enabling conditions. From their observations they derived that networks "develop through different phases of maturity and network-ability". While the study concerned IT as the enabler, they emphasized that IT is a facilitator but not the major driver for the direction and development of the network. "[It] is the organisation, its professionals and management that ultimately drive networking." Similarly when Avison and Young (2007) investigated the failures of ICT projects in the field of health care, they identified two main reasons: For one, health care should not be treated at an enterprise level but on a national scale. For another, they emphasized that "better person-to-person models are needed to understand how the collegiate and interpersonal elements of care delivery could be embodied better in the systems used for care delivery." Thus, while focussing IT support they again also emphasize the need to consider social interactions.

We thus agree with the views expressed by Avison and Young, and Peterson et al. and others, e.g. (Coiera, 2004): "Since health systems are sociotechnical systems, where outcomes emerge from the interaction of people and technologies, we cannot design organisational or technical systems independently of each other". Therefore, we have employed the Trust-Confidence-Distrust (TCD) framework, as described in the next section, to investigate the social interactions in the transfer of stroke patients from an acute ward to a rehabilitation ward. We have paid special attention to the perceptions that the people involved have of this process; in particular, how staff members of the two wards see the other ward's goals and priorities. As Wachter and Shojania (2004) state, "Psychologically, human beings simply communicate better and more often with people they know than with strangers—particularly if they feel those others are on the same team, have the same interests, and share the same goals".

The next section describes the Trust-Confidence-Distrust (TCD) framework in more detail.

THE TCD FRAMEWORK

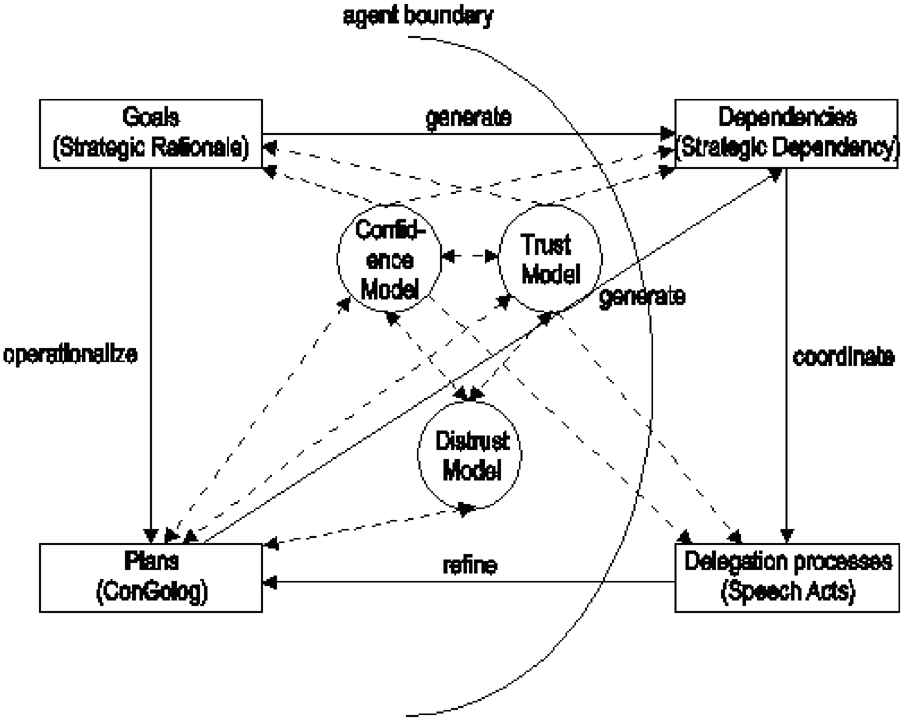
The TCD framework was developed for application in a social network, which Gulati (1998) defines as "a set of nodes (e.g., persons, organizations) linked by a set of social relationships (e.g., friendship, transfer of funds, overlapping membership) of a specified type". Weyer (2000) expands on this idea by defining a social network as an autonomous form of coordination of interactions whose essence is the trusting cooperation of autonomous, but interdependent agents who cooperate for a limited time, considering their partners' interests, because they can thus fulfil their individual goals better than through non-coordinated activities. The "agents" in this definition can be organizations or people, or people representing, or working for organizations. According to Powell (1990), networks rely on reciprocal patterns of communication and exchange, and reciprocity and complementarity are essential for the success of a network: "In essence, the parties to a network agree to forego the right to pursue their own interest at the expense of others". As Powell (1990) states, networks are well suited for situations where there is "a need for efficient, reliable information."

In contrast to those of a network, Powell (1990) lists stability, reliability, and accountability as the main strengths of an organization (also called a hierarchy). In an organization, management defines work roles and administrative procedures. Work is often highly specialized and therefore interdependent. As Powell (1990) states, "relationships matter and previous interactions shape current ones, but the patterns and context of intra-organizational exchange are most strongly shaped by one's position within the formal hierarchical structure of authority". In an organization, there is less freedom of choice for the individual agents, as they are constrained by organizational rules and policies. Given that our case study took place in an organizational, rather than a network, environment (cf. next section), we were particularly interested to see whether the TCD framework was applicable to our setting.

In our investigation of trust, confidence, and distrust, we stay in accordance with the definitions given by Gans et al. (2003): We follow the definition of Mayer et al. (1995) of trust as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party". Trust thus occurs between two agents, the trustor and the trustee, and has an element of risk, since the trustor cannot ensure that the trustee will perform the action. In social networks, trust needs to be distinguished from what Gans et al. (2003) call confidence, and Luhmann (1988) calls system trust, in the network as a whole. This is because a network's mesh of dependencies is not completely visible to, let alone manageable by, the trustor. Thus, participation in a social network results in a double vulnerability: to identifiable opportunists, and to the generally incomprehensible mesh of dependencies between all the network partners. Participation in such a network therefore requires confidence in the network (e.g. its rules and stability) as a whole. The third relevant concept described by Gans et al. (2003) is distrust, which the authors distinguish from lack of trust; cf. also Lewicki et al. (1998). For example, a dissatisfied network member can cultivate, but hide her distrust while still exhibiting trustful behaviour. This means that the agent continues as a network member, postponing her decision for voicing dissatisfaction or exiting the network, but starts to collect information (which can be costly and time-consuming), by, for example, monitoring other network members' actions. The agent then typically interprets this information in a subjective way that is strongly influenced by her distrust. According to Luhmann (1988), distrust therefore has an inherent tendency to become stronger.

Gans et al. (2003) call the model describing the interplay of trust, confidence, and distrust, and its effects on the relationships within the network the TCD framework. Figure 1 shows how the TCD framework can be formalized as a multi-perspective framework based on formalisms taken from requirements engineering and computer science at large. By managing the static and dynamic interrelationships through reasoning and/or simulation, the possibly conflicting perspectives and viewpoints can be dealt with. The left side of Figure 1 depicts the intra-agent modelling aspects of the framework, that is, an agent's goals, which are represented by i* strategic rationale models described by Yu (1995), and plans. Plans are based on the strategic rationale diagrams together with pre- and post-conditions using the ConGolog formalism. ConGolog, described in De Giacomo et al. (2000), is a logic-based high-level planning language used in artificial intelligence approaches which is suitable for describing and representing processes. The right hand side of Figure 1 shows the inter-agent aspects, namely, the strategic dependencies between agents, represented as Yu's (1995) i* strategic dependency diagrams, and the implementation of these dependencies in delegation processes formalized as Speech Act diagrams (see Schäl (1996)). We prefer the i* formalism (strategic rationale (SR) and strategic dependency (SD) models) to other languages like UML, ER diagrams, or Petri nets, because it is explicitly designed to cope with strategic goals and agents' intentions, and furthermore is equipped with formal semantics. Thus, as a main feature, it allows not only to reason about the "how" but also about the "why" of different alternatives. The solid lines in Figure 1 indicate the nature of the interrelationships between these different perspectives. For example, strategic dependencies shape and lead to delegation patterns, and the latter are evaluated partially with respect to the former. Conversely, strategic goals lead to operational plans, which

Figure 1. Interplay between modelling perspectives



then potentially generate strategic dependencies on other agents. Trust, confidence, and distrust, depicted in the middle part of the figure, influence the four main components of the framework, as well as each other (represented as broken lines). For example, the level of trust between agents will influence one agent's propensity to become dependent on the other, say for specific tasks or resources, and the level of distrust can lead to the addition of monitoring tasks to the operational plans. These monitoring tasks may increase or decrease the level of distrust felt by the agent.

While trust has been studied in the social sciences for many years, its formalization from a computational point of view has not been studied for very long. Some approaches like us, view trust as a subjective probability or provide logical approaches to modelling trust. None of the approaches in the literature seem to give distrust a special status. In (Gambetta, 1988), the prevalent view of trust is that of a subjective probability, which, roughly, amounts to the likelihood (assigned by the trusting agent) that another agent will perform a task or bring about a desired situation on which the trusting agent depends. Other work along this line includes (Coleman, 1990; Marsh, 1994; Witkowski et al., 2000). Game-theoretic approaches analyze trust using the iterated Prisoner's Dilemma as a benchmark (Axelrod, 1984; Boon and Holmes, 1991). Castelfranchi and Falcone (1999; 2001) propose a more fine-grained model. It takes into account the agent's mental attitudes such as the trusting agent's beliefs about the trustee's opportunity, ability, and willingness to perform a desired task. A quantitative measure of trust has the advantage that it lends itself nicely to computing a decision whether to delegate a task to a trustee or to update the level of trust depending on the outcome of an interaction with the trustee. Gans et al.'s method for modelling trust is also different from Yu and Liu (2001)'s approach to describe trust relationships in i*. Yu and Liu (2001) propose a purely qualitative approach using softgoals with corresponding contributions.

THE CASE STUDY: TRANSFER OF STROKE PATIENTS BETWEEN WARDS

The goal of this case study was to investigate trust relationships between wards along a clinical pathway with the aid of the TCD framework described in the previous section. The study was commissioned by Southern Health, a large metropolitan health service in South Eastern Melbourne, Victoria, Australia. Southern Health provides public hospital services, aged inpatient, community and home care services, and inpatient and community mental health services across an area in excess of 2,800 square kilometres with a population of over 700,000 people (see http://www.southernhealth.org.au/). Southern Health services are provided through five major hospitals and nine community health services centres. Two clinical services directors together with operations directors at each location manage the different services. Each director reports to the chief executive, who reports in turn to the hospital board. Thus, Southern Health can be classified as a (distributed) organization rather than a network of independent partners. Our study involved the investigation of stroke patient transfers between an acute ward and a rehabilitation ward located on different sites. A mix of medical and allied health staff are involved in the transfers. These people report to different program managers, although ultimately the management responsibility for both the acute and sub-acute patients lies with the head of the Neurology program.

Stroke is the third highest cause of death, and the leading cause of chronic disability in adults in Australia (see Pollack and Disler (2002)). In our investigation we focused on the handover process of stroke patients from the acute ward (AW) to a specialized rehabilitation unit (RW). This unit is the major stroke rehabilitation facility. Stroke patient rehabilitation is a scarce resource needing a coordinated, multi-disciplinary team approach (Pollack and Disler (2002) give an overview of the different roles and stakeholders in stroke patient rehabilitation), so there is a significant amount of cooperation required within a ward, and between wards such as AW and RW. AW and RW are physically located in two different hospitals, separated by a 30-minute drive. Patel et al. (2000) claim that, given that face-to-face communication is an important part of developing and maintaining a shared understanding of team goals and maintaining trust, geographical separation is a potential obstacle to implementing good team processes. Consequently, we were interested in finding out whether the two wards managed to see each other as a team working together towards the shared goal of caring for the patient, or whether there were significant misconceptions about the other ward's work. As Suchman (1995) notes, "work has a tendency to disappear at a distance, such that the further removed we are from the work of others, the more simplified, often stereotyped, our view of their work becomes" (see also Wachter and Shojania (2004)).

Because our focus was on the trust, confidence, and distrust relationships between wards AW and RW, we wanted to capture the stakeholders' perceptions of the handover process. In this context, the stakeholders are the wards; specifically, the health professionals in the acute ward who prepare patients for discharge to the sub-acute area and those in the rehabilitation ward who carry out the patient admission procedures. Stakeholder perceptions are an important indicator of the performance of the transfer processes; in particular, the perceptions in one ward can identify failures in the process not evident to the other ward.

RESEARCH METHODOLOGY

To collect the required information, we followed the Co-MAP method described by Kethers (2002) to obtain the process information for the "a priori goal and capability analysis" postulated by Gans et al. (2003). The main advantage of this method is the strong semantic model underlying the captured data, which allows formal mapping of the data into different perspectives on the investigated process. After an initial meeting with the Nursing Director and members of the Allied Health Rehabilitation and Aged Services Program, we conducted two focus group meetings, each with a team from one ward, to capture that ward's view[2] of the interactions within the ward and with external units, including the other ward. In these meetings, the group developed informal process diagrams (see Figure 2 for an example) that focus on the interactions and information flows within and between the two wards. Information flows between agents are captured as arrows between ovals representing sender and receiver of the information. Graphical symbols are used to represent the media for information flows (for example, phone, formal document, or meeting), and the recipient's perception of the quality of the information flow (e.g., a tortoise for "too slow", or a stop sign for "does not occur at all"). A more detailed description of the different graphical symbols is given by Kethers (2002). During one of the focus group meetings, we became aware of the role of the Rehabilitation Liaison Officer (RLO) who acts as an interface between the wards, so we conducted an additional interview with her.

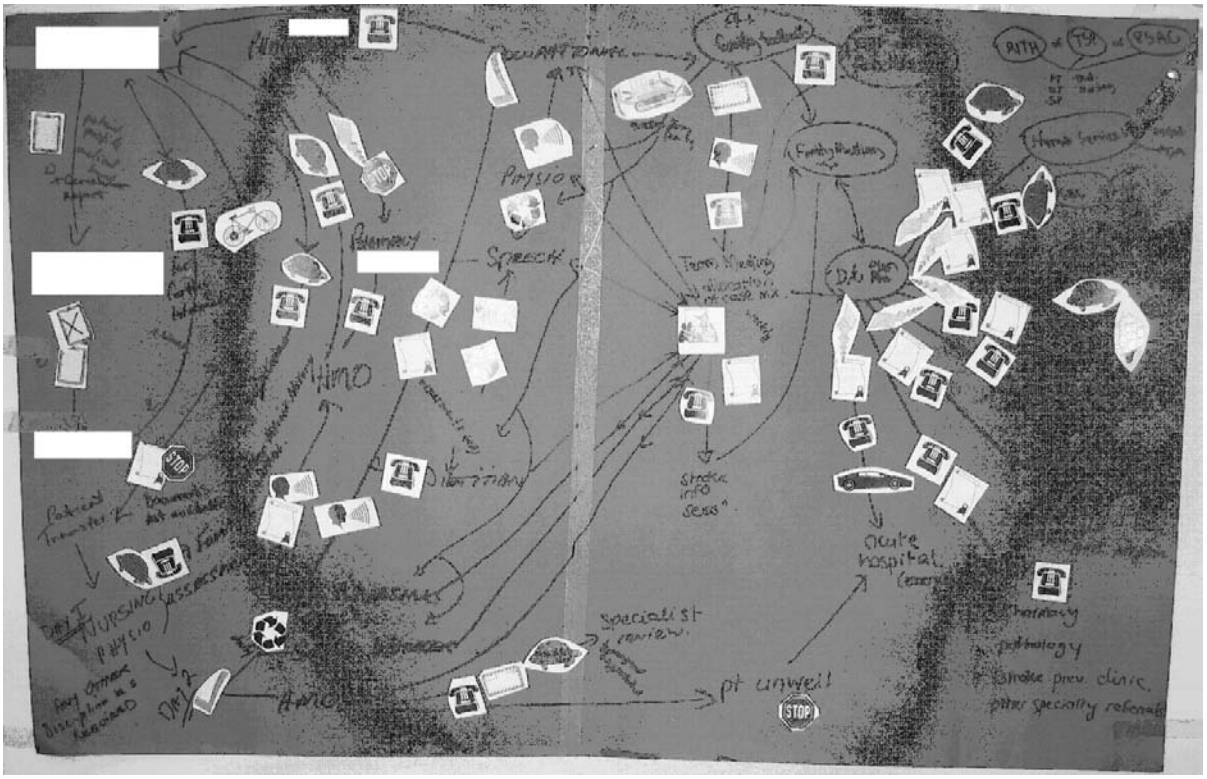
Based on the informal process diagrams, meeting notes, and additional information collected, we developed the different perspectives on the process shown in Figure 1. As a first step, we developed two strategic dependency (SD) models (see Yu (1995)), one for each ward's perspective concerning the patient transfer process. In a second step we refined our models to strategic rationale (SR) models in order to regard the actors' internal actions as well as their interactions. To identify trust, confidence, and distrust issues in a third step, we then analyzed the different diagrams by regarding the different stakeholders' (the two wards' and the RLO's) perceptions of the process, identifying conflicting views of what is really happening in the scenario, tracking the effects on trust relationships between the wards, and recognizing the effects of these relationships on the process.

APPLICATION OF THE TCD FRAMEWORK

The SD model (a detailed description is given in Yu (1995)) describes the network of relationships among agents (nodes) by specifying dependencies (links) between them. A dependency relationship enables the depender to do things that she would otherwise not be able to, but also makes her vulnerable if the dependee does not fulfil the dependencies. The model offers four dependency types: goal, task, resource, and softgoal dependencies, which differ according to the degree of freedom they leave for the dependee.

The SD models shown in Figure 3 are structured as follows: The circles show the two wards, the arcs show what one ward wants or needs from the other ward. The direction of the 'D's on an arc shows the direction of a dependency. For example, the lowermost arc in the left half of Figure 3 (RW's view) shows that RW depends on AW for a "quick reaction if a patient is unwell". Rectangles represent a resource, such as a piece of information, for example "Feedback about patient" as shown in Figure 3 (AW's view). Boxes with rounded edges represent goals that can be measured, for example in Figure 3 (RW's view), the need expressed by RW for "one contact person for each discipline" at AW. The irregular shapes represent so-called "soft goals" – goals that are

Figure 2. Informal process diagram

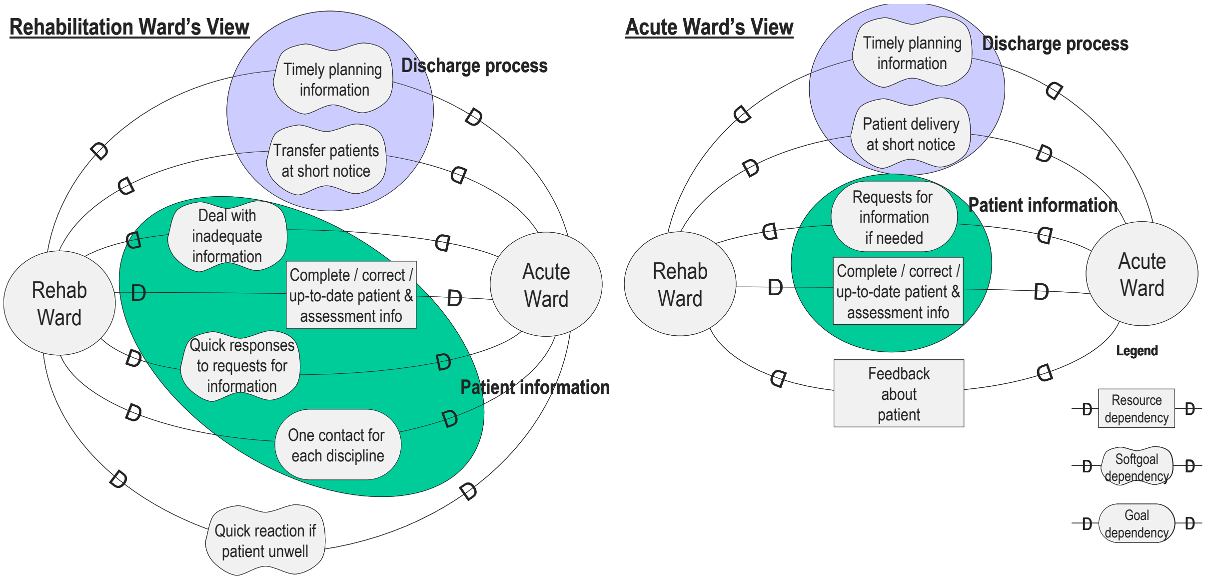


subjective and cannot be precisely measured, for example RW's requirement for a "quick reaction if patient unwell" from AW. In this case, does 'quick' mean 5 minutes or 2 hours?

The SD models show that each ward attributes different and sometimes very stereotyped goals and intentions to the other, even though the main goal for both wards should be (and is!) the welfare of the patient. As an example taken from Figure 3, for the patient transfer process, RW sees AW as trying to move patients out as fast as possible (RW's view, softgoal: "Transfer patients at short notice"), whereas AW sees RW as expecting patients to be handed over at very short notice (AW's view softgoal: "Patient delivery at short notice"); sometimes, we were told, in as little as three hours. Because the discharge documentation that has to accompany the patient has to be compiled by different staff members, by the pharmacy, etc., this extreme time pressure can lead to a lack of coordination in the collection of discharge documents. As a result, incomplete or outdated information can be transmitted from the acute to the rehabilitation ward, which is not what RW expects or wants (RW's view, resource: "Complete / correct / up-to-date patient & assessment info").

Based on the dependency diagrams, and the additional information obtained in the focus group meetings and interviews, we developed extended SR models as described by Gans et al. (2003) for AW, RW, and the RLO. SR diagrams (see Yu (1995)) describe the intentional relationships that are internal to actors, so that they can be reasoned about. Nodes of the model represent goals, tasks, resources, and softgoals, respectively, while links represent either means-ends links, or task decomposition links. The original SR mod-

Figure 3. Strategic dependency diagrams

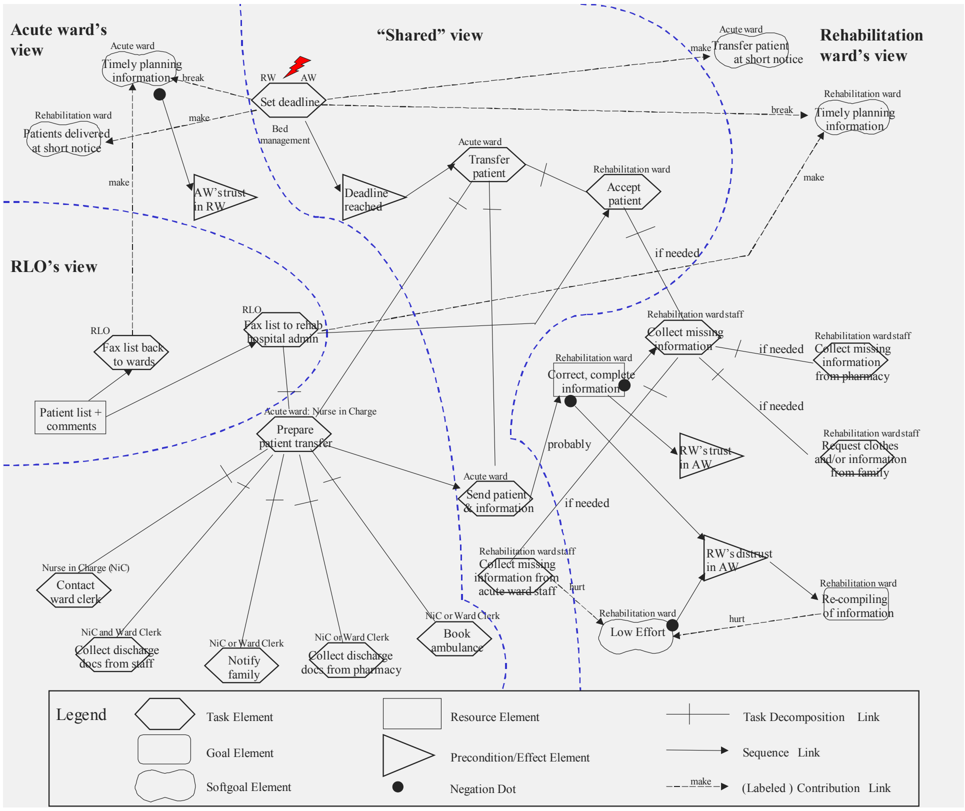


els contain only strategically relevant elements; hence, Gans et al. extended them for operational use. For example, in Figure 4, the task "Transfer patient" is decomposed into five subtasks which are timely ordered. Negation dots, e.g., at the resource "Correct, complete information", stand for a missing resource or the logical negation of a precondition, goal, or softgoal. Contribution links are labelled according to their effects on softgoals (make, break, help, hurt) and finally only if the "Deadline reached" precondition holds the "Transfer patient" task can be initiated.

Relevant excerpts from the three different views of the patient transfer process as held by AW, RW, and the RLO, respectively, are integrated into a combined SR model shown in Figure 4. Interestingly, as can be seen in Figure 4 and was stated by the RLO in the interview, AW should know in advance which patients will need to be handed over within the next few days, since a list of those patients is faxed to the wards. Thus, AW should be able to compile the discharge documentation with sufficient prior warning. In addition, the patients' complete medical record is sent, together with the discharge documents, to the rehabilitation hospital's administration, where it would be available to RW staff for a few days before admission. Also, given that the rehabilitation hospital administration receives the list of patients, RW does – at least in theory – have access to timely planning information, as well. Unfortunately, however, neither AW nor RW seem to be able to make use of this information.

The conflicts which were identified on the strategic dependency and strategic rationale diagram level, of course, affect the trust relationships. First of all, the models reveal that there was little direct and positive interaction between AW and RW, and there were no trust-building or relationship-building activities planned into the process. Information flowed from AW to RW, but there was almost no information flowing back from RW to AW. In particular, although AW mentioned that they would like to hear about "their" patients' progress in the rehabilitation ward (see the "Feedback about patient" resource dependency in Figure 3), there is no communication of patient status information from RW to AW unless some-

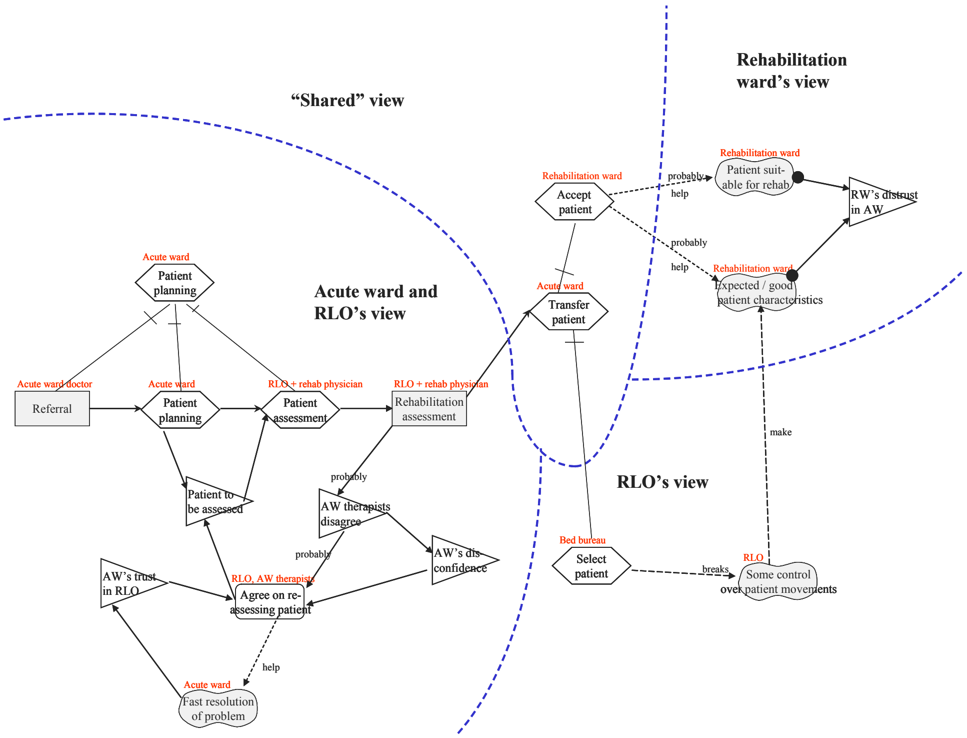
Figure 4. Combined extended SR mode: Patient transfer between wards



thing untoward happens to the patient, when RW expects (and gets) a quick reaction from AW. This is not conducive to establishing trustful relationships between the wards. In contrast to this, the physical proximity of team members within each ward (including, in the case of AW, the location of the RLO in the same building) leads to good relationships, trust, and understanding, resulting in extremely good (ad-hoc) communication and cooperation.

A main source of distrust in the patient transfer process results from the accompanying patient information documents. There are conflicting ideas about who is actually responsible for ensuring that the patient information is complete (cf. Figure 3). RW staff members consider it their right to receive complete, correct, and up-to-date information; and chasing up what is missing takes up a large amount of time, which is seen as frustrating. AW on the other hand holds the opinion that RW receives as much information as is possible under the circumstances (remember that AW sees RW as driving the timeframes for the transfer process). Thus, RW staff should be able to cope with the information they receive, and, if not, it is their responsibility to request additional information that is required. This difference in expectations creates resentment and increases distrust on both sides. For RW, this distrust means that the information coming from AW is often not trusted, even when apparently correct patient information is provided. Instead, RW duplicates AW's work by compiling the information again. As another example, consider the extended SR model of the patient assessment shown in Figure 5. The assessment of a patient is performed by RLO and a rehabilitation physician, who visit the patient on the acute ward. The outcome of that assessment determines whether

Figure 5. Combined extended SR model: Patient assessment



the patient is send to a rehabilitation ward. RW sometimes considers some of the patients that AW sends them unsuitable. However, RW does not seem to discuss these cases with AW, and has no direct access to the RLO, who is located in AW's hospital. In fact, RW staff did not mention the RLO at all during the focus group meeting. Instead, RW can get frustrated at seemingly unsuitable patients being sent from AW, and RW's distrust in AW increases.

Confidence is a less important issue here, because the metropolitan health service is a stable organization with less choice for the agents involved, and more rules and constraints than the social networks described by Gans et al. (2003). However, due to dis-confidence, by which we mean dissatisfaction with these rules and constraints, agents sometimes circumvent those rules and processes that are seen as producing the wrong results. In the patient assessment example (see Figure 5), AW therapists sometimes disagree with the patient assessment results. The therapists feel that they know the patient better, due to their long-term observation, than a doctor could from a short visit, especially if the patient has a bad day. In these cases, the therapists often use the strong relationship they have with the RLO to voice their concerns and initiate a reassessment at short notice (see the bottom left corner of Figure 5), which is not intended to happen in the clinical process. As described above, RW does not have that option.

EVALUATION AND CONCLUSION

In this evaluation of the applicability of the TCD modelling approach, we applied the framework in a more organizational setting than described by Gans et al. (2003). This means that there are more rules, constraints, and procedures than in a typical social network. This in turn leads to less freedom for the agents (individuals or wards) to change their work processes, for example by changing their delegation behaviour, according to their level of trust, confidence, or distrust in the other agents. In addition, the delegation processes were predetermined due to lack of alternatives, as well, so they did not provide many insights, either. From this it follows that we do not need to apply the more dynamic perspectives from the TCD framework, namely plans and speech acts. In this case study, SD and extended SR diagrams are sufficient to extract information on the trust relationships between the wards.

The data capture method we employed focused on recording the different parties' perceptions of the patient handover process, which we later found very useful in understanding the trust and distrust relationships between the people involved. The information flow diagrams (Figure 2) indicated not just the different agents' activities, but also, for example, where information was perceived as being too late, or of too low quality. The SD and SR diagrams (Figure 3, Figure 4, and Figure 5) resulting from the initial process diagrams, together with our meeting notes, indicated (real and perceived) conflicting goals and expectations that were not met. These lead to manifestations of distrust, which in turn lead to re-work, e.g. recompilation of information by RW, and dis-confidence, e.g. when AW staff exploit their good relationship with the RLO to circumvent the defined patient assessment process. Thus, generally, we found the TCD framework to be applicable also in this more organizational setting.

We believe that understanding and evaluating trust relationships is crucial to supporting people's work processes, and that, ultimately, any ICT aimed at improving the performance of people working together will need to take such 'soft factors' into account to be truly effective. While many aspects of this problem are still open research questions, we hope that our case study has provided some validation of the TCD framework as one methodology for investigating trust relationships in both organizational and network settings preceding, and complementing, the development of any ICT support.

FUTURE TRENDS

An integration of the findings of research on trust, distrust, and confidence in cooperation processes – as it has been presented here – into environments for computer-supported cooperative work (CSCW), such as shared workspaces (e. g. see BSCW (http://www.bscw.de)), seems a logical next step. A key point in this regard concerns addressing awareness issues (Dourish and Bellotti, 1992). Recent approaches try to tailor the awareness notifications to the current, situation-dependent needs of each collaborator (Wang et al., 2007). This fits quite well with the consideration of monitoring within the TCD framework. Gans (to appear) describes a framework of monitoring in social networks that is mainly controlled by distrust and dis-confidence. He states that discrepancies between expectations on one hand and objective as well as subjective experiences on the other hand combined with current distrust and dis-confidence steer the wish to monitor or observe ongoing activities or processes. Comparing this wish to monitor with the costs of monitoring, it leads to real monitoring activities by gathering information that are beyond the usual information flow. The new information firstly is added to the experiences made in this context, secondly influences distrust and dis-confidence, and thirdly leads to activities, for example activities that should change misleading processes.

Hence, in distrust and dis-confidence related parts of our health care domain (for example, the patient transfer) it could be interesting to ask questions of the following kind: How important could it be to observe the activities between AW and RLO? How costly is monitoring in this context and therefore how efficiency-reducing? Which conclusions can be drawn by RW besides the cultivation of distrust and dis-confidence, for instance, to what extent can RW influence, and therefore improve, the patient transfer process? Is the level of distrust or dis-confidence already above a certain threshold where self-strengthening effects take place? Here, the more dynamic parts of the TCD methodology could also provide viable input.

Furthermore, social network analysis is recently gaining more and more attention. Westbrook et al. (2007) use it as a means to understand how the impact of information and communication technologies in health care organizations can be investigated. Ongoing work tries to integrate social network analysis with the i* modelling language and the TCD approach in particular (Jarke et al., 2008). Of particular interest are the extensions that are able to take the dynamics of evolving relationships into account. First approaches (Klamma et al., 2006) that match expectations in regard to emerging structures modelled with i* with the outcome of social network analyses via a suitable pattern language already exist, but have not yet been applied to a health care setting.

KEY TERMS AND DEFINITIONS

Confidence (also system trust): Trust in the network/organization as a whole that is due to the mesh of dependencies neither completely visible nor manageable by the trustor. (Luhmann, 1988)

Cooperation: Cooperation denotes the relationships between two or more organizations or parts thereof, which aim at fulfilling some shared goal, are based on written or oral (legal) agreements, and keep the partners legally independent. (Kethers, 2000)

Distrust: "The expectation of opportunistic behaviour from partners" (Gans et al., 2003)

Process: A process is a set of identifiable, repeatable actions which contribute to the fulfilment of the objective (or goal) for which the process was designed. Actions are in some way ordered, performed by actors, and possibly subject to limitations or constraints. Actions can be activities (tasks), or be related to information flows or communication. (Kethers, 2000)

Social network: An autonomous form of coordination of interactions whose essence is the trusting cooperation of autonomous, but interdependent agents who cooperate for a limited time, considering their partners' interests, because they can thus fulfil their individual goals better than through non-coordinated activities. (Weyer, 2000)

Strategic Dependency model: "The Strategic Dependency (SD) model provides an intentional description of a process in terms of a network of dependency relationships among actors. […] [It] consists of a set of nodes and links. Each node represents an "actor", and each link between two actors indicates that one actor depends on the other for something in order that the former may attain some goal." (Yu, 1995)

Strategic Rationale model: "The Strategic Rationale (SR) model provides an intentional description of processes in terms of process elements and the rationales behind them. […] [It] describes the intentional relationships that are "internal" to actors, such as means-ends relationships that relate process elements, providing explicit representations of "why" and "how" and alternatives." (Yu, 1995)

Trust: "The willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party." (Mayer and van der Hoek, 1995)

ENDNOTE

Chapter 6.4

Analyzing an ES Implementation in a Health Care Environment

Albert Boonstra
University of Groningen, The Netherlands

ABSTRACT

At the present moment, many hospitals are going through a process of change directed at the integrated delivery of health care. Enterprise Systems (ES) are increasingly used to support this process and to manage hospitals on a coherent basis. We also know, however, that ES implementation itself, can be viewed as an organizational change process that affects many stakeholders. For that reason it is relevant to study how ES implementation takes place within hospitals and how it tends to impact the existing organizational arrangements. The purpose of this chapter is therefore to describe and analyze how ES implementation within a hospital affects the interests of stakeholders and which specific problems may arise as a result. This chapter uses the evidence of a case study to reveal some important dimensions of the organizational change issues related to ES implementation within hospitals.

INTRODUCTION

Many hospitals are going through a process in which they are changing from loosely coupled units into more integrated entities. Hospital managers are increasingly accountable for the cost-effectiveness and the quality of their organizations, which explains their need for more integration and control. To achieve this, the managers are looking for information systems that can help them to manage their hospitals on an integrated basis (Merode, van et al, 2004). This is why in recent years many hospitals have started to implement enterprise systems (Jossie et al., 2005). Enterprise systems are software packages that facilitate the integration of transactions-oriented data and business processes throughout an organization (Klaus et al., 2000). Traditionally, enterprise systems are used in manufacturing, which differs in many respects from a hospital context. It is therefore relevant to describe and analyze how ES implementation within hospitals takes place and which specific problems are faced by the implementers and managers.

In this chapter we will describe and analyze the implementation of an enterprise system in a medium-sized hospital in The Netherlands. We will analyze this implementation by focusing on the roles of the various stakeholders involved, the meaning that they attach to the system, and the actions they take throughout the project. We have chosen this perspective because stakeholders involved in hospitals differ significantly from those involved in other industries. This chapter aims to provide insight into the role that the different stakeholders involved in hospitals may play during ES-implementations. Understanding the possible impact of ES on particular stakeholder interests may help project managers and others to manage ES implementation within hospitals in a more effective way.

There are only few descriptive accounts of how groups and individuals related to hospitals interpret IS proposals in general and ES systems in particular, and how they respond subsequently (Levine et al., 1995). Especially empirical case studies that focus on the role of politics and stakeholders in relation to ES implementation within hospitals are scarce. As a result, our insight into the role of stakeholders in the implementation of IS applications within hospitals in general and that of ES applications in particular is limited. This means that we have a lack of understanding of why groups and individuals act in the way they do. Knowledge of barriers to implementation and approaches to analyze them is of importance to practitioners, such as project managers, who are involved in implementing ES within hospitals, and hospital managers, who have to decide whether to implement ES.

The chapter is organized as follows. In the next section we will explain the distinctive features of enterprise systems and describe theory and models that the research has been based on, which may help us understand the relevance of studying enterprise systems in health care environments. After that, we will describe the methodological background of the research. The following section presents the case study and then an interpretation will be given of this case study on the basis of the model. In the final section we will put the study in a broader perspective and put forward some views about the practical implications for managers responsible for ES implementations within hospitals.

BACKGROUND

Enterprise systems are software applications aimed at integrating a range of business functions in order to acquire an overview of the business based on a single information architecture (Merode, van., 2004). Starting from manufacturing and financial systems, enterprise systems may eventually allow the integration of inter-organizational supply chains (Markus et al., 2000; Fowler et al., 2003). Enterprise systems are multi-functional and cover a range of activities, such as logistics, human resources and finance. These functions are integrated in such a way that whenever data are entered into one of these functions, they become available to all related functions. Enterprise systems are modular and can be used in many combinations of modules. They link the different organizational units by coordinating the business processes.

Because these systems affect so many aspects of an organization's internal and external operations, their successful deployment and use are critical to organizational performance and survival. In the case of ES successful implementation is important, since the costs and risks of these technology investments rival their potential payoffs. Failure of enterprise system implementation projects may lead to bankruptcy (Markus et al., 2000; Davenport, 1998; McAfee, 2003). The ES implementation as described in this chapter also brought the hospital into severe problems, which almost led to bankruptcy.

This illustrates that implementing enterprise systems is a complicated enterprise, not only from a technical point of view but also from many other perspectives, including strategic, organizational, political, and cultural viewpoints. One very important issue is that a large number of stakeholders from different organizational units are involved. Since as a result the decisions are no longer taken on a local or departmental level, the question of who participates in the analysis, development and implementation of ES becomes more difficult.

We already mentioned that many hospitals are in a process of transformation, directed at the integrated delivery of health care through a more homogeneous range of health care products. Motives behind this change are a higher level of cost control, the need for organizational procedures for patients, and an increasing accountability of the hospital managers for the way in which the hospital operates. This process toward integration can be stimulated by information systems that help managers organize the central planning and control (Haux, 2006). Since enterprise systems have helped organizations in various industries to integrate and organize the real time information delivery, they are now also applied in many hospitals. Suppliers of enterprise systems have developed modules that are specifically customized for hospitals, such as patient management modules and electronic patient files. Modules used in other industries have been slightly adapted to fulfill hospital requirements (Paré et al., 2001).

The empirical research conducted for this chapter is based on interpretive (Walsham, 1993), processual (Boonstra, 2003) and integrationist (Orlikowksi, 1992) models of change. These models emphasize how various groups of people in organizations may have different interpretations of information systems, which may shape their actions and influence the implementation and evolution of such systems. The change view is rooted in social constructivism, which is focused on the meaning that people attach to a particular technology (Pinch et al., 1992). Social constructivism found its way to IS research by the so-called interpretive approaches (Walsham, 1993, Orlikowski, 1992) and emphasizes the subjective meaning that an actor ascribes to an information system, which is based on particular interests, preferences, history and so on. From this perspective, system implementation can be explained by studying the interplay of attitudes and actions of various stakeholders, which may be subject to change over time (Dawson, 1994).

Pettigrew (1988) argues that organizational change can be understood by considering the interactions among the substance, context and process of change within the organization and their continuous interplay. The implementation of change is an 'iterative, cumulative and reformulation-in-use process'. Successful change is a result of the interaction among the content or 'what' of change, the process or 'how' of change (implementation) and the organizational context or 'where' of change (the internal and external environment). He also suggests that the change agent must be willing to intervene in the political systems of the organization, and to legitimate the change in the face of competing proposals and ideas. Bennis (1984) suggests that management of change is 'management of meaning', involving the attempt to convince others of the credibility and legitimacy of particular definitions of problems and solutions, and to gain consent and compliance (Boddy, 2002).

It is well documented that the development of information systems requires the participation of the parties interested and that the willingness and the effectiveness of this participation influences the success of the resulting system. Normally these participants include developers, intended users and managers. However, in the case of enterprise systems within hospitals, this range of people and parties is much broader and crosses organizational functions, which means that the stakeholders are more loosely coupled. Identifying these stakeholders and exploring their perspectives in terms of their interests in the system and their power to 'make or break' the system is essential.

When the stakeholders are identified, their interests can be related to the enterprise system. This means that part of the analysis consists of the assessment of the stakeholders' perception of the ES. How do they interpret the ES and to what extent do they believe that it will be instrumental in attaining their objectives and that it will fit in with their values? In other words: what are their perceived interests in the system?

However, an enterprise systems does not depend solely on the interests of stakeholders but also on the power relations among the parties involved. A powerful party with a clear interest in a particular ES can apply its power to force less powerful parties to use it, regardless of their perceived interest in the system (Standifera, 2003). At the same time, it might be rather difficult for parties with a great deal of interest in a particular enterprise system, but with a lack of power to implement it successfully, if the other parties are not really interested. In this chapter, we will define power as the capacity to exert one's will over others in order to realize certain intended goals (Boddy, 2002). Since power is a capacity to exert one's will, it is possible to indicate the source of this capacity, or in relation to ES: parties may possess different sources of power to force others to cooperate and use (or not use) an ES. The power and interests of stakeholders may change during the course of a project and may affect the role they play.

To characterize this role during a certain phase we have used the stakeholder typology of Mitchell et al. (1997). They identify seven types of stakeholders: dormant, discretionary, demanding, dominant, dependent, dangerous, and definitive stakeholders. *Dormant stakeholders* have the power to influence, but this power remains unused for a certain period of time. *Discretionary stakeholders* possess legitimacy, but have no power to influence the project. *Demanding stakeholders* have urgent claims, but neither possess the legitimacy nor the power to materialize these claims. *Dominant stakeholders* are both powerful and legitimate. Their influence in the relationship is assured, since as a result of this power and legitimacy they form the dominant coalition. *Dependent stakeholders* are characterized by a lack of power, but have urgent and legitimate claims. These kinds of stakeholders depend on others to carry out their will. *Dangerous stakeholders* possess urgency and power but no legitimacy and may be coercive or even dangerous. *Definitive stakeholders* possess power, legitimacy and urgency.

METHOD

To conduct this case study, we used a diverse set of qualitative methods, including in-depth interviews, participant observation and documentary research (Ammenwerth, 2003). The initial access to stakeholders was negotiated with a staff member of the IS department. We focused the research on what we regarded as the most immediate stakeholders in the ES project. During a period of six months the authors visited the hospital five times. They conducted interviews, which lasted approximately 1- 2 hours, with members of the general management, IT, the administrative staff, the medical staff, and with external consultants. A snowball sampling strategy was used to identify the subsequent respondents. This means that later on, discussions were held with other members of staff, who were either working with or affected by the enterprise system. The interviews began with a generic question that allowed the interviewees to express how they experienced the ES implementation process. After that, more specific questions were asked about critical incidents, the specific stakeholders' interests, and the meaning they attached to the system. Handwritten notes were taken and individual reports of the interviews were made. The accounts based on these notes were presented to the interviewees and revised slightly on points of detail, if necessary. The data were analyzed by reviewing the respondents' comments, placing them on a time line and dividing them into categories based on their attitudes to the enterprise system. The data are presented in the following sections.

CASE HISTORY

The hospital studied is a medium-sized general hospital located in the western part of The Netherlands. It has 375 beds and 1250 employees. The hospital is divided into six main units: 1) clinical care, 2) ambulant care, 3) physicians, 4) facilities, 5) personnel, and 6) IT and Finance. The physicians are largely remunerated through a service-based fee, and they normally use information systems that function separately from the hospital systems to manage their practices and support their medical treatments.

Episode 1. Preparation

The initial motive to implement an enterprise system was the conclusion of a contract with the former vendor of the Hospital Information System (HIS). HIS was actually a set of separate systems that were loosely linked. The system was not being maintained appropriately and the contacts with the vendor were not very good. This is why the board of management as well as the IT department were interested in a modern product that could help them to establish an integrated, modular and adaptive hospital system. Management also had the ambition to be the first in combining the billing process of the hospital with that of the physicians. At that time, medical treatments involved two separate types of invoices: one from the hospital and one from each relevant physician. A member of the board of management argued:

We were struggling with a set of outdated systems that only supported some business functions separately. We lacked the proper management information and were in need of a system that had the potential to support all hospital processes in an integrated manner.

The hospital aimed at a system that could be adapted to the operational processes of the hospital, and not vice versa. Based on these requirements, a long list of potential vendors was reduced to a shortlist, and a multidisciplinary team selected a number of SAP modules to be implemented by an external consultancy. This consultancy claimed to be experienced in implementing SAP in hospitals. An internal IT manager said:

The consultancy convinced us that it was an expert in adapting and implementing SAP within hospital environments. The company claimed that SAP was very flexible and could be easily adapted to the specific requirements of any hospital.

Another consultancy delivered an external project leader, responsible for the implementation project. One member of the multidisciplinary team (a representative from the nurses) said about the start of the process:

We were invited by the project management to celebrate the start of the project. We all got champagne and everyone seemed to be in agreement. Management and the external consultants promised that the new system would solve all the problems caused by the old and isolated hospital systems. The organization would become a unity with one single information base for all main processes.

However, the actual participation of the hospital's administrators and physicians was quite passive. They were in fact merely bystanders or passive recipients of information about the project. Moreover, the promoters were very confident about the benefits of the system and others did not have the expertise or experience to challenge that.

Episode 2. Start

After the selection of this particular software package, four working groups were formed to prepare the implementation in more detail and to adjust the system to the organization. Technical, administrative, policlinic and billing issues were the focus points of these four groups. They were chaired by the department heads. The board of management and the project leader put a great deal of pressure on them to work fast, whereas all members, including the chairmen, had to combine the preparation of the implementation with their regular tasks. The time pressure was so high, because the hospital was no longer allowed to use its former system. Because of this time pressure, the company's communication with the prospective users was very limited. One chairman of a working group said:

The real objectives of the system did no longer seem relevant, and the only objective that remained was to get it implemented. We were all working very hard, but we could not explain why we were doing so much work only to replace one system with another. Through all of this work we lost track of the initial motives to implement the system.

In actual fact, the mutual adjustment of the various modules and the adaptation to the organization was limited. All energy was put into the technical and organizational complexities. It became clear that the external consultancy was not as experienced in implementing SAP as they had claimed to be. In other hospitals they had adjusted processes to SAP rather than the other way around. Due to the time pressure, the project manager decided to follow the same strategy here.

One member of a working group who had been involved right from the start said:

During the preparation phase, the inherent flexibility and the potential functionalities of the system were emphasized. However, when it came to implementation, we were forced to rush and make sure that the system was installed in time.

A member of the medical staff could recall about this phase:

We attended some of the meetings, but we got the impression that the system was merely a toy for the managers, and not suitable for actual use. However, we did emphasize how complex some of the processes, including the billing processes, are. But the implementers did not seem to be impressed by these remarks.

After implementation of the system, a number of problems arose. Both at the policlinic and at various other clinics, the administrative staff did not know how to use the system, since no formal opportunities had been offered for training. In addition, there was a lack of motivation to use the system, because the staff was not properly informed about the motives behind the SAP implementation. Many people also felt that the degree of user friendliness of the system was lower than that of the old system. And a few of the more conscientious employees even discovered that some output of the system was erroneous.

Episode 3. Crisis

As already mentioned, the hospital followed two billing procedures, one of the hospital and one of the medical staff. Both procedures had to be integrated into one system. Since the income of the medical staff depends directly on a well-functioning billing process, a successful change-over was crucial to them. Up to then, the medical staff had not really been involved and was hardly interested in the ES implementation. However, after a few days of system use, some people discovered that some treatments were not invoiced at all, whereas other treatments were invoiced incorrectly or double. A representative of the medical staff said about this phase:

The implementers totally underestimated the complexity of this crucial process. They assumed that by means of their so-called efficient flow charts each treatment could be invoiced in the *same way. However, the reality of our practices is very different from their world of schemes, charts and systems.*

A few ingenious administrators tried to keep the system working by so-called 'work arounds', which means that, only after having checked each invoice manually, they were sent away. These work arounds led to new problems; the medical staff as well as the patients and insurers started to complain. They believed that the hospital was no longer in control of its main financial processes. A real crisis developed when the regional press became aware of the problems. The medical staff became convinced that they were missing out on revenues. They informed the board of management that they did not have any confidence in the system and that they refused to use it any longer. The representative of the medical staff said:

Both the implementers and management were clearly not in control. They panicked.

The board of management was forced to intervene and agreed that a separate billing system was acquired beside the SAP system. This separate invoicing system was already used by some groups of the medical staff. From that moment on, all invoices were checked manually and compared with the new shadow system. At the same time, the SAP system was gradually adapted. All these problems led to the immediate retirement of the CFO. In addition, the hospital decided to sue the external consultancy for having failed to meet the main terms of the agreement. After six months, all the adaptations and extra attention seemed to have some effect. However, due to this crisis, some people think that the hospital missed out on at least 10% of its annual revenues and was very near to bankruptcy because of the implementation of this system. Various people commented that the lower administrative staff had 'saved' the implementation by using redundant systems and checking all financial flows manually. An observer said:

This project was initiated by the top and by externals, but it was realized by the loyalty of the lower administrative staff.

The crisis was overcome by using additional and redundant systems and by gradually adapting the enterprise system to the old working practices. This took approximately six months, during which the administrative staff, nurses and physicians actually adapted and succeeded in managing the operation of the system. At that time, the in-house IT department, which had been left out the preparation and implementation phase, recaptured its tasks. Externals stepped back and the normal operations were once again continued.

Episode 4. Use

After some time, the system was assimilated and the organization became used to it. However, management did not feel that it stimulated the improvement of the management information or led to a more integrated organizational structure. Because its implementation had been rushed, little attention was paid to the further possibilities of the system. For this reason a new project was started, which aimed at generating management information and reports. Only a few clinics have used the SAP system in an optimal way, and many other clinics still use only a limited number of functions. Management is not convinced that the system has helped to achieve the objectives on which the project was based.

ANALYSIS

In this section the roles and interests of the different stakeholders during this process and the meaning they attached to the system will be discussed. After that, we will interpret some successive actions that affected the process. Then we will list what went wrong during this implementation and what lessons can be learned from that. This analysis will be conducted on the basis of the theoretical backgrounds as presented in the third section.

Positions of Stakeholders

The most important stakeholders involved in this implementation project were the board of management, the external consultancy, the external project leader, the physicians, the administrators and the IT staff. Many of these stakeholders are groups with many internal varieties, but also with a relatively high level of consistency with regard to their perceptions of interests, problems, solutions and meaning in relation to this project.

The board of management had a clear interest in a successful and efficient implementation of the enterprise system. They strongly felt that one integrated system would provide them with the management information the needed. The system was intended to replace many local and outdated operational systems, which did not deliver any useful information to the board. The board of management clearly acted as a definitive stakeholder, possessing power, legitimacy and acting from a sense of urgency. After the first stages, however, they delegated a number of their responsibilities to external parties, which means that they became a dormant stakeholder.

The external consultancy had accepted the project on a fixed price basis and obviously had a clear interest in a fast and smooth implementation process. The company was hoping that it could use its previous experiences to realize an effective implementation in this case. But it underestimated the power and roles of the medical practices, which required a system that would comply with the established processes and medical practices. The external project leader, who was from another consultancy, had similar views on the interests, problems and their meaning. Both can be characterized as dependent stakeholders. They both felt a clear urgency, and they both had been given authorization by the board, but they did not really have the power to force other stakeholders to comply.

The administrators can be regarded as users of both the old and the new system. They did not have a clear interest in the new system, since they were used to the current working practices. The external implementers did not really involve the administrators in the implementation process. This was due to time pressures but also because the implementers tried to adapt the hospital processes to the system rather than the other way around. Physicians and administrators argued that the external parties underestimated the hospital's internal complexities and that they lacked a clear interest in its current processes.

The IT staff and the board of management agreed upon the desirability of a single compact and modern IT package for the whole organization. The IT department, however, lacked sufficient knowledge about such systems, and for the time being it had to be busy with maintaining the old set of systems. This is why during the implementation process IT played a background role.

In general, the medical staff want to do their work with some degree of autonomy and without too much managerial interference. In addition, they tend to seek systems that reduce their non-medical workload as much as possible. One member argued that it would be in the interest of the doctors to have loosely-coupled systems, which are tightly adapted to their own specific medical practices. This was not in line with the interests of the board of management, who wished to have an overview of all main processes. The physicians were mainly bystanders during the early stages of the project. They felt that it was an issue to be dealt with by the managers but not by them. This is why they can be characterized as dormant stakeholders; they possessed the power but neither felt the urgency nor had the legitimacy to interfere. This changed dramatically once they became aware that there were serious problems with the billing processes. They then instantly became definitive stakeholders, who clashed with the only other definitive stakeholder: the board of management.

What Went Wrong?

A number of things went wrong during the implementation of this ERP-system. The most important ones are the following:

Management and consultants showed a lack of attention for organizational change issues. In this case history, hospital management attempted to implement an integrated system in a loosely coupled organization without paying much attention to organizational change issues. Management mainly focused on their own goals, namely the replacement of the old hospital system and the implementation of a modern integrated product. They did not consider the consequences of this product for other powerful stakeholders. The external consultancy argued that it was possible to use this ERP solution not only as a replacement, but also as a solution of a number of other management problems. By doing so, they adopted an exclusive 'management rationalism' approach (Heeks, 2006), while ignoring process complexity and diversity and power of the workforce (see section 3).

