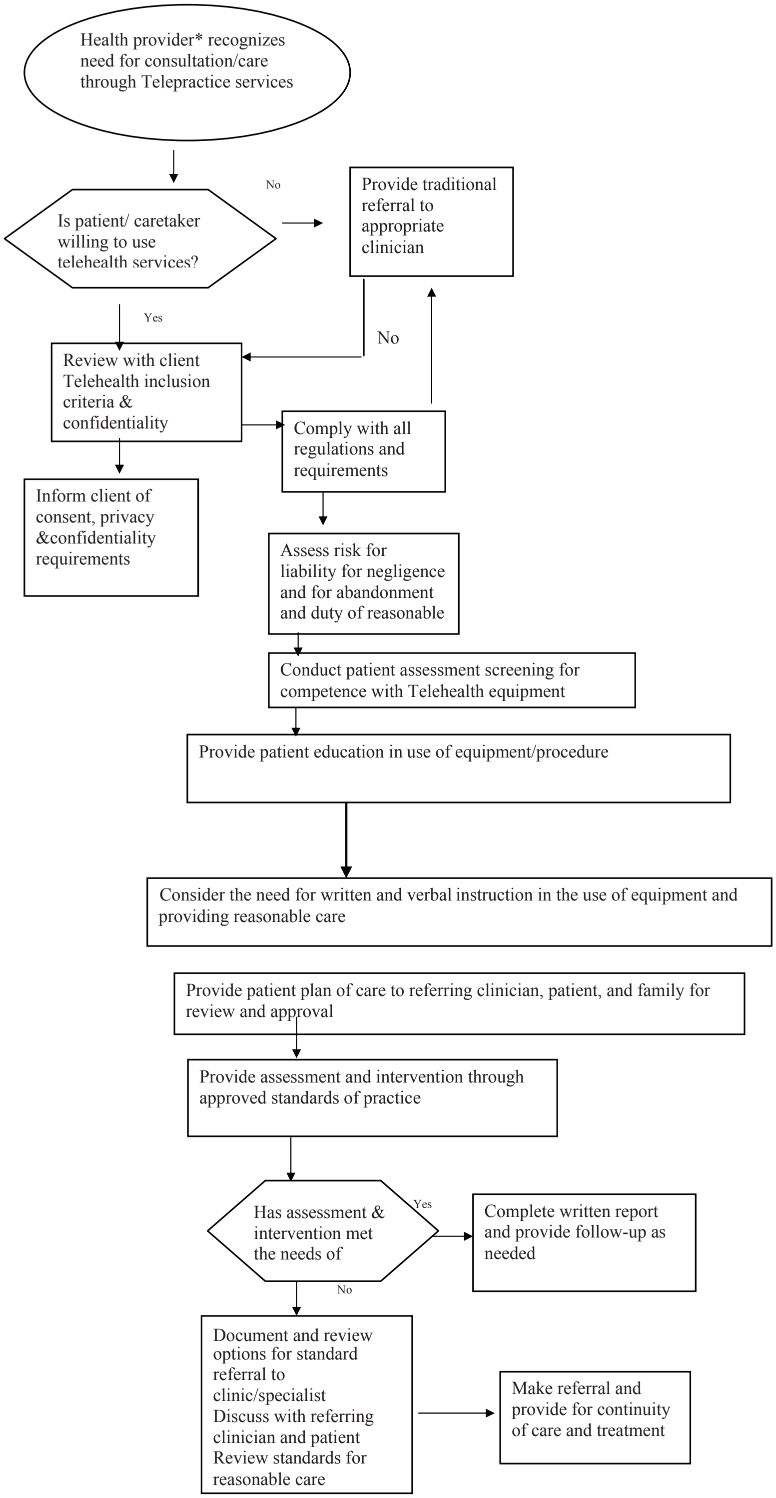
In an electronically mediated society, concerns regarding security, privacy and confidentiality may take on new meaning with telepracticeOne of the most serious compromises to security and to one's privacy is the unauthorized access to confidential patient health and educational information. Fortunately, these risks may be reduced by utilizing secure or closed networks, encryption programs, and by adhering to the standards set forth in the Health Insurance Portability and Accountability Act (HIPAA) which provides national

Figure 2. Model alogorithm for telepractice consultation & healthcare



standards to reduce health care inefficiencies by encouraging the use of information technology to better secure and protect patient information. In addition, one must consider technological risks that originate from software or computer systems. For example, computer viruses may be designed to destroy data or disrupt computer systems. To avoid these dangers, system managers must continually update virus scan programs, be alert for system glitches, and work to ensure compatibility of all system components (Stamm, 1999; Striefel, 2000).

Transmission Quality

Along with variations in the technical infrastructure and expenses required for various telehealth applications, the quality of data transmission also varies accordingly. When considering options for videoconferencing, providers must take into account both the clinical demands on the system as well as the type of transmission infrastructure required to reliably support a particular application. Videoconferencing systems vary in the type of transmission channel required and thus may operate at different bandwidths. As a measure of a communication channel's ability to carry information, bandwidth directly influences the quality of video transmission. In other words, if detecting fine motor movements is critical, a system with higher bandwidth would be most suitable. On the other hand, lower bandwidths might be more appropriate when movement is not an important factor or when the cost of the infrastructure needed to support higher bandwidth is prohibitive. Among U.S. telehealth programs, the most common transmission rate is currently 384-786 Kbps (Mahue, Whitten, & Allen, 2001).

Level of Use Satisfaction

Regardless of the specific type of technology implemented, the success of a telecommunications system often hinges on its acceptance among participants. As noted by Young and Irenson (2003), once providers and clients become familiar with telehealth technology, there seems to be an acceptable level of satisfaction with the use of this equipment. Adequate and appropriate training based on the intent of the users of such equipment is essential. Beyond training, it is important to normalize the equipment as part of the environment to desensitize those unfamiliar to telepractice practices and technology.

Scope of Practice

The legal and ethical issue of licensure and scope of practice in the use of telepractice may well extend beyond state boundaries or jurisdictions. Licensure requirements, as a limitation to interstate practice, are often cited as a major barrier to the development of services. As with most health care professionals, licensure is on a state-by-state basis, which requires that a practitioner hold a full, unrestricted license in all states him or her practices. For many professionals, acquiring and maintaining multiple licenses is a significant professional and financial burden, which falls particularly hard on rural health care providers who often experience significant travel, lost work time, and other costs in complying with multiple state regulations.

Technology Costs

The cost of acquiring and maintaining the necessary technology including maintenance and update expenses) should be considered. Fortunately numerous options, which vary in price point, exist for creating virtual connections. With availability of the Internet, e-mail, listservs, and chat rooms may serve as a cost effective, accessible medium of communication. Equipment needs are minimal; requiring only a computer and Internet access at each location.

Where practitioners at healthcare delivery sites interested in incorporating technology-mediated face-to-face contact, several types of videoconferencing applications exist. When considering these options, providers must take into account both the clinical demands on the system as well as the type of transmission infrastructure required to reliably support a particular application. Options for videoconferencing applications include, but are not limited to, videophones, PC-based desktop systems, and/or high-quality integrated videoconference units. Given the rapid pace of advances in technology, prices for the above equipment vary from a few hundred to several thousand dollars. Ironically, the cost of developing and maintaining telehealth systems tends to be the highest in the regions where telehealth would be most beneficial (e.g., rural areas) (Nickelson, 1998). Fortunately, federal programs such as the Universal Service Program for Rural Health Providers may help to defray the operating costs of such systems (Stamm, 1999).

In anticipation of legislative changes with respect to the use of telecommunication technology, there have been efforts on the part of the medical and nursing professionals to develop alternative licensure models for their professions. For instance, Texas offers a "special purpose license" for out-of-state physicians who provide telepractice services to Texas residents. Similarly, the Joint Commission on the Accreditation of Healthcare Organizations recently revised its Hospital Medical Staff Standards which now state that practitioners who treat patients via telemedicine are subject to the credentialing processes of the organization that receives the telemedicine service (Joint Commission on the Accreditation of Healthcare Organizations, 2003). Utilizing a different approach, the National Council of State Boards of Nursing has developed a mutual license recognition program which allows nurses who hold a valid license in one state to enjoy a "multi-state licensure privilege" to practice in states that are members of the licensure compact (DeLeon, 2003). Legally and ethically the direct and immediate delivery of patient care is always the responsibility of the on-site licensed professional.

Applications for Telehealth in Rural Educational Settings

Numerous applications hold significant potential for educational settings seeking to meet the health related needs of students through telehealth. These include:

1. Clinical interview and/or evaluation by a clinician specialist; consultations for crisis stabilization in the school setting;
2. Brief screening and assessment prior to comprehensive evaluations for various diagnostic entities;
3. Team assessment and treatment planning may include multiple links with physicians, child psychiatrists, school psychologists, occupational therapists, physical therapists, speech-language pathologists, counselors, nurses, teachers, social workers, and others;
4. Diagnostic testing with the assistance of a technician at the site;
5. Short-term health education and counseling interventions;
6. Vocational assessment, placement and counseling services;
7. Evaluations and diagnostics related to second opinions;
8. Short-term case management for children with special needs;
9. Consultation-liaison services for parents and children;
10. Consultation with primary care physicians and/or specialists, clinicians and educators regarding children with special needs;
11. Continuing medical and health education for administrators, faculty, students, parents and others.

CONCLUDING COMMENTS AND LESSONS LEARNED

Twenty-first century use of electronic based technology for the provision of healthcare services internationally and its interface with various critical components of society needs to examine the potential benefits over risks in providing healthcare consultations and services through the educational settings available. Health care provision through rural school systems utilizing telepractice technology must be vigilant to the challenges and cognizant of the added value when realizing that this technology will reach populations who have been traditionally underserved because of their remote location to needed services.

Examined herein has been a model, which demonstrates the capability of reducing time and distance barriers in the provision of health care and education through telepractice technology. Best practice guidelines have emerged and provide both ethical and legal parameters for practitioners (Miller & Wader, 2002). Vignettes highlighting the usage of this technology through educational settings have been address as has the advantages and potential disadvantages of its use. Several suggested applications have been noted, as have the changing paradigms in delivery of healthcare through community-based services. When consultation with a needed health care professional is not readily available, the use of video teleconferencing technology by healthcare clinicians and providers in rural settings is a viable medium for providing needed diagnostic and clinical consultation for underserved and rural populations globally.

ACKNOWLEDGMENT

The authors wish to acknowledge the support and assistance of Rob Sprang Director of University of Kentucky Telecare, Deborah Burton Ph.D., Charles Lowe Ph.D. Chair Department of Psychology, University of Connecticut and Jeffrey Fisher Ph.D. Director Center for health intervention and Prevention. In addition appreciation is extended to Lon Hays, M.D., Patricia Beckenhaupt RN, MS, MPH, Catherine Russell, Jill Livingston MLS, Lane J. Veltkamp MSW, and Brenda Frommer in the preparation of this manuscript. This article is based on initial research presented in the "Handbook of Research on Information Technology Management and Clinical Data Administration in Healthcare."

Chapter 2.10
Integrated Digital Health Systems Design:
A Service-Oriented Soft Systems Methodology

Wullianallur Raghupathi
Fordham University, USA

Amjad Umar
Fordham University, USA

ABSTRACT

The application of information technology in healthcare has focused primarily on the implementation of specific systems such as electronic health records (EHRs) and clinical decision support systems (CDSSs), mainly for intra-enterprise use. However, for the integrated health system (IHS) to function effectively in a complex inter-enterprise healthcare delivery environment, designers must focus on approaches such as soft systems methodology (SSM) to enable the design of robust integrated digital health systems (IDHSs). A service-oriented architecture (SOA) offers a flexible framework for IDHSs to become de-centralized, fully functional and modular systems with interoperability. This article identifies the design issues in IDHS and explores the potential of an SSM methodology-based SOA for the development of interoperable IDHSs. In the process we compare and contrast the functionalist socio-technical approach to the interpretive SSM. We also describe a prototype SOA application for an IDHS setting and discuss challenges in the application of SOA to healthcare.

INTRODUCTION

The delivery of healthcare services in the United States is a complex, fragmented, and disconnected process, and in 2006, cost almost $2.1 trillion, or 16% of the GDP (Melvin, 2008). Studies published by the Institute of Medicine indicate that the disconnectedness, disorganization and inaccessibility of clinical information adversely affect healthcare quality and compromise patient safety (Institute of Medicine, 2003). In addition, long-standing problems with medical errors as well as inefficiencies increase the costs of healthcare delivery.

The potential of health information technology (HIT) in public and private integrated health systems (IHS) already has been established, and yet implementation of HIT applications has been haphazard. Missing is the necessary planning and attention to the long-term viability of such applications as electronic health records (EHRs), clinical decision support systems (CDSSs), regional health information networks (RHINs), and the national health information network (NHIN). Large-scale implementations, absent consideration of significant design issues such as interoperability and compliance with standards (Chaudhry et al., 2006; Himmelstein and Woolhandler, 2005), can result in the failure of the applications. Note, for example, reports that the U.K. National Health Services program to create a nationwide e-health records system is in trouble, the cost having escalated from 2.6B pounds to at least 13B pounds today (Charette, 2006). So while the call for information technology in healthcare is a positive trend, the need has led to the ad hoc creation of stopgap applications that never will be able to "speak" with other systems that come along.

Newer approaches to design are needed to produce viable IDHSs. A soft system methodology, for example, combined with a decentralized and distributed architecture such as a service-oriented architecture (SOA) offers viability. In this exploratory research, we discuss the application of soft systems methodology (SSM) to the design of IDHSs to support RHINS and the NHIN. The SSM methodology is mapped to the SOA approach (Nadkarni and Miller, 2007) to developing distributed, loosely coupled, interoperable IDHSs. The rest of the article is organized as follows: First, we identify design issues in IDHSs, focusing primarily on interoperability. Then, we discuss the potential of the SOA for IDHS design. Third, we compare and contrast the socio-technical approach to SSM in the context of IDHS-SOA design. Fourth, we apply the SSM to the design process, map the outcomes of the SSM to an SOA framework, and illustrate each stage of the SSM with examples. We also describe a prototype application for an IDHS setting. Fifth, we discuss the challenges in implementing SOA-based IDHSs. And finally, we offer our conclusions and future directions for research.

DESIGN ISSUES IN IDHS

Typically, IDHSs support large integrated health systems that feed into RHINs. For example, the Partners Healthcare Systems—a federation of hospitals in the Boston metropolitan area made up of several hospitals, clinics and laboratories —is a large integrated delivery network. The network uses a combination of centrally or locally managed information system resources. In Indiana, the Regenstrief Institute created the Indianapolis Network for Patient Care (INPC) in 1995 with the goal of improving the medical care of patients. The network is an operational community-wide electronic medical record system that includes an active surveillance component built around real-time electronic laboratory reporting. The Santa Barbara County Care Data Exchange is another pilot example of the trend towards operational health information networks (Overhage et al., 2005). Other examples of integrated health systems include the Taconic IPA (independent practice association) in New York, which uses its physician base as a core for a comprehensive, practice-oriented health information infrastructure that includes clinical information systems and secure networks (Frisse, 2005). Hospitals, clinical laboratories, health plans, and pharmacies subscribe to its network to communicate more effectively with practitioners. IPAs in Colorado, Oregon, and other states are adopting similar models (Frisse, 2005). The Mid-South eHealth Alliance is one more example of a regional comprehensive health information initiative for three counties in Southwest Tennessee.

At the national level, the Department of Health and Human Services released a Strategic

Framework report in July 2004 entitled "The Decade of Health Information Technology: Delivering Consumer-centric and Information-Rich Health Care." The report calls for the creation of a "national health information network" to enable nationwide interoperability as well as regional health information networks (RHINs), which would provide local leadership, oversight, fiduciary responsibility, and governance for the development, implementation, and application of secure health information exchange across care settings (HHS, 2004; Overhage et al, 2005). And yet, prior attempts to build community health information networks (CHINs) in the 1990s have failed. Explanations include inadequate buy in and conflicting missions, lack of trust, the need for centralized databases and desire for control, data ownership issues, lack of financing, and the high cost of network technology (Overhage et al., 2005). This unfavorable history does not augur well for the design of the current IHSs and RHINs. McDonald (1997) also points out electronic patient information—such as laboratory, pharmacy and physician dictation data—reside on many "isolated islands that have been very difficult to bridge." According to the author, each island system contains different data, different structures, and different levels of granularity, and each uses a different code system to identify similar clinical concepts. The external islands differ even more than those within an organization. They tend to use different patient, provider and location identifiers, and the number of these independent systems is legion (McDonald, 1997).

While there have been attempts to build distributed systems in specific domains (e.g. Katehakis et al., 2007; McMurry et al., 2007; Wright et al., 2007), no unified system currently exists for the exchange of comprehensive healthcare information across the wide spectrum of healthcare networks. Regional health information organizations (RHIOs) and a national health information network (NHIN) have been proposed as vital building blocks for providing such a system, but these face many challenges, including delineation and implementation of accepted standards for healthcare data, accurate patient identification and record matching, and the definition of incentives for accelerated deployment of health information technology. The formation of a healthcare data exchange depends on a common set of standards to facilitate communication (Gold and Ball, 2007; Yasnoff et al., 2004). The design and operation of these types of networks therefore, face key challenges.

The next section examines the potential of the SOA for IDHS design.

SERVICE-ORIENTED ARCHITECTURE FOR IDHS

According to Walker (2007), "an SOA is a component model that interrelates the different functional units of an application called 'services,' through well-defined interfaces and contracts between these services. The interface is defined in a neutral manner that should be independent of the hardware platform, the operating system, and the programming language in which the service is implemented."

Here we discuss the drivers for an SOA approach, adapting the discussion from Carter (2007), Raghupathi and Kesh (2007) and Walker (2007):

- **Healthcare delivery is process driven:** Healthcare delivery organizations view HIT responsiveness and flexibility as high-priority. To meet these goals, HIT has to ensure that IT is process driven and responds quickly to changing healthcare delivery conditions. For example, new healthcare (patient) requirements and treatment protocols must be added dynamically to the process models.
- **Promote healthcare delivery as a service:** The goal is to manage the common IHS as-

sets and establish a standard IHS vocabulary for health data used by the SOA framework. For example, a unified common view of patient information can be provided by a web service that makes aggregated patient data accessible; this data would originate from patients' "touch points" at several healthcare delivery participants' systems.

- **Promote reuse:** SOA enables reuse through the "build once and use many times" approach. As the inventory of healthcare delivery services increases, more functions can be created as composite health services.
- **Leverage and modernize legacy systems:** Legacy applications in the IDHS can be upgraded through the use of service encapsulation methods. Upgrading existing applications in this way instead of replacing them allows limited IT resources to be redirected. Healthcare patterns can be developed to simplify the reuse of legacy applications.
- **Incorporate third party products:** By using service interfaces and web services, the architecture accommodates the range of alternatives, including off-the-shelf, custom-built and modified products.
- **Enhance inter-enterprise transactions:** SOA-enabled interoperability with other IDHSs enable extension into regional networks.

Considering the above discussed benefits, an SOA offers a more dynamic and flexible solution to the IDHS design.

SOCIO-TECHNICAL APPROACH VERSUS SOFT SYSTEMS METHDOLOGY

While numerous researchers have proposed a socio-technical approach to health information system design (e.g. Aarts et al, 1998; Berg, 1999; Berg et al, 2003) and distributed systems and network architectures have been discussed in the literature (Blobel, 2006; Kuhn and Guise, 2001), the approach has been interpreted narrowly to imply a man-machine system. Here, building on our prior work (Raghupathi and Kesh, 2007, 2008) and that of other researchers (see Stowell (2008)), for an excellent summary and references on the application of SSM to information systems), we argue for the application of a soft systems methodology for SOA-based IDHS design. A socio-technical approach (Enery and Trist, 1960) is quite appropriate for monolithic electronic health records and clinical decision support systems, which have specific objectives with definite boundaries. However, a "social system" is more desirable in that it captures the essence of complex, distributed systems such as IDHSs and regional health information networks (Raghupathi and Kesh, 2008). We do not imply a reductionist approach, but rather advocate the use of SSM (Checkland, 1981) as a meta model to elicit the high level service requirements. Table 1 compares and contrasts the socio-technical approach (functionalist perspective) and the SSM (interpretive) approach.

At the primitive level, the system may consist of identifiable technical artifacts (Kroes et al., 2006) with the designers focusing on the user interface working within well-defined user requirements and system scope. However, at higher levels in large-scale, heterogeneous systems such as health information networks, the various stakeholders (e.g. health care delivery participants, technical architecture such as IDHS-SOA) and the overall social infrastructure (e.g. the public/citizenry) become an integral part of the overall health system. As Kroes et al (2006) ask, "how are the relations to be conceived between the various technical artifacts that are supposed to glue together these artifacts into a system, a unified whole?" Stowell (2008) also reiterates that "the importance of understanding the relationship between information

Table 1. SOA design: socio-technical approach versus soft system methodology

CONCEPT	**Socio-technical Approach**	**Soft System Methodology**
Conceptual/philosophical basis (Checkland, 1981; Burrell & Morgan;, Deetz, 1996; Jackson, 2000)	Functionalist systems thinking; Organization-as-systems approach	Interpretive systems thinking
Perspective (Adapted from Ulrich, 1980)	Simon's *The Sciences of the Artificial – The Architecture of Complexity*	Churchman's *The Philosophy of Social Systems Design – The Design of Inquiring Systems*
Design Principles		
System type	Relatively simple systems – design enforces hierarchy and order; Electronic health record, clinical database, etc.	Relatively complex systems – cannot be reduced to hierarchies; Integrated digital network, regional health information network, global health grids, etc.
Subjectivity	Designer's primary tool is objectivity: Objectivity is emphasized and systems have specific functionality; Axiomatic models	Designer's main tool is subjectivity: Subjectivism is embraced, designer considers different viewpoints and diverse knowledge; Conceptual learning models
Participant relationship	Unitary	Pluralist
Holism	Is not considered, modularity and components are emphasized; decomposition is an operational principle	Holism is critically considered, the whole is greater than the sum of the parts; difficult to reduce systems that mirror 'social systems'
Reductionism	Is an important design principle and source of design knowledge; complex systems can be described by reducing them to simple process logic	Is not critical to the design process, embracing complexity is encouraged; the uniqueness of system components is considered
Key design challenge (Adapted from Ulrich, 1980)	How to decompose complex systems into simple systems (divide)	How to describe the unique qualities of each subsystem; how to define boundary of networks; "ethics of whole systems"
Advantages & Benefits (adapted from Jackson, 2000)	Optimization of system requirements helps scope a project	Satisfying or 'good enough' solutions inevitable in situations with many stakeholders and conflicting goals
	Does consider limited technological & social aspects	Considers SOA design from a social perspective emphasizing people issues
	Organizations are considered as 'open systems' but intra-organizational	Systems are inter-organizational and boundary spanning
	Workgroups (e.g. development group) are empowered	Entire organizations collaborate in the development of integrated systems
Limitations (adapted from Jackson, 2000)	Underplays teleological or 'purposeful action'; Tendency to 'reify' the organization	Some groups may tend to dominate, for example in 'service' definition'

continued on the following page

Table 1. continued

	Cannot explain the dynamics of change and conflict	May not provide an 'operational model' that is implementable but rather an understanding of the situation
	Tends to emphasize a single point of view (managerial bias)	Diverse stakeholder groups may never agree on 'service' definitions or a acceptable SOA governance model
	Focus is more likely on survival as opposed to integrated goal(s)	Perceived lack of theoretical or conceptual underpinning
Methodology Steps (adapted from Checkland, 1981; Chern, 1976; Jackson, 2000)	*Establish* Compatibility with design objectives; *Define* minimal critical specifications, how development is to be carried out and who should carry it out; *Control* for variances from specifications (e.g. creeping user requirements); *Perform* multi-tasking, parallel development; *Identify* boundary for system development activity, location, control; *Manage* information flow, provide information to work teams; *Support* congruence, organization-system alignment; *Consider* human values and ethics in design; *Use* iterative design process	*Stage 1*: The need for integrated digital health system is recognized, explored and defined in a distributed, 'service-oriented' way. This is in the applied, real world. *Stage 2*: The system requirements under consideration are expressed in a meaningful way, typically in a graphical form. This is called a rich picture. *Stage 3*: This stage is called the 'root definition' stage in which the steps out of the "real" world and into the abstract realm of systems, and is the stage from which all further processes are identified *Stage 4*: Draw a conceptual model from the root definition using system conventions. *Stage 5*: Compare the model to the real world. Stage 6: Develop desirable and feasible system interventions. Stage 7: Identify actions to improve the situation (operationalize the model).

and associated connections within an enterprise cannot be overstressed."

A SOFT SYSTEMS METHODOLOGY FOR SOA-BASED IDHS

IDHSs that provide the underlying IT architecture for IHSs are complex systems that reflect the intricacies of the healthcare delivery process. Participants and stakeholders have varied properties (e.g. non-profit vs. for-profit entities) and diverse objectives (e.g. disease treatment vs. home care), are subject to large-scale changes (e.g. impact of drug discovery on treatment protocol), and have loosely coupled interactions with each other (e.g. health data exchange). Jackson (2003) has proposed the use of such methodologies as systems dynamics, organizational cybernetics, complexity theory and soft systems and postmodern approaches if the "systems of the problem situation tend to be complex (Jackson, 2003)." Considering the overall absence of integrated theoretical models and frameworks to guide IDHS design, there is an urgent need to adopt a systems approach to their development.

The IDHS exists in the context of a complex interconnected health system. Such interconnectedness makes the IDHS difficult to design and implement; however, the use of systems concepts such as holism, boundary management, feedback and control clearly hold promise for the design of IDHS. A modular architecture (e.g. SOA) can express dynamic services. Central to a systems approach is the understanding of the healthcare delivery system as a complex adaptive system, giving rise to dynamic services through a confluence of stakeholder actions. Each stakeholder (participant) is conceived as actor or agent, taking independent action (Warren, 2004).

Traditional approaches to design, such as a database approach, are adequate for "hard systems" such as electronic health records or clinical decision support systems with specific objectives (Raghupathi and Kesh, 2008). But "soft systems" approaches (Checkland and Holwell, 1998; Christie, 2005) are needed to model complex, dynamic systems such as IDHSs. According to Checkland, systems engineering, or the hard systems approach, is only applicable in situations in which goals or needs are precisely defined. Systems engineering looks at 'how to do it' when 'what to do' is already defined." This was found to be the failure of systems engineering, however, when it was applied to ill-defined problem situations (Checkland and Scholes, 1990; Christis, 2005). Ill-defined or messy problems such as IDHS design are characterized by the fact that both the 'what' and the 'how' of problem solving are unclear. Because healthcare delivery organizations, as social systems, have to reach many different goals and needs or have to solve many different problems simultaneously, messy problems will be the routine. In such situations, "many different but plausible definitions of system objectives (are) possible. In this situation, systems engineering methodology appears to break down" (Checkland, 1995). Additionally, "SOAs contain a substantial amount of behavioral content because those initiatives are process-driven and span organizational boundaries. The 'soft issues' of an SOA strategy must address the organizational issues and challenges that may help or inhibit SOA adoption, such as services ownership the business and IT relationship, budgeting practices, and more. Organizational, cultural and process issues thread through several facets of an SOA initiative (Marks and Bell, 2006)." Questions that need to be addressed in an environment characterized by multiple stakeholders, incompatible legacy systems and conflicting organizational goals include: What are "services" in the health care delivery environment? How should health care services be identified? How does the designer model and implement services that are "good enough" for the IHS? How does one define criteria for reuse and granularity levels? How does one rank order the identified candidate services? How should the SOA governance model be described? Who defines the controlling policies?

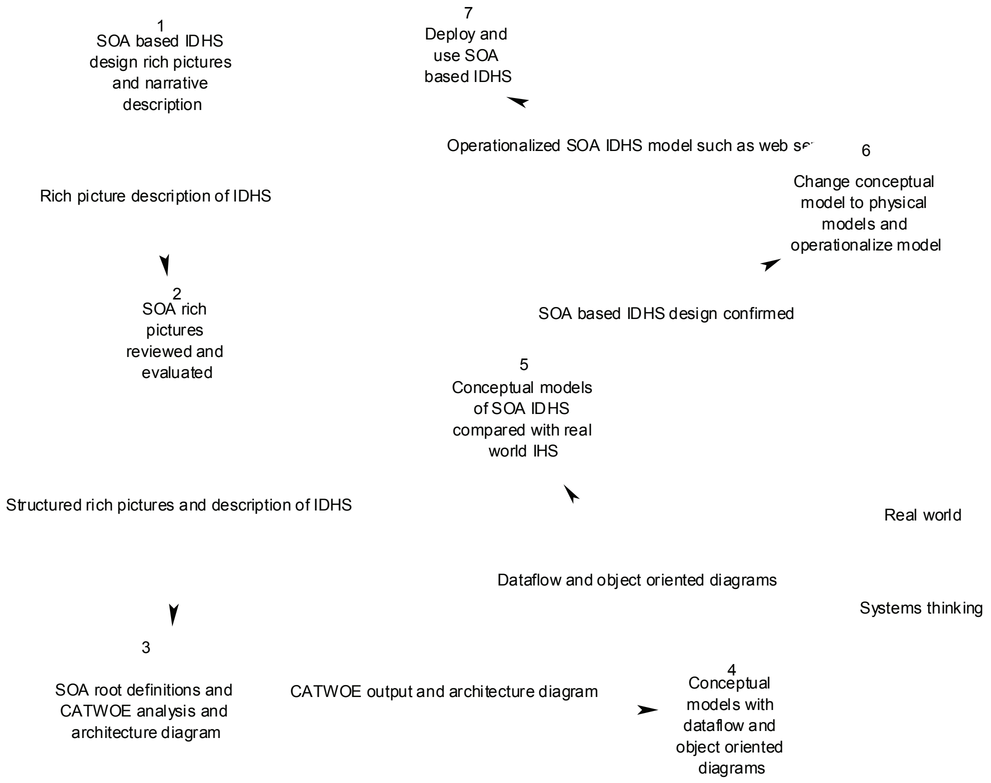
Soft systems methodology (SSM) offers a methodology for a design process in which the various stakeholders involved can evaluate different system models of a problem in a collaborative fashion. These different models are used to structure the debate about problems and solutions. If in the debate some form of accommodation between the interested partners arises, action can be taken to fix the problem (Christis, 2005). Essentially, SSM has been developed for use in ill-structured or messy problem contexts where there is no clear view of what "constitutes the problem" or what action should be taken to overcome the occurring difficulties. In fact, SSM in action should prevent decision makers from rushing into poorly planned solutions based on preconceived notions about assumed problems (Basden and Wood-Harper, 2006; Chujo and Kijima, 2006; Checkland, 1981; Flood and Jackson, 1991). Ultimately, SSM enables the consideration of the views of a diverse set of participants in the SOA development and governance process. The seven-stage SSM methodology for SOA-based IDHS design is outlined in Figure 1 (based on discussion in Brocklesby, 2007; Checkland, 1976, 1981, 1988, 2000; Checkland and Holwell, 1998; Checkland and Scholes, 1990 Jackson, 2000; Luckett and Grossenbacher, 2003; Mobach, 2007; Stowell, 2008; Whitman, 2005).

Stages 1 and 2

In Stage 1, the stakeholders begin to consider interoperability within the proposed IDHS. Rich pictures of an SOA-based framework can be developed to represent the various participants and the shared healthcare services.

Figure 2 represents an example of an overall integrated healthcare delivery framework that the SOA can support (Raghupathi and Kesh, 2007). It highlights the input-service-output components of a typical health system. To the left, the sources of input data are identified. These include in-house legacy hospital systems, databases and other newer information systems. The systems are mostly intra-enterprise and the bulk of the health data is stored in these systems. In the middle, components of the various services are shown. These include governance, patient record management, healthcare delivery and clinical DSS (decision support systems). Governance-related services may include provision of security as well as privacy and compliance procedures for HIPAA. The Patient Record Management services may include patient registration and visit management. Regarding health care delivery, services included are admission, diagnosis, treatment, and those relate to discharge and insurance. The clinical

Figure 1. SSM stages for SOA-based IDHS design



DSSs include a range of physician-related services such as evidence-based services. For example, a physician might prescribe medications upon an evaluation of a patient's symptoms. The services' component of clinical DSSs would include Web Services, which deliver the services via web interfaces. A physician could check laboratory reports for a patient under clinical DSS via a web page, for instance. Gateways to access external health information residing in other systems are enabled by standardized data exchanges.