The project was characterized by the rush to implement and the ambition to innovate, which led to ignorance of problems and complications. Management and implementers were in a rush since the hospital was not longer allowed to use the old hospital system. Besides, management expressed the ambition of 'being the first in combining the billing process'. This limited timeframe led to 'hard design'(Heeks, 2006) and also to sloppy thinking with regard to process details. The billing process was also much more complex than the consultancy expected and was actually too complicated to capture into the new system. The underestimation of this complexity led to errors and a decreasing confidence in the system by staff and physicians.

There was a low degree of real participation and a lack of attention to the interests of important stakeholders. Physicians and administrators reported that participation during the initiation and start phase was limited. This low degree of participation caused a lack of co-ownership and explained that physicians did feel the responsibility to co-operate in replacing their own billing systems by the new ERP-system. Physicians argued that this was a project of management and consultants so they did not feel a reason to spend time to the realization of this new system. When the actual billing procedure proved to be unreliable, physicians, as being powerful bystanders, could enter the arena and blame others for the installation of an unreliable new system.

Communications about project objectives were ambivalent and sometimes incorrect. On the one hand, management and the consultancy argued that the hospital needed a software product that would help the hospital to become integrated and to deliver consistent and up to date management information. On the other hand, they told the administrators and physicians that the system would be adapted, in order to adjust the system to the organization. This ambivalence caused misunderstanding among members of working groups and physicians. In case of adjustment, experts had to study hospital processes and to modify the system. In case of change, physicians and administrators would be more affected.

Competencies of external consultancy were not adequate. The consultancy claimed to have expertise in implementing in ERP in hospitals, but this expertise was mainly in adjusting hospital processes to systems, rather than the other way around. They also lacked expertise in dealing with organizational change processes, since they had a technical focus.

Lessons

Based on this case history, the following lessons can be learned that are relevant for vendors/consultants of hospital ERP and senior management of hospitals.

1. ERP implementation in hospitals is a combination of technology change and organizational change and should be managed accordingly. This means that project management should use expertise from both fields to implement such change successfully. Markus (2004) provides a number of useful principles for adequate project management in case of the implementation of technology combined with organizational change.
2. In case of a high time pressure or a short time frame, the objectives and ambitions of ERP implementation in hospitals should be brought back to realistic levels. After the initial implementation other projects can be started to make further steps. Since process complexity in hospitals is often high, close attention and time is needed to translate them into the system in adequate ways.
3. Active participation of key stakeholders leads to co-ownership and a responsible attitude during the various stages of implementation. Especially in case of highly affected and powerful stakeholders, such as physicians in hospitals, it is essential to secure active roles and responsibility of physicians or their representatives. Principles of 'soft design' (Heeks, 2006) should be applied in such cases.
4. Management has to be very clear and consistent to anyone affected about the objectives of ERP implementation. Especially about the choice to adjust the system to the organization or to change hospital processes to the system is very crucial. This decision determines how the project has to be managed and how participation of stakeholders has to be organized.
5. In case of process change, adequate change managers have to be in charge. In case of the use of external consultancies, management has to make sure that these consultancies have relevant expertise in realizing such change in hospitals.

CONCLUSION

Enterprise systems are not only technical artifacts, but also a reflection of management philosophies, which may or may not fit in with existing organizational arrangements. This implies that ES implementations may challenge vested interests, and may lead to opposing views of various players. Especially in hospitals, where physicians possess discretionary power to organize their processes and to manage their practices, ES may clash with their interests and viewpoints. Enterprise systems are designed to integrate functions and to standardize business processes, which were previously dispersed and diverse. The physicians affected do have the power to choose whether they wish to adopt or to reject such systems.

For these reasons it is essential for managers of ES implementations within hospitals to be aware of the ways in which ES affects the established institutional settings (Yi et al., 2006). During the initial stages of the implementation process, decisions have to be made about necessary changes in either the system or the organization, or in both. These changes can be required to meet certain needs of stakeholders in order to make sure that they cooperate and participate in effective ways. It is not acceptable if potential influential players remain passive until the actual use phase starts. This case illustrates that aggressive resistance after implementation can lead to a counter-productive crisis, which could have been prevented by a thorough analysis of the interests of the key players right from the start. Such an analysis could be followed by a discussion that leads to an agreement among the most important stakeholders upon how to implement the system and how to adapt the relevant processes. Such an agreement could be a compromise of various contrasting interests.

The chapter also shows that ES implementation within hospitals is a dynamic process. This means that certain views, which are held by stakeholders at one point in time, may change during the project. There may be various reasons why views change, including cognitive, political and opportunistic ones. In this case the physicians and administrators remained relatively passive, until problems arose during the use phase. It indicates that implementing ES within hospitals is a complex venture, in which the opportunities and limitations of the system have to be aligned with the existing and always changing organizational arrangements, including various perceptions, quests for power, leadership and subtle processes to gain support for further continuation of the project.

In this case a power vacuum (caused by the board of management) stimulated behavior that was more politically-oriented, and resulted in a lack of agreement on the direction and use of the system. Through this lack of agreement, the various stakeholders mainly followed mainly their own goals and undermined to some extent the hospital-wide explicit objectives of the project. The chapter shows that the promoters of the hospital-wide enterprise system took a too optimistic view of the power of such a system to improve the operation of the hospital's processes. In the rush to implement, no careful attention was paid to the complexities of the internal processes, the stakeholders' interests and their mutual relations. The rational image of system implementation could not conceal its poor understanding of the deeper organizational realities, such as history, culture and power.

KEY TERMS

Enterprise System: Enterprise systems are software applications aimed at integrating a range of business functions in order to acquire an overview of the business based on a single information architecture

Power: Power is the capacity to exert the will over others in order to realize certain intended benefits.

Power (Re)distribution: Power (re)distribution is the degree to which power is distributed within and between organizations and the extent that an enterprise system changes that division of power.

Stakeholder of an Enterprise System: An individual or group who can affect or can be affected by the implementation of an enterprise system.

Stakeholder Salience Theory: Divides stakeholders in seven types depending on their degree of power, urgency and legitimacy. These types are: dormant, discretionary, demanding, dominant, dependent, dangerous and definitive.

Interest of Stakeholders: The interest of a stakeholder reflects the perception that an IOS contributes to the overall goals of the stakeholder.

Chapter 6.5

Practical Applications of Case Management Software for Practitioners in Health and Human Services

Lesley Cooper
Wilfrid Laurier University, Canada

Dana Fox
Athena Software, Canada

Diane Stanley-Horn
Athena Software, Canada

ABSTRACT

This chapter aims to demonstrate the capabilities and practical applications of a case management software system for not-for-profit organizations. Whilst a variety of software systems are available, for the purposes of this chapter the authors will use/refer to "Penelope," a system designed by Athena, a Kitchener, Ontario software company. Penelope is a sophisticated piece of technology that can collect and analyze information on clients, services, human resources and outcomes. Although a wide range of data can be collected using this software, it cannot make decisions about what to record or how to scrutinize the data. The "what to record" and the "how to analyze and interpret" are management and clinical decisions. Effective use of case management software requires technical, management and analytical skills combined with leadership and imagination. Case management software systems and the information they provide are only as good as the planning and organizational systems in which they are used. The best starting point for practitioners and managers seeking answers to questions about their clients, services, community and policy, and to maximize the capabilities of case management software systems is the development and application of a program logic model unique to the agency in question. A program logic model focuses on the services and programs provided by the agency describing its' inputs, activities, outputs and outcomes. Understanding how to develop and apply their model allows practitioners and managers to perform tasks such as performance monitoring,

experimental and quasi experimental approaches program evaluations, and client satisfaction and outcome studies to demonstrate the effectiveness of their services to funding bodies, consumer groups, and their boards of directors whilst also providing a tool that can be used to enhance agency performance.

'To err is human but to really foul things up requires a computer'. -- Farmers' Almanac for 1978 'Capsules of Wisdom' in Oxford Dictionary of Quotations (2004, p.670:70).

INTRODUCTION

Case management software programs enable organizations to collect data describing their client population and service provision as well as the outcomes and effectiveness of these services. These programs facilitate agency collection of data about clients and the services provided to them and may be extended to enabling communication, scheduling, billing, clinical notes and evaluation tools. Case management software systems may be purchased as a propriety package or designed in house by organizations to manage their client service data. For the purposes of this chapter, we will confine our comments to the Penelope Case Management Software developed by Athena Software, based in Kitchener, Ontario. This package was designed for health and human service agencies and is based on traditional concepts of case management. In this chapter we will describe Athena's Penelope and use it to demonstrate its' capabilities and practical applications in needs studies, program evaluation, quasi experimental designs demonstrating outcomes and efficacious services.

We will focus on the practical applications of case management software for a variety of reasons. Studies on the not for profit sector reveal that agencies collect data about clients and their programs (get authors). This data collection process is traditionally paper based frequently imposing an ever increasing administrative burden with organizations committing time and substantial resources to meet the specific needs of funders rather than those of the organization and its clients. Eakin (2007, p.1) in a review of accountability and compliance requirements in Canada asserts that *nonprofits are swept up in complex, time consuming and very detailed accountability reporting systems and controls*. Whilst meeting funders' requirements, many not for profit agencies are unable to transform the data into a form suitable for purposes more immediately useful to them. These purposes encompass grant proposal development, program evaluation, fiscal monitoring, project planning, and enhancing their understanding of social problems as well as assisting with day to day management issues. Few organizations employ specialist staff to advise on using and analyzing existing data. Instead of hiring skilled staff to perform these tasks in house, they are likely to use external agencies and consultants at great expense. In this situation, the not-for-profits are at the mercy of the funders' demands and perceptions and the consultant's model of good evaluations. The clear view from the not for profit perspective is that they collect data required by their funders, but are not able to utilize this data for internal purposes because they are overstretched. Not for profits are caught in a dilemma. On one hand they are expected to collect data but on the other, the demands and costs of compliance with funder accountability requirements mean that there is little time or in-house skill to use the data for management and evaluation.

ACCOUNTABILITY REQUIREMENTS

The not-for-profit sector faces particular challenges from funding bodies which are increasingly requiring greater accountability. This accountability has two components traditional financial accountability and, increasingly, measurement of outcomes. There are rising expectations that services will be targeted at those most in need. These expectations are held by funding bodies including government and community foundations. Quite simply, funding bodies want a return on their investments. To meet these requirements organizations need access to sophisticated information systems that allow ease of data collection and the statistical and analytical capacity to use these systems to best advantage.

The United Way of America (1997) has provided an overview of various accountability demands in the sector over the past 25 to 30 years. Accountability initially focused on fiscal responsibility and documentation of how funds were spent; this focus remains a fundamental concern. A focus on the products or outputs of programs was the next step. These new measures included the number of products delivered (e.g. counseling sessions) and the number of people assisted. Whilst products delivered and people assisted are important and useful statistics, they are crude indicators of quality of service delivery. Over time, funders have focused more on service standard measures that demonstrate and ensure the quality of services and adherence to standards. Some of these standard measures include staff qualifications, staff-client ratios, specific service practices, record keeping and privacy protection. With recent reductions in health and welfare budgets, there has been a shift from looking at standards to addressing whether services were targeted to those most in need. Agencies are increasingly required to provide data that demonstrates services are delivered to those who most need them.

Key Performance Indicators (KPI's) and client satisfaction studies are more recent developments. Key performance indicators were developed by public accounting firms and include ratios of inputs, services, outputs and total costs. Client satisfaction measures have also been developed as part of overall quality assurance measures. These latter measures seek the views of clients on a range of variables including accessibility and customer satisfaction. They provide information to funders about the agency and its operations. Unfortunately these newer measures do not tell funders about the effectiveness of funded programs and whether clients are better or worse off. The current focus has moved to measurement of program outcomes and benefits for clients. Funders are now seeking quantitative results and evidence from agencies that demonstrate their service effectiveness.

Evidence of changing accountability requirements can be found by "googling" funding guidelines. Several community foundations, as part of their funding application process, ask questions about inputs, activities, outputs, and outcomes (short, medium and long term). Implicit in this request is a program logic approach. They also ask applicants to provide evidence that their proposed intervention is the most effective one to use for the intended beneficiaries. This suggests the importance of measuring outcomes, i.e., a move towards evidence based practice and research. For example, the US Department of Justice, Drug Court Discretionary Grant Program provides funding for non-violent substance abusers with a goal to reduce substance abuse and recidivism of offenders. Agencies funded under this program must provide data to measure the results of their work which includes the percent of participants who re-offend while participating in the drug court program. Specifically this means total number of participants, the number arrested on drug-related charges, the number arrested on non-drug related charges and the number of clients with drug court program violations. The funding body also wants quantitative data on clients who have successfully participated in programs. Compliance with these measures requires good information systems and the analytical skills of staff.

One recently emerging and dramatic pressure on both for profit and not for profit organizations comes from the managed care approach. Here traditional fee for service arrangements are replaced by a system where costs and services are controlled by limiting the amount and type of services provided. The focus is on reducing the costs whilst simultaneously improving quality of care by collecting and using evidence on the effectiveness of clinical interventions. For example, take a person receiving treatment funded by /an insurance company following a car accident. In earlier times, this patient may have been able to receive physiotherapy, massage therapy and chiropractic care simultaneously. This would be a costly arrangement and, as these services were provided concomitantly neither the insurance company nor the therapists themselves would know what particular interventions were successful or to what degree. By taking a managed care approach and monitoring costs and services, insurance companies might now recommend that service providers begin with one therapeutic intervention and only introduce other services after a period of time where the efficacy is demonstrated or where there is a demonstrable need and evidence to provide additional services.

In the managed care environment, providers are expected to have and adhere to explicit practice standards, to review the way their services are utilized and to address quality improvement in their work with clients. This places demands on practice management and is only possible with good electronic information systems. The managed care revolution requires that agencies and practitioners keep accurate patient records, manage their billing, write clear statements about the client's problem and set clear therapeutic goals and outcomes, develop research skills and adhere to standards of practice and established clinical protocols for a variety of clinical problems. There are parallels in the mental health system where Gregoire and Jungers (2007, p.735) expect that counselors need to provide 'a good treatment plan that includes the following elements: a clear statement of the client's problem, specific goals with measurable criteria and time frames for completion of the goals, and a clear statement of the means to be used to achieve these goals'. The elements of a good treatment plan fit with the components of the logic model as described later in this chapter.

ADMINISTRATIVE BURDENS

The process for applying and reporting on funding adds to an agencies administrative burden. In a study of not for profits in Ontario, Eakin (2007) asked agencies to rate the complexity of funding application and reporting processes from simple to complex. A simple application proposal is short with readily accessible information and straightforward program descriptions, whilst a complex proposal has time constraints, requires specific data that is not readily available and specificity on programs and outcomes. In reporting on funding, simple reporting processes require readily available information while extreme reporting requires data that is difficult to obtain, requires exercise of both management and clinical judgment, much additional data and is demanding of staff time. Many not for profit agencies rated the application and reporting process as extreme with few rating them as simple. This reporting process is made more difficult when organizations receive funding from multiple sources thus having numerous reporting requirements. All this takes time and expertise that few agencies are equipped to deal with.

Privacy legislation in Australia (Privacy Act 1988) and similar provisions in other countries require compliance with client information management standards which take account of the importance of data security and data quality, provide capacity for individuals to access and correct their personal information whilst emphasizing care in the use of sensitive information. Management information systems such as case management software programs allow organizations to collect and present information to funding bodies whilst maintaining compliance with such legislative demands.

In the health sector, evidence based practice is a standard professional expectation. Evidence based practice is the *conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients* (Sackett, Rosenberg, Gray, Haynes and Richardson 1996, p.71). It brings together integration of clinical expertise and compassionate care of patients with the best available evidence from research. Whilst its utility in health care has been clearly demonstrated, the development of evidence based practice in the human services is in its infancy. There are, nevertheless, promising ways in which this approach can be used for improving knowledge about service and provider users, practitioners, organizations, policy and research (Johnson & Austin 2006). It is expected that evidence based practice and research will be increasingly used in response to greater accountability requirements made by funders leading to specific demands for: outcomes measurement, increasing availability of expertise and resources for evidence based practice, and rising expectations that the not for profit organizations will manage for results.

Managed care is practiced in Canada and the USA and to a lesser extent in other countries. There are, nevertheless, pressures on all not for profit organizations to use aggregated program data to demonstrate their effectiveness. Local foundations are an increasing source of program funding for the not for profit sector. On one hand foundations with tax exemptions are expected to demonstrate results to governments and in turn, foundations demand efficiencies and outcomes from recipient organizations. Governments are result oriented, requiring information from the not for profits sector about their program, progress against objectives and specific results. They now demand that funded programs demonstrate achievement of particular outcomes and outputs as well as effective, efficient and efficacious services. Many organizations are required to achieve these requirements and conduct their own evaluations in order to receive ongoing funding. If not for profits do not have the internal capacity to undertake these evaluations, they may need to hire external consultants, an expensive exercise. Large not-for-profit organizations receive funding from multiple sources including federal, state, regional or local organizations with increasingly complex, and possibly overlapping reporting requirements. Unless organizations have, or are able to purchase the analytical and research capacity to separate inputs, activities and outcomes from various programs and transform this data into specific results, their ongoing funding may be jeopardized.

Despite these demands, governments and private funders in the US were generally dissatisfied with the research data that organizations provided to justify grant proposals and support evaluations (Stoeckler 2007, p.111). Funding is not a right or entitlement in the non-government sector. Acceptance of funding means responsibility. Funders expect that services will be directed and targeted to those most in need. It is assumed that there will be fiscal responsibility, accountability for funding and measurement of outcomes. Quality standards are expected, these including use of service protocols, adherence to practice standards, appropriate use of qualified staff, participation in quality assurance, and meeting accreditation standards. Finally governments expect that, wherever possible, practice is based on demonstration of effectiveness. Whilst these are the funding bodies' expectations it does not mean that these bodies will necessarily pay for costs associated with achieving accountability.

In summary, funder demands for greater accountability are outpacing the technical and research capacity of the not for profit sector resulting in many agencies being unable to meet the specific accountability and program evaluation demands of funders. How then can case management software be used to address funders' demands for program monitoring purposes and to develop and address the effectiveness of services? Case management software is a tool providing an organization the capacity to manage, evaluate and monitor programs, research and plan services. The utility of the software is a significant human resource consideration. It may be necessary for agencies to spend money to save money, in other words to weigh up the costs and benefits. The training and development costs could be amortized over time whilst there will be savings with a move from paper based and error prone system to collation and analysis done by the system.

To fully realize the value of software programs, their introduction requires leadership, the organizational readiness to change and the research capacity of staff to maximize the utility of information systems. The introduction of software may also entail a significant diversion of staff from management, administration and service provision to participate in the necessary training.

PENELOPE

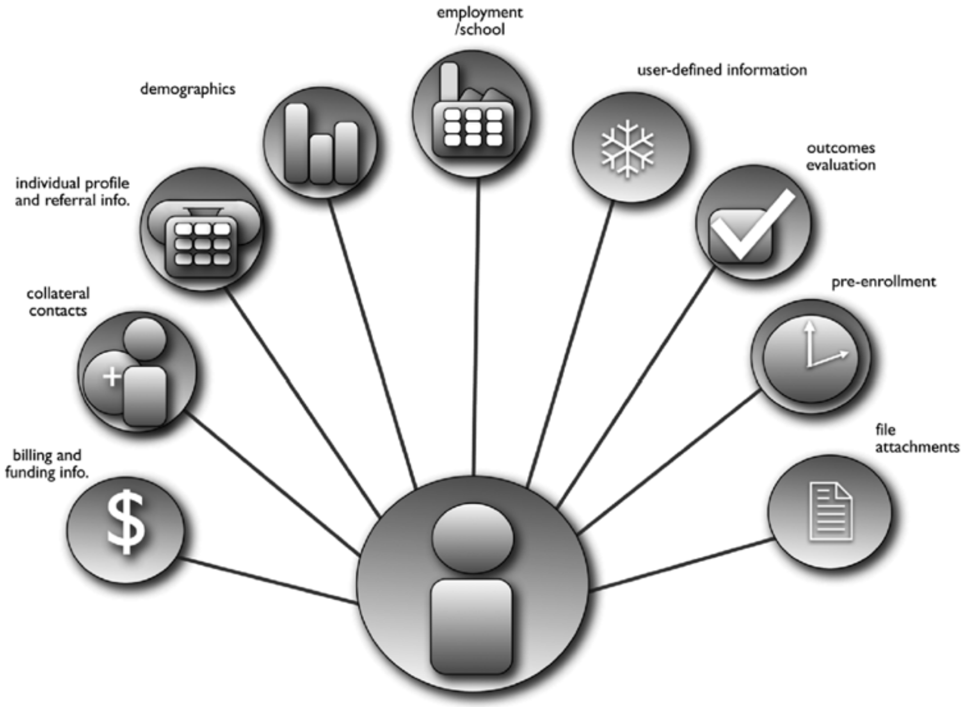
Penelope by Athena Software is a feature-rich and flexible case management and client information management solution for mental health and human service providers. The software brings together billing, clinical documentation and outcome management - into a secure and easily implemented web-based package. Penelope is a client-centric system that captures the spectrum of services a client may be receiving, from individual, family and group clinical services to educational and preventive programs. A wealth of demographic, referral, risk and bio-psycho-social information can be collected and custom recovery plans can be built into the system. In addition, the MIS (Management Information System) captures progress notes, signature forms and attachments such as images and external documentation.

At an enterprise level system, Penelope not only accommodates hundreds of concurrent users but facilitates coordination of care through assignment of providers to cases. This provider assignment can encompass different models ranging from primary or multiple providers for a single service, a multi-disciplinary team approach or a single pairing approach for one-to-many services. The integrated scheduler component captures service provision through time and also coordinates service among administrative and clinical staff; an (optional) integrated billing function accommodates a complex variety of funding and payment scenarios with efficiency and ease. Users, from clinical service providers, to reception, billing staff and management have user-defined authorized access to various aspects of the system and benefit from the specific workflow and reporting features relevant to them. By integrating all components of service provision whilst customizing the user experience the system is extremely efficient and easy to use. With little to no duplicate data entry a wealth of information can be captured, Penelope can be used to report on a wealth of information of interest to the organization as a whole in addition to complete individual case files. Program and funding utilization statistics and client and program outcomes can be related to such service characteristics as length and/or frequency of service, participation in and/or receipt of multiple services, presenting needs/diagnoses, staff and staff caseloads and attributes (qualifications, specializations), demographic variables and more. Such powerful reporting allows organizations to identify strengths and gaps in service, identify and secure recurring and additional funding opportunities and monitor progress towards internal benchmarks. This chapter will focus on this particular aspect of the software.

Core Features

The case file is a central component of the practice information system in all health and human service agencies. In a paper based office, these files hold personal and service information about individual clients and their families. The case file is also a key component in the case management software environment being stored and managed electronically rather than in a file room or cabinet.

Figure 1. Individual information



In a case management software environment, files are based on individuals participating in, or receiving services from the agency. When an agency accepts a client referral and provides a service, the agency collects, as part of the intake process, information about that individual client. This includes personal identifying and demographic information such as age, address, family size and structure, school information, income and education. The reason for referral is also a critical part of the intake process with details of the referring agency or worker, a critical part of this process being recorded in the data base. In some agencies, information about insurers or account information will also be included. Figure 1 shows the range of information that might be collected about an individual.

Table 1 shows the possible range of information for collection. Whilst user defined variables are not shown in the diagrams these variables comprise data and information unique to the agency and client group, for example in a child protection agency user defined variables may include notifications of child abuse, name and demographic information about those reporting, and reasons for reporting. This agency may also include information about foster care arrangements, names of carers and respite care arrangements.

Demographic information is supplemented by narrative documents including intake summaries, presenting information, treatment or recovery plans, progress assessment reports, details of incoming and outgoing telephone calls, social history, service provision, intervention and summary statements. The case file provides information about the individual client, case documents, intake summary and referral information and file attachments containing essential information necessary for working effectively with clients as illustrated in Figure 2.

Table 1. Range of information for collection

Individual profile	**Demographic information**	**Collateral contact information**	**Billing / account information**
First / last name Date of birth Gender Address Post code Country Phone details Site of service Contact instructions Referral source	Educational attainment Employment status Occupational type Income source Income range New Australian Country of birth Citizenship status	Full name Relationship Organization Address Post code Phone	Total invoiced Total applied receipts Total unapplied receipts Total applied write offs Balance Transaction history Debits Credits
Employment / school information	**Outcomes evaluation information**	**Pre-enrollment information**	**File attachments**
Employer name Work contact Address Phone Email Work comments	Pre / mid / post stage evaluation Surveys completed	Reasons for waiting Waiting for program Waiting for worker Comments Waiting since	Letters Reports Documents of any data type

Workers can use the system to schedule activities and appointments, and log information about whether the client has attended their appointments. Although many agencies do not bill clients or insurers, the program incorporates a system that is able to invoice and record payments, track billable services and provide for single and batch invoicing and provide summary financial information.

INFORMATION DOMAINS

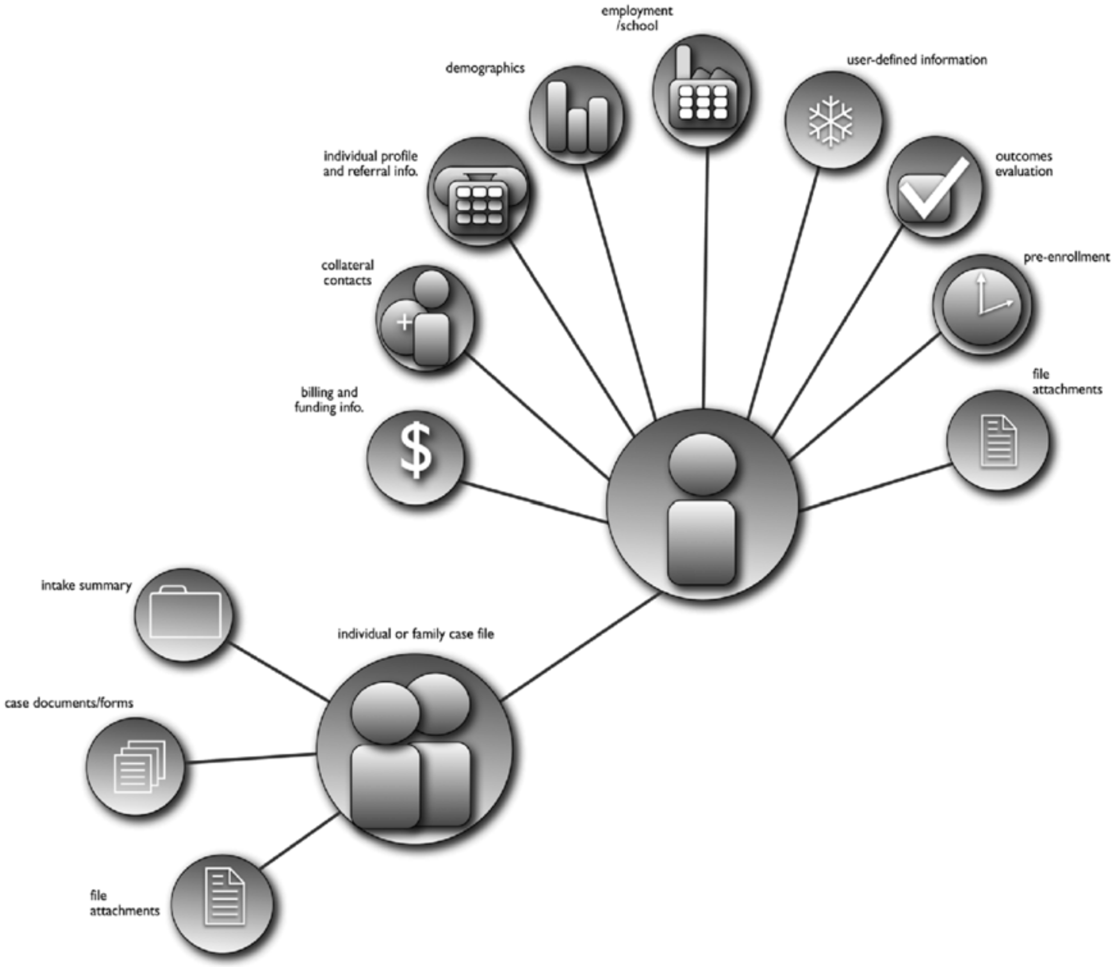
Although the Penelope case management information system provides information about individuals and cases that can enable practitioners to manage their case loads effectively and efficiently, the system, more importantly allows aggregation of information into many domains. Put simply information is collected about individual clients at the case level, program and services level and at the activity level. These information domains with examples of associated outcomes are illustrated in Table 2.

Aggregated data allows agencies to use data in a variety of different ways to serve the needs of clients, management of human and financial resources, assessing client satisfaction, program planning and managing funding requirements. Given its simplicity of use the package presents may opportunities for agencies.

WHERE TO START?

Information domains provide a conceptual framework for the collection of standard demographic and user defined information. This is the easy part of the journey. The transition from information collection to management and utilization of this information is more challenging for agencies. The transition from data collection to using data for monitoring and analysis of programs should not be feared by administrators or practitioners. It is helpful to start with some very simple questions and link these ideas to concepts and strategies in the literature.

Figure 2. Individual and case file information



- What are our questions about our programs? Practitioners have questions exploratory questions about the services provided and administrators have questions about the use of agency resources to deliver these programs. Both have questions about clients, services to community and policy. These are who, what, how and why questions. They are the questions of interest to the agency and not questions imposed by funders.
- What questions do we have about our services to clients and community and how do we measure the work we do? At the most simple level these questions relate to performance monitoring. The issues for consideration are what information is collected and how do we interpret the information in the agency.
- What are trying to achieve in our agency? This is a deliberate question about the intentions of programs and services, and expectations about the outcomes we hope to accomplish. These simple questions link to the idea of the program logic model, a map which is unique to every agency and program. What we are trying to achieve should

Table 2. Information domains

Clinical domain	**Service delivery domain**	**Outcomes evaluations domain**
Personal and family information Demographic data Employment data Collateral contact information User defined information Case documentation and notes Clinical activities	Case load statistics Activity status statistics Activity statistics Program specific statistics Presenting issue statistics Case flow statistics	Client self ratings at pre, mid, and post stages of service Percentage change over time Frequency distribution over time Qualitative feedback Client satisfaction results Outcomes reporting by program and funder13

fit with agency plans, funding submissions and formal evaluations.

- How do we demonstrate the effectiveness of our intervention and use these results to change services? This is a research question. This process can be a more complicated and exhaustive when combined with complex analytical and interpretative approaches.

We therefore have four types of questions: exploratory, monitoring and interpretative, intentions and evaluative. Before understanding these questions, it is necessary to understand the concept of the program logic model which assists in understanding these questions.

Logic Model

In simple language, a logic model is a graphic representation used as a guide to convey what agency services are intending to achieve. This guide, unique to every agency provides a mechanism to communicate to funders, researchers and community about services and outcomes. At a more formal level, Frechtling (2007, p.1) defines a logic model as a 'tool that describes the *theory of change* underlying an intervention, product or policy'. This theory of change simply means that when resources and activities are combined in particular ways they will lead to intended outcomes for clients. *If* a particular set of actions are prepared, *then* specific results are expected. These logic models are important aids to assist organizations in applying for grants as they clarify the intended purpose, activities, outputs and outcomes. In addition, these models provide a framework for developing an evaluation study, setting a framework for the information to be collected and also documenting the intervention and how it worked. Logic models are not fixed as they can be developed at any time during the life cycle of the program and can be modified if the circumstances of the program change. For organizations using a case management software system, logic models provide the elements for data collection enabling compilation of relevant information, and a focus for analysis. Although this chapter will focus on technological aspects of the logic model, it should be remembered that developing logic models is a collaborative endeavor and a dynamic process involving agency staff and other stakeholders. Over time, the logic model used may need revision as practitioners work with the clients and develop new practice knowledge of activities and outcomes.

Logic model components are simple and include inputs, activities, outputs and outcomes. The inputs are resources which are brought to a program including financial, material and human resources. Some programs may have multiple funding sources whilst human resource can include volunteer support, in kind assistance or partnerships with other agencies. Activities are those action steps taken in the program to achieve its stated goals and outputs. Outputs are the results of the program such as products, services and reports produced. Outcomes are the changes to people and situations resulting from the activities and indicate that the aims of the program have been achieved. Documentation of these outcomes provides evidence of the success of the program. Outcomes can be written as short term, medium term and longer term. It is not possible here to address issues in developing program logic models but substantial online resources are available from such organizations as the United Way, Kellogg Foundation as well as print material (Frechtling 2007; Wholey, Hatry & Newcomer 2004).

Although the logic model is a clearly structured approach, its development is a dynamic and iterative process that requires involvement of all staff and takes place over time. McLaughlin and Jordan (2004, p.15) suggest that managers regard the logic model as a process that involves both program participants and other stakeholders associated with the model's implementation. Above all logic modeling is part of long term cultural change. Understanding the program logic model is fundamental in demonstrating outcome measures to funders, preparation of grant application and using data in other forms of inquiry.

The program logic model provides a structure for demonstrating outcomes to funders, a framework for funding applications, and a series of questions for formative and summative program evaluation. As a theory of change is embedded in the logic model, the model with associated outcomes allow for testing of the effectiveness of the change strategy. The particular value of the program logic model lies in program evaluation, a process that includes:

- Development of a conceptual model of the program and identification of key evaluation points
- Development of evaluation questions and definition of measurable outcomes
- Development of an evaluation design
- Collection of data
- Analysis of data
- Provision of information to interested audiences (Frechtling 2007, p.127).

WHAT ARE THE EXPLORATORY QUESTIONS ABOUT OUR PROGRAMS?

This is something that practitioners and administrators do every day although they may not describe this as an investigative, analytical and/or interpretative process. Questions about practice emerge because practitioners and administrators have hypotheses about practice and want confirmation of their intuition. There are many questions that practitioners and management may ask on a day to day basis. Generally, the software program enables practitioners and administrators to use data collected to provide the answers. Listed below are examples of the questions that may be asked.

Questions about services to clients

- How long is our waiting list?
- How quickly do we respond to urgent cases?
- How many hours of service do we provide per client?
- What is the demographic profile of our client group?
- What is the diversity of our client populations?
- How many cases of elder or child abuse have we received?

- What sorts of complaints do we receive from clients about our services?
- How many clients return for further assistance?
- What are the most common problems experienced by our clients?
- What are the health and social risk factors of our clients?
- What sort of health and mental health problems go together?
- What are the most intractable mental health concerns experienced by our clients?

Questions about resources

- How many years of experience do agency staff have?
- What is the range of staff qualifications?
- What is a reasonable workload for staff in a particular service area?
- What is the cost of group work activities and individual therapy?
- How many hours of supervision per year are provided to new and experience staff?
- What is the cost per person attending training programs?
- Are some staff more effective in working with some clients than with others?

Questions about the agency in the community

- How does our client service profile compare to similar agencies?
- What are the social problems in the neighborhoods served by our agency?
- What are the most urgent unmet needs identified by the clients and community?
- What is the network of referrals and how do we work with these agencies?

Questions about policy

- How does a particular social policy impact on the clients in the agency?
- What are the challenges for clients in accessing health and welfare services such as housing, health services or income support?
- Does the allocation of resources for services match the costs of delivering those services?

The above questions are useful but they need to be linked to a commitment on the part of the agency to engage in measuring and monitoring performance and outcomes. There are several steps in this process including:

- Obtaining and holding the support of managers and stakeholders
- Identifying the questions that the agency wants answered
- Defining the criteria to use in answering those questions
- Understanding the data that needs to be collected
- Determining how that data is to be presented and analyzed.

The steps in beginning this process are elaborated by Wholey (2004) using the concept of evaluability assessment, that is a process undertaken by the agency to determine what evaluations might be useful, explore what evaluations would be feasible and design evaluations.

WHAT ARE THE MONITORING AND INTERPRETATIVE QUESTIONS ABOUT THE WORK WE DO?

Administrators and practitioners also have questions about the quality of their services and programs and rely on quantitative descriptive accounts to track and monitor performance on a regular basis. These questions may relate to resource management, outputs, activities, productivity, service quality, customer satisfaction (Poister 2004). This information can assist agencies to manage for results. Although the data is descriptive, it can also supplement more complex evaluative tools.

Performance monitoring is an important tool in the management and planning of services bringing together collection of data, accountability requirements, theories of social change and performance monitoring measures. The aim of performance monitoring is to track performance in a timely and scheduled manner using a range of measures related to agency programs providing information to managers, stakeholders and policy makers. It can assist agencies to assess how a program is operating and the extent to which program objectives are being achieved in the service delivery. Where objectives are not fully achieved, performance monitoring can assist in rethinking aspects of delivery. Performance monitoring uses client satisfaction measures and can report on cost effectiveness and productivity.

Performance monitoring may be imposed by funders to compare services or deliberately used by agencies as part of their operations. For example; in the Australia health care system, performance monitoring is imposed with hospitals required to measure and report indicators such as patient waiting time for elective surgery or the number of patients who wait longer than 24 hours in emergency. Within a human service agency, similar measures track can what is happening with program outcomes. Measures collected are descriptive and it is not possible to attribute causation. The value of some measures can also be challenged. For example, the size of a case load may not reflect the actual workload of individual practitioners as some cases are complex and other cases have a relatively simple intervention. Similarly, the length of a hospital waiting list may mean that there is a very effective early detection of problems rather than a queue of more serious problems. Once these measures have been developed and there is clarity about their reliability, they can then be used in a variety of different ways by the agency including;

- Use of particular resources used in program areas (e.g. number of support workers needed to care for an older person in their home)
- Output measures (number of cases or clients serviced)
- Productivity measures (cost per investigation of child abuse)
- Service quality especially turnaround time, accessibility, safety, waiting time for diagnostic assessment or time from application for a pension or benefit until a decision is made and provided to the customer
- Outcomes or the extent to which a program is effective
- Cost effectiveness or the ratio of costs to outcomes (cost per discharged consumer)
- Customer satisfaction (for various aspects of service delivery such as therapy, financial assistance, child care or home help) (Poister 2004, pp.99-102).

Much of the information described above can be taken directly from the data management system. The data can be raw numbers, percentages, averages, or indexes which are generally composites representing a particular characteristic. Some performance measures require additional information for collection but this can be part of the intake, assessment and intervention process. This can include questionnaires such as the Health Status Questionnaire, measures of risk factors, social functioning, observations by therapists, follow up data on clients after a set period and surveys. It is important to bear in mind that measures should be specific and oriented to results, understandable, and be reliable, (objective and dependable) and valid (fair and unbiased).

WHAT DO WE INTEND TO ACHIEVE?

Software management programs provide agencies with a tool to record information about their clients and services and then use this information deliberately for a variety of administrative and research purposes. Unfortunately, many social service organizations do not utilize software management programs or management information systems to their full potential if indeed they do possess such programs. Stoecker (2007) notes that not-for-profits collect a lot of data but do not use much of the data collected. One step in effectively using the tool is to think systematically about programs delivered by the agencies asking what in particular is this program intended to achieve and with what results for the client group. The name given to this approach is the logic model and here agencies specify inputs, activities, outputs and outcomes.

Interpretative Approaches to Outcomes

The program logic model is quantitative in orientation. There are also qualitative evaluative approaches rather than quantitative using interpretative orientations guided by social constructivist theories. Here participants create their own understanding based on past and current experiences alone and in collaboration with others. This interpretative model allows practitioners, to learn as they proceed with the program and modify and adapt according to the clients and issues faced along the way with outcomes developed through the process rather than planned before the program commences. It is particularly relevant in service delivery when the services and problems are complex.

Although interpretive models are qualitative, there is logic to interpretative evaluation with stages that include engagement, discovery, sense making and unfolding (Netting, O'Connor & Fauri 2008, p.136). These stages are not necessarily sequential but more of a spiral progression. The process of engagement and relationship building with diverse groups, discovery and sense making happens simultaneously with a deepening of understanding with the development. Information collected in this process comes from multiple sources including qualitative and quantitative data, narratives from logs or case studies, observations, views of all participants or even the discovery of tensions and ambiguities.

When using interpretative approaches, accountability and the use of information systems pose special challenges. Funders may not like these approaches because outcomes are not clearly quantifiable and therefore hard to evaluate and compare with similarly funded programs. Nevertheless, it is possible to meet funder accountability requirements using information systems. The emergent interpretative models rely on description and documentation of multiples views, relationship building, understanding of complexity, consensus building processes, options and possibilities and the learning process. These can be documented in reflective journals, narratives of critical incidents, day journals, contact logs, methods journals, notes of meetings, and transcripts of significant meetings. These can be supplemented with various forms of quantitative data. Case management software programs can be used to store this data, make and edit notes. They can be stored in the system and retrieved for analysis by exporting them to such programs as NVIVO.

HOW DO WE EVALUATE THE EFFECTIVENESS OF OUR WORK?

There are three ways to demonstrate effectiveness: experimental, quasi experimental designs and evaluations that examine impact. Generally these evaluations are done by large scale organizations rather than the small not for profit. The gold standard for effectiveness studies is experimental randomized studies. These require that participants are randomly assigned to either a treatment group or a non treatment group, called the control group. Generally, these studies are difficult to implement. The outcomes of these groups are then compared to determine the impact of the service or intervention. Quasi experimental designs are similar to experimental designs and are more common because the allocation of subjects to groups is not random. There are several variations of randomized designs including time series based on repeated measures, before and after comparisons and post program comparisons. Finally, effectiveness is evaluated by examining changes in risk or outcomes amongst the client populations. Risk factors that include for example mental health or general health problems are measured to determine the impact of the program.

CASE MANAGEMENT SOFTWARE AND REPORTING

Software programs provide a mechanism for information collection. Penelope software allows tracking of client activity from demographic characteristics of the population and program related perspectives to clinical outcomes. A wide variety of reports can be used to answer basic practice and administrative questions and to allow performance monitoring. Custom surveys can easily be built into the system by users. In addition, the Penelope case management software system includes public domain outcome and evaluation templates that can be used in outcome studies and for inclusion in quasi experimental designs and randomized experimental studies. Examples include Brief Psychiatric Rating Scale, General Satisfaction Survey, Hamilton Anxiety Rating Scale, Global Assessment of Functioning Scale, and Family/Couple Outcomes Survey. Proprietary scales can also be used with this software.

Although this software is both powerful and flexible, the introduction and ongoing management of performance measures, outcome studies and the incorporation of experimental studies does present challenges for organizations. The United Way of America (2000) recognizing that many not for profit organizations were using performance monitoring, required the development of outcome measures as part of funding requirements. They followed up many funded organization with a survey examining the impact of this requirement. Many agencies identified outcome measurement as helpful as it enhanced record keeping and facilitated success in competing for additional funding and resources. On the other hand they identified lack of access to technical resources to solve problems and inadequate software and staff time to complete these requirements.

Introduction and effective use of case management software systems, such as Penelope will take time. There are some fundamental requirements including the involvement of all staff and stakeholders in the planning, and the support of senior management and the board of directors. Data collection methods, analysis and interpretation of results may need to be supported with additional technical expertise. The system is developed on a trial and error basis with a process of testing, evaluating and making improvements before it meets the needs of management, practitioners and funding bodies. Once established, improvements and modification will also be required. Throughout this process, a range of problems will be presented especially in relation to the quality of agency records. Hatry (2004) identified issues in relation to missing and incomplete data, aggregated data where information is not classified into useful and pertinent categories, quality control for the reasonableness of data and privacy issues.

THE FUTURE

Demonstration of effectiveness using management information systems is here to stay. Software programs to support these initiatives will increasingly be adopted with funder demands and as organizations effectively using such systems will gain competitive funding advantages. Effective software solutions in the human services sector will be ones that address a combination of priorities including cost effectiveness, ease of use, user and system security, decision support and evaluative support. In addition, flexible systems that can accommodate the diverse needs, best practices and specific logic models of human service organizations will have the greatest impact on their success.

There will be an increased public accountability for funding. This will go beyond financial accountability to include service quality and service outcomes. Performance indicators and programs outcomes are likely to be made more public enabling comparisons to be made by the clients they serve. Savvy consumers may elect to attend programs which can demonstrate the best outcomes. This is already occurring in the health sector with use of service indicators such as infection rates of particular hospitals and the community. Scrutiny of performance and outcome measures for funded programs will be undertaken with attention to the relevance, rigor, and interpretation. For example some funding bodies already specify the measures required as part of funding. With this data they are able to make comparisons between the costs and service outcomes. They may use this knowledge to determine future funding. Benchmarking is a process that allows funders to compare of performances, outcomes and associated costs for similar services. It allows examination of performance in particular periods of time, outcomes for different target groups, variations of service delivery and performance in similar organizational structures and geographical areas (Pathfinder 2003). Funders may well classify services according to what they interpret as a "good" performance although such as classification system would need to done with some care as different client groups, neighborhoods or populations may exhibit different results.

CONCLUSION

Case management software programs are sophisticated tools with practical capabilities enabling improved management performance and demonstration of outcomes. At a basic level, these software programs facilitate collection of data about clients. Agencies that do not go beyond data collection are under utilizing the system's capabilities and not getting a return on their investments. With increased accountability requirements from funders, there are expectations that the not-for-profit sector will need to demonstrate outcomes for clients. This chapter, using Penelope case management software as an illustration has provided practical examples of the way agencies can make the transition from data collection to performance monitoring and demonstration of effectiveness.

Chapter 6.6

An e-Healthcare Mobile Application:

A Stakeholders' Analysis Experience of Reading

University of Cyprus, Cyprus

ABSTRACT

This chapter presents a longitudinal study on the implementation of an e-health mobile application, DITIS, which supports network collaboration for home healthcare. By adopting the stakeholders' analysis, the study explores the various groups that have directly or indirectly supported the system during its implementation. The system was originally developed with a view to address the difficulties of communication and continuity of care between the members of a home healthcare multidisciplinary team and between the team and oncologists often hundreds of kilometers away. DITIS evolved to be much more than that and even though it was introduced 5 years ago, it is considered a novel application. Despite this, its implementation has been slow, and several challenges, including the system's sustainability, have to be faced. This chapter aims to understand these challenges and the results of the study point to a diversity of interests and different degrees of support.

INTRODUCTION

Healthcare is an environment that has been experiencing dramatic progress in computing technology in order to process and distribute all relevant patient information electronically and overall to improve the quality of care. In particular, mobile e-health involves a spectrum of information and telecommunication technologies to provide healthcare services to patients who are at some distance from the provider and also to provide supporting tools for the mobile healthcare professional. The benefits of such mobile applications are numerous, with the main one being improvements in access to medical resources and care.

Recently, the healthcare and related sectors have been found to embrace mobile technology in e-healthcare applications. Though there have also been cases of mobile workstations being implemented at small medical units to facilitate easier access to specialist medical advice (e.g., Salmon, Brint, Marshall, & Bradley, 2000), most of the applications have been introduced to support patients at home. These could either be patient centered where patients and/or caretakers are given direct access to a mobile phone for communicating with the provider (e.g., nurse, doctor, counselor, etc.), or nurse centered where nurses who visit and care for patients at home have direct access to mobile applications for communicating with other medical staff.

It follows that the practice of e-health projects is often a collaborative activity requiring extensive and interactive communication within and between members of specialized occupational groups to coordinate patient care services. This becomes necessary when dealing with patients requiring a multidisciplinary team approach to their care, and who are treated outside the hospital environment. In such a case, the team is mostly geographically dispersed and rarely sees the patient together. This requires the creation of virtual multidisciplinary teams of care whose management and coordination can be supported by technology. In the study, we aim to explore the role of diverse stakeholders in an e-health application involving virtual multidisciplinary teams of care. Diverse stakeholders get involved at different stages of the project implementation and may experience different degrees of knowledge about the system itself, its significance, and its novelty. These along with their different backgrounds, interests, and expectations may contribute to different meanings and understanding about the system, its role, and its significance, which will ultimately affect system implementation.

BACKGROUND

Stakeholders' Analysis

The role of stakeholders in IS implementation has long been recognized in the literature, though it has only been during the last few years that the identification of different stakeholders as well as the roles and interrelationships between them was found to be important for uncovering some of the complexity in system implementation (Pouloudi & Whitley, 1997).

Despite this, researchers have given different definitions to stakeholders. Sauer (1993), for example, makes reference to stakeholders as supporters, those who provide funding, information, and influence, whilst Beynon-Davies (1999) argues that there is a need to broaden this definition. As he puts it, "…not all groups with an interest in the development of an information system necessarily support that development. Some stakeholder groups may have a definite negative interest in the success of a given project" (p. 710). Following from these, in this chapter, in an attempt to keep a broad definition, stakeholders are defined as those with a direct or an indirect interest in a project.

According to Mitchell, Agle, and Wood (1997), stakeholders can be distinguished in terms of three relationship attributes: power, legitimacy, and urgency. Power is the ability to impose influence on the relationship; legitimacy is "a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions" (Suchman as cited in Mitchell et al., p. 574). Finally, "[u]rgency is based on time sensitivity and criticality" (Mitchell et al. as cited in Howard, Vidgen, & Powell, 2003, p. 31). A combination of these three attributes contributes to different types of stakeholders who have different roles and expectations.

EMPIRICAL STUDY

In this section, we present the case of an e-health mobile application and adopt a stakeholders' analysis to understand its implementation process and the challenges faced.

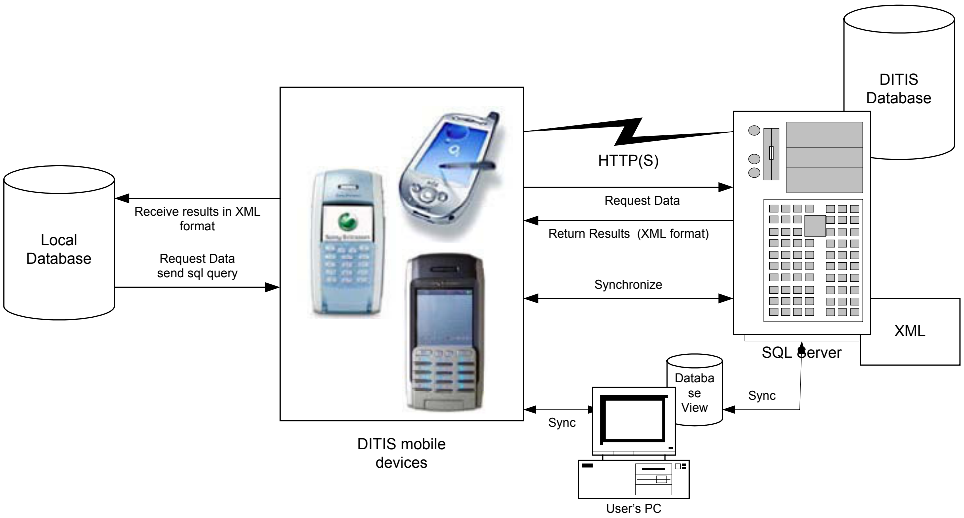
Mobile applications are an increasingly important technology for improving the quality of health services, especially at the point of care. They enable the formation of virtual teams of care, and timely, effective, and quality patient management are the expected outcomes. The role of stakeholders in supporting such innovative applications is vital.

The System

DITIS: Virtual Collaborative Teams for Home Healthcare (http://www.ditis.ucy.ac.cy) is an Internet- (Web) based group collaboration system with secure fixed and mobile (GPRS [general packet radio service], GSM [Global System for Mobile Communication], WAP [wireless application protocol]) connectivity (see Figure 1).

It enables the effective management and coordination of virtual collaborative healthcare teams. It provides a secure access to e-records from anyplace and anytime via desktop computers (at work) or a variety of mobile devices (when on the go). It includes a set of tools for effective scheduling and coordination of team members, with features including automatic notification and alerting. It makes use of supportive tools relevant to home care that improve efficiency and minimize errors. The collaboration platform is based on identified roles and scenarios of col-

Figure 1. DITIS system architecture



laboration, analyzed using the unified modeling language (UML).

The DITIS project was initiated in 1999 to support the activities of the home healthcare service of the Cyprus Association of Cancer Patients and Friends (Pasykaf). The goal of DITIS is to deliver a product that can improve the quality of the citizen's life. Contrary to today's health processing structure, which is, in all practical terms, facility-based care, this project aims to shift the focus onto home-based care, where everything is moving around the patient, supported by a team of multidisciplinary healthcare professionals. Given that the team cannot be by the side of the patient at all times, DITIS developed a collaborative software system to support dynamic virtual healthcare teams, customized for the differing needs of each patient at different times. The virtual healthcare team is supported in its provision of dedicated, personalized, and private service to the home-residing patient on a need based and timely fashion, under the direction of the treating specialist. Thus, it is expected that chronic and severe patients, such as cancer patients, can enjoy optimum health service in the comfort of their home (i.e., a focus on wellness), feeling safe and secure that in case of a change in their condition, the healthcare team will be (virtually) present to support them. The present users of the system include the healthcare professionals treating cancer patients (home-care nurse, oncologist, treating doctor, psychologist, physiotherapist, social worker, etc.) and the Pasykaf administration. It is expected that the system will be extended to other paramedical professionals, as, for example, the Pharmacist and the Cancer Registry, currently located at the Ministry of Health. Furthermore, the system can be adapted to cater to other home healthcare needs, as, for example, cardiac, renal, or diabetic patients.

DITIS deploys a novel networked system for tele-collaboration in the area of patient care at the home by a virtual team of medical and paramedical professionals, implemented using existing networking and computing components (the novelty of the system and competing approaches are briefly discussed in A. Pitsillides et al., 2005; B. Pitsillides et al., 2004). The system was originally developed with a view to address the difficulties of communication and continuity of care between the home healthcare multidisciplinary team (Pasykaf) and between the team and the oncologist often many miles apart. DITIS has through its database and possibility of access via mobile or wire-line computers offered much more than improved communication. Its flexibility of communication and access to the patient's history and daily record at all times, anywhere (in the case of home patients, outpatients, or an emergency hospital admission), has offered the team an overall assessment and history of each symptom. DITIS thus has the potential to improve the quality of life of the patient, for example, by offering the nurse the possibility of immediate authorization to change prescriptions via mobile devices, and the oncologist the possibility of assessment and symptom control without having to see the patient. It also offers the home-care service provider the opportunity to plan future services and lobby for funding by offering audit, statistics, and performance evaluation, and with these in place, the possibility for research.

The User Organization

Pasykaf, the user organization, was founded in 1986 to provide support to cancer patients and their families during their period of rehabilitation and is manned with highly qualified medical, paramedical, and nursing staff. In 1992, it started a home-care service for cancer patients. Specially trained palliative-care nurses in close cooperation with doctors (general practitioners and oncologists), physiotherapists, and psychologists attend and care for patients at home, focusing on maintaining the best possible quality of life, including medical care and psychological support.

In the context of home care, home-care professionals visit patients at home. Traditionally, the team of professionals was (loosely) coordinated by weekly meetings, or in case of some urgent event, information was exchanged by telephone calls or face-to-face meetings. Often, the same information is requested from the patient so each professional can build his or her own medical and psychosocial history and treatment notes (handwritten). Traditionally, these handwritten notes were filed at the Pasykaf district offices once the healthcare professional returned to the office. On a scheduled visit, the file had to be removed from the office and taken with the healthcare professional to the patient's house. This was inflexible and restrictive as there was no possibility of access by another healthcare professional at the same time. Furthermore, after hours, on-call professionals had to make a special visit to the office to collect the patient file (even if there was no other business with the office). For a patient visit to the hospital, especially in an emergency, there was no possibility of immediate access to the patient file from the attending home-care nurse. Therefore, there was limited possibility for continuity of care.

As with every manual system, there was limited possibility for audits and statistics, research was difficult, evidence-based medicine was not supported, dynamic coordination of the team was almost impossible, and communication overheads were very high and extremely costly in human and monetary terms. DITIS aims to address these problems in the provision of home-care services by a team of professionals.

Generally, given the limitations of the existing home-care delivery models, the need for improved ICT-supported practices emerged. Even though the context of health reform may vary across countries, major objectives are similar and include the following:

- A move toward people-centered services.
- A commitment to healthy public policy and a desire to improve the health status and quality of life of individuals and communities.
- Increased emphasis on knowledge- and evidence-based decision making, and efficiency and effectiveness in service delivery.
- A shift from facility-based health services and a focus on illness to community-based health services and a focus on wellness.
- The integration of agencies, programs and services to achieve a seamless continuum of health and health-related services.
- Greater community involvement in priority setting and decision making.

DITIS aims to support the above healthcare reform objectives. We focus our analysis on home healthcare of cancer patients, but expect our results to be applicable to home healthcare in general as well as cross-cultural and cross-border interoperability. Thus, through DITIS, we expect to assist in the delivery of better home care by offering the healthcare team services that are aimed at achieving a seamless continuum of health and health-related services despite the structural problems of home care as compared to facility-based care.

The system was initially deployed in one district, District A, and was gradually implemented in another three districts. The study has adopted the longitudinal approach in data collection for the first 5 years of the system from 1999 to 2004.

Methods and Data Collection

This research is interpretive as our aim is to capture stakeholders' interpretations of the system itself and their use of the system. To this end, our research method is qualitative in nature, examining "humans within their social settings" (Orlikowski & Baroudi, 1991, p. 14).

The fieldwork has taken place in various district sites of Pasykaf. Each site is served by a number of palliative-care nurses who visit patients regularly in their house to offer support. Data on

DITIS were collected on different stages of the implementation process.

Phase 1: The preliminary part of the research has studied the use of mobile telephones by a group of palliative-care nurses during the period of August to September 2000. Interviews with three nurses and one doctor in District A have enabled the study of nurse-to-nurse interactions and nurse-doctor interactions via the use of mobile telephones, whilst also contributed to gathering information on their level of awareness about DITIS and its potential use in palliative care.

Phase 2: This part of the study took place in May 2001 and involved the use of a structured questionnaire that was sent to DITIS developers and potential users. It aimed to explore stakeholders' expectations regarding DITIS. A copy of this questionnaire appears in the appendix.

Phase 3: The third phase of data collection took place in April 2003. By this time, DITIS was implemented in four district sites. During this phase, current users of the system in three district Pasykaf offices were interviewed: one psychologist and three nurses. The main issues explored during interviews included the participants' actual use of DITIS, their own explanation of why they use DITIS the way they do, and their understanding of what users' and others stakeholders' role should be for achieving effective DITIS use.

Phase 4: This final part of the study took place in April 2004. Interviews included users (nurses and psychologist) as well as members of other stakeholder teams. During this phase, it was found that even though DITIS has been implemented effectively with the right support from the project team, anxiety was identified at different levels with regard to its future.

Table 1 summarizes the data-collection approach adopted.

RESULTS

Overall, the data reveal that DITIS offers innumerable opportunities for palliative-care nurses and other cancer-care practitioners. DITIS is currently widely accepted as an invaluable tool in palliative care. Nurses, psychologists, and doctors acknowledge that DITIS has numerous

Table 1. Summary of the adopted data-collection approach

Phase	Time Period	No. of Interviews	Purpose
Phase 1	August-September 2000	4	Understand context of work, users' awareness about DITIS
Phase 2	May 2001	7	Users' expectations
Phase 3	April 2003	4	Level of usage & explanations given
Phase 4	April 2004	5	Stakeholders' own evaluation of DITIS

advantages and that they are willing to incorporate it in their work activities. DITIS can improve communication, coordination, and collaboration among members. Due to the huge amount of data regarding new and old patient records that need to be handled on a daily basis, DITIS enables users to access data quickly either from their office or remotely. Furthermore, it can be used as a statistical tool for producing internal reports for the district offices and the head office as well as external reports required by the Ministry of Health and other government departments.

"Pasykaf will be able to extract more information and statistics about cancer symptoms. Information about cancers and their occurrence by region will help to detect possible reasons that may be responsible about cancer (e.g. factories in the areas, etc.)" (Developer, Phase 2).

"Life will be so much easier with DITIS to fill in the gaps from unknown to known" (Nurse, District B).

Interestingly, even though technophobia was identified in Phase 1 of this study as a possible negative factor in the effective implementation of the system, it was later expressed by nurses across different district sites that participated in Phase 3 that users are generally willing to adapt the system in their day-to-day work because they expect that their tasks will be executed faster and easier, saving time and effort.

It was agreed among all participants in the study that the project was a novel one, that it was a radical departure from what existed previously, and that it was designed to be at the core of Pasykaf's activities (i.e., the provision of healthcare to home-based cancer patients).

Implementation Problems

During the first three phases of the study, there was a general feeling that DITIS had not yet been sufficiently incorporated in the daily work activities of the healthcare workers and that this would be a slow process. The main problems identified were with regard to the implementation process. A nurse in District B clearly said that this process "has been slow from all points of view" (Phase 3).

It has been widely recognized that the effectiveness of the system implementation was jeopardized due to financial resources being constrained or at times becoming unavailable. The limited budget that the project development team had to work with mainly had two major implications. First, only a small number of mobile handsets could be acquired. As a result, only nurses in one district office (District A) were given a mobile device with DITIS application, whilst other district offices have to rely only on PC- (personal computer) based applications of DITIS. The latter, however, restricts the use and the potentials of DITIS, which has been developed as a wireless application to promote virtual collaboration in cancer care. Second, limited financial resources have influenced staff availability on the project implementation team. The project has been experiencing staff discontinuities since the early stages of DITIS development. Mainly graduate students have been used for this project under the guidance of two computer-science academics, both members of the DITIS project team. Even though the latter remained the main drivers of the project, DITIS was only one of several projects that they were involved in and therefore could not give their full attention as required by the criticality of the project nature. To quote a nurse, "The system was done on borrowed time" (District A, Phase 3), indicating that for most of the implementation period, there were no full-time project members; rather, even though the system had gained the enthusiasm of several people who committed themselves to the system, none of them could make a full-time commitment. Instead, there were several temporary project members throughout the duration of the implementation process leading to staff turnover.

Therefore, the high staff turnover and the lack of full-time staff brought inconsistencies and delays in the project development.

As the psychologist who participated in the study (Phase 3) put it, "There is no person in charge and this leads to communication problems." The same person suggested that there was a need for frequent meetings to keep users informed about the state of the implementation process, alleviate doubts, and improve coordination among cross-groups (e.g., nurses, doctors, psychologists).

Based on the results of the longitudinal assessment, corrective measures were taken, including the creation of a more stable team due to the commitment of all relevant actors and availability of funding. These corrective actions were acknowledged by all the users interviewed in Phase 4 of the study. During this phase, there was a general feeling of satisfaction about the use of DITIS in the day-to-day work practices as users have by now begun seeing the benefits of the system.

> "*The system is more reliable.*"
> "*It is 100% better.*"

Despite these positive results, there appears to be some anxiety among users about the sustainability of the system. DITIS has been successful in attaining the initial goals set. However, several difficulties, some non-technical in nature, were encountered during the development and deployment of DITIS in Phase I. These are outlined below:

- Underestimation of the workload involved in order to populate the DITIS database, and misjudgment of effort for encouraging users who are used to a paper-based system to switch to a new system, which was in essence still incomplete and under construction
- Network technology limitations (e.g., WAP over GSM). The migration to new technologies (GPRS/UMTS [Universal Mobile Telecommunications System] and ADSL) is resolving many of the original technical problems: Service is always available and bandwidth is much higher.
- Deployment with mobile devices has been limited mainly due to the cost related with having each member of the home-care team have his or her own mobile device, and the pace of new device launches with enhanced functionality. Recently, 30 mobile devices were acquired and are being deployed. This will allow a number of multidisciplinary teams to operate.
- Sustainability of DITIS due to uncertain financial support. Potential funding may derive from the government through its spin-off company initiative. Another one is the Ministry of Health for its planned community-care service.

Stakeholders: Relationships and Roles

The main stakeholders of DITIS derive from inside as well as outside the user organization. A key stakeholder group consists of the nurses and other members of the medical team in the district offices, for example, psychologists who directly use the system. Gradually, the nursing team has begun to embrace DITIS and overcome the initial resistance that was mainly caused due to the delays in implementing the system.

A second group involves the university computer scientists who designed the original system and currently manage the project development and implementation. They have the intellectual property of the system and are the ones who actively promote the system to national and international organizations in order to attract funding that would enable them to continue developing and improving the system. Their interest is in "the expansion of the collaborative system for usage in other fields (e.g., cardiac home care, insurance sales, etc.) and its eventual commercialization" (interview with project leader). The cost of setting up such an infrastructure and supporting it vs. the benefits, such as quality of life and time saved, are difficult to justify in monetary terms; also, there is the potential benefit of using GPRS and ADSL (Asymmetric Digital Subscriber Line) (always connected, higher speeds) vs. the earlier GSM/WAP mobile telephone device and ISDN (integrated services digital network) for the fixed computer lines (dial-up, low bandwidth), and the costs of maintaining such a telecom infrastructure to consider. Another barrier is the high cost of handheld devices and rapid change of technology, which have hindered projects development Cyprus-wide.

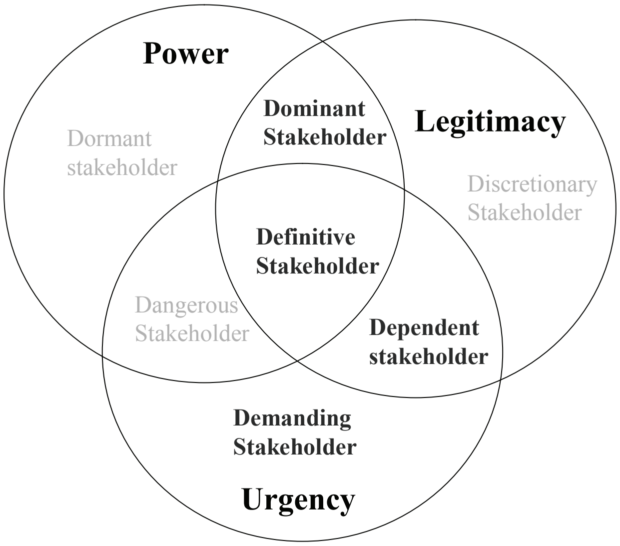
An independent commercial software organization that supported the initial idea and design of DITIS has also been a key stakeholder. This organization has recently withdrawn from the project after the first stage of its implementation as they could not see the financial viability and profitability of the project and were no longer interested in investing in mobile-based applications. Another commercial software organization with a focus on mobile e-services has recently joined the project.

Finally, an important stakeholder is Pasykaf as the user organization that hosts the system in its district offices as well as in the headquarters. Pasykaf, a charity organization, is interested in the project as it can see that the system can predominantly enable it to produce national and regional statistical information on cancer and cancer patients, which are required by the government. Our study, however, has shown that the involvement of Pasykaf management in this project has remained limited. Several users recognized that Pasykaf in particular should undertake a more active role in the implementation of the project by investing more time and administrative support.

Accordingly, the stakeholders derive from diverse sectors, and even though they all want DITIS to succeed, their expectations are different. From our data, it was found that all stakeholders agree on the important role that the system could have in cancer support.

In what follows, we describe these different types of stakeholders and identify their relevance to the DITIS project. Based on Mitchell et al.'s model (1997), Figure 2 depicts the stakeholders'

Figure 2. Stakeholder typology (Mitchell et al., 1997, p. 874)



relationship attributes and the different types of stakeholders.

Definitive stakeholders possess power, legitimacy, and urgency. The project initiators at the university fall in this group. Due to their active involvement in the design and promotion of the system, they possess both power and legitimacy whilst simultaneously are aware of the risks involved if no funding is secured. For this, they have a clear and immediate mandate to give priority to the project and have considered several options, one of which is commercialization.

Demanding stakeholders exist where there is urgency but no other relationship attribute. Within this category, we place the commercial organization that became involved in the initial design of the system. It did so for commercial interests. Due to the financial difficulties that the project faced, the company decided to withdraw their demands for commercialization and thus profitability has not been met.

Dormant *stakeholders* **are the** *stakeholders* who possess power to impose their will, but by not having a legitimate relationship or an urgent claim, their power remains unused…Dormant *stakeholders* have little or no interaction with the firm. However, because of their potential to acquire a second attribute, management should remain cognizant of such *stakeholders*, for the dynamic nature of the stakeholder-manager relationship suggests that dormant *stakeholders* will become more salient to managers if they acquire either urgency or legitimacy. (Mitchell et al., 1997, pp. 874-875)

In the case of DITIS, the dormant stakeholder is the government and other funding bodies that have shown an interest in the system. Because of their potential role in the future of the system, the project management team (university) should remain cognizant of such stakeholders. It is expected that the government's power will be exercised when there is a better recognition of the potentials of the system not only in cancer care but in the other health areas, too.

Dependent *stakeholders* **are those** "who lack power but who have urgent legitimate claims as 'dependent,' because these *stakeholders* depend upon others [e.g., other *stakeholders*] for the power necessary to carry out their will" (Mitchell et al., 1997, p. 877). Nurses represent this type of stakeholders. Their voice has mainly been represented through Pasykaf (management) itself, and, as it was found in the study, their interest in the system is predominantly for efficiency and accuracy in statistical analysis.

Dominant stakeholders are both powerful and legitimate. Their influence in the relationship is assured since by possessing power and legitimacy they form the dominant coalition. In our case, we find that Pasykaf itself belongs to this group of stakeholders as it represents the only host of the system. However, as a charity organization, it has been unable to fund the project itself and therefore its position has remained weak and the management team needs to look elsewhere for financial support. It is expected that when other funders are found, for example, the government, or with the commercialization of the system, the power of Pasykaf will be reduced as other host organizations will emerge, such as those for cardio-care support.

Other stakeholder groups that were identified in Mitchell et al.'s (1997) framework and shown in Figure 2 but not found in our own study are as follows:

- Discretionary stakeholders possess legitimacy, but have no power for influencing the firm and no urgent claims.
- Dangerous stakeholders possess urgency and power but no legitimacy; this may result in the use of coercive power.
- Non-stakeholders possess none of the attributes and thus do not have any type of relationship with the rest of the group.

Accordingly, it is found that in the case of DITIS there were five different distinct types of stakeholders. The diversity in their views, which is expressed in the reasons they give to the legitimacy of the system, as well as the perceived urgency and their ability to influence the system have all contributed to different degrees of support. In this study, apart from the commercial organization, all the other stakeholders have been positively supportive of the implementation process. They have been doing so differently, however, with some, such as the university team, taking a more active role in securing funding and hosting the project team whilst others, such as Pasykaf, remaining more passive. This passiveness is not, however, due to a lack of interest but rather due to other priorities.

FUTURE TRENDS

The potentials of mobile applications in e-health are tremendous. They could be used for supporting health professionals in offering care through improved e-tools (e.g., for improved access to patient records by all health professionals, improved collaboration, and streamlined workflow), which are especially useful for the community-care environment. However, even though mobile technology is a key factor for enabling the formation of geographically proximate medical teams at the point of care, their effective implementation depend not only on the level of support provided to users, but also by the extent to which there is a shared understanding and support among diverse groups of stakeholders.

An important contribution of this study is an examination of the role of diverse stakeholders on the implementation of such a novel e-health initiative. With a growing recognition that e-health can make an impact on the provision of healthcare as well as that e-health applications are becoming even more global, investigating the diversity that may exist among the various stakeholders is becoming vital for their success.

CONCLUSION

This chapter presents a longitudinal study on the implementation of an e-health mobile application, DITIS, which supports network collaboration for home healthcare. Our study has found that users' support has gradually improved over the last years as they have been increasingly exposed to the system capabilities and have recognized the advantages of the system in their day-to-day work for both administrative and consultation purposes. Another reason for this is that the nurses have gained participation in the project team with periodical meetings with the project manager and developers. Yet, the future of the system is uncertain as future funding to gain sustainability may not be available. Such a complex and novel system has not gained shared support by all parties concerned, with one company dropping out (while another one joined) and others not taking an active role. The long-term solution is commercialization, which is currently pursued, but as with any new ideas and products, there is considerable risk involved. The study has adopted the stakeholders' analysis (Mitchell et al., 1997) and found that there are different relationship characteristics among the key stakeholders who show diversity in interests, expectations, and levels of involvement in the system implementation.

DITIS has appeared to act as a useful fuel for improving patient records and promoting an integrated approach that has a direct impact on the quality of treatment and healthcare support to home-based cancer patients. However, even though this is a novel application and despite the fact that it was introduced 5 years ago, the implementation has remained slow and the system has not yet been able to secure its place and its future in the health sector; rather, it has gradually been making an impact on the healthcare support provided by some nurses and medical staff. Lack of organization ownership makes the future of the system uncertain. What has enabled it to survive was the enthusiasm of some key individuals, mainly the university team and those users who could see the direct benefits of the system on the quality of cancer care. Speedy commercialization of the system seems to be the solution for its long-term survivability, and this is the current focus. In the meantime, DITIS is at present being deployed for its healthcare collaboration and patient-management aspects in the context of two EU- (European Union) funded e-TEN (deploying Trans-European e-services for all) market validation projects (HealthService24 and LinkCare) involving trials for cardiac-patient monitoring.

APPENDIX

DITIS Implementation Project, May 2001

Please take a few minutes to answer the following questions. I would appreciate if you return the completed questionnaire to me by e-mail.

Thank you very much for your contribution.

Please tick that which most identifies your involvement in the DITIS project.

Designer/Developer: ☐
User (Nurse): ☐
User (Doctor): ☐
Other (please specify): ☐

What do you think the main benefits would be for implementing DITIS within Pasykaf?

After implementation, how do you expect DITIS to be used on a day-day to basis?

What would you expect the results of the pilot study to be? Please identify in your answer those factors that you think might enable or constrain the success of this pilot.

This work was previously published in Web Mobile-Based Applications for Healthcare Management, edited by L. Al-Hakim, pp. 101-117, copyright 2007 by IRM Press (an imprint of IGI Global).

Chapter 6.7

Business Associates in the National Health Information Network:

Implications for Medical Information Privacy

Edward J. Szewczak
Canisius College, USA

Coral R. Snodgrass
Canisius College, USA

ABSTRACT

This article examines the role of the business associate of healthcare providers (BAHP) in the National Health Information Network. Current Health Insurance Portability and Accountability legislation has little to say about BAHPs and their potential impact on medical information privacy. For the good of the business enterprise, managers who are BAHPs or who supervise BAHPs need to be aware of the potential pitfalls of ignoring medical information privacy and take a proactive stance in protecting medical information privacy within the National Health Information Network. Among the approaches that managers can adopt include creating legal contracts between a business and BAHPs, proactively adopting more effective transmission security technologies, and insuring that BAHPs properly dispose of medical information after their use. Such proactive approaches will help to insure that the business is protected against a serious data breach that may result in popular and/or legal challenges to the business.

INTRODUCTION

In his 2004 State of the Union address, President George W. Bush stated that, by computerizing health records, it would be possible to avoid dangerous medical mistakes, reduce medical costs, and improve medical care (The White House, 2006). Drawing on a report from the Institute of Medicine (2001) and on the conclusions of a panel of IT experts, Kaushal *et al*. (2005) reported that the creation of a national system of electronic health records and a National Health Information Network electronically connecting electronic heath records to healthcare providers, insurers, pharmacies, laboratories and claims processors will be possible at a cost of $156 billion. Four companies (Accenture, Computer Science Corporation, IBM and Northrop Grumman) have been selected by the Department of Health and Human Services to develop regional versions of the National Health Information Network with a view toward developing interoperability in the near future. A report from the Office of the National Coordinator for Health IT (Rishel, Riehl & Blanton, 2007) suggests that the National Health Information Network will be a: "network of networks" that will securely connect consumers, providers and others who have, or use, health-related data and services, while protecting the confidentiality of health information. The NHIN will not include a national data store or centralized systems at the national level. Instead, the NHIN will use shared architecture (services, standards and requirements), processes and procedures to interconnect health information exchanges and the users they support (p. 2).

Electronic health records contain an individual's medical information that can take many forms such as text, photographs, video, x-ray, sound, etc. One definition of information that is directly relevant to medical information privacy is data that have been evaluated to be relevant and useful for making particular decisions or classes of decisions (King and Epstein, 1976). Though the account was originally provided for the context of business management decision making, it is clearly applicable to the situation of various medical practitioners as well as a business associate of a healthcare provider (BAHP) such as an insurance agent, a billing agent, a consultant, or a transcriptionist. Generally speaking, a BAHP is anyone who works closely with a healthcare provider in non-treatment contexts in both healthcare related businesses as well as non-healthcare related businesses. (The term "private contractor" is also used to describe BAHPs in government, for example, by the Veterans Administration.) For example, a BAHP may be interested in developing patient profiles with a view toward customized marketing aimed at a particular profile or class of related profiles.

Despite government efforts to ensure medical information privacy, no comprehensive national strategy to safeguard medical information privacy has been developed and implemented (Koontz & Melvin, 2007). As such, the National Health Information Network poses a real threat to individuals' medical information privacy (Szewczak, 2007). This article considers the role of the BAHP in the context of the National Health Information Network, identifies potential threats to individuals' medical information privacy, and proposes solutions to management challenges presented by the current and future availability of medical information made possible by the National Health Information Network.

THE MEDICAL RECORD

Traditionally medical data were collected and stored as records in physician's offices and in hospitals. Often the data were recorded manually and retrieved manually. Patient data forms the medical record and its contents (Electronic Frontier Foundation, 1993). Medical records may contain patient personal data such as name, address, age, next of kin, names of parents, date and place of birth, marital status, religion, history of military service, Social Security number, and name of insurer. Medical records also contain medical data such as complaints and diagnoses, medical history, family history, previous and current treatments, an inventory of the condition of each body system, medications taken now and in the past, use of alcohol and tobacco, diagnostic tests administered, and findings, reactions and incidents. Records may also contain subjective information based on impressions and assessments by healthcare workers such as mental ability and psychological stability and status. In addition to data about the patient's current condition, a patient's medical record may also contain the results of genetic research and testing that enable predictions of future medical conditions and the prospects of developing specific medical problems.

Typically the creation and maintenance of medical records was done manually by healthcare professionals. But IT has changed this practice (Kilman and Forslund, 1997). Notes hand-written by doctors and nurses are being put into electronic form in the name of faster, more extensive access to needed information. Healthcare companies are competing to get doctors to write prescriptions over the Internet and to persuade people to place their personal health records on the Internet (Consumer Reports, 2000). Companies have made available software that an individual can use to create an Internet-based "personal health record" that can be used to organize family medical histories, including medical conditions, medications and allergies. These personal records may be transmitted to healthcare professionals over a computer network (Rubenstein, 2005; Lawton & Worthen, 2008).

Medical records are available online to medical practitioners for the purposes of decision making and improving healthcare as well as medical research. They are also available to other users and institutions in non-treatment contexts. Medical records are used to conduct federal government-mandated medical community audits of physician competency and performance. They are also used by insurance companies in the assessment of an applicant's eligibility for health and life insurance and in claims processing to detect medical fraud. Medical information is also used by private employers, educational institutions, credit investigators, and law enforcement agencies for a variety of non-medical reasons. It is in these non-treatment contexts that the BAHP plays an important role.

MEDICAL INFORMATION AND PRIVACY

Cate (1997) identified a number of conceptions of what constitutes privacy from the literature. Privacy has been viewed as an expression of one's personality or personhood, focusing on the right of the individual to define his or her essence as a human being; as autonomy – the moral freedom of the individual to engage in his or her own thoughts, actions, and decisions; as citizens' ability to regulate information about themselves, and thus control their relationships with other human beings; and as secrecy, anonymity and solitude. In the area of medical information, the definition of privacy as "the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others" (Westin, 1967, p. 7) is appropriate. This article will focus on medical information exclusively, though the problems and challenges of information privacy are not necessarily unique to medical information (Szewczak, 2009).

The Westin definition is consistent with the confidential relationship between doctor and patient. Confidentiality refers to how data collected for approved purposes will be maintained and used by the individual, group or institution that collected it, what further uses will be made of them, and when individuals will be required to consent to such uses. In this regard, privacy may be construed as a balance struck by society between an individual's right to keep information confidential and the societal benefit derived from sharing the information for the purposes of medical research and public health management, and how the balance is codified into legislation giving individuals the means to control information about themselves (Office of Technology Assessment, 1993; Rindfleisch, 1997).

As personal information, medical information has a special status. As Krzysztof & Moore (2002) observe:

Medical information about the individual patient is considered highly private, and the general public is extremely fearful about disclosure…. We all enjoy the benefits of medical research conducted on other patients, but we are very often reluctant to contribute or release our own information for such purposes. When medical data are published it is expected that the researchers will maintain the dignity of the individual patient, and that the results will be used for socially beneficial purposes (p. 15).

This observation has been supported by various public opinion polls conducted since 1993 that have uncovered a basic concern people have about the privacy of their medical records and how these records may be used (Electronic Privacy Information Center, 2006). Major areas of concern are:

- Employment/career advancement. People are concerned that employers may use personal health information to limit job opportunities. They are also concerned that medical information will be used for many non-health purposes, such as determining promotions and job advancement.
- Insurance eligibility. People are concerned that insurance companies may use personal health information to deny an application for various kinds of insurance coverage (e.g. medical insurance such as long-term disability insurance).
- Computerized versus paper records. The trend toward computerizing the healthcare system and keeping records electronically threatens medical information privacy. People feel more secure when medical records are kept in paper form.
- Genetics research. People do not want medical researchers to be allowed to study an individual's genetic information without obtaining the individual's consent.
- Medical records security. People feel protecting the confidentiality of medical records is essential to healthcare reform. Weak data security may lead to leaks of sensitive health information. People also think that insurance companies get more information from doctors than is needed.
- Mistrust of government. People worry that existing federal health privacy rules protecting patient information may be reduced or ignored in the name of efficiency. In addition, people fear that government agencies and researchers are allowed to see medical records without a patient's permission.

One might think that legislation addressing the issues and problems of safeguarding medical information would have solved many of the problems involving the mishandling of medical information. However, the effectiveness of legislation in establishing and maintaining medical information privacy is questionable at best, despite legislative efforts to the contrary. Federal and state governments have attempted to deal with privacy issues in ways that satisfy the needs of various stakeholders such as doctors, insurance companies, researchers, law enforcement, and data processing firms as well as individuals. The result has been various legislative measures that provide legal compromise. For our purposes, the most significant measure is the Health Insurance Portability and Accountability Act (HIPAA) of 1996.

HIPAA provides the first comprehensive set of federal regulations of health information. It provides for two rules related directly to medical information privacy: the Privacy Rule (45 Code of Federal Regulations 164.500 – 164.534) (Federal Register, 2002) and the Security Rule (45 Code of Federal Regulations 164.103 – 164.318) (Federal

Register, 2003). It is the Privacy Rule that is most relevant to the issue of medical information privacy. The Security Rule will be discussed briefly later in this article in a discussion of transmission security technology as a management challenge. Interested readers are referred to the Health Information Technology website of the Department of Health and Human Services (www.hhs.gov/healthit/healthnetwork/background/) for current details of the National Health Information Network technical implementation.

The HIPAA Privacy Rule provides the federal floor of privacy of protected health information in the U.S. It only applies to medical records maintained by "covered entities" (healthcare providers, health plans, and health care clearinghouses/data processing firms) in any form (electronic or non-electronic, including oral). It allows more stringent state laws to continue in force. An individual has a number of rights under the Privacy Rule including the following (adapted and expanded from Electronic Privacy Information Center, 2008):

To access, inspect and copy protected health information held by hospitals, clinics, health plans and other "covered entities" with some exceptions

To Request Amendments to Protected Health information held by Covered Entities. To request an accounting of disclosures that have been made without authorization to anyone other than the individual for purposes other than treatment, payment and "health care operations" (i.e., medical practice evaluations for accreditation conducted by organizations such as the Joint Commission for the Accreditation of Healthcare Organizations and the National Committee for Quality Assurance)

To Request Restrictions on Uses and Disclosures of Protected Health Information. The HIPAA Privacy Rule does not prohibit the disclosure of protected health information when such disclosure is required or permitted by other federal law. For example, the Gramm-Leach-Bliley Act does not prohibit the sharing of information among affiliated companies (such as banks and brokerages, which are not covered entities). So an individual's credit card account transactions may include data about where an individual goes for healthcare, and this data may be shared among affiliated companies and is not protected by HIPAA. The HIPAA Privacy Rule also explicitly includes exceptions to the rules for use and disclosure. In fact, there are a number of uses and disclosures of information for which an authorization or opportunity to agree or object is not required (for example, for judicial and administrative proceedings, and for law enforcement purposes), including the use of protected health information for marketing purposes (which, according to the Department of Health and Human Services, may be too difficult to distinguish from treatment purposes) (Privacy Rights Clearinghouse, 2007).

The HIPAA Privacy Rule is particularly difficult to implement when it comes to managing BAHPs under contract who perform an action on the healthcare provider's behalf and to whom the healthcare provider is releasing protected health information. These business associates often have free access to a patient's protected health information. They include people such as insurance agents, billing agents, consultants, and transcriptionists. If a healthcare provider discovers that a BAHP has breached or violated a contract with respect to safeguarding protected health information, the healthcare provider must take reasonable steps to remedy the problem or terminate the contract. If the contract cannot be terminated, the healthcare provider must report the problem to the Office of Civil Rights, which may exact civil penalties against the business associate. Criminal penalties can approach $250,000 and/or 10 years imprisonment if the offense is committed with intent to sell, transfer or use protected health information for commercial or personal gain, or for malicious harm (Federal Register, 2006; Wilson, 2006).

However a healthcare professional may not know that a BAHP has breached or violated a contract with regard to safeguarding protected health information. Because HIPAA does not prohibit the sharing of protected health information among various covered entities or their BAHPs, protected health information could be used in ways other than for treatment or billing. For example, an individual could be charged higher loan rates because of some piece of data in his/her medical record, and it would be impossible to prove the data were shared because there is no required disclosure audit for non-covered entities.

In addition, data networks may be Internet-based and global in reach. Individual health records may be transmitted overseas and handled by a subcontractor (a kind of BAHP) in ways the individual is completely unaware of and would object to under any circumstances (Consumer Reports, 2006; Ferris, 2008).

Another related security challenge is the data breach. A hacker, a BAHP, an ex-employee, or even a trusted employee can steal data from a computer system and offer them for sale to interested parties. Data breaches are not all that uncommon in today's technology-oriented world. A case in point is the 2005 LexisNexis data breach with 310,000 possible consumers affected. In some cases computer programs were used to generate IDs and passwords matching those of legitimate customers. In other cases hackers used computer viruses to collect IDs and passwords from infected machines as they were being used (Washington Post, 2005). Another case is the 2007 TJX data breach with 45.6 million credit and debit card numbers stolen over a period of 18 months by an unknown number of intruders. TJX was hit by several lawsuits after disclosing the data breach. It settled many of the suits to a total of about $250 million (Computer World, 2007, 2008).

Finally, if the history of dotcom business is any guide, companies that run into financial difficulties may choose to sell customer data to meet obligations, even though the companies have published privacy policies. As the following details, such customer data may contain individuals' medical information.

PUBLICLY AVAILABLE SOURCES OF MEDICAL INFORMATION

There are a number of sources of an individual's medical information, including medical databases, company and government databases, public records, and consumer volunteered information. In the case of databases, the information is structured formally so as to facilitate system organization and maintenance. In instances when database organization is lacking, the information will be stored in unrelated files. All of these sources will be accessible in the National Health Information Network.

Medical databases will be major sources of medical information on the National Health Information Network. However a database is implemented, the electronic health records comprising it will be accessed by many interested parties over the National Health Information Network.

One of the largest central databases of electronic health records is the Medical Information Bureau (MIB). It is shared by insurance companies to obtain information about life insurance and individual health insurance policy applicants. If the applicant reports a condition that the insurer considers significant, or if the results of a required examination, blood test, or urine test raise questions for the insurer, the insurer will report that information to the MIB. MIB electronic health records consist of codes indicating a particular condition or lifestyle (such as the individual smokes cigarettes). As such, MIB does not include the totality of an individual's medical record (Privacy Rights Clearinghouse, 2007).

Another example is the Children's Hospital of Philadelphia (CHOP). CHOP is collecting DNA profiles on as many as 100,000 child patients in order to develop an anonymous database that researchers can use to study children's genetic profiles. Research results may reveal which genes underlie problems affecting children such as diabetes, obesity, asthma and cancer. This research could lead to the development of diagnostic tests and drugs. By linking genetic information to electronic health records, CHOP may obtain research funds and patents and forge partnerships with drug companies (Regalado, 2006).

Another recent development in the storage of medical information is the creation of electronic warehouses by Microsoft and Google where individuals can store their health records and make them available to health care providers. Neither company is considered a covered entity, so neither is subject to HIPAA rules (Steinkraus, 2007).

There are a number of benefits as well as disadvantages of medical databases (U.S. Department of Education, 2006). Among the benefits are:

- A patient's medical information would be immediately available to an attending doctor, including life saving information
- Researchers would be able to track certain diseases as well as patients' responses to certain drugs
- Medical databases would allow for better organization and more legibility of medical files
- Electronic health records may be more secure than paper records since security systems can monitor medical databases

Among the disadvantages of medical databases are:

- Employers may access medical information about their employees which they might use to deny employment or job advancement
- Insurers may use medical information to deny insurance to people they consider to be high risk
- Digitizing medical records will allow many more people legitimate access to medical records, with the increased possibility that the information may be misused by one or more of them

It is important to note that, in general, inaccuracies in databases are widespread and that the ability of individuals to detect these inaccuracies is limited (Straub & Collins, 1990). In addition, the problem of missing values – values accidentally not entered or purposely not obtained for technical, economic or ethical reasons – is widely encountered in medical databases since medical data are collected as a byproduct of patient care activities rather than rigorously collected and evaluated for use in research (Krzysztof & Moore, 2002). These inaccuracies and omissions only accentuate the disadvantages of medical databases.

Inaccuracies also exist in non-medical databases. It appears likely that businesses may acquire medical information that is contained in company databases as a result of acquiring these databases in the course of merger/acquisition activities. It is also likely that they may also have access to medical information in other companies' databases in the course of maintaining friendly strategic alliances with these companies. In addition, BAHPs are in a position to collect and store medical information in company databases for use in business decisions (for example, determining loan rates). As was discussed earlier, HIPAA does not prohibit the sharing of protected health information among various covered entities or their BAHPs. There are a number of security risks to medical information may come from inside a business as well as from external sources. Though a BAHP may try to safeguard an individual's medical information privacy, it may be jeopardized by a number of internal security risks such as accidental disclosures, insider curiosity, releasing medical information to outsiders for revenge, spite or profit, and uncontrolled support functions (Rindfleisch, 1997).

Government databases at the federal, state and local levels contain personal (including medical) information. The federal government maintains electronic files on hundreds of millions of Medicare claims. State governments collect and store medical data on their citizens, including registries of births, deaths, immunizations, and communicable diseases. Many states mandate collection of electronic records of every hospital discharge, and maintain registries of every newly diagnosed case of cancer. Most of these databases are available to any member of the public who asks for them and can operate the database software required to read and manipulate them (Consumer Reports, 2000).

Although many of these government database records are stripped of information which could be used to identify individuals (such as Social Security numbers), it is still possible to link the records to private sector medical records using standard codes for diagnoses and procedures employed by the United States healthcare system. The codes are usually included on insurance claims and hospital discharge records. In addition, a patient's anonymity may be compromised by the fact that personally identifiable health information is needed for a variety of research purposes (e.g. to check for duplicate records or redundant cases, and for longitudinal studies) (Electronic Privacy Information Center, 1999). Straub & Collins (1990) relate how a user can retrieve information about a specific person from large statistical databases with a small number of unsophisticated queries. As a case in point, a computer privacy researcher at Carnegie Mellon University was able to retrieve the health records of the governor of Massachusetts from an "anonymous" database of state employee health insurance claims by knowing his birth date and ZIP code. The researcher demonstrated that she could do the same for 69% of the 54,805 registered voters on the Cambridge, MA voting list (Consumer Reports, 2000).

Electronically available public records (e.g. court records) are also a source of an individual's medical information (Ogles, 2004). An individual's medical record may be entered into court documents (say, if an individual sues over payment claims) which are available on-line. Public records also have a connection to junk mail, since state counties have sold information from public records to commercial companies that then repackage it and resell it to other companies and individuals (Leach, 2004). Junk mail in itself may not be overly troublesome to an individual. But what these companies and individuals may do with public record information in addition to creating and sending junk mail is cause for some concern.

Much personal health information that is available to the public is volunteered by individuals themselves, by responding to 800 numbers, coupon offers, rebate offers and Web site registration. The information is included in commercial databases like Behavior-Bank sponsored by Experian, one of the world's largest direct-mail database companies. This information is sold to clients interested in categories of health problems, such as bladder control or high cholesterol. Drug companies are also interested in the commercial databases (Consumer Reports, 2000). With the implementation of the National Health Information Network, this interest will be heightened as hospitals link up electronically with doctor offices' records (Landro, 2006).

BAHP often want access to medical information for data mining purposes. Data mining of medical data offers the health care industry the ability to address issues related to fraud detection and abuse, to profitability analysis, to patient profiling, and to patient retention management (Payton, 2003). However, patients are often unaware that their medical information is being used for data mining purposes, making it unlikely that patients will object to the practice. The challenge to organizations that conduct data mining with medical information is how to respond when and if patients become aware of the data mining. For some patients, the awareness will make no difference; for others, the reaction may be very negative.

MANAGEMENT CHALLENGES OF MEDICAL INFORMATION

Since companies have relatively easy access to individuals' medical information, the adequate protection of the privacy of this information must be considered an important management challenge, especially in the context of the National Health Information Network.

For healthcare-related businesses, the requirement to safeguard patients' medical information is specified by HIPAA. In their dealings with BAHP, healthcare-related businesses should create legal contracts between the business and any BAHP given access to individually identifiable medical information requiring the BAHP to safeguard the data. Ongoing internal review of data access records should be performed in order to uncover possible security violations (Saul, 2000).

For businesses in industries other than healthcare, the challenges center on how to adequately safeguard an individual's medical information acquired in mergers/acquisitions, from public records, from customer volunteers, or simply in the course of doing business (for example, hiring new employees). Though it is not required by law, businesses should attempt to respect as much as is relevant and possible the rights of individuals under the HIPAA Privacy Rule. In particular, businesses should honor individual requests to restrict the use and disclosure of medical information. It is not simply a matter of behaving ethically. Calculating the impact of a potential loss of medical information from a security breach is very difficult. Customer backlash in response to a business' failure to safeguard medical information is a very real and potentially costly possibility (e.g. a grassroots protest in the form of a boycott of a company's goods and services). Another possibility is an expensive class action lawsuit that could last a protracted period of time and result in monetary damages. Given how strongly people feel about the privacy of their medical information, either form of customer reaction could also damage the business' public reputation, especially if the reaction attracts the attention of the various news reporting agencies.

In addition, proactive managers should take the initiative in surpassing HIPAA in two important areas: use of transmission security technology, and treatment of BAHPs. In fact, the proactive manager will intentionally surpass the baseline requirements of HIPAA, thereby realizing the enhancement of individual medical privacy protection.

Use of transmission security technology. The HIPAA Security Rule (45 Code of Federal Regulations 164.103-164.318) provides security standards and implementation specifications for three kinds of safeguards (administrative, physical and technical) to protect protected health information in electronic form. It also divides the implementation specifications into required and addressable (i.e., not required but recommended). Covered entities have a certain amount of flexibility in implementing addressable specifications. In deciding which security measures to adopt, the covered entity must consider its own size, complexity and capabilities, its technical infrastructure, hardware and software security capabilities, the costs of the security measures, and the probability and criticality of potential risks to electronic protected health information. For example, covered entities may choose to adopt encryption as a technical safeguard for the transmission security standard, but since encryption is given as an addressable implementation specification, it is not required by HIPAA but simply recommended.

HIPAA is not specific as to the exact technology that should be used to implement transmission security, since technology changes and progresses in ways that are difficult to predict. The current implementation of transmission security will most likely involve the use of firewalls, user authentication, encryption/decryption, anti-virus software, and anonymizers (Cheng & Hung, 2006). These implementation choices will be replaced as newer and more effective technologies become available.

The proactive manager should actively pursue the most effective transmission security technologies available, and not simply wait for Congress to update HIPAA with respect to more effective technological requirements.

Treatment of BAHPs. Any amended HIPAA legislation should explicitly consider the role of BAHPs in safeguarding medical information privacy. For healthcare-related businesses, the requirement to safeguard patients' medical information is specified by HIPAA. This includes the following activities (Saul, 2000):

- Develop policies to evaluate and certify that appropriate security measures are in place in the business
- Create legal contracts between the business and any business associates given access to individually identifiable medical information requiring the business associates to safeguard the data
- Develop contingency plans for response to emergencies, in a data backup plan and a disaster recovery plan
- Establish a system of access control that includes policies for the authorization, establishment and modification of access privileges
- Perform ongoing internal review of data access records in order to uncover possible security violations
- Supervise systems personnel responsible for systems maintenance activities
- Train system users in system security, including user education on virus protection, monitoring login failures, password management, and how to report discrepancies or suspicious activities
- Establish termination procedures for when an employee leaves the business (voluntarily or involuntarily) or whose data access privileges are revoked

For non-healthcare-related businesses, while BAHPs are bound by HIPAA regulations that limit their use of medical information to what they need to provide their services to the contracting agency, stricter rules are needed to ensure that the information is properly disposed of after use. Though data breaches are not always caused by BAHPs, the keeping of data long after their usefulness is ended could result in a data breach affecting many innocent people. Though BAHPs may be technologically savvy in their use of National Health Information Network technology, this may not always be the case. Despite a BAHPs best intentions, data breaches may be the result of a BAHP not having the technical or procedural skills to safeguard medical information in the environment of an emerging technology. Managers must be wary of a BAHP's technical competence and demand proof that the BAHP is qualified to effectively safeguard medical information.

Lastly, management of the relationship with BAHPs becomes even more problematic when the BAHP is located outside of the United States. There is ample evidence to show that there are substantial differences among nations concerning the value of privacy and the sanctity of respecting the legal obligations to control access to information. As an example, the most recent review by the United States Trade Representative's office on the protection of intellectual property rights cites continued and excessive violations of intellectual property in many of the same countries where many BAHPs are located (Office of the United States Trade Representative, 2008). This is in spite of years of work by the World Trade Organization to protect intellectual property and very stringent rules and penalties written into all new trade agreements. Thus it would seem unlikely that simply relying on written agreements to protect medical information would be prudent. Managers are advised to be very careful in choosing companies outside of the United States for the handling of medical information.

There are sources of information that can be used to assess the potential for the loss of control of medical information. International organizations, such as the World Bank, maintain websites that report on assessments of riskiness for ventures in various parts of the world (World Bank, 2008). Universities, such as Michigan State University, also maintain websites that provide information on the state of international business activities around the world (Michigan State University, 2008). Trade Associations also maintain directories of subcontractors. Managers are well advised to visit all such sources of data before entering into a relationship with a firm outside the United States.

CONCLUSION

Given the potential for mishandling medical information acquired in the course of doing business, management must exercise vigilance in the safeguarding of this information. Though many businesses are not typically interested in acquiring and dealing with medical information, the possible negative consequences of mishandling medical information that is acquired from various sources cannot be ignored. This basic reality will only become magnified once the National Health Information Network is implemented, making it technologically possible to inadvertently disseminate medical information nationally as well as internationally. Companies whose employees act as BAHP in various capacities must be particularly vigilant to ensure the integrity of individuals' medical information. Management must move to preempt negative consequences before serious damage to the reputation of the business occurs as a result of BAHP mishandling medical information.

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of health information systems, which include issues related to privacy, security, and quality. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters address the impact of privacy legislation on patient care, quality assurance approaches to healthcare, and improving the quality of healthcare research data sets. Overall, contributions within this section ask unique, often theoretical questions related to the study of health information systems and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1

Exploring Information Security Risks in Healthcare Systems

Amy Ray
Bentley College, USA

Sue Newell
Bentley College, USA; Warwick Business School, UK

INTRODUCTION

The volume and severity of information security breaches encountered continues to increase as organizations, including healthcare organizations, struggle to identify more effective security policies and procedures. Publicly available guidelines such as GASSP or ISO17799 that are designed to facilitate development of effective security policies and procedures have been criticized for, among other things, inadequate attention to differences in organizational security needs (Baskerville & Siponen, 2002), and for inadequate attention to the social dimensions of security problems (Dhillon & Backhouse, 2001). In this contribution, we argue that the diversity of organizational security needs, as well as the need to recognize the social dimensions to security problems, will continue to grow as companies move away from employing unique, proprietary approaches to software and network development, in favor of adopting standards-based plug-and-play applications, and related standards-based methods and technologies designed to enable interorganizational as well as local systems interoperability.

We use complexity science and adaptive structuration theory to support our arguments that current security management policies and procedures focus on what technologies are used, and on planned systems use to the exclusion of unplanned—but real—emergent use and emergent development of systems. A more holistic approach to security that adapts to emergent systems developments—and most importantly, addresses alternative, emergent uses of systems—is needed, we argue. Throughout the article, we use examples from the healthcare sector to illustrate our points. We do this because Electronic Health Record (EHR) systems that will enable information to be shared across a variety of organizations (local doctors' offices, hospitals, health insurance providers, research organizations, and so on) and users (doctors, administrators, nurses, researchers, and so on) are at the early stages of adoption in many countries, so that much can be gained by starting with an informed view of what can lead to security risks, so that policies and practices are adopted that can protect the information that is being shared.

BACKGROUND

Software development has been described as a "craft" industry, because software applications are developed one at a time, and labor is by far the most significant cost of any development project. Various *standards*—or generally agreed-upon activities, methods, functions, protocols, interfaces, systems, equipment, materials, services, processes and products (De Vries, 2005)—have been introduced and employed in efforts to reduce the labor costs associated with IT projects, especially in terms of standards designed to facilitate creation of Web applications (e.g., TCP, HTML, HTTP, XML, SMTP, UDDI, SOAP).

These standards are generally referred to as Web standards or Web-based standards, and their power to provide interoperability between two or more systems has been established for decades. However, while these standards have benefits, it is important to recognize that using standards has an unintended consequence. More specifically, it can be argued that, as a result of *successful* use of Web-based standards for local systems development and systems integration, overall systems architectures are more complex, ultimately resulting in an environment of greater information security risk. In the next section, we explain why standards-based development and integration increase the overall complexity of the systems architecture, and subsequently consider how this influences emergent use and architectural complexity, and so information security risk.

INFLUENCES ON ELECTRONIC HEALTHCARE RECORD SECURITY

IT Standards-Enabled Planned Systems Development and Complexity

At a local level, using IT standards simplifies the process of connecting one computer to a network of other computers. For example, employing Web standards, countless computers and computing devices around the world are connected, making the Web infinitely multidimensional and nonlinear. However, while Web standards simplify individual systems integration efforts, they potentially increase the complexity of the overall system architecture by enabling connections among heterogeneous systems.

Complex systems are defined as systems that interweave components in such a way that they display variation without being random, and result in a structure that is more than the sum of its parts (Lissack & Roos, 2000). Complexity science research has shown that many highly complex systems—including systems as diverse as the central nervous system, the biosphere, the stock market, telecommunications systems, and human immune system—are not only multidimensional and nonlinear, but are also made up of many selfsimilar components or properties that, in turn, enable development of more complex systems. EHR systems are good examples of such complex systems.

A number of healthcare data standards (e.g., medical code, individual and entity, and transaction processing standards) are now in place for electronic transmission of administrative data as a result of the Health Insurance Portability and Accountability Act of 1996 (HIPAA). Insurance claims data for a patient may be filed on a laptop computer or handheld device in a physician's office, processed by a claims manager from a terminal at an HMO, and otherwise accessed from any authorized device by a user with legitimate (or stolen) authorization. The challenge of mapping the network of authorized access points to HIPAA information grows as the network grows, and the network grows as the application of standards grows. In addition, in order to comply with HIPAA, many healthcare organizations have outsourced claims processing to healthcare clearinghouses (Ivans, 2003), increasing the complexity of the flow of data, as well as increasing the number of individuals with access to patient data. Thus, applying HIPAA transaction standards to systems integration efforts in healthcare simplifies the process of filing an insurance claim, but increases the complexity of the overall network architectures in healthcare.

Web Standards and Emergent Systems Development and Use

In an organizational or interorganizational context, Web-based standards are used to develop information systems applications in support of particular business processes. However, considerable research now exists which illustrates how actual use of IT is often different from the intended use. Users improvise by adding applications to the original system in order to support local practices (Ciborra et al., 2000; Pozzebon & Pinsonneault, 2005), and/or by simply using the system in ways not initially anticipated (Orlikowski, 2000). structuration theory (ST) (Giddens, 1979) and adaptive structuration theory (AST) (DeSanctis & Poole, 2004) are proven as useful frameworks for demonstrating how technologies are adapted and used by individuals within organizations. ST and AST address how social structures are changed via the interaction between a user and a technology, thus helping to explain the emergence and evolution of system use. In this sense, the real nature of a technology and its consequences emerge from the actions of individuals as they engage with and use the technology in practice (Orlikowski, 2000). These consequences can only partially be planned for in advance, and will vary across time and space as context, history, and process impacts the ways in which users develop knowledge through their reflective practice with the technology.

We again turn to healthcare to provide another example of this phenomenon. Since EHR are typically enabled by Web-based—as well as propriety—standards, and are employed by a highly diverse set of users, they are prime candidates for emergent development and use. EHR are designed to support documentation of clinical healthcare. However, physicians, researchers, nurses, insurance company employees, pharmacists, and many others are users of these systems, so it is reasonable to expect that different uses of the systems will emerge across user groups. For example, insurance companies are in the very early stages of adopting pay-for-performance systems to reward physicians based on information collected from EHR about the efficacy and efficiency of care provided to patients. Similarly, researchers are searching for new opportunities to use data available in the standardized, categorized formats enforced by EHR. In fact, EHRs are actually examples of emergent systems' development efforts as they emerged from foundational efforts to create standards for HIPAA (Fedorowicz & Ray, 2004).

The following are examples of simple, emergent uses or developments that can have a dramatic impact on the complexity, and thus manageability, of the overall information systems:

- A nurse adds a wireless network within a department without notifying the IT personnel.
- An individual doctor loads a set of organizational data on a USB drive to take home and analyze on a home computer.
- A sales manager finds that an application designed for one use (repeat orders) is also useful for another purpose (individualized marketing).

The purpose of these examples is to show that system connections and uses are dynamic, rather than to say that they cannot be secured. If uses are known, then effective security policies and procedures may be put in place. However, in an environment where uses are regularly and frequently emerging, existing security policies and procedures may quickly become inadequate, as discussed in the following section.

Architectural Complexity and Information Security Risk

We have presented arguments that standards-enabled systems development and integration methods ultimately increase the complexity of organizational systems' architectures, and support unintended emergent systems development and use. Current security frameworks do not factor in the consequences of emergent systems and system uses, which exacerbates problems noted by other researchers of inadequate attention to differences in organizational security needs (Baskerville & Siponen, 2002) and inadequate attention to the social dimensions of security problems (Dhillon & Backhouse, 2001).

The use of well-understood standards to develop uniquely complex systems creates a triple threat for security managers. First, standards are well-documented and well-understood, which means that any known flaws are typically documented. Documented flaws, for example the ability to exploit knowledge about the IP standard to spoof an IP address, means that hackers—as well as security professionals—have access to this knowledge. Second, the growing complexity of overall systems architectures that result from standards-enabled extension and integration translates into decreasing abilities to understand and manage systems. Since security managers may not even be aware of emergent systems developments and uses, rendering the ability to set effective policies for secure use impossible. Third, the complexity of systems in an environment where systems managers may not be aware of every development and use can contribute to an insecure environment by allowing hackers more points of access to exploit, as well as potentially providing more opportunities to cover their tracks when using unknown access points into systems.

Information security guidance is typically either strategic-level guidance based on organizational goals and primary uses of data, or focused on highly detailed technical issues, such as protecting access points with effective passwords, protecting networks with properly configured firewalls, and appropriate use of encryption. The latter category dominates organizational spending, and using terminology from complexity theory may be referred to as a reductionist approach where security management strategies involve application of solutions to small fractions of a system at a time (e.g., passwords to secure access to an application, firewalls to protect network traffic, and so on). Evidence suggests that reductionism also drives IT security investment (Ernst & Young, 2005). Even strategic security guidance such as HIPAA and ISO17799 make recommendations based on consideration of methods for securing systems components rather than considering the vulnerabilities based on alternative uses of technology, or from considering risks associated with the overall architectural choices supporting the information systems infrastructure. Reductionism is clearly necessary, but it is also increasingly insufficient for effective security management, because, as we have demonstrated in this contribution, it ignores the ways in which systems architectures and uses are dynamic and increasingly complex.

FUTURE TRENDS

In most countries, national health record development efforts are in their early stages, so there is time to consider the full gamut of potential risks, and to design these systems with appropriate measures of protection, both technical and organizational. However, there is little research that has focused on the creation of security policies in contexts that are emergent, rather than static (Baskerville & Siponen, 2002). Instead, most approaches to security, as we have seen, are reductionist in nature. These reductionist approaches are always going to be limited for the reasons discussed above. Instead, what seems to be important is to develop holistic approaches to security, which encompass social, as well as technical, elements, and which is dynamic, so that security issues are considered each time a new use is adopted, even if this use is not formally instigated. This could include, for example, dynamic monitoring for changes in systems architectures, and comprehensive training to not only educate users about risks from intended uses of systems, but to also provide them with methods for considering risks associated with emergent uses of systems.

In considering how this could be approached in an organizational context, it is important to identify who will be responsible for championing this more holistic approach. One new management position in many organizations with complex systems is the Information Systems Architect, whose job responsibilities include approving new systems development projects, and using whatever tools and processes are necessary to remain knowledgeable about the true architecture of the existing information system. For example, the information systems architect might employ network monitoring tools on a regular basis to ensure that rogue wireless networks are identified and appropriately controlled. We suggest here that either the Information Systems Architect also have security management responsibilities, or that key security managers such as Chief Security Officers at least occasionally adopt a practice of considering security risk management from a holistic perspective to complement existing reductionist security policies and practices. We further suggest that much work needs to be done to ensure that security policies are reviewed and updated frequently, and that appropriate steps are adopted for ensuring that security policies and practices are as adaptive as the complex, emergent systems they must protect. A good starting point is to consider developing metapolicies for adaptive development of security policies, and when they are needed (Baskerville & Siponen, 2002). In keeping with our analysis, it is also important to emphasize the principles of security management during training, so that the various users of complex systems such as electronic health record systems will build in their own security practices as the system evolves, even when the emergent applications have inherent security gaps. Metapolicies would be useful for establishing this practice as well. Research exploring the best ways to achieve this holistic understanding and appreciation of the importance of securing data in large complex EHR systems is clearly going to be an important challenge for the future.

CONCLUSION

Our research contributes to the literature by demonstrating the potential domino effect of Web standards-enabled systems integration and development efforts. Standards facilitate rapid development of planned and emergent systems, but can ultimately lead to overall systems architectures that are very complex to manage. When this happens, organizations are at increased risk of security breach. Including security features in individual application design will only be effective to the extent that the interactions between multiple applications in the larger system have all been anticipated during the design process, and that the system is used only in ways that were originally intended. As our contribution suggests, neither of these conditions is very likely. This suggests the need for a more holistic approach to security management.

We have presented numerous examples in this article to support our analysis, but much research is still needed. We believe such research is critically important, given the early stages of Web standards-enabled systems development efforts and the potential for either tremendous gain or tremendous chaos, especially in the context of highly complex interorganizational healthcare systems. This research agenda is not only theoretically important, but also tremendously important from a practical point of view, especially in industries where data processed is of a sensitive nature, such as in healthcare. Here, the development of electronic heath record systems that connect a wide variety of disparate organizations and users is in its infancy. Developing approaches now which can help to secure these systems from security breaches is likely to provide huge cost savings, avoiding, for example, litigation claims when a patient's data has been inappropriately divulged, or simply human misery when an individual is unable to get a job because an unethical employer has managed to extract some private data from a health record. Research which can identify approaches to security management that take into account the problems associated with system complexity, as outlined in this article, would thus be very timely.

KEY TERMS

Complex Systems: Systems that interweave components in such a way that they display variation without being random, and result in a structure that is more than the sum of its parts.

Complexity Science: The study of complex systems, broadly defined.

Emergent Use: The use of systems in ways not initially anticipated, stimulated by users improvising to add applications to the original system in order to support local practices. Emergent use can be planned or unplanned.

Holistic Information Security Approaches: Security management strategies that encompass social as well as technical elements, and which are dynamic so that security issues are considered each time a new use is adopted, even if this use is not formally instigated.

IT Standards: Generally agreed-upon activities, methods, functions, protocols, interfaces, systems, equipment, materials, services, processes, and products that have been introduced and employed, in efforts to reduce the labor costs associated with IT projects.

Metapolicy: Establish how policies are going to be created in an ongoing way.