Lastly, on the right side of Figure 2, the output applications are identified. As a result of service processing of various health data, outputs may include query-response (which patients made visits today?), generation of reports (daily visit summary report) and online analytical processing (drugs prescribed vis-à-vis allergic reactions analysis). These outputs aid providers in making timely health-related decisions. The SOA architecture becomes less challenging to develop once the various components are identified (Raghupathi and Kesh, 2007).

Figure 3 is a graphical framework of the overall SOA framework for the health clinic setting (Raghupathi and Kesh, 2007).

Different services can be configured and offered by service providers who process the service implementations, provide their service descriptions to the registry and provide support. Since services may be offered by different participants—such as hospitals, labs, payers, pharmacies and providers—and communicated via the Web, they provide a distributed computing infrastructure for both intra- and inter-enterprise application integration and collaboration. The virtual connection line can be termed a service bus.

In Stage 2, the different relevant 'services' are confirmed.

Stage 3

In Stage 3 we start to articulate the services in a more operational way, leading to the conceptual models in Stage 4. An overall architecture, derived from the SOA framework-rich pictures painted in

Figure 2. An SOA-based integrated digital health system framework (source: Raghupathi and Kesh, 2007) – Stages 1 & 2

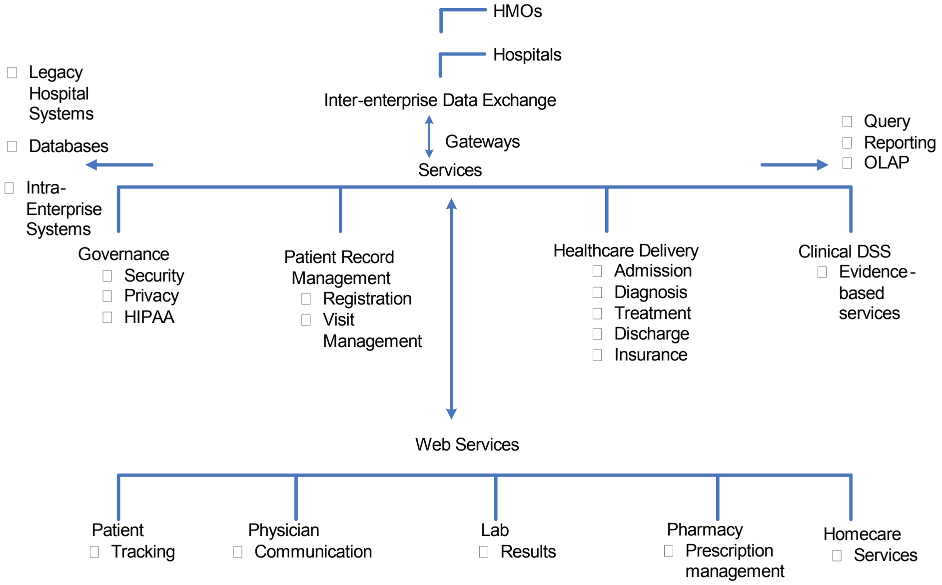


Figure 3. Examples of "services" in the SOA-based IDHS – Stages 1 & 2 (source: Raghupathi and Kesh, 2007)

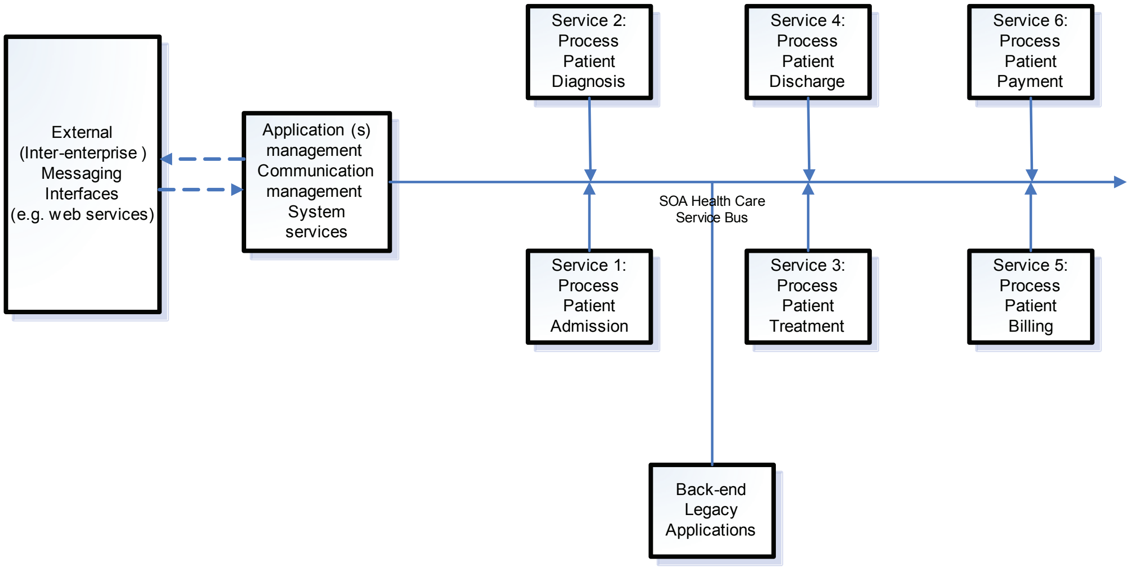
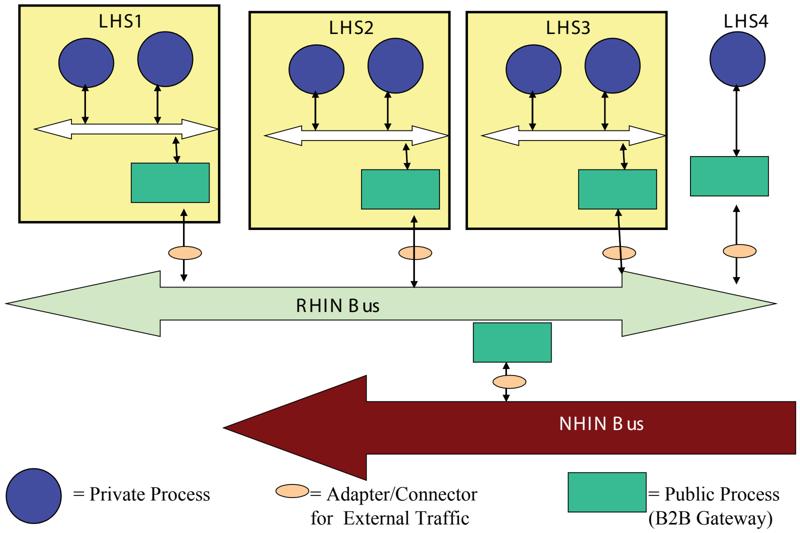


Stages 1 and 2, is evolved. This diagram shows the various components in a more specific way. Figure 4 shows an overall SOA-based view of how local, regional, national and global healthcare systems could interoperate with to form a large scale IDHS. This architecture would provide a loosely coupled, digital, service-oriented healthcare system where local healthcare systems interact with regional health information networks (RHINs), a national health information network (NHIN), and even a global health information network (GHIN). Basically, an SOA-based service bus exists at local, regional, national and global levels. For example, LHS1 represents a local small physician's office that connects to a hospital, lab, pharmacy, etc through a local service bus. Many of these (e.g. LHS1, LHS2, LHS3, etc) together form an integrated health system such as those of Geisinger, Kaiser Permanente or United Health. These in turn connect into a RHIN, a state-wide or multi-state system, through an RHIN bus. The RHINs could similarly connect into an interoperable NHIN through an NHIN bus. National surveillance systems are examples of how this model can be used. Over the long term, NHINS potentially could link into GHINs, for example, for pandemic monitoring and tracking as well for enabling portability of health data. In addition to flexibility and interoperability, this architecture provides needed privacy and security services through public and private processes and at different levels. Basically, private processes in LHS1 only communicate with other private processes in LHS1, through the service bus. A public process based on the B2B gateway pattern, deals with all external interactions and thus shields the private processes from external processes. The B2B gateways also translate the data between external and internal processes by using adapters and converters. Depending on the application, different types of adapters can be used. For example, if a doctor in LHS1 (Lansing, Michigan) needs to exchange information with a laboratory in LHS2 (Ann Arbor, Michigan), the B2B gateways at the Lansing and Ann Arbor sites will provide the security and privacy checking, and the adapters will provide data translation between the two sites. These adapters also can

Figure 4. Overall SOA-based IDHS SOA architecture – Stage 3



be used to connect legacy applications into the IDHS using screen scrapers.

The root definitions of each relevant service (service descriptions) can also be developed. Typically, within a healthcare delivery environment, a service can be a simple healthcare process capability (such as GET MEDICAL HISTORY DATA or VALIDATE INSURANCE), a more complex transaction (PROCESS INSURANCE POLICY DATA or PRODUCE BILL) or a routine system service (VERIFY PATIENT KEY DATA or VERIFY PRESCRIPTION KEY DATA). Services may be low-level or complex high-level (fine-grained or course-grained) functions, and there are very real tradeoffs in performance, flexibility, maintainability and reuse, based on these definitions. The level of granularity is a statement of a service's functional richness. For example, the more course grained a service is, the richer the function offered by the service. Services are typically course-grained healthcare functions such as EDIT EXISTING PATIENT DATA because this operation may result in the execution of multiple, finer-grained operations, such as REQUEST SERVICE, VERIFY PATIENT KEY DATA, and so on (Raghupathi and Kesh, 2007).

Each root definition may be verified using the techniques outlined by Checkland (1981, 1995) and characterized by the acronym CATWOE (Customers, Actors, Transformation process, Worldview, Owners and Environmental constraints).

- **Customers:** Patients are the beneficiaries of the IDHS activities (services); stakeholders, such as clinics, hospitals, and insurance companies, are also beneficiaries in the sense they achieve interoperability with the SOA.
- **Actors:** Healthcare providers/participants are the agents who execute the various services in the IDHS and thereby carry out the transformation of patient care.
- **Transformation process:** The patient is transformed from a "sick" person to a "well" person. The services contribute to this transformation.
- **Weltanschauung/Worldview:** The overall goal is to deliver quality health service at reduced costs whereby the patient is treated effectively and the health service is delivered in an integrated manner.

- **Ownership of the system:** This is difficult to identify in an SOA-based IDHS. For example, who owns or governs a particular service? It is conceivable that the stakeholder who initiates the service (e.g. a hospital admission clerk) may be the "owner." Or, it could be the insurance claim processor in a health maintenance organization. However, in the IDHS collective ownership and accountability can be envisioned.
- **Environmental constraints:** The designer must consider regulatory issues (e.g. HIPAA) as well as privacy and security issues. A constant survey of the healthcare delivery environment is critical.

The application of CATWOE is iterative and continual. As participants enter and leave the SOA bus and services are added and deleted, ongoing evaluation is necessary for feedback and modifications.

Stage 4

In Stage 4 the designer takes the root definitions (e.g. of the overall architecture, components and services) and translates these into conceptual models using a variety of diagramming and modeling tools. For example, a context diagram using structured systems analysis can highlight the inputs to and outputs from the IDHS. Additionally, a high level dataflow diagram can indicate the "services (processes)," "dataflows" and "data stores (files)." A series of dataflow diagrams represents the various levels in the SOA. These diagrams can be augmented with diagrams in the Unified Modeling Language (UML). Use case and class diagrams can be developed to represent particular services (methods) as well as the data (attributes) of the entire IDHS. These can form the basis of the physical model for implementation. Code can be generated for the methods.

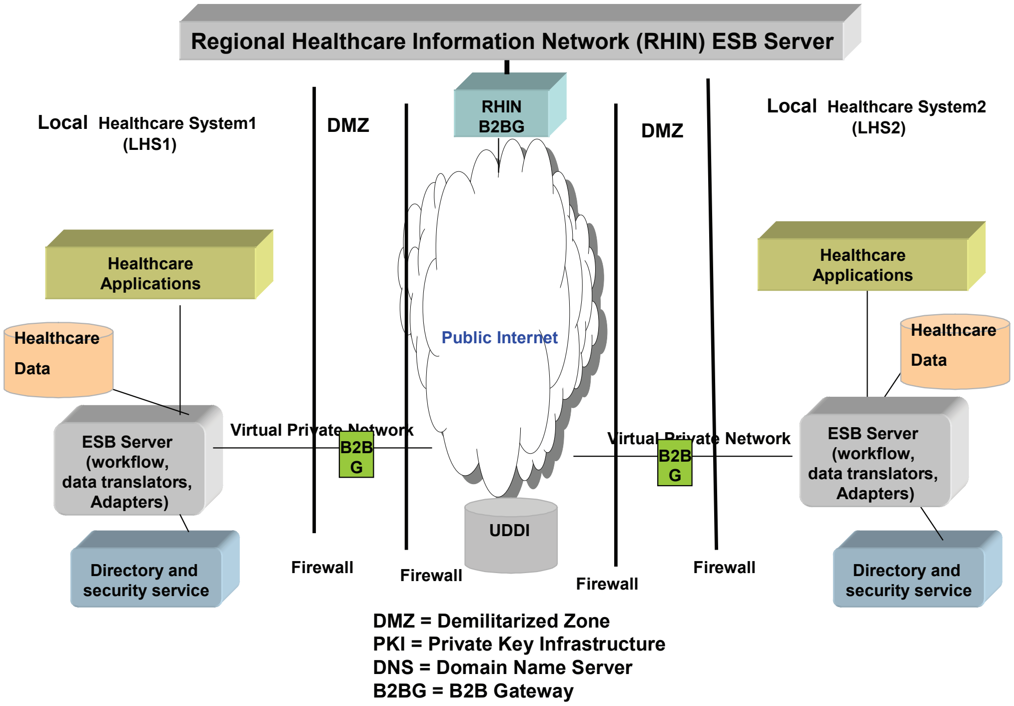
Stage 5

Whether or not a transformation to a service-oriented paradigm takes place, the conceptual models developed in Stage 4 are compared with the rich pictures from Steps 1 and 2. We cross back from the "systems thinking" world to the "real world." The various participants and stakeholders in the IHS may identify differences (e.g. the definition of a service) within the actual healthcare delivery processes.

Stage 6

The various models are vetted in Stage 6 by the stakeholders. Accommodations are sought through a negotiation process so that all stakeholders in the IHS agree on the governance and use of the IDHS. This is done in the context of the prevailing organizational culture, politics, technology acceptance environment and history. The conceptual models are operationalized into more tangible physical models for the purpose of implementation. Figure 5 translates the logical SOA-based architecture into a physical SOA-based architecture that shows how two LHSs actually communicate with each other. At each LHS, an ESB server, such as IBM WebSphere or Microsoft Biztalk Server 2006, is installed. These servers provide workflow, data translation and adapter capabilities. The B2B gateways manage the communications between different systems over the Internet by using the virtual private network capabilities. The B2B gateways themselves are placed in so-called demilitarized zones that are protected through multiple firewalls. In addition, directory and security services are provided for secure communications between the healthcare applications (private processes) at each LHS. An RHIN connects to this network through an RHIN B2B gateway as shown in Figure 5.

Figure 5. SOA architecture – a physical view – stage 6



Stage 7

This stage involves taking "action" based on the outcome of Stage 6. The physical architecture can be implemented as a series of web services. Web services (WS) technologies play an important role in this model. The public applications, supported by the B2B gateways, have WSDLs that are stored in a B2B UDDI directory shown in Figure 6. The B2B traffic between the RHIN and the LHSs operates at the B2B gateway level by using the B2B UDDI directory as a basis for discovery and connections. As more LHSs are added, more B2B gateways are added to this network and more entries are added to the B2B UDDI directory for discovery by the participants when they search the directory. Thus, new LHSs can be easily added to an RHIN.

Of course, there are several issues with implementation. The following discussion illustrates how a patient service, provided by a hospital (hospital1.com), can be defined, discovered, and invoked by using the following implementation steps:

Step 1. Define a patient service (in WSDL) that supports an operation (QueryPatient). It receives a query and processes it. Other operations, such as REGISTER PATIENT and DISCHARGE PATIENT, can be defined. The listing in Figure 6 simplifies WSDL for the patient service with an operation QueryPatient. A WSDL service definition consists of the following elements (all represented in XML):

- **Port:** Defines the service (PatientService) and the operation (QueryPatient) which uses the message types for input/output. The port associates the binding with the URI http://hospital1.com/QueryPatient where the running service can be accessed.
- **Message:** Defines input and output messages for the question that is sent to the directory

Figure 6. WSDL definition for a patient service

```
WSDL Definition for a Patient Service

<definitions name=”PatientService“
        …  initialization instructions ..

<portType name=”QueryPatient”>
    <operation name=”QueryPatient”>
      <input message=”Patient-Name”/>
      <output message=”Answer”/>
    </operation>
 </portType>

 <binding name=”Query_Patient” type=”tns:Purchase”>
    <soap:binding style=”rpc”
      transport=”http://schemas.xmlsoap.org/soap/http”/>
    <operation name=”QueryPatient”>
      <soap:operation soapAction=””/>
      <input>
        <soap:body
          encodingStyle=”http://schemas.xmlsoap.org/soap/encoding/”
          namespace=”urn:examples:healthcareservice”
          use=”encoded”/>
      </input>
      <output>
        <soap:body
          encodingStyle=”http://schemas.xmlsoap.org/soap/encoding/”
          namespace=”urn:examples:purchaseservice”
          use=”encoded”/>
      </output>
    </operation>
 </binding>

</definitions>
```

(by a person) and the information returned (a phone number).

- **Binding:** Tells that the communication is through SOAP (RPC). It also shows some technical details such as the type of encoding used, and so on.
- **Definitions and Types:** (not shown). Deals with data types that are defined using XML

Schema and some simple message types that are defined from the data types.

Step 2. Publish this service and the hospital (hospital1.com) that provides this service in UDDI. In many cases, a WSDL can be read directly and a SOAP message then issued to the service provider. In real life, this situation is comparable to being a recognized customer at the market you frequent. But, if you are looking for bargains, then you may have to "discover" different suppliers. In these situations, the real power of Web Services is displayed. That is, services are defined in UDDI and then discovered by the clients. UDDI provides a directory for all services and defines the following data types (although not all are required):

businessEntity: Business Details (name, contacts, etc.)
businessService: Web services provided by business (online-ordering, etc.)
bindingTemplate: Technical details to invoke Web services
tModel: Technical fingerprints used to access service specifications
publisherAssertion: Show relationship between business Entities

The UDDI statements in Figure 7 define the hospital1.com and the service (HealthService). The service provider can add extra information in the service such as service guarantees, cost, etc.

Step 3. Find (discover) the hospital and the service from the UDDI directory. The UDDI services can be discovered by SOAP messages. These messages use APIs for discovery. To search for a company, "Hospital1.com" defined in the above UDDI, we would create the following query within a SOAP envelope:

```
<find_business generic=”1.0“
    xmlns=”urn:uddi-org:api”>
        <name>Hospital1.com</name>
</find_business>
```

To search for a service, "PatientService" defined in the above UDDI, we would create the following query within a SOAP envelope:

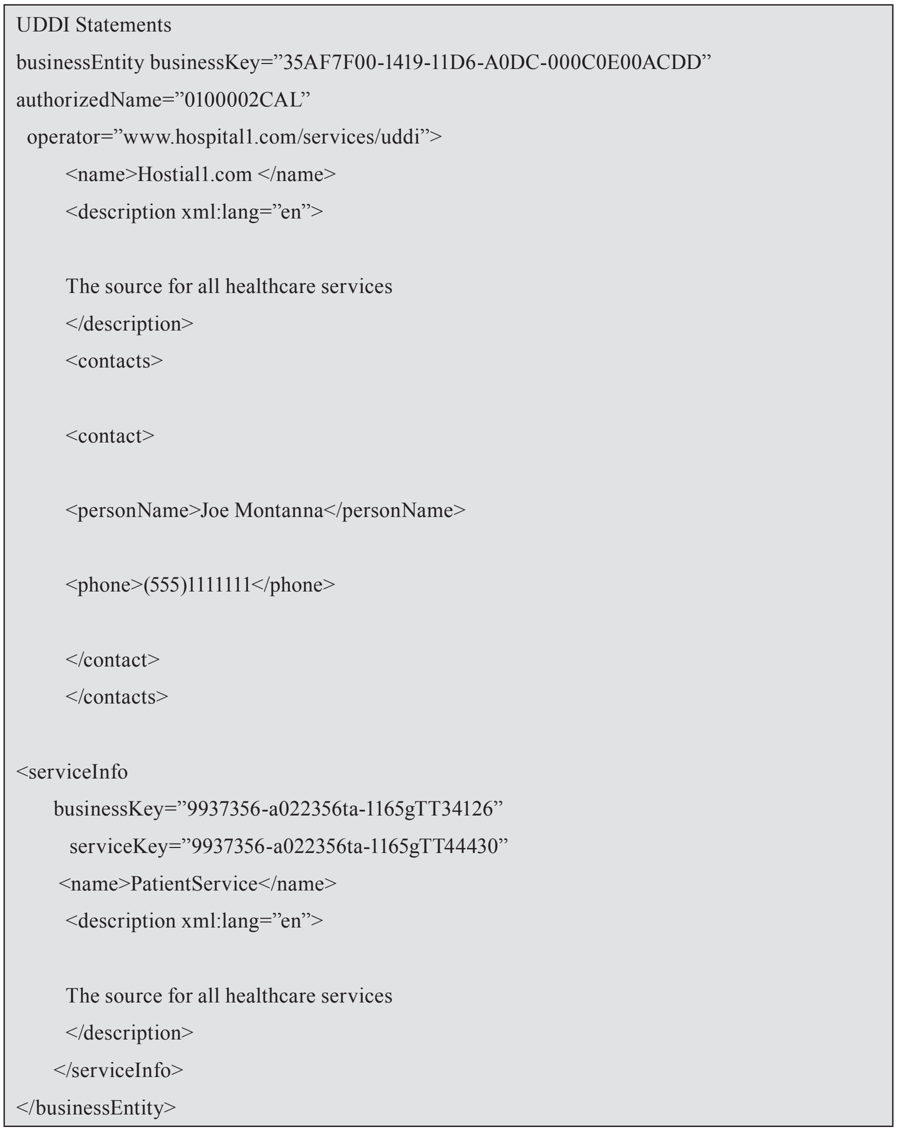
```
<find_service generic=”1.0“
    xmlns=”urn:uddi-org:api”>
        <name> PatientServcie </name>
</find_service>
```

Step 4. Invoke this service by sending and receiving SOAP messages. The SOAP messages can be used to invoke the WSDL service defined above. The SOAP message in Figure 8 activates the patient service and issues a query for a patient "Sam Nun." Figure 9 shows the SOAP message with the response that the patient (Sam Nun) is in the emergency room.

The overall SSM approach can be evaluated in terms of efficacy, efficiency, effectiveness, ethics, and elegance, which, like the components CATWOE, have special meanings (Checkland, 1995):

- **E1 – *Efficacy***. Does the system work? Is the transformation achieved? Are patients treated and records digitized?
- **E2 – *Efficiency***. Will the system work with minimum resources? Is the system worthwhile? To answer this, a comparison of the value (not necessarily monetary) of the system's output and the resources needed to achieve that output is necessary. How many patient records are processed per day? How much money is saved compared to manual processing? How does the IDHS compare to the manual IHS?
- **E3 – *Effectiveness***. Does the system contribute to the enterprise? Does the system achieve its long term goals? Is there a reduction in medical errors? Is there an increase in delivery quality?
- ***E4 – Ethics.*** Is it sound morally? Are privacy and security issues considered in design?
- **E5 – *Elegance***. Is the IDHS aesthetically designed? Is the system functionally robust?

Figure 7. UDDI statements



```

This discussion is based on work reported in Raghupathi and Kesh (2008).

CHALLENGES IN SOA-BASED IDHS DESIGN

Several challenges need to be addressed in SOA-based design. Against the backdrop of a lack of uniform standards (although there are efforts in development), defining a service is very difficult considering the semantic issues. Additionally, moving to a service-based approach would entail major redesign of organizational processes. The issue of SOA governance is a still a work in progress. The SOA development process requires the application of multiple techniques such as business process modeling, conceptual modeling with methods, such as object-oriented methods. In addition, the evaluation and measurement of

SOA functionality is fairly complex and models and methods are not yet available. On the systems side, Checkland (1981) as well as Checkland and Scholes (1990) suggest that SSM may be supplemented by "other systems thinking." For example, strategic assumption surfacing and testing (SAST) (Mason and Mitroff, 1981) might be used to expand the inclusion of the range of alternatives while critical systems thinking (CST) (Jackson, 1991) might be brought in to help handle conflict. In practice, a hybrid approach that combines the SSM for high level meta analysis and modeling with specific socio-technical approaches to operationalize the model.

CONCLUSION

We have discussed the potential of the SOA in the design of interoperable IDHSs, and we have described a soft systems methodology for development of the SOA architecture, illustrated with a prototype implementation. Future research can focus on the operational and validation issues in the implementation of SOA in healthcare as well as on developing solutions to meet the SOA challenges discussed. Additional systems approaches need to be compared and evaluated for future design of RHINS and the NHIN to be efficacious. In the long-term, the challenge will be to design a global health information network (e.g. pandemic surveillance). And as ever, cost-benefit issues will have to be addressed.

Chapter 2.11

Evaluation Methods to Monitor Success and Failure Factors in Health Information System's Development

Jytte Brender
University of Aalborg and Virtual Center for Health Informatics, Denmark

ABSTRACT

This chapter discusses the extent to which factors known to influence the success and failure of health information systems may be evaluated. More specifically, this is concerned with evaluation of such factors—for screening, diagnostic or preventive purposes—by means of existing evaluation methods designed for users. The author identifies that it is feasible to identify evaluation methods for most success factors and failure criteria. However, there is a need for situational methods engineering as the methods are not dedicated to answering the precise information needs of the project management. Therefore, demands are being placed on the evaluators' methodical and methodological skills, when evaluating health information systems. The author concludes the chapter by pointing at research needs and opportunities.

DOI: 10.4018/978-1-59904-792-8.ch011

INTRODUCTION

"Evaluation is the act of measuring or exploring properties of a health information system (in planning, development, implementation, or operation), the result of which informs a decision to be made concerning that system in a specific context." (Ammenwerth et al., 2004, p. 480)

Many times health informatics professionals have suggested verbally that there are not enough evaluation methods that can be used to evaluate health information systems. A review of the evaluation literature regarding biases in assessment of medical IT-based solutions (Brender, 2006a, pp. 243-323) indicates that the general level of knowledge among evaluators is insufficient, that is, such methods and their assumptions are not appropriately known to their target users. This was also discussed among a group of key evaluation researchers and journal editors gathered in 2003 on the topic "New

Approaches to the Systematic Evaluation of Health Information Systems" (HIS-EVAL), sponsored by the European Science Foundation (ESF) (see Ammenwerth et al., 2004). The outcome of this workshop was a number of recommendations as regards the future of health information systems evaluation, also called the Innsbruck Declaration. Among others, the declaration suggests promotion of reports on methodological and methodical evaluation studies, and that evaluation studies should be grounded on scientific theory and rigorous approaches.

The above implicitly indicates that the literature on evaluation of health information systems is far from robust. Recent publications of textbooks, such as the *Handbook of Evaluation Methods* for *Health Informatics* (Brender, 2006a; a Danish version was published in 2004), have demonstrated that there exists a substantive number of evaluation methods applicable within health informatics. This handbook has the nature of an encyclopedia, since it takes a (critical) meta-view on an extensive list of evaluation methods while focusing on their areas of application, assumptions for application, tacit built-in perspectives as well as their perils and pitfalls, rather than putting emphasis on detailed cookbook prescriptions for application.

Therefore, the purpose of this chapter will be: (1) to verify whether there exist appropriate evaluation methods for the assessment of factors known to influence the success and failure of IT-based solutions, and (2) to identify potential needs as regards further development of evaluation methods, be it innovation or refinement of existing methods. More specifically, this chapter will emphasize the assessment of IT-systems from a user perspective within organizational settings, that is, this chapter is concerned with methods addressing interactions between a technology and its organizational, psychological and social components, as well as its effects. The methods in the handbook have been gathered from a variety of disciplines, ranging from psychology and social science to computer science and health informatics. Some of the methods are not designed as dedicated evaluation methods, but may be valuable as supportive means in an evaluation context. Thus, in such cases situational method engineering will be needed, thereby putting demands on the methodical and methodological skills of the evaluator.

There are two types of evaluation, constructive (or formative) and summative evaluation. Both types of evaluation serves the purpose of providing the (project) management with a decision-making basis in some context, cf. the definition given in the introductory citation. The difference is the overall context within which they each operate. For example, constructive assessment has the purpose of providing the foundation for identifying new or the need for altered directions with regard to subsequent development or implementation tasks. Alternatively, it can illuminate possible issues associated with specific problem situations. Since most IT-projects involve some compromises between an ideal solution and something realizable, controlled by local concerns, considerations and limiting factors, the role of constructive evaluation is to provide guidance to organizations in optimization of the dynamic health information systems development and/or implementation process.

The purpose of summative evaluation is to provide a concluding statement on properties of a health information system in a different kind of decision-making context. Examples of summative evaluation include: the evaluation of objectives fulfillment (i.e., assessing a health information system implementation in terms of its ability to fulfill organizational objectives), or assessing a system when it is delivered and one wants to ascertain that the system functions in accordance with the contractual agreement.

Some evaluation methods are retrospective in nature (like **root causes analysis** and **functionality assessment**). Others (like **balanced scorecard** and **delphi**) may guide the planning or revision of a health information systems development and thereby enable constructive evaluation. Still, other

Table 1. Examples of the hierarchy of success factor from Brender et al. (2006). The dots indicate that the list is continued at that particular place

Functional success factor

1. Careful preparation of the User Requirements Specification to appropriate and balanced take into account and express users' requirements, needs as well as demands
    a) (in general)
    b) Fulfill the needs (whether stated or not) rather than only the requirements of the users
    c) Enable and allow ongoing extension, while carefully controlling the aspect of moving targets
2. Alignment of the role and design of the IT-system
    a) …..
    b) Semantic understanding of the application domain
    c) The socio-technical nature of health information systems is understood
    d) The functionality has to be compatible with the users' way of thinking (cognitive aspects)
    e) …..
3. Coping with the complexity
4. ……

Organizational success factor

1. Collaboration and cooperation
    a) …..
2. ……
3. Work from the workflow
    a) …..
    b) Planning of new procedures must appropriately take existing patterns of collaboration into account
    c) …..
    d) The users show a willingness to change practice
4. …..

evaluation methods are not clearly prospective or retrospective in nature; rather they allow one to assess evolving situations.

BACKGROUND

The analysis of whether there exist appropriate evaluation methods for the assessment of known success and failure factor will be based on the union of factors identified within the literature. A huge number of studies of a single case have concluded on one or a few specific factors influencing the diffusion, penetration, or acceptance of IT-based systems, implying that the literature is a puzzle of findings. Consequently, we will take advantage of existing, significant reviews, based on different approaches.

Recently, Brender et al. (2006) conducted a delphi study where they identified a comprehensive list of success and failure aspects of health information systems development or implementation. The study was conducted as a follow-up initiative on the MIE2004 Special Topic Conference, in Munich, 2004, with the purpose of identifying success and failure characteristics of health informatics applications. Even though the study was conducted in the health informatics domain, its findings may also be valid for a number of other domains as well. In their work a total of 110 success factor and 27 failure criteria were identified and rated quantitatively for a number of different types of health information systems. These factors were organized in a hierarchical structure based on a number of categories, such as functional, behavioral, technical, managerial, cultural, and so forth; see the sample in Table 1. The reader is referred to Brender et al. (2006) for the complete list of factors, or alternatively, almost all of them are included in the below discussion on methods to support the evaluation of such factors.

Within the delphi study, none of the aspects identified were concluded to be insignificant by the expert panel at the final quantitative rating.

Therefore, none of the factors could be excluded from the list. Brender et al. (2006) suggest that the reason for including all of the success/failure factor arises as a consequence of the contextual nature of the factors themselves. If one uses this list of success and failure factor as a starting point only additional factors identified within literature reviews shall be included in the below analysis.

Three major case studies on IT systems' success and failure factor were reported in the 90s: Bikson and Eveland (1989), Crosswell (1991), based on quantitative and qualitative analysis of 55 and 39 cases, respectively. Lastly, Price Waterhouse (1997) conducted an extensive questionnaire survey of 500 cases worldwide. These three studies all indicate that there are a number of strong indicators of success and failure residing within the organizational context, from the beginning of the projects' lifecycle till full-blown operation. As compared to Brender et al.'s work (2006), one additional success indicator was reported by Bikson and Eveland (1989):

- Users' conception of their own status in terms of technological innovation

Croswell's work (1991) focused on obstacles and identified the following additional IT success and/or failure factors:

- Organizational coordination and conflicts
- Database structure and source materials
- Data communication and networking
- Software complexity/maturity

Croswell noted (with surprise) that there were few technical obstacles associated with IT failure. Nevertheless he observes more of this kind of obstacles than the two other reviews. These technical obstacles are included implicitly in the analysis below.

Price Waterhouse (1997) identified a number of success factor in addition to the set outlined in Brender et al.'s delphi study (2006):

- Competing resource priorities
- Insufficient communication
- Long lead-time for IT solutions
- Initiative fatigue
- Poor integration of IT and non-IT aspects of change
- Lack of HR policy re-inforcement

A more recent report by Stavri and Ash (2003) used a review of narrative stories of success/failures from a consensus conference on CPOE involving 13 experts. The study suggests that two additional factors (reported as success factor) are of relevance in our context:

- "When they say 'no way,' we asked 'what can you live with?'" and
- Change (goals, software, plans) based on lessons from pilot.

A recent, but smaller, literature review aimed at developing a better conceptual foundation for health information systems failure (and success), was presented by Heeks (2006). Heek's work identifies a couple of archetypes of IT failure that need to be added to the list of success/failure factor:

- Dominating design inscriptions—be they technological, managerial or medical—that incorporate particular cultural values, the failure arising when the stakeholder groups differ from the designer groups and/or includes different levels of formality and rationality
- Varying organizational conditions and cultures between private and public hospitals
- Differences in cultures between industrialized and developing countries, within and between countries of the latter type

These additional factors were included in the following analysis explicitly as separate factors or implicitly as part of the explanation of one or more given other factors.

In summary, the literature in general points to the presence of soft and organizational factors rather than hard-core technical factors as primary determinants of IT success and failure. Haimes and Schneiter (1996) reference the following definition of a 'system' (p. 483): "a system is all the components, attributes and relationships needed to accomplish an objective." With this definition of a system, the conclusion is not surprising: The soft human and organizational issues associated with a health information systems development and implementation range in complexity from addressing concerns about user interface aspects to the social nature of the employment and organizational context. The soft human and organizational issues also include the qualities and characteristics of the organization, its members as well as mutual interactions among individuals at every level (from a psychological, anthropological and sociological point of view to a legal and liability point of view). These factors all contribute to the shaping of organizations. Therefore, since the implementation of new IT systems inevitably induces changes in the organization as a whole, the mentioned soft human issues are not invariant factors. They will as primary or propagated effects influence the success or failure of IT-based solutions within the healthcare organization.

Delimitation

The primary objective of this study was to verify whether there exist appropriate evaluation methods for the assessment of each of the known success and failure factor. However, naturally, not all success factor and failure criteria need an explicit evaluation method for their assessment. For example, some forms of information need require simple 'yes/no' questions. Other types of success and failure factor, like 'evolution rather than revolution,' constitute (simple) project management aspects of a kind for which calling for a dedicated evaluation method would seem artificial. Furthermore, the study of political factors in general has another nature than those relevant in a pure evaluation context. All of these kinds are omitted from the below analysis, since space does not permit us to go detailed into each and every factor on the list.

There are a number of key themes that arise when one examines the success and/or failure of health information systems. For example, when one examines success/failure factor, one can see that some success factor are prerequisites for others. Therefore, these success factors have second or third order propagation effects upon the organization. For instance, senior management commitment is a prerequisite for strong, clear, and appropriate leadership, effective communication and resource allocation, but not for the ability to generate sustainable solutions. This was not taken into account in this chapter. As well, the issue of whether a given success/failure factor constitutes a root cause or a propagated effect was not addressed. They all represent the pattern of presentation of the success or failure much as a symptom is a part of a disease pattern.

In any case, it is the project management's responsibility to reduce the uncertainties as early as possible within the natural trajectory of a project—that is, to take into account the success/failure factor. This is where we perceive evaluation as a valuable means to timely address known symptoms. Preferably, one should look beyond the symptoms to the root cause. The project management should not merely tinker with problems (i.e., treat symptoms) but radically seek and address the root causes of problems. Such investment in evaluation during project management is necessary as only then will the chances of implementation success be dramatically increased. However, tinkering or not is not the issue of this contribution. In the following, there is merely a point to point correlation of an information need and candidate sources of information needed to ensure that a project succeeds. Some methods can dig deeper than others. Furthermore, evaluation methods can be combined and be used to explicitly address the root causes of identified problems; see for instance **root causes analysis** and **functionality assessment** in Brender (2006a).

CANDIDATE METHODS OF EVALUATING SUCCESS/ FAILURE FACTOR

In the present section of this chapter IT success/failure factor will be matched to evaluation methods. One factor or criterion at a time will be analyzed for its overall meaning and then matched with the individual methods' application area, location in the life cycle, and assumptions for application, perspectives, and so on.

Note that within the sections following, the success/failure factor are indicated in Italics between apostrophes. Likewise, methods (as named in Brender, 2006a) are stated in bold. For ease of referencing the names from Brender (2006a) have been kept; however, since these are usually identical with the original authors' own naming of their methods or intuitively understandable the reader may easily find alternative descriptions in the literature. The structure of this entire section follows the framework suggested in Brender et al. (2006).

Note also, that it is the decision-makers within the organization that ultimately are the responsible (liable) for the final outcome of the information system development and/or implementation process when it concerns operation of and with an IT-based solution. The following shall be perceived by the readers as suggestions for instruments supporting an organization at the development and/or implementation of such systems. However, it is entirely up to the project management whether or not to monitor for given success/failure factor, and whether he or she finds the issues relevant or the suggested methods useful in their specific project context.

Suggestions on Methods Applicable for the Evaluation of Success Factor

Functional Factors

The first functional factor is *'careful preparation of the user requirements specification to appropriate and balanced take into account and express users' requirements, needs as well as demands.'* More specifically, this factor is concerned with fulfillment of needs (whether stated or not) rather than fulfilling users' explicit requirements alone. The method **requirements assessment** supported by the method **framework for assessment of strategies** may address issues like feasibility, verifiability, completeness, and alike. These methods may also address whether the solution described is the right one ('relevance'). However, user needs are to some extent tacit, and consequently, user requirements may be very difficult to fully and reliably assess. Requirements addressing a functionality that is characterized by tacit needs cannot be fully assessed, but input based on a combination of focuses may at least support such an assessment; see for instance, the above mentioned **framework for assessment of strategies** and the methods **analysis of work procedures**, **stakeholder analysis**, and **organizational readiness**, as well as **future workshop**.

Another functional factor is *'enable and allow ongoing extension, while carefully controlling the aspect of moving targets.'* This factor is a consequence of the indeterministic nature of system development projects and is aggravated by the long lead-time for IT solutions. Extensions and modifications of project plans are necessary among others to take into accounts unforeseen tacit requirements as well as to handle project encounters. Such work calls for a strong project vision, a clear project purpose, as well as a defined strategy. A strategy is necessary in order to accommodate for emergent project changes while maintaining project direction. In such cases the use of an evaluation method like the **balanced scorecard** may be helpful in handling strategic and directional aspects, while methods like **BIKVA** and **KUBI**[1] might be better as a means in the initial social process of deciding on the project direction.

The overall factor *'alignment of the role and design of the IT-system'* includes a number of issues of relevance for the IT success and/or failure. A first component factor is *'the functionality has to be compatible with the users' way of thinking.'* For example, in case of users performing repeated activities, users can be trained to operate a system in spite of its cumbersome functionality. However, for systems dedicated to supporting users' decision-making and work procedures (like the electronic healthcare record) the functionality has to comply with user tasks and user methods of operating within the work environment. Otherwise, dissatisfaction and human operational errors will arise. Awareness of the need to change work procedures when implementing a new system is necessary in order to limit the number of changes to user activities to what is feasible within a given organizational context or domain. Since alignment of user role and design of an IT system is clearly related to the cognitive aspects of work, several **usability** approaches may be applicable in this respect, prospectively and retrospectively. Methods such as **cognitive assessment**, **cognitive walkthrough**, **heuristic evaluation,** and **think aloud** may be useful when the study is assisted by cognitive psychologists. More research is needed in this area, since really effective assessment methods for addressing cognitive aspects are sparse at present.

The second component factor is *'the system has to be usable and useful, helping the user in his/her daily routine work.'* The issues here include the defined system's coverage of daily practice and whether it supports the accomplishment of the primary goal of user activities. For a prospective assessment of whether the system is usable and useful the **analysis of work procedures** may be a valuable source of input. For a retrospective assessment of whether a system is usable and useful the **functionality assessment** is valuable to identify deviations and explore causal relations.

The third component factor is *'the role and the design of the system have to comply with the organizational context, including structure, people, information flow and external links.'* Of course, organizations need to adapt to the new technology during their implementation of a new IT-based system, but the number, nature and seriousness of changes is an invariant factor that determines the degree of the system's success or failure. Therefore, prospective studies of organizational change should bear this factor in mind. The means is—as above—systems analysis methods, like different approaches for **Analysis of Work Procedures**.

The fourth component factor is *'the IT-system has to be compatible with the organization's daily practice.'* The issue and the means for addressing this factor are the same as for the previous factor.

The fifth component factor is *'semantic understanding of the application domain is necessary.'* The syntactic aspects (i.e., corresponding to work procedures) are addressed by systems analysis and design approaches. The semantic aspects are concerned with the profession-oriented culture of the domain, like determinant factors in decision-making. For example, in healthcare this may be illustrated by the tendency by healthcare staff to consider and treat all patients as unique cases, as opposed to the opposite and rational perspective that prescribes strict compliance to clinical protocols and guidelines. There is no need for dedicated evaluation methods in this respect, but there is a need for awareness from the designers and managers side, as the perspective of uniqueness implies a huge need for flexibility.

The sixth component factor is *'the socio-technical nature of health information systems needs to be understood.'* Socio-technical aspects of health information systems address people issues. The socio-technical perspective espouses the view that IT systems are more than technical constructs and that a flexible planning that balance social and technical effort is recommended. Consequently, there is a need to develop policies for handling the people issues. However, there are strong cultural differences in this respect, as discussed in Brender (2006a, part III; 2006b). Also this factor does not need an evaluation method, but has to be an integrated part of the systems development approach.

The final two component factors to the mentioned overall functional factor are: *'coverage of daily practice has to be sufficient, compared with the defined role of the IT-system'* and *'addressing a real, high-impact problem area rather than a borderline problem area.'* These two (sub-)factors are addressing the issue of attracting the attention of the users. It is important that the IT-system supports the users in accomplishing the primary goal of their activities to avoid competing activities. And again, a means (systems design and/or evaluation-wise) is systems analysis methods such as **analysis of work procedures**.

The overall factor *'coping with complexity'* comprises three factors, all of which have the nature of systems analysis/design rather than objects for formal evaluation:

- 'The implementation project should apply explicit means for coping with the complexity'
- 'Keep it simple, but not simpler than needed'
- 'Evolutionary or incremental development as an approach to cope with complexity, including the educational aspect.'

The factor 'flexibility towards dynamic changes and changes in the organizational context' is closely related to organizational readiness and may therefore be evaluated prospectively by means of the method **organizational readiness**. On the other hand, too many organizational changes or fluctuations may become a problem in itself. Methods like the **balanced scorecard** and **risk assessment** may be used as a means for organizations that are hyper-innovative and where change is a constant.

The final functional factor is *'added functionality are provided by the IT-system, enabling the user to provide new or better services.'* It is related to the users' motivation for engaging. The sub-theme of this factor, *'the incentive for the user (and stakeholders in general) must be clear and visible,'* in itself indicates the solution, namely to establish a clear and visible motivation. No formal evaluation method is dedicated to assess this issue. If user engagement turns out to be a project issue or one wants to prevent this then it is relevant prospectively to assess whether the incentive for the users is sufficient (or what is further needed) to motivate the user. Here, the methods **focus group interviews** or **delphi**, in combination with **social network analysis** or a **stakeholder analysis** might be useful.

Organizational Factors

The organizational factor *'Collaboration and cooperation'* concerns the delicate issue of social and other types of relations between elements in an organization. Such relations can be horizontal (i.e., across organizational units) and/or vertical (i.e., hierarchical). Evaluation of aspects related to collaboration and cooperation of relevance for the health information system success/failure may all be addressed prospectively by means of methods such as **social network analysis** and **stakeholder analysis**.

The organizational factor *'make implementation a transparent process within the organization'* has a sub-theme *'generally open for debate.'* These two factors address the question of balancing between two issues: transparency versus covertness, and decision-making versus decision-taking. Both are culturally influenced topics, and culture can here be understood in either the national respect and/or in the organizational respect that also includes the organization's prior history. By "decision-making versus decision-taking" is referred to the distinction between a hierarchical, top-managed approach for the development or implementation process (i.e., decision-taking) as opposed to a process that leads to a decision among relevant stakeholders (i.e., decision-making). Decision-making does not preclude the management from concluding on a decision, but implies that stakeholders' issues are openly discussed. So, the issue in reality is whether the decision approach taken is aligned with the needs and interests of the (involved) stakeholders. Methods like **focus group interviews**, alone or in combination with **social network analysis** or a **stakeholder analysis** might be valuable in providing insight into these aspects.

The organizational factor *'work from the workflow'* concerns among others the issue *'planning of new procedures must appropriately take existing patterns of collaboration into account.'* Radical changes to workflow and patterns of collaboration can be disruptive to the delicate social balance in an organization. Consequently, radical change bears the risk of all kinds of negative social reactions. The method **social network analysis** addresses the relations between elements within an organization (such as individuals, professions, departments or other organizations). Therefore, this method may provide useful input into the design and other planning of health information systems development or implementation, and thus it constitutes the candidate evaluation method.

Behavioral Factors

The behavioral factor stating that *'the users are key'* is highly culturally dependent. In some cultures end users refrain from being involved at all due to their perception of the division of roles between the management and the employees, see the discussion in (Brender, 2006b). However, in the Western countries suitable involvement of employees is a significant success factor—that is, involvement of the right type, level, and scale of employees. Another relevant question here is whether the right competences are available and accessible—that is, a question of competing activities. **Stakeholder analysis** and **social network analysis** are valuable methods for assessing behavioral aspects related to the development or implementation process. Both of these approaches may provide input as to what users to involve and/or to involve in what situations.

The behavioral factor *'the personal attitude, engagement and commitment'* concerns end users, managers as well as other stakeholders. It addresses issues such as employee opposition, lack of middle management support, aspects of executive leadership, and managerial commitment. Employee opposition may be explored by means of **focus group interviews** throughout a project. Managerial commitment can be addressed indirectly, for example by conducting a situation analysis, such as using that of the **logical framework approach**. The success factor *'presence of sufficient motivational activities'* relates to all aspects of personal attitude, engagement and commitment.

The behavioral factor *'user conception of their own status as regards technological innovation'* was pointed out by one of the reviews as a motivating factor. User conceptions influence motivation and can be elicited by means of different kinds of individual **interviews** and/or **focus group interviews**. Both types of interviews are general methods and that are well suited towards illuminating individual' opinions, attitudes and perceptions regarding a phenomenon and observations (e.g., health information system implementation).

Cultural Factors

There are many types of cultures, ranging from national, over religious to professional cultures. The deeply rooted, tacit cultural factors in general are not factors that one should evaluate. They just are, and changes in this respect may not be a short term effort. For example, some national cultures perceive answering a question with a "no" as highly impolite. Therefore, imagine the potential bias in a questionnaire study or the effect of yes/no-buttons in a user interface when asking individuals with such cultural backgrounds to answer those yes/no questions. Hence, project management needs to understand how to take cultural factors into account, especially when transferring technologies and/or development methodologies or specific information systems from one culture to another.

More specifically, project management needs to be aware of a couple of factors related to the professional culture need awareness:

- *'Understand medicine and healthcare in general as a separate culture:'* The strong professional culture in healthcare implies that healthcare staff should be involved in the implementation process—if not being in the driver's seat. There may even be varying organizational conditions and cultures that are present between private and public hospitals. For example, Heeks (2006) suggests that accounting and billing procedures are less of an issue in publicly rather than privately funded hospitals. And certainly this difference is pronounced between American IT solutions and the majority from the European countries. Differences of this kind may be identified by means of **analysis of work procedures.** Here, comparisons can be made between a system's business or enterprise model, and/or data models.
- *'Understand the local culture:'* Even within a given domain there may be islands of differing professional cultures. This factor may be addressed in the same way as the previous factor, but requires a finer level of analysis.

The cultural factor *'preparedness and willingness towards cultural change'* refers to the need for cultural changes, however, mainly related to the professional culture, for instance in work procedures. It includes a number of issues, such as:

- 'Awareness of the need for cultural change'
- 'Readiness for a potential new business model'
- 'Readiness for solutions not invented in-house'

Implementation of a (new) IT-based solution inevitably changes the organization. It is therefore important to nurture a new local culture for it to embrace the new technology. One problem may be that there is no perceived need for change by the local culture. Therefore, it is important to evaluate the readiness of an organization along with the factors outlined. **Organizational readiness** as an evaluation method was explicitly designed for prospective assessment in this respect. Unfortunately, the impression is that it is not yet a fully matured evaluation method. Alternatively, both the **field study** (screening and monitoring) and the **equity implementation model** (diagnostic) approaches may be useful as they allow for retrospective assessment of organizational context in terms of cultural success/failure factor.

Management Factors

The overall factor *'management support'* is mentioned in several of the reviews and hence it must be considered a significant success factor. Management support includes a number of sub-factors. However, some of these are yes/no aspects or belong under project management solely, and therefore, they are excluded here.

The first management factor is *'formulation and expression of a clear vision for the enterprise showing the IT-system as part of it.'* In most cases project management need not initiate an evaluation activity to assess the clarity of an organization's IT vision. In cases where an organization wishes to evaluate management factors such as clarity of organizational IT vision, a more formal evaluation approach can be taken. For example, the methods **balanced scorecard** and **framework for assessment of strategies** both require a clear and operational vision and strategy to be able to proceed smoothly in a development or implementation process. These two methods may therefore be valuable indirectly to assess the clarity of the vision specifically with respect to aspects of strategic relevance for implementing information technologies. Such evaluation may be carried out by performing the preparatory steps of either of these methods to see if the vision is sufficiently clear and operational.

There are a number of useful methods for assessing the management success factor *'Setting goals and courses'* (i.e. clarity of objectives), for example:

- **Framework for assessment of strategies** may be used prospectively to analyze the feasibility, timeline, risks, viability, and so forth, of the defined IT goals and courses.
- **KUBI** elicits a set of user or customer/client defined values, norms and objectives, and may provide an alternative set of goals and courses for comparison.
- **Balanced Scorecard** is a strategic project management approach based on goals and courses. These goals are used as a kind of measuring stick at decision making throughout the project. Applying **balanced scorecard** even as a desktop pilot may provide users and project team members with feedback on whether the established set of goals and courses are operational or defined in a useful way.

Regarding the management factor *'understanding the return of investment (whether material and/or immaterial benefits)'*: Beyond economic assessment of material benefits, a **delphi** investigation may reveal and characterize the immaterial benefits, other bottomline benefits, as well as the attitudes towards these both prospectively and retrospectively.

The management factor *'flexible planning'* includes the following themes:

- 'Enabling and allowing change of project plans and time tables'
- 'Realistic time lines'
- 'Understanding that implementation of an IT-based solution is a non-linear (indeterministic) process'
- 'Response to shortcomings is constructive'

These success factors are attitudinal in nature and are concerned with the project management itself and are also dependent upon the actual project management experience with the kind of activities in question. They are not topics that are meant for dedicated evaluation efforts. Should an organization wish to evaluate these attitudinal topics, one could prospectively evaluate these factors by means of methods such as **interview** using an external evaluator. Retrospectively, one could assess these IT success factor using **root causes analysis**, investigating the history, events and initiatives associated with the project to identify patterns of problems and possible subsequent actions.