Reductionist Information Security Approaches: Security management strategies that apply solutions to small fractions of a system at a time (e.g., passwords to secure access to an application, firewalls to protect network traffic, and so on.).

Chapter 7.2

Security-Aware Service Specification for Healthcare Information Systems

Khaled M. Khan
Qatar University, Qatar

INTRODUCTION

With the rapid advancement of Web-based technologies, healthcare information systems are becoming increasingly heterogeneous in terms of their architecture, composition, and runtime characteristics. A healthcare system can be composed of several stand-alone service components, such as Web services available from various distributed sources for runtime execution. We use the terms *Web services* and *service* interchangeably in this chapter to refer to the same concept. A healthcare application system can be composed of multiple autonomous geographically dispersed software services. A healthcare software service is autonomous as it has its own executable code and uses its own data or files. The composition of a healthcare system can be dynamic or static, depending on how services are connected to each other to provide the services. Some of the services are downloaded directly from the Internet and executed dynamically with the application system. The use of independent services in the healthcare information system is appealing because it supports reusability of code and far efficient utilization of network resources, and it might be cost efficient.

Despite the benefits and usefulness of service computing, the characteristics of third-party services also present tremendous challenges for healthcare information security. As services are reused in far greater scale, there is a need for ensuring the security properties of third-party services to the composite healthcare system. Security is a systemwide property referring to the entire system composed of several services. Security architecture alone at the individual service level cannot protect a system unless the conformity of the security properties is checked with the enclosing application system in terms of required and ensured security properties. This issue of conformity of security properties between the individual service and the enclosing healthcare system has far-reaching implications because failure of this would seriously undermine the privacy of the patients and the reliability of the healthcare providers. Let us give a brief scenario (Han & Khan, 2006) in order to magnify the seriousness of the issue.

Consider a Web service that can generate various test data such as X-ray data, MRI images, CT scan images of the patients, and so forth. Another Web service uses these data as input and generates diagnosis reports to other Web services, which could ultimately produce prescriptions and prognoses of the patients' problems. Finally, the prescriptions are sent to another Web services that supplies medicines to the patients. In this scenario, we can see that the confidentiality and integrity issues of patient data are critical. Similarly, the authenticity of the service provider is an important issue, because the generated output of one service determines the outcome of the treatment produced by another service. Note that all these services are completely independent in terms of their development, their formation, and, most importantly, their security provisions. Different Web services have different security requirements as well as assurances during run-time processing of various sensitive patient data. The fundamental question is how service computing can cater various security requirements of different healthcare services in a composed federated e-healthcare system.

To address this question, this chapter proposes a framework of composing security properties for services used in healthcare information systems. It proposes a generic architecture of our proposed security-aware services and discusses the related issues. In contrast to most of the current initiatives that focus on incorporating existing security techniques into service computing, we see a great need and potential to develop a new framework for security-aware service composition in healthcare systems. The main objective of this chapter is to define a process that would enable us to compose various security properties of a federated healthcare information system that is assembled from various independent third-party software services.

BACKGROUND

The current practice of using software services in healthcare systems does not have any compositional process for properly evaluating the conformity of security properties between third-party services. This could dangerously lead to compromise to the enterprisewide security requirements of the healthcare systems, such as the confidentiality of patient data and the reliability of the services. Consequently, this risky practice of compositing systems of third-party services without due attention to the conformity of security properties could result in the degradation of system security. This practice virtually forces healthcare systems integrators to take undue risks by composing a system in order to achieve global services. Generally speaking, most systems integrators have neither the time nor the resources to examine the security properties of candidate software services. The required security functions that a healthcare system requires may not comply with the provided security profiles of a service.

A thorough examination of related literature reveals that very few research works in this area have been reported. Most research initiatives focus on how to make the individual services secure or how to make the enterprise systems more secure. In our opinion, these cannot solve the problem of "mutual" security conformity among various services

Web services paradigm is based on the Simple Object Access protocol (SOAP), the Web Services Description language (WSDL), and the Universal Description Discovery and Integration (UDDI). The Extensible Markup Language (XML) is the basic mechanism behind all of these technologies. Attempts have been made to extend WSDL to encode quality of services (QoS) properties (Curbera, Khalaf, Mukhi, Tai & Weerawarana, 2003) such as security, performance, and reliability. The aim was not to compose QoS properties along with the service composition, but rather to describe the QoS properties of Web services. None of the standards for XML-based definition language, such as Business Process Execution Language for Web Services (BPEL4WS) (Andrews et al., 2003), XML Process Definition Language (XPDL) (Kappel et al., 1995), Web Services Security Languages or WS-Security (Seely 2002), and Business Process Modeling Language (BPML) (BPMI, 2003), addresses the issue of the composition of security services to engineer the security properties of the composed Web services. WS-Security addresses Web service security by using existing security standards and specifications.

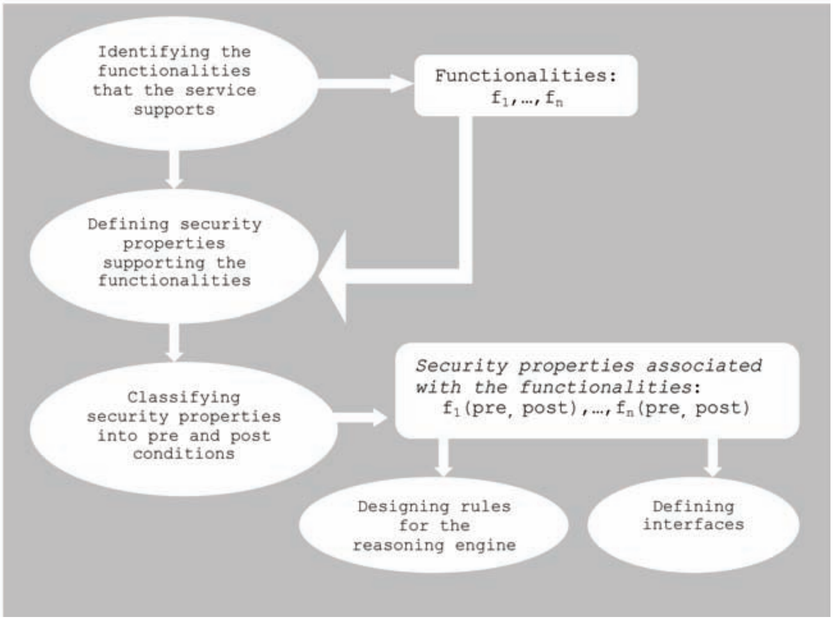
OUR FRAMEWORK

A healthcare software service may provide several functionalities; each may have quite different types of security properties from the others. For a software integrator, it is hard to predict what security properties a functionality supports unless they are well expressed with the interface of the functionality. Security properties are used for various reasons such as to authenticate a system, to authorize, and to ensure confidentiality and integrity. Examples of security properties can be passwords, private keys, secret keys, public keys, shared keys, and digital signatures. The protection of the service and its data and instructions is usually implemented with one or more security functions.

The security properties used to protect a functionality may have distinct security properties for a particular scenario. Security properties could also be grouped into two types based on their role in a functionality: security *precondition* and security *postcondition*. In order to verify whether the security precondition is met by the services user who wants to use the functionality, a reasoning engine is needed.

Based on these preliminaries, we can define the following types of *attributes* of a software service: (i) *the service has one or more functionality*; (ii) *a functionality may be protected with security functions*; (iii) *the security function is composed of security properties*; (iv) *the security properties can be classified as precondition or postcondition of the functionality*; and (v) *a reasoning engine is needed to verify the compliance of the security precondition and postcondition*.

Figure 1. A framework for specifying security attributes of the service



Addressing the compositional security concerns discussed in the previous sections, we propose a framework for specifying these attributes at the architectural level of a service, as depicted in Figure 1.

The framework proposed in Figure 1 shows five distinct tasks. The task for identifying the functionalities of a service involves enlisting the associated functionalities of the service. For example, a *prepare diagnosis report service* may include functionalities such as *receiving pathological data*, *providing diagnosis report,* and so forth. In the next task, each of the identified functionalities is associated with its security properties. For example, *receiving pathological data* function may be supported with the encryption and digitally signed security functions. In task four, the employed security functions are classified into security precondition or postcondition of the function. For example, *providing diagnosis report* function may have encryption and digitally signed as its two security postconditions. The receiving pathological data function could have a security precondition such as encryption of the data. The specifying of security precondition and postcondition could be achieved by using the security characterization approach proposed in Khan and Han (2003). The designing rules for the reasoning engine function involves issues on how to check the conformity of the security precondition as well as postcondition. It could be a rule-based approach or any other approach. The final task defines the interfaces so that other applications or services may contact the service.

In our approach, the security properties are associated with the interface of the services in such a way that the other services or application systems could read the security properties along with the functionality of the service. The approach could also provide a mechanism so that the application could check the conformity between the application and services. The output of this framework could be a service with its functionalities mapped with the associated security precondition and postcondition, as shown in Figure 2.

The diagram depicts that a healthcare service provides two distinct functionalities to other services of applications. Each functionality has its own security precondition and postcondition. The service has one common interface to access the functionalities of the service. The employed security properties are mapped with the functionality that a service supports. In order to use any of these functionalities, other services or application systems must comply with the security precondition of the candidate functionality. In return, the functionality ensures the specified security postcondition.

CONCLUSION

The chapter has outlined the problems related to the issue of compositional security of healthcare software services at runtime. It has proposed a high-level framework to develop security-aware healthcare software services. A security-aware service has its functionality mapped with an associated security precondition as well as postcondition. In order to get the service of a functionality, other application systems or services are required to meet the security precondition of the functionality. In return, the healthcare service ensures security postcondition to the application systems. The chapter argues that different healthcare information systems may require from the services different types of security functions in order to protect the information. Our approach advocates a need-based, security-aware composition; that is, a healthcare application can only be composed with a service that could comply with its security requirements. Similarly, a service may also require certain security properties to be satisfied by the enclosing healthcare system in order to receive the service. We acknowledge that further investigations need to be done in order to build a complete framework. The framework also needs to be tested in a real-world situation.

KEY TERMS

Healthcare Service Functionality: A functionality provided by a service is a task offered by the service to its environment. A healthcare service may have one or more functionalities to offer. The client healthcare application system could use these functionalities at runtime.

Healthcare Services: A platform-independent, self-contained software with defined functionality that can provide healthcare related computing services. It provides a standard way to integrate mechanism with healthcare applications over the Web. A service can perform one or more functionalities for the complex healthcare application system.

Security-Aware Service: A service that has its own security requirements to be satisfied by the service user; in return, it guarantees certain security requirements. The approach also provides a mechanism to verify the compliance of the security requirements of the service as well as the service user.

Security Function: The implementation of a security policy as well as a security objective. It enforces the security policy and provides required capabilities. Security functions are defined to withstand certain security threats, vulnerabilities, and risks. A security function usually consists of one or more principals, resources, security properties, and security operations.

Security Postcondition: An ensured security property is a postcondition in a sense that it is the responsibility of the service or the application system to maintain the committed security assurances during the composition.

Security Precondition: An invariant in a sense that other entities must satisfy this before a composition takes place. It is a precondition the service user must ensure to the service provider that the required security properties are met and their validity is ensured before a service can be obtained.

Security Property: An implementation element used in a security function. A set of security properties can form a security function. A security property is an element at the lowest level of the implementation.

Security Reasoning Engine: Verifies the security compliance between a service and the service user. The reasoning engine could use rules that comprise a set of criteria that could be used to assess security properties between two services. A security reasoning engine tests whether a security function has the desired security properties.

Chapter 7.3

The Impact of Privacy Legislation on Patient Care

Jeff Barnett
University of Victoria, Canada

ABSTRACT

This article looks at how privacy legislation in Canada may interfere with patient care and the use of electronic health records. A review of the literature shows that legislation across Canada is not uniform and varies to the degree in which it addresses issues of privacy and confidentiality. What is not clear is what impact legislation has on the movement towards electronic health records? A case study was undertaken to look at a specific project involving the design of an electronic health record as a means of sharing information between physicians and prostate cancer patients. Through interviews with those associated with the project, it was clear that legislation itself was not a barrier. The problem was that the legislation was open to interpretation. The author hopes that an understanding of the issues raised by this article will lead to further discussion and research on this topic.

INTRODUCTION

Patient privacy is a topic of great interest both in Canada and internationally. Many health conferences and academic journals often have several papers devoted to this topic. This issue has gained more attention in the last five years as there is a continuing trend in health care towards more electronic capture and sharing of information between providers and patients. It has been recognized that health care has typically been behind other industries, such as, airlines and banking, when it comes to embracing its users in the sharing of electronic information. Patients and their health care providers have expressed an interest in sharing of information to facilitate optimal patient care. Unfortunately, as more patient information is made available electronically, there is an increased potential for loss of privacy and confidentiality.

In Canada most provinces have legislation to ensure that there are safeguards in place to protect confidentiality and security of sensitive personal data. However, it may be that this legislation is too restrictive and interferes with patient care activities. Many initiatives, such as those led by federal and provincial governments, are looking at novel ways of providing access to and sharing of electronic patient information. Often these initiatives involve the use of the Internet or some form of information and communication technology (ICT). These initiatives may run into issues with current legislation, to the extent that they never get off the ground or at best are significantly delayed in implementation. In general, the topics presented usually deal with how to be compliant with legislation or how to go about addressing issues related to privacy. Little has been discussed that addresses how legislation may have an impact on patient care. Indeed, there is scarce information in the literature that looks at how the legislation in any particular jurisdiction may have an impact on novel approaches to the delivery of care.

The aim of this article is to look at a new and innovative project for the sharing of information for prostate cancer patients in the Canadian province of British Columbia (BC). A case study was undertaken in order to examine whether current legislation has had an impact on this project, known as the Provider Project.

BACKGROUND

The Provider Project

The British Columbia Cancer Agency (BCCA) provides cancer care programs for the people of BC, including prevention screening, early detection, diagnosis and treatment services, support programs, community programs, research, and education. BCCA, along with seven other provincially mandated health care agencies, is a member of the Provincial Health Services Authority (PHSA), which is responsible for governing, managing, and funding this group of health care agencies and services.

BCCA is committed to providing all patients with access to a full range of quality cancer services, regardless of where they live. To serve the people of BC, BCCA has a complete network of facilities, such as regional cancer centres, community cancer centres, research centres, and foundations. There are five regional cancer centres located in Victoria, Vancouver, Kelowna, Surrey, and Abbotsford. Through these five cancer centres located around the province, various cancer care programs are provided to patients, including assessment and diagnosis, chemotherapy and radiation therapy, counseling services, and follow-up care.

One of the many types of cancers treated at the BCCA is prostate cancer. Prostate cancer patients are often exposed to a variety of treatment options such as surgery, radiotherapy, hormonal therapy, and, rarely, chemotherapy. Prostate cancer is often referred to as a chronic disease. This is because the tumour is slow growing and with currently available treatments, patients remain very active and alive for many years after diagnosis. Caring for these patients during treatment is complicated and often involves a multidisciplinary approach to care. The members of the care team are usually radiation oncologists (specialized physicians), radiation therapists, nurses, pharmacists, social workers, and, most importantly, primary care physicians.

More recently with the increasing involvement of patients in shared decision making, patients have become very active members of their own care team. This is especially true for prostate cancer (PC) patients. Several studies have indicated that these patients are keenly interested in their care and are often very active in seeking out information. However, with the complexity of their care, gaps in information between PC patients and their care team can exist. It has been demonstrated that a growing number of patients now refer to the Internet as a source of information in order to fill those gaps. However, the Web sites dealing with PC are often generalized and do not provide patient specific information. PC patients, just like other patients with a chronic disease, need information pertinent to their condition. More recently, attempts have been made to develop personalized Web-based electronic health information as an innovative method of delivering patient specific information. The Provider Project is an initiative led by a physician at the BCCA'S Vancouver Island Cancer Centre. The Provider Project has been designed to provide a prototype Web-based patient electronic medical record system geared specifically for PC patients. This project has been ongoing for the last five years. The issues around privacy and confidentiality have been a major obstacle in getting this project launched. The vision of Provider Project is to give a group of PC patients access to a subset of data in a customized version of their current paper based and electronic medical record held at BCCA. However, the main challenge has been in dealing with issues of privacy and confidentiality.

In BC, in particular, there are two pieces of legislation that have direct authority as far as privacy and patient care in BC are concerned. One is the BC Freedom of Information and Protection of Privacy Act, or FOIPPA. This Act of the Province of BC was introduced in 1997. The main purpose of this act is to "make public bodies more accountable to the public and protect personal privacy by *preventing the unauthorized collection, use or disclosure of personal information by public bodies*" (emphasis is added here because this is where there has been controversy about what constitutes "unauthorized collection or disclosure").

A second important piece of legislation in BC is Bill 73, which is an amendment of the BC Freedom of Information and Protection of Privacy Act. It was drafted in response to the U.S. Patriot Act, a Federal Act of the United States that "allows access to personal information located in Canada that is involved in outsourcing of public body functions to a US linked contractor." Bill 73 came into law in October of 2004. Bill 73, in effect, eliminates access to any personal information outside Canada. It states, "A public body must ensure that personal information in its custody or under its control is stored only in Canada and accessed only in Canada." Again, the interpretation of this act has invoked controversy as to what constitutes access and storage. All health authorities and public bodies in BC, and many of the research bodies, are grappling with the implications of both pieces of legislation. Any clinician or program leader creating new initiative involving the collection of patient data may be required to fill out a Privacy Impact Assessment (PIA) document and, quite often, a "Bill 73" Impact statement.

Bill 73 had no effect on the Provider Project and is outside the scope of this article.

METHODOLOGY

Research Design

The research design used in this article consisted of a case study of the Provider Project that was broken out into three tasks:

- The first task involved a literature review to determine the major issues surrounding privacy legislation and how they may impact patient care. This was limited to North America with a focus on Canadian Law, as there are many differences in legislation between Canada and the United States.
- The second task was to interview two experts. These individuals were selected for their advice and knowledge in the area of privacy legislation and their knowledge of the Provider Project. One of these experts is a legal specialist from the University of Victoria. The other is a senior privacy officer

with the PHSA. The intent of the discussions with the experts was to gain a clear understanding of the relevant legislation in BC and any other legislation that may have an impact on the Provider Project.

- The third phase of this project employed several instruments to collect information about the privacy and confidentiality issues faced by the Provider Project during this phase. One of the main techniques used was structured interviews with the project sponsor and other stakeholders associated with the Provider Project.

Data Collection

The structured interviews were centred primarily on the understanding and interpretation of the main issues related to the privacy and confidentiality of patient data. The main focus of the interviews was to look at the challenges and potential roadblocks the stakeholders had experienced in this project. Here the intent was to obtain key factors and "lessons learned" in putting together a project of this nature. In-depth interviews with two experts in privacy were undertaken. The lead physician and members of the Provider Project were interviewed in depth. A record of each interview was recorded using a recording device. Consent to use the device was obtained prior to its use. Once the interviews had taken place, the recordings were reviewed and a transcript of each interview was created using Transana Software (Transana version 2.10 open source software from the University of Wisconsin). After the transcripts were written up, themes and keywords were identified using the software.

Secondary Data Sources

In addition to the interviews, the case study also involved direct observation and documentation review. Direct observation included attending formal team meetings of the Provider Project as to understand how issues of privacy impact the project. As well, with the permission of the investigator, passive observations also took place whereby the researcher sat in on discussions with Patient Information Management and Information Technology Staff at the BC Cancer Agency.

Several key documents were also reviewed:

- The Provider Project Plan
- An Executive Summary of the Provider Project prepared for the BCCA Executive
- The Privacy Impact Assessment (PIA) for Provider
- Provider team meeting minutes
- Other Provider Project documentation and e-mail communications between the various stakeholders

RESULTS

Review of Privacy Legislation in Canada

Most of the Canadian provinces have legislation covering the protection of personal information, in the form of a Freedom of Information and Protection of Privacy Act (FOIPPA, 1997). Some provinces like Saskatchewan and Alberta have legislation that is specific to personal health information, in the form of health information acts. As provincial governments develop these acts and implement policies addressing the protection of health information, it remains unclear as to what effect legislation has on patient care and an already complex health care system.

The world of research has been struggling with these issues for some time and there are many papers in the literature that deal with health research and patient privacy. The use of health information for research purposes is largely governed by the federal Personal Information Protection and Electronic Documents Act (PIPEDA), enacted in 2000. This is a federal act that sets out 10 principles of privacy provisions based on the Canadian Standards Association's Model Code for the Protection of Personal Information*,* recognized as a national standard in 1996.

In the research arena, several authors in Canada, North America and Europe have identified how legislation has an impact on research. McCarthy suggests that efforts to protect patient privacy may come into conflict with the ability to produce timely and valid research to safeguard and improve health (McCarthy, Shatin, Drinkard, Kleinman, & Gardner, 1999). The use of health records for research is well known, but Upshur suggest that more strict rules and strengthening of consent legislation may have adverse effects on health services research. He argues that it may also lead to an "authorization bias" in health services research (Upshur, Morin, & Goel, 2001). Earlier work by Gordis and Gold (1980) emphasizes the value of using medical records in research particularly for diseases like cancer, cardiovascular disease, and pediatrics. Yet, there are very few examples in the literature where the use of personal data for research purposes has caused harm to Canadians (Upshur et al., 2001). A further discussion of legislation and privacy issues related to health care research is beyond the scope of this review.

When it comes to health care delivery and health care information, we are only now just exploring the issues that are being brought by the movement to electronic health records (EHRs) and the exchange of health information by electronic means. In Canada, federal bodies, such as Canada Health Infoway, are pushing towards the goal of EHRs for all Canadians. All across Canada there are many new and innovative projects. The main aim of these projects is to improve the access, quality, and productivity of Canada's health-care system. Many projects involve new and innovative approaches to patient care which involves the interchange of patient information in an electronic format. E-health is becoming an accepted part of health care. Back in 2002 Richard Alvarez, the current head of Canada Health Infoway, who was at that time the President and CEO of the Canadian Institute for Health Information (CIHI), suggested that e-health now focused on the consumer, as we have evolved to a new consumer centric model for health care. He maintained that Canadians are demanding more from their health-care system and wish to become more involved, yet at the same time, they are increasingly concerned about privacy issues (Alvarez, 2002).

This poses an essential paradox, in that the needs of patient and their care must be balanced with their concern for privacy. A commentary in the *Canadian Medical Association Journa1* suggests that "A paradox looms: Canadians demand high-quality, accessible, and efficient health care *and* privacy for their personal health information" (Upshur et al., 2001). Yet, has this contradiction always been here regardless of whether health information is kept in an electronic or paper format? Prior to the advent of e-health initiative, privacy breaches did occur and usually involved individuals finding medical records in a back alley. Whenever a breach like this has occurred it would always make front-page news, but invariably not last long in the public eye. After the initial shock and dismay, the issue would die and be regarded as an isolated occurrence. With the advent of ICT in health care and the need for health care reform, there is a demand to look more closely at privacy issues. Some authors suggest that the issues of privacy and confidentiality of health information have always been with us. The only thing that has changed is the move from paper to electronic data capture. Berger states that "having one's electronic medical records accessible to any interested employee in a hospital or clinic (or to members of their family when the hospital allows telecommuting) is not that much different than having the various papers, charts and notes stuck in a manila folder in a filing cabinet that anyone in a white coat can access." In his book *Database Nation*, Garfinkel documents several major cases in the United States where personal health information was abused (Garfinkel, 2001). All the cases he documents have nothing to do with electronic records, but are results of unethical actions or mistakes made by health care providers. He goes on to suggest that the introduction of computerization into health care poses several threats that could severely impact patient privacy. These are based on the assumption that electronic records can be more readily accessed than paper records and are less secure. However, several authors have argued that this is not necessarily the case. In fact, there are many articles that suggest moving to electronic records will improve security. Morrissey suggests that handling patient data electronically may actually be more secure than paper based records (Morrissey, 2006). In his paper entitled "A day in the life of a Medical Record," he demonstrated how relatively unsecured a paper chart can really be. He goes on to say that, short of putting it in a locked filing cabinet, it will never be as secure as an electronic record can be made.

Health care in Canada and around the world continues to evolve into a multidisciplinary and multiple-agency networking approach (Weitz, Drummond, Pringle, Ferris, Globerman, Hebert, et al., 2003). There is a greater degree of service coordination in order to meet the complex needs of individuals. The move toward electronic health records and electronic patient records, coupled with the advancement in technologies, especially the Internet, are fueling this. The irony is that as regionalization continues across Canada and small health-care groups are collapsed into larger health care networks, the demand for information sharing intensifies. The so called health care networks are being created in order to gain efficiencies and thereby save scarce health care dollars. Yet, this is not enough. The health care system is also under increasing pressure to do more with less and ICT is seen as one of the ways to help solve these problems (Weitz et al., 2003).

Patients as consumers of health care are also demanding more and have become more informed. Physicians and other health care providers are expected to keep their patients well informed while, at the same time, keeping patient information confidential. Keeping patients informed is one of the main expectations in the consent process. The Canadian Medical Association has developed a privacy code that defines both confidentiality and consent within the scope of medical practice (Canadian Medical Association, 1998). It states:

Confidentiality, confidential mean that health information that is confided by a patient is to be kept secret and not disclosed or made accessible to others unless authorized by patient consent. A breach of confidentiality occurs whenever a health professional discloses or makes health information available to others without or inconsistent with the patient's consent.

Consent means a patient's informed and voluntary agreement to confide or permit access to or the collection, use or disclosure of his or her health information for specific purposes. Express consent is given explicitly, either orally or in writing. Express consent is unequivocal and does not require any inference on the part of the provider seeking consent. Implied consent arises where agreement may reasonably be inferred from the action or inaction of the individual and there is good reason to believe that the patient has knowledge relevant to this agreement and would give express consent were it sought.

This is where discussion about consent and confidentiality of health information gets mired in debate. Weitz et al. (2003) suggest that the argument comes back to the balance between protecting the individual's rights to privacy and autonomy while, at same time, allowing providers access to information they need to care for their patients.

In Canada, legislation has been brought in as an attempt to provide a framework of how health information can be collected, shared, and accessed. However ,there is a problem in Canada, in that there is a patchwork of federal statutes, provincial legislation and codes of conducts of the various health care professionals (Bennet, 1996). The type and extent of legislation varies from province to province and has a different impact on users of health care depending on the province they live in. As stated previously, most Canadian provinces have legislation covering the protection of personal information in the public sector, in the form of FOIPPA.

The approach across Canada is far from uniform. The different rules, practices, and customs within the various provinces, health districts, hospitals, and clinics do not allow for consistent, effective practices for sharing of data or protecting patient privacy (Berger, 2002). Clearly this is a problem for health care delivery. Saskatchewan, for example, has the Health Information Protection Act that actually allows individuals to refuse to have their information stored in an electronic format in the Saskatchewan Health Information Network (SHIN). Patients also have the right to restrict access to other providers of health. Weitz suggests that Saskatchewan's act may be one of the most limiting in Canada, as individual rights may place unreasonable limits on what type of health information providers can access.

In Canada, the current state of privacy suggests that, aside from legislation, there is already some infrastructure in place. A survey undertaken by Infoway in 2002 indicated that 9 out of 10 organizations require staff to sign confidentiality agreements and 4 out of 5 regulate access of employees and physicians to clinical records. On the other hand, over 50% have policies regulating remote access to clinical records and less than 50% have policies governing patient consent to information sharing (Canada Health Infoway, 2002). The concept of an electronic record is well supported by the Canadian public. An Ekos survey by Infoway suggested that 85% of Canadians do support electronic health records. The same survey showed that Canadians say the following will make them feel more comfortable about electronic health records (Canada Health Infoway, 2002):

- Find out when and who accessed their record 71%
- Serious criminal offense for unauthorized access 64%
- Clear and accessible privacy policy 61%
- Ability to access, verify, and correct record 57%
- Supported by their doctor 57%

When it comes to information sharing and patient perception, there is very little data available in Canada. Weitz suggests that there is a lack of public input into the discussion (Weitz et al., 2003). He suggests that little is known about how patients feel about this issue. In 1997 Saskatchewan's Minister of Health sent out consultation packages to the public, health providers, district health boards, consumer groups, special interest health groups, researchers, MLAs, and the media. This package was intended as part of a public consultation process on the protection of health information (Saskatchewan Health, 1997). When the respondents were asked specifically about information sharing, over 95% agreed that health information necessary for treatment should be available to service providers where and when they need it. In addition, 89% agreed that hospitals, health boards, physician's offices and others should be able to exchange health information when it is important for health services. Ironically, Saskatchewan has legislation in the form of the Health Information Act that is more restrictive than some of the other provinces, such as BC. Sometimes the public may be consulted on issues such as this, but do not ultimately have some bearing on the text of legislation. The consultation process may be more of a public relations exercise.

A similar survey done in the Netherlands on inpatients suggested that patients expect that members of their health care should be able to share vital personal health information without their consent for that communication (Klop, van Wijmen, & Philipsen, 1991). In the provinces like Alberta and Saskatchewan that have legislation governing health information, the legislators have tried to take this into account. The legislation that sets out the rules regarding disclosure of information, particularly between health care providers, was created with intent to clarify how disclosure may come about and with less legal or regulatory obstacles. The use of ICT in health care has grown rapidly over the past decade, but legislation is only now trying to keep pace. It is ironic that health information legislation addressing disclosure has come about in response to advances in technology. Yet as previously mentioned, the issues it addresses have always been with us and are not entirely new. A paper chart in a hospital can be accessed by any staff member or anyone walking into the hospital.

Initially, some provincial legislation was considered too restrictive and not practical to implement. For example, when the Health Information Act (HIA) was first introduced in Alberta, section 59 required consent from individuals before information could be disclosed. This section stated that for consent to be valid it must include:

a. An authorization for the custodian to disclose the health information specified in the consent.
b. The purpose to which the information may be disclosed.
c. The identity of the person to whom the health information may be disclosed.
d. An acknowledgement that the individual providing the consent has been made aware of the reasons why the health information is needed and the risks and benefits to the individual of consenting or refusing consent.
e. The date the consent is effective and the date if any on which the consent expires.
f. A statement that the consent may be revoked at any time by the individual providing it.

Section 59 was repealed in 2003 because it was felt that it was too costly to comply with this legislation. Physicians and other health care providers felt that they had to spend extra time obtaining patient consents. The Alberta Privacy Commissioner in fact suggested that getting consent to provide information to a provincial EHR would be too costly and impractical. Cornwall, in *Connecting Health,* looked at Alberta's Pharmaceutical Network and found that physicians were spending an inordinate amount of time explaining the system to patients (Cornwall, 2002). This was largely driven by the current legislation and the physicians' fears around legal liability. Shaw suggested that the desire to provide provincial health networks where information can be shared is bogged down by the lack of privacy legislation in some provinces (Shaw, 2000). He suggests that some projects are slow to move ahead and are suffering because policy is not keeping up with technological change. He raises the suggestion that some projects may be suffering from policy paralysis.

As the EHR is gradually being developed in each province, policy makers, both in government and in health authorities, will continue wrestling with the issues of privacy and confidentiality. However, it is important to point out that in order to make the roll out go smoothly, several authors suggest that the public must be consulted. The success of Newfoundland's provincial patient registry is in part due to the involvement of stakeholders and getting a good understanding of the privacy issues way up front. Rather than waiting for legislation to be created by the provincial government the project leaders created privacy guidelines that they shared with their stakeholders which were then presented to the government.

Reis writes that legislation specifically for health information is still relatively fresh, as are the projects associated with information sharing. A balance must be struck between the need to protect the privacy and confidentially and the ability to administer the new systems coming into place (Reis & Moysa, 2005).However, she notes that in some provinces, such as Ontario, current provisions of legislation places the burden of implementing appropriate security measures on the custodians of information. This is where problems may occur, as it places the onus on the custodians to create reasonable safeguards. Failure to do so could be subject to investigations by provincial privacy commissioners (Reis & Moysa, 2005).

Interviews

Over the summer of 2006 interviews took place with the two privacy experts and members of the provider team. Each of the interviews lasted over 1 hour. The two privacy experts were given the same interview instrument. This was slightly different than the one administered to the members of the provider team. A set of 10 questions was given to the privacy experts and a different set of 10 questions was administered to the team members. As the questions were open-ended, there was a great deal of discussion between the interviewer and the interviewee. Once the interviews were recorded, a transcript of the interviews was created and this was analyzed using the Transana software. From the interviews with both the team members and the experts, the following themes were apparent:

- Privacy legislation in BC is highly subject to individual interpretation
- Challenges around staff and resources had an effect on provider
- There is a need for better regulatory interoperability between jurisdictions
- Protection of patient information is not well defined
- Patient consent is an over-riding principle
- BC lacks a Health Information Act similar to Alberta

Privacy Legislation Can Be Highly Subject to Individual Interpretation

All of the interviewees stated that the current privacy legislation can be open to interpretation, depending on the individual's biases and background. In the case of the BCCA the legislation that was always referred to in regard to Provider was FOIPPA. Although this legislation has been around since 1996, there appears to be a difference of opinion as to how it affects use of patient information in health care. What is important to note is that this piece of legislation does not mention keywords like patient, health record, or electronic record. The Act does not, in fact, specifically address health information. So it is not surprising that it is subject to interpretation. In the case of Provider, FOIPPA was used initially as a reason not to allow for the release of information in the early stages. The stakeholders all echoed the comment that the initial resistance to allow for the transfer of patient information came from individuals within BCCA who said it could not be done because of privacy concerns and FOIPPA. As the Provider project evolved, it became clear that there was a willingness on the part of senior IT staff at the BCCA to move ahead. The issues around release of information became more focused on the release of information by electronic means. BCCA had policy that allows for the release of patient information directly to the patient. Like most health care institutions, patients are able to go to the health record department and request their paper chart. They could sign a release of information form. This would allow health records staff to give out a copy of all or part of their health record. The Provider proponents were well aware of this, but felt that if the patient signed a release, they could also have that information released in an electronic format. Here in theory, if the patient was consenting to the release of information, the format should be irrelevant. Initially Provider team members were told that this was not possible due to privacy legislation. Subsequent requests for the release of the information in an electronic form were denied, not due to legislation, but by the simple fact that health records staff were not set up to provide information in an electronic format. It became clear that no one at BCCA or PHSA was interested in looking at Provider as a new way of delivering information to patients. To be successful it had to become a research project. As with any research project, it had to have an ethics review and approval by the BCCA, which it obtained successfully. In addition, the project team was required to fill out a Privacy Impact Assessment (PIA) document as part of the process. The intent of a PIA was to ensure that a new program or initiative avoided any violation of the relevant legislation and could mitigate any security risks. As Provider moved into a design phase, issues of privacy were still a prime concern. The members of the project team were initially given limited advice on how to best deal with privacy and confidentiality issues. In the end the team obtained legal help from an expert in the area of health law, who helped draft the PIA. This PIA addressed many potential issues that the Provider project could encounter. Doing the full PIA was time consuming and required several iterations before it was acceptable to senior management at BCCA. Even then, it did not help solve the issue of electronic transfer of information.

Challenges Around Staff and Resources Had an Effect on the Provider Project

One of the issues that came up during the interviews was that the Provider Project started to evolve at a time when BC was undergoing health restructuring. The project was initially discussed with the Chief Information Officer (CIO) at BCCA. At that time, BCCA was a semi-autonomous body that reported directly to the Ministry of Health. Under restructuring it became an agency under PHSA. The departments of Information Management and Information Technology at BCCA were merged into centralized departments of PHSA. The CIO of BCCA became the CIO of PHSA. One of the managers in information management in BCCA became the Corporate Director for Information Management at PHSA. Both individuals were familiar with the Provider project, but once they assumed new roles, they took on corporate projects and priorities. The Provider project was not seen as a high profile project and it was felt that there were limited or no IT resources that could be devoted to the technical tasks that were required in the project. At one point the main investigator for Provider offered to fund PHSA IT staff to work on the project, but this request was not acted upon.

The main issue for the project that required assistance from IT was getting some specific information out of the Cancer Agency Information System (CAIS). CAIS is BCCA's electronic patient record that contains an electronic version of most information contained in the paper chart. The main pieces of data required for Provider residing in CAIS were specialized lab values, such as Prostate Specific Antigen (PSA), appointment data, radiation therapy treatment, and records of drug therapy. The intent was to have this data transferred electronically into Provider for specific patients. Help was requested from PHSA IT to accomplish this. In the end, because IT support from PHSA was not forthcoming, due to issues related to workload and concerns about privacy, the Provider team abandoned this approach. In its place they came up with an approach by which patients who had consented to be part of the Provider project would obtain a paper copy of their information through the release of information process. This would be manually entered into Provider by a research assistant. This process was outlined in the PIA and agreed to by PHSA.

There Is a Need for Better Regulatory Interoperability Between Jurisdictions

As mentioned in the literature review, privacy legislation has been enacted at the federal and provincial levels. Different provinces have different statutes and regulations concerning the exchange of patient information. This varies from province to province. The problem can be compounded within a province where different health authorities or regional health districts have jurisdictions over an organization. These health authorities may have different rules and procedures. Provider was initially planned when the BCCA was an agency of the Ministry of Health and had its own policies and procedures around patient information. When BCCA became part of PHSA, it was governed by the rules and regulations of PHSA. Overlying both organizations was the provincial FOIPPA legislation. In addition, Provider eventually moved into a project involving researchers from the University of Victoria (UVIC). UVIC had policies and rules that had to be taken into consideration as well. Of particular concern was the proposed electronic transfer of information from the BCCA to the university. The computers that would house the Provider project were located in a secure computing facility at UVIC. The intent was to transfer pertinent data from BCCA to the university. A collaborative agreement was reached between BCCA and UVIC to allow for the handling and sharing of data. This was all part of the PIA. UVIC was willing to allow for the information exchange to take place electronically, but PHSA would not, for reasons already discussed. One of the difficulties for the Provider Team was that there was a great deal of confusion about the need for data sharing agreements vs. a collaborative research agreement between the University of Victoria research office and PHSA. Several discussions took place, which created a delay for the project. In the end, no agreement was reached between PHSA, UVIC, and the Provider team. An alternate possibility was discussed with regard to getting lab data into Provider. It was thought that because most of the lab data in CAIS originated from labs outside of BCCA, this data could be obtained from the original source. Patients seen at the Vancouver Island Cancer Centre as part of the Provider project routinely would be getting their lab test done at labs in the city of Victoria. The lab test results were generally available within the Vancouver Island Health Authority (VIHA). One possibility considered was lab data originating in VIHA could be obtained directly from VIHA, rather than going through BCCA/PHSA. However, it was felt that the security and privacy issues that would arise in dealing with another organization would further complicate and delay the project.

While discussions between the Provider team and PHSA were taking place, there were no other data sharing agreements in existence between organizations that would allow for innovative projects like Provider to take place. Health authorities in BC were relatively new and were starting to develop policies and procedures around health information. Only within the last few years has there been a move for the privacy officers in each of the health authorities to get together to share information. In the past, privacy officers were operating in an ad hoc fashion addressing only what they found out about, as opposed to being proactive.

Protection of Patient Information is Not Well Defined

A good deal of the discussion around the Provider project centre on the protection of patient information. As mentioned, the Provider proponents did complete a PIA. In general, the point of doing a PIA is to perform an appraisal of the possible effects that a particular activity or proposal may have on privacy. The Provider team used a PIA template designed by PHSA. This template states that a project would require that PIA be completed if "transition from paper-based system to electronic system (even if it involves no new uses, collection, disclosure or flow of data)." It also states that this should be completed for information sharing to/from other systems, public bodies, or agencies.

The PIA written for the Provider project did take this into account. In spite of this, the transfer of information from BCCA to the Provider Web site could not take place electronically. The Provider team settled on having information transferred from the paper based chart. One of the points that came up in the interviews with Provider team members was the comment that it was difficult to believe that a paper based process was any more protective of patient information. FOIPPA is vague in this regard as section 30 of the act states, "A public body must protect personal information in its custody or under its control by making reasonable security arrangements against such risks as unauthorized access, collection, use, disclosure or disposal." It does not specifically address the issue of paper vs. electronic. All interviewees appreciated that having patient information in an electronic format raises a different set of issues, but the legislation focuses on the fact that a public body must protect the information. One of the experts suggested that electronic transfer can be made more secure than a paper process. Yet, the perception existed that the opposite was true.

FOIPPA also mentions that disclosure can take place provided that the patient has consented in writing. Again, it does not say how that disclosure can or cannot take place. This was a central problem for the Provider team. Consent for the release of information was to be obtained from the patient, but the interpretation of the legislation was that it could not be released electronically.

Patient Consent Is an Overriding Principle

Ironically, one of the reasons that Provider came about was to address the information needs of prostate cancer patients. A literature review and survey by Provider's proponents suggested that this group of patients was highly information seeking. They contended that prostate cancer patients are motivated to be involved in their care and obtain as much information as possible about their condition. The patients surveyed by the proponents of Provider were all keen to participate in the project and all desired access to their health information. Both experts interviewed agreed that patient consent was an important issue. Both stated that if patients consent, legislation should not prevent transfer of the information. They felt that current legislation in BC does not provide any barriers. Both also stated that there may be other issues, such as workload or lack of procedures, that would be more of a barrier. But more often than not, the legislation is used as a "scapegoat." The legal expert interviewed suggested that once consent has been given, there was no legislative or regulatory reason that data from BCCA/PHSA could not be used to populate Provider. Both experts agreed that informed consent should be the overriding principle but more often than not it is overlooked. Both experts also stated that consent is not the piece of paper that the patients signs, it is an ongoing process involving the patient and from which the patient can withdraw at any time. This sometimes gets forgotten and issues irrelevant to the consent process evolve to become barriers. In the case of Provider, all interviewees agreed that patients were very supportive of the project and were keen to have information about their disease available in a timely fashion. This echoes what is reported in the literature about patient access to health information (Denton, 2001; Hassol, Walker, et al., 2004; Pai & Lau, 2005).

BC Lacks a Health Information Act Similar to Alberta

An issue that came up with both experts is that BC lacks legislation similar to other provinces like Alberta. Both FOIPPA and the private sector legislation, called the Personal Information

Protection Act (PIPA), make little reference to health care and electronic records. On the other hand, Alberta has legislation, called the Health Information Act (HIA or the Act), which became law on April 25, 2001. This legislation protects the privacy of Albertans and the confidentiality of their health information. It attempts to balance the protection of privacy and confidentiality with the need to enable health information to be shared and accessed where appropriate, to provide health services, and to manage the health system. The legislation also provides individuals with the right to access their own information and to have that information protected from inappropriate collection, use, and disclosure. At the same time it defines who are the custodians of the health information and provides a legislative framework for how those custodians can collect, use, and disclose health information. BC does not have similar legislation. The experts agreed that this is one reason why the existing legislation can be subject to interpretation and is often referred to as a "moving target." Although the Act may be lacking in some situations or considered overkill, it does specifically cover electronic records and electronic databases. Most importantly, one of the main reasons for its existence is "to enable health information to be shared and accessed, where appropriate, to provide health services and to manage the health system." This Act, as pointed out by the legal expert, sits at the provincial level and sets out a legislative framework for all health regions in Alberta. For the Provider, similar legislation in BC may not have assisted in getting it off the ground more quickly, but the perceived legislative barriers around privacy would not have occurred. It would also provide a framework for the health authorities, so that issues of privacy and sharing of health information would not be subject to interpretation by individuals within each authority.

DISCUSSION

The concept of providing patients access to all or part of their health records is not new. Several papers (Denton, 2001; Hassol et al., 2004; Mathhews & Johnson, 2002; Smith & Protti, 2001) have appeared in recent years that discuss the concept of the Personal Health Record (PHR). Indeed, there are many Web sites in the U.S. where patients can interact with their care provider and track their own health care. The spectrum is quite wide, all the way from reading disease information to actually monitoring treatment outcomes such as lab results. One example is Epic System's MyChart which is used by many hospitals and clinics throughout the U.S. At Fairview Health Services in Minneapolis, patients use MyChart (http://www.fairview.org/mychart/) to perform many functions such as read lab results, schedule appointments, access family records, and communicate with providers just to name a few. There are many examples of this type of PHR in the U.S., but in Canada it is very limited. However, one site stands out and this is the Grand River Hospital in the Waterloo region. They have created a patient portal called My Care Source (https://mycaresource.grandriverhospital.on.ca/portal/). As with Epic's MyChart, patients are enabled to access information and tools to help manage their care. There is an argument that this type of information should be available in Canada. Perhaps the personal health record is the ultimate patient centric approach and should be driving the process. But clearly it is not as yet. There are papers in the literature that support the notion that patients are interested. An early study in 2001 by Denton (2001) suggested that patients are interested in keeping some sort of personal record. The author surveyed 330 patients who had been provided a commercially available electronic personal health record (EPHR). Over 90% of the respondents felt that they should keep some sort of EPHR. One important aspect of this study was that 63 respondents were happy to have an EPHR, but they did not want the computer that housed the

EPHR connected to the Internet due to Internet fraud. By comparison only, four respondents were comfortable with their information being on a computer connected to the Internet. A more recent study by Hassol of the MyChart system (Hassol et al., 2004), used in the Gesinger Health system, suggested that patients have a positive attitude to online access to their EHR and only a minority had concerns about privacy and confidentiality.

On a national level the creation of Canada Health Infoway came in 2001 and the move to electronic health records was boosted by the release of the Romanow report in 2002. Canada began to embark on a journey towards developing an electronic health record. At the same time, some clinicians and researchers were also looking at the concept of a patient centred care. Several authors recommended that patients must be at the centre of the health system and must be treated as partners by health professionals, "as equals with different expertise" (Coulter, 2002). Provider was an attempt at creating a form of a patient health record or PHR for a group of prostate cancer patients. At the time the concept of a PHR was very new and IT departments and managers did not really know how to deal with it. The project raised several issues around privacy and security, which were highly subject to interpretation, as current legislation on BC was vague.

Through discussions with the experts and various stakeholders, it was evident that the Provider project was started in at a very challenging time. It was important for the project team to be aware of the issues around privacy, but there was confusion as to what the issues were and, more importantly, how to resolve them. As already stated, privacy legislation does not specifically address issues around patients, electronics records, or the manner in which information can be disclosed. What FOIPPA does state under section 33 is, "A public body must ensure that personal information in its custody or under its control is disclosed only as permitted under section 33.1 or 33.2."

Section 33.1 states that: A public body may disclose personal information referred to in section 33 inside or outside Canada as follows:

a. in accordance with Part 2;
b. if the individual the information is about has identified the information and consented, in the prescribed manner, to its disclosure inside or outside Canada, as applicable." However, the initial advice given was that the transfer of information from the electronic record in CAIS to Provider could not take place due to privacy concerns. An important question in this regard was that no one clearly had an idea of what the privacy concerns were and how the legislation prevented the transfer of data from the electronic record required for Provider. At first, the issue was whether this data could ever be obtained and then the issue changed to whether it could be obtained in an electronic format. The advice that the proponents eventually got was that transfer of this information could take place, but not by electronic means. Throughout the years, when Provider was discussed and planned, records of Provider meetings and e-mails indicated that managers and agencies voiced concerns about privacy legislation and this prevented the project from moving forward. Yet the existing legislation, FOIPPA, had no direction mentioned of electronic health records or patient privacy. The act is written in general terms and was subject to interpretation. This indicates that the legislation was actually not a barrier to Provider, as was suggested by senior managers in IT. This lack of clarity might have been reduced if BC had legislation similar to Alberta, as has been mentioned. Some may argue that legislation is not perfect, but at least it has set out the legislative groundwork that would have been of great assistance to the Provider team. Others may also suggest that BC health

information legislation would come with its own interpretations by people and biases.

One could also argue that the desires and wishes of the patients were not being addressed and this may be considered another issue of balance. Here, patients had been consulted and were interested in a new approach to their care. They were willing to take part in a pilot study and would consent to the transfer of information. In spite of this expressed desire on the part of the patients, the Provider Project has been slow to evolve.

It is important to state that once a legal expert was consulted and brought into assist with the writing of a PIA, the barriers began to fall. The advice from the legal expert ensured that the PIA addressed any of the issues that could possibly be questioned by individuals with regard to FOIPPA legislation. More importantly, her legal expertise was used to clarify what the pertinent issues were and how to proceed once the PIA was written. Her help was invaluable because it was based on knowledge of the relevant legislation and not subject to bias or personal opinion. However, the fact that it took a great deal of time to do this was an indication that there was and still is a "legislative void" in BC. Today most of the health authorities in BC in fact do have Privacy Officers, who are charged with the task of being familiar with the current legislation and policies of the health authority. These individuals belong to the Information Privacy and Security Working Group (IPSWG), where information is shared and current projects within each health authority are discussed.

Yet, without legislation similar to the other provinces, there is still the potential for interpretation and bias when dealing with these issues. Gostin suggests in reference to a similar situation in the U.S. "The lack of a uniform policy on interstate dissemination of health care information imposes hardships on almost everyone" (Gostin, 1997). This is very similar to Canada, in that different provinces have different legislation. Should this be dealt with at a federal level? Gostin thinks so, as he argues that "National safeguards that protect the privacy of health care information should be based on fair information practices. Federal legislation should establish uniform and comprehensive privacy protection of health care information. Privacy protection should cover all health care information regardless of its form (paper, microfilm, or electronic), location (in storage, transit, or archives), or user or holder (government, provider, or private organization)."

In Canada this is a challenge in that most Canadian health care issues fall under the jurisdiction of the provincial government. Could more health information acts in Canada help solve some of the problems highlighted in Provider? Plater Seeley, and Dixon (1998) suggest that the provincial "FOIPPAs make protecting privacy one of their stated purposes, privacy issues are secondary to enhancing the flow of health information in HIAs." As information technology becomes more complex and the demands by consumers to address complex health concerns the issue of access to and sharing of increases, information will become more complex.

CONCLUSION AND RECOMMENDATIONS

The Provider Project encountered several challenges as it grew from a concept in response to a patient care need. Throughout its development, issues around protection of personal privacy were very much on the minds of those involved. As an isolated innovative concept that grew into a research project, it encountered several hurdles from inception to proposal. The main point of this case study was to look at the impact that provincial legislation had on the project. In doing this research, it was clear that several issues need to be addressed:

- Health organizations will need to look at the logistics for the release of patient data electronically when it is requested by patients or researchers. In the case of Provider, information requested for the project Web site is available as part of an electronic chart. Patients taking part in the project are expected to obtain access to their own information, which they could get through a release of information request. However the only way those patients could get their own information was in a paper format. No mechanism exists to provide this information electronically. Although Provider is a small scale project with a small number of select patients, this is worrisome for projects on a larger scale.
- Legislation itself did not prevent Provider from moving forward. Rather, it was how the legislation was interpreted or how individuals felt it should be applied that impacted the project. The apparent lack of specific health care legislation had an impact on this project. Although the health information acts of provinces like Alberta may not be the perfect solution, they could clarify the process of information exchange and disclosure between different organizations. This would help to minimize the amount of interpretation, opinion, and bias with regard to how and when information can be released.
- FOIPPA legislation recognizes that a balance is required between individual privacy vs. the public good. Two specific goals of the legislation are to establish strong and effective mechanisms to protect the privacy of health information and to enable health information to be shared where appropriate to provide health services. The degree to which this balance is achieved is directly related to the degree of control patients have over their information. It identifies what can be collected and used with or without the specific consent of the patient.
- Further research into the privacy legislation and its impact on patient care is needed, as there are many projects moving forward that have the potential to encounter some of the issues that the Provider Project ran into

Chapter 7.4

Privacy Management of Patient-Centered E-Health

Olli P. Järvinen
Finnish Game and Fisheries Research Institute, Finland

ABSTRACT

This chapter introduces the privacy management framework as a means of studying patient-centered e-health. The chapter raises some important issues in regards to the privacy domain of e-health and offers a privacy framework to look at the issue that addresses some of the concerns people and industries have regarding privacy. The framework does not neglect the important distinction between the different interests affected by e-health. It acknowledges the voluntary nature of the way in which individuals have surrendered control over personal information in exchange for the benefits that information technology brings. Because the applications of information technology are logically malleable, there are sufficient strategic reasons to suggest that privacy management as a concept and practice will survive, and that to ignore privacy issues might be fatal for the success of PCEH.

INTRODUCTION

Transactional and interactive patient-centered e-health (PCEH) has many direct impacts on health service. Most e-health Web sites are pitched publicly as tools that give individuals greater control over their lives and their healthcare. Electronic health information on the Internet can be easily accessible to many different people. A health provider's ability to quickly access a customer's entire medical record, assembled from various sources, can facilitate diagnosis and eliminate medical errors, such as prescribing incompatible medications. Health records are kept and shared for diagnosis and treatment of the customer, payment of healthcare services rendered, public health reporting, research, and even for marketing and use by the media. Individuals can interact with doctors and other participants in chat rooms and by e-mail, and they can obtain healthcare services, such as second opinions and medical consultations, and products such as prescription drugs, online (Choy, Hudson, Pritts, & Goldman, 2001).

Unfortunately, such information practices may conflict with individuals' desires to be shielded from unauthorized use of their personal information. All of these activities involve the exchange of information with or without the consent of the individual, and with or without their knowledge. Mouse clicks and keystrokes are frequently recorded by online health organizations. That means information about which Web sites he or she visits, how long he or she stays there, and where he or she goes afterward are recorded. The majority of data exchange is visible to the individual, but there are many methods through which a Web site can gather information without the individual being aware, including cookies and data-mining. Whenever he or she visits a Web site, a large amount of information may easily become available to the Web site. When transactions are stored and exchanged using electronic services, personally identifiable information become more widely accessible and potentially vulnerable. Even when a customer orders a medicine from an online pharmacy, transactional information about the purchase is recorded, and information about that particular transaction can be (and frequently is) used for future business decisions and actions (Järvinen, 2005).

The ability to provide differentiated, consistently superior service on the Internet will be crucial to the survival of healthcare providers and affiliated organizations, and the customer vulnerability is exceptionally high, due to the sensitive nature of information. The protection of individuals' personal health information is not an option but a necessity, but the study of 39 U.S. health providers' privacy policies submits that health providers' Web sites are still at relatively early stages in their privacy issue evolution (Järvinen, 2005). Many practices suggest privacy is not a fundamental priority for those organizations. Most Web sites do not meet fair information practices—such as providing adequate privacy notice, giving customers some control over their information, and holding business partners to the same privacy standards. Every analyzed Web site had a privacy policy, but the responsibility is left to the customer to read and understand the entire privacy policy at every visit. Many of the analyzed privacy policies contained technical and confusing language (i.e., unnatural language) that makes it difficult for the customers to fully understand what they are agreeing to.

When the ethical problems involving e-health are considered, none is more paradigmatic than the issue of privacy. Given the ability of information technology to widely gather, endlessly store, cheaply transfer, efficiently sort, and effortlessly locate information, we are justifiably concerned that e-health may provide the means to invade our privacy and reveal information that is harmful to us. Information and knowledge easily cross cultural, institutional, organizational, and many other boundaries, and e-health application and its context may be so novel that there are no convenient customs or laws established anywhere to cope with privacy issues. A vacuum in terms of privacy practice may occur in every culture. The key detail of the Internet is that there is no such thing as "absolute privacy." There is no central authority or management, and no one to install the technology or establish network-wide security and privacy policies. We are, however, reluctant to give up the advantages and the services of the Web technology. We appreciate the easy access to the Web site services when checking health information, buying the drugstore items, and many other things. The number and kinds of PCEH applications increase dramatically each year, and the impact of the Web technology is felt around the planet.

The widespread use of personally identifiable information (PII) and the complexity of Web infrastructure is a combination that makes solitude and privacy more essential to the individual. Privacy has emerged as a central policy concern as more people go online every day. Not surprisingly, a great many people are fretful about the things that could happen online and the way in which data about them might be gathered and used. A strong sense of distrust shadows individuals' view of the online world, and the uneasiness has grown. An overwhelming majority of customers are concerned about businesses or people they don't know getting personal information about themselves or their families. (Fox, Rainie, Horrigan, Lenhart, Spooner, & Carter, 2000b). Customers are afraid of Web sites selling or giving away information about them, about insurance companies learning what they have done online and making coverage decisions based on that, and about their employers learning what they have done (Fox & Rainie, 2000a).

Privacy concerns can pose a serious impediment to expanded growth of PCEH in the future. Even the most convenient PCEH services may function ineffectively, because sharing personal medical and health information requires a certain leap of faith—or at least a strong sense of privacy and trust (Fox & Fallows, 2003). Trust is a critical factor in any relationship in which the individual does not have direct control over the actions of company, the decision is important, and the environment is uncertain (Mayer, Davis, & Schoorman, 1995).