The management factor *'prospective and proactive control'* includes a number of sub-factors, such as:

- 'Project management in general'
- 'A high degree of delegation and involvement combined with good coordination and communication'
- 'Sufficient communication,'
- 'Organizational coordination and conflicts'
- 'Stringent risk management'
- 'Cost-active control'

- 'Coordination'
- 'Appropriate action in response to unanticipated events'
- 'Sanction bottom-up signals as valuable input for steering'

Although this list is long, all of the items are related to good project management. One would not normally make these success factors the object of a formal and dedicated evaluation study in its normal sense. If a project is proceeding in ways that it should not and the project management is experiencing difficulties in diagnosing the causes, a **root causes analysis** could be carried out. Alternatively, if a **root causes analysis** is too difficult to undertake simpler approaches such as the situation analysis in **logical framework approach** would probably suffice in most cases.

The management factor *'consider IT implementation as a change process'* has four sub-factors related to IT success. These sub-factors can serve as guidelines for project management rather than requiring time taken away from project processes for the purpose of evaluation. These sub-factors include:

- 'Acknowledging that the IT-system represents a chance to support a change in the care delivery process'
- 'Stepwise progression rather than reengineering everything'
- 'Good supervision to enable a smooth and continuous change management'
- 'Poor integration of IT and non-IT aspects of change'

The essentials of the management factor *'change (goals, software, plans) based on lessons from pilot'* is that lessons from a pilot application should deliberately be used and taken action upon. Pilot studies allow the project management to find potential project flaws and to address those flaws prior to full IT implementation, irrespective of the nature or causal relation of the flaws. The **functionality assessment** method is perfectly suited for a retrospective investigation of problems and their causal relations. The principle within this method is that problems in the functionality (irrespective of cause) will reveal themselves in terms of unexpected or changed/changing work procedures—that is, resulting in observable, propagated actions and initiatives within the organization's work procedures (other than those that are planned or expected). Consequently, such emergent work procedures reflect the problems and therefore constitute candidates for subsequent exploration and potential action.

The factor *'coping with the impact of change'* concerns the ability to handle the necessary change processes. The method **organizational readiness** is an obvious candidate approach for prospective evaluation of the organization's ability to cope with the impact of change. The evaluation method **equity implementation model** can help in the retrospective assessment of users' reaction to the impact of implementing a new system, and thus this method may be valuable in understanding user behavior.

The factor *'user involvement'* (in general) is highly culturally dependent. **Stakeholder analysis**, as a user assessment strategy, allows one to determine if user involvement is appropriately being dealt with. **Stakeholder analysis** not only assesses who is involved, but how they are involved and engaged? Are they (i.e., the users) engaged in terms of representatives of stakeholder groups? Are users available? And in what way are users engaged: informed, consulted or actively engaged in the decision-making processes? The **stakeholder analysis** addresses these issues, taking into account the culture and existing organizational practice.

Another aspect of the *'user involvement'* factor is the sub-factor *'time must be freed or funding allocated for users to participate in the process.'* This aspect of IT success is closely connected to another sub-factor, *'competing resource priorities.'* These aspects of user involvement may prospectively be dealt with using a **risk assessment** approach, for instance by means of the concept of 'external factors' from the method **logical framework approach**. Retrospectively, user involvement may be explored in many ways, such as **interview** methods in general, **questionnaires**, or for instance, the situation analysis in **logical framework approach**.

One further management factor is *'when they say "no way," we asked "what can you live with?"'* This factor is concerned with the management approach to dealing with stakeholders' attitude. No formal evaluation method is needed to assess whether a given approach is the right solution for a given case, but the **balanced scorecard** and **KUBI** are two evaluation methods that can stimulate stakeholder-management dialogue in finding the way forward.

The factor *'strategy'* refers to the ability of an organization to formulate the foundation for all significant decisions and action plans (i.e., plans, methods, or series of maneuvers or stratagems for obtaining a specific goal or result). In terms of evaluation approaches organizational strategy can be evaluated using the method **framework for assessment of strategies.** The **framework for assessment of strategies** is a valuable method that can be used to assess an organizational strategy or to choose among alternative organizational strategies for instance with respect to feasibility, time lines and implicitly also sustainability.

A sub-factor where organizational strategy is concerned is *'synergy between initiatives.'* Synergy between IT initiatives may be assessed during the IT development and/or implementation by analysis of flows of information between relevant initiatives, combined with **stakeholder analysis** and/or **social network analysis**.

The last management success factor is *'handling the diversity within stakeholder goals.'* This includes the organization's capacity in the following respects:

- 'Awareness and mediation of diverging goals'
- 'Handling of hidden agendas'
- 'Initiative fatigue.'

Evaluation in the context of an organization's ability to handle diverse stakeholder goals may be accomplished by using evaluation approaches such as **stakeholder analysis** and **organizational readiness analysis**. With respect to the first two of the listed issues, a **stakeholder analysis** may be useful in providing a rich picture of individual stakeholder goals and interests. **Stakeholder analysis** raises awareness and reveals the stakeholders who will benefit from as well as be victims of the new IT solution. *'Initiative fatigue'* implies the loss of organizational capability for change. Here, **organizational readiness** as an evaluation approach can be used to identify the severity of initiative fatigue.

Technical Factors

A number of the technical factors that affect IT success/failure were identified in the delphi study and the literature reviews mentioned in the background section. These technical factors are to a great extent of a nature that renders it obvious for them to be assessed as an integrated part of the **technical verification**. They will not be mentioned individually here. A factor such as *'integrated functionality and communication standards'* includes sub-factors like (1) *'integration with legacy system,'* (2) *'interoperability'* (connected systems logically and functionally co-operating in real-time), and (3) *'interconnectivity.'* From an IT evaluation perspective the previous mentioned technical factors are considered part of the **technical verification**, but may require special skills for their in-depth evaluation. Especially the technical interoperability of interconnected legacy systems may be challenging to assess in practice because of its dependency on timing for all kinds of transactions (requesting, cancelling, modifying, and reporting), to verify that timing is not an issue in practice. Technical verification may also involve determining if the system has semantic interoperability. Evaluating semantic interoperability requires special expertise and includes activities related to ensuring that the meaning of communicated data and information is the same when it appears in two different but interfaced systems. In today's practice, the latter involves aspects of communication and architectural standards, medical vocabularies, and the use of appropriate terminology servers (see for instance Blobel et al., 2006; Engel et al., 2006; Ingenerf, Reiner, & Seik, 2001).

The factor *'usability'* (i.e., the technical implementation of usability aspects) is also a critical IT success factor. A number of methods are dedicated to the evaluation of system usability, either constructive evaluation or summative evaluation: **cognitive assessment**, **cognitive walkthrough**, **heuristic evaluation**, **think aloud**, and **video-recording**.

Another technical factor is *'balance between flexibility and stability.'* IT flexibility enables variation in work procedures. However, flexibility can severely increase the complexity of an IT solution and therefore tends to counteract the stability. And consequently, finding the right balance between flexibility and stability is a dilemma for the project management. A limiting factor may be organizational readiness as regards change. Consequently, the method **organizational readiness** may be valuable here.

The last technical success factor is *'evolution rather than revolution'* in combination with a couple of its sub-topics: *'stepwise progress following functional needs as well as technological achievements and potentials'* and *'flexibility and adaptability, enabling future functional and technical changes.'* These factors are project management issues and will not be further dealt with here.

Strategy Factors

The overall factor *'strategy'* may be subdivided into three topics (see also *'strategy'* in the section on management factors): *'national,' 'regional,'* and *'organizational.'* There is a dedicated approach designed to assess alternative strategies, in particular aspects related to their feasibility and timing aspects: **framework for assessment of strategies**. Furthermore, **interviews** in general can help to elicit individuals' opinions, attitudes and perceptions regarding phenomena and observations, including those related to a strategy. And in particular, the **focus group interview** method is suited, when a model solution is discussed.

Another factor related to strategy is *'Accepted also at lower levels.'* Here, in particular the **focus group interview** method is well suited when addressing whether a given strategy is acceptable by the stakeholders.

Economy

An IT success factor related to economy is *'there has to be a return of investment (whether material or immaterial).'* The return of investment is concerned with the justification of the system prior to any decision to move forward on initiating a given IT project. Organizational arguments in favor or against an IT project have to be balanced against time, resources, and fiscal investments, as well as the inherent risks. If it's difficult to prospectively assess such justification, a **delphi** approach may get arguments on the table regarding the immaterial benefits. Retrospectively, **impact assessment** or a **field study** may be valuable to assess immaterial effects, but are themselves quite laborious, thereby indicating that their own return of investment may be questionable.

Education

The factor '*sufficient training*' in general points at two other factors: '*to make the best out of the* *daily operation*' and '*to provide an understanding of its limitations and future potentials*.' How much education employees need to use a system effectively depends on the actual system and its future organizational context. Unfortunately, the level of education and training users will need is not something one can fully assess prior to operating a system, but one can learn from the experiences of reference sites and other organizations. Moreover, one may get a good hint (prospectively) by means of one or more of the methods designed for **usability** assessment. In daily operation (retrospectively) one can follow up on deviations from desired operation in terms of user errors in the operation of a system. Here, for instance the **functionality assessment** method may be valuable. However, **functionality assessment** may be too stringent to use in all such cases.

User Acceptance

'User acceptance' is a factor, for which a number of dedicated tools and studies have been published in the health informatics literature. The approach applied is mainly **questionnaires**; see also **user acceptance and satisfaction**. However, also the **equity implementation model** and **focus group interviews** approaches may be valuable in this respect, depending on what precisely one wants to know. Of these, the latter may be applied prospectively, the others only retrospectively.

Suggestions on Methods Applicable for Evaluation of the Failure Criteria

Functional Criteria

The first functional failure factor is *'limitations in the way the user can express him or herself.'* Such limitations may be caused by either usability problems or by functional barriers. The usability may prospectively—or retrospectively—and constructively be dealt with by means of one or more of the **usability** evaluation approaches (human factors engineering). This can even be done as part of the selection among bids, see examples under **bids assessment** in Brender (2006a). If the problems are not (solely) of an ergonomic or cognitive nature, but are caused by an awkward functionality the organization may retrospectively analyze the IT system using the **functionality assessment** method.

The functional failure factor *'moving target'* is risky. It is risky but also inevitable because of the long lead-time for IT solutions, because it means that the project conditions, plans and directions may get out of control. For example, the technologies of healthcare organizations change rapidly as a function of the technological evolution and knowledge gain. Or the moving target may arise as a consequence of indecisiveness or of increased insight into the opportunities created by the new IT technology. If the moving target issue is considered a problem in a project one may use the **balanced scorecard** to assess each individual suggestion for change.

Organizational Criteria

The overall organizational failure factor *'not understanding the organizational context'* includes at least the below three topics.

The first of the three sub-factors is: *'not understanding or foreseeing the extent to which the new IT-system affects the organization, its structure and/or work procedures.'* This type of lacking insight is a bad foundation for the design or purchase of an IT-based solution and can be risky for the organization. The organization's commitment to forecasting the extent to which the work procedures will change is considered an obvious concern during planning activities. A **future workshop** may provide some input for the decision making in this respect. However, judging whether the organization is capable of making the necessary changes to the organizational structure and/or work procedures also requires assessment of **organizational readiness**.

The second sub-factor is *'too many changes of work procedures.'* Project management may overestimate the organization's capability for change. **Organizational readiness** as an evaluation method may help proactively but probably only partly to support assessment of organizational ability to accept and implement planned change. Presently, true organizational capability for change—that is, the number and severity of changes that an organization can cope with is still guesswork. Bearing such knowledge in mind the identification of a limited organizational readiness at evaluation is important prior to the preparation and assessment of the user requirements, as well as at bids assessment. Retrospectively, the method **equity implementation model** may be effective in understanding users' reaction to information systems by focusing on the impact that such a system brings about.

The third failure sub-factor related to organizational aspects is: *'Analysts dominate the development at the expense of those understanding the organizational context.'* Such cases may arise when stakeholder groups differ significantly from the designer groups and/or include different levels of formality and/or rationality. A **stakeholder analysi**s would reveal those stakeholder characteristics and the relationship dynamics that influence IT implementation success. A stakeholder analysis normally has the purpose of identifying participants for the completion of a given task, problem solving activity or project, and thereby stakeholder analysis as a preventive action may lead to the best balance of the two parties in a project.

Behavioral Criteria

The behavioral failure factor *'overloading the user'* is concerned with planning and designing the functionality of a health information system. More specifically, designs that forces the user to remember too much (data or sub-tasks) in order for him or her to complete an activity may lead to an overload of the mental capacity of a user. Therefore, this factor is tightly connected to aspects dealt with by methods of **usability**. And consequently, differing types of usability studies that could be employed—for preventive and/or curative purposes—are: **cognitive assessment**, **cognitive walkthrough**, **heuristic evaluation**, **think aloud**, and **video-recording**.

The factor *'underestimating user acceptance'* is a complex issue. User acceptance is not only affected by usability but also by psychological aspects beyond the functionality of the IT system. For example, aspects may be grounded in the implementation process itself. Therefore, **user acceptance and satisfaction** evaluation approaches are important where there is a need to measure the level of user satisfaction retrospectively. Alternatively, the **equity implementation model** may provide a deeper understanding of the reasons behind potential IT system problems.

The last failure factor related to behavior is the factor *'resistance because of fear or loss of control of own job situation.'* Indications of resistance may be explored prospectively by means of **focus group interview** as well as **interview** methods in general, as these methods are particularly suited for elucidation of individuals' opinions, attitudes and perceptions regarding phenomena and observations.

Cultural Criteria

Two cultural failure factors are addressed here. The first is *'assuming that what works at one place also works somewhere else.'* Many managers tend to make the mistake of assuming that what works one place also works in their organization. Such mistakes are often made during the technology transfer between industrialized and developing countries (or vice versa), but they also occur at transfer of technologies between countries of the former type. Differences in legislation or legislative processes, in professional culture, in specialized equipment, and even in the profession-oriented terminology may hinder the transferability of an IT-based solution. This is well-known for knowledge-based systems, where even more invariant factors are present, such as the epidemiology; see (Nolan et al., 1991). Consequently, there is a need to study the transferability of a health information system to explore the system's applicability at new sites. Such transferability evaluation may involve almost any existing evaluation method. Presumably **analysis of work procedures** is the best general approach for preventive (prospective) purposes, while **functionality assessment** may fulfill the information need for curative, retrospective purposes.

The other failure factor addressed here is *'users have too high expectations.'* This failure factor may indeed be prevented by proactive evaluation of the expectations followed by communicative actions that focus at aligning or harmonizing expectations. Here, **interviews**, in particular **focus group interviews**, are suited as these methods may elicit individuals' opinions, attitudes and perceptions.

Technical Criteria

There are a number of technical failure factors, of which the first to be addressed is *'limitations in the way users can express themselves.'* This factor is parallel to the functional success factor with the same name, see above. Project management need to be cognizant of the technical limitations of a system and discuss this with the user organization, including how a system affects users' expressions of themselves. However, the functional consequences of the technical barriers in the perspective of this factor compares to a needle in a haystack, if you do not know what to look for then the solution space is too big and too undetermined to even think of initiating an evaluation study.

Another technical failure factor is *'the technology is so restricted that it impacts design and implementation choices.'* According to the author's personal experience restrictiveness is usually correlated with the capabilities of analysts, designers, and implementers rather than the technology itself. Complexity as well as software immaturity may also influence technological restrictiveness. However, rather than being a topic specifically for evaluation technical restrictiveness is an issue for the project management to prevent and/or take action upon at an early point in the development process.

The factor *'response rate and other performance measures'* has two component aspects: a general one regarding the traditional technical performance (response times, throughput times, reliability, etc.) and a functional regarding *'the time needed to complete the users' tasks.'* The technical performance is normally evaluated as part of a **technical verification** provided that technical performance is specified as part of the contract. Technical verification normally takes place in an experimental set-up of a system within an organization, and it may require deep functional insight to define and establish the right evaluation set-up with realistic workloads and patterns of work activities. The second factor mentioned above (*'time needed to complete user tasks')* compares to a kind of organizational response and throughput times, sometimes denoted service delivery times. An example is the time from a flight lands till the customers get their luggage, or the time from receipt of an order in an electronic healthcare system to the submission of the end result to the requester of the information. Service delivery times may be dealt with in a fashion similar to the technical counterparts. Evaluation of such service delivery times for user tasks requires before-and-after time-motion studies (time measurement for paradigm use scenarios and tasks: **prospective time series**). Some of the measures may be provided by the IT-system involved. Unfortunately, these measures may be more difficult to realistically evaluate in an experimental set-up in systems that are deeply interwoven or integrated with and dependent on other technologies and/or medical instruments.

This is especially the case for some kinds of information systems (e.g., the production support part of laboratory information systems).

Another two technical failure factors are: *'vendor did not support the functionality quoted'* and *'insufficient verification of conformity with requirements specification.'* These factors are closely related. One has a small chance of realizing the former if the latter factor is present, and this may result in unpleasant surprises when the system is placed into daily operation. Even a trifle in the functionality that is not supported may have a great impact on organizational practices or resource consumption. The means for preventing this is to tenaciously and meticulously verify the delivery of the agreed functionality by means of **technical verification** using the contract (or other formalized agreement) as the frame of reference. The author recommends that the user evaluation in this respect takes the user organization's daily reality in terms of tasks and work procedures as the starting point and design test scenarios that mimic the daily work in all its details. Therefore, not only should prescribed organizational rules be tested, but the entire variation in organizational activities as well as exceptions to activities that arise in daily organizational work should be tested. This is the only way to prevent surprises during daily operation, but such an approach assumes that the contract (the requirements specification) is an adequate frame of reference.

Educational Criteria

An educational failure factor identified is the *'visible discrepancy between successive versions of the IT-system.'* Obviously, visible discrepancy between successive system versions implies a need to provide users with continuous learning and support. No evaluation method that is dedicated to assess this criterion has been identified. If the discrepancies between versions of an information system are too large for the organization to deal with prior to operation the organization should recognize that there will be some temporary inefficiency that will arise in work procedures and that will be accompanied by operational errors involving the system. Problems associated with version changes and education may originate from a lack of communication, understanding or foreseeing the extent to which the version changes affect the organization, its structure and/or work procedures. Such lack of communication, understanding or foreseeing of the need for education may slow down proactive educational activities. As well, organizations must also recognize that such issues may arise from users' inability to cope with change (see this separately).

DISCUSSION

The first objective of this chapter was to verify the existence of appropriate evaluation methods for the assessment of known factors that influence the success and failure of health information systems. The chapter is based on a comprehensive set of IT success/failure factor synthesized from a number of literature reviews as well as a delphi study conducted by Brender et al. (2006). This approach leads the author to suggest that the list of success and failure factor itself is fairly complete. Therefore, the union of factors is a reasonably good instrument for analyzing whether adequate evaluation methods exist for monitoring or preventing given success and failure factor for health information systems. The author suggests it is feasible to identify suitable approaches for evaluating most of the IT success and failure factors.

There was one surprise that arose from the analysis: The author had expected risk management approaches with monitoring of risk factors to be high scoring as an approach particularly valuable for optimization with respect to the identified success and failure factor. It was not. This certainly does not rule out risk management as an integral part of best practice for systems development or implementation. It just shows that more is needed.

The top eleven methods referred to in the above are (in order of decreasing significance. However, some of the methods—like the bottom five methods—are ranked with the same significance):

- Stakeholder analysis
- Focus group interview
- Interview
- Social network analysis
- Analysis of work procedures
- Organizational readiness
- Framework for assessment of strategies
- Usability
- Equity implementation model
- Functionality assessment
- Balanced Scorecard

Almost all of these evaluation methods focus on the soft human aspects, such as who is affected by IT related decision-making, patterns of decision making, and management of change. The outcome of the present study simply reflects the fact that most of the factors identified in this work are related to the soft human factors outlined previously. Therefore, at least in the Western countries where most of the incorporated reviews originate, the organizational issue, as well as project management of information systems related issues are central: policy, commitment, and approaches.

FUTURE RESEARCH DIRECTIONS

The second objective of this chapter was to identify the potential needs as regards further development of evaluation methods. The main problem in many cases is that evaluation methods are not designed in a dedicated fashion to the assessment of those specific success factor and failure criteria. An example of this is **analysis of work procedures** approach, which has been adopted from the domain of systems analysis. Therefore, methods engineering is necessary.

Many places above a reference to a method is stated as "might be valuable"—or similar. This means that the method in question may not be dedicated to answer that specific information need. All of these evaluation approaches are obviously candidates for methods engineering and further evaluation research. Furthermore, evaluation methods need to be made more accessible to the common, organizational evaluator. Until then, practical application of such candidate evaluation methods requires methodological and methodical skills, imagination and flexibility in order to adapt the methods to a specific case, its conditions and its particular information need.

One method is explicitly mentioned as possibly needing more maturation as an evaluation method: **organizational readiness**. Organizational readiness is a very complex phenomenon, and relevant in connection with numerous success/failure factor. Organizational readiness ranges from the hospitality (openness) to solutions not invented in-house, to the capacity of organizations to invent efficacious IT-based responses to changes within the healthcare environment, to triggering the invention of such IT-based solutions, and to building the capacity to develop sustainable solutions.

Furthermore, several of the methods referred to in this chapter are designed to provide exhaustive and highly accurate information, bordering on scientific stringency. This implies that large investments of calendar time and/or resources are needed to undertake such evaluation studies—which may be out of the question in a practical evaluation setting. Therefore, in the practical context of a specific project, the challenge may be to modify or simplify a specific evaluation method to the practical needs of the organization, again, the situational methods engineering is required.

As Rigby emphasizes: "Adequately funded evaluation, based on proven sound techniques, is the means of moving forward to a credible discipline …" (Rigby, 2006, p. 119). Implicitly, he says in his conclusion that there is a step ahead of us before the evaluation methods are sufficiently dedicated and matured for their application purpose. This conclusion is in agreement with the statement in the review by (Berghout & Remenyi, 2005, p. 88) that "… there has been only marginal improvement in the maturity in this field over the past eleven years." Implementation of IT-based solutions (and therefore also the implied evaluation needs) are somewhat indeterministic. However, the present study indicates that we do have a foundation of approaches valuable for most evaluation purposes. From this foundation of evaluation approaches we may adapt or develop and mature evaluation methods dedicated to the specific information needs. Still, major research efforts are needed.

Finally, according to Brender (2006b) there are a number of evaluation research challenges ahead of us: Research needs to focus on constructive evaluation of cognitive and work process-oriented aspects of IT-based solutions to cope with the full complexity. This full complexity includes the dynamics, the variation, and the evolution of the target domain—here health care. The analysis in the present contribution could not go into sufficient detail to confirm or reject this hypothesis.

CONCLUSION

Evaluation is perceived as a means to optimize the likelihood of success while minimizing the likelihood of failures of health information systems development and/or implementation. A list of success and failure factor identified within the literature was examined to identify candidate evaluation methods. It turned out being feasible to identify suitable approaches for most of the factors. However, there is a need to undertake situational methods engineering in many situations as the evaluation methods referred to in this chapter often are not dedicated to answering the precise information needs of an organization. This therefore, also points at the research needs and opportunities.

Chapter 2.12

Developing Information Communication Technologies for the Human Services:

Mental Health and Employment

Jennifer Martin
RMIT University, Australia

Elspeth McKay
RMIT University, Australia

ABSTRACT

This chapter introduces a design process for developing useful information communication technologies for the human services. Key to the success of the design process is an in-depth knowledge and understanding of user needs and requirements. The stages involved in the design process are presented in this chapter and include: user and task analysis, persona and scenario development and the establishment of measurable usability goals. A case study illustrates the application of this design process to develop a Web enabled electronic work requirement awareness program (e-WRAP) for people recovering from mental illness seeking employment. The challenge for social workers is to use these new technologies to improve service provision and enhance quality of life without compromising ethical standards of practice; particularly in relation to client confidentiality, privacy and self-determination.

'After the idea, there is plenty of time to learn the technology'. -- James Dyson (1947-), English inventor and businessman, Against the Odds, 1997 in Oxford Dictionary of Quotations (2004, p.294:20).

INTRODUCTION

Information communication technologies today are in abundance. People of all ages, particularly young people communicate through the Internet to access the social networking sites MySpace and Facebook; the online video site YouTube; microblogging sites Twitter and Plurk and the virtual world of Second

DOI: 10.4018/978-1-60566-735-5.ch010

Life. In addition to these are Internet sites such as Wikkipedia, MSN and Google. Most organizations today have a web presence for marketing, attracting users and conducting business. Increasingly organizations in the human services are adopting web technologies to reach user groups to communicate their messages and to increase organizational efficiencies. However the profusion of information on the Internet makes it difficult at times for users to actually locate the information they are seeking. This may be due to diversion sites that can cause considerable frustration, confusion and time delays or an overload of information, with many Internet sources unverified. Access to the Internet can be costly requiring constant updates and virus protection with some media requiring the latest versions of sophisticated software to access them. Available software and the Internet service provider will also affect access and speed.

These new technologies create both challenges and opportunities as designers try to reach their intended user groups using the most appropriate means and messages, delivered in a timely manner. Central to the success of designing useful and usable information communication technologies for the human services is in-depth knowledge and understanding of the target audience, referred to hereafter as "users". The stages involved in the design process are presented including: user and task analysis, persona and scenario development and the establishment of measurable usability goals. This is followed by a case study of mental health and employment illustrating the application of this design process to develop a web enabled Electronic Work Requirement Awareness Program (e-WRAP) designed for people recovering from mental illness seeking employment.

USER ANALYSIS

The main features of user groups are identified by conducting a user analysis. This involves thinking and forming assumptions about what users would like. The next crucial step is to test these assumptions against the "reality" of the users in an endeavor to understand their needs, expectations, knowledge base, experience and preferences. Information is also gained on technologies and software that users have available to them, for example via broadband or dial up, as well as the physical environment where the Internet is accessed. By involving users in the pre-design stage they become active and important partners in the design process. Research techniques that complement each other for conducting a user analysis comprise: contextual interviews, individual interviews, surveys and focus groups (United States Department of Health & Human Services, 2008). The more techniques used the greater the depth of knowledge gained about the needs of users and the less likelihood of design errors. A common mistake to avoid is choosing "flashy" technology over accessibility.

Contextual Interviews

Contextual interviews are similar to participant observation, and involve observing and listening to users while they are engaged with the technologies. These interviews provide information on the physical and social environment as well as the technologies available including means of access, familiarity and level of comfort and support. For instance a person's use will vary according to whether they are on broadband or a modem. Dial up access to the Internet may mean that the users want to use the web quickly so that a telephone line is not tied up for extended periods. Access will vary according to the Internet service provider with many limiting or denying access during peak periods. Insights are gained on whether or not users have anyone who can assist them with the technology and the nature of this support. Contextual interviews are usually informal with the interviewer mindful of not imposing any changes on the environment that is being observed. This is achieved by watching and listening to users and interviewing them by means of questions, probes and reflective statements to gain an understanding of what they are doing, thinking and feeling. The interviewer does not ask users to perform specific tasks or respond to case scenarios.

Individual Interviews

Individual interviews are different to contextual interviews in that they involve collecting information directly from the user and do not include contextual observations. The ultimate goal is to gain deeper understanding and insight into users' ICT needs. Individual interviews allow for a deep understanding of users' attitudes, beliefs, experiences, desires and fears. Individual interviews provide an opportunity to have a detailed one on one discussion where the user has the full attention of the interviewer. This information is usually gained during a 30 minutes to one hour interview that may be conducted in person, on the telephone or by computer aided means such as instant messaging. Information collected during the individual interviews will complement that already gained in the contextual interviews by providing further information as well as confirming or denying observations already made.

Participants are selected on the basis of their embodiment of the main features of the intended user group. An interview protocol, with interview questions designed in neutral language, provides focus and structure with the interviewer mindful of applying this flexibly. The interview style and approach can be adjusted to the personality and communication style of the interviewee, making them feel comfortable and engaged in the interview process.

Interview skills in listening, questioning and follow up probes are useful, particularly those aimed at clarification where the individual interview and contextual interview information differs. For instance, how does the level of comfort with ICT observed in the contextual interview correspond with the user's individual interview responses? This is also an opportunity to gain feedback on particular ICT applications and content by asking users to rank or rate these. The granting of permission to tape record and transcribe interviews or to have note takers will ensure that as accurate a record as possible of interview responses is obtained.

Individual interviews can assist in refining the questions to be included in online surveys or they can be conducted following online surveys to provide more detailed information about particular users.