This chapter concentrates on privacy issues and problems in two main interests; namely, the online customer and the online health provider. Customers of PCEH are active and involved participants, and therefore, our target is to consider individual needs and capabilities as the primary criteria for designing PCEH services and privacy practices. In this chapter, a framework for PCEH privacy management is presented. The framework balances the rights of individuals to privacy against the possibility of companies to use this technology opportunistically. This understanding is critical, because individuals are becoming increasingly privacy aware and more interested in knowing how to protect their own privacy. At the same time, individuals desire a wide range of new PCEH services.

BACKGROUND

Perspectives on Privacy

Privacy, which is often associated with, and sometimes described in terms of liberty, autonomy, solitude, and secrecy is a concept that is not easily defined (Tavani, 1999a, pp. 137). "Unlike privacy, secrecy appears to have a tight connection to information" (Thompson, 2001, pp. 15). If something is secret, there is at least one person to whom the information is not known. "While confidentiality continues to be an important ethical problem for computer professions, and while security is an increasingly important technical issue, privacy is a red herring" (Thompson, 2001, p. 14).

The term "privacy" is sometimes used to designate a situation in which people are protected from intrusion or observation by natural or physical circumstances. Natural privacy rights are intended to protect a sphere of activity, often a physical place but sometimes an interpersonal relationship, from intrusion by government and other third parties, *the right to be let alone* (Warren & Brandeis, 1890).

Many analysts use the expression "informational privacy" or "information privacy" to refer to a distinct category of privacy concern. Informational privacy is a category of privacy with a set of issues that are distinguishable from privacy concerns related to intrusion and interference (Tavani, 1999a; Tavani, 1999b). When we consider informational privacy "one often finds oneself in a conceptual muddle", because "the issues are not trivial matters of semantics" (Moor, 1998, pp. 16). There are cases when general knowledge of private matters does not breach persons' privacy in any morally significant way. A person's health information may be widely known, but that in no way makes them less private. Having information about a person's sensitive matters may make it possible for someone to violate that person's privacy by discriminating for or against them in an inappropriate way. Such information is widely available in most societies, and "the significance of such information lies not in simple knowledge of it, but in its further use […] Medical information can be used to deny employment and other opportunities to which a person is entitled, and embarrassment is a form of emotional harm that can have extreme consequences in certain situations" (Thompson, 2001, pp.15). "Many Americans know that violation of copyright is a crime, and many believe that violation of their privacy should be a crime too. Why is distributing a corporation's software without its permission called 'piracy,' while distributing a person's information without permission is called 'sharing'?" (Fox et al., 2000b, pp. 11).

A normatively private situation is a situation protected by ethical, legal, or conventional norms. When we frame the debate simply in terms of how to balance privacy interests as an individual good against interests involving the larger social good, support for those interests believed to benefit the latter good will likely override concerns regarding individual privacy (Regan, 1995, pp. 213). There is almost a paradox about our feelings in the personal and social costs of sabotage and the concomitant personal and social benefits of tight security. For the sake of my safety, I would like all others' e-mails monitored to eliminate any possibility that they will be able to damage society. At the same time, I would prefer that my e-mails not be monitored. My wish to maintain privacy for my personal e-mails is, however, unreasonable against the generalization of everyone's wish for their safety. "In isolation my desire for privacy is reasonable; it only becomes unreasonable in the contemporary social context" (McArthur, 2001, pp. 125). If the monitoring of e-mails would add security in a community or would raise that community's standard of living, then a decision to add monitoring would likely be perceived as yielding a greater overall good than would a decision to protect the privacy of individuals. Theorists working in sociological traditions have tended to interpret the emergence of computerized information technology as something that enables an evolution in social power relations that favors governmental and commercial organizations against the interests of individual citizens (Johnson, 1994; Gotlieb, 1995). And it includes elements of the threat of overly broad normative law that contains the possibility for misinterpretations. Human nature has also shown that security fears can be used to hurt a community with big brother style invasions of privacy used to support one social group over another.

There are two main solutions to deal with the legitimate rights of informational privacy. The more common is to use the regulatory powers of the state. This practice is predominant in the EU, which uses very strict directives concerning the privacy matter1. The other solution is the voluntary basis. That practice is very predominant in the U.S., where the greatest likelihood is that industry will be left to develop voluntary guidelines2, rather than Congress imposing regulations.

There was little legal protection for health information—online or off-line—until the release of HIPAA regulation in the U.S.3 But while HIPAA regulation is an important step, its application is limited. The regulation does not cover a significant portion of the health-related activities that take place online. The HIPAA analysis of Choy et al. (2001) shows that many who engage in online health activities will fall outside the scope of the regulation. "People often believe they are invisible and anonymous online, but they are often exposing their most sensitive health information to online healthcare sites that are not required by law to protect the information or keep it confidential. The potential for abuse is enormous" (Choy et al., 2001, pp. 25).

If we put conceptions of privacy together with distinction between normative and natural privacy, we get a situation-dependent issue of privacy: "An individual or group has normative privacy in a situation with regard to others if and only if in that situation the individual or group is normatively protected from intrusion, interference, and information access by others" (Culver, Moor, Duerfeldt, Kapp, & Sullivan, 1994, pp. 6). The general term "situation" is useful because it is broad enough to cover many kinds of informational privacy: private locations such as a medicine delivery record in a database; private relationships such as an electronic prescription to one's pharmacy, and private activities such as the utilization of computerized health information. Privacy situation covers also role, time, and place-dependant issues.

If an unauthorized entry is made into a normatively private situation, "privacy has not only been lost, it has been breached or invaded" (Moor, 1997, pp. 30). If a worker uses an online system for the delivery of a medicine and processes a customer's healthcare treatment using the older information of the medicine deliveries, then the worker is not invading the individual's privacy. She is allowed in this situation and working role to investigate the customer's medicine history. However, if that same worker were to "open" that same customer's case record after hours just to browse around, then the worker would be breaching the individual's privacy although the worker may gain no new information. The worker has legitimate access in the first situation but not the in the second.

Value of Privacy

The Internet technology has created a "universal" technology platform, and to justify the importance of privacy more exactly in the global setting we can continue by asking whether informational privacy has instrumental and intrinsic value. Instrumental values are those values that are good because they lead to something else which is good. Intrinsic values are values that are good in themselves (Moor, 1997).

Privacy has instrumental value, because privacy offers us protection against harm, but "to justify the high instrumental value of privacy we need to show that not only does privacy have instrumental value but that it leads to something very, very important" (Moor, 1997, pp. 28) One of the most well-known attempts to do this has been given by James Rachels. In a 1975 article, Rachels lists several cases where "information about a person might provide someone with a reason for mistreating him in some way" (Rachels, 1975, pp. 351). Rachels suggests that such cases are misleading when they are taken to indicate why privacy is important. Privacy is valuable because it enables us to form varied relationships with other people. Privacy also enables us to form intimate bonds with other people that might otherwise be difficult to form and maintain in public. In a society where individuals have no privacy, friendships, intimacy, and trust cannot develop (Fried, 1970). If we want such relationships, we must have privacy. However, the need to relate to others differently may not ground privacy securely "because not everyone may want to form varied relationships and those who do may not need privacy to do it" (Moor, 1997, pp. 28). This view is based on the principle that some people simply do not care how others perceive them.

Some arguments tie privacy more tightly to autonomy, because privacy is understood to be not just a means of autonomy but a part of the very meaning of this term. We don't seek privacy in order to get autonomy, but "autonomy is inconceivable without privacy." (Johnson, 1994, p. 89). Autonomy is not just one among many values (i.e., autonomy is fundamental to what it means to be human and to our value as human beings). Privacy is necessary for diversity of relationships, and privacy is an essential aspect of autonomy. Assuming that autonomy is intrinsically valuable and privacy is a necessary condition for autonomy we have the strong and attractive claim that privacy is a necessary condition for an intrinsic good. But, is it true that autonomy is inconceivable without informational privacy? Suppose an online pharmacy collects information about customer purchases into database. Normally, customers recognize the collection process when they fill medicine prescriptions online. Consider the situation in which the online pharmacy does not share the information with anyone else or take advantage of customer in any way whatsoever. Customers have complete autonomy, just no privacy (Moor, 1997, pp. 28). Thus, it follows that privacy is not an essential condition for autonomy on PCEH services. It is conceivable to have autonomy without privacy.

We can continue by asking whether privacy is a core value. Core values are set of values that are shared by most, if not all, humans and are familiar to all of us. They are shared and fundamental to human evaluation, for example, life and happiness are two of the most obvious. It is possible to test for a core value by asking whether it a value that is found in all human cultures. The core values provide standards with which to evaluate the rationality of our actions and policies. They give us reasons to prefer some courses of action over others. They provide a framework of values for judging the activities of others as well (Moor, 1997; Moor, 1998).

It seems that privacy is not a core value per se, because “the concept of privacy has a distinctly cultural aspect which goes beyond the core values. Some cultures may value privacy and some may not” (Moor, 1997, pp.29). Maybe privacy is not a core value per se, but it is deeply linked to the value of security. Gotlieb (1995, pp. 168) points out that “what must be secured in every civilized and free society is, of course, security of person.” Protection from strangers who may have goals antithetical to our own is sought, and all cultures need security of some kind because without protection species and cultures don’t survive and flourish. “As societies become larger, highly interactive, but less intimate, privacy becomes a natural expression of the need for security.” (Moor, 1997, pp. 29). In particular, a highly computerized culture where lots of personally identifiable information is manipulated, stored, and transferred, it is almost inevitable that privacy will emerge as an expression of the core value, security.

In summary, the justification of privacy is firm because privacy can be grounded instrumentally and intrinsically—instrumentally, in support of the core values, and intrinsically, as an expression of security and more. Because privacy is instrumental in support of the core values, it is instrumental for important matters. Moreover, because privacy is an expression of the core value of security, it is a critical, interlocking member of our systems of values in our increasingly electronic culture. If an online company collects a lot of personally identifiable information without consent (which does not harm its customer when it collects, stores, and manipulates), it nevertheless seems to be doing something wrong intrinsically. The subjects’ security is being violated by the company even if no other harm befalls the person. The seminal article of Warren and Brandeis (1890) initiated the view that privacy is a positive good, and that individuals have an interest in maintaining a political right to privacy. Privacy is also a necessary means of support in a networked electronic healthcare, and thus, privacy is well grounded for our consideration. People have a basic right to protection, which, from the viewpoint of the patient-centered e-health, includes privacy protection.

PRIVACY FRAMEWORK

Privacy seems to be something of very great importance and something vital to defend, but also a matter of individual preference and culturally relative. The attempt to find one general measure for global privacy policy fails—there are too many situation-dependant aspects to consider. Privacy matters are deeply situation-dependent issues and cannot be found by applying a predefined list without considering the situation widely. A privacy problem may arise in a specific situation, and it may occur as the result of an unpredictable incident. Privacy constantly includes a large number of evolving situations that are difficult to conceptualize clearly, and it is hard to find justified practices. Therefore, privacy involves more than rote application of existing norms.

This section presents existing privacy theories and consider how they apply to PCEH. Finally the privacy framework is presented. It acknowledges the voluntary nature of the way in which individuals have surrendered control over personal information in exchange for the benefits that information technology brings.

Privacy Theories

Two privacy theories, which relate to personal information, are the "control" and the "limitation" theories.

According to the control theory, one has privacy if and only if one has control over information about oneself. "Privacy is not simply an absence of information about us in the minds of others, rather it is the control we have over information about ourselves" (Fried, 1984, pp. 209). The control theory correctly recognizes the aspect of choice that an individual who has privacy enjoys in being able to grant, as well as to deny, individual access to information about oneself. Control theory has some weaknesses. No one is able to have complete control over every piece of information about oneself, although Michelfelder (2001, pp. 134) states that "because the richness of the lived world is not mirrored in the online world, there are fewer relevant privacy values to be concerned about." But still the control theory has that practical problem. It is highly desirable that we are able to control information about ourselves. However, in a highly networked society it is simply impossible. We are not able to control vast amounts of electronic information about ourselves. Personally identifiable information is well greased and slides rapidly through networks around the world, around the clock.

The needed amendment to the control theory is a situation dependence, which limits the matters to consider. A theory offering assistance in this area is called the limitation theory by Tavani (1999b). The limitation theory recognizes the importance of setting up zones of privacy. Privacy consists of the condition of having access to information about oneself limited or restricted in a certain situation. One important weakness of the limitation theory is that "it tends to underestimate the role of control or choice that is also required in one's having privacy" (Tavani, 1999b, pp. 267). Some variations of the limitation theory suggest that a person's privacy correlates with the extent to which information about a person is limited. Therefore privacy according to the limitation theory would seem to be very closely related to secrecy. It seems, however, that in some cases, the word "private" is virtually synonymous with the word "secret"; or "confidential." Thompson (2001, pp. 15) points out that when we say "They want to keep some aspect of their life private in order to avoid embarrassment," or "Medical records should be kept private," we can substitute the word "confidential" for "private" without altering the meaning of the statement.

Limitation theory has many good features, but the theory ignores the fact that someone who has privacy can choose to grant, as well as to limit or deny, others access to information about oneself, thus it needs some amendments to be adequate for online practices for PCEH. Control theory has that missing feature, but because it does not include the condition of having access to information about oneself limited or restricted in certain situations, its perspective is too wide and open-ended to be practical.

Moor (1997) presents a theory, the control and restricted access theory, that covers both the preceding weaknesses. The main thesis of the theory is in order to protect ourselves we need to make sure the right people and only the right people have access to relevant information at the right time. Basically it has the advantages of the control theory for giving individuals as much control (informed consent) over personal data as realistically possible. But it also incorporates the strength of the limitation theory in maintaining that privacy needs to be understood in terms of situations where access to individuals is limited or restricted. So it recognizes the importance of setting up zones of privacy. Finally it incorporates the strength of both theories in holding that individuals affected by a certain situation need to have some control or choice in determining whether that information will be kept private or not.

In our considerations, it is important that the customers can make the most convenient choices in terms of their own needs and values from a number of alternatives, because what one customer considers a privacy invasion may be a valued feature or service to another customer. Rather than regarding privacy as an all or nothing proposition, the control and restricted access theory acknowledges the situation in which information is authorized to flow to some people some of the time. Ideally, those who need to know have access and others do not.

The control and restricted access theory also helps explain some anomalies about private situations. So far we have discussed situations in which individuals possess damaging personally identifiable information they want to keep others from knowing. Moor (1997, pp. 31) points out that "situations can be private in other circumstances." Moor presents an example that occurs in a physician's waiting room where scores of customers are waiting for their appointments. A couple begins to argue loudly and eventually shouting to each other about a problem they are having. They go into excruciating detail about various events and catastrophes. Everyone can hear them and many customers feel uncomfortable as they sit there with nothing special going on. Finally, one customer, who thinks he can help, cannot stand it anymore. He asks whether they would like his advice. The couple in unison tells him, "No, it's a private matter."

As funny as couple's comment may be in that situation, it does make sense on several levels. It is not reasonable to claim that an invasion of privacy has occurred, since the couple was the original cause of the information's becoming public. But "in private situations the access to information can be blocked in both directions" (Moor, 1997, pp. 31). The couple did not want to allow information from the customer although they themselves had been rude in revealing details to everyone.

In our considerations, it is important that the access to information is possible to be blocked in both directions by the individual. Because the Internet is an effective tool for receiving and sharing information, e-health providers can use very large pools of data from multiple sources and suggest similar advice using e-mails and much more.

Privacy Principles

McArthur (2001, pp. 124) presents two useful principles that emerge from the preceding examples:

The Mischance Principle: We cannot reasonably expect to maintain privacy over that which another person could discover, overhear, or come to know without concerted effort on his/her part to obtain this information.

Arguing loudly in the waiting room would certainly fall into this category. The mischance principle works, as McArthur (2001, pp. 124) points out, "in a range of possible instances because it is relatively easy to figure out what precautions to take to maintain privacy against casual observation." And thus, "anything put by a person in the public domain could be viewed as public information" (Fulda, 1997, pp.28).

The Voluntary Principle: If I choose to decrease the relative amount of privacy for myself and information under my control by exposing it to view, I thereby decrease the reasonableness of any expectation that this privacy will be observed.

Decreasing the relative amount of privacy is accomplished by increasing the likelihood under the circumstances that the information will come to another's attention through mischance, and therefore our examples would certainly also fall into this category. McArthur (2001, pp. 125) points out that "one of the ways in which the voluntary principle is sometimes interpreted is that the failure to attempt to maintain privacy constitutes willingness for that information to become public." By arguing loudly in the place where people are gathered, the person is positively increasing the likelihood of that information becoming known. By arguing loudly in the room where no people are gathered, the person is negatively increasing the likelihood that the matter will become known. This principle is referred to as the negative voluntary principle. The extent to which expectations of privacy are reasonable takes into account the social norms governing the particular form of information may have as well as the context. Therefore, the interpretation of whether the person is positively or negatively increasing the likelihood of that information becoming known is not always easy to make.

As DeCew (1997, pp. 7) states, we should presume in favour of privacy and then develop ways that would "allow the individual to determine for themselves how and when that presumption should be overridden." Combined with the mischance and voluntary principles, application to PCEH of Moor's (1997, pp. 32) three principles, the Publicity Principle, the Justification of Exceptions Principle, and the Adjustment Principle enables us to do as DeCew states:

- *The Publicity Principle*: Rules and conditions governing private situations should be clear and known to the persons affected by them.
- *The Justification of Exceptions Principle:* A breach of a private situation is justified if and only if there is a great likelihood that the harm caused by the disclosure will be so much less than the harm prevented that an impartial person would permit breach in this and in morally similar situations.
- *The Adjustment Principle:* If special circumstances justify a change in the parameters of a private situation, then the alteration should become an explicit and public part of the rules and conditions governing the private situations.

The strength of Moor's principles is a very practical one because customers do not need to have absolute or unlimited control in order to have privacy on PCEH. The publicity principle suggests that we can plan to protect our privacy better if we know where the zones of privacy are and under what conditions and to whom information will be given. The publicity principle encourages informed consent and rational decision making, which are important factors for expanded growth of PCEH.

Once policies are established and known, circumstances sometimes arise which invite us to breach the privacy policy. Privacy policy breaches should be avoided as much as possible because they undermine confidence in the policy. However, exceptional circumstances sometimes occur in the cases related to special health issues, which are discussed later.

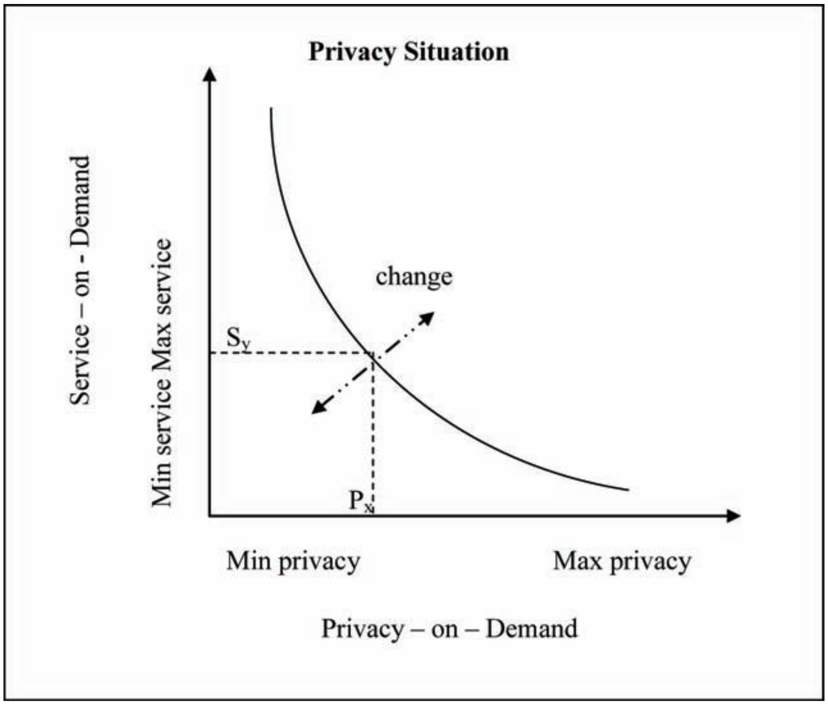
The adjustment principle normalizes the changed privacy situation. It is an important principle of PCEH where situation-dependant issues, possibilities of technological change and development of new services are pervasive.

Model of Privacy Management

The presented framework, including five principles and the control and restricted access theory, results in privacy responsibilities and advantages for both e-health customers and providers. The framework has the advantage that privacy and service functions can be fine tuned with consideration to the privacy situation.

The idea of the privacy management model of PCEH is presented in the Figure 1, where customer privacy (Privacy-on-Demand function

Figure 1. Privacy management model



P_x) is related to the service (Service-on-Demand function S_y). Employing an interactive dialog by demanding or consenting, customers are able to choose from "max service" to "min service" to be polarized into the concept of privacy (i.e., "min privacy" or "max privacy" and vice versa).

The model does not downplay the voluntary nature of the way in which customers of PCEH have surrendered control over personal information in exchange for the benefits that information technology brings. This model is consistent with exchange theory (Thibaut & Kelley, 1959). According to exchange theory, individuals form associations on the basis of trust, and try to avoid exchange relationships that are likely to bring more pain than pleasure. "Developmentally, a relationship among parties who have not had prior association is expected to emerge incrementally and to begin with small actions that initially require little reliance on trust" (Jarvenpaa, Tractinsky, & Vitale, 2000, pp. 46). If the actions are reciprocated, trust tends to spiral upward. If they are not reciprocated, trust spirals downward (Sitkin & Roth, 1993). One of the consequences of trust is that it reduces the individual's perception of risk associated with opportunistic behavior by the organization (Ganesan, 1994).

Web site interactive content can add considerable value for both the company and its customer. In the model, the customer has the opportunity to choose and "manipulate" online health service and privacy practices. Typically, more services means less privacy and more privacy means less service possibilities. The interactivity possibilities of Web applications have the means to customize privacy and service functions more exactly to the needs of PCEH customers, thus enabling them to choose privacy practices and make more informed decisions concerning to whom they entrust their personally identifiable information and what kind of service they prefer or don't prefer. Employing an interactive dialog by demanding or consenting, customers are able to change Privacy-on-Demand and Service-on-Demand functions. If the company changes privacy situations without consent or demand by the customer, it is leaning toward opportunism.

One important aspect of the model is that it proposes possibilities and advantages for both customers and companies. The model proposes flexibility for PCEH privacy policy, but also demanding rules and principles. The model normally illustrates the situation where a customer is able to give informed consent and to make rational decisions—a customer is able to opt-in to (or opt-out of) privacy and service levels (Järvinen, 2005).

Almost 90 percent of Internet users are in favor of "opt-in" privacy policies that require Internet companies to ask people for permission to use their personal information. Online applications should ask individuals for permission to use their personal information, which is the kind of system has been adopted by the EU. However, this view challenges the policy negotiated by the Federal Trade Commission and a consortium of Web advertisers, which gives users of U.S.-based Web sites the right to "opt out." An "opt-out" scheme would compel individuals to take steps to protect their privacy (Fox et al. 2000b, pp. 3).

Example of Privacy Management Model

Next the data mining of genetic information is discussed to illustrate the use of the privacy management model in practice.

Advances in data mining techniques for large databases are a technological trend that heightens ethical concerns, because they enable companies to find out a lot of detailed personal information about individuals. Data mining causes privacy concerns because individuals are often not aware of data mining practices in advance. Data for which they may have given their consent for collection and use in one context is being mined in ways they had not explicitly authorized.

Suppose a customer decides to get tested for a breast cancer gene. Breast cancer runs in her family, and she wants to know whether she is genetically disposed to have breast cancer. She goes to the laboratory for tests for the gene and the results are positive. The laboratory results are stored in her electronic medical record so that the test results are available to medical researchers and physicians to encourage aggressive testing for the disease in the future. Because the information will be computerized, it means that many health providers and researchers may have access to the information. For example, if the customer's health insurance company gets access to it, then it could mean problems to the "owner of the information." Information of this kind could be detrimental to the individual when obtaining life insurance or future health insurance. Eventually, if the medical information slides through enough networks and information systems, it could be detrimental to the individual's relatives when obtaining insurance and applying for employment, even though they have shown no signs of the disease and have never been tested (Moor, 1997).

The model suggests that Web application should set up a zone of privacy for customers (P_x) who only want predictive testing done (S_y) because there is, as Moor points out (1997, pp. 32):

> *a difference between predictive genetic testing in which the patient is tested for genetic information that may be indicative of future disease and diagnostic testing in which the patient is tested for genetic information that may confirm a diagnosis of an existing disease.*

The health provider should establish a private situation for predictive testing so that the customer's analyst results were not incorporated into the regular medical file. If we think about privacy issues from the perspective of the privacy model, these medical records would be computerized but not accessible to all of those who have access to the general medical record. This practice (S_y) allows adjustment of the access conditions to increase the level of privacy (P_x) for the customer.

According to the framework, it is clear that customers should be told what will happen to the analysis information. The customers can choose their privacy situation better if they know where the zones of privacy are and under what conditions and to whom information will be given. Rules and conditions governing private situations should be clear and known to the persons affected by them, so customers are able to determine service and privacy levels accordingly. The customers might prefer ("opt-in") to have the analysis information included in their regular medical record.

The genetic test gives us also an example that describes the nature of the justification of exceptions principle. Suppose that after some predictive genetic tests are run, new information about the consequences of the analysis results is uncovered by means of the data mining process. The customer's old health information in combination with the analysis results show that the customer surely must have transmitted a devastating disease to her offspring, but that the disease can be treated effectively if caught in time. The physician's duty to keep the customer's secrets confidential is an important protection of privacy and the values related to it, but it is by no means absolute in medical law or ethics generally (Sommerville, 1999; Mason, McCall, & Smith, 1985).

> *In the context of genetic information, the most prominent reason for breaches of confidentiality is the harm inflicted on others by their ignorance [...] But the strength of arguments like this varies from case to case, depending on the specific nature of family relationships between the individuals involved (Häyry & Takala, 2001, pp. 408).*

In such circumstances, it would seem that the health provider should notify not only the customer but also her adult offspring even though that was not part of the original privacy policy. The breach is justified because the harm caused by the disclosure will be so much less than the harm prevented. Using the justification of exception principle, a health provider may determine the change of privacy policy without the threat of opportunism. The ethical significance of beneficial outcomes should be included in discussions of privacy. We should not, however, presume that beneficial outcomes can always be used to counterbalance harmful outcomes in any straightforward manner. It should be avoided to override customers' wishes as much as possible because they undermine confidence. Using anonymity or fake names (Fox et al., 2000b; Uslaner, 2000) in the health service process is not a convenient practice because it might be even a threat to sufficient health operations.

> *To shield themselves from what they consider harmful and intrusive uses of their health information, customers have engaged in privacy-protective behaviors, such as providing incomplete information, thereby putting themselves at risk from undiagnosed, untreated conditions. The lack of complete and accurate health information on patients impacts the community as well. Healthcare information used for important research and public health initiatives downstream becomes unreliable and incomplete (Choy et al., 2001, pp. 1).*

The adjustment principle in this example states that those who continued to have predictive genetic testing would know what information would be released in stated exceptional circumstances. They would know the possible consequences of their decision to have predictive genetic testing and could plan accordingly. According to the adjustment principle, the privacy policy should indicate the new service and privacy practice.

According to the model, it is important that the customerl is given the opportunity to decide what information is to be used and whether it may be used for new purposes after changes of practices. Normally privacy policies should provide assurance that previously gathered data won't be used in any new way before consent of the customer. If the customer does not accept the change, then the customer should be able to remove all data, update it, or freeze information usage at the level of the old service and privacy practice. Concerning the change of privacy and service functions customers should have possibility to choose as follows: (a) customers do not agree with the new practices at all and demand that their personal information be deleted; (b) customers want their personal information frozen at the previous state of practice; and (c) customers agree to the new practices.

When informed about the details of new practices, some customers would perhaps be inclined to choose Option A and elect not to participate in the company's processes at all in the future. Some customers elect to have their personal information used in older ways, because they are used to getting services based on that level, provided that they can be assured that information about them would not be used in new ways. Other customers might elect Option C and consent to their information being used in new ways, probably because of certain perceived new benefits they might receive.

The important point of the model is that through explicit and open notification and the opportunity to choose different alternatives, individuals could have a greater say or choice regarding how information about them is being used. The interactivity properties of Internet technology give us an efficient manner to deal with the proposed practice of the model (see Järvinen, 2005, pp. 139–147; 201–226).

FUTURE TRENDS

Today's Web-technology enables new means to provide services for knowledge-intensive industries such as insurance, banking and healthcare. A key characteristic of the Internet is that individuals are totally in control of which sites they visit and how long they stay and perceived risk negatively influences willingness to use Web-services. Therefore, trustworthy privacy and service management are obviously imperative sources of value creation and competitiveness. In the future, companies will compete to give individuals the services and the privacy they want. In that scenario, very strict normative privacy regulations according to the privacy framework mean that individuals may not receive satisfactory services. The industry in the U.S. has vowed to self-regulate, but privacy and service management of Web-based e-health services are underdeveloped in general. In that situation, from the perspective of privacy, confidentiality and trust, individuals need more comprehensible tools to gain control over Web-organizations' privacy and service practices. From the perspective of information and communication technology, service providers need more comprehensible methods for the design of Web-based privacy and service management.

It is relatively easy to set up a Web site, but far more difficult to create a Web-based business model. The medical establishment is beginning to recognize both the potential benefits and pitfalls of using electronic communications in healthcare (Fox & Fallows, 2003). As customer demands continue to increase and the availability of informational and interactive Web site content continues to proliferate, the bar for acceptable performance by health providers will continue to rise.

CONCLUSION

It seems that privacy is a broad and, in many ways, elusive concept. Privacy is a social, cultural, and legal concept, all three aspects of which vary from country to country. However, the justification of informational privacy is firm because privacy can be grounded instrumentally and intrinsically—instrumentally, in support of the core values, and intrinsically, as an expression of security and more. Thus, there is a presumption that privacy is a positive value that is worth protecting.

Concerns about informational privacy generally relate not to the collection of information itself, which many individuals would gladly give for appropriate use in a specific situation, but to the manner in which personal information is used and then disclosed. When a business collects information without the knowledge or consent of the individual to whom the information relates, or uses that information in ways that are not known to the individual, or discloses the information without the consent of the individual, information privacy is seriously threatened.

The situations that are normatively private can vary significantly from culture to culture, situation to situation, and time to time. This does not mean that the privacy standards are arbitrary or unjustified; they are just different. A safe retreat to a realm of pure facts, without any consideration of values is never possible, and that also includes privacy and service management of patient-centered e-health.

According to the privacy framework, the attempt to find one general measure for global privacy management fails—there are too many situation-dependant aspects to consider. In general, the amount of privacy individuals have, and can reasonably expect to have, is a function of the practices and laws of society and publicity and voluntary principles. Privacy matters of healthcare are deeply situation-dependent issues and cannot be found by applying a predefined list without considering the situation thoroughly. Information practices of e-health may conflict with individuals' desires to be shielded from unauthorized use of their personal information. The framework focuses on what we should be considering when developing privacy management for protecting our privacy in that situation. It does not neglect the important distinction between the different interests affected by PCEH. The strength of the framework is its ability to distinguish between the condition of privacy and the right to privacy and between a loss of privacy and a violation of privacy.

The privacy management model acknowledges the voluntary nature of the way in which individuals have surrendered control over personal information in exchange for the benefits that information technology brings. The interactivity features of the Internet provide health providers with many opportunities for online management so that the individuals can make the most convenient choices in terms of their own needs and values from a number of alternatives. What one customer considers a privacy invasion may be a valued feature or service to another customer. Interactive Web site content can provide considerable added value for both the health provider and its customer.

Because the applications of information technology are logically malleable, there are sufficient strategic reasons to suggest that privacy management as a concept and practice will survive, and that to ignore privacy issues might be fatal for the success of PCEH. If we naively regard the issues of privacy management as routine or, even worse, as unsolvable, then individuals are in the greatest danger of being harmed by information technology, or those services will not be used at all. If privacy is understood, not merely as a value involving the good of individuals, but as one that also contributes to the broader business and organizational good, then the concern for privacy might have a greater chance of receiving the kind of consideration it deserves.

ACKNOWLEDGMENT

The Foundation for Economic Education is acknowledged for their support. This support has been very important and it has enabled fluent progress of the privacy management project. Some anonymous reviewers of the manuscript have also contributed through constructive comments.

Chapter 7.5

Healthcare Ethics in the Information Age

Keith Bauer
Marquette University, USA

ABSTRACT

This chapter reviews key debates about the meaning of telehealth and also considers how new and emerging systems in telehealth work to protect patient confidentiality, improve healthcare relationships, and diminish instances of compromised access and equity in the healthcare system. This chapter also looks at how these same telehealth systems could undermine those goals, making it important to assess the way in which these emerging technologies are implemented. Various technologies are examined to show how their implementation can ensure that their benefits outweigh their risks.

INTRODUCTION

The growing use of information and communication technology (ICT) is producing widespread changes in society. One area in particular that is quickly being transformed by ICT is the field of healthcare. This is evident in the relatively new field of telehealth, which utilizes the Internet, electronic patient records systems, hand-held computers, among other types of ICT. Telehealth has great potential to improve the quality and provision of healthcare services, but there are a number of subtle ethical issues that should be considered as society moves forward with its use. The aim of this chapter is, therefore, to provide an ethical assessment of telehealth. The specific questions this chapter addresses are as follows:

1. What are the distributive justice implications of telehealth? Will medically underserved populations gain greater access to healthcare services? If so, what sorts of tradeoffs, if any, between access and quality will be required?
2. What are the implications of telehealth for provider-patient relationships? For example, will an increase in the quantity of provider-patient interactions lead to a corresponding increase or reduction in the quality of those interactions?
3. What are the implications of telehealth for medical privacy and patient confidentiality?
4. What are the future trends in telehealth and how will they affect patient care and the healthcare system in general?

BACKGROUND

In order to understand what telehealth is, it is necessary to understand its history and its meanings. The literal meaning of the word *telehealth* is *health from a distance*. Combining the word *health* with the Greek prefix *tele*, which means end, far off, or distance, produces this definition. We see similar combinations in the words *telephone*, which literally means, *sound from a distance*, and *telegraph*, which literally means *writing from a distance*.

Various definitions of telehealth are currently in circulation within the healthcare community. One common view of telehealth makes it synonymous with two-way audio-video systems that allow for interactive consults between patients and healthcare professionals. However, other definitions are equally common and may include the use of ICTs (e.g., computers) that capture, store, manipulate, and display medical data but not include the use of interactive communications between patients and healthcare providers. Consequently, a fax machine used to transmit patient medical information or the telemonitoring of a cardiac patient would not count as telehealth under the first definition but would under the second definition (Denton, 1993; Preston, 1994).

Although no universally accepted definition of telehealth exists, there is agreement that any definition of it must include at least three elements: (1) the use of ICT, (2) geographic distance between the participants, and (3) health or medical uses. On the basis of these three characteristics, the Institute of Medicine (IOM) defines telehealth/telemedicine in the following manner:

> *Telemedicine [telehealth] is the use of telecommunications and information technologies to share and to maintain patient health information and to provide clinical care and health education to patients and professionals when distance separates the participants. (Field, 1996, p. 27)*

The IOM's definition can be made more specific, depending on whether (a) emphasis is given to a particular technology (e.g., video conferencing or Internet) (b) a distinction is made between clinical and non-clinical applications, and (c) whether telehealth is conceived of as an integrated system of healthcare delivery rather than a mere collection of electronic tools.

Non-clinical applications of telehealth typically include professional education, healthcare administrative duties, management meetings, research, and the aggregation of health data, but usually exclude medical treatments and decisions for specific patients. Clinical applications of telehealth involve patient care and include medical decisions, diagnostics, and treatments for particular patients. This distinction, however, can be difficult to maintain because some ICT allow for the convergence of non-clinical and clinical activities, for example, when e-mail communications between patients and providers are automatically stored in a computerized record system.

In addition, there are a number of ways in which clinical telehealth can be subdivided. One way is to classify clinical applications by the point of service or the patient's location, for example, rural, correctional, and home. Another classificatory scheme common to clinical telehealth is to organize services by specialization, for example, telepsychiatry and telepathology (Peredina & Allen, 1995; Peredina & Brown, 1995). A third approach is simply to categorize telehealth services in terms of present and future healthcare reimbursement policies, for example, emergency care, follow-up care, consultation, and the transmission of diagnostic images (Grigsby & Kaehny, 1993).

The IOM's tripartite definition of telehealth--geography, ICT, and medicine—can be expanded upon when it is conceived as a system of healthcare rather than as the use of a particular ICT in a healthcare setting. According to one view, a *telehealth or telemedicine system* can be defined as follows:

> *A telemedicine system is an integrated, typically regional, health care network offering comprehensive health service to a defined population through the use of telecommunications and computer technology. (Bashshur & Sanders, 1997, p. 9)*

When telehealth is defined as a system of healthcare, the distributive and integrative strengths of ICT to form a seamless healthcare network are highlighted. This definition, because it highlights the systemic nature of telehealth, also helps to illuminate many of its social and ethical aspects not readily visible in other definitions.

KEY ETHICAL ISSUES

Most evaluations of telehealth have not centered on its ethical dimensions. In what follows, I explore three key ethical concerns surrounding the growth of telehealth. I begin with an examination of the potential distributive justice ramifications of telehealth.

Distributive Justice

Much of the debate over healthcare justice in the United States remains focused on the lack of access to healthcare services and inadequate health insurance coverage. The reason for this is that there are approximately 42 million persons who lack health insurance coverage (Schroeder, 2001). At this time, there are about 700,000 physicians practicing in the United States, which means there are approximately 275 physicians for every 100,000 persons. However, even with this doctor-to-patient ratio, many citizens still lack access to adequate healthcare services (Marwick, 2000). From a public health perspective, this is a serious problem. For, as numerous empirical studies have demonstrated, there is a strong correlation between positive health outcomes and access to healthcare services (Davis, 1991). But the problem is even more serious for health profession shortage areas, as they tend to have higher percentages of poverty, elderly people, people lacking health insurance coverage, and people with chronic diseases. From a distributive justice perspective, this means that one of the least fortunate and medically needy populations in the United States faces the greatest burdens in gaining access to healthcare services. As a way of ameliorating these healthcare disparities, telemedical initiatives are being devised to meet the healthcare needs of underserved populations. The good news is that telehealth services have the potential to produce a more equitable or fair distribution of healthcare resources. The bad news is that the Internet and other telecommunication technologies are not yet universally available, which in turn raises an entirely different but related set of distributive justice concerns about the digital divide—the equitable distribution of ICT.

However, before looking at the distributive justice pros and cons of telehealth, it will be useful to be more precise about what *distributive justice* in healthcare means. The general answer is that it pertains to questions about access and the fair allocation of healthcare benefits and burdens among populations. More specifically, distributive justice in healthcare requires the application of *fair standards* that make *quality* healthcare *available* and *accessibl*e to persons in an *efficient* manner (President's Commission, 1982). It is these five elements—fairness, quality, availability, accessibility, and efficiency—that are typically involved when distributive justice in healthcare is at stake. But what do these elements of distributive justice mean and how should we understand them in the context of telehealth?

A healthcare system is typically considered *fair* when (1) persons are not denied healthcare services on the basis of *prima facie* morally irrelevant criteria, such as class, race, and gender; and when (2) persons can secure an adequate level of care without excessive burdens (IOM, 2001). Because geography can create burdens for medically needy populations, geographic location, the place where one is born and lives, should not be used as a criterion for deciding who gets healthcare services. Rather, medical need should be the decisive factor.

Next, *quality* in the distribution of healthcare means not only that services are delivered with an eye towards avoiding errors, but should also be provided in a competent, compassionate, and respectful manner (IOM, 2001). The problem for many telehealth services at this time is that it is not fully known under what clinical conditions ICT should be employed and when, if at all, they should supplement or replace face-to-face interactions between patients and providers, for example, online psychiatry with severely depressed or suicidal patients. Consequently, standards of care and questions of whether telehealth improves or decreases the quality of healthcare have to be better understood.

The importance of *availability* and *accessibility* for distributive justice is that persons should receive services when they need it without *undue* burden. In some cases, services may be available within a geographical region but remain inaccessible because of inadequate transportation. The Internet along with advances in digital technology, for example, now make it possible to deliver some healthcare services to persons in underserved areas who would otherwise need to travel long distances. Telehealth technology, especially when located in the home, can make it easier to provide healthcare information and services over long distances and minimize the physical and financial burdens and lost time of patients who must travel long distances to meet with healthcare providers (Ostbye & Hurlen, 1997; Bauer, 2001).

Finally, *efficiency* is also an important variable in the distributive justice equation for telehealth. Because of limited healthcare resources and the high demand for them, the healthcare system should minimize inefficiencies such as duplicated services and errors to the greatest extent possible. For example, rather than replicating expensive services and technologies at different sites, a telehealth network could electronically link multiple sites to a centralized healthcare center where patients' records are stored.

Thus, efficiency, along with fairness, quality, accessibility, and availability, are the core elements of a general conception of distributive justice in healthcare and important to an ethical assessment of telehealth. If healthcare justice is to be a reality, no one of the aforementioned elements should be pursed to the exclusion of the other. A problem with this goal is that the five elements of distributive justice frequently come into conflict with each other. For example, improvements in the quality of some services may require placing limitations on the availability of other services because they lead to an unacceptable increase in the aggregate cost of healthcare and produce an unfair allocation of limited healthcare dollars. Also, ICT is likely to increase access to medical services, but the quality and confidentiality of those same services might not meet current standards of care established for traditional face-to-face medical encounters. Nevertheless, given the option of no healthcare services, telehealth, even if of lower quality, may be preferable.

As more healthcare information goes online and as more telemedical services are made available to the public, the digital divide (i.e., the unavailability or inaccessibility to ICT) should also be viewed as a healthcare justice problem. The digital divide is relevant because persons who lack access to information technology or the skills needed to operate the same technology may have greater burdens obtaining telemedical services compared to persons who have training and access to the Internet and computers (AMIA, 1997). Therefore, those who are the least well off and have the greatest medical needs—disabled elderly persons who live in health profession shortage areas—will have greater burdens in obtaining online health information and telehealth services that rely on the Internet. Until this gap in digital services is filled, telehealth services will remain limited for this medically needy population (Borberg, 1995).

But digital inclusion may not be the panacea that it appears to be for telehealth initiatives. If, as discussed above, digital inclusion becomes a reality in the near future for health profession shortage areas, there is the possibility that electronically mediated healthcare services will be of a lower quality compared to face-to-face healthcare services. If so, we will need to answer some important questions: When, if at all, should telehealth services either replace or supplement in-person services? What sorts of tradeoffs between access and quality are ethically acceptable and who gets to decide? Or, on the other hand, instead of pushing for digital inclusion and the establishment of telehealth systems, maybe a just healthcare system should require more effort and financial resources be devoted to enticing physicians and other healthcare professionals to practice in medically underserved regions.

Provider-Patient Relationships

Before looking at how telehealth is reshaping the provider-patient relationship, it is important to first identify the core goals and values that should be used to evaluate this relationship. For the purpose of this chapter, there are at least three major and overlapping healthcare goals and values that are central to an ethical evaluation of provider-patient relationships. These are (1) to achieve the best quality of patient care, (2) to balance the art of healthcare with the science of healthcare, and (3) to balance patient autonomy with professional autonomy (Hanson & Callahan, 1999; Kaplan, 2000). As will be discussed subsequently, various telehealth services may advance or retard any one of the three aforementioned healthcare goals and values.

First, *quality of patient care* refers to the ability of a new medical technology to improve patient care and health outcomes. Sometimes, however, acceptance of a new medical technology by providers has more to do with their belief in it than whether it can be demonstrated to improve the quality of patient care. For some, telehealth is a threat to the provider-patient relationship; to others, it is no threat at all. The reality is that until telehealth services have been adequately evaluated, we are left with competing speculations. Nevertheless, the belief that a new medical technology either harms or benefits the quality of patient care and the provider-patient relationship will play a large role in whether telehealth is accepted.

Second, *healthcare as both an art and science* has an extensive history and is closely connected to the quality of patient care. *The science of healthcare* refers to standardized clinical practice guidelines, automated procedures, scientific evidence, and the employment of medical technology. As is the case with science generally, the science of healthcare is always changing as new discoveries are made and better techniques emerge. *The art of healthcare* refers to the individual clinical judgements and intuitions of healthcare providers. The art of healthcare also refers to the emotional dimension of the provider-patient relationship. When the art of healthcare is practiced well, providers are able to genuinely feel and express empathy and compassion for their sick and vulnerable patients. Unlike the science of healthcare, the art of healthcare encompasses what is likely a universal and unchanging aspect of the human condition—the experience of being ill, being vulnerable, being dependent, and being healed. The art of healthcare requires a deep moral sensitivity to the experience of illness. Concerning this experience, Edmund Pellegrino states the following:

> *It [illness] is only in part defined medically as a concrete organic or psychological aberration. It is the perception of the change in existential states that forms the central experience of illness---the perception of impairment and the need to be made whole again---to be cured, healed, or cared for. (Pellegrino, 1981, p. 71).*

If Pellegrino is correct, then both the art and science of healthcare are desirable and necessary for the provision of technically sound and ethically appropriate healthcare services. Since Hippocrates' day, however, there have been tensions between the science and art of healthcare. According to Pellegrino and Thomasma, modern medicine is characterized by an imbalance in which technology and the science of healthcare dominate the provider-patient relationship:

> *The temptation to employ technology rather than to give oneself as a person in the process of healing is a "technological fix." The technological fix is much easier to conceptualize and to implement than the more difficult process of a truly human engagement. The training and the skills of modern health professionals overwhelmingly foster the use of technological fixes. (Pellegrino & Thomasma, 1993, p. 124).*

At this time, some applications of telehealth have proven to be easier and cheaper. Although the verdict is out on whether telehealth is simply an instance of modern man's proclivity for easy technical solutions to complex human problems, Pellegrino and Thomasma think, I believe correctly, that an overemphasis on technology and technical competence at the expense of compassion in medical education gives us good reasons to be concerned.

Autonomy is the final healthcare value basic to the acceptance of new medical technology and the provider-patient relationship. Modern healthcare, with its use of ICT, clinical practice guidelines, and research protocols, tends to give more weight to the science of healthcare and less weight to the expertise and judgments of individual providers. This is already the case in most healthcare settings where teams of providers, rather than individual providers, are more likely to care for a single patient. As such, the professional autonomy of individual providers is diluted because unilateral decision-making has given way to consensus building and shared decision-making. The rise of telehealth has intensified this trend. According to Douglas Walton:

> *The Hippocratic treatises are quite right to cite excellence of craftsmanship as a central ethic of competence for medical treatment. But in modern terms this competence must be understood to entail a sharing of scientific knowledge. Hence a corporate and institutional notion of technology as the coordination of a team effort is necessary. It is futile to try to go back altogether to the model of the caring family doctor as the bringer of treatment. (Walton, 1985, p.60).*

Moreover, as telehealth evolves, it is likely that patients will take on more responsibilities for administering and regulating their own healthcare, thereby, further limiting the role providers have in direct patient care. As more patients self care with the aid of telehealth technology, providers will not only work in teams, they will work in virtual teams that are geographically and temporally decentralized, lacking, in many instances, any face-to-face interactions with their patients and colleagues. Consequently, more effort at coordinating patient care will need to be made. This, in turn, is likely to increase the responsibilities and autonomy of patients, but place new restrictions on the professional autonomy of providers.

Changes in the provider-patient relationship are not new. A myriad of social, economic, and technological forces have continuously reshaped the provider-patient relationship since the dawn of medicine. Until relatively recently in medicine's history, the provider-patient relationship has been characterized by a substantial imbalance of power between patients and healthcare providers. Within the traditional provider-patient relationship, providers, especially doctors, have had more control and authority than their patients have. In simple terms, providers have had a dominant and active role while patients have had a subordinate and passive role in healthcare decision-making.

This unequal distribution of power is predominately a consequence of the medical expertise that providers have but patients lack but need in order to get well. Of course, imbalances in medical knowledge and power still exist within contemporary provider-patient relationships, but they are considerably less pronounced as they once were due to ICT.

For some theorists, the gradual realignment of power within the traditional paternal provider-patient relationship is, and continues to be, the result of *modernity*, which consists of convergent social, economic, and technological forces associated with the process of industrialization. Cockerham has the following to say:

> *Modernity promotes social relations that span the globe, moves social life away from traditional practices, and features the progressive use of knowledge to organize and transform society. In this context, medical science becomes increasingly accessible to laypersons. This situation, along with the desire of modern individuals to be in control of their lives, points towards a modification in the physician-patient [provider-patient] relationship in the direction of greater equality between the two parties. (Cockerham, 1993, p. 48).*

Cockerham does not explicitly mention telehealth, but the expanded use of ITC in healthcare can also be seen as an elaboration of modernism.

Telehealth, as a manifestation of modernism, raises a variety of ethical concerns. However, concerns about medical technology are not new. In fact, alarm over the increasing use of technology within patient-provider interactions also has a long history that includes the introduction of low-tech medical instruments such as the now commonly used stethoscope. When introduced, many physicians considered this device controversial because they believed it dehumanized the provider-patient relationship by putting physical distance between providers and patients. On this point, Evans has this to say:

> *Many chroniclers claim that high-tech medicine has evolved at the expense of the doctor-patient relationship, that machines have created a cold and impersonal chasm between the healer and the patient. In their minds the doctor has become a mere technician, a "body mechanic," who can treat disease but not the person. (Evans, 1993, p. 82).*

"High-tech" healthcare, however, does not have to be synonymous with an impersonal provider-patient relationship; it can also be associated with a personal and "high-touch" provider-patient relationship. This is possible because we need not accept, on the one hand, the view that medical technology is singularly responsible (i.e., technological fix) for the changes, good or bad, which have occurred within the provider-patient relationship. Nor need we accept that view, on the other hand, that the consequences of medical technology for the provider-patient relationship are tantamount to an endless stream of interpretations and rootless meanings. Rather, it is possible to adopt a middle course in which the meanings assigned to a new medical technology are as important as the technology itself in altering the provider-patient relationship. From this standpoint, technology, culture, institutional contexts, and the values and goals held by providers and patients all play a significant role in either the adoption or rejection of a new medical device. This was the case in the changed attitudes toward the stethoscope, which is now taken for granted as a basic and reliable medical tool. Thus, it would be premature to conclude that the high-tech of telehealth is inherently incompatible with a compassionate or high-touch provider-patient relationship (Turkle, 1984; Schement & Curtis, 1995).

Although modernism and the introduction of new medical technologies have had the overall effect of reducing the authority of providers, it has also given them greater power in the relationship in other respects. First, unlike the vast majority of their patients, providers understand how sophisticated medical tools function. Second, many medical devices have modified provider-patient interactions by facilitating the creation of an objective scientific nosology (i.e., classificatory scheme) that allows providers to diagnose a patient's disease independent of the patient's subjective reports. Third, because of an objective nosology and the relatively simple and universal manner in which medical devices are used, doctors are now able to delegate time-consuming activities to nurses and support staff, making doctors less directly involved in basic patient care. According to Evans:

> *With medical instruments, doctors [healthcare providers] could subject patients and their symptoms to objective scrutiny. As doctors gained more data from instruments, the quality of the information related by the patient seemed less important. Doctor and patient shared less knowledge; there was less common ground between them. A medical instrument acted as a lens through which the doctor could see the disease unfiltered by the patient's interpretations. Instruments thus altered the doctor-patient relationship, making the patient's experience of illness less important. (Evan, 1993, p. 90).*

Concerns about the impact of ICT on provider-patient relationships also have a long history. As early as the 1880s some physicians were lamenting the use of the telephone as a means of communicating with their patients. They were concerned that geographical distance and the lack of a hands-on approach with patients would undermine their ability to care for their patients. Before the telephone, the telegraph was subjected to similar criticism. Now, with the advent of modern-day telehealth the same worries have emerged. Like their ancestors, some contemporary healthcare providers and patients are apprehensive about the possible consequences ITC will have on the balance between the art and science of healthcare, professional autonomy, and the quality of patient care (Sanders & Bashsur, 1995; Wooton & Darkins, 1997).

First, some speculate that as telehealth services become more commonplace, providers will be less adept at understanding their patients' experiences of living with and dying from disease. One particular concern is that physical separation and electronically mediated communication may make the establishment of emotional connections between patients and healthcare providers more difficult. On the patient side, confidence, trust and dependence on providers may be diminished as patients increasingly obtain their medical information from websites, receive emotional support from on on-line support groups, and electronically communicate with their providers by means of e-mail and interactive video (Bero & Jadad, 1997; Eng & Gustafson, 1999). If this happens, there is concern that telehealth may deleteriously affect the quality of patient care. In support of these worries, a number of studies using randomized controlled trials have demonstrated that the quality of clinical communication is related to positive health outcomes. In other words, the more cumbersome and awkward provider-patient communication, the more likely patients will not get well (Kaplan & Greenfield, 1989).

Second, although some telehealth applications have the capacity to enhance patient autonomy and well-being, they also have the capacity to undermine patient autonomy and well-being especially when, for example, telemedical tools are limited to automated telemetry-capable medical devices and computerized patient records (Beasly & Graber, 1984; Howe, 2001). The reason for this is that providers will have little or no physical contact with their patients, interacting only with abstract patient data sets that have been transmitted through electronic networks and stored as computerized patient records. On this point, George Marckmann argues that under these conditions healthcare providers may (1) fail to include patients in decision-making about the patient's care and (2) inadvertently dehumanize their patients. He writes the following:

> *Without the physical presence of the patient there will be an increasing probability of unilateral decisions by physicians, thus conflicting with the ideal of a shared decision-making between physician and patient. (Marckmann, 1999, p. 60).*

And later:

> *If the personal consultation of specialists is replaced by teleconsultations, there will be an increasing risk that not the individual patient but just the digital data set-the gnostic analogue of the patient---becomes the object of diagnosis and treatment. Electronic patient records must be considered as a highly abstract, possible erroneous "artifact" which should not get a life of its own: not the data set but the patient needs treatment. (Marckmann, 1999, p. 60).*

If Marckmann is correct, then telehealth may modify the level of *interconnectedness* that exists between patients and providers and, thereby, detrimentally transform the provider-patient relationship. In brief, the concept of *interconnectedness* refers to the effects of ICT on social relationships. Interconnectedness at the individual level has particular relevance to provider-patient relationships that take place within telehealth:

> *At the micro level, individuals experience interconnectedness as a change in the nature of their social relationships. For most people, this means an increase in the number of relationships, but a decrease in their depth. That is, we are in regular-if not frequent contact with more people, but we don't know many of them very well. (Schement & Curtis, 1995, p. 47).*

Similar notions about the quality of social relationships are expressed in the *theory of social presence*. According to this theory, *social presence* is the feeling one has that other persons are involved in a communication exchange. The degree of social presence in an interaction is hypothesized to be determined by the communication medium: the fewer channels or codes available within a medium, the less attention that will be given by the user to the presence of other social participants. As social presence declines, messages become more impersonal and task oriented (Walther, 1995).

Assuming that the concept of interconnectedness and the theory of social presence are accurate, the primary goal of many electronically mediated relationships may turn out to be neither the person nor the relationship, but the information. Of course, the accurate and timely exchange of information between patients and providers has great benefits in the diagnosing and treatment of patients and in the cost-effective management of healthcare organizations. Moreover, easy access to health information and healthcare workers via telehealth technology may enhance the autonomy of patients, reduce their anxiety, and provide for an overall better quality of life for them. However, an effective and ethically appropriate provider-patient relationship will most likely require more than the efficient accumulation of patient data; it will also require a patient-centered relationship infused with empathetic communication and an awareness of the patient's existential state in the midst of illness.

Privacy and Confidentiality

Defining *privacy* and privacy-related concepts such as *confidentiality* is not a simple task, as there is no universally accepted definition, theory, or justification for privacy within the philosophical, legal, and public policy literature. Because of this lack of agreement on the scope of privacy, identification and analysis of important privacy issues within telehealth can be difficult, if not entirely overlooked. It what follows distinctions among physical privacy, informational privacy, and confidentiality will be made and their relevance to telehealth discussed.

Physical privacy generally refers to the restricted access that others have to our bodies, relationships, and living spaces. Physical privacy is ethically significant because it allows for intimacy, solitude, personal control, and peace of mind (Allen, 1995). Telehealth, especially when used in the homes of patients, is significant because it has the potential to reduce the number of unwanted in-person intrusions by healthcare workers. As teleconsultation and telemonitoring increasingly substitute for in-home visits, it may be possible for patients to gain more control over their homes, personal relationships, and daily schedules. On the other hand, these same patients may want to have more in-person visits than televisits, willingly sacrificing a measure of physical privacy for greater in-person social interaction. Whatever patients decide, the point is that telehealth services will give them options that don't widely exist today.

Informational privacy refers to the *confidentiality* and *security* of identifiable patient health information and clinical data found in patient records and in communications among healthcare professionals and patients (Allen, 1995). *Confidentiality* is the protection of private information, once it has been disclosed by a patient to a healthcare professional (e.g., during a medical examination or taking of a medical history). In short, confidentiality requires patients to give up their informational privacy. Once the patient discloses medical information, it becomes confidential and is no longer private. Although there are exceptions to the maintenance of confidentiality, providers are legally and ethically prohibited from sharing patient information with others who are not directly involved in the patient's care.

Telehealth's use of computerized patient records, electronic mail, medical websites, online support groups, and video conferencing tools create new threats and opportunities for the physical and informational privacy of patients. On one hand, patients can gain greater physical privacy, but, on the other hand, patients' informational privacy may be a greater risk, especially when the security of socially stigmatizing health information is breached by hacking or the accidental transmission of patient information to unintended recipients. In such scenarios, patients may not only lose their informational privacy, they also may be subject to social ostracism, job discrimination, loss of insurance, and social control in the form of blackmail (Shea, 1994).

Total informational and physical privacy is not realistic in telehealth and healthcare generally. First, other goods like medical research and public health require that limits be placed on the privacy of health information. Second, in order to treat and cure their patients, healthcare professionals must sometimes compromise the informational and physical privacy of their patients. Healthcare professionals must be able to touch their patients and obtain information about the intimate details of their patients' lifestyles and personal habits. Hence, patients must give up some informational and physical privacy to achieve the benefits of medical expertise. Depending on the site or point of care (e.g., hospitals, ambulatory clinics, and patients' homes), patients will have more or less informational and physical privacy.

Unfortunately, much of the telehealth literature on privacy simply fails to distinguish between informational and physical privacy. Furthermore, even when distinctions among physical and informational privacy are acknowledged in the telehealth literature, the focus is more often than not on informational privacy and the confidentiality of identifiable health information (Field, 1996). When these distinctions are not recognized, many of the privacy issues of telehealth that should be considered will be overlooked. For example, electronic mail and video conferencing can enhance the physical privacy of patients by reducing the number of in-person visits from healthcare professionals. Yet, these same patients may increase their risks to their informational privacy as their physiological data and electronic communications stream through standard phone lines and over wireless networks. In short, if the distinctions between physical and informational privacy are minimized, then ethically significant conflicts between these kinds of privacy and the need for possible compromises will be missed and remain unarticulated in policies, laws, and procedures affecting telehealth services.

FUTURE TRENDS

Before concluding, I want to discuss two future trends in the evolution of telehealth, which include the creation and use of smart homes and implantable biosensor technology.

Smart homes refer to the use of ITC to augment the range of services that homes and other buildings can provide for their occupants, for example, using computers to turn lights on and off without human assistance (Bauer, 2007). More advanced forms of ambient intelligence and ubiquitous computing technology can even monitor the time, frequency, and variety of a person's activities, including, for example, how often a person is waking up and walking, using the toilet, or opening his medicine cabinet to take medication. Moreover, software is presently being tested that analyzes the various activities detected by sensors embedded in patients' homes. This information is then used to assist either the inhabitants of the house directly or passed on to others, for example relatives and healthcare providers. The benefit of smart home technology is that it gives patients greater physical privacy and simultaneously allows providers to obtain real-time and comprehensive information about their patients' activities and living environments without being physical present, and to do so in a non-intrusive manner. Moreover, even though smart home technology is ubiquitous in most cases, it is invisible by being architecturally integrated into patients' homes.

One type of smart home technology gaining use with dementia patients is object recognition systems that track certain objects when they're put down. The system works by taking a picture of any object. Then, with cameras placed throughout the house, it goes and looks for the object. A patient uses the system by asking the computer where a specific object is located, for example, a pair of reading glasses, and the computer tells them where the requested object is located in the home. Another smart home technology being developed is the health detector. Like the recognition system above, this system is also made up of multiple cameras. These cameras, however, regularly take pictures of the patient's face and body and compare those pictures to others taken previously. The aim of the health detector is to identify any changes in physical appearance that may indicate a decline in function or, for example, the presence of skin cancer or the loss of weight. As this system is part of a larger telehealth network, the collected data can be simultaneously transmitted to the patient's healthcare providers to be analyzed (Coye, 2007).

Although in limited use at this time, *implantable biosensors* are now increasingly being used (Bauer, 2007; Viseu, 2003). Unlike smart home ICT, these sensors go one step farther by embedding ICT directly into the patient's body. In conjunction with smart homes, implantable biosensors are likely to facilitate independent living and continuum of care. Second, increased use of implantable biosensors is likely to make healthcare more proactive and preventative rather than reactive and episodic. These trends in telehealth are likely to help move healthcare delivery from institutional settings to non-institutional settings such as the home, giving patients more autonomy and a greater role in managing their own healthcare.

Two specific uses of implantable biosensors that are on the rise in telehealth are prosthetic and monitoring functions. First, neurotrophic brain implants are now being tested as mental prostheses to compensate for a loss of normal function in persons unable to speak, for example, because of stroke, spinal cord injuries, or ALS (McGee, 1999; Kennedy & Bakay, 1998). As recently as 2004, the Food and Drug Administration gave approval to begin systematic clinical trials to implant microchips in the brains of paralyzed patients (CNN.com, 2004). A neurotrophic brain implant works by implanting an electrode into the motor cortex of the patient's brain. Neurons in the brain then transmit electrical signals to the electrode, which, in turn, transmits the same signals to a receiver placed on the patient's scalp. These recorded signals are connected to a computer and are used as a substitute cursor or mouse. As patients learn to control the strength and pattern of electrical impulses being produced in their brain, they are able to direct the cursor to a specific point on the computer as they wish. In doing so, patients are able to communicate and can even send email.

Second, implantable biosensors are being used to monitor patients. For example, implantable cardiac biosensors that use wireless technology are being linked to sophisticated Internet-based monitoring networks that allow patients to transmit device and physiologic data to their providers without leaving their homes. Providers can remotely monitor the condition of their patients by logging into a secure website. Patients may also have access to the same website where they can obtain health-related information and personalized device data. In some locations, providers can access patient data by means of a handheld computer or personal digital assistant (PDA) (DeVille, 2003).

What makes smart homes as well as prosthetic and monitoring bioimplants revolutionary is that they have the potential to create a continuum of care that is seamless and more proactive. How will these future trends in telehealth achieve this goal? The general answer is that these technologies will better enable the integration of the patient's body with its immediate environment and the larger healthcare community. Since smart homes and implantable biosensors, like many other kinds of ICT, are interactive, they can help facilitate damaged or less than optimal person-environment interactions that are due to illness or environmental barriers (e.g., lack of transportation). The traditional view in medicine has been to view the purpose of technology as a way to fix persons, not environments. The problem with this view is that it construes persons as being distinct from their environments and overlooks the essential reality of person-environment interaction. As implants, smart homes, and other telehealth services become more commonplace in the provision of healthcare, this traditional view will and should dissipate.

Second, as smart homes and implantable biosensors more fully integrate patient bodies with their environments, patient care is likely to become mobile and migrate from institutional to non-institutional settings such as the home (Medical News, 2005). Home sensors in concert with implantable biosensors will likely exhibit a collective, synergistic intelligence that not only monitors, stores, and transmits biometric data to healthcare providers, but also allows patients to more easily regulate their home environments and to travel anywhere at anytime with the peace of mind that they are under continuous medical supervision. By giving patients more control over their environments and lifestyles, implantable biosensors and smart homes have the capacity to enhance the autonomy and well being of patients.

Third, much of the healthcare system today can be characterized as reactive and episodic, rather than proactive and preventative. As such, it is expensive and does a poor job of detecting medical conditions and preventing and responding to medical emergencies. Consequently, the present model of healthcare is less likely to maximize both the quality of patient care and patient health outcomes. In conjunction with external ICT, how might smart homes and implantable biosensors help us transition from a reactive to a preventative healthcare system? In answering this question, take, for example, the cardiac biosensors discussed earlier. These biosensors, which allow for the continuous real-time monitoring and transmission of a patient's cardiac functions, can be coupled with desktop telehealth units and the Internet, which, in turn, can automatically alert an emergency call center in case of a cardiac event.

Unlike a reactive and episodic approach that responds after a cardiac event is in progress, an automated telehealth system that incorporates implants and smart home technology is preventative because it can detect and report a cardiac event even before the patient knows what is happening. In doing so, not only are opportunities to prevent serious patient harms or death increased, the costs of treating and managing cardiac patients is likely to decrease. In concrete terms, a proactive healthcare system that can prevent emergencies is a healthcare system that is more likely to be more efficient and lead to better health outcomes for patients.

CONCLUSION

Telehealth has its risks, but this author believes that the overall impact of telehealth is likely to be positive for patients and healthcare providers alike. In closing, this chapter has explored how telehealth is substantially transforming our healthcare system, arguing that three key ethical issues should be examined as telehealth services are implemented: 1) distributive justice, 2) provider-patient relationships, and 3) privacy. This chapter also identified two overlapping and developing trends in telehealth—smart homes and implantable biosensors—that are likely to improve the continuum of patient care, facilitate independent living, and make the healthcare systems less reactive and more proactive in the future.

KEY TERMS

Art of Healthcare: Individual clinical judgements and intuitions of healthcare providers.

Confidentiality: The protection of private information, once it has been disclosed by a patient to a healthcare professional (e.g., during a medical examination or taking of a medical history). Confidentiality requires patients to give up their informational privacy.

Distributive Justice: A sub-field of ethics that deals with questions about access and the fair allocation of healthcare benefits and burdens among populations. More specifically, distributive justice in healthcare requires the application of *fair standards* that make *quality* healthcare *available* and *accessibl*e to persons in an *efficient* manner.

Ethics: The descriptive and prescriptive study of what is right, wrong, good, and bad, of what ought and out not be done.

Implantable Biosensors: Sensors that are directly embedding into the human body to monitor vital signs and to provide prosthetic functions, often in concert with smart home technology and larger telehealth networks.

Informational Privacy: Refers to the security of identifiable patient health information and clinical data found in patient records and in communications among healthcare professionals and patients.

Interconnectedness and Social Presence: The quality and feeling of communication exchange with other persons, with or without ITC.

Modernity: The social, economic, and technological forces that have shaped the contemporary provider-patient relationship.

Physical Privacy: Refers to the restricted access that others have to our bodies, relationships, and living spaces.

Science of Healthcare: Standardized clinical practice guidelines, automated procedures, scientific evidence, and the employment of medical technology.

Smart Homes: The use of ITC to augment the range of services that homes can provide for their occupants without human assistance, for example, monitoring the time, frequency, and variety of a person's activities, including how often a person is waking up and walking, using the toilet, or opening his medicine cabinet to take medication.

Telehealth/Telemedicine: The use of ICT to share and to maintain patient health information and to provide clinical care and health education to patients and professionals when distance separates the participants.

Technological Fix: The temptation to employ technology as a panacea rather than to give oneself as a person in the process of healing patients.

This work was previously published in Handbook of Research on Technoethics, edited by R. Luppicini and R. Adell, pp. 170-185, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 7.6

Quality and Reliability Aspects in Telehealth Systems

Anastasia Kastania
Athens University of Economics and Business, Greece

Stelios Zimeras
University of the Aegean, Greece

ABSTRACT

In this chapter the authors investigate telehealth quality and reliability assurance. Various models and standards can be applied to assess software quality and reliability in telehealth platforms and there are also general principles for total quality management which can be adopted. There are also models to assess the quality of the system and the quality of care which are also presented. The approach based on user satisfaction, considers the expectation measurement as information which is not inextricably linked to quality. A different approach is the one based on expectations as well as on disconfirmation of user expectations. The underlying structural model is based on a modified SERVQUAL approach that consists of five dimensions (Tangibles, Reliability, Responsiveness, Assurance and Empathy) which have been consistently ranked by customers to be most important for service quality across all industries. The model can thus be used for evaluation of healthcare services and for planning improvements on services. All these aspects for telehealth systems design are discussed to formulate epistemic criteria for evaluation purposes.

INTRODUCTION

In this chapter the authors investigate measures and models for telehealth quality and reliability assurance. Telehealth is defined as “the exchange of health information and the provision of health care services through electronic information and communications technology, where participants are separated by geographic, time, social and cultural barriers” (Hebert, M., 2001). There are two basic components to quality: quality assurance and quality control (Whitney, C.W., Lind, B.K. and Wahl, P.W., 1998). The following quality evaluation issues should be considered in telehealth design and evaluation: system, software, care, patient satisfaction and management.

Very different measures are necessary for measuring the effectiveness of an information system.

Related to the information systems effectiveness the dimensions of information systems success have been defined (DeLone, W. H. and McLean E. R., 2002). Other researchers (Cameron, K.S. and Whetten, D.A., 1983) have proposed a useful framework for selecting appropriate measures for future information systems research focused on organizational performance. In the scientific literature it is also proposed (Seddon, P.B., Staples, S., Patnayakuni, R. and Bowtell, M., 1999) that the diversity of information systems effectiveness measures is to be encouraged. Guidelines for standardisation of quality assurance in clinical trials are also described (Knatterud, G.L., Rockhold, F.W., George, S.L., Barton, F.B., Davis, C.E., Fairweather, W.R., Honohan, T., Mowery, R. and O'Neil, R., 1998).

The transcedental aspect of product quality (Ward, W.A. and Venkataraman, B., 1999) is identified with the sense of perfection that each person has. Because of this subjectivity, the methods and the models for the improvement of quality are necessary. With regard to the user view, a product is of quality if it satisfies the user. From the product view quality depends from its acquired characteristics and can be appraised from the presence or absence of certain attributes/characteristics. The manufacturer view is focused to the fulfillment of the required specifications and determines quality as a function. The value based view determines the quality as the means that offer the required services in financially accessible and acceptable cost. Empiric methods are also described to model the factors of software quality (Thomas, W. and Cerino, D. A., 1995). These are separated in functional characteristics (reliability), in programming characteristics (development cost and duration) and in maintenance characteristics. The method they propose (Thomas, W. and Cerino, D. A., 1995) is set from qualitative indicators for the evaluation of quality from the first stages.

Quality of care is a fundamental issue worldwide. There are many different approaches to monitoring the quality of services provided by an individual telehealthcare system, but one of the most valuable is obtaining feedback and opinions from users of the services. One of the main methodological problems in modern literature deals with the interpretation and the comprehension of the role of "expectation" in systems. "Expectation" represents a complex and dynamic concept (Harvey, J., 1998), defined within the framework of two prevailing trends. The approach based on user satisfaction, considers the expectation measurement as information which is not directly linked to quality. With respect to this there are a variety of tools for assessing the quality of a service but one of the most popular is SERVQUAL, an instrument designed by Parasuraman, and colleagues (Parasuraman, A., Berry, L.L., Zeithaml, V.A., 1988). This consists of a set of five dimensions which have been consistently ranked by customers to be most important for service quality, regardless of service industry. According to the general definition, expectations relate to the user's "predictions" for the services, whereas, on the basis of the second, expectations refer to the user's evaluation regarding the level of the services the provider needs to offer. The user's expectations of the quality of the healthcare services provided derive from a combination of characteristics and factors (Lewis, B.R and Mitchell, V.W., 1990) (Liljander, V. and Strandvik, T., 1994) (Rose, R., Uli, J., Abdul, M. and Ng, K., 2004) which are summarized as follows: (i) previous experiences the user has gathered from the service. (ii) third party suggestions (physicians, relatives, friends and other involved parties). (iii) factors relating to communication (direct & indirect) between the user and the service. (iv) factors relating to the Public or non -Public status of services: (iv.a) personal needs within the framework of the user value system, demographic – social- economic characteristics of the users etc. (iv.b) users perceive the healthcare system mainly through the institutional role of competent public services and the local administration. Lastly, measurement of the levels of user expectations allows the investigation of causes for quality problems in the organization.

ISO and standards facilitate the development of a quality management system, which serves as a basis for continuous process improvement and ensures consistency in processes (Hysell, D., 1999).

Worldwide, systems to measure service quality have been developed which have subsequently been modified according to the particular case and adopted by major organizations. With reference to the nature and structure of the service provided, the public sector is conducting user-satisfaction measurement research in competitive environments in order to develop prior principal and support services with the aim of improving the relationship between the providers and the user. User satisfaction and/or service quality (SERVQUAL) constitute essential components of healthcare (Donabedian, A., 1988). Users determine the strategy for quality management in healthcare services (Hasin, M.A.A., Seeluangsawat, R., Shareef, M.A., 2001). Methodological issues concerning service quality measurements have been discussed in the international literature (Lin, B. and Kelly, E., 1995) for many years and have been the subject of topical studies throughout the world (Ovretveit, J., 2000). Significant efforts have been made to develop user satisfaction models (Grigoroudis, E. and Siskos, Y., 2002) (Athanasopoulos, A., Gounaris, Sp. and Stathakopoulos, Vl., 2001) as well as to assess user satisfaction in healthcare services (Angelopoulou, P., Kangis, P., Babis, G., 1998) (Merkouris, A., Yfantopoulos, J., Lanara, V., Lemonidou, C., 1999) (Moumtzoglou, A., Dafogianni, C., Karra, V., Michailidou, D., Lazarou, P. and Bartsocas, C., 2000). The fact is that "user satisfaction" and/or "service quality" are complex phenomena involving intricate operations such as the measurement of quality in healthcare services, currently under examination, their perceived "value", and the social image of the organization.

DEFINITION OF QUALITY IN HEALTHCARE

Satisfaction with service quality depends on a large number of dimensions - both tangible and intangible attributes of the product-service offer. It is necessary to explain the importance of adopting common semantics when developing health geo-information services that span administrative boundaries and carry geographical information for the evaluation of the healthcare sectors. With reference to the nature and structure of the service provided, the public sector is conducting user-satisfaction measurement research in competitive environments in order to develop prior principal and support services with the aim of improving the relationship between the provider and the user. The final objective lies in increasing the market share of the organization. This observation also refers to the close relation between quality management and the marketing policy. With regard to healthcare services, a range of actions within the framework of a "special Marketing" can be introduced, which apart from taking into account the user satisfaction measurement will also aim at meeting user expectations. Quality measurement objectives in the Public Sector differ from the ones in the Private Sector as illustrated by the following statements (Robinson, St., 1999) (Teas, R.K., 1993): (i) Questions regarding service pricing rarely arise, whereas data concerning the user's perceived "value" of the service provided are taken into consideration. (ii) Often questions asked refer to the Public dimension of the Healthcare System, which must function in keeping with the concept of public interest, safeguarding its basic principles such as equal treatment, protection and safety, totality as well as accessibility to health services. (iii) The "user expectations" parameter assumes major importance for user "acceptance" of the services provided and also for the final "value" (Parasuraman, A., Berry, L.L. and Zeithaml, V.A., 1991) attributed to the public system of healthcare services. The trilogy for quality management (Juran, J.M., 1988), is consisting of Quality Planning, Quality Control and Quality Improvement. Quality planning involves identification of customers and their needs, and development of products to satisfy customer needs, and processes to produce those product attributes. Quality control involves evaluation of the gap between actual and targeted quality performances and the actions to fill the gap. Quality improvement deals with development of infrastructure, identification of improvement goals, establishment of project teams and allocation of resources to implement quality improvement projects.

The approach based on user satisfaction, considers the expectation measurement as information which is not inextricably linked to quality. Satisfaction is a cognitive state *(it follows the implementation of the service)* and derives from service quality. Moreover, it offers additional information such as meeting the needs *(expressed and implied),* perceived performance, perceived value of services and assessment of the benefit deriving from services. Therefore, according to this approach, quality determines the level of user satisfaction following a comprehensive assessment of the service provided. Similar approaches are the "service performance" (SERVPERF) which defines quality as equal to the user's performance perception of the service (*Service Quality = perceived performance*) and the approach of Teas (Teas, R.K., 1993), which presents a weighted SERVPERF model: *Service Quality = perceived importance × perceived performance.* A different approach is the one based on expectations as well as on disconfirmation of user expectations. In this case, the established model is the SERVQUAL "Service Quality" model (Parasuraman, A., Zeithaml, V., Berry, L.L., 1985). Moreover, within this approach Service Quality (SQ) is measured by comparing Perceptions "P" with Expectations "E" and is defined as the difference between perceptions and expectations (SQ=P - E). Regardless of the numerous distinct views voiced within the framework of this specific approach, (Liljander, V. and Strandvik, T., 1997) it is agreed that the user perceives "high" quality when perceived performance exceeds his or her expectations. Another broadly known methodology relating to the expectation disconfirmation approach lies in the expectation disconfirmation model (Oliver, R.L., 1996). The expectation concept is gradually incorporated into scientific approaches to Total Quality Management (Perkins, W.St., 1993) (Donaldson, W.G., 1995).

SERVICE QUALITY IN HEALTHCARE

Service quality is relating to meets customers satisfaction needs, leading to the investigation of preserved service quality in order to understand customers. Preserved quality is the difference between customers' expectation and their perceptions of the actual service received. Customer satisfaction is an individual emotional response to the evaluation of an object (or a service) (Parasuraman, A., Zeithaml, V., Berry, L.L., 1985).

It is difficult to measure service quality due to fewer tangible cues available when customers purchase services (Parasuraman, A., Zeithaml, V., Berry, L.L., 1985), fewer search properties but higher in experience and credence properties (Parasuraman, A., Zeithaml, V., Berry, L.L., 1985), as compared to services. There are a number of different definitions as to what is meant by service quality. One that is commonly used defines service quality as the extent to which a service meets customers' needs or expectations. Service quality can thus be defined as the difference between customer expectations of service and perceived service. If expectations are greater than performance, then perceived quality is less than satisfactory and hence customer dissatisfaction occurs.

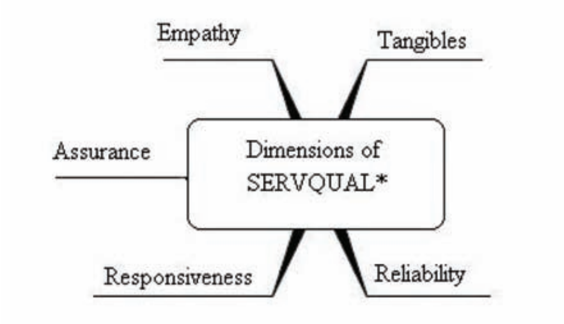
Although the SERVQUAL model has raised debates about dimensionality, the need to measure expectations, the reliability and validity of difference-score formulation, and the interpretation of expectations, it have been the predominant method used to measure consumers' perceptions of service quality. It represents a multiitem scale that can be used for measuring expectations and perceptions of service quality- as perceived among consumers. The SERVQUAL model, a 22-item scale has five generic dimensions or factors and is stated as follows: (1) Tangibles, (2) Reliability, (3) Responsiveness, (4) Assurance, (5) Empathy (Figure 1). When referring to surveys related to healthcare institutions the dimensions of service quality can be adjusted as follows:

1. **Reliability:** Ability to perform the service dependably and accurately
2. **Tangibles:** Appearance of physical facilities and provision of appropriate equipment
3. **Responsiveness**: Willingness to help customers
4. **Assurance:** The knowledge of employees and their ability to inspire trust and confidence.
5. **Empathy:** The caring individualized attention the firm provides to its customers.

It is important to note that without adequate information on both the quality of services expected and perceptions of services received then feedback from customer surveys can be highly misleading from both a policy and an operational perspective. To improve quality services to these customers we must first of all understand their needs. In order to understand their needs, we must in turn understand the quality attributes embraced by the customers. People perceive quality differently.

When analyzing the data gathered most of the surveys are based on the '**gap theory**', that is, the difference between clients' expectations about performance of a service and their assessment of the actual performance of service. For example 'gap theory' in healthcare context has been used to develop a number of questions in order to compare what customers 'look for' (expect) and what they 'experience' from doctors, equipments, healthcare services e.t.c.

Figure 1. SERVQUAL's five dimensions



It is important to note, that the SERVQUAL is designed to investigate the aforementioned gap; nevertheless it is important to recognize the existence of four other gaps:

- **The understanding gap:** The difference between what consumers expect of a service and what management perceives consumers to expect.
- **The design gap:** The difference between the management perceives and consumers expect and the quality specifications set for service delivery.
- **The delivery gap:** The difference between the quality specifications set for service delivery and the actual quality of that service delivery.
- **The communications gap:** The difference between the actual quality of service delivery and the quality of that service delivery as described in the 'firm's' external communications.

When gathering the data from the questionnaires, in the case study of the survey, there may be a 'mismatch' between customer's expectations and their perceived quality. The analysis of the gathered data may be descriptive as well as inferential. A researcher assessed the scale's reliability by calculating the *Cronbach alpha*; for analyzing the service quality, the mean and the standard deviation scores for each of the items were calculated for the perception level (P) and the expectation levels (E). The mean perception scores were compared to the mean expectation scores for the various customer requirements and the design characteristics, so as to identify the Gap scores (P-E=Gap). The underlying dimensionality was tested through an exploratory factor analysis conducted on each of the correlation matrices of the perception, expectation, and Gap scores. The QDF matrix was framed with rows representing 'customer requirements'-'what'- and the columns representing the 'design characteristics'-'how'. Customers were asked the level of importance they assigned to the different customer requirements. They were also asked to give their perception of the relationship between items of each row and the items of each column. Thereafter the *QDF* matrix was used, wherein the respondent was required to specify the relationship between the customer requirements and design characteristics. Finally, the quality function deployment technique along with correlation analysis was used to identify the minimum set of design elements (synonymous to the quality components) able to cover the customer requirements.

Current literature on SERVQUAL applications in healthcare services describes variations of the initial model according to the following: (Robledo, M.A., 2001)

- The first category of the SERVQUAL model variations deals with the definition of different dimensions and/or service characteristics in order to measure quality (Brady, M.K., Cronin, J.J., Brand, R.R., 2002) (Conway, T., Willcocks, St., 1997) (Hwang, Li-Jen J., Eves, A., Desombre, T., 2003). In this specific field, it is hard to be original and consequently, similar characteristics are presented in dissimilar forms.
- The second category of SERVQUAL refers to the introduction or the non-introduction of different weight in the dimensions and/or characteristics. This way, models with similar or different weights are produced. The Overall Service Quality (OSQ) is estimated by the main value of the five dimensions. The weights employed in SERVQUAL models arise either by introducing a third section of questions for the estimation of weight by the users themselves or by the personnel in the organization through preliminary empirical studies *(structured survey or interview)* or through a combination of the aforementioned.
- The last category of the SERVQUAL model variations relates to the measurement scales employed. The Likert measurement scales may be identical or distinct per measurement section (perceptions, expectations and/or importance). The choice of scale is made on the basis of the respondents' understanding, the required level of sensitivity and the impact on the internal reliability of the questionnaire. The latest approaches to service quality (Rose, R. Ch., Uli, J., Abdul, M., Ng, K.L., 2004) (Butler, T., Kendra, J., Grimley, R., Taylor, B., 1996) (Kandampully, J., 1997) (Sohail, M.S., 2003) (Zimeras S., Lambrinoudakis C., Fournaridis G., Fournaridis I, 2005) involve a uniform high sensitivity Likert scale.

In the SERVQUAL model gaps between user service perceptions and expectations are known as GAP 5. Gaps arise either when the service falls short of the user's expectations or when the service fails to meet the user's needs. Numerous surveys conducted in health services have provided information about GAP 5 (Butler, T., Kendra, J., Grimley, R., Taylor, B., 1996) (Kandampully, J., 1997) (Sohail, M.S., 2003). The *"Gap Zone"* is divided into positive (expectations exceed to a great extent user perceptions), intermediate (discrepancy observed between expectations and perceptions is not striking) and negative (expectations fall short of user perceptions). The extent of each of these zones allows the categorization of the GAP 5 SERVQUAL score gaps. The intermediate zone is of utmost importance because it relates to healthcare services that are generally considered tolerable (neither satisfying nor dissatisfying) by users and this is called Zone of Tolerance.

DATA ANALYSIS PROCEDURES

Some researchers, in order to test whether the initial conceptual framework was optimal, they use two types of factor analyses, namely exploratory factor analysis (EFA) and confirmatory factor analysis (CFA), followed by reliability analysis and qualitative analysis. Confirmatory factor analysis is first performed to evaluate the validity of the original SERVQUAL conceptual framework. Exploratory factor analysis is then performed for determining the number and structure of the dimensions that are underlying the data. Then the resulted dimensions from the exploratory factor analysis are then confirmed again by using the confirmatory factor analysis and reliability analysis. The derived dimensions and items are then compared with the findings of qualitative analysis for its validity and usefulness.

The use of statistical methodologies comprising multivariate analysis techniques (Mardia, K.V., Kent, J.I., Bibby, M., 1979) may elucidate the variables of overriding importance for the complex problems under investigation and depict correlations. Multivariate statistics provide the ability to analyze complex sets of data. Multivariate statistics are provided for analysis where there are many independent and possible dependent variables, which are correlated to each other to varying degrees. The method of principal components allows the replacement of the plethora of interrelated variables by groups of factors (hypothetical sections) exhibiting similar behavior to the major statistical variables. Principal components analysis (PCA) was applied to a single set of variables to discover which sets of variables form coherent subsets that are relatively independent of one another (Zimeras, S., Kostagiolas P. and Lambrinoudakis C., 2007).

Also cluster analysis could be considered in cases we investigate the effectiveness of the characteristics into spatial regions. Using this technique, we could justify which regions are important so we could direct our analysis to these areas. Cluster analysis is a technique used to classify objects into relatively homogeneous groups called clusters. Objects in each cluster tend to be similar to each other and dissimilar with objects in the other clusters (Malhotra N.K. and Birks H. 2003). A very useful graph in displaying clustering results is the dendrogram. The dendrogram is read from left to right. It shows where the clusters are joined together as well as the distance at which the clusters are jointed. It is very useful to decide the appropriate number of clusters.

In recent years, there has been an unprecedented demand for measures of quality in the healthcare industry. It is therefore crucial to develop effective tools for monitoring the quality of the medical services offered. Furthermore, in order to ensure the reliability of the results it is necessary to have a large number of patients, and in some cases medical personnel, participating in the evaluation process. With respect to healthcare, information services and the internet provides a unique platform that enables the creation of important information systems that can be accessed from anywhere and any time. The goal is to establish a consistent level of e-support to healthcare professional learners of Total Quality Management concepts, quality methods and tools.

Brainstorming, fishbone diagram, flowchart, run sheet, Pareto analysis, control chart and histogram are some of the tools that can help to zero in on quality problems. Quality function deployment helps to concentrate on customer needs while developing new services. For example *brainstorming* is a systematic approach to generate ideas from a group. A brainstorming group consists of individuals who can help to develop ideas relevant to a problem to be solved. Each individual suggests ideas (or directions) without regard to their validity. After all ideas are collected, they are critically reviewed. Brainstorming is a method to identify problems, develop ideas and improve creativity. Also *fishbone diagram* is a graphical approach to represent "cause and effect". The effect is desired outcome and causes are the spines. In practice most applications will have more branches where there will be a single outcome that we wish to improve or eliminate. A well drawn fishbone diagram can help to detect effects of quality quickly so that an alternative action can be taken. An alternative would be a tree diagram, which is much easier to follow. Finally a *control chart* essentially presents the expected range of variations in a stable process. A process is stable when all the data points fall within the prescribed control limits. Control chart is an excellent technique to monitor a process which is subject to variations. The control chart is a graphical representation of hypothesis testing. All these tools could be used for different purposes, considering the needs of the individual groups (doctors, technicians, administrative department, etc.) (Figure 2)

CONSIDERATIONS FOR THE STRATEGIC EVALUATION OF TELEHEALTH SYSTEMS

The following aspects should be studied, criticized and adopted or adapted (Figure 3).

The Hebert Quality of Care Framework In Telehealth Applications

The Hebert Quality of Care framework (Hebert, M., 2001) contains inquiring questions related with the Quality of Care. For patients, providers and organizations the structure, the process and the outcomes are studied.

With regard to the *structure*, the individuals that participate in studies for the evaluation of quality of Information Systems in Health usually are individuals that have the study problem and after they are informed on this, they accept or not to participate. During the selection of these individuals we want not to be connected as relatives, to belong in a wide age-related spectrum, be from different regions and suffer from the same illness. Each one of them can participate for various personal reasons. Nevertheless they exist probably also other reasons. Somebody with a chronic/serious disease needs intensive medical follow-up and probably the intervention of an expert. Persons that live in borders and inaccessible areas are those with the bigger need and who will profit more from the program. Usually these patients have minimal alternative solutions for provision of care. The health care providers are selected on the basis of criteria that are determined by each research framework. They should be the more suitable and most capable for the particular place. They participate in the studies in order to contribute in the growth of their company, for projection, research and mainly in order to provide the better possible services of health in the patients. Alternative solutions for the providers exist but usually they choose the most

Figure 2. Likert scale

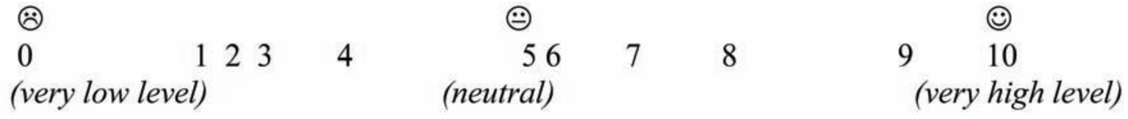


Figure 3. Telehealth evaluation aspects

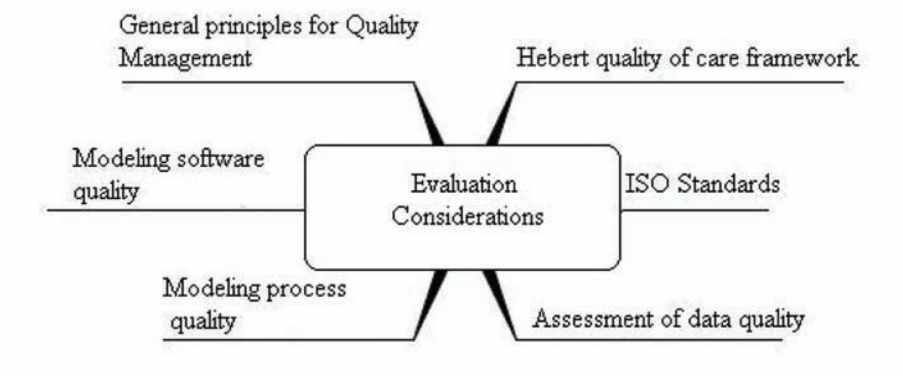

lucrative for the interest of the company. Good provision of services ensures satisfied customers and consequently good quality. To provide services using a Health Information System their training is necessary. The organizations that use these technologies can be public or private health care providers. Various types of technology have been adopted. Computational systems, medical instruments, robotics, high performance computing and communications, videoconferencing contribute in the implementation of Telemedicine services.

With regard to the *process* the relation patient-doctor using telehealth is not anymore direct but indirect. The patient may not have personal contact with his doctor but he is provided the same medical care from distance. To achieve this a medical patient record should exist. Health care providers feel “comfortably” offering care with the use of electronic means, because they can offer more, time is saved from them and better service of patients exists. Nevertheless they are certain questions which influence the benefit of care with the use of telemedicine/telehealth technologies. Specialized personnel is needed and specialized patients to have knowledge of computers and be capable to handle the new technology. Via this technology the organizations want to achieve prevention, clinical care, even social support.

As far as the *outcomes* are concerned patient satisfaction is one of the desirable results. It becomes perceptible from the comments of patient on the program of care, but also from the perceptible improvement of his/her health. The outcomes that are important from the patient side are mainly the patient requirements satisfaction from the program. If the patient is satisfied and the program is characterized by ease of use then its success is ensured. The customer indications give useful information, empiric elements and indications for the needs, expectations and wishes, essential elements for the determination of objectives for customer satisfaction. From the health information systems and the interventions related to telehealth all patients can benefit from but mainly these with chronic diseases, these in some critical stage of health, and those that live far from health care centers. The organizations apply/adapt the technology depending on their needs and with that they want to use. The organizations change the initial way of technology use after certain comments from the patients, the providers or other colleagues in the organization. Success for a program is to achieve its initial aim, while at the same time increases its quality. The recording of these incidents becomes with many different ways. Usually via evaluation questionnaires or a Process Failure Mode Effects Analysis.

ISO Standards

According to the International Standards Organization, the ISO standards define the requirements for products of advanced technology, services, mechanisms, materials and systems, for evaluations of good conformity and for administrative and organizational applications. The most known existing models for quality certification are the Maturity Model in USA and the ISO standards that are recognized on International level (Saiedian, H. and McClanahan, L., 1995). A product to be imported in the European Union should be ISO-compatible. (Rada, R., 1996)

- **ISO 9000:** The International Standards Organization has developed a series of ISO standards for quality certification. Up to the 70's existed various models for the determination of quality. In November 1992, the countries of the European Union agreed to use ISO 9000 as the national model of quality (Dadoun, G., 1992)

ISO 9000 refers to quality management. This means that "an organization is supposed to satisfy the requirements of the customer for quality and the applicable regulating requirements, while at the same time it aims at continuous improvement of efforts".

ISO is divided in the parts 9001, 9002 and 9003. ISO 9001 refers in activities as planning, growth, production, installation and maintenance, ISO 9002 is applied in the production and installation and ISO 9003 covers the final control and trial (Dadoun, G., 1992). In the year 2000, the series 9001, 9002 and 9003 were included in ISO 9001:2000. This is the only standard in the ISO 9000 family that is certified by an external agency.

- ISO 9004: 2000: It extends the advantages of ISO 9001:2000 in all the interested teams (e.g. employees, employers, owners, providers and society). The 8 principles for quality management that are formulated in ISO 9000:2000 & ISO 9004:2000 are:
  - **Principle 1:** Focus in the customer
  - **Principle 2:** Leadership
  - **Principle 3:** Collaboration of individuals
  - **Principle 4:** Process based approach
  - **Principle 5:** Systemic approach in the Administration
  - **Principle 6:** Continuous improvement
  - **Principle 7:** Realistic approach in decision-making
  - **Principle 8:** Mutually beneficial relations of suppliers

These principles form the basis for requirements for ISO 9004:2000.

ISO 9000:2000 and ISO 9004:2000 have been designed as a single pair of standards, for easier use and flexibility. Starting from 9001:2000 a first level of performance can be reached. Applying then ISO 9004:2000 a more efficient system of quality management can be achieved.

ISO 9004-4 refers to the Administration of Quality and in the elements of Quality Systems. The 4th part provides governing directives for the Administration, so that Continuous Quality Improvement is applied in an organization.

- **ISO 15504 or SPICE:** Additional to ISO 9001. It offers confidence in the quality management of the suppliers and a framework that determines if the candidate suppliers are suitable. It also helps the evaluation process.
- **ISO 9126:** It is a extensive model for the sector of Medical Informatics. ISO 9126 provides a framework for the estimation of software quality. According to this the six characteristics of software quality are: Functionality, Reliability, Usability, Performance, Maintainability, and Portability.

- **ISO 15504 in comparison with ISO 9001:** ISO standards ensure the continuous improvement of quality; the user knows that he has to deal with regularly qualitatively products and services (Hysell, D., 1999). They provide better perception of quality, better recording of processes and control of operations. Due to the permanently increasing need for qualitative products and services, more companies record the processes, their tactics of operation and their organizational duties (Schuler, K., 1996).

The need for certifications of safety or interoperability helped in the growth of Information Technology Standards of safety (Ferris, J.M., 1994). These are developed under accreditations of the International Standards Organization and depending on the specifications that follow they can be characterized as international, national or even local.

ISO 9000 was developed for industrial operations (Averill, E., 1994). For software operations it was needed an extension that was given with the creation ISO 9000-3. ISO 9000 is important because (Rada, R., 1996) it provides directives with regard to the way that an enterprise will improve the quality and promotion of her products. The conformity of an organization with the ISO 9000 can be checked from the organization, or from the one in which are addressed the products or the services provided by this organization, or from a third independent organization that is specialized clearly in such certifications. For an organization to be certified, both its documentation and its human potential should follow the specifications of quality. Despite the fact that ISO 9000 began for constructional companies and organizations, it is also extended also in the health sector, where the certification of quality is very important. The certificates provided by certain third persons, are more prone in errors due to the involvement of the human factor (Ungureanu, V., 2001).

Assessment of Data Quality

A model has been proposed for data quality measurement from the user viewpoint. (Cappiello, C., Francalanci, C., Pernici, B., 2004). According to this, the users are separated in age-groups, where each age-group is constituted by users with common characteristics. The age-group of user selector determines which dimensions of data quality will be delivered with the information that the user has asked. The service sends the demand in the selector and depending on the characteristics of age-group of user, the department of evaluation sends in the end the data in the user with the results from quality evaluation. If the information is of low quality, that is to say if the requirements of user are not satisfied, an alert message is presented.

MedCritic system and the QUIL (Quality Indicator Language) are another way of quality evaluation (Advani, A., Shahar, Y., Musen, M. A., 2002). QUIL allows the determination quality indicators and the modeling of the medical directives so that the determination of quality from the side of patient is easier.

Another way of quality measurement from the user viewpoint is the protection of his/her personal data. A model exists (Kam, L.E. and Chismar, W.G., 2003) which combines the discretion in the collection of data from the patients, with the sensitivity of content and the qualitative feedback. A secure platform has been proposed (Taylor, K.L., O'Keefe, C.M., Colton, J., Baxter, R., Sparks, R., Srinivasan, U., Cameron, M.A., and Lefort, L. A., 2004), for personal data named Health Research Data Network (HRDN).

The collection of medical histories should have evident definitions of data, settled guidelines and specialized personnel for this purpose (Arts, D. G. T., de Keizer, N. and Scheffer, G. J., 2002). The guarantee of data quality depends from the prevention, the localization and the actions that will follow (Knatterud, G.L., Rockhold, F.W., George, S.L., Barton, F.B., Davis, C.E., Fairweather, W.R., Honohan, T., Mowery, R. and O'Neil, R., 1998)

.

Modelling Process Quality

A quality model for information technology systems has been proposed (Marchetti, C., Pernici, B., and Plebani, P.A., 2004) that separates evidently the planning of services, from the network and the devices. The quality as conceived by the user in such a system mainly depends from the quality of the media that are used for the provision of services (network, devices) and less from the quality the services it provides. The supplier of services and the user of services sign a contract agreement for the quality of services. This contract describes the offered quality level with regard to the quality of data, the safety and the availability. It is supported (Nejmeh, B. A., 1995) that the best methods of evaluation of progress of processes are: SEI (Software Engineering Institute) CMM (Capability Maturity Model), ISO9000, Tick-IT, SPICE (Software Process Improvement and Capability dEtermination) and the Malcolm Baldrige National Quality Award.

Modelling Software Quality

- McCall's Quality Model (McCall, J., Richards, P., and Walters, G., 1977): It describes the quality as relation between the factors, the criteria and metrics of quality (Ward, W.A. and Venkataraman, B., 1999).

Quality measurement is performed in the following steps:

1. Identification of all factors that can influence software quality
2. Recognition of criteria for each factor.
3. Definition of metrics for each criterion and determination of relation between metric and all the criteria that are reported in each factor
4. Assessment of metrics
5. Correlation of metrics with a line of directives that should follows each team of software development
6. Development of recommendations for metrics collection

ISO 9126 (see aforementioned description)

Dromey model (Dromey, R. G., 1995) is based on the following steps for the development of software quality models. In the first step, we define the attributes of high quality. Then we determine analytically the various parts of a product, and for each part we categorize the most important properties of quality. Afterwards we propose connections between the quality-carrying properties and the quality attributes. We repeat the aforementioned steps using a process of assessment and perfection.

General Principles for Quality Management

The fact that a lot of models exist for the improvement of quality can mean two things: either it is very difficult to model right the quality or it is impossible (Saturno P.J., 1999). The right collection, verification and interpretation of data is one of the most usual problems for the cost of data quality (Keogh W., Atkins M.H., Dalrymple J.F., 2000). Further research is needed in order to clarify the long-lasting dimensions of telemedicine and the derived results in the expenses of health (Roine, R., Ohinmaa, A., Hailey, D., 2001).

According to the Centre for Human services, any measure that improves the quality can be considered as Quality Assurance (QA). Usually it is constituted from a QA tool, a QA approach and a QA program. Teams from a variety of health care organizations have reported the successful usage of methods like team work, flow charts, data collection and graphic analysis of data (Plsek P.E., 1999).

Statistical Process Control (SPC) and various other examples of practical applications of control charts have been used in health care (Benneyan J.C., Lloyd R. C., Plsek P. E., 2003). Almost all these models have the same steps: "planning-monitoring –improvement".

To achieve quality at low cost is essential the adoption and use of methods as the Continuous Quality Improvement (CQI) or the Total Quality Management (TQM) (Shortell, S.M., Bennett, C. L., and Buck, G. R., 1998). CQI it is the continuous improvement of processes performed to offer a service that corresponds in the needs and expectations of customers.

There are quality concepts and criteria to record quality. The engineers and managers are responsible for the quality during the process of the construction of a product. Quality metrics check how much the product corresponds in the requirements of the customer. ISO and other standards have as basic condition the installation, maintenance and control of recorded remaining processes.

The challenge is in the planning of models that keep pace with good medical practice (Abston, C. K., Pryor, A.T., Haug, P.J., Anderson J.L., 1997). The implementation guidelines should include rules for when we begin and / or we avoid interventions in health care.

There are also data mining challenges (Kastania, A.N., 2004) in the design of telehealth platforms that should be taken into account during the telehealth quality and reliability evaluation process. Especially those related with intelligent decision systems participation in the evaluation process of telemedicine models for primary care (Kastania, A.N., 2004).

CONCLUSION

Herein, we have investigated aspects related to quality and reliability assurance in telehealth. We have defined quality and service quality in healthcare combined with data analysis strategies based on SERVQUAL as a tool for reliability assurance. Finally we have presented a set of considerations for the strategic evaluation of quality in telehealth systems.

KEY TERMS

Telehealth Quality: The quality measurement of telehealth services should be based on product characteristics that contribute to user satisfaction and on product attributes that can be present or absent. In order to measure quality, the user view, the developer view, the product view and the value-based view should be considered.

Telehealth Reliability: Reliability is the probability that software will not cause the failure of the system for a specified time under specified conditions. For the reliability assessment, models exist that present graphically the number of failures of system operation in the time. When users think for software quality they usually mean the reliability on the basis of the existing reliability model: IEEE/

ANSI standard 982.2. The code should be reliable according to the deviating views of individuals that develop software, check software or are users of software. A developer-based view focuses on software faults; if the developer has grounds for believing that the system is relatively fault-free then the system is assumed to be reliable. On the other hand a user-based view emphasizes the functions of the system and how often they fail.

Chapter 7.7

Electronic Medical Records, HIPAA, and Patient Privacy

Jingquan Li
Texas A&M University-Kingsville, USA

Michael J. Shaw
University of Illinois at Urbana-Champaign, USA

ABSTRACT

The continued growth of healthcare information systems (HCIS) promises to improve quality of care, lower costs, and streamline the entire healthcare system. But the resulting dependence on electronic medical records (EMRs) has also kindled patient concern about who has access to sensitive medical records. Healthcare organizations are obliged to protect patient records under HIPAA. The purpose of this study is to develop a formal privacy policy to protect the privacy and security of EMRs. This article describes the impact of EMRs and HIPAA on patient privacy in healthcare. It proposes access control and audit log policies to safeguard patient privacy. To illustrate the best practices in the healthcare industry, this article presents the case of the University of Texas M. D. Anderson Cancer Center. The case demonstrates that it is critical for a healthcare organization to have a privacy policy.

INTRODUCTION

The strategic utilization of information systems/information technologies (IS/IT) has played a central role in enabling organizations across many industry segments to address many business challenges and achieve a level of sustainable competitive advantage (Croasdell, 2001; Hammond, 2001; Holt, Love, & Li, 2000). Healthcare is noted for embracing new scientific discoveries and using leading edge technologies to enable better cures for diseases and better means to enable early detection of most life threatening diseases. Ironically, the healthcare industry in the United States, which has a greater need for more accurate and timely information, has experienced less development of IS/IT than other industries such as banks or airlines. The Health Insurance Portability and Accountability Act (HIPAA) of 1996 is the largest governmental law in healthcare since Medicare. HIPAA mandates new federal standards for electronic transactions, such as payment processing, patient's medical information privacy, and security procedures that secure the privacy protections. Currently healthcare organizations are contending with relentless pressures not only to implement IS/IT technologies but also to become compliant with HIPAA.

The growing use of healthcare information systems (HCIS) has provided healthcare organizations with tremendous benefits, including significantly reduced costs, reduced harmful medical errors, and improved quality of care. But the resulting dependence on electronic medical records (EMRs) has also kindled patient concern about patient data privacy and security. EMRs often contain some of the most sensitive information about who and what we are, such as mental and physical illness. Perhaps more than any other type of data, the confidentiality of EMRs is absolutely essential. When doctors' file cabinets held the bulk of medical records, the employees working in those practices had access to them. As hospitals and clinics switch to electronic record keeping, however, many more people might have access to private medical records. Under HIPAA, new healthcare privacy provisions designed to protect data transmitted and stored electronically went into effect April 14, 2003. The requirements of HIPAA and compliance issues are getting the attention of top executives in the healthcare industry.

Having a formal privacy policy is a key step in implementing any HIPAA compliance program. It should expressly cover how a health organization is protecting EMRs; the rules and limits on who can access and use EMRs; and the capability to track who has disclosed sensitive data and the circumstances of disclosure. A positive, formal, and continually practiced privacy policy by all employees can establish rules and limits on who can access and disclose EMRs and thus minimize the possibilities of privacy breaches. On the other hand, a poorly defined and improperly implemented and managed privacy policy can make EMRs ripe for privacy abuse. The HIPAA privacy rule puts an emphasis on access control and audit trails to protect patient data. This study investigates the use of access control and audit log policies to safeguard patient privacy.

The objective of this study is to develop formal access control and audit policies to protect the privacy of EMRs. The development of HIPAA compliance program and security policies has been addressed by several studies (Kieke, 2003; Messmer, 2003; DeMuro & Grant, 2001; Li & Shaw, 2004; Patient privacy, 2001). There are also several papers addressing the issue of protection of EMRs (Ateniese & Medeiros, 2002; Swartz, 2004). The closely related works to this study include the following. Zunkel (2005) studied how to use biometric technology to protect personal information and found that biometric technology does not endanger personal information; it protects it. Borrowing the principles of reporting and auditing from the accounting sector, Stevens (2002) found that through comprehensive reports of network activity logs and regular auditing of security measures and devices, healthcare organizations can generate the proof of HIPAA compliance. While these studies are devoted to technical aspects and particular access control and audit log technologies, this study takes a management-oriented approach to develop access control and audit log policies to protect EMRs strategically.

The rest of the article is organized as follows. In the second section, we discuss the issue of patient privacy in healthcare. In the third section, we describe the HIPAA privacy rule and its privacy implications. In the fourth section, we investigate access control and audit log policies to protect patient privacy. To illustrate the impact of EMRs on patient privacy and the importance of having a privacy policy in the healthcare system, we present a case example of the University of Texas M. D. Anderson Cancer Center in the fifth section. We conclude with a summary in the final section.

Patient Privacy in Healthcare

Traditionally, our medical records were kept in paper documents in different doctor's offices. Cumbersome paper records not only contain too many errors and inefficiencies but also hinder communication between healthcare providers. According to the *Journal of the American Medical Association*, each year, as many as 98,000 patients die in U.S. hospitals from preventable medical errors, such as receiving the wrong medication. Nearly half of all patients do not get all the treatments or tests that they should have received. These problems persist because of industrywide failures connected to the lack of accurate and reliable health data.

As many hospitals and health systems begin to implement healthcare information systems, electronic medical records have become the primary means for storing health data, and electronic communications have been the preferred way of doing business. Storing and sharing patient health records electronically benefits both patients and doctors by speeding up access to patient information and ensuring that information is accurately and reliably available in the right place at the right time. HCIS enable doctors, nurses, and lab technicians to access medical records from a computer, instead of having to track down paper files. HCIS can also use networked computer databases to inform doctors about best practices for treating patients. With HCIS, for instance, a click of a mouse pulls up a patient's full medical record. The computerized system can alert doctors to everything from a patient's current medications to drug allergies. According to research firm Harris Interactive (Taylor & Leitman, 2001), the major causes of medical errors include multiple physicians treating the same patient without all having access to all the patient's medical records and with each storing different, incomplete medical records in different places. There is near consensus among healthcare industry experts that the widespread use of EMRs, accessible to all those seeing and treating a patient as well as to the patient, would substantially improve the coordination and quality of health care, in addition, electronic prescribing would further reduce errors that result from handwritten, hard to decipher prescriptions. Converting paper files into EMRs can significantly improve quality of care, reduce harmful medical errors, lower costs, and streamline the entire healthcare system. As a consequence, many healthcare organizations are now fully dependent upon their EMRs and HCIS.

The implementation of networked healthcare information systems has provided healthcare organizations with tremendous opportunities to improve quality of care. But the resulting dependence on EMRs and electronic communications also creates significant potential problems that can result in major harm to healthcare organizations. One of the problems will be the invasion of patient privacy. EMRs contain some of the most sensitive information about who and what we are, such as mental illness, sexual behaviors, HIV/AIDS, communicable diseases, cancer, and other stigmatized conditions. Perhaps more than any other type of data, it is important for healthcare organizations to keep medical records confidential and ensure that only personnel authorized to see the data get to view it.

When a patient's health records were kept in paper files in doctor's offices, these records were protected through the doctor–patient code of confidentiality, and third-party access to records was at the doctor's discretion. As hospitals and clinics switch to electronic record keeping, however, EMRs now can be transmitted with the click of a computer mouse. The Internet age, with free and easy exchange of data over open networks, exacerbates the situation. It is realized that the code of confidentiality is inadequate to protect the patient's interests because too many people will see your medical records. Through networked electronic medical records systems, doctors today interact with other health practitioners, diagnostic services, and hospitals, all of whom contribute to the medical records. Others who have access to patient data are: support staff, receptionists, clerks, administrators, transcriptionists, laboratory technicians, insurers, and healthcare providers. Once your medical records are exposed intentionally or accidentally, they will live forever on the Internet. But what happens to healthcare when the privacy of patient data is not protected and insurers and employers have access to an unprecedented amount of information? There will be (and there has been) potential for real harm to patients. For instance, some patients are likely to withhold health data from their physicians or reluctant to seek care if they do not trust that their personal data will be kept confidential. For that reason, implementing HCIS systems that protect patient privacy, yet are able to communicate needed information, is the key to whether healthcare information systems move forward or back. Furthermore, patient privacy and security concerns are driven by HIPAA.

HIPAA Privacy Rule

Healthcare organizations have long been under scrutiny when it comes to implementing patient privacy policies and procedures, but the Health Insurance Portability and Accountability Act of 1996, passed by the U.S. Congress and signed into law in 2000, has elevated its importance and placed comprehensive new privacy requirements on the U.S. healthcare industry. HIPAA calls for standardization of electronic patient health, administrative, and financial data, and unique health identifiers for individuals, employees, health plans, and healthcare providers. The greatest challenges among these standards for health organizations will be those regarding patient privacy (Li & Shaw, 2004). HIPAA mandates that healthcare organizations follow certain guidelines of privacy protection and that patients are given some specific control over how personal medical information is used and transmitted electronically. The U.S. Department of Health and Human Services (HHS) issued those patient-data privacy guidelines, as ordered under the HIPAA regulations. Subject to interpretation, the HIPAA privacy rule demands that any organization providing healthcare services—and any of its business associates handling protected patient data—apply "administrative, physical and technical safeguards" to ensure confidentiality.