Online Surveys

Online surveys are structured interviews with users recording and submitting their responses online. These surveys generally generate a greater number of responses than individual interviews but often they do not have the same depth of information. Individual interviews can inform the survey questions. Online surveys are readily accessible on the Internet and very user friendly. Data collection is relatively easy and efficient as users record their own responses rating and ranking ICT applications and content.

Information can be collected in online surveys during an initial planning phase to learn more about who users are and what they would like. Alternatively they can be conducted after ICT applications have been designed to seek feedback from users as to whether or not these meet their needs and if they have suggestions for improvement. This latter approach is particularly suited to use of new or innovative ICT that users have limited knowledge or experience of. A further possibility is for the survey to remain active for instant feedback at all stages throughout the design, implementation and evaluation process. This allows for ongoing incremental improvements and suggestions while they are fresh in the mind of users. A series of online surveys may be conducted at significant stages of design.

The design team needs to be clear on the purpose of surveying users. Survey distribution may be a pre-existing website for the organization or another site where users go. If multiple postings are made it is important to consider the possibility of multiple responses from the one user and whether or not this poses a problem. It may give a false idea of numbers of users who have responded, yet a frequent user may a have a lot of good ideas. Issues of how the data will be recorded, stored and managed need to be considered carefully with ethical approval obtained where necessary.

Group e-mails through listservs are useful for making direct requests to users to participate in online surveys. A letter of request sent directly to the user, with an embedded hyperlink opening directly to the survey, provides for an easy and immediate response. The more complicated the task the less likelihood of users participating, particularly if it is voluntary. When designing an online survey it is best to keep it short, with 10 or less questions preferred. Questions might include demographic information about users, prior experiences of ICT and what they would like.

Ease of completion is a central consideration with the survey preferably taking 10 minutes or less to complete. Open questions provide rich qualitative data about users' needs and experiences as well as the terminology they use. Closed questions provide aggregate numbers and can be useful when collecting demographic information and for asking users for rankings or ratings of ICT applications, the data analysis being quicker and easier than responses to open ended questions. Time and resources available for compiling and analyzing data will influence the number and type of questions asked. More detailed information can be gained in a further online survey, individual interview or focus group.

Focus Groups

Focus groups are a commonly used research technique, particularly amongst social work researchers, educators and practitioners. Information is discussed and shared within the focus group about attitudes, needs, concerns and interests with regard to the design and application of the technologies in relation to the specific context of the user group. This provides a deeper understanding of how users engage with the technology and the problems they face. Information is gained about the culture of the group and shared or diverse viewpoints that can trigger more in-depth discussions. It is also an opportunity to gain information on users' responses to ideas and prototypes.

Focus groups usually comprise of between eight and 12 users, or potential users, for the duration of approximately two hours. During this time a moderated discussion occurs on a range of pre-determined topics or themes. Desired learning outcomes of the focus group are identified and used to structure the discussion by writing a script for the moderator to follow with topics to cover and questions to ask. This script is to be applied flexibly so that the discussion flows smoothly and all participants have an opportunity to contribute to the discussions. This may mean that the moderator changes the order of questions or topics covered but ultimately has covered everything during the time allocated for the focus group. This requires a skilled moderator who is able to keep the discussion focused, deciding when further discussion of a topic is needed and when to move on.

Tape recordings of group sessions and one or more note takers are critical for an accurate recording of the focus group discussions. As the focus of the moderator is managing the discussions and intervening when necessary it is not appropriate for this person to also be a note taker, unless this role is shared with a co-facilitator. In co-facilitation the moderators may take it in turns to chair the group and take notes. Reliance on recordings alone can be problematic, particularly in instances when more than one person is talking at the same time due to background noise and difficulty identifying the speaker. A task analysis provides detailed information on how users achieve their goals and the steps involved.

TASK ANALYSIS

Task analysis is useful in identifying the processes and tasks associated with project design to achieve the desired outcomes (Pruitt & Grundin 2003, p.12). As with user analysis this is influenced by psychological, social and cultural factors, as well as the user's physical environment. Prior knowledge and experience will also influence how tasks are approached. The question of what tasks users need to complete using ICT is considered as well as different levels or types of uses. For example, a tertiary student may be paying a university account, conducting library searches or accessing lecture notes and course materials. The specific steps that students follow in undertaking these tasks are examined. This activity may or may not involve use of ICT. The student may go to the library to conduct their research, rely solely on electronic sources or a mixture of both. A task analysis provides information on how this activity is being conducted and the number of steps involved. How users currently perform tasks is examined with consideration of how efficient this. If ICT can assist in producing more efficient outcomes this needs to be considered according to how well these match with users' ways of thinking and working as well as contextual factors.

A task analysis provides information on the tasks and activities that the ICT must support and the scope and nature of these. It will inform decisions on the choices of different technologies for different activities that match users' goals, tasks and the steps involved. These steps will be refined to support users achieving their goals in the most efficient and effective manner. Once the user and task analyses have been completed the persona is designed.

PERSONA

The persona is a hypothetical construct that embodies the main features of the population that the project is being designed for. The persona assists in understanding user information needs informing design and accessibility and ultimately suitability. However, it must not become a replacement for active user involvement. User profiles have been used for some time in marketing with the persona introduced in project design by Alan Cooper in the late 1990s. Cooper's (1999) early work focused on goal directed design by creating fictional personas used as a basis for creating activity scenarios. In later years more detailed personas were developed by using interviews and ethnography to gain a clearer picture and understanding of intended user groups across a much wider range of disciplines (Bloomquist, & Arvola, 2002). Lang (2007) stresses the importance of locating the persona within the relevant discipline and the disjuncture that can often unwittingly occur in beliefs and actual practices across disciplines. Where interdisciplinary differences exist these can be managed and resolved by basing decision making on what is best suited to the needs of the persona (McKay & Martin, 2007). Research conducted by Ronkko (2005) in Sweden cautions against tokenistic and inappropriate use of personas to justify design decisions without proper user consultation as well as problems that can occur when power is used inappropriately within the design team.

For personas to be used effectively a strong commitment is required by all members of the project team. The use of abstract representations to guide design have been used extensively, however often designers do not have a shared view of their intended user group and can fall in to the trap of designing for themselves. Cooper (2004) argues that designing for a persona is better than designing for the designer, or for a vaguely defined user group. Hourihan (2002) warns against the project team designing for themselves and losing sight of the intended user group. She comments, 'We thought we were the primary persona. Like a recovering substance abuser, it's a constant challenge for me to refrain – I can always imagine that I'm the user' (p.3). Use of the persona can create a safeguard against this by developing empathy between the designer and the user. It can also prevent "design creep" by providing a constant reference point for all design decisions. "Constant" is not to be confused with "static" as with all human computer interaction it is the dynamic nature of this interaction that is central to its relevance and currency.

Personas superseded the so-called "elastic users" by replacing them with a real identity that becomes an integral part of the project design process. The persona provides a conduit for transmitting a wide range of information about design and use. Whilst Cooper (2004) was not particularly concerned with the persona being representative of the user group, Grundin & Pruitt (2002) argue that representation of the user group is crucial and that this is the main advantage of using a persona. A persona provides a lens that includes the socio-political context and addresses issues around quality of life and difference. By focusing attention on a particular user group, personas assist in identifying different kinds of users as well as those who are not being designed for.

Designing the right persona or set of personas is particular to the main features of the user group and is time and culture specific. Decisions are often made to create maximum effect with others brought up to speed later, or perhaps left behind. Increasingly in the human services decisions are geared to particular user populations with this seen in targeted media campaigns, particularly for young people such as the "safe sex" campaign using text messages on Valentines Day and World Vision's Teenage Affluenza video on YouTube (Ryan 2008).

Personas were used to assist in the development of Microsoft Windows and MSN Explorer. Both of these products were designed to cater for varied and complex user groups across all generations and cultures. When designing Windows two target audiences were identified by using personas and customer segments. The Window's persona team comprised 22 people including technical writers, graphic designers, usability engineers, product planners and market researchers who developed six personas. A panel of 5,000 users who matched the persona profiles was established and consulted as part of the design team on a regular basis (Pruitt & Grundin, 2003). Like Microsoft, many other organizations including Ford Motor Company, develop and use personas reporting numerous benefits from doing so such as better understanding of users needs, shorter and improved design periods and a superior end product. Similarly, personas aid in educational design for the human services workforce (Martin, McKay, Hawkins & Murthy 2007).

The persona comes to life as a "real person" for whom the project is being designed. Decisions are now being made about a person with a name and identity, albeit hypothetical. Detailed written documentation that succinctly describes the main features of the persona is essential. The level of detail suggested by Freydenson (2002) for a persona includes; 'at least a first and last name, age, goals, background story, a telling quote, e-mail address, job title and a photograph', (p.1). Other features might include: gender, educational background, family, class, health, ability/disability, race, ethnicity and culture, sexuality and spirituality. Cooper (2004) comments, 'All things being equal I will use people of different races, genders, nationalities and colors' (p.3). The persona will change and develop with the project and at times more than one persona may be required, particularly in instances of extreme diversity amongst potential user groups. Freydenson (2002) recommends the development of primary and secondary personas. These personas extend beyond the user to include others such as managers and funding bodies. The main focus is on the primary persona, whilst also being mindful of the needs of secondary personas. Ultimately the primary persona must be satisfied with the system that is delivered, with a common vision and commitment to the persona essential for successful design and implementation. Effective communication is important, particularly with those who may be absent from meetings where the persona is discussed. Creative strategies are required to keep the persona relevant and the focus of activity. It is useful to have something to signify this. This may simply be an empty chair at meetings that represents the presence of the persona in discussions and decision-making.

SCENARIOS

Scenarios are short stories, or narratives, that provide greater detail about users and their particular needs. Depending upon the size and scope of the project, between 10 and 20 of the most common scenarios that depict users and the tasks they need to perform will be written. This keeps the focus on users rather than organizational structures, creating a greater understanding of the content to include in the design and how to best structure this. Scenarios can be created during user analysis. These scenarios can be given to users to follow in usability tests to see if they match their requirements. Three main types are goal based, full scale task and elaborated scenarios (United States Department of Health & Human Services, 2008).

Goal based scenarios include only the activity the user is required to do. An example is a social worker registering a client's name and address on an electronic database. Simple goal based scenarios inform the architecture of the site and content.

Full scale task scenarios support goal based scenarios by including all of the steps involved in achieving a particular goal. This is a technique familiar to workers in the human services using behavior modification programs. Task scenarios can be developed by watching and recording the steps taken by users when performing a task or they can be developed independently by the project team. Most benefits are gained from an approach that is customized to the user group's style of engagement, with the project team adding improvements and efficiencies that sit comfortably with them.

Elaborated scenarios provide greater detail, allowing for deeper understanding of users' level of comfort and skill in using ICT as well as their motivations and possible fears. This more in-depth understanding assists in developing the required content at an appropriate level. For example an elaborated scenario of the goal based scenario might be this social worker not only required to enter basic registration data but to move from a paper based system of client file notes to an electronic one. An elaborated scenario might be:

A social work practitioner with over twenty years experience who uses a computer in her work to access e-mail and write reports. She has been told that the new system will allow for file notes to be sent electronically between agencies. She is not comfortable with the idea of writing personal information about clients on a web site and is particularly concerned about issues of privacy and confidentiality. As a result she has decided that when the new system is introduced she will limit what she puts in her file notes.

An elaborated scenario would include these fears and concerns with strategies developed to address these and avert the possibility of users limiting or modifying the level or type of engagement due to a distrust of the new technologies and how they will be used.

The persona and scenarios are tested, evaluated and further developed by feedback from usability testing with actual, rather than fictitious members of the user group.

USABILITY TESTING

Continuous feedback is obtained by conducting usability tests frequently, particularly early on in the design process. This means problems can be identified early on and are therefore less costly to fix, as well as providing valuable feedback on whether or not the design is achieving its intended outcomes. When conducting usability testing it is important to remember that it is the ICT and its application that is being tested, not the users. Data is collected through observations and user ratings. Five point scales can be used to assess levels of user satisfaction. These tests are generally conducted over a one hour period, with the size of a usability testing group usually between eight to 16 users. This number may vary according to the main characteristics of the user group, with four to six people appropriate for user groups that are fairly homogenous. Smaller groups with varied membership may be used to test particular aspects of a design at different stages of the design process. The staff who have developed the ICT and activities observe and listen carefully, taking notes on user experiences as they follow scenarios to implement the ICT given to them by the project team. This information is used to reflect upon how to improve the design.

It is preferred that usability testing be conducted throughout the design period on a series of proofs and prototypes rather than on a final product only. This requires adequate planning for the allocation of sufficient time and resources. For each round of testing it is important to identify what the specific goals are and to focus on these. For instance, the focus in an early round might be on testing for levels of user comfort, and in a later round on levels of satisfaction. The aim of the test is to determine how well each goal is being met. Typically a usability test is assessing both user performance and preference by collecting data on: usability problems, user performance, task completion, speed, and levels of satisfaction.

Successful, accurate completion of a task in a timely manner is generally considered a more important measurable usability goal than user satisfaction. Results on performance are more reliable than user preference as the latter may be based on levels of comfort, keeping in mind that learning new tasks will generate stress. Low user ratings indicate that the ICT applications need to be improved. However, high ratings do not necessarily mean that problems do not exist. This could be due to the influence of extraneous factors such as users blaming themselves for difficulties encountered, unwanted personal attention and the particular tendency amongst human services workers to be kind to members the project team.

Ultimately the measure of usability is that the application of the ICT allows users to do their tasks in the same amount of time or less, with similar or improved levels of success and satisfaction. No doubt there will be varied needs and experiences amongst members of the user group with the design tailored to meet as many user needs as possible to successfully complete the required task. Ideally the ICT will improve upon other ways users have achieved their goals or they are not likely to embrace them unless they are compelled to do so. If this is the case, ongoing conflict management strategies will need to be employed while further user and task analysis is conducted (Martin & McKay 2007).

The following case study demonstrates the application of the project design stages of user and task analysis, persona and scenario development, and usability testing for the development of a web based resource to assist people recovering from mental illness gain employment.

CASE STUDY: DESIGN OF ELECTRONIC WORK REQUIREMENT AWARENESS PROGRAM (E-WRAP).

Background

Web based resources available for finding work are primarily listings of positions that can be searched according to type of position, location and pay rate. Templates and examples of resumes are available as well as tips for interview. These sites are targeted at the general population and do not address issues of self-esteem, motivation, concentration, discrimination, stigma and perceptual difficulties associated with recovery from severe mental illness and long term unemployment. The World Wide Web Consortium (W3C) standards for web-design and accessibility do not include design features tailored to meet the needs of people recovering from mental illness (W3C, 2005). Instead, these standards concentrate on the machine-dimension of human computer interaction. As such, they focus on web-access protocol development and browser privacy issues. Despite the Web Access Initiative (WAI) there are no web enabled work searching systems designed for people recovering from mental illness (WAI, 2002). e-WRAP was developed to provide a tailor made web based resource to assist people recovering from mental illness gain employment. Project team members were users, carers, practitioners and academics with expertise in the areas of mental health, psychology, social work and information communication technology. The team's first task was user analysis.

User Analysis

Contextual interviews were conducted with people who were recovering from mental illness by observing and discussing the approaches and strategies they used when looking for work. Useful information was gained on work searching strategies and the varied paper and web resources available. Of particular note was the range of web resources accessed designed for the general population and the lack of sites designed specifically for people recovering from mental illness. Valuable information was also gained on type of Internet access and levels of comfort with accessing and navigating these sites, concentration and frustration when using them, as well as the suitability of the content and design features.

Individual interviews were conducted with users as well as experts in the fields of information communication technology, mental health and vocational rehabilitation and employment. These experts were chosen due to their knowledge and experience with the user group. The individual interviews supplemented the contextual interviews with further information provided on web-based employment services designed to provide open, flexible and distributed access for people who may experience difficulty in returning to work after a long absence. An immediate challenge for the project team was to provide evidence of the need for a more specialized web-mediated work searching system designed specifically for people recovering from mental illness if the project was to proceed.

The project team held many focus group meetings with users and experts. An outcome of these meetings was the need to focus on easily accessible information related to employment as well as support and education concerning mental health and well being. This was in order to enhance the self-confidence of people (all age groups) recovering from mental illness who may have been out of work for many years, or have never experienced paid employment. There was general consensus that the design needed to ensure that navigation was kept simple and that a person could take regular breaks and easily return to the site. It was suggested that in order to return to the Login Screen, the user should only need to press a Close button to finish a session. Re-entry should be made possible again by repeating a simple Login procedure. It was suggested that touch screen technology be used to facilitate easy access to information. This meant that the system should function without a keyboard and mouse. The outcome of much discussion with a user focus group, was that the Home Page should welcome the user through an audio greeting that could be toggled to a textual description as an alternative. Key job seeking options were identified during the focus groups.

Electronic Work-finding Requirements Awareness Programme

Welcome to eWRAP - this system provides helpful hints that are useful when looking for work

Task Analysis

A task analysis enabled identification of the processes and tasks associated with the goal of gaining and maintaining suitable employment, as well as promoting and supporting positive mental health and well being. The design was informed by knowledge of the difficulties and frustrations navigating a range of print and electronic work search systems and the absence of any facility designed especially for people recovering from mental illness wanting to re-enter the workforce. Brainstorming assisted in identifying the five key tasks of looking, applying, commencing and keeping work as well as surviving and maintaining motivation and positive self-esteem if unsuccessful. These were developed as the main search menu for site entry and navigation as shown in Figure 1.

Task analysis was used to identify all of the steps involved in each of these activities, informing the development of a persona and scenarios.

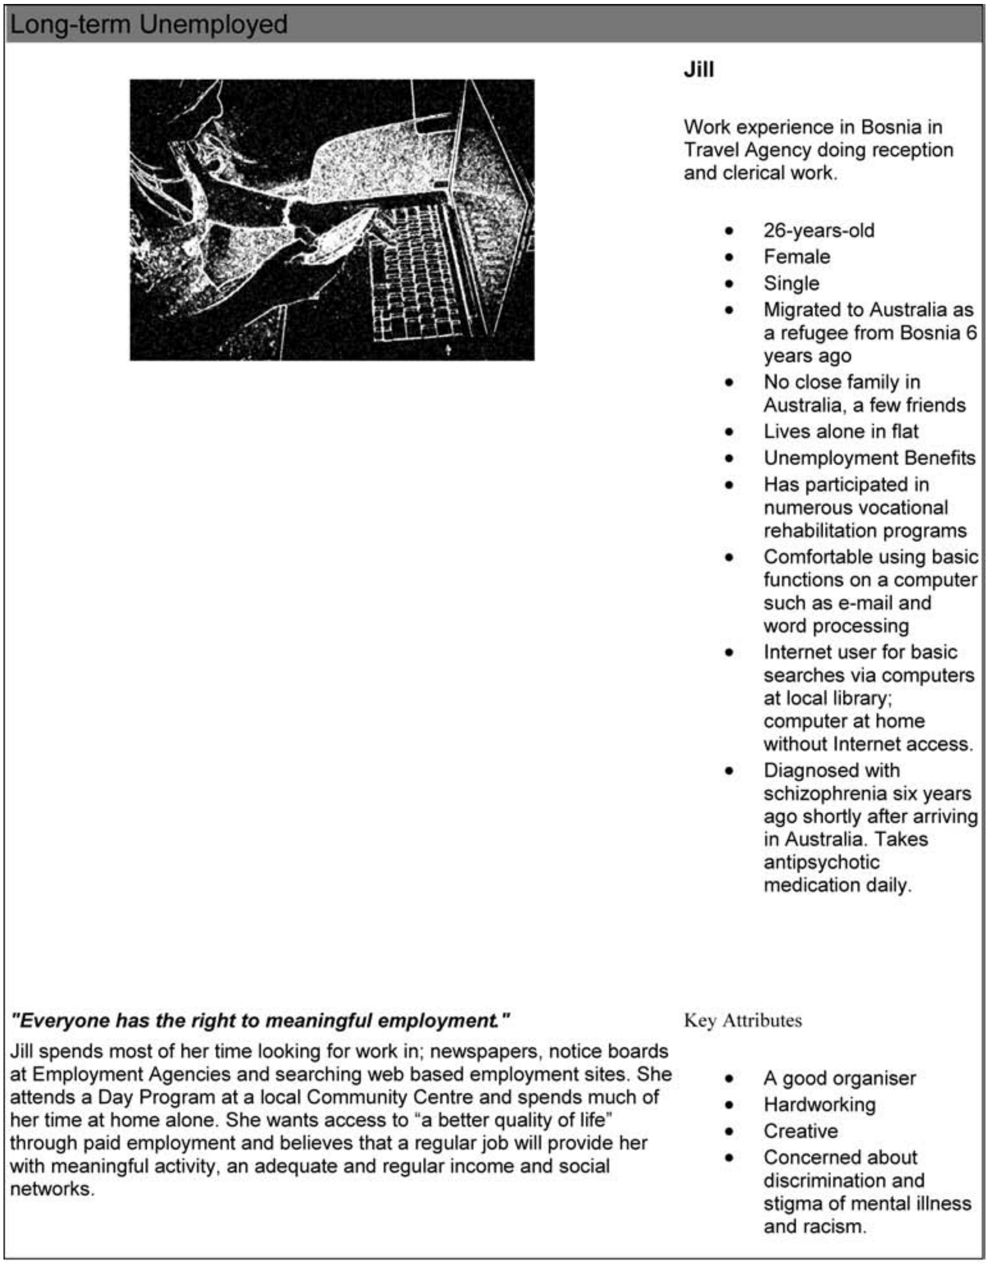
Persona

The personal and disciplinary background of members of the project team member led to divergent interests and priorities. A persona proved useful in providing a focus for the project team to develop a more in-depth and shared understanding of what a potential user might look like. A brainstorming process was used to develop the main features of the persona. A name that could be used for both sexes was originally preferred so as to avoid gender bias in the design. However, it soon became apparent that the persona needed a gender to enable effective communication between team members and to create empathy. Inadvertently team members were referring to the persona as female so this was formalized by naming the persona Jill.

Jill was now the main reference point for all further discussions about the project design and implementation. She came to life with not only by name but also in terms of age, gender family, educational background, health and mental health, employment history, housing, socio-economic status and race ethnicity and culture. This was done in a manner that was respectful in the realization that Jill could not possible represent the diversity of people recovering from mental illness who might be looking at returning to work. Figure 2 provides an example of a brief description of a larger persona developed for Jill.

By including in the "Jill persona" several features of disadvantage, that are not uncommon to people recovering from mental illness seeking employment, the project team was able to cater for a wider range of contingency factors in the scenarios developed.

Figure 2. Persona of Jill



Long-term Unemployed

Jill

Work experience in Bosnia in Travel Agency doing reception and clerical work.

- 26-years-old
- Female
- Single
- Migrated to Australia as a refugee from Bosnia 6 years ago
- No close family in Australia, a few friends
- Lives alone in flat
- Unemployment Benefits
- Has participated in numerous vocational rehabilitation programs
- Comfortable using basic functions on a computer such as e-mail and word processing
- Internet user for basic searches via computers at local library; computer at home without Internet access.
- Diagnosed with schizophrenia six years ago shortly after arriving in Australia. Takes antipsychotic medication daily.

"Everyone has the right to meaningful employment."

Jill spends most of her time looking for work in; newspapers, notice boards at Employment Agencies and searching web based employment sites. She attends a Day Program at a local Community Centre and spends much of her time at home alone. She wants access to "a better quality of life" through paid employment and believes that a regular job will provide her with meaningful activity, an adequate and regular income and social networks.

Key Attributes

- A good organiser
- Hardworking
- Creative
- Concerned about discrimination and stigma of mental illness and racism.

Scenarios

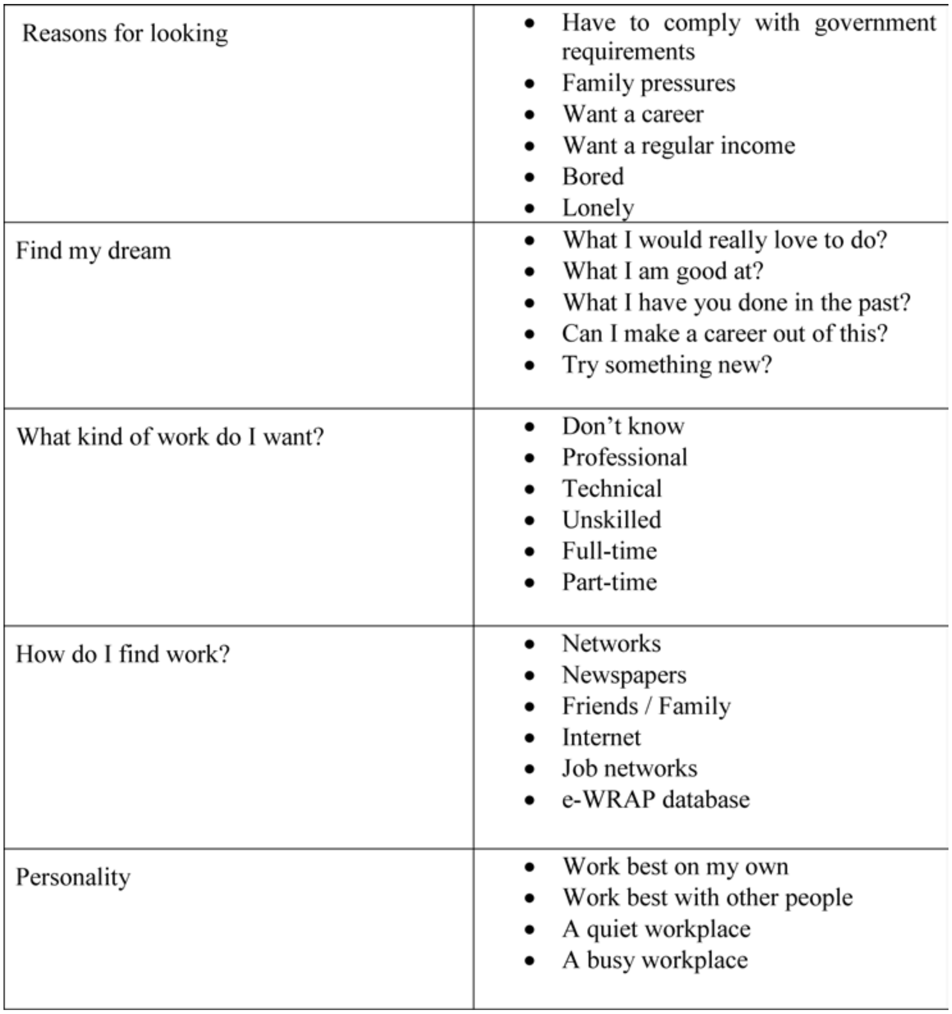
A mapping process assisted in the development of scenarios by identifying Jill's needs, interests and concerns when looking for work and use of ICT. Full scale task scenarios were used to assist Jill achieve particular tasks. For instance, Jill did not have suitable clothes to wear to interviews leading to an additional design feature of information on clothing banks. Elaborated scenarios were written for the five key tasks of "looking, applying, starting, keeping and surviving", identified in the task analysis. A key question was, "What kind of work does Jill want?" with the addition of the search icon "Find My Dream Job" under "Looking For Work." Questions invariably started with "What if?" What if Jill did not want to return to work but simply needed to comply with government requirements to keep government benefits?" "What if Jill wants to pursue a career or perhaps she wants a change of career?" Questions were asked around voluntary work vis-à-vis paid employment and the possibility that Jill might need to pursue further education to gain qualifications in the area she wanted to work in. "Was an adequate income a main priority for Jill?" "What was her level of English – written and spoken?" "How had Jill adjusted with issues of resettlement in Australia and possible trauma?" Care was taken to consider at all of the possible scenarios that Jill may encounter.

When unwell Jill struggled with motivation, had reduced levels of concentration and an increase in paranoid thoughts and auditory hallucinations contributing to lowered self esteem. Technical aspects were designed so as to be responsive to Jill's mental health and issues of motivation and level of perceptual comfort using e-WRAP. This led to the inclusion of design features that meant Jill could log in and out without losing any data stored as well as addressing issues of privacy. These features were consistent with recommendations made by participants in the focus groups during user analysis. The stigma and discrimination Jill experienced both when seeking employment and in general, as well as already lowered self-esteem, led to the inclusion of design features on dealing with knock backs, general health and well-being, self-care and building self-esteem. Low-cost leisure activities were built into the design in recognition of the loneliness and boredom that Jill experienced, also taking into account the difficulty of managing on a low income. What initially began as an employment focused project broadened into quality of life. Figure 3 shows the menu hierarchy designed for "Looking for Work".

Touch screen technology was used to design a computer system that was easy to use and tailored to the needs of people recovering from mental illness considering employment. Main features of e-WRAP were design features that were responsive to the difficulties people using the system may experience in relation to motivation, cognition and perception. Pictures, photos, graphics, video streaming and quizzes were used to add variety and make the design interesting, relevant and fun to use. The graphics and images were designed mindful of Jill's mental state.

The instructional designer worked tirelessly to be responsive to the needs identified for Jill to design appropriate screen chattels. For instance, a simple press of each key option was designed to deliver a sub-level menu. The screen chattels were always on display and included: an orientation button (top of screen), audio/text toggle button, page navigation mechanisms: back button (previous screen), a home page button, and the full menu of key job seeking options displayed along the bottom edge of the screen. This framework presented an intuitive/inquisitive approach to information where the user has complete control over where they may wish to go next. In keeping with the 5-star principles of instruction (Merrill 2003) the prototype offered video on demand (Okamoto, Matsui, Inoue & Cristea 2000). These vignettes showed users everyday activities concerning health and safety issues, preparing for an interview, typical job environments, and

Figure 3. Looking for work



Reasons for looking	• Have to comply with government requirements • Family pressures • Want a career • Want a regular income • Bored • Lonely
Find my dream	• What I would really love to do? • What I am good at? • What I have you done in the past? • Can I make a career out of this? • Try something new?
What kind of work do I want?	• Don't know • Professional • Technical • Unskilled • Full-time • Part-time
How do I find work?	• Networks • Newspapers • Friends / Family • Internet • Job networks • e-WRAP database
Personality	• Work best on my own • Work best with other people • A quiet workplace • A busy workplace

benefits of socializing at work. Four categories of work were offered; professional, community, health and education, and trades and services. Video On Demand buttons were located beneath each category. The focal point of the prototype was the interactive job selection module with a comprehensive employment knowledge system including job vacancy listings and specific position descriptions (McKay & Martin, 2007).

Usability Testing

A pilot study of e-WRAP was executed over a four month period. Arrangements were made with users to test system components as they were finished progressively. Specific goals were set at each stage of testing to assess; usability problems, user performance in terms of navigation, successful completion of tasks, speed and levels of satisfaction. Preliminary qualitative feedback, including that of several people who were not regular users of computers, was very positive. They found the system easy to use and a helpful resource and were able to relate to the characters in the various Video On Demand vignettes. The prototype was launched at a Mental Health Conference run by the psychiatric disability support sector. This conference attracts a large number of consumers and carers as well as service providers in vocational rehabilitation. A display was set up in the foyer with people able to use e-WRAP at their leisure. Members of the project team were able to observe how people used the navigation system as well as seeking informal and formal feedback. Participants who identified themselves as users, carers, workers, students or academics were asked to complete a short questionnaire on the usefulness and functionality of e-WRAP. Both quantitative and qualitative data was collected on degree of comfort, ease of use, areas for improvement with specific feedback sought on use of video on demand, employer data bases and types of jobs. Respondents were asked what they liked the most about e-WRAP and what they liked the least. Five point rating scales were used to assess levels of satisfaction. Users were asked where they would prefer e-WRAP to be located to ascertain where people would like to access this resource and ultimately whether or not they would use e-WRAP themselves or recommend it to family or friends recovering from mental illness seeking employment.

Observations at the trials and Conference, combined with informal and formal feedback, indicated that users were able to complete tasks with ease and success as well as having high levels of satisfaction. The project team was mindful of the importance of the successful completion of tasks in a timely manner as more significant than reported user satisfaction. Participants acknowledged that whilst there are numerous work search systems available none of these are tailored specifically to the needs of people recovering from mental illness and that e-WRAP is a much needed and welcome resource to assist people recovering from mental illness to achieve their vocational goals. All respondents commented favorably about e-WRAP and supported the idea of developing a live version that included data bases of employers as well as links to all of the other databases indicated as links on the proto-type.

CONCLUSION

As illustrated in the case scenario of e-WRAP, developing useful and usable Information Communication Technologies for the human services requires in-depth knowledge and understanding of the intended user group. Techniques for user analysis include contextual interviews, individual interviews, online surveys and focus groups. Contextual interviews provide essential information on the intended user group through careful listening and observations of users while they are engaged with the technologies. Individual interviews, online surveys and focus groups allow for more in-depth understanding of users attitudes, beliefs, fears and concerns and the degree to which these are shared amongst members of the user group. Task analysis assists in identifying the processes and tasks associated with project design to achieve the desired outcomes focusing on how users achieve their goals and the steps involved in doing so. Personas aid the design of suitable ICTs by providing a constant reference point for all design decisions on a hypothetical user that embodies the main features of the intended user population. Scenarios based on personas provide greater detail about users' goals and associated tasks, needs and levels of comfort with ICTs. Usability testing throughout all stages of the design process assists in assessing both user performance and preference as data is collected on navigation, successful completion of tasks, speed and levels of satisfaction. This design process facilitates in the development and application of information communication technologies that are relevant for the human services. Social workers are encouraged to embrace new technologies to improve service provision and enhance quality of life without compromising ethical standards of practice pertaining to client confidentiality, privacy and client self-determination.

Chapter 2.13

Enhancing ‘Fit’ of Health Information Systems Design Through Practice Support

Craig E. Kuziemsky
University of Ottawa, Canada

ABSTRACT

The design and implementation of healthcare information systems (HIS) is problematic as many HIS projects do not achieve the desired outcomes. There exist a number of theories to enhance our ability to successfully develop HIS. Examples of such theories include ‘fit’ and the sociotechnical approach. However, there are few empirical studies that illustrate how to understand and operationalize such theories at the empirical level needed for HIS design. This chapter introduces a practice support framework that bridges the gap between the theoretical and empirical aspects of HIS design by identifying specific process and information practice supports that need to be considered to actively produce fit of an HIS within a healthcare setting. The chapter also provides an empirical case study of how practice support was used to develop a computer based tool in the domain area of palliative care severe pain management.

DOI: 10.4018/978-1-59904-792-8.ch003

INTRODUCTION

The design and implementation of healthcare information systems (HIS) is problematic as many HIS projects do not achieve the desired outcomes. It has been reported that up to 30-50 percent of implemented HIS fail (Anderson, Aydin, & Jay, 1994) and in fact we may not know the true rate of failure of HIS due to the disincentives to publish about failures (Pratt, Reddy, & McDonald, 2004). Part of the problem is that a HIS needs to reconcile the complexity of both a healthcare domain area and an information system. Introducing a technical artifact such as a HIS will impact workflow, communication and other clinical tasks. Having some understanding about user requirements to achieve those clinical tasks will enhance our ability to design and implement HIS that meet user needs.

The concept of ‘fit’ refers to the need to establish fit between HIS and the organizational context where it is being implemented. ‘Fit’ was first introduced by Southon, Sauer and Dampney (1997) and further described by Kaplan (2001). Aarts, Dooreward, and Berg (2004) suggest that fit is not a passive process but rather needs to be actively produced between the HIS and organization where the HIS is being implemented. Although the citations on 'Fit' have acknowledged its importance to HIS design there are few empirical studies that illustrate how to understand and operationalize fit at the detailed level needed for HIS design. Fit requires methodological rigor through qualitative research methods for understanding how HIS implementation impacts healthcare settings and for actively constructing fit between a HIS and a healthcare setting. However, the range of analysis that is possible in qualitative studies can be an obstacle as it can be difficult to determine how to study a healthcare setting to establish fit.

This chapter extends existing research on 'fit' by introducing a framework called practice support. Practice support refers to the need to understand all perspectives of how a HIS will impact healthcare providers when implemented in a healthcare setting. The chapter will describe existing theories and models related to fit of HIS and outline some of the limitations in the theories and models. It will then introduce the practice support framework and methodology, and provide a case study illustrating how the practice support framework was used to construct fit of a computer-based tool for palliative care severe pain management.

BACKGROUND

Theories and Models Related to 'Fit' of HIS

There exist a number of theories and models to explain the fit of HIS with healthcare providers and settings.

Berg describes the sociotechnical approach, which refers to increasing our understanding of how information systems or other communication techniques are developed, introduced and become a part of social practices (Berg, 1999). Sociotechnical approaches emphasize the interrelation between information systems and the social environment where they are used (Berg, Aaarts, & van der Lei, 2003). HIS design from a sociotechnical perspective is about finding the synergy between the particularities of healthcare and information and communication technologies (Berg, 2003). The sociotechnical approach is also about designing interactions between users and technology such as interfaces and information retrieval not from the view of the technology but rather from the view of the agents that work with the technology and the work practices where the technology is embedded (Coeira, 2003). However Berg, Aarts, and van der Lei (2003) subsequently point out that there is no actual sociotechnical per se, but rather it has many roots including methods such as participatory design and fields such as computer supported collaborative work.

The concept of 'fit,' which refers to the need to establish fit between the HIS and the organizational context where it is being implemented, has been discussed by Southon, Sauer, and Dampney (1997) and Kaplan (2001). Kaplan (2001) summarizes studies about fit that identify a number of dimensions as being part of fit including clinical workflow (Kaplan, 1995; Safran, Jones, Rind et al., 1998; Sicotte, Lehoux, & Denis, 1998), healthcare providers level of expertise (Sicotte et al., 1998), organizational setting and cultures (Kaplan, 1988; Massaro, 1993), communication patterns (Aydin, 1994) and cognitive processes (Patel, Allen, Arocha, & Shortliffe, 1998). An important consideration is that Aarts et al. (2004) suggest that establishing fit is not a passive process but rather fit needs to be actively produced between the technology and the practice where the technology is being implemented.

As the HIS discipline has evolved so has the appreciation for conducting studies within an interpretative framework. Interpretative studies have shown to be valuable for "producing an understanding of the context of the information system, and the process whereby the information system influences and is influenced by the context" (Walsham 1993, pp. 4-5). Interpretive research does not predefine dependent and independent variables, but focuses on the full complexity of human sense making as the situation emerges (Kaplan & Maxwell, 1994).

Although quantitative methods have historically been the predominant methods used to capture data for HIS design and evaluation the limitations of relying solely on quantitative methods has been shown. Qualitative research methods are valuable for studying how HIS intersect with healthcare providers and for providing answers to the how and why questions about HIS usage that quantitative methods cannot provide (Ash & Berg, 2003). Kaplan and Duchon (1998) conducted a joint qualitative-quantitative evaluation of a laboratory information system and advocate using mixed methods because qualitative-based interviews, observations, and open-ended questions revealed a number of significant human and contextual findings about the system that were not identified through a quantitative based survey.

Models also exist from the behavioral science and management information systems (MIS) disciplines and such models have been applied to HIS research. Examples of such models include the technology acceptance model (TAM) from the behavioral sciences and DeLone and McLean's information system (IS) success model from the MIS discipline. TAM purports that user behavior with technology is dependant on intention to use technology, which is derived from the attitude towards usage, perceived ease of use and perceived usefulness of the technology (Kukafka et al., 2003). In healthcare, Chismar and Wiley-Patton (2002) used TAM to study internet and information technology usage in pediatric care. DeLone and McLean's IS success model, which was originally published in 1992 and revised in 2003, contains six concepts used to measure IS success (DeLone & McLean, 1992, 2003). The six concepts are system quality, information quality, service quality, user satisfaction, intention to use and net benefits. DeLone and McLean's IS model has been applied in healthcare for telehealth evaluation (Hebert, 2001).

How to Operationalize 'Fit'?

The previous section advocated the need for fit and sociotechnical based approaches for understanding the social, behavioral and human contexts of HIS usage but there is a gap between such approaches and the means of operationalizing them. Empirical details are needed about the elements that comprise fit in order to inform HIS design. As stated in the previous section there is no actual sociotechnical approach but rather it is a combination of methods, frameworks and theories to support an understanding of the social and technical aspects of HIS implementation. Further, fit was defined as a concept that needs to be actively produced in each unique healthcare setting as opposed to a cookbook approach that applies to multiple settings.

The need to embrace qualitative methods and interpretative approaches is critical to studying and understanding the context of how HIS are developed and used in specific clinical settings. However, a challenge lies in how to apply qualitative methods to understand and establish fit. Qualitative research methods, particularly interpretative studies, provide a wide range of opportunities to study and analyze healthcare settings. Combine that with the complexity and unstable nature of healthcare and it can be difficult to determine what factors to consider for establishing fit. The literature in the previous section identified a number of studies that provided multiple dimensions of fit and those dimensions are certainly not exhaustive of the dimensions of fit. It would enhance our ability to establish fit if there was a methodological approach to studying fit coupled with a framework for understanding fit of an HIS within a healthcare setting.

Models such as TAM and DeLone and McLean's IS success model have value for understanding HIS usage but there are two shortcomings to such models. First, much of the application of these models has been to evaluate HIS usage with less research being conducted to identify critical factors for HIS design. Outcome based studies often do not provide sufficient detail about the processes that lead to the outcomes. It would be more useful to open up the black box outcome concepts into specific variables that can be used to inform subsequent HIS design revisions. DeLone and McLean's IS success model uses information quality as one outcome measure but how do we define information quality with respect to HIS design? Second, models such as TAM and DeLone and McLean's IS success model are from the general IS domain and thus they are intended for use in multiple settings. Therefore there is the need to operationalize the models for use in healthcare settings. Concepts such as perceived usefulness from TAM or intent to use a system from DeLone and McLean's model are both very broad and need to be articulated in the context of healthcare delivery.

CASE STUDY

A case study will be used as the basis for the remainder of the chapter. The case study will introduce the domain of palliative care severe pain management (SPM) and the desire for a computer based SPM tool. It will then describe the research methods and data sources used in the study. The practice support concept and framework will be presented as a means of understanding 'fit' of a healthcare setting. An empirical example will then be illustrated of how practice support was used to design a computer based SPM tool.

Palliative care is care provided to patients with terminal illness when curative therapy is not an option. Palliative care has only been established as a formal discipline of medicine since the 1960s and is still an emerging field. However as our population ages and people live longer with chronic illnesses the need for palliative services will increase. A central aspect of palliative care is relief of symptoms, particularly pain. Severe pain is pain scored as 8, 9, or 10 on a 10 point numeric rating scale. When a patient reports severe pain they are saying they have the worst pain imaginable and thus prompt interventions are required. However, pain is a complex entity that has physical, psychosocial and spiritual dimensions and an episode of severe pain needs to be understood in the context of all of those dimensions. Further, using an inappropriate intervention for pain can cause undesirable side effects, which can actually make the pain worse.

To enhance our understanding of severe pain management (SPM) a group of palliative care providers developed a paper based severe pain tool called clinically applied pain information tool (CAPIT). CAPIT contains 11 categories that outline why a patient may report severe pain and each category contains a listing of signs, symptoms, interpretations and strategies for relief (Downing, 2006). CAPIT also contains a set of fundamental considerations to understand the unique aspects of pain for each individual including impact of disease trajectory and ethical and cultural elements of pain. The palliative care providers who developed the paper based CAPIT also wanted a computer-based SPM tool as they recognized that the paper based CAPIT was limited in functionality. The need for a comprehensive understanding of the SPM domain suitable for design of the computer based SPM tool was the motivation for this study.

A METHOD FOR UNDERSTANDING 'FIT'

Understanding fit requires a methodological approach to understanding the processes that take place in a healthcare setting, the users who conduct the processes and the information required to support those processes. A grounded theory-participatory design (GT-PD) hybrid approach was conceived for understanding the processes that take place in a healthcare setting and the information required to support those processes (Kuziemsky, 2007). The hybrid approach was chosen to provide a means of capturing user requirements through PD and then analyzing and developing theory from the user requirements through GT. The goal of PD is not only to design a product but rather to ensure the usability and utility of the product by engaging end users in design (Shrader, Williams, Lachance-Whitcomb et al., 2001).The extensive user involvement of PD allowed interaction between the palliative care providers to get different perspectives on how severe pain is managed and what support is needed in different situations to assist with SPM.

The data obtained through PD was coded using principles of GT in order to establish concepts and categories that became the practice support requirements. GT is a means of developing theory through coding of empirical data. The hallmark of GT is three coding cycles: open, axial and selective coding (Straus & Corbin, 1998). Open coding establishes concepts and categories from the data which are connected in axial coding based on similarities. Selective coding involves final refinement of the multiple concepts and categories that emerge from axial coding. The resulting analysis is both rich and concise as it emerges from multiple coding cycles.

The GT-PD approach draws out the strength of both methods. PD provides the means of user engagement to obtain a rich perspective on clinical practice and how HIS need to be designed to support such practice. GT develops concepts and categories from the data to develop empirically based understanding about the data. The GT-PD approach emphasizes the methodological approach of capturing and understanding both the content and context of the data that is being used.

Data Sources for Understanding Fit

Three data sources were used with the GT-PD approach to understand fit: practice experience, patient charts and research literature. Each is described below.

- **Practice experience:** Consists of two sources. First is 150 hours of meetings with 12 palliative care providers (three physicians, three nurses and three counselors) to discuss and model how severe pain gets managed. The second source is clinical observations where a researcher spent 40 hours doing qualitative observation and documentation of pain management on the clinical ward of a 17-bed inpatient hospice.
- **Patient charts:** A chart audit was done of 88 retrospective patient cases with at least one severe pain episode. Data collected included medical data (such as current and past disease), severe pain episode (such as onset, duration, location, quality) and interventions (both pharmacological and non-pharmacological).
- **Research literature:** A literature search was done on severe pain in palliative care as well as general pain management. 30 relevant pieces of literature brought in current evidence on severe pain management such as randomized controlled trials on medication, conceptual models on pain management and educational resources on assessment, diagnosis and management of different types of pain. The screening and identification of relevant literature was done by the palliative care providers.

The three data sources were used to provide different perspectives of fit from the view of different palliative care providers (physicians, nurses, and counselors) and also to allow cross validation of the data. It was possible to compare what providers described in meetings with what was observed in day to day practice on the clinical ward. Research literature was used to identify opportunities for incorporating literature into practice settings as a means of knowledge translation of research findings. Patient charts provided information on how patient cases are charted and communicated across different providers, and the vocabulary that is used in charting. Patient charts also provided a baseline for how data is currently charted and communicated around patient cases, which allows comparison with the level of data collection desired through practice experience meetings.

Practice Support

The practice support concept is based on the principle that a HIS is often designed to support a specific clinical task (i.e., decision support or physician order entry). However, in the context of clinical practice it stands to reason the task does not occur in isolation but rather it will interact with other processes both before and after its completion. A clinical decision support system (CDSS) can help establish a diagnosis but it will require patient data to be collected both before and after the diagnosis has been made. Further, once a CDSS helps establish a diagnosis there will usually be clinical tasks such as treatment and follow up care that need to be provided. Practice support also considers issues related to different contexts of HIS use such as levels of clinical expertise, needs of different types of healthcare providers (i.e., physician or nurse) and location of care delivery (i.e., acute care centre or community based care).

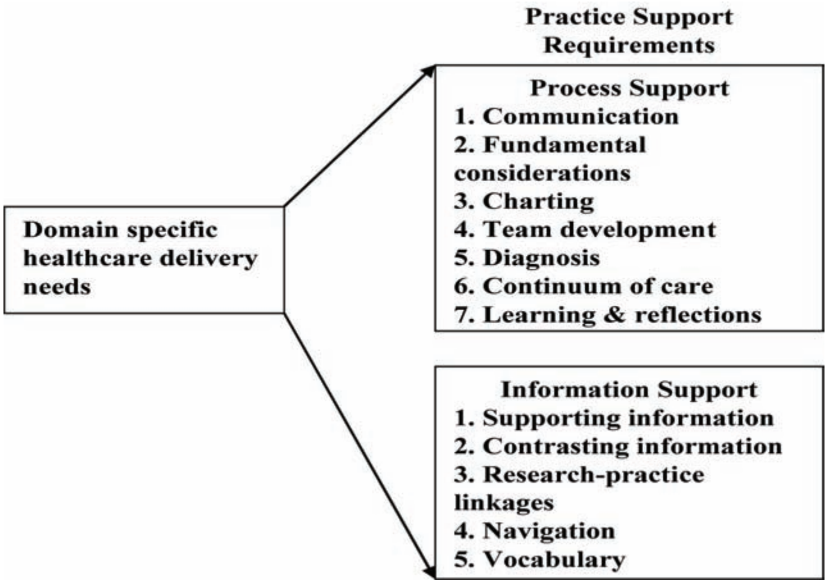
The practice support framework is the summation of the results of applying the GT-PD approach to the three data sources to actively construct fit of the computer-based SPM tool. The data acquired through PD were used to develop concepts and codes through GT. As the coding became more refined and relationships were established between the codes a set of core codes were identified that became the practice support framework for HIS design. The practice support framework is not meant to be another model that explains the fit of healthcare providers and HIS usage, but rather it is meant to operationalize the use of theories such as fit and the sociotechnical approach by providing empirical approaches to those theories. Practice support also provides the means to operationalize some of the models described in the review section. The information quality concept in the DeLone and McLean IS success model is operationalized through the practice support framework by providing specific details on the different types of information support needed for HIS design.

HIS Practice Support Framework

Figure 1 shows the HIS practice support framework. The practice support framework has two sections to it, the domain specific healthcare delivery needs shown on the left side of figure 1 and the practice support requirements shown on the right side of Figure 1. The practice support requirements were categorized into two types: process and information support. The rationale for the two categories is that in order to provide practice support for healthcare providers we not only need to define the processes that are done, the information needed and the relationships between the processes and information. Identifying a process done as part of clinical practice (i.e., a diagnosis) without the necessary information to support that process (i.e., supporting and contrasting information to support different types of diagnoses) will not provide the necessary practice support for a given clinical task.

The process and information supports from the practice support framework are described in the following two sections.

Figure 1. Practice support framework for HIS design



Process Supports

Seven process supports were identified. The seven process supports are listed out in the following.

1. **Communication:** Effective communication needs to be promoted between all healthcare providers such as between physicians and nurses or between multiple nurses during shift change. Communication is also needed to support the ongoing care of a patient given that different providers may take part in patient care and care may take place in multiple settings.
2. **Fundamental considerations:** Cultural, social and ethical factors need be considered with respect to the patients receiving care as well as the healthcare providers and setting where a HIS is being used. Edwards and Roelofs (2006) showed that the domain of healthcare organizations, which included communication and monitoring and reporting mechanisms, varied across cultures and countries.
3. **Charting:** HIS need to ensure that all requisite data is charted about a patient case to facilitate other processes. Diagnoses, communication, team development and continuum of care all depend on requisite data being available.
4. **Team development:** As more patient care is provided from an interdisciplinary team perspective HIS will need to promote team development and team practices.
5. **Diagnosis:** Different types of diagnostic processes are used in healthcare and the different processes require different support. The identification of reasoning strategies used by clinicians may be critical to the optimal design of CDSS (Arocha, Wang, & Patel, 2005).
6. **Learning and reflections:** The level of expertise between users of an HIS will vary. Because of the ability of an HIS to store and retrieve information it can be used as a teaching tool for students and new staff to learn about processes such as diagnosis or team development. HIS can also support reflective practice, which is how *individual*

professionals address uncertain and non-routine, yet repetitive, problems in practice. Reflective practice has been described as a vehicle for learning by intertwining practice and theory (Schon, 1983).

7. **Continuum of care:** Healthcare delivery is not a one time occurrence and continuous communication and monitoring of patient cases are needed to support ongoing patient care. Once a patient has a diagnosis confirmed by a CDSS they may receive treatment or require diagnostic tests that will require follow-up.

The key aspect for each of the processes for practice support is to understand how the functionality of an HIS can implement the processes. Reflective practice is encouraged as a means of helping healthcare providers improve their practice. However, because reflective practice is removed from routine day to day clinical tasks such as charting and provision of medications, it is not something healthcare providers routinely think of doing. Using HIS to provide the means of doing reflective practice one computer screen away from the charting screen is a way of incorporating and encouraging reflective practice as part of routine practice.

Information Support

The second part of the practice support framework provides specific details on the types of information that can be structured in an HIS to support different elements of practice. The information support is broken down into five specific categories.

1. **Supporting information:** Supporting information provides a 'show me how' or 'help me do this' functionality. Waitman and Miller (2004) emphasize that healthcare providers often take a 'show me' stance with respect to CDSS and therefore want both a recommended intervention and detailed steps involved in its implementation.
2. **Contrasting information:** Contrasting information is used to provide information to support diagnostic processes where more than one option exists. A patient may have signs or symptoms present in two or more disease conditions and contrasting information provides a 'show me why' functionality for differentiating the diagnostic options.
3. **Navigation:** As HIS get more complex and make available more information so must our ability to provide guidance for using such information. Part of the fit of information is navigation that provides the right information at the right time as well as ensuring that screens and interfaces have a flow that fits with the practice setting where the HIS is being used.
4. **Common vocabulary:** Part of interdisciplinary care is promoting common vocabulary between different health care providers. Healthcare providers all have their own vocabularies and if HIS are to facilitate interdisciplinary practices then the vocabulary must be acceptable to all providers.
5. **Research/practice linkages:** Because HIS have the ability to store and retrieve information they can be used to promote research-practice linkages as a means of knowledge translation.

APPLICATION OF THE PRACTICE SUPPORT FRAMEWORK TO PALLIATIVE SPM

A specific example of how the practice support framework was used to operationalize fit will be illustrated using the case example of the computer based SPM tool. The sections below illustrate how fit was established for each of the process and information supports from the practice support framework.

Charting and Communication Processes

While collecting the design requirements for the computer-based SPM tool the charting and communication processes were identified as crucial processes for nursing practice. The paper-based CAPIT is a comprehensive knowledge base of palliative SPM and acts as a reference about different etiologies of severe pain. However the paper based CAPIT is not specific to any patient. At the first practice experience meeting with nurses they very adamantly questioned how a computer-based SPM tool would help them if they had a patient in severe pain? Nurses felt the lack of specificity of the paper based CAPIT to a patient case takes away from its utility as nurses do a large amount of the patient charting. Nurses would be more likely to use the computer tool if it could be made specific for a patient by enabling a patient case to be charted. Nurses did not want to use a computer tool to view details about severe pain and then have to go to another application (either paper or computer-based) to chart the patient case. The computer-based SPM tool would provide practice support if they could view the information from the computer based tool and then develop and chart the patient's case directly in the computer based SPM tool.

Further emphasis of the importance of fit between the charting and communication processes was described as nurses stated that it is not uncommon for a patient to have more than one type of severe pain and each type will have its own clinical details such as signs and symptoms. However, the nurses also said that all requisite information about a patient case does not always get effectively communicated across different palliative care providers, which can adversely affect patient care. The charting component of HIS design should not be just an afterthought as charting provides the data that feeds the communication processes around patient care. It is critical to understand the intricate details of patient cases to ensure appropriate charting is supported and to use reminders to ensure charting is actually completed.

Continuum of Care Process

Another process that was identified by physicians and nurses was continuum of care, which is the ability to support ongoing care for a patient. It was pointed out that palliative SPM is not a one time event and often takes place over hours, days, and even weeks. Further, many of the management strategies such as supporting counseling, screening for clinical depression or reduction of neuropathic pain can take days to complete and it is important that such strategies are followed up to monitor their effectiveness. The initial design of the computer tool was a 'one shot' process where a patient case was developed and not revisable unless all the data was reentered. However that 'one shot' functionality would not fit with the context of palliative practice given the ongoing nature of care. Once the computer tool is used to help assess, diagnosis, and recommend a management strategy for a patient's pain there will be follow up care that needs to be monitored. The ability to add progress notes to a previously developed case was devised as a solution to enable continuum of care to be supported.

Team Development Process

Another key process of SPM is team practices. Much of palliative care is done in the context of an interdisciplinary team consisting of two or more types of palliative care providers. Part of the team development process is ensuring that the vocabulary for information used in the computer based SPM tool is appropriate for the different types of healthcare providers (physicians, nurses, and counselors) that will be using the tool. Team development is more complex in instances where an interdisciplinary team is not co-located such as a remote area where there is only a family physician or homecare nurse. In such situations it is important that healthcare providers do not ignore the need to think from an interdisciplinary perspective. Therefore, practice support information resources should be made available to help a palliative care provider consider a team perspective when no team is available. One means of doing that is to have links to websites that offer both information resources about team functionality and in some cases real time interactions such as messaging with other healthcare providers to act as a virtual team. In essence the computer tool becomes the team when no team is available.

Diagnostic Process

In the practice support framework it was described that the fit of the diagnostic processes are important for acceptance of an HIS. The GT-PD approach was helpful for obtaining depth of detail about the diagnostic reasoning support needed in palliative SPM. One of the concepts in the paper based CAPIT is an 'interpretation.' When palliative care providers were queried as to what an interpretation consists of it was articulated that it is two types of diagnostic reasoning, a differential diagnosis and a provisional diagnosis. A provisional diagnosis is when a palliative care provider is relatively sure of the category of severe pain the patient is experiencing but they need some additional information to confirm the diagnosis. A differential diagnosis is when a sign or symptom is present in multiple categories of severe pain and the care provider needs help determining the correct category. Therefore provisional diagnostic reasoning needs to go top down, from an etiology to an explanation of signs and symptoms whereas differential diagnostic reasoning needs to go bottom up, from signs and symptoms to an etiology of severe pain. Those two types of diagnostic reasoning also dictate how information support needs to be structured. Supporting information provides depth for drilling down about a concept (during a provisional diagnosis) whereas contrasting information provides breadth to support decision making across different options (during a differential diagnosis).

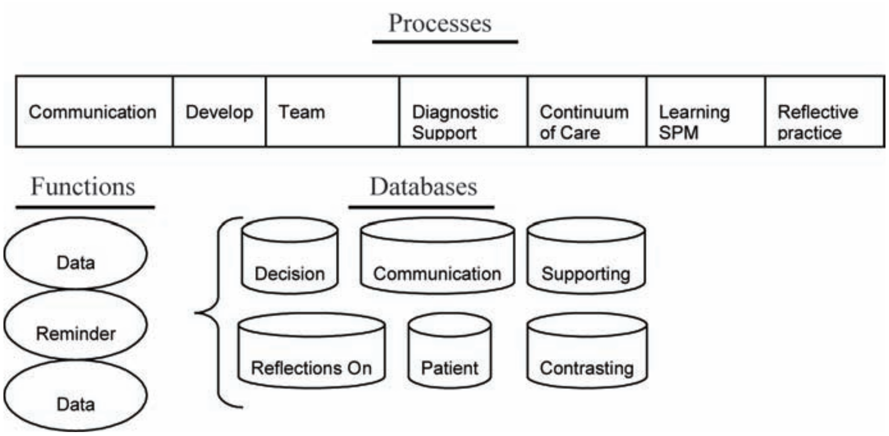
Learning and Reflection Process

Although the computer based SPM tool was designed to support specific aspects of palliative care (assessment, diagnosis, and management) during the GT-PD sessions palliative care providers described how some of the knowledge needed for SPM comes from general pain management and palliative care knowledge that is not contained in the paper based CAPIT. If a student or junior clinician is using the computer tool they may not have the background knowledge about pain or palliative care and thus would need access to educational resources. Supporting information about pain and palliative care needs to be made available.

Fundamental Consideration Process

One issue with designing a HIS is that it may be looked at as mitigating the human factor of patient care. To emphasize the importance of the human factor one practice support process is fundamental considerations. Fundamental considerations draw attention to factors such as the social and cultural issues of HIS usage. When the concept of the computer-based SPM tool was first discussed there was concern, particularly from the counseling staff, that the computer tool may slot a patient into a physical etiology of pain while ignoring the psychosocial dimensions of care. Palliative care is a branch of medicine that emphasizes all dimensions of care including physical, psychosocial, and spiritual dimensions and for a computer tool to be accepted in palliative practice it needs to represent all those dimensions. A number of specific fundamental considerations were derived that need to be considered as part of palliative care delivery. Those fundamental considerations include disease trajectory (i.e., how sick the patient

Figure 2. Architectural diagram of computer-based SPM tool



is), cultural and ethnical aspects of care such as how pain perception and subsequent treatments may differ across cultures and ethnicities, and the context and meaning of both the illness and the severe pain based on the individual uniqueness of each patient. Alerts and checklists were devised as part of the computer tool to ensure the fundamental considerations are incorporated and charted as part of a patient's case.

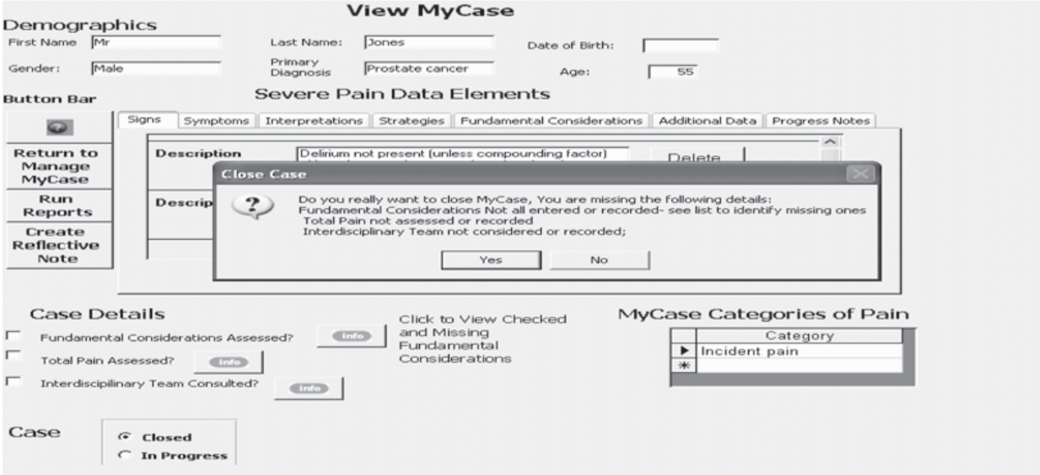
Systems Design and Implementation of Computer-Based SPM Tool

Following the capture of all the requirements of fit for the computer-based SPM tool an architectural diagram was developed for the tool. The architectural diagram is based on the practice support requirements for SPM that were detailed in the previous section. Figure 2 shows the architectural diagram consisting of three sections: processes, functions and databases.

The information practice support requirements were used to design the database tables. The functionality of the computer-based SPM tool is achieved through the data query, data entry and reminder functions. For example there are database tables to store supporting and contrasting information, which can retrieved through a data query. There are also database tables to store patient cases, which can be developed via data entry functions or retrieved and viewed through a data query function. During data entry there are reminders to ensure that requisite data is collected about a patient case and to ensure the fundamental considerations such as cultural elements of care are assessed and charted.

Figure 3 shows the physical implementation of the computer-based SPM tool. The processes and functions from the architectural diagram became the screens of the computer-based SPM tool to allow the entry and query of information. Figure 3 shows the data entry functionality that illustrates many of the practice support requirements that were described in the previous section. Figure 3 shows how specific patient cases can be entered including progress notes for continuum of care and checkboxes for completion of assessments on interdisciplinary teams and the fundamental considerations. There are 'info' buttons next to the interdisciplinary team and fundamental consideration checkboxes in case the palliative care provider needs supporting information about those concepts. Figure 3 also shows a reminder box pointing out that some requisite data has not been charted, which was identified by palliative care providers as a requirement needed to support the communication process.

Figure 3. Screen shot of computer-based SPM tool



First Name: Mr
Last Name: Jones
Date of Birth:
Gender: Male
Primary Diagnosis: Prostate cancer
Age: 55

Description: Delirium not present (unless compounding factor)

Do you really want to close MyCase, You are missing the following details:
Fundamental Considerations Not all entered or recorded- see list to identify missing ones
Total Pain not assessed or recorded
Interdisciplinary Team not considered or recorded;

☐ Fundamental Considerations Assessed?
☐ Total Pain Assessed?
☐ Interdisciplinary Team Consulted?

	Category
▶	Incident pain
*	

Case
● Closed
○ In Progress

The other practice support requirements such as provisional and differential diagnostic support, the ability to engage in learning and reflective practice about palliative SPM and real time interdisciplinary team support are available through other screens of the computer-based SPM tool.

DISCUSSION

This chapter has presented a practice support framework and a methodological approach for establishing fit of a HIS. The practice support framework identified seven process supports and five information supports that should be considered as part of establishing fit of an HIS in a healthcare setting. The chapter also provided a case study illustrating how the practice support framework was used to operationalize fit in order to design a computer-based SPM tool.

The practice support framework is meant to extend existing theories and models by providing the means to operationalize them. Theories such as the sociotechnical approach or fit, and models such as the technology acceptance model are valuable for understanding fit of an HIS, but because clinical practice takes place at an empirical level we need the means of understanding the fit of a HIS in its practical usage. The practice support framework bridges the gap between theoretical and empirical by identifying specific process and information supports that need to be considered to actively produce fit of an HIS within a healthcare setting.

The practice support framework and other research on human and social issues described in this textbook have implications for students and systems designers of HIS. Education implications include illustrating the scope of practice support that is needed in an HIS as well as the need to educate healthcare providers to engage critically in the design of HIS. In the past, the design and implementation of HIS have often been portrayed as two different processes where design takes place in a laboratory and implementation takes place in a healthcare setting. Separating design and implementation leads to issues of weakened communication, lack of reflection and inability to track the continuum of care. Many of the practice support requirements in the case study were not part of the paper based CAPIT and were only identified after extensive engagement and in some cases criticism by the palliative care providers. It was the nurses' criticism of the lack of case specificity in the paper-based CAPIT that led to that function being designed for the computer-based

SPM tool. Similarly it was the counselors fear that the computer-based SPM tool would dehumanize palliative practice that led to the development of specific fundamental considerations and reminders to ensure they are assessed and documented. If the paper-based CAPIT had been implemented as a computer-based SPM tool without the practice support enhancements such as enhanced charting and reminders it would have failed because of human and work practice issues.

System design implications include providing methodological guidance and a framework for engaging in qualitative and interpretative based HIS research. Although systems design is often taught using traditional approaches such as the system development lifecycle (SDLC) studies have shown that such approaches are problematic. Brender (1999) describes a paradox in systems development in that traditional approaches, such as the SDLC, do not consider that requirements change during the design process. The practice support framework and accompanying GT-PD approach provide a different perspective on HIS design through a qualitative based method for understanding the richness of detail of what practice support is needed for an HIS. Greater use of qualitative methods and interpretive research would help us understand the social, human, and work practice issues associated with designing and implementing HIS.

FUTURE RESEARCH DIRECTIONS

Despite the existing theories and models about 'Fit' and the findings presented in this chapter there is still much future research needed to help us understand and implement fit in different healthcare settings. Although this chapter described the importance of qualitative and interpretive research methods such methods are still underutilized in healthcare settings. Chiasson, Reddy, Kaplan, and Davidson (2007) point out that medical informatics as a field uses research methods that are primarily quantitative and experimental. This chapter emphasized that the sociotechnical approach has roots in different research methods and approaches including participatory design and computer supported collaborative work (Berg et al., 2003). Continued research is needed to explore methodological approaches to understand and implement perspectives of fit and the sociotechnical approach. Despite its utility for involving users in HIS design and for helping system designers to understand the users perspective there are few studies that empirically illustrate how to use methods such as participatory design in practice settings. Research is also needed to explore using hybrid methodologies such as the GT-PD approach presented in this chapter. Methods for qualitative analysis such as grounded theory or content analysis are a useful means of making sense of data to enable a comprehensive understanding of how technology and clinical practice intersect. Perhaps most importantly, further research is needed at developing the means of implementing concepts of fit, the sociotechnical approach and other user centered models into the HIS design phase. Relying on models to evaluate failure after the fact does not make full use of their potential. Fit and the sociotechnical approach need to do more than just describe how HIS are used. They must inform the design of the functionality of HIS including interfaces and data entry, retrieval, and decision support functionality.