HIPAA defines three main groups as "covered entities": healthcare providers, health plans, and healthcare clearinghouses (DeMuro & Grant, 2001). "Healthcare providers" refer to organizations that provide medical or health services and transmit any health data in electronic form. "Health plan" is defined broadly to include any individual or group plan that provides or pays the cost of medical care. HMOs, health insurers, and group health plans, including employee benefit plans, are considered to be health plans. "Healthcare clearinghouse" is defined as a public or private entity that processes or facilitates the processing of nonstandard data elements of health information into standard data elements. Billing companies are considered to be healthcare clearinghouses. Working closely with these groups are "business associates." Business associates are defined by HIPAA as persons who perform functions or activities involving the use or disclosure of protected health information (PHI) on behalf of "covered entities." This includes claims processing or administration, data analysis, utilization review, quality assurance, billing, benefit management, practice management, legal, actuarial, management, accreditation, or financial services.

Under the HIPAA privacy rule, healthcare organizations are obliged to protect patient records. A central feature of the HIPAA privacy rule is a set of limitations on the use and disclosure of protected health information. According to the regulation, PHI is individually identifiable health information that is a subset of health information, including demographic information collected from an individual, medical data related to the past, present, or future physical or mental health or condition of an individual, and financial information related to the past, present, or future payment for the provision of healthcare to an individual. Examples of PHI include personal information such as name, address, phone, social security number, credit card number, e-mail, identities of doctor and patient, and so forth. Since PHI includes the most sensitive information in medical records, the HIPAA regulation prohibits PHI from being released to third parties, or used by the healthcare industry, except as directly by the patient in signed consent or authorization forms.

The HIPAA privacy rule outlines severe penalties to individuals or organizations misusing patient information, intentionally or otherwise. Compliance is required by April 14, 2003; non-compliance will carry stiff civil and criminal penalties, including fines up to $25,000 for multiple violations of the same standard in a calendar year and fines up to $250,000 and/or imprisonment up to 10 years for knowing misuse. Because of HIPAA, healthcare organizations are now open to a range of potentially damaging consequences, including fines, liability claims, criminal charges, and even prison terms. Healthcare organizations should become knowledgeable about HIPAA and consider the requirements of HIPAA in their planning, management, and implementation efforts. A formal privacy policy must be in place to protect patient privacy.

The Importance of Privacy Policies and Procedures

Under HIPAA, healthcare organizations must not only ensure the privacy of PHI, but also ensure that business associates with which they do business maintain the privacy. Today as medical databases become networked in more complex healthcare information systems, healthcare organizations are facing a rising number of privacy attacks. In fact, many healthcare organizations are unprepared to safeguard the confidentiality of patient medical records as the healthcare industry prepares to move from archaic paper files to EMRs. Loss or compromise of sensitive EMRs can occur from hackers and identity thieves, or even from internal sources in the form of disgruntled employees or corrupt executives. It is fundamental for any healthcare organization to formulate a formal privacy policy because technical mechanisms must be accompanied by formal organizational policies for controlling the access to EMRs. Without privacy policies and procedures in place to protect EMRs, patients' right to privacy is at risk. This is the reason why it is so important to take the strategic, management-oriented approach starting with privacy management policies and procedures.

Privacy policies are the management directives that give guidance to personnel on how their organization will handle EMRs and patients' right to privacy. These policies identify classification of medical data based on their sensitivity. The policies include requirements to implement appropriate policies and procedures to prevent intentional and accidental disclosures of protected information; establish training programs for all employees of the covered entity who may have access to protected information; designate a privacy officer with primary responsibility for ensuring compliance with the regulations; establish a system for receiving and responding to complaints regarding the covered entity; and implement appropriate sanctions for violations of the privacy guidelines (DeMuro & Grant, 2001). Some weak and ignored policies include: (1) access controls are not being applied; (2) inadequate monitoring and auditing of information systems; and (3) lack of a security incident and disaster recovery plan (Schneier, 2000). The HIPAA privacy rule puts an emphasis on access control and audit logs policies to protect EMRs. This study investigates the importance of access control and audit log policies around patient privacy.

Access Control

If access is more limited and tightly controlled, EMRs are more privacy sensitive than paper files. Two most common access control approaches are credentialed data access and authentication. In the credentialed data access, access control policies should grant access to patient data on a need-to-know basis only, and they should be the driving force in the implementation of healthcare information systems. An organization should identify the persons or classes of persons, as appropriate, in its workforce who need access to the sensitive data to carry out its duties. For each such person or class of persons, the organization should identify the category(s) of potential sensitive data to which access is needed and any conditions appropriate to such access. The organization should make best efforts to limit the access of such persons or classes of persons identified above to the types and amount of sensitive data required to do their jobs. Access to confidential data is limited to persons with a legitimate "need to know" to perform their jobs within the organization. The credentialed data access thereby reduces the exposure of sensitive data within the organization.

Another approach is authentication. Authentication usually involves a user name and a password, but more companies are implementing multifactor authentication that includes other methods of demonstrating identity, such as access cards, hardware tokens, fingerprints, or voice recognition. The acceptable forms by which humans can authenticate themselves are something the person is which can be biometrically identified such as voice or retinal patterns, fingerprint, vein, iris, hand geometry, face, and signature; something the person has such as an access card or hardware token; and something the person knows such as a password or personal identification number.

Information systems managers have devised clever and complex password systems requiring frequent changes, rules for alphanumeric and symbolic characters, and prohibitions against repetition of character strings. Password management and allocation often becomes so complex that a user resorts to typing the password into a text file and leaving it on his or her electronic desktop, or worse, writing it in a post-it note and sticking it to the monitor. When IT managers also require a "what you have" factor—such as an access card that transmits the password to the terminal—it may end up in a desk drawer or hanging on a cord suspended from a push-pin, readily accessible to others.

The use of biometrics provides a means by which healthcare records can be kept confidential (Zunkel, 2005). Biometric technology provides a "who you are" solution to these issues, ensuring the person gaining access to data is, in fact, the person authorized. As with any credential-based access system, the biometric technology employed must be reliable, user friendly, and, most of all, manageable, and technology developers have pushed to meet those requirements.

Audit Logs

While many healthcare organizations have wisely deployed technical safeguards, such as firewalls and encryption technologies, to keep patients' data confidential, proving that those safeguards are successful is harder. Audit logs provide the capability to track all accesses to EMRs and audit tools that allow more frequent examination of audit logs to detect inappropriate accesses to EMRs. In the field of databases, database engine records every transaction in a transaction log to maintain database consistency and to aid in recovery. The log is a storage area that automatically tracks changes to a database. If the system fails, the automatic recovery process uses the transaction log to roll forward all committed transactions and roll back any incomplete transactions. The concept of transaction log in database systems can be extended to protection of EMRs in medical databases. Every time someone accesses the patient record, information systems have got to know what she or he has accessed, when it was accessed, and what they did.

Audit logs provide several benefits. First, through comprehensive reports of database activity logs, healthcare organizations can generate the proof of compliance that HIPAA demands. In the case of litigation, it is interesting to note that in general, courts have been lenient when dealing with organizations that have privacy policies and procedures in place, even if these policies are not perfect. They are generally less lenient with organizations that can demonstrate nothing in regards to managing patient privacy. In this sense, through comprehensive reports of database activity logs and regular auditing of established privacy policies and safeguards, healthcare organizations can generate the proof of HIPAA compliance, which is extremely important.

Second, audit logs help track criminals when a privacy breach occurs. For those companies that suffered privacy breaches, they found that it was difficult to figure out where the data was initially compromised and to find the trail back to where that the data was compromised. Therefore, it is very important for organizations to know exactly where the data lies and to be able to provide an auditable trail of their activities.

Finally, audit logs demonstrates a commitment to the highest level of legal and ethical conduct in the manner in which an organization gathers, stores, uses, and protects patient medical records. Knowing that the organization takes seriously its obligation to follow the HIPAA privacy rule makes patients and their loved ones feel safer that their personal details are not floating around in the public domain. Privacy management is a continuous process. The organization needs to continue to reassess and change its technical safeguards over time, as business environment is dynamic. Therefore, it is very important to collect and analyze information from the audit logs to make improvements.

The M. D. Anderson Case: Overview and Findings

To illustrate the impact of EMRs on patient privacy and the importance of having a privacy policy in the healthcare industry, we now consider the case of the University of Texas M. D. Anderson Cancer Center. EMRs promise to promote better medical outcomes, lower costs, and streamline the entire healthcare system. The development of the electronic medical records system with a major focus on the integration of research and clinical data has been identified as a key strategic initiative at M. D. Anderson. Meanwhile, M. D. Anderson is strongly committed to maintaining the security and privacy of patient medical records under HIPAA. To this end, M. D. Anderson has developed data access and audit trail policies to protect the privacy and confidentiality of medical data. In this section, we illustrate how a best practices standard, such as the EMRs initiative, would work in conjunction with the enhanced formal privacy policy that M. D. Anderson proposes. We focus on how M. D. Anderson applies data access management and audit trails to ensure the privacy and security of EMRs.

M. D. Anderson Cancer Center in Houston is a premier cancer hospital in the United States. With more than 16,000 faculty and staff and 1,600 volunteers working in more than 25 buildings around Houston and in central Texas, M. D. Anderson is one of the largest cancer centers in the world. The center, which treats more than 70,000 patients a year, includes an in-patient pavilion with 512 beds, an out-patient clinic, two research buildings, a faculty building, and a patient-family hotel. M. D. Anderson is also a top research center; the center invests more than $400 million on cancer research each year; about 11,000 patients participated in therapeutic clinical trials last year. M. D. Anderson has identified improvement in electronic processing and communications of medical records as a key to enhance the safety and efficiency of its patient care. The center has developed an electronic medical records system that would integrate patient records with clinical research data. In a healthcare institution like M. D. Anderson, everyone wants to keep all the medical data forever and has it accessed immediately. The electronic medical records system has now between 600 and 800 terabytes of data that is in a high-availability environment. Probably the best example of that is the center's imaging environment. Technologies such as computed tomography (CT) and magnetic resonance imaging (MRI) has been an integral part of clinical cancer care and imaging techniques are continually improving and finding more and more applications in clinical and research situations. The center has more than 200 million images online available for our clinicians. That environment is completely replicated, so the center actually have 400 million images online—a copy of each one—and the center has a third backup maintained off-site that is an extract of the images. The creation of the electronic medical records system improves quality of care by speeding up access to cancer patient information and ensuring that information is more complete and readily available for diagnosis, treatment, and claims-payment purposes. The new system also promises to improve medical research and innovative treatment at the center by integrating clinical trials data with clinical data. The increased availability of electronic medical records carries significant benefits for M. D. Anderson. But this has put increasing demands on the underlying privacy protection mechanisms. Like other medical providers, M. D. Anderson is bound by the HIPAA privacy rule to provide adequate protection for the personal medical data.

M. D. Anderson has always been a leader in standing up for patients' rights since it was established in the 1940s. The center is committed to safeguard patient confidences and privacy with the constraints of HIPAA requirements. It has developed formal policies that explicitly articulates how EMRs to be protected. The center believes that patients "own" the data about themselves (as defined by HIPAA's PHI definition) and they only allow its use by others under certain circumstances. Since access is one of the areas most vulnerable to privacy breaches, the center needs ability to authorize access to EMRs and keep audit logs over complex heterogeneous information systems and networks. The truth is that the more access and availability there is, the more risk there is.

The center stresses formal role-based data access policies and procedures that clearly define who in the organization have privilege and need to access to particular data, the rules determining a person's right of access, the reasons for denying access to individuals, including how access is granted, modified, and denied. If you are a physician, you can only see certain things; if you are a nurse, you can only see certain things; if you are a pharmacist, you can only see certain things; If you are a cancer researcher, you can only see certain things; if you are an administrator in the Department of Cancer Medicine, you can only see certain things. For example, clinical EMRs may be used and/or disclosed for certain research purposes. All research projects at the center are subject to review and approval by an Institutional Review Board (IRB). An IRB committee responsible for protecting individual research subjects and insuring that research is conducted ethically. You will not be enrolled in a research project that is not reviewed and approved by an IRB. The goal is to restrict the access and/or release of protected health information to authorized individuals and prevent unreasonable possibility of unnecessary, inadvertent, wrongful, or malicious access to protected information.

M. D. Anderson has established the formal auditing policy based on HIPAA regulatory requirements and security best practices. The center has a substantial department of information security that watches over access to the electronic medical records system very carefully. The system maintains records of all access to EMRs. A required accounting must include: (1) the date of the disclosure; (2) the name and address of the entity or person who received the medical information; (3) a brief description of the medical information disclosed; and (4) a brief statement of the purpose of the disclosure. Audit logs for systems containing EMRs should be retained and reviewed regularly according to the M. D. Anderson privacy policy. No security information system is foolproof. The center has audit trail tools that allow more frequent examination of audit logs to detect inappropriate accesses to EMRs. Once a privacy breach happens to data, IT professional will be indispensable in locking down the systems, then determining the extent of the breach, data compromised, and source of attack.

The case of M. D. Anderson demonstrates that it is critical for a healthcare organization to have a formal privacy policy. Electronic record keeping presents a massive threat to patient privacy—PHI in particular. Keeping patient records private and secure is a huge concern for any healthcare organization. By establishing privacy policies and implementing them with state-of-the-art security technologies, a healthcare organization can actually turn the privacy issue into a benefit when it uses EMRs. Paper medical records are not immune to privacy risks. There is no way to restrict who sees them, or to detect inappropriate accesses to them. In contrast, EMRs provide the potential for greater protections with access controls and audit trails. The access control policy expressly defines who in the organization have privilege and need to access to particular data and ensures that they access only a small part of the database to carry out their job duties. The formal auditing policy maintains audit logs of all access to clinical information (EMRs) and allows frequent examination of audit logs to detect privacy breaches.

CONCLUSION

Patient privacy is a major concern for most healthcare organizations today due to the continued growth of healthcare information systems and the resulting dependence on EMRs and electronic communications. Healthcare organizations in the United States face governmental and regulatory pressures to become compliant with the HIPAA privacy rule. In this article, we described the importance of patient privacy in the context of EMRs and HIPAA compliance. We found that it is crucial for a healthcare organization to have a formal privacy policy. We developed and analyzed access control and audit log policies to protect the privacy of EMRs. More importantly, to illustrate the best practices in the healthcare industry, we presented the case of the University of Texas M. D. Anderson Cancer Center and developed insights into the impact of EMRs on patient privacy and the importance of having a privacy policy. Further research about privacy protection in healthcare should try on a systematic view of security and privacy of EMRs. We also notice that the explosive progress of IS/IT, including Web-based systems and mobile computing devices, causes healthcare information systems more porous. In this case, new privacy management practices need to be developed to safeguard patient privacy.

Chapter 7.8

A Quality Assurance Approach to Healthcare:

Implications for Information Systems

Mark C. Shaw
De Montfort University, UK

Bernd Carsten Stahl
De Montfort University, UK

ABSTRACT

Despite decades of research, healthcare information systems have been characterised by cost over-runs, poor specifications and lack of user uptake. A new approach is required which provides organisations with a reason to invest in this type of software. W Edwards Deming argues that quality is not an entity but derives from using feedback, iteratively to seek improvement to processes, in order to increase productivity and to make better use of resources. The authors propose that supporting this form of quality assurance (QA) using information systems (IS) has the potential to deliver a return on investment. An object-oriented analysis, where healthcare is viewed as the delivery of interdependent processes to which Deming's form of QA is applied, results in a class model of data types that has some useful characteristics. It is able to store data about medical and non-medical events; to save descriptions of procedures and to represent the QA process itself. With software based on the model, organisations will have a memory of previous attempts at making improvements as well as data about feedback from patients and staff to drive future change. A critical research in information systems (CRIS) analysis of this model proposes a number of criticisms deriving from theories about rationality; concepts of technology; politics and hidden agendas, as well as the social consequences of technology. The view that QA is a standardised, ongoing conversation about the important characteristics of a process pre-empts many of these counter arguments. The CRIS critique also highlights the need to ensure that development is in harmony with the needs of the many stakeholders in healthcare IS. These concepts lead to new directions in healthcare IS research. The class model needs to be tested against clinical and non-clinical use-cases for its viability not only as support for QA but also as an electronic patient

record. A standard terminology is required for processes and for how objects from the model should be used to represent them. The model predicts that user interfaces will have to collect more detailed data than hitherto. Also use of the software should be tested in controlled trials to demonstrate whether the required improvements in quality not only benefit the patient but also the organisations managing their care.

INTRODUCTION

The primary aim of W. Edwards Deming's approach to QA is to improve productivity by avoiding re-work, thereby making better use of man-hours and machine-time (Deming, 1990e). The effect is a reduction in the costs of manufacture of good product. The method requires an organisation continuously to seek improvement to processes as a result of systematically obtaining feedback. We propose that the delivery of health care can be modelled as a set of interdependent procedures and that there is every reason to apply Deming's ideas, even though they were developed for manufacturing industries.

What are the implications for healthcare information systems and their fundamental data structure - the electronic patient record - of being designed to support Deming's form of QA? By drawing on the theories that underpin his approach, the meaning of QA in the context of healthcare is examined and a generic class model that supports the process is developed, using object-oriented analysis.

If an information system is created using our set of classes, what factors will influence its success? A step back is taken and a judgmental eye cast on the model from the perspective of CRIS. We argue that even when a completely different interpretation of the nature and purpose of QA and healthcare IS is adopted, there remain good arguments to support our approach. Having outlined our concepts, we conclude by proposing new directions for research.

BACKGROUND

Why Invest in Health Information Systems?

Reviews of individual health information systems for the management of patients with chronic diseases are positive (Dorr et al., 2007) as are those of computer based nurse documentation (Ammenwerth et al., 2001). There is agreement that the overall costs and benefits have rarely been fully assessed (Herbst, Littlejohns, Rawlinson, Collinson, & Wyatt, 1999; Shekelle, Morton, & Keeler, 2006) but none-the-less Shekelle (2006) states that:

"Despite the heterogeneity in the analytic methods used, all cost-benefit analyses predicted substantial savings from [Electronic Health Record implementation.] The quantifiable benefits are projected to outweigh the investment costs. However, the predicted time needed to break even varied from three to as many as 13 years."

This conclusion is open to question because an understanding is required of how different research methods influence results (Moehr, Anglin, Schaafsma, Pantazi, & Grimm, 2006; Wyatt & Wyatt, 2003; van't Riet, Berg, Hiddema, & Sol, 2001). Consequently some authors have suggested the need for a broadly accepted, standard evaluation framework (Rahimi & Vimarlund, 2007; Ammenwerth, Graber, Herrmann, Burkle, & Konig, 2003; Ammenwerth et al., 2004).

An overview of academic medical informatics (Jaspers, Knaup, & Schmidt, 2006) suggested that:

"The computerised patient record ... is playing a growing part in medical informatics research and

evaluation studies, but the goal of establishing a comprehensive lifelong electronic health record ... is still a long way off."

Why should healthcare organisations invest in information systems that are yet to provide an electronic health record and which offer, at best, a modest economic benefit? We propose that they are most likely to gain if they establish a QA process and use software to support it.

What is Quality?

The concept of 'quality' has been criticised because the meaning is elusive. A narrow definition focussed mainly on customer satisfaction, has been used to legitimate increasing managerial control over healthcare professionals (Palfrey, Thomas, & Phillips, 2004b). On the other hand, making 'quality' synonymous with high professional standards is seen as forcing staff to adhere to yardsticks imposed by senior management (Palfrey, Thomas, & Phillips, 2004a).

Additional barriers to the success of QA in the British National Health Service (NHS) have been: lack of resources; lack of expertise or advice on project design and analysis; lack of an overall plan for audit; organisational impediments and problems between groups and group members (Johnston, Crombie, Alder, Davies, & Millard, 2000). It is no surprise that the effects of quality improvement projects are variable, depending on the context in which they are used and the way they are implemented (Walshe & Freeman, 2002).

Quality Assurance

We avoid arguments over the meaning of the word: 'quality' by proposing that healthcare can be modelled as a set of interdependent processes. Viewed this way, we can apply Deming's ideas about: 'seeking continuously and forever, iteratively to improve process and product' (Deming, 1990d).

Deming suggested that each process should be described in terms of a specific test of its action and a pass/fail criterion (Deming, 1990b). When tracked over time, the proportion of failures to meet these 'operational definitions' will fluctuate and statistical boundaries can be set for the extent of the variation.

When the proportion of failures lies outside pre-defined, statistical limits: 'special causes' are said to be present. These require to be investigated and to be remedied on a case by case basis as soon as possible after they are detected. Often they represent rare or exceptional circumstances, such as equipment failure.

When the proportion of failures lies within pre-defined statistical limits, a process is said to be in statistical control and variation is due to: 'systematic causes', which require management to improve the method of working.

As part of an agenda to avoid developing better systems, management may argue that each patient is 'one-of-a-kind' due to biological variation. This logic is faulty because it is likely that patients can be classified into one of a set of variants and care tailored accordingly.

A consequence of defining healthcare as a sequence of interdependent processes is that errors in preceding activities, if left unaddressed, will accumulate and affect the correct performance of their dependants. This is another reason for management not to avoid its responsibilities.

For manufactured goods, quality may be defined in terms of improvements in three areas: the product; the customer's use of the product and the requirements for maintenance of the product. In contrast, we propose that the quality of a service may be defined in terms of improvements to the design of its constituent processes. Enhancements should be sought in the actions undertaken and the operational definitions needed, using feedback from patients about the process and its effects and from staff about the resources needed to keep consistently delivering without fault.

Meaningful feedback needs to be obtained in a systematic way. The plan, implement, observe and review approach suggested by Shewhart and popularised by Deming (1990c) offers a useful methodology. Planning defines the process and desirable changes. Implementation executes the alteration on as small a scale as can be demonstrated to provide meaningful results. Observation gathers data about the effects of the modification. Review examines what was learnt and what can be predicted regarding future operations. This should be an iterative process which acts as a permanent driver for improvement.

Continuous Quality Improvement

Continuous quality improvement (CQI) is the application of Deming's form of QA to healthcare. It has been used to improve cardiac care in a hospital, over a 10 year period (Brush et al., 2006), as well as in an emergency department to reduce complaints and increase patient satisfaction (Welch & Allen, 2006). Without a control group however, it is difficult to ascertain whether these reported changes follow from the QA process or other factors such as better technology.

Data collected before and after the CQI implementation of a number of care pathways, showed that most lead to better treatment (Panella, Marchisio, & Di Stanislao, 2003). The investigators reported difficulty obtaining results from existing information systems and pathway failures were attributed to the inability to engage clinicians in the process of quality improvement because of a lack of timely statistics about changes to care.

A randomised controlled trial demonstrated that CQI had no effect on the care delivered to patients with asthma in two geographic areas of the United States. There were methodological problems with the assessment of effect and external factors such as financial stringency and organisational change confounded the results (Homer et al., 2005). In contrast a second trial examining the effect of CQI on the management of depressed patients, demonstrated modest improvements in the process and outcome of care: more completed the required programme and more functioned better socially (Rubenstein et al., 2006).

Deming (Deming, 1990a) suggested that initial change will be dramatic as special causes are removed. What is left thereafter is the need to change the methods of work, which is altogether a more difficult and longer-term undertaking. The results reported in the research on CQI are to be expected because the investigators have yet to take full account of this possibility.

IMPLICATIONS FOR INFORMATION SYSTEMS

Object-Oriented Analysis

In order to examine the effects on information systems design, we performed an object-oriented analysis (Booch, 1994) of Deming's form of QA as applied to healthcare.

When dealing with health, it is useful to be able to follow the patient for long periods of time. We argue that this can only be achieved only if there is knowledge of data type and location. These pre-requisites ensure that the correct comparison procedure can be applied.

In quantitative research, classification of data into groups, using the appropriate comparison operation, leads to the ability to count them and thereby to the performance of statistical analyses. In qualitative research, comparison permits identification of terms used to describe themes of interest.

In our analysis, we have attempted to apply these principles to arrive at a description of QA that avoids the need for free-text, wherein the location and the type of the data are unknown (at least until there is reliable, automated natural-language comprehension).

Class Model

In the following section, the classes of information employed in the model are written in capital letters, when they are first mentioned.

Processes may be represented as combinations of ACTIONs, performed by ACTORs.

The test component of an operational definition may be represented as an action from which an OBSERVATION may result.

The 'pass/fail criterion' of an operational definition requires classifying observations according to some standard. We propose that an ANALYSIS type of action should be used to represent this and other methods of summarising and interpreting data.

Groups of analyses may be recognised as forming a set. The resulting HYPOTHESIS about the cause of a problem may lead to the PLANNING of remedial TASKS. Each task will require a set of CAPABILITIES, such as a person's SKILLs or a machine's FUNCTION, for its successful conclusion. Part of planning will be to choose appropriate actors to fulfill the requested capabilities.

An advantage of real time data gathering is that it is possible to provide people with an opportunity to record why they succeeded or failed to perform a task (Buetow, 2005). The INDICATION class handles both these scenarios, providing the capability to determine whether a hypothesis was "in favour" or "against" a task.

Machines may perform actions on behalf of people, such as monitoring blood pressure. LOCATIONS describe where an event took place in space and may be composed of sub-locations. Arguably, locations may perform actions on behalf of people and so we propose that an actor could be a PERSON, a piece of EQUIPMENT or a LOCATION.

No individual acts in isolation; each lives in a physical and social environment and inherits a genetic legacy. A person has a RELATIONSHIP with other people. This might be genetic, marriage or friendship. Also an actor may have a ROLE within an ORGANISATION. Examples are employment or membership of a sports club. Organisations may themselves be composed of a number of sub-organisations and may have a location in space.

For QA, actors must have the ability to remember PLANs about what tasks to undertake when a particular hypothesis pertains. Plans need to be made sensitive to circumstances by being able to represent decisions. Since tasks can lead to actions which result in observations that are analysed: it can be argued that one or more hypotheses may pertain following a task. Plans may be created to define what to do for each of these expected hypotheses.

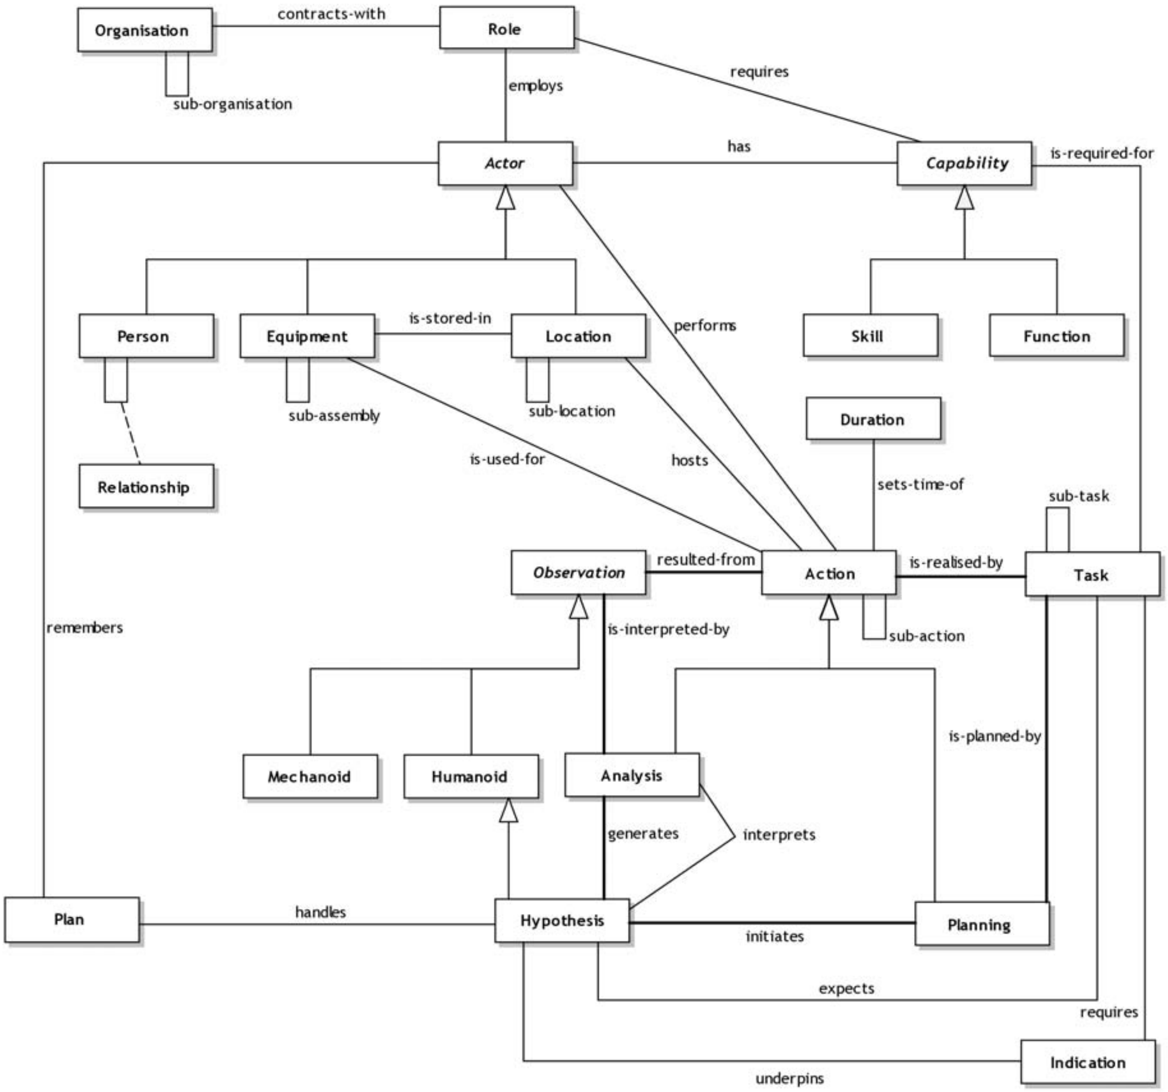
Figure 1 shows the class diagram that was created following the above analysis. Links are to be read from left-to-right and from top-to-bottom. The QA feedback loop is characterised by the following relationships:

An OBSERVATION "resulted-from" an ACTION, which a PERSON "performs".
An OBSERVATION "is-interpreted-by" an ANALYSIS, which a PERSON "performs".
A PERSON "performs" an ANALYSIS, which "generates" a HYPOTHESIS.
A HYPOTHESIS "initiates" PLANNING, which a PERSON "performs".
A TASK "is-planned-by" PLANNING.
A PERSON "performs" an ACTION, which "is-realised-by" a TASK.

More About Observations

Deming suggested that operational definitions should be couched in terms of objective tests such as the red, green and blue settings needed to achieve a particular colour. We note that whilst such observations are common in medicine there

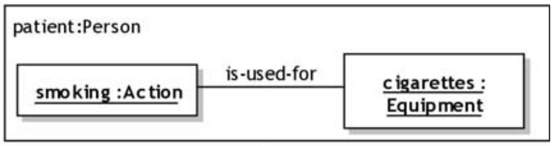
Figure 1. Class model, showing the QA loop



are many, such as symptoms and signs, which involve a degree of subjectivity on the part of the observer. We propose the use of 'mechanoid' and 'humanoid' observations to distinguish the two.

A mechanoid observation is defined as one where a machine makes a record of a measurement directly from sensor data and provides the same report of previous measurements to multiple independent observers. In contrast, a humanoid observation is one where no data about what the sensor detected are available; only a person's interpretation of what was present. Both types of observation may involve data loss. In the case of mechanoid observations, the nature of the loss and the processing that generated it is, in principle, explicit and available for all to examine and verify. In the case of the humanoid observation, there are no such guarantees.

Figure 2. Representation of a person smoking



Modelling Health Care

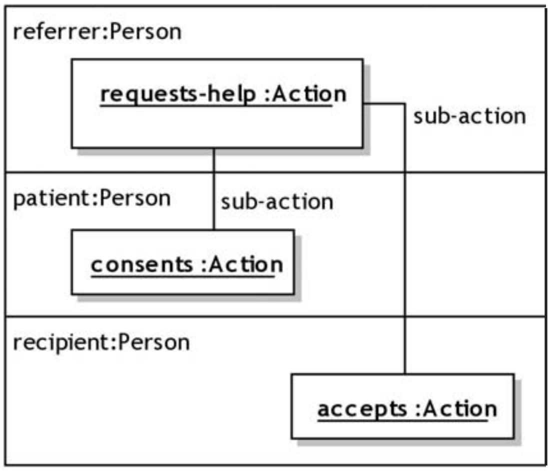
In the following sections, we demonstrate that useful concepts regarding the management of patients in a healthcare setting can be modelled using the classes and relationships in figure 1. This is not intended as proof of validity but rather as an illustration of potential utility in representing medical and administrative processes.

Risk Factor

A 'risk factor' increases the chances that a person may contract a disease.

In Figure 2, the box surrounding 'smoking:Action' and 'cigarettes:Equipment' is a swim lane. In the diagrams in this section and those which follow, swim lanes are used to show an actor performing an action.

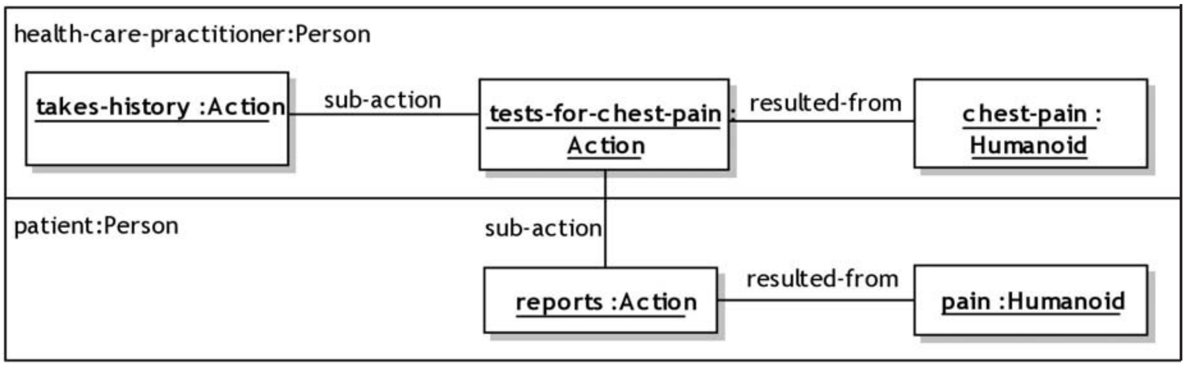
Figure 3. Representation of a referral



Referral

A referral is a request for help made to a health care professional either by a patient or a colleague. One approach to modelling this is to use the idea that a patient consents to the action and that a recipient accepts the request. (see Figure 3)

Figure 4. Representation of a symptom



Assessment

Assessment is the process of gathering observations about the patient by listening to a description of the problem (taking a history), by conducting a physical examination and by organising investigations, such as sampling blood, taking x-rays or ultrasound images, measuring physiological parameters or examining tissue samples taken during operative procedures.

While taking the history, the clinician interprets what has been said and applies labels mapping the description to accepted medical terminology for symptoms. During physical examination, the professional's senses (vision, touch, hearing and smell) are used to look for manifestations of disease (Nardonne, 1990). Humanoid observations should be used for symptoms, signs and those physiological measurements where no independent record is taken. The use of mechanoid observations should be reserved for investigations where a record of the sensor's output is kept.

In Figure 4, a health care practitioner takes a history, during which the patient is asked about chest pain. Pain is reported, leading to a positive test, represented by the existence of the chest-pain humanoid observation.

In Figure 5, the patient is examined for an irregular pulse. If the humanoid observation were missing, it would be reasonable for an analyst to deduce that the clinician examined the forearm and found nothing. If the examines-for-irregular-pulse action were absent, no such inference could be made. This demonstrates how the class model

Figure 5. Representation of a sign

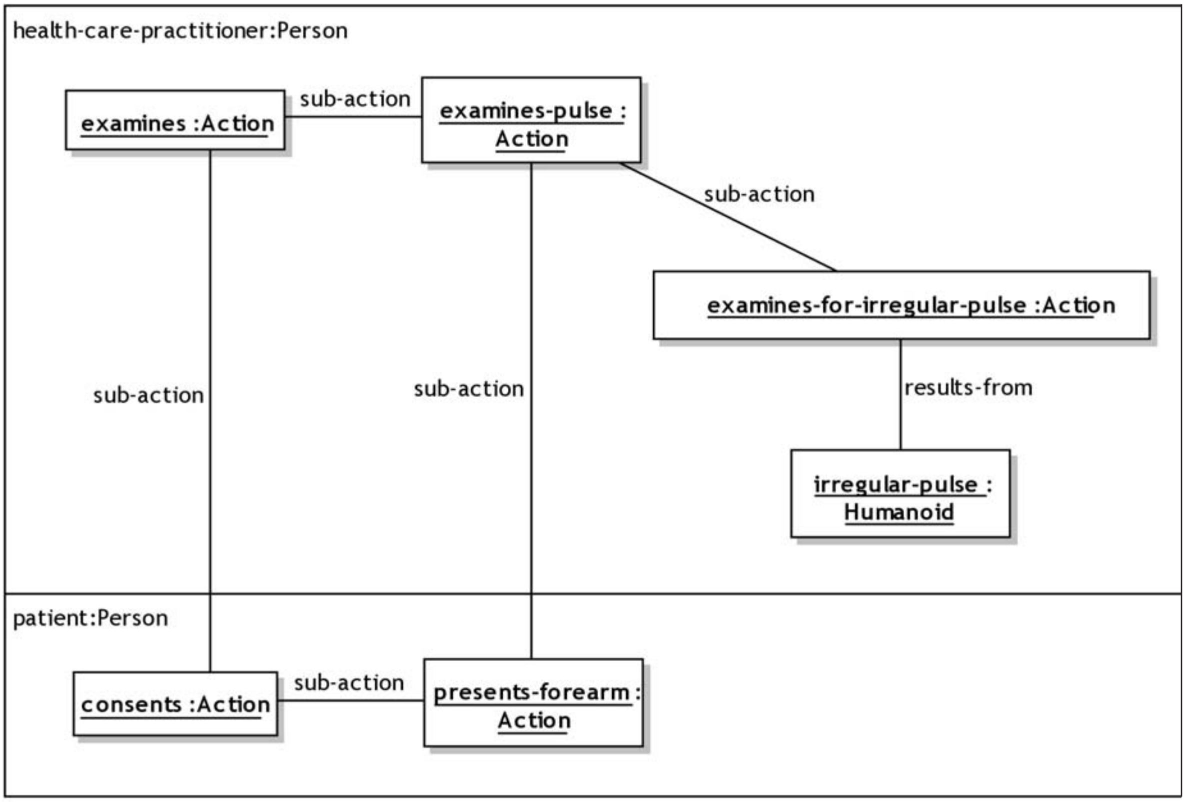


Figure 6. Representation of an investigation

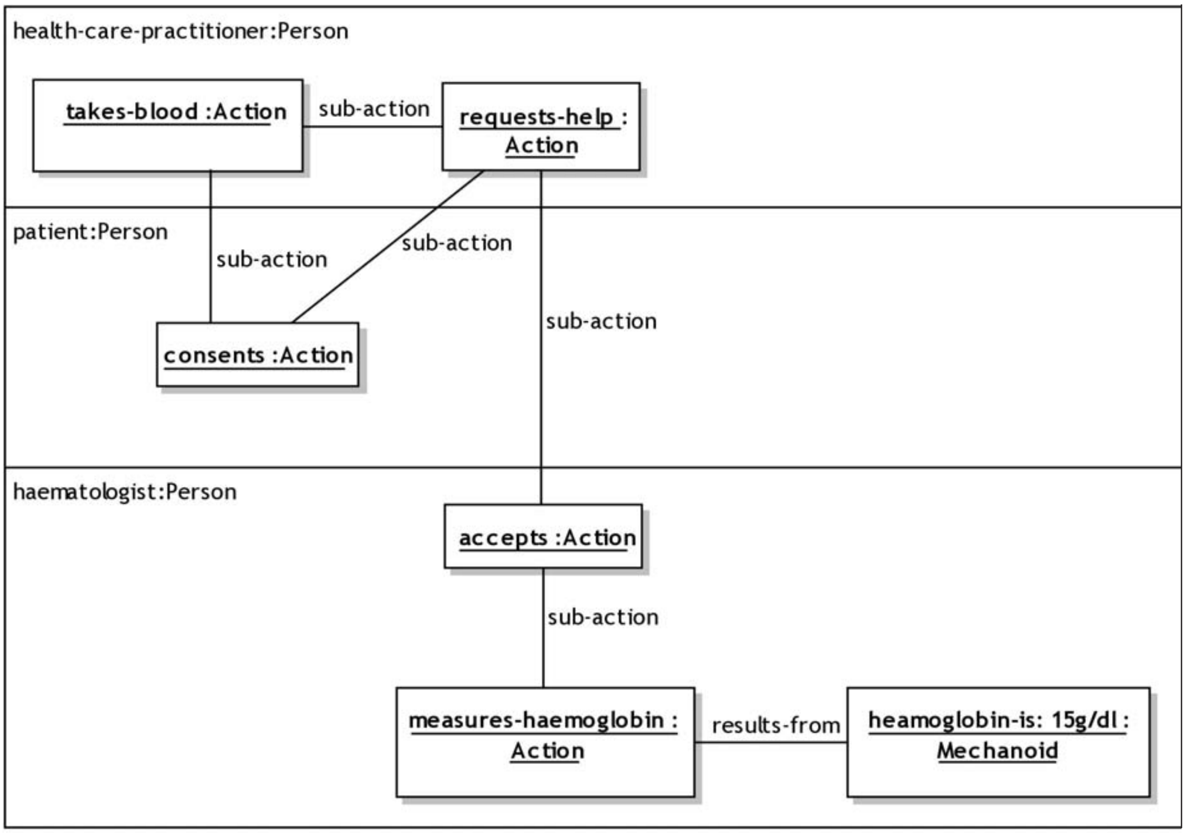


could handle an important concept in medical diagnosis: the contrary finding (see *Diagnosis*).

Figure 6 presents a simplified view of the analysis of a blood sample. Many details such as the method of taking blood, the administrative procedures, the equipment used and the process of transporting the blood sample, are not shown.

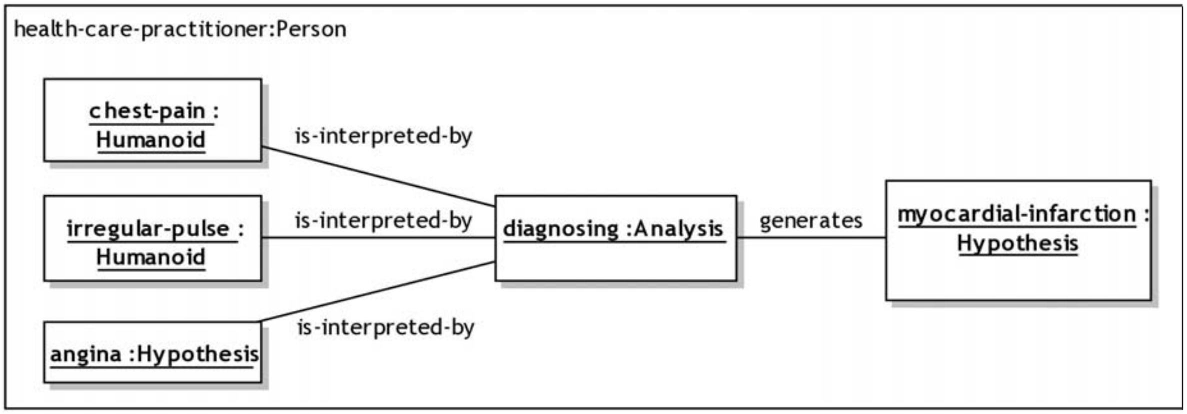
Diagnosis

Diagnosis is the process of labelling clusters of observations; the clinician selects which ones form a set, based on recognised patterns or the characteristics of disease processes (Nardonne, 1990). The technique for synthesising observations into a diagnosis has been described as one of hypothesis generation followed either by refinement or by elimination, as a result of a contrary finding (Nardonne, 1990) making the ability to store the latter important to an electronic patient record. (see Figure 7)

Management

Management is the selection, planning, execution and monitoring of tasks appropriate to the

Figure 7. Representation of a diagnosis



handling of a patient's problems. Usually the diagnosis forms the basis upon which treatment is selected but the clinician may also choose to use symptoms or signs, either because of the distress they are causing or because an urgent intervention is required (Nardonne, 1990).

While planning a task, decisions are made about who will perform the procedure, where, when and how. Clinicians marshal appropriate resources, none of which are under their exclusive control and take account of what skills are available, as well as the patient's circumstances, consent and ability to comply.

Monitoring is a repeated assessment, which takes place after treatment. It is focussed on the set of symptoms, signs and investigations that best indicate progress. During this phase, new problems may come to light, requiring that a new diagnostic review is initiated.

In Figure 8, a diagnosis of myocardial infarction initiates myocardial infarction care planning. This involves two tasks: monitor electrocardiograph (ECG) and administer morphine. The patient consents to receiving morphine and the task is realised by the health care practitioner giving morphine. The monitor ECG task is realised by the ECG machine's leads being attached to the patient's chest and the machine displaying a trace.

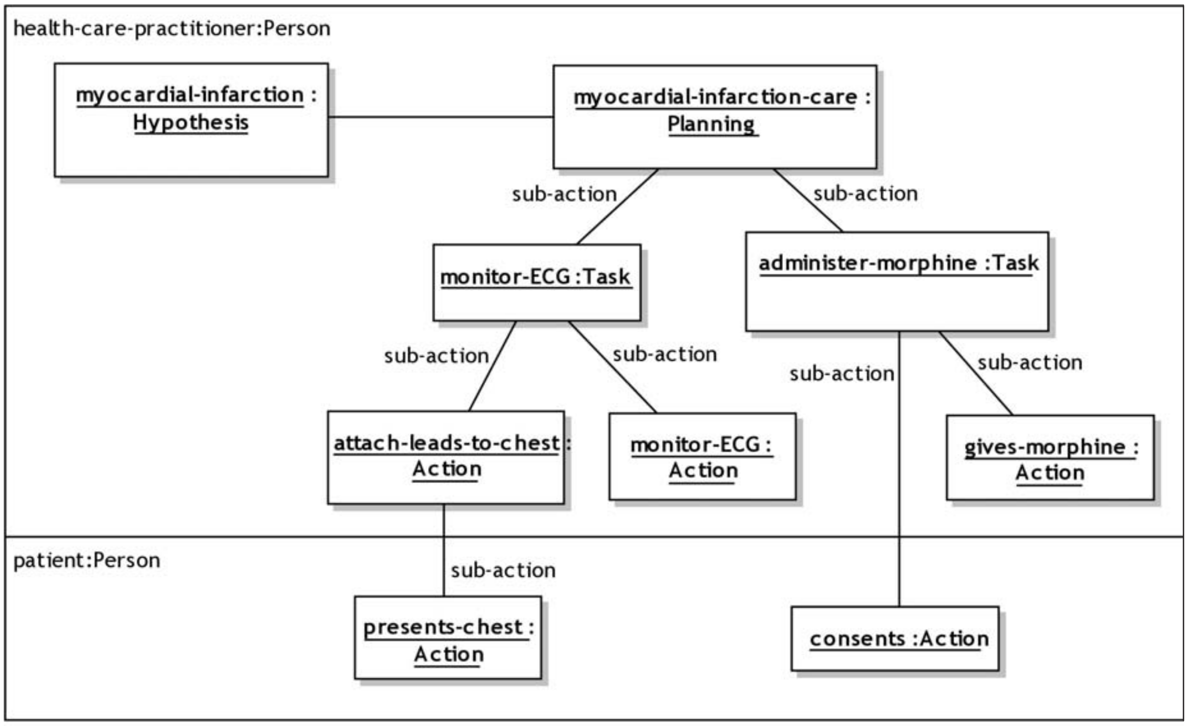
Organisational Memory

An example plan is provided for part of the management of ovarian cancer (Shaw, Wolfe, Devaja, & Raju, 2003). The hypothesis that a woman has ovarian cancer initiates the task of planning for a laparotomy (a procedure to assess the presence and extent of disease in the abdomen).

The laparotomy task requires that a midline incision is performed (the details of which are not shown). Next peritoneal fluid or washings should be sampled in order to determine whether the disease has spread from the ovaries to other tissues, which has implications for further treatment. Determining the correct stage requires the surgeon to take a sample of peritoneal fluid or if there is none, to perform a peritoneal lavage and then to take a sample of the resulting fluid in the abomen.

In figure 9, the task to sample peritoneal fluid or washings begins by asking the surgeon to examine for peritoneal fluid. Two possible outcomes are shown by the 'expects' relation: either fluid is present or absent in the abdominal cavity. If

Figure 8. Representation of the early management of a heart attack



fluid is found, a sample is taken. If there is none, peritoneal lavage is performed and a sample of the lavage fluid (washings) taken.

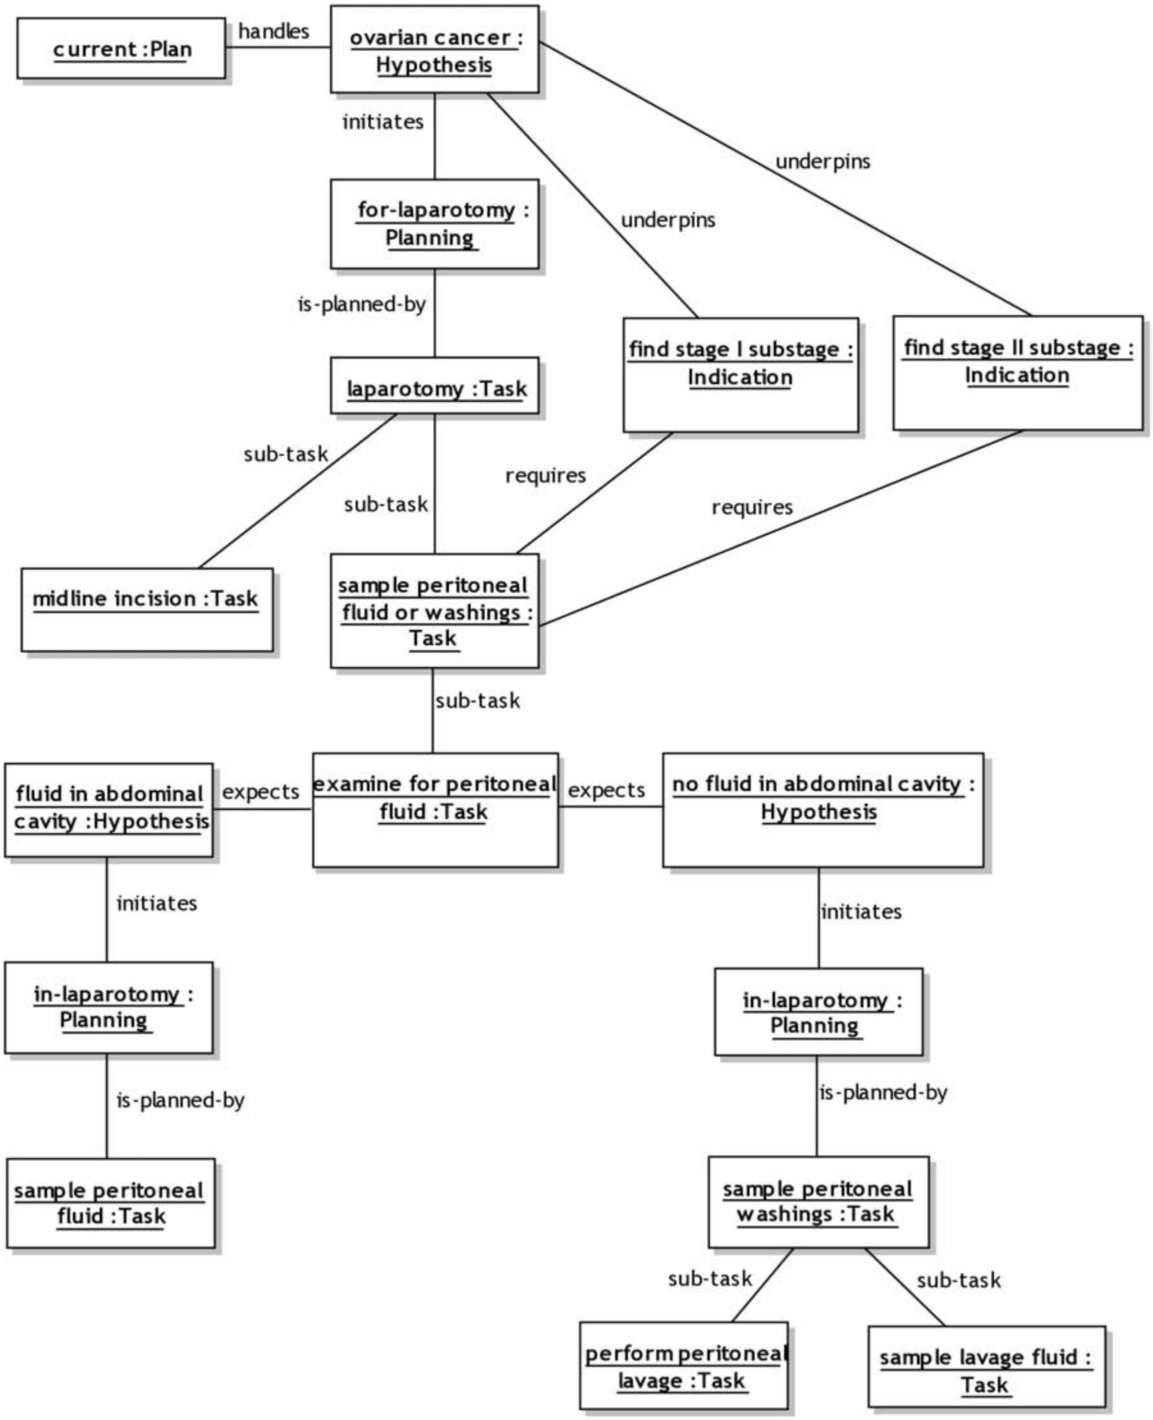
It should be noted that there is a requirement to determine the sequence of peer tasks in a plan. In Figure 9, the tasks should be carried out in left-to-right order.

Whereas the health care practitioner performs actions on a person and gains feedback from observation of that individual, QA performs actions on plans and gains feedback from observation of the results. Figure 10 shows how the QA process might be represented using classes from the model. Initially observations of the process are analysed to generate a hypothesis about how it might be improved. Next the alteration is planned, and a task defined which is realised by an action to change the process. The effects of the alteration are then monitored by gathering further data.

CRITIQUE OF THE QA MODEL

The QA model of healthcare information systems is based on assumptions that may be familiar with medical as well as ICT professionals. It implicitly assumes that reality can be described in a relatively straightforward manner. Patients as well as medical professionals are viewed as rational individuals who seek to communicate in order to achieve a mutually beneficial outcome. The technology required to underpin the QA system has not been considered in any detail and is presumed to be unproblematic. Use of technology follows functional requirements. Briefly, the model we have developed follows the positivist mainstream model of information systems research and practice. This approach has the advantage of being familiar to many of the relevant stakeholders of

Figure 9. Plan for the early stages of a laparotomy for ovarian cancer



healthcare information systems. At the same time it may cause problems. A primary indicator of the shortcomings of the mainstream understanding of information systems is the persistently high failure rate. Despite decades of research on information systems, the majority of systems can still be considered failures due to price overruns, poor specifications, lack of user uptake etc. Wilson & Howcroft (2002) have pointed out that the concept of failure is problematic per se. It is probably unproblematic to state that the history of ICT projects in the NHS is a history of failures.

The Critical View

Developing a new approach, such as the QA approach we are suggesting here, should thus consider early on whether there are factors that are likely to cause systems to fail despite sound conceptual underpinnings. We will use this section to sketch a possible counterargument to our QA approach in order to then propose how the model could be used to address these.

For this purpose we will briefly look at the position of Critical Research in Information Systems (Howcroft & Trauth, 2005) and explore which issues this may raise for our model. Critical Research in information systems (CRIS) is an approach to IS that draws from critical theories in the social sciences and attempts to discover angles typically overlooked by traditional research. A main aim of CRIS is to promote emancipation understood as the ability of individuals to live a self-determined life. CRIS is a useful choice of approach to our QA model because it emphasises aspects of social reality that our model so far neglects, such as organisational and national politics, gender, class, conceptualisation of technology and others. Moreover, CRIS, because of its emphasis on emancipation, has an ethical underpinning (Stahl, 2008), which maps well onto the implied ethical dimension of healthcare. The purpose of healthcare provision in general can be seen as emancipatory.