CONCLUSION

Practice support encourages HIS designers, users and educators to think about the range of processes and information that form healthcare practice. Practice support includes traditional HIS functions such as decisions support and information management and it also encourages us to think about those functions in light of different practice settings, social norms and cultures of system use.

Chapter 2.14

A Framework for Capturing Patient Consent in Pervasive Healthcare Applications

ABSTRACT

In this chapter, the authors describe a new framework for pervasive healthcare applications where the patient's consent has a pivotal role. In their framework, patients are able to control the disclosure of their medical data. The patient's consent is implicitly captured by the context in which his or her medical data is being accessed. Context is expressed in terms of workflows. The execution of a task in a workflow carries information that the system uses for providing access rights accordingly to the patient's consent. Ultimately, the patient is in charge of withdrawing consent if necessary. Moreover, the use of workflow enables the enforcement of the need-to-kwon principle. This means that a subject is authorised to access sensitive data only when required by the actual situation.

INTRODUCTION

Healthcare Applications are characterised by the integration of software systems in healthcare environments. Healthcare applications seamlessly assist patients and carers in performing their tasks and provide them ubiquitous access to required information. As such, healthcare application can be considered as *pervasive computing systems* (Weiser, 1991). Real-world medical environments present several research challenges that need to be addressed for developing robust healthcare applications. As a showcase for our approach, in this chapter we focus on technology-assisted living, where the domains to be administered are units of personal living. Here, someone may be living alone, perhaps in sheltered housing, perhaps post-operative, perhaps with one or more disabilities, perhaps elderly and infirm. In this scenario, the healthcare applications are composed of several services to monitor the patient conditions, and to assist the patient or the carer in performing the appropriate treatments.

Monitoring the physical condition of a patient is carried out by means of body sensors. Several types of sensors are commercially available to measure blood pressure, blood sugar, pulse rate, etc. Another form of monitoring can be achieved using infra-red cameras that avoid the invasiveness of video surveillance. Combining infra-red cameras with motion detection, such as in the Irisys technology (2007), makes it possible to detect the number of people or animals such as guide dogs that are present, and to make a note of any visitors, in order to find out whether carers are visiting according to schedule. This information, together with the data gathered from sensors could be used to detect critical conditions for the patient and raise an alarm to summon help.

Healthcare applications provide to the carers and relatives visiting the patient's home easy access to patient's medical data. The virtualisation of the patients' medical records allows electronic storage, transmission, display and analysis of healthcare information that can improve and streamline healthcare delivery. However, it also poses new challenges to individual privacy. Healthcare information contains sensitive personal information; i.e. it may include the details of a person's history of diseases and treatments, history of drug use, genetic testing, sexual orientation and practices etc. Improper disclosure of this data can influence decisions about an individual's access to credit, education and employment. Therefore, it is crucial that healthcare information systems should offer adequate protections to address these concerns.

The European standards on confidentiality and privacy in healthcare (2007) states that *patient information is confidential and should not be disclosed without adequate justification. The justification for disclosure should normally be consent*. However, most security models for clinical information systems are merely variations of Role-Based Access Control (RBAC) which make access decisions based on the role of the user rather than patient consent. There are some exceptions, for example the BMA policy model (Anderson, 1996a; 1996b) and Cassandra (Becker & Sewell, 2004a; 2004b). The BMA policy model is the first security model which requires the patient's consent for accessing healthcare information. Cassandra is a trust management system designed for securing electronic health records which captures consents as special roles in the system. Nevertheless, they have some common problems. First, how to capture patient consent properly. Patient consent can be *explicit*, e.g. in written form, but more often is *implicit*, e.g. the context in which the access is being executed could carry enough information for implicitly obtain consent. In general, when the use and disclosure of patient information is for the patient's own healthcare purposes, and provide the patient or his legal representative has been informed of what information sharing is necessary for such purposes, implicit consent is sufficient. But in the BMA model and Cassandra, the consent must be explicit. This requirement adds unnecessary workload to healthcare professionals. Second, how to ensure that the consent is obtained on a well informed basis. A valid consent requires that the patient has been informed as to what information is intended to be used or disclosed, and for which purposes. Consent that has been obtained does not imply information has been given. However, none of the current models handle this.

In this chapter, we make us of a home-based healthcare scenario to address two main problems of current access control mechanisms. The first problem is the integration of patient consent with access control. Most access control models are designed for non-healthcare systems and do not have the concept of patient consent at all. However, patient consent occupies a pivotal role in legitimising the use and disclosure of healthcare information. Patients have a right to control access to and disclosure of their own healthcare information by giving, withholding or withdrawing consent. Therefore patient consent should serve as the ultimate foundation of access control decisions in healthcare systems. The second problem is related to the **need-to-know** principle. According to this principle, even when one has the necessary approvals, i.e. if the patient consents, access should not be given unless one has a specific need to know. An access decision should be justified by not only who is requiring access and what is being accessed, but also why the information needs to be accessed. Capturing and enforcing the access is also useful for mitigating exposure of healthcare systems to insider attacks (Anderson 1996a). For example, browsing a patient's medical record by a doctor should be allowed when the doctor is diagnosing the patient, but should not be allowed if the doctor is off-duty. Access control models such as RBAC cannot capture the access needs precisely. For example, in RBAC, the permission assignment is decided by "job functions" assigned to the role. The set of permissions is assigned to the role statically to enable the subjects playing this role to perform all the job functions. The subject has all the permissions all the time even when they are not performing certain job functions.

We believe that to better protect patient privacy, access control should not just be based on rules of who should or should not access what. Enforcing a correct procedure is also important. That is why we introduce a workflow based control framework. The framework is designed for healthcare systems and can enforce consent-based access control as well as the need-to-know principle and various other constraints. In addition, it releases end users (e.g. the medical professionals) from security related configurations so that they can concentrate on their medical duties.

This chapter is organised as follows. Section 2 discusses other approaches related to our work. In Section 3, we describe the benefits of workflow systems in healthcare environments. Section 4 describes in details the components in our framework for capturing patient consent. For validating our ideas in Section 5 we introduce a case study where a medical procedure is implemented using our framework. We conclude in Section 6.

BACKGROUND

The BMA policy model was developed in late 1990s in response to the National Health Service (NHS) project of building a nationwide medical database. The access privileges for each medical record are defined in the form of access control lists (ACLs) and managed by a responsible clinician who is the only one can change the ACLs. The main goal of the BMA model is to enforce the principle of patient consent, and to prevent too many people getting access to too large databases of identifiable records. A prototype implementation has been built in a General Practice environment (Hassey & Wells, 1997). Apart from the weakness we discussed in the introduction, other criticisms include the ACLs are not flexible and expressive enough, and the model is more clinician-centred rather than patient-centred.

Cassandra is a role-based trust management language and system for expressing authorisation policy. Cassandra supports credential-based authorisation between administrative domains, and rules can refer to remote policies for credential retrieval and trust negotiation. Cassandra focuses on healthcare systems. Cassandra has been used to develop a policy for the UK national electronic health record (EHR) system, based on the requirements of the NHS' National Programme for Information Technology (NPfIT). The notion of consent is captures in Cassandra as a special role. The consent is given to a subject, that is assigned to a special role, only if the subject requests the consent from the patient. This requirement adds extra workload for the healthcare professionals.

As we shown in this paper, in most situations the consent can be implicitly derived from the context.

Also relevant to our discussion is the RBAC model proposed in (Sandhu, 1996}. RBAC is motivated by the observation that in the real-world most access control decisions are based on the subject's job functions in an organisation. This observation is valid for organisations that own the data that is being accessed. For healthcare organizations however, the medical data that is being accessed is ``owned'' by patients. Ideally, medical data should only be disclosed when consent is obtained from patients. But the notion of consent is not captured by the original RBAC model. Thereby, extensions to this model are required for its applicability in healthcare systems (such as Cassandra).

The idea of using the workflow concept for deriving access rights was first conceived by Atluri and Huang in (Atluri, 1996), where they introduce the Workflow Authorisation Model (WAM). In WAM, authorisation constraints for data and resources are synchronized with the execution of workflows. Our framework described here is a refinement of the WAM model where the patient consent plays a crucial role in the access control decisions.

WHY WORKFLOW?

One of the significant benefits of using workflow is that it provides better process control. Users must follow predefined procedures, ensuring that the work is performed in the planned way and meets business and regulatory requirements. Workflows can also provide feedback to carers. For instance, if an action defined in a medical procedure is not performed within a certain amount of time then an alarm could be raised. The use of workflows enables the logging of the actions being executed by subjects. These logs can be used for assessing and improving the performance of carers. Moreover, logs should be made available to patients, or they representatives, in case they want to audit the medical procedures to which they were subjected and track responsibilities of subjects in case of negative experiences during their treatment.

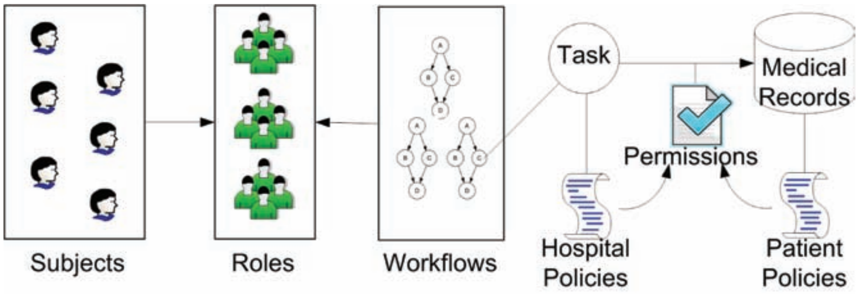
Obtaining patient consent can be easily captured as a mandatory step in a medical workflow before any use or disclosure of patient healthcare information. By executing the workflow, the control requirements for patient consent can be enforced.

A workflow also provides a way of limiting access permissions to the context in which an action is being performed enforcing the need-to-know principle. The intuition behind this is that subjects need to access specific parts of the patient's medical record only when they are executing a specific task in a workflow. Therefore by associating permissions with tasks and tracking the execution of tasks, we can ensure that the subjects can access medical records only when they have a need.

Another reason why we consider workflow is that many efforts has been made in developing and experimenting with automated or semi-automated medical workflow systems which support evidence-based medical procedures, therapies and hospital administrations (Ardissono, 2006; Poulymenoulou, 2002; Quaglini, 2001).

In our work, we assume that governmental organisations such as the National Health Service in the United Kingdom are responsible for designing and providing to hospitals standard medical procedures. Workflow systems help with this through secure auditing mechanisms that can track and record accesses, and support analysis of anomalies, failure etc.

Figure 1. Overview of our consent-based framework



CONSENT-BASED FRAMEWORK

Our workflow based framework consists of the following components: subject, role, workflow, task, policy, permission and medical records (see Figure 1).

Each **workflow** is defined according to a medical protocol or administrative process. It consists of multiple **tasks**. Each task is associated with a set of **policies**. The policies define the **constraints** for executing the task. Policies can be defined by both the hospital and the patient.

A **subject** is an entity who needs to access a medical record, e.g. a doctor, a nurse. Each subject has a set of attributes. The attributes can be used for authorisation decisions.

A **role** is a named collection of subjects. Unlike in RBAC, which assign permissions directly to roles, in our framework roles are associated with a set of workflows.

Permissions define the access right the subject has on the medical records when they are executing this task. The permissions define what actions can be operated on which part of a medical record by the subject who is executing the task. Permissions are derived from the enforcement of the policies defined on the task.

A **medical record** is the container of a patient's healthcare information. Most current electronic medical record standards define hierarchical substructures which help organising the information and make it possible for us to define fine-grained permissions on these substructures.

In our model, a permission to access a patient's medical record is granted by combining and enforcing two separate sets of policies. The first set contains medical policies that are defined by the carers' medical institutions that treat the patient (i.e., hospitals, sheltered houses for elderly people, GP and dentist studios). Policies in this set can be used for defining constraints related to time and location (i.e., a carer can perform a task only in a specific location during working hours) or to address separation-of-duty (i.e., a doctor prescribing a medication should not be also the pharmacist that sells that medication). The second set of policies contains policies specified by the patients for protecting the privacy of the information stored in their medical records.

When a subject executes a task that requires access to the medical record of a patient, the relevant policies are chosen from each set and enforced accordingly. The overall access control mechanism can be thought of as a two-step process and is represented in Figure 2. In step (1), the Policy Enforcement Point (PEP) enforces authorisation policies defined in the subject's institution (in this case a hospital). If authorisation is granted then the access is evaluated against the set of policies defined by the patient that are enforced by the PEP in step (2). If permission is also granted here, then in step (3) it is possible to get access to the actual data in the medical record.

The implementation of our framework is realised by integrating two main systems that are described in the following.

YAWL Workflow System

We use the YAWL system for the specification and enactment of workflows (Van der Aalst, 2004). YAWL provides a very powerful workflow language together with a workflow execution engine, and an editor for creating workflow specifications. YAWL can be customized to export to external components certain events that occur in the lifecycle of workflow instances. On receiving a task-enabled event, a component may decide to "check-out" the task from the engine. On doing so, the engine marks the task as *executing* and effectively passes operational control for the task to the component. When the component has finished executing the task, it will check it back in to the engine, at which point the engine will mark the task as *completed*, and proceed with the workflow execution.

It should be realised that our framework is independent of the specific workflow language/engine used as long as the workflow system provides means for interacting with our framework.

Ponder Policy Language

The other component in our framework is the policy-based system based on the Ponder policy language and interpreter developed at Imperial College London (The Ponder2 Project, 2008). The language supports the specification of policies for governing the choices in the behaviour of a system (Sloman, 2002). Ponder supports the specification of authorisation policies and event-condition-action (ECA) policies. The policy interpreter organises the entities and resources on which policies operate in hierarchical domains of **Managed Objects**. A managed object has a management interface that the object has to implement in order to be managed by the interpreter. Domains allow the classification and grouping of managed objects in a hierarchy. Furthermore, domain paths can be used to address managed objects in policy specifications. Domains can be used to group resources (e.g., data repositories, printers, X-ray machines, etc.), devices (e.g., sensors), and people (i.e., nurses, doctors, GPs, etc). An assisted living scenario is highly dynamic, as entities, including medical professionals, carers and sensor equipment, may frequently enter and leave a particular care domain. This dynamism means that the system must autonomously manage these entities, by identifying them, assigning the requisite privileges and triggering various events and/or workflow tasks. Another aspect of entity management, particularly important in the healthcare domain, concerns the performance of an entity. Actively monitoring and evaluating the behaviour of an entity allows for a higher quality of service, by allowing active intervention whilst functioning as a deterrent against misbehaviour.

Figure 2. Steps executed for granting a permission

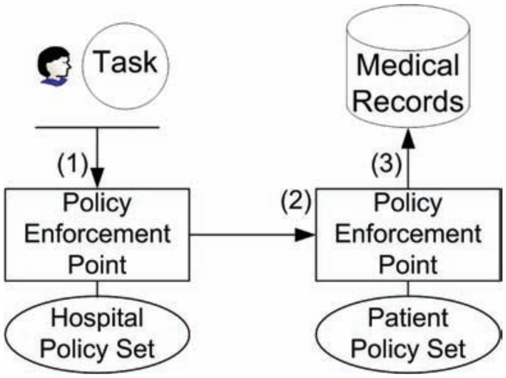


Figure 3 shows how Ponder's domain structure may be used for organising the entities and medical data for a sheltered home scenario for a patient Bob Arkwright being visited by a nurse Jane. Carers are represented by means of **Subject Managed Objects** (SMO) that could be assigned to the respective domain according to the subject's role. An SMO can be thought of as an electronic credential that identifies a specific individual working for a medical institution. The Electronic Health Record (EHR) of a patient, that

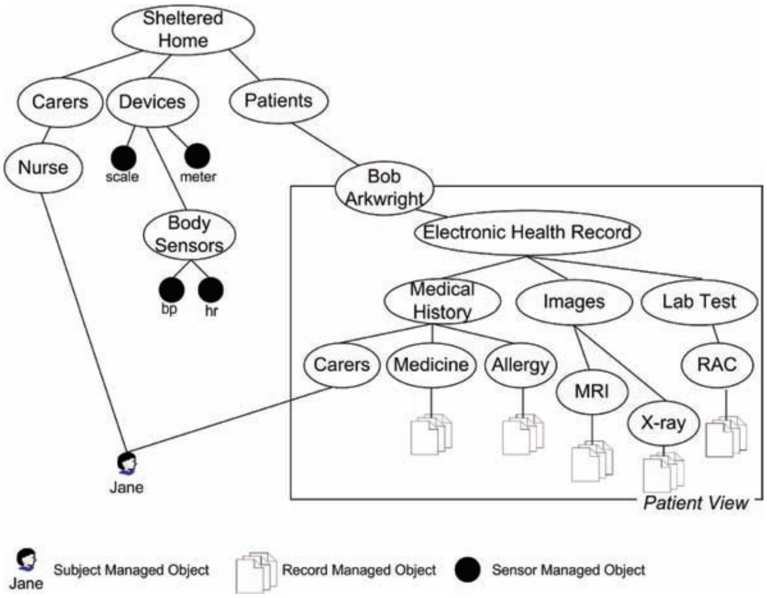
Figure 3. Representation of a sheltered home domain using ponder

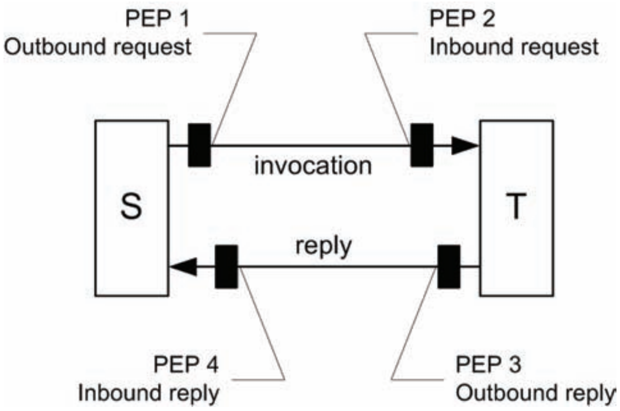


is the digital representation of a patient medical record, is also represented as a domain structure. The leaves in this domain structure are **Record Managed Objects** (RMO). RMOs represent specific instances of medical documents, such as the record of allergies, the list of current and past medications, an MRI picture, and so on. It should be noted that, although Figure 3 shows Bob's EHR within the structure of the sheltered house, the actual storage of the EHR itself could be done in a remote location. As a matter of facts, the EHR structure can be seen as a collection of distributed resources. For instance, RMOs could be stored within the organisations that created them, i.e. the X-ray images in Bob's EHR could be stored in another hospital where Bob attended when he broke is leg. Domains in Ponder transparently support external links to point to domains and managed objects contained in domain structures residing in remote location.

The sensors and devices that are deployed in the environment are represented by means of **Sensor Managed Objects** (SeMO). In this way, the devices can interact with other managed objects sending events and reacting to changes in the environment.

The EHR represents the patient's *private view* of her digitalised medical information shown as a square around Bob's EHR in Figure 3. As such, in our framework patients are enabled to specify access control policies that govern the access to such resources. In Ponder, authorisation policies are used for controlling the rights that entities have on the resources managed in a domain structure. In our case, entities are medical personnel and resources are the patient's medical data, represented as SMOs and RMOs, respectively. Sensors can be seen as resources but also can invoke actions of other managed objects. For instance, if a sensor detects an anomaly it can send an alarm to the nurse in charge. Authorisation policies are defined on (subject,target,action)-triples. The language also supports negative authorisation policies, that when applied negate the execution of the defined action. To be able to specify authorization policies, patients need to refer to the subjects executing the accesses. For this reason, the domain **Carers** in the patient's EHR is used for containing refer-

Figure 4. The fine-grained access control model supported in Ponder



ences to SMOs, as shown in Figure 3. This domain contains a collection of references to SMOs of medical personnel known to the patient. Actually, this domain represents an important part of the medical history of the patient because it provides an overview of the medical personnel that have provided care to a patient.

Fine-grained Access Control in Ponder

An important feature of the authorisation model in Ponder is the fine-grained access control mechanism. Authorisation policies can be independently specified for controlling the subject-side and the target-side of an action. A full description of the model can be found in (Russello, 2007). Here, for brevity reasons, we just recall the details of the model that are relevant for our discussion.

As shown in Figure 4 the access control mechanism provides 4 different PEPes to enforce policies. Policies can be specific for the subject and the target side of a request. The policies enforced at PEP 1 control the subject when it sends out a request. We name such policies *Subject authorisation (SA)* policies. The PEP 2 is used for enforcing authorisation policies for control on the target side. We name these policies *Target authorisation (TA)* policies. The policies enforced at PEP 4 and PEP 3 are the dual of SA and TA policies. These policies, called respectively *Subject-return authorisation (SRA)* and *Target-return authorisation (TRA)*, are used for controlling the return part of an action. SRA policies can be used for protecting the integrity of a subject (i.e. checking that the reply does not contain malicious data). TRA policies can be used for filtering the data that is returned to a subject.

Using SA and TA policies (enforced at PEP 1 and PEP 2), it becomes possible to employ this mechanism for implementing our consent-based model. In particular, hospital policies are specified and enforced as SA policies. On the other hand, patients can use TA policies for controlling the access to the private view of their medical data. A patient uses the references contained in the Carers domain for specifying which SMO a TA policy is to be applied.

In case of authorisation conflicts, that could happen when authorisation policies of different signs apply to the same triple, the interpreter is also able to autonomously resolve those conflicts. For more details on the rules that are applied for resolving conflicts, we refer the interested reader to (Russello, 2007).

Ponder ECA policies are used to dynamically adapt the system to changes of either context or behaviour of applications. Events are trigged by such changes and are propagated using an event bus. ECA polices capture events and execute actions for adapting the system. For example, ECA policies can change the domain structure adding/removing domains and managed objects, can invoke action on managed objects, can enable/disable other policies and can trigger other ECA policies by sending more events.

IMPLEMENTATION OF A HOME CARE SCENARIO FOR EDEMA

In this section, we present the implementation of a simple healthcare application for the Edema treatment based on situated workflows and implement using our framework.

Edema refers to swelling caused by excess fluid in body tissues. Monitoring involves a carer taking various measurements and performing tests. This example allows us to show several aspects of our approach in more detail:

1. Authentication of the carer when entering the home healthcare domain.
2. Assignment of careplan for Edema treatment to the carer.
3. Carrying out treatment procedures according to patient's consent.
4. Departure of the carer from the home environment.

Carers are provided with portable devices, such as PDA, that helps them in performing their task. The PDA has a domain structure instantiated where an SMO representing nurse Jane is already instantiated. The domain structure for the sheltered home is instantiated on the home PC.

Entering the Home Domain and Assignment of Careplan

Figure 5 shows the steps executed in the framework when a carer enters the patient's home. On entering the patient household, the PDA carried by the nurse and the home PC discover each other (1). The discovery of the home domain will raise an event on the nurse device that triggers an ECA policy (2). This policy forces the nurse SMO on the PAD to present the electronic credential to the Authentication Service of the home domain (3). The Authentication Service verifies the credentials and activates the nurse SMO that is contained in the domain structure of the sheltered home (4). The local nurse SMO will act as a proxy for the nurse SMO instantiated on the PDA and a mutual reference is exchanged between the two SMOs. In this way, the nurse can follow the Edema treatment procedures for this particular patient using her device. The nurse SMO also instantiates the workflow for the Edema Treatment that the nurse Jane is required to follow (6). This is done by means of the **WMS-MO** (7), a managed object that is interfaced with the YAWL engine instantiated in the home domain.

Treatment Procedures

The specification of the workflow for the Edema treatment is shown in Figure 6. The workflow is specified using the YAWL editor (shown in Figure 6) and then saved as an XML file. When an instance of the workflow needs to be instantiated, the workflow engine loads up the XML specification and enacts the first task.

The Edema treatment consists of the following tasks. First the carer checks the previous measurements. Following, the petting test is executed. Afterwards, a new set of measurements is collected for blood pressure, weight, and body measurements. In the end, the set of measurements is saved in the electronic medical record. These measurements are performed using devices and body sensors, such as scale, meters and the blood pressure sensor (BPS) already present in the home.

In our framework, the execution of a medical workflow is associated with the **Implicit Consent with Explicit Deny (ICED)** policy. The main idea

Figure 5. Authentication phase when the nurse's device is detected in the sheltered home domain

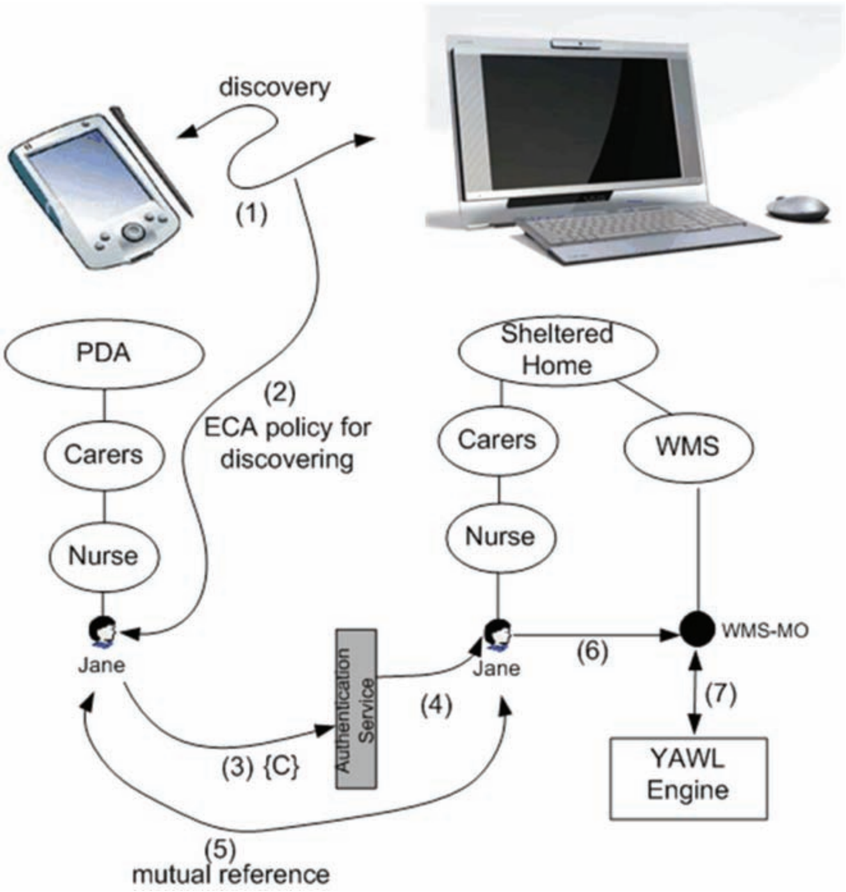


Figure 6. Specification of the workflows using the YAWL editor

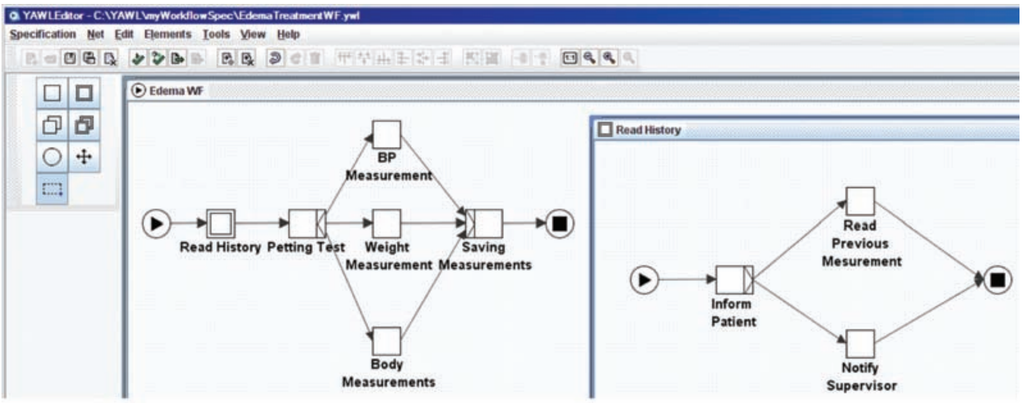


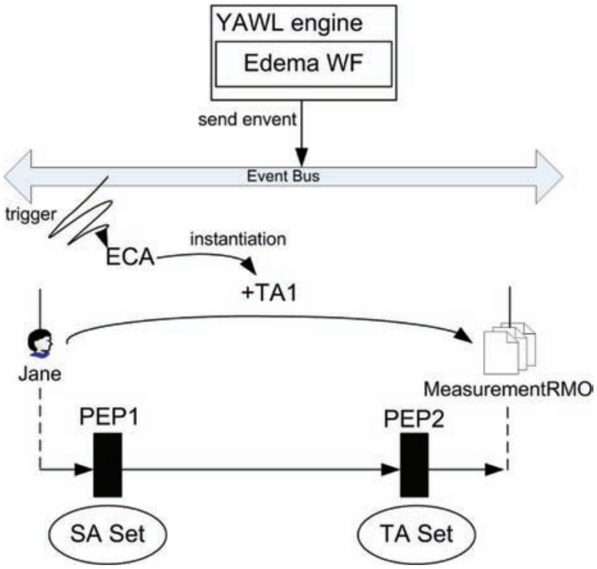
behind this policy is that a patient implicitly allows a subject executing a workflow concerning her health to access sensitive information contained in the EHR. However, the patient can explicitly deny access to one or more subjects involved in the current or any future workflows.

Implicitly allowing subjects executing a medical workflow to access an EHR means that the patient is not required to explicitly specify permissions for the subjects. The system can derive the permissions from the context in which the access is being executed and automatically generate the required permissions. In this way, the **need-to-know** principle is enforced without giving unnecessary burdens to the patients. However, a subject executing a medical workflow should provide information to a patient on each access to the EHR. This means that before the access is performed the subject should explain to the patient which part of the HER needs to be accessed and the motivations that justify such an access. If the patient thinks that the given motivations are not exhaustive or that more information than necessary is being accessed, the consent can be withdrawn.

In our framework, the enforcement of the ICED policy is achieved using the following two mechanisms. In order to inform a patient that an access is going to be executed, the task that represents the access to the previous measurements is divided into sub-tasks. Figure 6 shows the subnet of tasks for the "Read History". The "Inform Patient" task requires the subject to inform the patient that an access to the record containing previous measurement is going to be executed. If the patient consents then the "Read Previous Measurements" task can be executed. However, if the patient denies the access, then alternative tasks need to be executed. For instance, in the case of Figure 6 the subject should inform her supervisor that the patient denied her access. The main workflow is then resumed and completed accordingly. It might be the case the tasks in a workflow do not capture alternative tasks when access is deny to complete a task. If no alternative tasks are available, then the subject executing the workflow can be notified by the workflow engine to manually take some actions. Related research investigating specification and handling of exceptional situations in medical workflows be found in Han *et al.* (Han, 2006).

The automatic provision of access rights is performed by means of Ponder ECA policies. Figure 7 provides an overview of the generation of such permissions. The example shown is that of nurse Jane that wants to read the history measurements of Bob. After nurse Jane obtains Bob's consent to proceed, the ``Read Previous Measurements'' task is declared *executing* by the YAWL workflow engine and an event with this information is sent. The event also carries context-dependent data, such as: the specific instance of the task that is activated, that the task is part of a medical workflow, the subject that is executing it, the target and action that is performed, the location and time. This event triggers an ECA policy and using the data carried by the event generates and activates a positive TA policy. This policy, called +TA1, is shown in Figure 7 as an arrow connecting nurse Jane's SMO to the MeasurementRMO. When the nurse, via her SMO, performs the action of reading the measurements, the access control mechanism captures such an action and enforces authorisation policies at PEP1 and PEP2. The SA policies enforced at PEP1 are specified by the nurse's organisation. We assume that the nurse complies with the organisation policies and that from the point of view of the organisation the action is allowed. Another enforcement of authorisation policies is done at PEP2. Here, the mechanism searched for TA policies. Because policy +TA1 is already in place the action can be authorised. (Although, it could be the case that there are conflicts with other policies previously specified by Bob; we discuss this case later in this section). Another important step that is not shown in Figure 6 is that of automatically disabling the authorisation policy. After the task is concluded,

Figure 7. Generation of authorisation policies by means of ECA policies

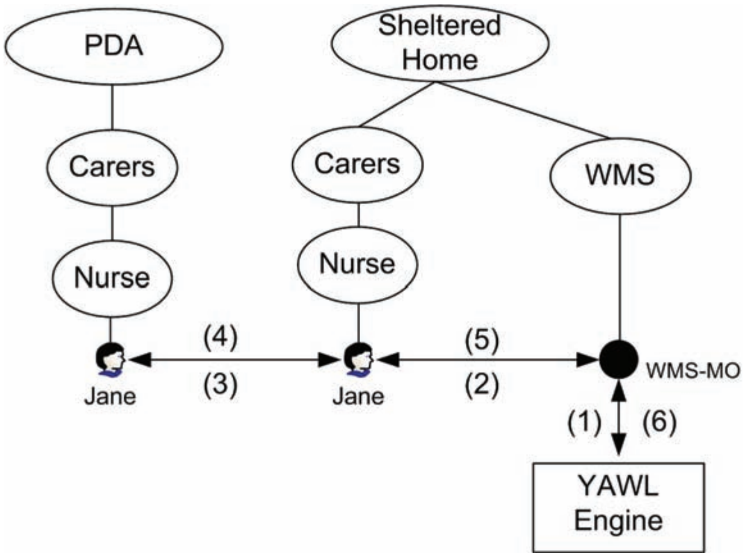


the YAWL engine sends an event that triggers another ECA policy. This ECA policy will take care of disabling policy +TA1. This use of ECA policies guarantees that the permission for accessing the record is available only for the execution of the specific task.

Our framework enables a patient to define negative authorisation policies that deny subjects to access the EHR. Once the SMO reference becomes available into the Carer domain in the EHR, the patient can define a negative TA policy for that specific SMO. When the system generates the positive TA using the mechanism described above, this positive TA will be in conflict with the negative TA created by the patient. In this case, the conflict resolution mechanism will give priority to the patient's negative TA policy. This means that the access is denied and an alternative action must be taken.

The nurse can use her device for following the workflow execution. The YAWL workflow engine is responsible for the enactment of tasks. Figure 8 shows how the engine communicates to the entities involved in the execution of a given instance of a workflow. Let us assume that the nurse completed all the measurement tasks. The only task left is the recording of the measurements into Bob's EHR. The YAWL engine notifies the WMS-MO which is the next task to be executed ("Saving Measurements") (1). The WMS-MO keeps track of which instance of an entity is involved in the execution of a workflow. In this case, the WMS-MO knows that the task is to be executed by the nurse Jane's SMO and therefore it communicates the information about the task to be completed (2). The nurse's SMO in the home domain sends this information to the SMO instantiated in the PDA domain (3) that visualises the information to the nurse via the PDA screen. The nurse checks the measurements are correct and requests the logging of the information by pressing the `log measurements' button that will appear on the PDA screen. Once the operation is completed, the task fulfilment is communicated back to the engine following the inverse path (steps (4), (5) and (6) in Figure 8). The WMS-MO can be also used for adapting the execution of workflows to the actual situation. For instance, if the biometrics of the patient presents an anomaly, the sensors can raise an alarm/event that triggers ECA policies.

Figure 8. Controlling the enactment of tasks



Depending on the situation, the ECA policies can require the WMS-MO to stop the current workflow execution and switch to an emergency workflow to cater for the actual condition of the patient. The changing of the workflow is also notified to the nurse via her PDA.

Leaving the Home Domain

When the nurse completes her visit and leaves the patient's home the resources allocated for her in the home domain must be relinquished. For instance, the Nurse Entity must be removed from the home domain and the policies associated with it deactivated. These operations are executed by means of an ECA policy that is triggered by the event "NurseOutEvt". This event is sent when the system detects that the nurse left the patient's home. When the ECA policy is triggered it disables the policies associated with the entity managed object and invokes the remove action of the domain where the Nurse Entity is contained.

The "NurseOutEvt" event can be sent in several ways. The carer can send it manually by pressing a button on her PDA to notify that the treatment is completed (according to her) and she is ready to leave. Alternatively, the system can recognise that the nurse left the sheltered house. For instance, when the nurse's device is out-of-range from the home PC or after a certain amount of time allocated for the carer expires.

These methods can be used in different situations. For instance, if the nurse has to leave before completing her procedures due to an emergency in another sheltered home, then either the manual disconnection or the out-of-range detection allows the system to promptly react (i.e., the system can report via an alarm that some procedures need to be completed). On the other hand, the time-out disconnection can be used by the system to recover from erroneous situation (i.e. the nurse left behind her device without notifying the system when she departed from the patient's house).

FUTURE TRENDS

Our framework for capturing patients' consent is based on the use of workflow systems to express contextual information when an access is being executed. In future healthcare systems, workflow systems will play a central role as it is analysed in (Dwivedi, 2001). However, one of the main issues of today workflow management systems is their inefficiency in handling *exceptional situations*. An exceptional situation refers to a state not contemplated in the workflow specification. Often exceptions require manual intervention of the subject executing the workflow. Exceptions are logged and if a particular type of exceptions happens too often then the workflow specification can be updated in order to handle it. However, such action can only be taken after execution time. This is acceptable when workflow systems are deployed in low-pace medical environments, as it is the case in the scenario of the case study presented in this chapter. In more demanding environments, such as an Emergency Room in a hospital, workflow systems may become a burden to use for the medical carers and redundant in case that exceptions have to be handle manually. As pointed out in (Han, 2006), research in this area is being investigating solutions for handling exceptions in workflows more dynamically. We also believe that improvements may derive from employing a less fixed structure for workflow specifications. Currently, a workflow specification is represented as a net of tasks that has to be strictly followed during execution. However, a specification where the execution of tasks is expressed in terms of temporal constraints (i.e., interval of time) within the different tasks could prove to be more flexible and suitable for dynamic high-pace environments.

CONCLUSION

Healthcare applications are pervasive systems that facilitate patients and carers access to medical information. In particular, healthcare applications allow electronic storage, transmission, display and analysis of healthcare information that can improve and streamline healthcare delivery. However, it also poses new challenges to individual privacy. Healthcare information contains sensitive personal information that if not properly disclosed can influence decisions about an individual's life. Therefore, it is crucial that healthcare information systems should offer adequate protections to address these concerns.

In this chapter, we presented a framework for pervasive healthcare application where patients' consent has a central role for granting permissions to carers for accessing patients' medical data. Our framework combines a workflow system for deriving contextual information and a policy-based system for automatically generating access rights. Patients can fine tune access rights by creating their own authorisation policies and effectively control the subjects to which consent is given or withdrawn. Additionally, the use of workflows allows us to enforce the need-to-know principle whereby a subject can access the patient's medical data only if there is a specific need. In our framework, this need is associated with the execution of specific workflows.

ACKNOWLEDGMENT