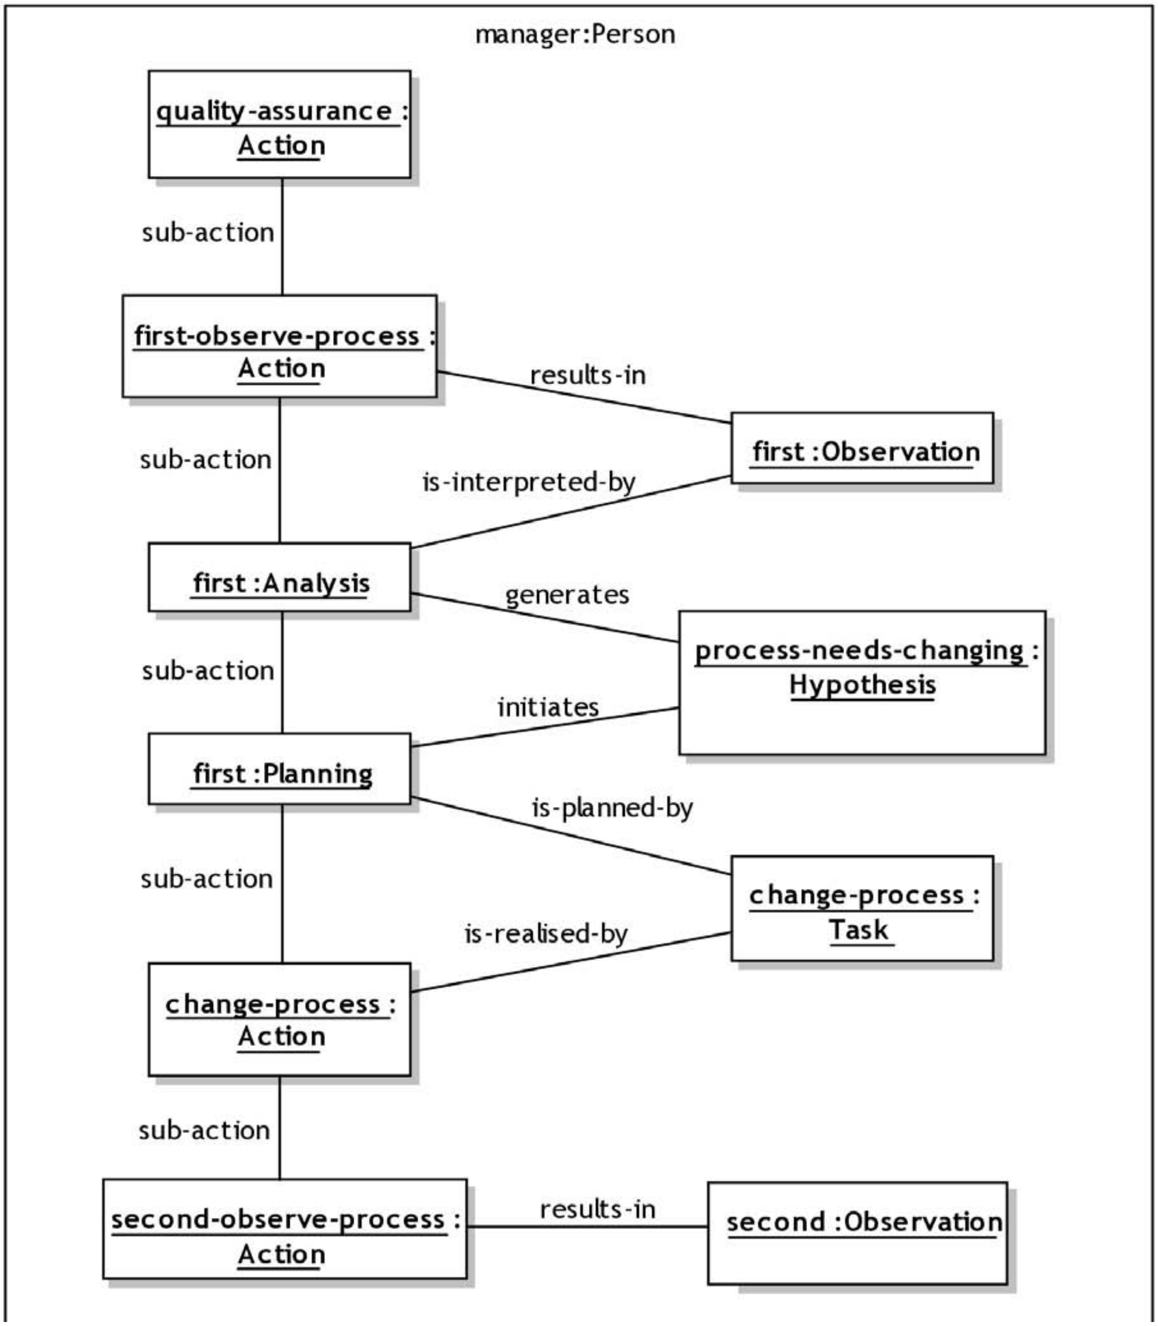
CRIS draws on a range of theoretical roots and it is impossible to undertake a comprehensive analysis of our model from a CRIS point of view. We will therefore draw on the CRIS literature that explicitly refers to healthcare IS in order to identify dominant issues that our approach so far has not covered.

Rationality

A good point to start a critique of mainstream IS that might be applied to our model is the concept of rationality. Like most complex concepts this one is difficult to grasp and define. Its clearest example may be the autonomous individual on whom neoclassical economic theory is built. Such an individual is rational because she has a complete set of preferences and acts in order to maximise her utility according to these preferences. Translated into a healthcare setting, this means that individuals, be they patients, doctors, or any other stakeholders, act in a way to maximise the overall utility. It is easy to see that this will break down at the point where preferences are not identical. The patient may want a maximum of healthcare, whereas the doctor may view this as medically unwarranted and the manager as too expensive. In addition, patients are often described as irrational when their actions do not contribute to their health, or doctors are seen as irrational when they do not follow organisational goals.

The concept of rationality has been critiqued for a variety of reasons. It may simply not be possible for humans to be rational in the sense described above. Our individual preferences are not complete and often contradictory. In addition we lack the knowledge and cognitive capacities to make optimal decisions. A system based on the idea that people are and will be have rationally is thus likely to face problems. An additional problem arises when technical systems are introduced to increase the rationality of healthcare provision. Empirical evidence suggests that the ‘irrational’ nature of human interaction does not change by

Figure 10. Representation of the QA process (Note: the vertical swim-lane)



the introduction of information systems. In fact the introduction of such systems often introduces new irrationalities (Berg, 1999).

A further problem of rationality arises due to competing demands. We have already indicated that healthcare IS are often seen as ways of saving money (Palfrey et al., 2004a). This is a legitimate aim. However, one should see that it will in many cases conflict with the similarly legitimate aims of other stakeholders (Adams & Fitch, 2006). The use of information systems to promote a financial perspective on rationality can thus be seen as an attempt to promote a particular agenda.

A further problem of rationality is that there are different types of rationality that determine our social reality. Information systems tend to represent an abstract rationality, which is arguably often not compatible with the practical rationality of healthcare practitioners. Hanlon et al. (2005) give an example of the NHS direct system, a nurse-based 24 hour health advice system, whose technical base represents a rationality that is not compatible with the rationality of the nurses operating it. A different example of problems of competing rationality is developed by Klecun & Cornford (2005) who show that a traditional view of rationality when used for evaluating healthcare systems fails to pick up relevant issues.

Concepts of Technology

A central question in critical discourses revolves around the conceptualisation of technology. Critical scholars often draw on other discourses such as the social construction of technology but also on traditional critical theory to develop an account of how the very concept of technology affects social outcomes (Feenberg, 1991; Feenberg, 1999). The point here is that technology is not a neutral tool that can be used to whatever purpose the user decides to employ it. Instead, technology is seen as endowed with certain values and affordances that favour certain uses over others.

This point is linked with questions of technical determinism. Much mainstream work on ICT seems to assume that technologies have certain uses that they are built for and that users will make use of the options of technology in the way they were planned for. On the other hand there are numerous examples of technology either not being used or being used for purposes different from those envisaged. This has to do with what has been termed the "interpretive flexibility" of technology (Doherty, Coombs, & Loan-Clarke, 2006) (or interpretative flexibility (Cadili & Whitley, 2005)).

An important aspect of the concept of technology is the capacity of ICT to capture reality. In our model this issue is highlighted by the distinction between humanoid and mechanoid observations. Technologies are much better at capturing some aspects of reality than humans and vice versa. Healthcare information systems are likely to favour mechanoid observations because they are easier to integrate in technical contexts. This is likely to lead to reductionist perspectives on healthcare which can blend out the immeasurable, which arguably is often an important aspect of medical practice (Hanlon et al., 2005).

The main point here is that a naïve reliance on an intuitive understanding of technology is not likely lead to the success of a new approach. If the QA model is to be successful, then design and implementation should be aware of competing demands on technology but also different users' conception of technology.

Politics and Hidden Agendas

One reason why the above two points are of relevance to our approach is that technology is often used for political purposes. Such purposes can stem from organisational politics as well as national politics. The primary example of this is the growing influence of financial considerations. One main benefit of healthcare IS is that they tend to allow a more detailed breakdown of costs of treatments and a clearer allocation of these costs to different stakeholders. At the same time this leads to a strengthening of cost considerations when compared with others.

The UK government has promoted new ICTs in the NHS partly on the grounds of facilitating more choice for patients. This can be seen as a positive aim as few would dispute that the ability to choose one's doctor is bad. However, one needs to understand that this rhetoric of choice can also lead to a fundamental restructuring of healthcare provision and change the balance between market and state allocation of resources (Mol, 1999).

A different example is the distribution of power in organisations. Traditionally, healthcare in western countries tends to be very much centred on doctors. They hold the knowledge; they make decisions and allocate resources. Doctors' autonomy is a highly valued tradition. However, in complex modern healthcare organisations, power is increasingly taken away from doctors and moved towards managers. Such power struggles are normal and can be found in most sectors and organisations. What is important for us to note is that technology can be used as a tool in such struggles. This can lead to the acceptance or rejection of a technology

Social Consequences of Technology

A final point worth mentioning here has to do with the social consequences of technology. The wide availability of healthcare information via the internet has already started to impact on doctor-patient relationships. Patients are better informed and often have specific demands on doctors. Doctors, on the other hand, often resist this change of role which threatens their traditional position of authority.

A further social consequence of the introduction of ICT into healthcare is that it will inevitably lead to changes in procedures. The mere fact that data is to be recorded changes the way doctors interact with patients. This is of course usually intended and thus not to be lamented. However, the changes will often go beyond what was envisaged. If, for example, a system captures the number of patient a doctor sees, then this is likely to affect management's view of the doctor. As a consequence the doctor is likely to pay attention to the number of patients seen and may make choices on which patients to see. An unintended consequence may be that easier cases will find it easier to be treated than difficult ones because they take less time and improve the doctor's performance record. This is what Zuboff (1988) described as "informating", a property of ICT that not only captures but also produces information, which then changes the original processes.

While the nature of interaction between stakeholders can change, the very practice of medicine can also be changed. Again, this is intended, and our QA model explicitly aims to improve healthcare provision by allowing doctors to better understand the consequences of their decisions. On the other hand, there is a danger that it will lead to increased bureaucracy and medicine by algorithm. The danger of "cookbook medicine" based on standards and protocols developed on the basis of collected data (Berg, 1997) is not to be underestimated.

The QA Model Response

The above critique of the QA model does not claim to be complete. Its purpose is to show that there are aspects of healthcare IS that our model does not capture but that still have the potential to affect its success.

We believe that all of the points are valid and relevant but do not have to lead to the downfall of the QA model. The important point to avoid these issues is to start the QA process with a suitable interpretation of what QA is about. QA is an iterative process that allows continuous interaction with the aim of improving outcomes. This means that it must be open to changes in focus and criteria of quality as well as a shifting view of relevant data and ways of collecting it. Understood this way, QA can be seen as a standardised ongoing conversation about important characteristic of a process.

Such an open understanding of QA would pre-empt much of the critique discussed earlier. It would not make assumptions about appropriate standards of reality and allow for a questioning of implied standards via the QA process. It would be open to different concepts of technology including the resulting means of collecting, formatting, and storing information. These larger contextual issues, including political and social consequences of technology, may be impossible to include in the technical model that we have started to develop in the *Background*. However, the QA process as a whole will have to be sensitive to them, given that they are arguably important not only for user acceptance of technology but for the entire QA process in healthcare.

One could argue that this will require something like a 2nd order QA process. We need to think about some way of continually ensuring that the QA process is of high quality. Again, there is a question whether this can be technically implemented and in what way it will require organisational changes.

A final issue has to do with development and implementation of a QA system. While we have tried to make a sound statement on some of the conceptual basics, the critique has shown that context sensitivity will be required. It is unlikely that the same implementation of the same system in different contexts will lead to comparable results. This is where the socio-technical approach to systems design and development (Mumford, 2003) is likely to be able to address many of the challenges by allowing for participation of a range of stakeholders, most importantly of end users.

CONCLUSION

We have argued that healthcare organisations should focus on establishing QA and then invest in information systems to provide timely data to help engage clinicians in the process. We used object-oriented analysis to develop a class model describing Deming's form of QA, assuming that healthcare can be modelled as a set of interdependent processes.

Our model could provide organisations with a memory of a process's history as well as detailed data about practise and its effects. In conjunction with research, such an information system would deliver timely data to support systematically making changes to healthcare procedures. This should result in care that provides the patient with the solution to their problem and that minimises their contact with health services, thereby increasing capacity and productivity. If this is indeed correct, healthcare organisations should obtain a return on their outlay on IS.

We took a step back to look at possible counterarguments against our approach as might be voiced by critical scholars. We suggest that our model is open to some critical arguments but understanding QA as a standardised, ongoing conversation about the important characteristics of a process overcomes many such objections. This review also highlighted the need to develop information systems in harmony with the needs of their many stakeholders.

Future Research

The class model needs to be validated by examining whether a wide of variety of use-cases induce changes.

How objects in the model are used to represent health care processes needs to be standardised as well as how they are named by terminologies for diagnoses, clinical and administrative procedures.

In principle, the level of detail in the model offers the possibility of defining the meaning of diagnostic codes for diseases, in terms of actions, observations and analyses. The value of this capability in actual use will need to be assessed.

Little in our class model is specific to medicine. It could support comprehensive data collection not only about healthcare but also about the various non-clinical supporting processes. To realise this, collection of data would need to be more detailed and from a wider range of staff than existing systems. Will user interfaces need to change in order to cope? Will the availability of these additional data be useful to healthcare organisations?

The next step of our research will be to examine these questions as well as the effect of the model on clinical processes. We plan to build a prototype and undertake a quantitative and qualitative evaluation in an environment where a comparison can be made with the effects of alternate software systems.

KEY TERMS AND DEFINITIONS

Continuous Quality Improvement (CQI): The application of Deming's form of QA to healthcare (see *Quality Assurance* below).

Critical Research in Information Systems (CRIS): An approach that draws from critical theories in the social sciences and attempts to discover angles typically overlooked by traditional research. A main aim of CRIS is to promote emancipation, understood as the ability of individuals to live a self-determined life.

Electronic patient record (EPR): allows health care providers, patients and payers to interact more efficiently and in life-enhancing ways. It offers new methods of storing, manipulating and communicating medical information of all kinds, including text, images, sound, video and tactile senses, which are more powerful and flexible than paper based systems. The policy of governments appears to favour a national healthcare infrastructure with a longitudinal patient record covering a patient's complete medical history from the cradle to the grave. (Rogerson, 2000)

Healthcare Information Systems: An information system (IS) is a system of persons, equipment and manual or automated activities that gather, process and report on the data an organization uses. A healthcare information system is one used by an organisation involved in the delivery of health care.

Object-Oriented Programming: A programming paradigm that uses "objects" and their interactions to design applications and computer programs. Programming techniques may include features such as encapsulation, modularity, polymorphism, and inheritance.

Quality Assurance: W Edwards Deming defined quality assurance as the continuous, systematic, iterative improvement of processes by obtaining feedback from clients and from staff. It may be viewed as a standardised, ongoing conversation about the important characteristics of a process.

Rationality: Best exemplified by the autonomous individual on whom neoclassical economic theory is built. Such an individual is rational because she has a complete set of preferences and acts in order to maximise her utility according to these preferences.

Stakeholder: A person, company, etc., with a concern or (esp. financial) interest in ensuring the success of an organization, business, system, etc. (taken from OED Online: http://dictionary.oed.com/).

Chapter 7.9

Improving the Quality of Healthcare Research Data Sets

Biswadip Ghosh
Metropolitan State College of Denver, USA

ABSTRACT

The goal of many healthcare research projects and evidence based medicine programs within healthcare organizations is to support clinical care team members by mining evidence from patient outcomes to support future treatment recommendations. In these research studies, the data is often extracted from secondary sources such as patient health records, benefits systems, and other nonresearch data sources. Good data is important to facilitate a good research study and to support clinical decisions using the results. Often multiple applicable healthcare data sources are available for a research study, some of which may be internal to the organization, while others may be external, such as state or national databases. This chapter attempts to develop an understanding of how the quality of data for healthcare research data sets can be established and improved when using secondary data sources, such as clinical or benefits databases, which were created without primary intentions for research use.

INTRODUCTION

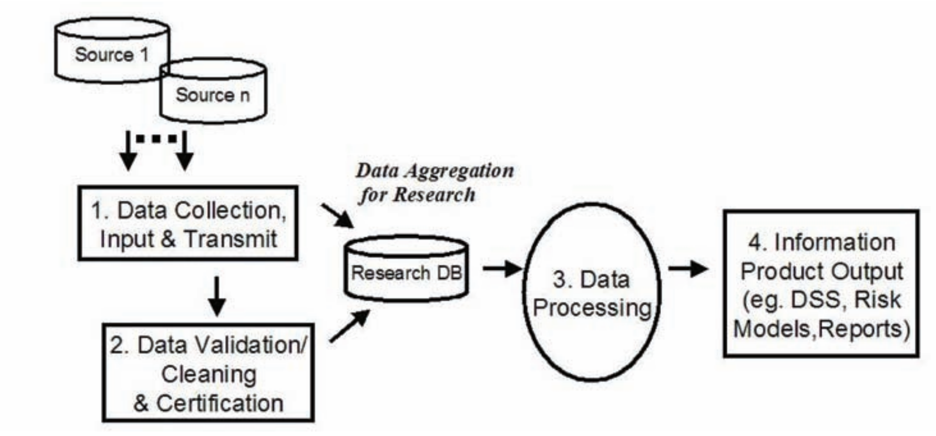
Asserting data quality is a critical component of any information systems based research project (Brodie, 1980). In healthcare organizations, research is often conducted using secondary data sources such as databases set up for patient medical records, insurance billing and benefits administration. As in other domains, data quality problems are increasing in such organizational databases (Wang, Strong and Firth, 1995; Storey and Miller, 1995). Prior studies have reported that between 50-80% of records in many such databases may be inaccurate, incomplete or ambiguous (Redman, 1998). The ramifications of using poor quality data in a research study can be quite costly –incorrect results that are flawed and unusable. Information systems built upon data sets of poor data quality with missing information and processes that allow information to bypass key managers can lead to catastrophic failures (Fisher and Kingma, 2001). To build validity in research results, data quality must be established, particularly when using secondary data sources, which are subject to multiple recording bias (Terris, Litaker and Koroukian, 2007). This chapter addresses several techniques that are suitable for implementation via organizational processes, managerial actions and technological and statistical approaches that can help build data quality. A case study is also illustrated that uses these techniques to establish data quality for data obtained from secondary data sources, such as patient records and benefits databases for use in a healthcare research project.

This chapter applies a data product lifecycle approach towards improving data quality. This approach views data as a product, and uses a value stream for the product similar to manufacturing processes (Lee and Strong, 2003). Data quality is an overarching concept that must be addressed in the entire process starting from data collection to data storage to the end production of the data product (e.g. reports and a decision model) and its usage. Data quality cannot not be simply viewed as the aggregate quality of the data elements; rather it must also include the quality of the data collection process, the support of the access methods and ways in which users manipulate the data, the actual processing of the data and the usage of the end (information) product produced from the data. Dimensions such as efficiency and timeliness of the collection phase, the completeness and accuracy of the data items, the accessibility and security of the data and the data output products by the different users, all play a large role in the definition of data quality. This concept of a data lifecycle is extremely important in the establishment of data quality. The role of different organizational stakeholders in establishing data quality and the interventions required to ensure data quality can be better evaluated using the lifecycle approach (Lee and Strong, 2003).

A typical data lifecycle for a research study using secondary data is shown in Figure 1.

Data from multiple secondary sources are extracted, transmitted and collected (step 1) into the research database (DB). The collected data is checked for inconsistencies, incompleteness and other validity problems during the database storage phase (step 2). Rather than rejecting problematic records and causing data loss, records with inconsistencies are flagged and systems are used to clean and subsequently certify the aggregated data in the research database. Appropriate updates (step 2) are made and data quality managers then certify the data set. The data is then processed (step 3) into information products, which are output (step 4) for users to access and use. Note that each step in the lifecycle must focus on the data as well as the management of the data by the people in the process. Hence, each step in the

Figure 1. Typical data lifecycle



illustrated process has organizational and managerial elements. How this triad of (1) technology, (2) organizational practices and (3) management practices can address the threats to data quality and enhance quality will be described in this chapter.

DATA QUALITY CHARACTERISTICS

The research literature in data quality has established multiple dimensions in the definition of data quality (Wang and Strong, 1996; Strong, Lee and Wang, 1997a). Some definitions view data quality as an intrinsic property of the data and include such characteristics as accuracy, completeness and objectivity of the data. The intrinsic category also has organizationally derived characteristics that include such factors as reputation and believability of the data as well. But other definitions provide a much broader concept of data quality that also includes an extrinsic category that stems from the organizational standpoint of data quality. The later view accepts the fact that the quality of data cannot be established without the inclusion of additional factors that originate from (a) the management of the data and (b) the users of the data and information products produced from the data. This extrinsic category therefore also includes the access and ease of understanding and use of the data. The extrinsic category can be influenced by such factors as the volume of data, the timeliness of availability of the data as well as the means of accessibility – both technologies and processes and security of data storage/access. For this study, data quality consists of the following four categories– (1) Intrinsic, (2) Accessibility, (3) Contextual and (4) Representational (Strong, Lee and Wang, 1997a). The last three categories are referred to as the extrinsic categories of data quality. Each of the data quality categories is defined by several dimensions and the threats to each category can originate from multiple sources.

Intrinsic Data Quality

The Intrinsic data quality is defined by the actual problems with the data. Such problems may result in problems in accuracy, where the data is incorrect, or lacks objectivity because there was subjective judgement involved in the collection of the data. Such issues may also arise if multiple sources exist for the same data and they conflict with each other. The reputation of the sources of data can also influence the believability of the data. In such situations, additional organizational approaches must be established to improve the validity of the data by introducing data certification processes.

Accessibility Data Quality

Accessibility is an important dimension for data quality as proper access has to be provided to the right people to the data during all phases of the data lifecycle – collection, cleaning, processing and output. If access is too restrictive in the collection phase, then incorrect and incomplete data may be collected. During the data cleaning phase, the key members of the data collection team must be given access to correct, update and certify their representational data. All of these activities require adequate technology support together with management of access rights. Any deficiency in the technology infrastructure supporting the data project will lead to data quality issues.

Access can also be too restrictive, where the right users do not get access to the data and/or the end information product results from the processing of the data. Data access can be too loose and result in unauthorized users getting access to data and compromising the integrity of the data in the process. The volume of data can also be an issue leading to data quality problems. Proper partitioning of the data can help if there is a large volume of data to work with, which may become cumbersome and delay all phases of the data lifecycle. Partitioning also allows the data to be made avail to the right subset of users. In a distributed environment, when data is obtained from multiple sources and users, there is a need for coding and standardization of fields and values, otherwise objectivity can be compromised.

Representational Data Quality

This category of data quality issues arise from concerns about the interpretability and understandability of the data. These issues are profound when data collection and/or consumption is distributed across different groups. Timeliness of the data must be supported by encouraging prompt updates from the users. Standards and uniform coding allow for better representational quality of the data and less inconsistencies due to multiple data sources. Such standards and coding can be encouraged thorough organizational training and development activities and data lifecycle management.

Contextual Data Quality

Contextual data quality represents the issues when the data collected does not support the requirements of the project. Perhaps the data fields have not been correctly defined or the data is not measured and/or organized properly. Projects related to the data collection, processing and information generation results in some key elements missing leading to a lack of meaning in the results for the users. Ensuring completeness of the data fields and their proper definition are required during both the build and execution phases of the data lifecycle to ensure that the efforts surrounding the data project result in useful data and data products.

ASSESSING DATA QUALITY

Measures of data quality have been described in other studies (Ware and Gandek, 1998; Lezzoni, 1997; Gandek, et. al., 1998). Such measures fall into (1) the checking for completeness of the data set, (2) passing validation checks for value ranges (systolic blood pressure between 50-250), (3) establishing relationship among fields (eg: date of death after date of birth) and (4) coding accuracy and consistency across sources. Other checks include the use of statistical scales such as correlations among items to assess discriminant and convergent validity, reliability metrics such as Cronbach's alpha and measures of centrality, variance and range.

From the data lifecycle approach to collecting data and using data as an input to the information product additional data quality measurement items are necessary. These include the assessment of the resources being used to efficiently collect data, to check the data against validation rules, the timely resolution of exceptions, conflicts, and quality problems uncovered by the checks, the methods of organizing and partitioning the large data sets and the means of access to the data across the system are important as well.

Table 1 summarizes the four categories of data quality – intrinsic, accessibility, representational and contextual, by defining those categories and their dimensions and lists the possible measurements to assess each of the categories.

THREATS TO DATA QUALITY

This section elaborates on the threats to data quality. Prior research has also identified several threats to data quality (Strong, Lee and Wang, 1997b). These threats can compromise data quality if not addressed with adequate organizational, managerial or technological solutions during the data lifecycle. These threats are also common in the health informatics domain and often lead to

Table 1. Summary of dimensions of data quality and their assessment

Data Quality Categories	Dimensions	Measurement Items
Intrinsic	Accuracy, believability, objectivity and without multiple source conflicts	Completeness of dataset and fields
Accessibility	Role specific access rights for users, Partitioning, Technology to support efficient data lifecycle.	Adequate collection resources, Partitioning and Access
Representational	Interpretability and understandability of the data, Timeliness and the Establishment of Standards	Agreement on coding and subjective scales, Timeliness of collection and resolution of exceptions
Contextual	Definition of fields; Proper meaning and organizational purpose, Completeness	Number of validation rules passed; Number of conflicts and duplications removed

problems in producing quality clinical research data sets. The threats to data quality along with some solutions to avert the threat in healthcare research are discussed below.

Multiple Sources

Multiple sources for the same piece of data has the potential to produce conflicting values. The conflict maybe in the way the data is coded, or the value itself. For example in the healthcare setting, a database targeted at recording patient health records may have fields coded and stored lees stringently than a systems geared for insurance billing. The patient records may contain multiple treatment and symptoms in textual form, while the later only contains the primary disease codes and treatment codes that are reported for insurance purposes. Distributed heterogeneous systems without proper integration mechanisms lead to inconsistent definitions, formats, rules and values of data.

Such contradictions create problems, when data extracts received from such data sources are processed with automated programs to generate the research data set. The original meaning of data may be lost or distorted as data flows between systems and is retrieved from a different system, time and place for the same or different purpose. In these scenarios, data quality must be established with organizational interventions and processes to have human data collectors certify the research data sets, when discrepancies arise. Data aggregation processes must be established along with common norms and knowledge across the dispersed data collection team. Data management processes such as timely and secure data transmissions, aggregation and certification help to resolve issues arising from distributed heterogeneous systems.

Subjective Judgments

The data collection process in healthcare often involves subjective judgment of one or more human users. For example, a particular patient’s symptoms and their severity, such as regarding whether they are life threatening or less adverse are often the judgement call of the clinician at the patient’s side. However, once the value is entered into the system, the value is treated as a fact. Data collection at multiple hospitals can produce even greater issues – as the training and practices of the clinicians performing the data collection may be greatly different. The data collected and used in different areas of specialization are coded differently, leading to data quality issues. Some departments may still collect patient data using detailed notes in a patient record system, while other department may be collecting the same data using electronic forms that require selection of a range for each patient parameter. Such divergence in coding of data collected through subjective judgments cannot be simply processed with automated programs to generate the research data set. It is impossible to establish data quality without organizational interventions and establishment of processes to have human data collectors certify the research data sets for data elements identified as requiring subjective judgement in the collection stage.

Healthcare organizations have highly organic structures with limited formalization or standardization of behaviors of the clinicians (Ghosh and Scott, 2008). The clinical staff – physicians and nurses mostly work in highly specialized jobs and departments in a fairly autonomous fashion. Hence codes and conventions across disciplines are hard to establish. While technology can help somewhat in transcribing between formats, it is impossible to establish data quality without organizational interventions and establishment of processes to have human data collectors convert the clinical data into research data sets using uniform coding schemes. These are well supported using data entry templates that guide the data collector to enter fields in the right coding for the research data set and training to calibrate data collectors on the data scales.

Limited Computing Resources

The deployment and use of computing resources are extremely important in all stages of the data product lifecycle. Technology can play an important role in the collection, update and certification, protection and access of the data and its end products. Without adequate computing resources, which data collectors can efficiently use in the collection phase, the chance of data not being recorded increases leading to data loss and incomplete records. Likewise, if the technology is slow, a bottleneck situation is created leading to further data loss. As technology advances and becomes cheaper and faster, powerful devices can be placed with the data collectors and during the use stage of the data product cycle to allow for ubiquitous use and improve the quality of data. In the surgical setting, by providing hand held devices to nurses equipped with templates and forms for data entry, the research team can ensure that all the needed data fields about the patient are captured and coded per the requirements of the research study.

Access to data during the data product lifecycle is an important requirement to allow certification of data quality. Users collecting and/or using the data need to have efficient and easy access to the data to input, review, update and use. Any problems with access can lead to loss of data and lower data quality. In healthcare, regulations require that only authorized people, who are caring for a patient to be able to view the patient's data. Hence security policies in healthcare can restrict access and not allow others involved in collecting, processing or using the research data from accessing the data. This trade-off between security and accessibility can be resolved by de-identifying patients in their data, as well as proper training in data security and privacy for staff, who are involved in the data product lifecycle.

The volume of data poses unique access problems. Patient record systems often contain millions of records and capture minute details about the patient's interactions across all departments and specializations that the patient comes in contact with at the hospital. However, a research study may only need a certain set of patients over a defined short range of dates and a type of care. In this scenario, access to records may be unnecessarily slowed down by the volume of the data set. In such cases, data collectors and users can be reluctant to collect, update and use the data due to access speed/convenience issues. To address these problems is it advisable to receive extracts of the patient records that are relevant to the research study with only the relevant fields (for the research study) and then perform subsequent manipulations of the data in a separate store from the original data system. Another technique used involves partitioning the data so that selected users only access the data they are responsible for.

This also increases the access speed and provides some security as well.

Input Rules Too Restrictive

Input rules that are too restrictive may impose unnecessary controls on data input and lose data that has important meaning. Data entry clerks may also skip entering data into a field that imposes difficult checking, resulting in data loss. They might enter a different arbitrary value just to get past the checking and hence compromise the accuracy of the data in the process. The better approach is to allow data to be collected, but questionable values or empty fields could be flagged for future resolution in the data cleaning process. Again organizational interventions and establishment of processes will have to be done to have human data collectors either correct fields that may be inconsistent or certify those fields as actually correct (exceptions), even though values may violate consistency rules.

Changing Data Needs

Often the form in which the data is collected, stored and/or used can change over time particularly if a research study is replicated or completed multiple times. This may lead to data quality issues as the data could have been coded in a way to support one research project that makes it unusable for a different study. Moreover, certain data fields may be missing as well. It is desirable to be able to go back to the original data source - clinical, billing, etc. and be able to produce a new research data set once again. This is only possible if a repeatable set of process steps have been established, recorded and tested of how those data sets are being manipulated to produce the research data set.

FRAMEWORK TO ESTABLISH DATA QUALITY

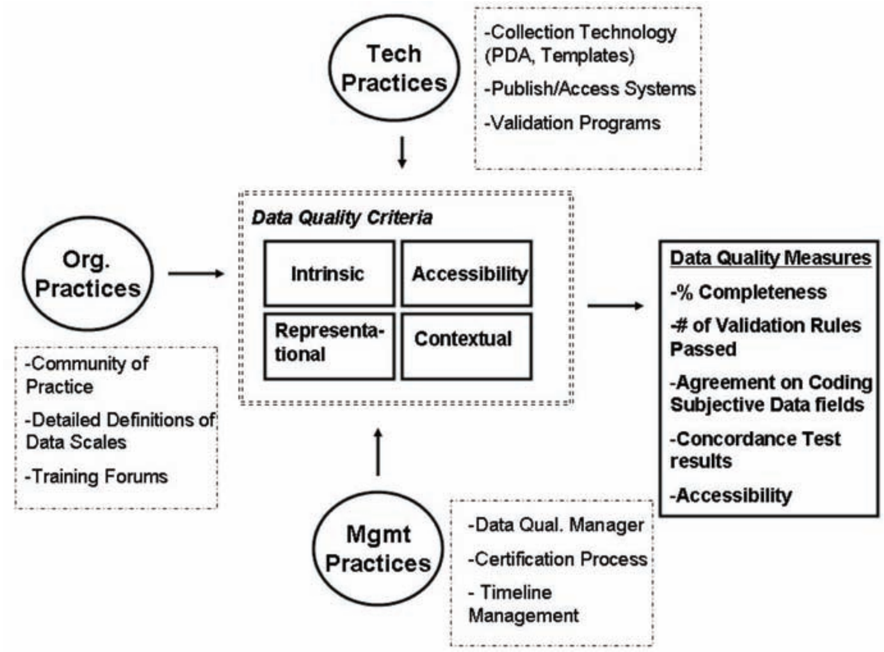
The threats to data quality can be alleviated by treating the generation of the research study data set as an information product and applying techniques and processes to strengthen the data quality. The methods to improve the data quality and the quality of the information products generated from that data can be classified into three approaches: (1) organizational, (2) managerial and (3) technological. For most information systems scenarios, all three approaches must be combined to address the multitude of threats to data quality described in the previous section. Figure 2 shows the research framework with the four dimensions of data quality and the three categories of practices to improve data quality together with measurement items.

Organizational Practices

Organizational approaches must be established when data collection or usage activities spread across multiple departments, who may or may not have standardized approaches to handling data. Often these data lifecycle activities span department boundaries and common understanding must be established between members across departments for the success of data projects. Organizational practices can also help to build bridges to allow data related activities to transcend formal organizational charts.

Some of the important organizational practices include (1) establishing communities of practice, (2) holding periodic forums/conferences, (3) developing a sharing culture and (4) supporting continuous training and education. Communities of practice foster an environment conducive to learning and innovation with respect to data quality activities. A community of practice is defined as a group of people bound together by shared practices, experiences and expertise for a command

Figure 2. Data quality improvement framework



purpose (Wenger and Snyder, 2000). The essential feature of a community of practice is that mutual engagement through interpersonal interaction is an essential activity that allows a sense of joint enterprise in a loosely connected team (Brown and Duguid, 1991). The users involved in these activities can share their experience with others across department boundaries as well as tap into the expertise of others by posing questions to the community. Such sharing builds standards and commonality of operating methods among data lifecycle staff, even when across their reporting departments, standards rarely exist.

A complementary channel to the informal communities of practice is the hosting of formal forums and conferences on a periodic basis. Such forums bring all stakeholders together as such events should be designated as mandatory participation. Events held every 6 months are a good frequency for most projects that are not undergoing too much change. For data projects that are just starting up or encountering a lot of change, more frequent forums must be held, perhaps quarterly or even monthly. The forums also encourage sharing and build appreciation of all the stakeholder's roles, perspectives and concerns. They are a channel to disseminate up to date information on project status and introduce new practices into the group in a formal way.

The efforts to build culture among the stakeholders and all users involved in the data lifecycle can be approached through multiple channels, both formal and informal. The culture should promote trust and safety to report any data quality problems. By building group identification among members of the data project, regardless of their physical dispersion or reporting departments a cohesive culture can emerge that can help in times of project crises. Culture also promotes shared norms and expectations and builds trust among the group.

Finally, training and certifications must be a central part of the organizational approach. Refresher courses on regulations, data privacy, technology and other aspects must be completed by all users. This places an emphasis on learning among the group members and protects against the abuse of data. In the healthcare setting, the data is often patient identifying and if improperly handled can lead to significant privacy issues for the organization.

Managerial Practices

Managerial practices are important components of countering many of the threats to data quality by putting a focus on the complete data lifecycle. Managerial practices must encourage the management of the data together with the products of the data. A simplistic focus on only data quality without a comprehensive approach to improve the quality of the overall data product lifecycle is not desired as the focus of the organization shifts to the wrong goal. Managerial attention in the data lifecycle involves defining and staffing the roles in the process and also staffing a data quality manager who is responsible for the managing the information processes and products. Managerial attention must be also focused on finding out about any new knowledge and implementing them in the process to improve data quality in a continuous fashion.

The managerial practice also involves setting goals such as the timely aggregation of data, appointing staff, who can view and/or update the data and assigning roles to users and defining who can access what in the final product. The data manager is not usually responsible for the storage and networking infrastructure, as the IT staff takes care of that. However, the data manager's responsibilities span the data lifecycle and the quality of all data and data products. Managerial attention must also be placed on the organizational practices that have been established earlier and ensuring that those activities are working suitably.

Technological Practices

Technological approaches to improving data quality include taking steps to address threats such as possible accessibility and security issues as well as working with large volumes of data by partitioning them into manageable pieces. Building software code to check data elements as they are entered into the repository and the execution of consistency checks can also be done with the aid of technology. Care must be taken to not burden the data entry person with too restrictive entry rules, or that might result in loss of data. The better approach is to allow the data to be input and stored, but flagged for further investigation and needing possible correction before use.

Technology also can be used in the data collection stage by providing forms and templates to the data collectors to use during that process (Chen, et.al., 2007). This allows for standardization of the data collection process across departments thorough the use of software. Technology, such as wireless handheld devises may be put in to the hands of the data collectors to allow for a more efficient collection process. The end result of the data collection, the data product itself can be placed in the users hands to also increase the adoption and use of the data product. Technology can also be used to perform format conversions and allow data from multiple sources to be aggregated. Statistical tools can be used to compare the concordance of two data sources, when there are common fields between those sources. Metrics that report the agreement between the sources can be used as confidence boosters in the aggregation of data fields.

Table 2 summarizes the threats to data quality and potential approaches to alleviate the threats.

CASE STUDY

This remaining portion of the chapter illustrates the practices of a live healthcare research project that has implemented many of these interventions to improve data quality. The goal of the healthcare research project illustrated here is to produce a

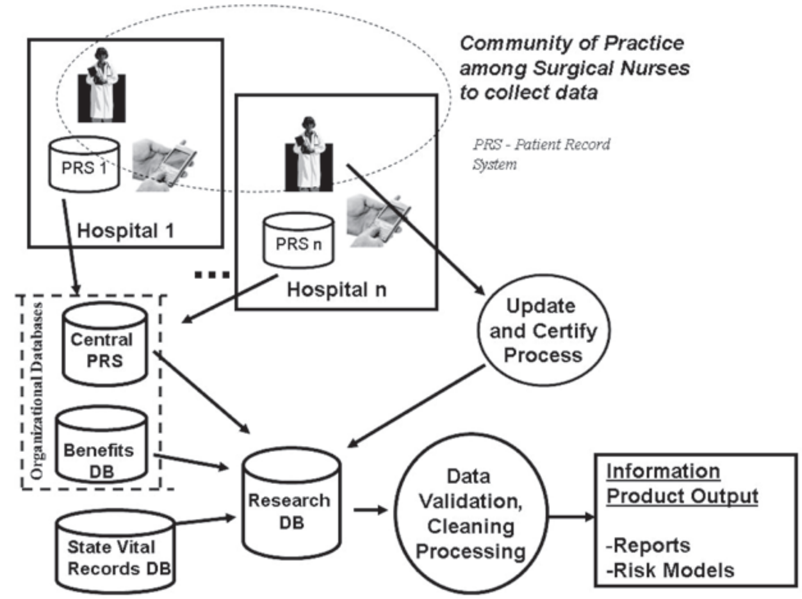
Table 2. Summary of data quality threats and alleviating practices

Threat to Data Quality	Data Quality Category that is Impacted		
	Organizational Intervention	Managerial Intervention	Technology
Multiple Data Sources	Establish Knowledge sharing Communities of Practice/forums	Data aggregation and certification process	Concordance Testing; Database Validation Checks
Subjective Judgments	Establish Norms on Values and training data collectors	Defining levels for a variable to make it a more objective measure; Process to certify final research data set	Data collection Templates with choice boxes; Aggregation of data using database programming
Limited computing Resources	Training on technology to allow efficient use	Control access rights to data by partitioning data and assigning responsibilities and user roles	Update computers; Handhelds to assist in data collection Partitioning Data set
Restrictive Input Rules	Prevent data loss by training users on data entry forms/templates	Establish process of flagging and fixing defects	Data Validation rules and integrity checks
Changing Data Needs	Future data needs planning and training activities	Select new data to capture per requirements	Save copies of original data sets with more variables outside the research data set.

surgical risk model to be used by surgeons to make decisions on the expected mortality or morbidity of performing an elective surgery. The model is produced based on data collected on past surgeries and their outcomes – including mortality, morbidity and other complications. Over 35 variables indicating the conditions of the patients before and after surgery such as blood pressure, weight, height, past surgical history, alcohol use, etc. are collected and used to generate the regression model supporting the decision support system. The risk model is updated every quarter based on new surgeries (and their outcomes) that took place in the past quarter. Data is collected throughout the quarter using a defined process. The data is certified at the end of the quarter, before the statistical processing is done to generate the risk model and distribute it to the surgeons. The surgeons use the risk model to assess the risk of a surgical procedure for their patents on an ongoing basis.

The healthcare system in which this project is being conducted is a national system, with multiple hospitals, where surgeries are performed. Most of the hospitals use a single patient record system, into which information collected on patient visits and treatment and procedures are recorded. Patient record systems can be a source of medical data about the patient but have certain characteristics that make it difficult to process the data in the system. Data may include images, such as X-rays, as well as physician's notes that are in free format. Such free format notes may be processed using sophisticated text mining to find usable data for research purposes (Cam, Efthimiadis and Hammond, 2008). Moreover, in a distributed health care network, practices surrounding what needs to be recorded and the conventions around the data entry into the patient record system varies greatly across hospitals and care facilities and as well as across specializations within those hospitals and care facilities. Additionally, some hospitals are using their own patient records system, which is different from the central system used by the health care provider network. When a patient subscribing to the healthcare system visits one of those centers, often the data is only migrated several months later through a manual process into the central patient record system. The process is illustrated in Figure 3.

Figure 3. Data lifecycle for healthcare research project



The healthcare system also maintains an administrative/benefits system that tracks additional biographical information about the patients/subscribers and benefits received. This later system also tracks the deaths, as a death benefit is paid to the patient's beneficiary of record. While occasionally some deaths may occur during a hospital stay or patient visit, most deaths happen outside the healthcare system's facilities. Therefore, death information is entered when a relative claims a death with a death certificate. For patients without beneficiaries, state or national death registries need to be manually checked by the research personnel to pull death information into the healthcare systems database on a periodic basis. Death information is particularly important as the risk model utilizes mortality and morbidity rates within 30 days of surgery, rates during the 30-90 days after surgery, rates during the 90-180 days after surgery, rates during the 180-360 days after surgery and rates during the 360day-3years after surgery for different surgeries.

Threats to Data Quality

The healthcare system has deployed necessary systems to electronically store patient records and information about their benefits. These databases are not primarily research oriented. Hence, standards are poor, and the data put into these systems vary greatly across hospitals and the clinicians doing the recording. Yet these secondary databases can provide a rich source of research data, which can be used when adequate steps have been established to clean and certify the data. The threats described earlier in this chapter all exist for this scenario as well. Multiple data sources often contain data for a patient and they need to be consolidated when the patient undergoes a surgery and becomes part of the pool of patients who have had surgery and now their data is used to produce the risk model every quarter going forward.

Table 3 summarizes the threats to data quality and the approaches used to counter the threats in this case study.

Table 3. Data quality threats and interventions pursued

Threat to Data Quality	Origins of the Threat	Interventions Used to Improve Research Data Quality
Multiple Data Sources	Multiple hospitals and providers using different patient record systems	Creating a data certification process (Managerial) Data validation checking for ranges, values and field comparisons (Technological) Use of data source concordance tests to establish reliability of data from multiple sources (Technological)
Subjective Judgments	Patient data entry and the coding of variables vary greatly between hospitals, providers and specializations.	Standardization of the coding of the variables that are part of the research study and training and support for nurses/physicians to adopt standards (Organizational) Provide templates & FAQ on handheld devices to ensure adherence to data collection standards (Technological) A research focused database in common format was created to receive and store patient records of surgeries and updates for patients who have become part of the "surgical pool", every quarter. (Technological)
Limited computing Resources	The system handles a very large volume of surgeries as the total number of subscribers is over a million strong. The centralized patient record system and the benefits systems are hosted on mainframes, where typical jobs can wait several hours to complete due to the number of users trying to access the system simultaneously. Multiple users with different roles needing access to different data/model.	A research focused database was created to receive and store patient records of surgeries and updates for patients who have become part of the "surgical pool", every quarter. (Technological) Handheld appliances with data entry templates provided to clinicians to ease data collection. (Technological) Establish Web site with different user roles to support correct level of access to the research data (Technological) Support clinicians in a community of practice to ensure stakeholders understand each others roles (Organizational) Handheld appliances with the risk model provided to surgeons to use in their patient evaluations (Technological)
Restrictive Input Rules	Extracts and Feeds received from multiple systems result in validation issues when put into the research data warehouse.	Database procedures and code is created to check for data to be in specified ranges and also fields are checked against each other for value conflicts (Technological) The invalid data is not rejected, rather violations are flagged for later verification by humans – tracked by a data quality manager (Managerial)
Changing Data Needs	New types of surgeries and/or new research publications require that different variables be collected for new risk models.	Support clinicians in a community of practice to ensure they understand each data element and new ones as well (Organizational) Database extracts can be merged into the research database to bring in new variables (Technological)

Summary of Methods to Improve Data Quality

The following sections describe the main practices (summarized in the table 3) used to improve data quality in the research data set.

Use of Data Concordance Tests

Concordance Tests take comparisons of records using prevalence-adjusted and bias-adjusted kappa scores to establish confidence before mapping research constructs to data items and proceeding with the research study (Looney, 2002). Kappa scores can be computed on categorical data and is useful for assessing the agreement between multiple data sets. An important first step in this study was to confirm death events, the date of death, and cause of death by comparing and verifying records from multiple data stores – benefits, state and national sources, particularly when none of the databases might be considered a gold standard for death events. The sensitivity of the risk algorithm to correct recording of patient deaths implied a need to perform verification across multiple data sources. The first step was to evaluate reliability for death events reported in the benefits system and the patient's home state vital records system, where death events are recorded. Second, the accuracy for date of death for those identified events was assessed via comparison between state vital records and the benefits system as well. Again the state vital records is not a gold standard as the death may have happened in a different state and may not have propagated to the patient's residence-state vital records system yet. Prevalence-adjusted and bias-adjusted kappa's were calculated to get a measure of agreement between two data sources. Kappa scores in the high 90% (above 97%) signified satisfactory concordance between data sources- the benefits system and the state vital records. This raised the confidence of using the benefits system (an internal organizational database) as a source of information on patient death events.

Use of Technology: Database Servers and Handhelds

The data project was supported by technology in several places. In the collection phase, surgical nurse recorders in each hospital were given handheld devices with data collection templates to make their data collection more efficient. These devices allowed the nurses to collected data using ranges of values from menus. Unlike the patient record system, the menu based handhelds allowed for standardization of data across multiple facilities. Data from both sources were used – the clinical records and the handhelds. However, the clinical records were mainly to ascertain the number of surgeries in a quarter and to ensure the nurses did submit data for each surgery from their handhelds. Technology in the form of a server, database management system and web portal site, allowed the authorization of the right data collectors to use the site to view, update and certify the surgical data for their patients only. Finally the risk model (a regression model linking the multiple patient variables to the outcomes of surgery – no complications, complications with morbidity and mortalities over the different post surgery time periods) was also installed on a handheld device for distribution and use by surgeons in assessing the risk of a patient for an elective surgery. Threats to data quality from accessibility, security and inadequacy of technology were clearly addresses in this project.

Database Validation Processes

The database is setup with programmed objects to check for completeness and validity of the fields. The programming checks include:

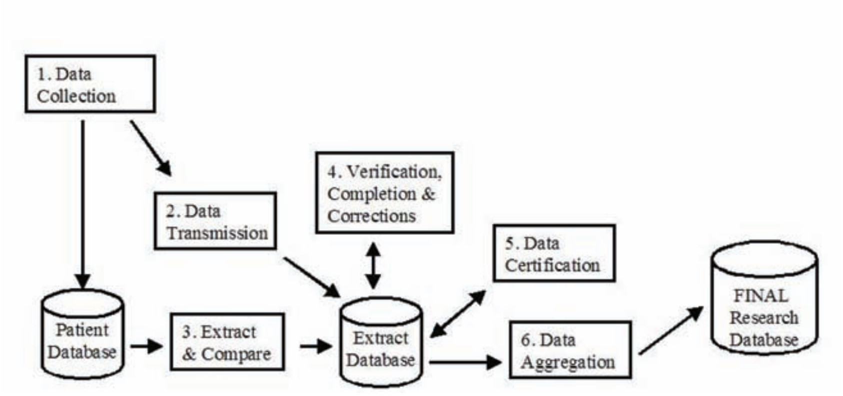
1. Check for the completeness of the records: All fields are present and all surgeries for the period are accounted for.
2. Check for range of Values: e.g. systolic blood pressure between 50-250.
3. Check for consistency between fields: e.g. date of death after death of birth.
4. Check for duplication and flag all exceptions for manual certification.

Validation failures are flagged for manual certification using the data certification process described below. The data quality manager is responsible for the timely resolution of data quality failures.

Building Communities of Practice

Communities of practice focus on fostering an environment conducive to learning and innovating with respect to data quality activities among the stakeholders of the data project. They create a learning culture, build trust and encourage sharing of experiences learned from participation in the data lifecycle. When questions might arise about a data field, its coding, etc. the community of practice allows the dissemination of up to date information and fosters an appreciation of each stakeholder's role and responsibility. As such threats to data quality arising from multiple data sources and the subjectivity of each hospitals data recording procedures were alleviated. In this

Figure 4. Data cleaning/certification process



research project, communities of practice were established for the surgical nurse recorders to help them understand the meaning of data items being captured for the research study through monthly conference calls, an email distribution list, a FAQ web page and a web based discussion board.

The Data Certification Process and the Data Quality Manager

A data quality manager was in charge of the quarterly data certification process. Each recorded surgery from the patient record system was collected into the research data base and surgical nurses were asked to make updates to the data from their handheld devices. After this was done, each hospital's designated contact person (i.e. the surgical nurse recorder) had to certify the data as correct. The data quality manager was responsible for this process and made sure that timely certifications were done, so that the research data could be used to generate the data products – reports and the risk model. Therefore the data quality manager through their managerial activities was able to alleviate the threats to data quality arising from multiple data sources, hospital systems and manage any fallout from the input data checking process.

The certification processes was done at two points, the first part was at the input stage, where data fields flagged as problematic (failed checking or missing values) were corrected by the surgical nurses using web based forms. The nurses collected the data on their handheld devices as a supplementary system to the patient record system. The second part of the certification process involved certifying the final set of patient surgery cases in the past quarter before the processing was started. This was the responsibility of the chief of surgery for each hospital, who relied heavily on the surgical nurses. The data quality manager was fully responsible for the smooth running of the data certification process and timely updated to defective data. (See Figure 4)

RESULTS

The results from the data quality improvement program were positive. All fields were represented by discrete input scales to avoid semantic data entry problems. A brief survey to assess the agreement of the data collectors on the meaning of the data fields and the correct interpretation of input rating values showed strong agreement. Kappa scores in the 90% were obtained when comparing ratings entered by multiple collectors on given patient scenarios. Over 100 validation checks are programmed in the database, and the data set has to pass each one every quarter. The completeness of the data set is estimated to be close to 100%. All indications suggest that the triad of practices established have substantially improved the quality of the data set.

CONCLUSION

Healthcare research data is often extracted from secondary sources such as patient record systems and patient benefits and other non-research data sources. The quality of such data can be problematic as multitude of threats exist that can hamper data quality. In this chapter, practices to establish data quality suitable to support research studies were illustrated. Good data is important to facilitate a good research study and resulting clinical decisions. Good quality data, which is timely and accurate and can be easily represented and understood, can significantly improve healthcare research projects and patient outcomes. A case study was also illustrated that uses these techniques to establish data quality for data obtained from secondary data sources, such as patient records and benefits databases for use in a healthcare research project. This chapter applied a data product lifecycle approach towards improving data quality. This approach views data as a product, and uses a value stream for the product similar to manufacturing processes. Data quality is an overarching concept that must be addressed in the entire process starting from data collection to data storage to the end production of the data product and it usage. A multifaceted approach involving managerial practices, organizational practices and technological practices were implemented to counter threats to data quality. These practices are fairly generic and allow for use in many different data projects. However, these practices require a strong commitment of resources – labor, capital and equipment. The application of such magnitude of resources should be commensurate upon the needs for data quality and a cost benefit analysis should be done. A future research may address these issues of cost benefit tradeoffs and quantify the measures of data quality and the relationships between these interventions and what threats/dimensions of data quality they address.

Chapter 7.10

Space–Time Cluster Analysis:

Application of Healthcare Service Data in Epidemiological Studies

Joseph M. Woodside

ABSTRACT

Spatial epidemiological approach to healthcare studies provides significant insight in evaluating health intervention and decision making. This article illustrates a space-time cluster analysis using Kulldorff's Scan Statistics (1999), local indicators of spatial autocorrelation, and local G-statistics involving routine clinical service data as part of a limited data set collected by a Northeast Ohio healthcare organization (Kaiser Foundation Health Plan of Ohio) over a period 1994—2006. The objective is to find excess space and space - time variations of lung cancer and to identify potential monitoring and healthcare management capabilities. The results were compared with earlier research (Tyczynski, & Berkel, 2005); similarities were noted in patient demographics for the targeted study area. The findings also provide evidence that diagnosis data collected as a result of rendered health services can be used in detecting potential disease patterns and/

or utilization patterns, with the overall objective of improving health outcomes.

INTRODUCTION

The increasing demand for health data analysis in spatial and temporal scale has made emerging technologies such as Geographic Information Systems (GIS) an essential tool for healthcare information systems. In healthcare settings application of such new technology are proving useful in the analysis of health data and planning of healthcare services (Pfeiffer, Robinson, Stevenson, Stevens, Rogers, & Clements, 2008). The ability of GIS to manage and retrieve georeference data has demonstrated its value in the integration of complex epidemiological models through visualization of spatial and temporal relationships. This has been recognized by the World Health Organization (WHO):

Geographical information systems (GIS) provide ideal platforms for the convergence of disease-specific information and their analyses in relation to population settlements, surrounding social and health services and the natural environment. They are highly suitable for analyzing epidemiological data, revealing trends and interrelationships that would be difficult to discover in tabular format. Moreover GIS allows policy makers to easily visualize problems in relation to existing health and social services and the natural environment and so more effectively target resources. (World Health Organization, 2008)

Geographical analysis is not only important for the identification of patterns of healthcare outcomes it also offers insight into understanding the association or linkage to political processes and policy makers (Cromley, 2002; Gatrell, 2002). Health data from managed health care organizations offers the opportunity to analyze unusual geographical patterns of disease. Routine, aggregated healthcare data stored in health systems can be utilized to identify disease clusters or utilization patterns. Recently methods have been sought to further improve identification within case and disease management programs.