This research was supported by the UK's EPSRC research grant EP/C537181/1 and forms part of the CareGrid, a collaborative project with the University of Cambridge. The authors would like to thank the members of the Policy Research Group at Imperial College for their support.

ABSTRACT

Urgent requests and critical messages in healthcare applications must be delivered and handled timely instead of in an ad-hoc manner for most current systems. Therefore, we extend a sophisticated alert management system (AMS) to handle process and data integration in healthcare chain workflow management under urgency constraints. Alerts are associated with healthcare tasks to capture the parameters for their routing and urgency requirements in order to match them with the specialties of healthcare personnel or the functionalities of Web Services providers. Monitoring is essential to ensure the timeliness and availability of services as well as to ensure the identification of exceptions. We outline our implementation framework with Web Services for the communications among healthcare service providers together with mobile devices for medical professionals. We demonstrate the applicability of our approach with a prototype medical house-call system (MHCS) and evaluate our approach with medical professionals and various stakeholders.

INTRODUCTION

Recent advances in Internet technologies have created a global platform for organizations and individuals to communicate with one another, carry out various commercial activities, and provide value-added services. Web Services (Chiu et al., 2003) provide loosely-coupled standard interfaces among autonomous systems within and among organizations in the form of a set of well-defined functions for both programming and human user interfaces. Web Services further support event-driven information integration for timely service provision and interactions (Chiu et al., 2004). In healthcare chain workflow management, both process integration and data integration among health service providers are vital. Besides organizations, individual practitioners (such as physicians and nurses), administrators, and patients are also involved heavily in the workflows. Tasks like medication monitoring, emergency hospitalization of patients, laboratory examination results, shipment of drugs, exchange of patient records among healthcare service providers, etc., produce large numbers of messages. That is, both process integration and data integration are necessary. Further, accurate and timely communication of such information is a key success factor for the provision of quality healthcare chain services. We refer to these urgent messages as *alerts* (Kafeza et al., 2004).

Existing practice of using cellular phones and pagers for communications is inadequate for seamless integration with existing and future healthcare information systems. In particular, healthcare applications must respond actively and timely to patients' needs as this is crucial to life or death. Most healthcare alerts have to be handled within a time period. Apart from service suitability, application specific considerations like costs, waiting time and service time may also be important. Routing, monitoring, and logging the alerts are also mandatory functionalities to shift the burden of these communications from the manual work to an automated system. To take advantage of the connected Internet environment, we extend an alert management system (AMS) for healthcare professionals (Kafeza et al., 2004) across organizational boundaries to become the key mechanism for both healthcare process and data integration with urgency support. The AMS aims to minimize delays by providing a monitoring system. This article generalizes and extends our previous work on workflow modeling (Chiu et al., 1999) and process integration (Chiu et al., 2004) in order to be applied in healthcare applications.

As compared with our previous work (Kafeza et al., 2004), the contributions of this article are the description and analysis of the following: (i) an enhanced conceptual model for specifying alerts based on the requirements of healthcare chain workflow management, which supports programmatic interfaces across organizational boundaries in additional to human users; (ii) alerts as a unified mechanism for capturing the requirements of healthcare process and data integration; (iii) a practical architecture for the AMS based on contemporary Web Services for programmatic interactions, together with multiple-platform support for human users; (iv) a practical prototype Medical House-Call System (MHCS) to demonstrate the applicability of our approach in healthcare chain workflow management.

In order to reach these objectives, we first discuss an overview of our methodology and the overview of a MHCS and compare related work. Then, we describe our system design and implementation as well as how data and process integration works in our system with a typical system walkthrough. Finally, we discuss the advantage of our alert-driven approach before concluding our article with our future work direction.

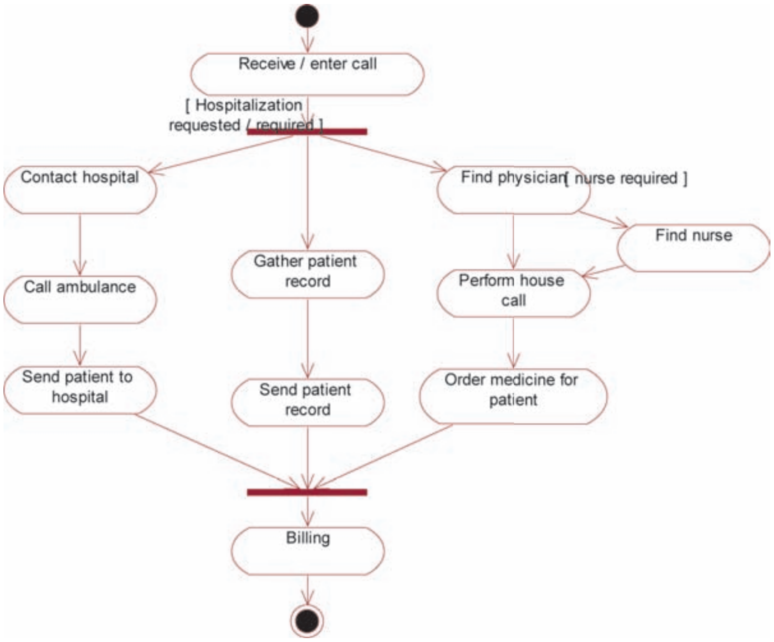
BACKGROUND AND METHODOLOGY OVERVIEW

In Hong Kong, some healthcare corporations provide "House-Call" services. Figure 1 summarizes the main workflow of a typical medical house-call center. Affiliated patients can call (either electronically or by phone) and request a physician to visit their home either immediately or at a requested time. The patients may also request to be sent to a hospital. In this case, the hospital and the ambulance call center are contacted for the delivery. A patient can specify a particular physician or let the call center find the first available physician with the required specialties (if any) from a list of off-duty physicians, then from a list of on-duty physicians, and lastly from a list of physicians from healthcare partners. A nurse may also be assigned in some cases to assist with the physicians' consultation. When the required personnel are contacted, the patient will be confirmed. At the same time, the patient's healthcare records may have to be sent from hospitals and other clinics to the physician's mobile device. After completion, the physician submits a report of the consultation together with any prescriptions. The prescriptions are routed to a pharmacy so that the medication can be delivered (by courier service) to the patient's home. Lastly, the patient or his/her insurance company is charged for the consultation.

However, the above only describes the normal and basic functional requirements. In particular, standard workflow technologies are inadequate to address the urgency and exception handling requirements. Different degrees of urgencies arise from the sickness of the patients as well as the requirements for quality services. Exception situations typically occur when services commitments cannot be fulfilled, e.g., when a physician cannot visit the patient at the specified time. Thus, we propose to augment the workflow with alerts for the modeling of these requirements and implement it with the support of an AMS.

Different from a hospital environment as we previously studied (Kafeza et al., 2004), the AMS

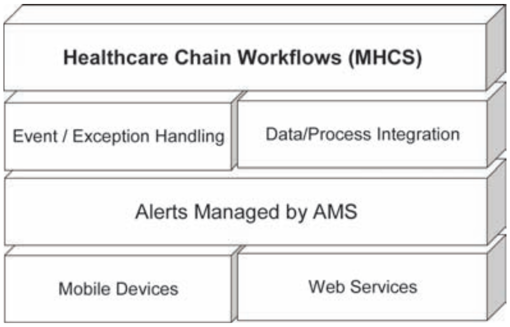
Figure 1. Main medical house-call center workflow in UML activity diagram



in this application is no longer a closed environment. It now requires a much wider coverage across the boundary of different organizations, connecting patients, their homes, medical practitioners, medical partners, and the call center. Thus, not only are communications with various personnel required, programmatic integration with partner organizations are also necessary. Further, as the relationships among different parties are partnerships rather than employee commitments, alert requests are more likely to be rejected because full personal schedules are not available.

Figure 2 summarizes the conceptual architecture of alerts extended from our previous work (Kafeza et al., 2004). The essence of alerts is to capture the urgency requirements as required by the healthcare chain workflows of the MHCS, which typically involves *synchronous* data (e.g., patient record assembly) and process (e.g., physician call) integration as well as *asynchronous* event or exception handling (e.g., physician's lateness or absence after commitment). Remarkably, exceptions are subclasses of events (Chiu et al., 1999; 2001). An *event* is a significant occurrence that affects either the system or a user application. Exceptions often, but not always, have urgency implications. Different from general events, alerts have more specific attributes, in particular, urgency (e.g., the degree of sickness of the patient) and service requirements (e.g., the specialty of the required physician). Different from exceptions, alerts need not be related to abnormal behaviors. That means, alerts can be (i) triggered *asynchronously* to handle an event or exception, or (ii) generated synchronously to satisfy the data or process requirement. Alerts received by a service provider may be *handled* by either (i) rejecting the service, (ii) its internal information systems, (iii) a human service provider through the Web or mobile devices, or (iv) requesting other external service providers in turn through Web services, where programmatic interfaces are usually required.

Figure 2. The role of alerts for healthcare chain workflows



Motivated by these extended requirements, we start off our study by gathering the objectives and requirements of the medical professionals and the medical house-call service provider. Nowadays, the progress in the medical field has resulted in the hyper-specialization of the physicians, the introduction of new and advanced types of examinations and processes, and the increasing request of the patients for better quality of medical care. At the same time, recent advances in information technology are being deployed to facilitate this new complicated healthcare environment. One of the most prominent objectives is the need for accurate, safe, and continuous communications among highly specialized medical professionals and healthcare service providers. There has been a great demand amongst the medical professionals for an alert management system that is *robust, efficient, cost effective, simple,* and *user friendly to* improve the communications.

Based on these objectives, detailed requirements were elicited and formulated into an alert conceptual model. Then we sketched an overall system architecture for the call house management system, with focus on the AMS design. We then worked out the detailed mechanisms for each component of the system. In the design, we also had to pay attention to flexibility so that alert management policies could be adapted to handle various situations for various partners. According to these designs, we built a prototype to demonstrate the functions to the medical professionals for evaluation.

As for deployment, we plan to split it into phases. The first phase is to establish a computerized call center to manage all the alerts for medical personnel, replacing the current manual system. After getting used to the new arrangements and fine tuning of the alert management policies, the second phase is to extend the system to connect to medical partners. In the third phase, we plan to include further intelligence into the system, in particular, with advanced capability reasoning (Chiu et al., 1999), scheduling with mobile location dependent information, service negotiation, and integration with traffic routing.

RELATED WORK

Raghupathi & Tan (2002) point out that new healthcare applications supporting information technology (IT) based strategies are required for meeting competitive challenges and estimated IT expenditure on healthcare in 2002 to be 21.6 billions in the United States. In particular, healthcare applications will take advantages of the technological advances in communications technologies and mobile devices (Olla & Tan, 2006). Ammenwerth et al. (2000) also report that one of the major benefits of mobile technologies is to help hospitals in communication and reachability management among the patients and the message senders as well as to address the urgency requirements. Hripcsak et al. (1996) preliminarily identify the need for event monitors and describe some of the requirements such as tracking healthcare events, looking for clinically important situations, and sending messages to the providers. Eienstadt et al. (1998) further categorize messages as *alerts, results,* and *replies*. The limitation of their approach is that they only focus on alerts that can be handled by 2-way pagers. Ride et al. (1994) argue that the problem of figuring out to whom the message should be sent is a difficult one. They only suggest some ad hoc solutions such as sending a message to whoever has recently examined the patient electronic record.

Although information integration issues are not new in database research communities (Sheth & Larson, 1990), Sheng & Chen (1990) identify that the application of workflow technologies in different hospitals has many unique properties that entail special integration design considerations. The health informatics communities (e.g., the International Medical Informatics Association, http://imia.org) have discussed the application of workflow technologies in health administrative data integration for a period of time. For example, Marsh (1998) presents a multi-model medical information system for demonstrating the virtual medical world. Takeda et al. (2000) present a system architecture for supporting networked electronic patient records. Liu et al. (2001) propose a web-based referral information system for sharing electronic patient records based on eXtended Markup Language (XML). Further, Grimson et al. (2001) propose a Synapses prototype system for supporting federated healthcare records that provides an integrated view of patient data from heterogeneous distributed information systems on the Internet. Al-Ali et al. (2006) propose a prototype system to provide real-time wireless integration of patient information system with mobile devices. However, none of these approaches can provide a seamless integration that permits the use of workflow technologies or alert mechanisms. In particular, the integration with manual access of legacy paper records through workflow management together with electronic records has not been presented as in this article.

Recently, the approach of Web-service-based information and process integration is receiving much attention. For example, McGregor (2007) suggests a framework for the design of Web service based clinical management systems to support inter- and intra-organizational patient journeys. Raghupathi & Gao (2007) explore a UML profile approach to modeling Web services in healthcare.

We have also proposed a methodology based on workflow views and Web services for this purpose (Chiu et al., 2003), where a survey of recent works on Web service composition can be found.

Concerning home-base healthcare monitoring, most of the existing studies focus on the application against long-term and critical diseases, instead of a public general healthcare service perspective. For example, Woodend et al. (2008) demonstrate the effectiveness of tele-home monitoring in patients with cardiac disease who are at high risk of readmission, based on video conferencing and phone line transmission of weight, blood pressure, and electrocardiograms. Pinna et al. (2007) also demonstrate that self-managed home tele-monitoring of both vital signs and respiration is feasible in heart failure patients, with surprisingly high compliance. Logan et al. (2007) develop and pilot-test a home blood-pressure tele-management system with Bluetooth and mobile phone technologies that actively engages patients in the process of care through blood-pressure alerts. However, a systematic approach to handling those alerts and signals collected has not been adequately studied.

Suomi and Tähkäpää (2003) study the requirements of a contact center for public healthcare with a case study in Turku, Finland and identify contact routing as the main system functionality. They also provide a good survey of call centers that run with older technologies. We proceed further to detailed system design and prototyping, with focus on urgency requirements for alert routing, employing additional mobile technologies and healthcare partner process integrations.

In the context of workflow management systems (WFMS), Chun et al. (2002) propose the automatic generation of workflows from domain knowledge. We have recently proposed to separate user alerts from user sessions to improve the system flexibility (Chiu et al., 2002) in our Mobile E-commerce Advanced Object Modeling Environment (ME-ADOME) WFMS. Online users are alerted through ICQ (I seek you) (Weverka, 2000) messages with the task summary and reply Universal Resources Locator (URL) as the message content. If the user is not online or does not reply within a pre-defined period, the WFMS will send the alert by email. At the same time, another alert may be sent via Short Message Service (SMS) to the user's mobile phone. Whatever the alert channel has been, the user may connect to WFMS on any other devices or platforms. For example, after receiving a SMS alert, the user may use his/her handset to connect to the WFMS via Wireless Application Protocol (WAP) or reply with an SMS. Alternatively, the user may find a computer with an Internet connection or use his/her personal digital assistant (PDA) to connect to the WFMS. As an extension to existing process models such as Sheng & Chen (1990), our process model abstracts information regarding roles and their schedules of service providers possessing these roles. We have employed a bottom-up data-driven methodology to extend information systems into Web Services (Chiu et al., 2004) and further incorporated alerts and their routing (Kafeza et al., 2004).

Besides healthcare applications, we have also pioneered in the application of alert management in a wide range of other application domains for process and data integration. For example, in electronic commercial applications, Lee et al. (2007) employ Web services and alerts to enhance workflow automation in insurance underwriting processes. Ng & Chiu (2006) study the feasibility of electronic government process integration with Web services and alerts through an emergency route advisory system. For industrial production, Chung et al. (2007) propose the use of an alert management system for concrete batching plants. Chiu et al. (2008) advocate alert management for ubiquitous support in distance education applications. To our knowledge, there are no other WFMS employing this approach. Further, there has been no other work on alert-driven process integration or data integration at this time.

DESIGN AND IMPLEMENTATION

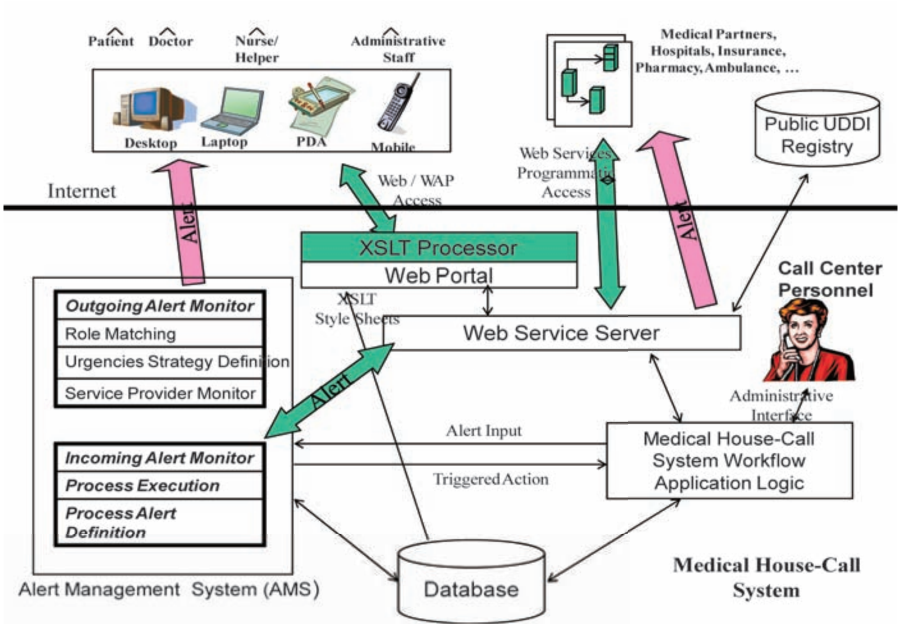
System Architecture

We have built a prototype for the MHCS on the J2EE and Oracle platforms (Price, 2000). Figure 3 depicts the overall implementation architecture of MHCS based on our previous AMS core (Kafeza et al., 2004). As the AMS manages only the alert, domain-specific application logic is required for a complete system. Upon data or process service requests, the application logic generates alerts with the necessary specifications to the AMS. Any subsequent processing that depends on the result of the external service has to wait till it finishes (as signaled by the AMS); otherwise the workflow can continue. On the other hand, the application logic is triggered by the Process Execution Module of the AMS to carry out timely appropriate actions in response to incoming alerts. In addition, the application logic supports an administrative interface for the call center personnel.

Our AMS supports an organization to be both a service provider and a requester. Each organization can use the AMS to both submit and receive alerts. The *Incoming Alert Monitor* is responsible for receiving and queuing alerts and enacting the corresponding services (processes). Incoming alerts are received as (i) invocation of a Web Service, (ii) SMS messages, or (iii) via the Web Portal. They can trigger the execution of the appropriate alert handlers in the application logic through the *Process Execution* module. In addition, the *Process and Alert Definition* module supports a tool with which users may define the tasks and their associated alerts according to their requirements.

The *Outgoing Alert Monitor* subsystem is responsible for creating and submitting the alerts by means of Web services requests to the corresponding service providers as well as monitoring their responses. As for human service providers (such as medical personnel), ICQ, SMS, and email are used instead. As such, a service provider supporting only manual record retrieval may still

Figure 3. System architecture highlighting the AMS

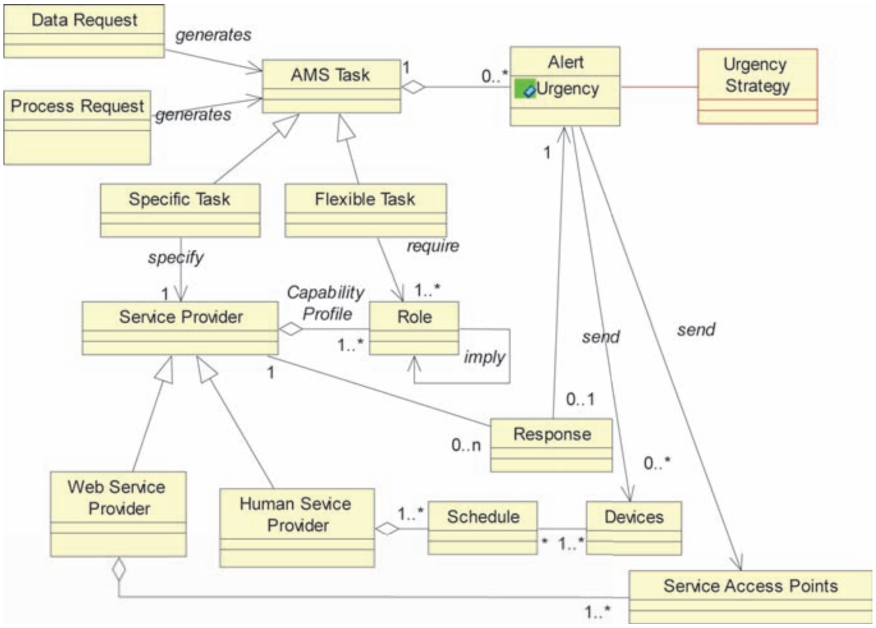


participate in data and process integration through a Web-based *alert response form*, through which a clerk can input manually the required response to an alert. The *Outgoing Alert Monitor* subsystem consists of three modules: the *Urgencies Strategy Definition*, the *Role Matching*, and the *Service Provider Monitor* modules. The *Role Matching* module is responsible for identifying the service providers to which the alert will be forwarded. The *Urgencies Strategy Definition* module specifies the policies that will be followed if the alert is not acknowledged within the deadline. The *Service Provider Monitoring* module is responsible for applying the strategies thus defined. Its functions include sending alert messages, receiving response, maintaining alert status, and logging information. For every response message received, it updates the status information of the associated alert. It tags that the alert has been "taken care of". If the alert message has been sent to several service providers, the first one to confirm is assigned to the task while the others will receive a cancellation message instead. Then for every alert in the *active alert table* with its deadline expired, the module checks the *urgency strategy table*, executes the associated action, and updates the status information accordingly.

Extended Alert Model

Figure 4 summarizes our design of a unified *alert conceptual model* in a class diagram of the Unified Modeling Language (UML) (Object Modeling Group, 2001). We have extended the notion of alerts (see our previous work (Kafeza et al., 2004) for a formal model) to include not only human users but also services with programmatic interfaces. We also include the notion of a flexible and a specific alert as explained below. Figure 5 depicts a typical life cycle of an alert with an activity diagram of the UML. All alert processing and messaging for an alert is logged ("Log alert" node) for auditing purposes. If the alert is a *specific* one (say, when a patient specifies his family doctor), there is no room for matchmaking. Otherwise, if the alert is a *flexible* one (say, when

Figure 4. UML class diagram of alerts with human and Web service support



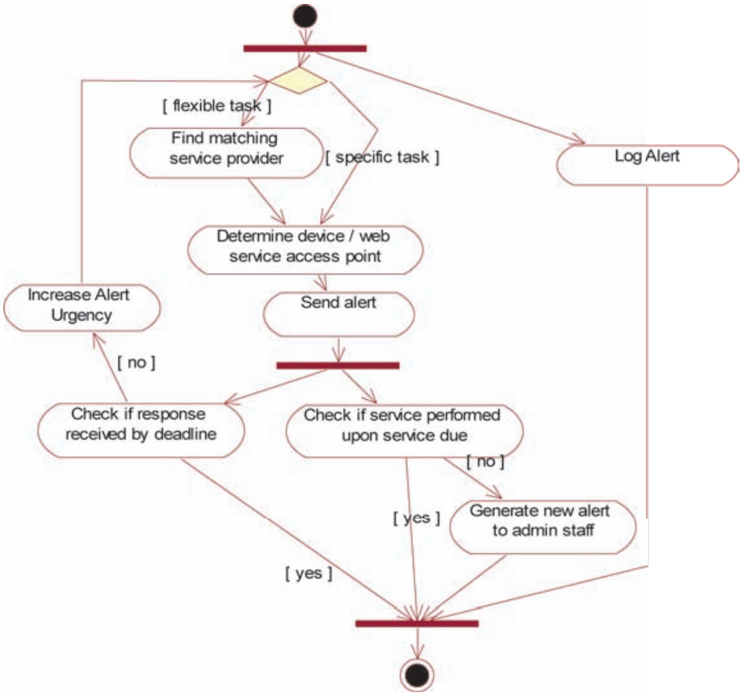
a patient just reports his sickness), a matching algorithm ("Find matching service provider" node) is invoked to search for a suitable service provider (Kafeza et al., 2004; Chiu et al., 1999). The "Determine device / Web Service access point" node determines the device for a human or the Web Service access point for a Web Services provider respectively. Then, the "Send alert" node sends the alert accordingly. If the "Check if response received by deadline" node fails, the AMS will increase the alert urgency, thereby triggering the alert message to be resent to either the same service provider or a different suitable one (as discussed in the next subsection).

The last tolerance level is guided by the "Check if service performed upon service due" node. If the service is not performed within deadline (e.g., the physician does not notify his arrival to the patient's location on time, or a patient record is not received within the deadline), then the AMS generates a new alert to the relevant administrator to notify this exception. In this way, additional manual or system assisted exception handling processes (Chiu et al., 2001) can be carried out.

Web Services Design for AMS

To facilitate cross-organization communication of alerts, we use contemporary Web Services technologies. An alert to a service partner can be requested through the Web Service *requestAlert*. In response, the service partner will send an acknowledgment to the requestor, indicating that the request is confirmed or denied, or the response will be deferred. Deferred responses can be returned through the requestor's service *receiveDeferredResponse*. The requestor may cancel the alert afterwards by calling the service *cancelAlert*. Requestors and services partners involved in an alert can check for the alert status with the service *checkAlertStatus*. In addition, service partners can check with the service *listActiveAlerts* for the list of active alerts in which they are involved. Administrative programs can also

Figure 5. Typical life cycle of an alert in UML activity diagram



use this service to check for list of active alerts associated with individual tasks. A selection of the Web Services is enlisted in Table 1.

SYSTEM WALKTHROUGH

In this section, we explain how data and process integration can be facilitated with the alert mechanism in our system with some typical scenario walkthrough.

MHCS Process Integration

Let us look at a typical scenario of the main workflow of the MHCS at the Call Center (see Figure 1), with focus on the important alerts and how various component of the system functions. A patient enters a request through the Call Center's Web portal through a personal computer or a mobile device (e.g., PDA or phone SMS message). Alternatively, the patient may phone the Call Center and the operator enters the request. The *workflow application logic* analyzes and validates the request, and then generates an alert with urgency according to the patient's condition (so that the system set various deadlines according to the administrator's urgency policy settings) and service requirements according to the sickness and the patient's preferences.

In the AMS, the *incoming alert monitor* receives the patient's alert and triggers an outgoing alert in the *outgoing alert monitor* to request a physician's service, passing the urgency and service requirements. According to our extended alert conceptual model (Figure 4 and Figure 5), the *role matching module* contacts the specific physicians (if the patient has specified them) or finds the appropriate ones by matching the specialties of the physician with the reported sickness. The *service provider monitor* can then handle all the communications with the physicians' devices, acknowledgements, retries, urgency elevation, rerouting (i.e., alternative physicians), and the monitoring of the physician's service (particularly the arrival of the patient's home) automatically. As our extended alert model supports Web Services, if all the appropriate physicians affiliated to this Call Center are not available, the alert can be re-routed to the AMS of other appropriate healthcare partners (as determined by the *role matching module*) via a Web Service. Similarly, an alert is triggered requesting a nurse's service if necessary.

If hospitalization is required, the *service provider monitor* sends an alert to call an ambulance via a Web Service of the ambulance call center, passing the destination hospital, urgency and the necessary information of the patient (particularly the address and sickness). This is now possible as our extended alert model supports Web Services. The *service provider monitor* sends another alert to contact the hospital for admission and any necessary preparation for the patient.

Table 1. Selected list of Web services for AMS communications

Service Name	Input	Response
requestAlert	AlertID, RequestorID, AlertMessage, Roles, Urgency, ResponseRequired (TRUE | FALSE), Deadline, Extra Data	AlertID, ServicePartnerID, Ack (Confirmed | Denied | Deferred), ResponseMessage, AlertReceiptTime
cancelAlert	AlertID, RequestorID	Ack (Confirmed | Denied | Deferred)
checkAlertStatus	AlertID, RequestorID	Alert Status
listActiveAlerts	(TaskID | ServicePartnerID),RequestorID	List of pending alerts associated
receiveDeferred Response	Item AlertID, ServicePartnerID, ResponseMessage, AlertReceiptTime	Ack (Confirmed, NotConfirmed)

In the case where a hospital is full or unable to admit the patient, an alternative hospital can be sought for (as determined by the *role matching module*) and the ambulance will be updated accordingly through another Web Service of the ambulance call center. Similarly, the AMS can automate an order to a pharmacy and the handling of unavailable medication by rerouting the order to an alternate source through Web Services. The *service provider monitor* can also monitor all the progress of these cross-organizational computer-to-computer interactions according to the urgency requirements of the patient.

To extend the availability of the *Web portal* for users on different platforms, eXtended Markup Language Stylesheet Language (XSL) technology is employed (Lin & Chlamtac, 2000). For example, different Hypertext Markup Language (HTML) outputs are generated for Web browsers on desktop PCs and PDAs respectively, while Wireless Markup Language (WML) outputs are generated for mobile phones. Figure 6 illustrates two sample *alert response forms* for a physician through WAP on a mobile phone and a PDA browser respectively.

The *service provider monitor* is responsible for the vital administrative function of monitoring the status of service progress and especially exceptions. Thus, the AMS generates alerts to relevant administrator(s) upon exception. For example, the administrator can monitor house-call status through a customized House-call Status Monitor page (cf. Figure 7) based on a customized view of the AMS's active alert table. Manual manipulations can be carried out through the *administrative interface* if necessary.

As such the AMS can support flexible workflow management and process integration with service partners, involving both human and programmatic interaction. With the support of an AMS, the urgency requirements associated interactions with the medical personnel and the service providers as well as the monitoring requirements of the administrators can be systematically and modularly captured into the AMS, instead of scattering around in the main workflow specification.

Healthcare Data Integration

Since we also model data requests as alerts, a healthcare data integration process ("Gather Patient Record" of Figure 5) can similarly be modeled as workflow, while individual data requests are modeled as alerts. Figure 8 depicts a sample workflow for healthcare data integration.

When the workflow application logic determines a need to gather to records of a patent, an alert is submitted to the AMS. In the AMS,

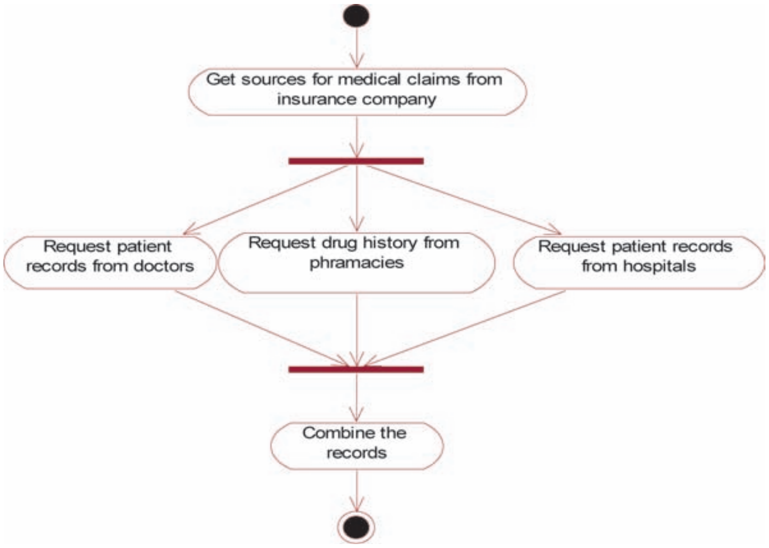
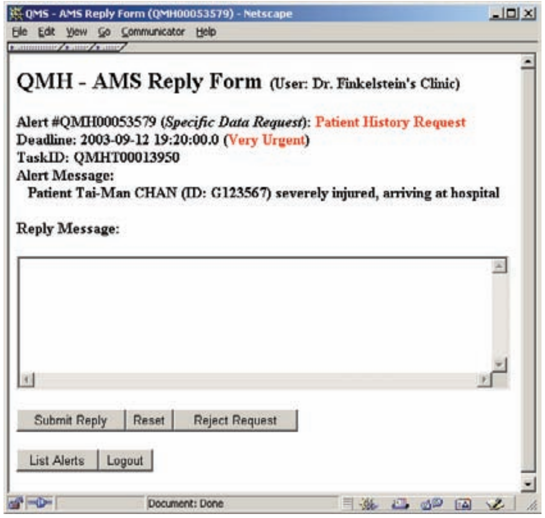
Figure 8. Sample healthcare data integration plan in UML activity diagram



the *incoming alert monitor* receives this alert and triggers an outgoing alert in the *outgoing alert monitor.* The *role matching module* finds out the destination insurance company and the *service provider monitor* sends an alert via Web Services to the insurance company to request the extraction of the list of healthcare service providers from the claim records of the patient. Based on the response, further alerts are sent to each of these healthcare providers again via their respective Web Services to request the relevant patient records. Urgency requirements apply as the physician needs the information by his arrival to the patient's home, while the hospital needs the information by the arrival of the patient. As such, the AMS not only caters for the interactions but also the urgency requirements for data integration.

In case some of these data sources can only support manual procedures, they can still participate in this process as our architecture provides web-based alert response forms (cf. Figure 9). Moreover, humans may be involved as approval may be required for accessing patient records. In this case, though some requests may be rejected or some of them cannot meet the deadline, at least

Figure 9. Sample data request alert response form



QMH - AMS Reply Form (User: Dr. Finkelstein's Clinic)

Alert #QMH00053579 (*Specific Data Request*): Patient History Request
Deadline: 2003-09-12 19:20:00.0 (Very Urgent)
TaskID: QMHT00013950
Alert Message:
Patient Tai-Man CHAN (ID: G123567) severely injured, arriving at hospital

Reply Message:

the data integration process can be speeded up as much as possible.

Handling Urgency and Service Provider Matching

Let us further look at how urgencies are handled by the *outgoing alert monitor* of the AMS. The *role matching module* is responsible for searching a service provider for each alert. The service provider matching algorithm searches for those service providers that can play the role required for the alert. The algorithm then selects those that have a response time that is less than the deadline. This further restricts the set of service providers that can receive the alert. If the matching is successful, one service provider is selected according to a user-supplied cost function (see Kafeza et al., 2004 for further details). In this application, the cost function can be based on the time required for service, distance to be traveled, charges of the service provider, etc. In case no matching is available (i.e., there exists no service provider with the requested role that can meet the deadline), the algorithm upgrades the alert by expanding the roles whenever possible (e.g., request a specialist instead of a general practitioner). After the matching, an *active alerts table* keeps all instantiated alerts and whether the alert has been acknowledged or not.

If an alert is resent, the service provider matching algorithm will take into account of the urgency strategy definition. The urgency strategy definition module is a tool for defining the policies according to which the urgencies of the alert will evolve. Moreover, this module is responsible for keeping and updating status information for the alerts. In our alert model, every alert is associated with an urgency value and a deadline, while every service provider is associated with an average response time for every service that it provides. During the specification phase, the administrator has to specify the *urgency strategy tables*. An *urgency strategy table* defines the policies for every urgency increase and the additional actions that should be taken. The administrator may define different urgency strategy tables for different types of alerts. For example, we could define the urgency values from the ordered set {Low, Normal, Urgent, Very Urgent, Critical, Very Critical} and a default *urgency function* as shown in Box 1.

Box 1.

$$U002(t) = \begin{cases} \text{Urgent} & t \le \mathrm{T} \text{ (default)} \\ \text{Very Urgent} & \mathrm{T} < t \le \mathrm{T} + \mathrm{dt}_1 \\ \text{Critical} & \mathrm{T} + \mathrm{dt}_1 < t \le \mathrm{T} + \mathrm{dt}_1 + \mathrm{dt}_2 \\ \text{Very Critical} & \mathrm{T} + \mathrm{dt}_1 + \mathrm{dt}_2 < t \le \mathrm{T} + \mathrm{dt}_1 + \mathrm{dt}_2 + \mathrm{dt}_3 \end{cases}$$

Table 2. Example urgency strategy table

Urgency002	*Action*
Urgent	default – send a message to the chosen physician
Very Urgent	Submit a second alert to the same physician, notifying about the approaching deadline
Critical	Redirect the alert to another SP that has the best response time
Very Critical	Send the alert to several SPs and accept the results of the one that response first, notify an administrator

Table 2 shows an example urgency strategy table. Here, let us consider the association of an alert with this table. Assume the alert is sent to the chosen physician at the default level *Urgent*. In case there is no response, the *service provider monitor* increases the priority to *Very Urgent* and creates another alert message to notify the physician about the eminent deadline. If still there is no response, the *service provider monitor* increases the priority to *critical* and the *role matching module* tries another find another physician with the same roles and the best response time. If this step also fails, the *service provider monitor* further increases the priority to *Very Critical*, where all available physicians with requested roles will receive the broadcast alert, while an administrator is notified.

APPLICABILITY DISCUSSIONS

Based on the prototype and system descriptions, we have discussed with the major system stakeholders, including medical professionals, patients, and the call center. We explain the significance of the alert mechanism in the MHCS and how various contemporary technologies help.

The main motivation of the MHCS is to solve the existing problems involved in the costly manual procedures required for the provision of quality services to patients effectively and efficiently. There is a strong need for automating the workflow because the processes involved are often urgent and error-prone and there are many possible exception cases, such as, failure of finding suitable personnel, absence and lateness of the personnel, etc. The root of such problems originates from the variety of parties and personnel to liaise with. Once committed to service a call, the call center has to satisfy their information need (in particular electronic patient records), together with the required process support. The AMS help select and communicate with the correct personnel or service partners through their available channel at the correct location with the correct information through the alert mechanisms as detailed in this article. In particular, the AMS automates such communications via various electronic channels as well as attempts alternate service providers (medical personnel via various mobile platforms and different service partners via Web service) in order to minimize the delay and costs involved in inefficient manual calls and retry calls. The AMS further keeps track of such alerts and therefore monitors the call center workflow processes, in order to make sure that the required services are provided on time, meeting the urgency requirements. Thus, the MHCS captures the knowledge and experiences of the call center staff and help them handle the patients' calls correctly and timely.

In particular, the patients' care outcome is the primary concern. With such improvements of the call center, timely and reliable house-call service from healthcare professionals of the required specialties can thus be streamlined. Further, when there are suddenly too many calls, phones may not be able to get through. This is not only frustrating but may also cause addition risks to the patients' health. With multi-channel access to the MHCS, patients can either enter their request through the Web via different (mobile) devices or with a traditional phone call to the call center. Patients with long-term sickness can also call via pre-programmed devices with a simple interface (such as just an electronic button).

Accurate, complete, and timely information routing also helps the care outcome. The MHCS also provides such a paperless distributed environment that minimized human intervention and therefore improves the accuracy and timeliness. We have explained in the previous section how patient records can be routed directly to the patients' house and to the physician in charge of the call via Web services through the alert mechanism. The details of a call (such as the location, patient's symptom, and equipment required) can also reach the physician accurately. Similarly, prescriptions can be routed to pharmacies automatically. In addition, we have explained how such automation and the possible governance provided through the MHCS help reinforce privacy and security.

With our approach, all the data accesses are performed through alerts. The AMS can therefore assure that only the necessary personnel are involved in the process because the matchmaking mechanism in the AMS (Kafeza et al., 2004) verifies the roles of the service providers for the alerts. Further, the scattered patient records can be sent *directly* to the patient's home personal computer or to the physician in charge of the current house-call with this platform. Thus, the privacy of patients can be protected. Further, because all such data access is recorded via the alert mechanism, auditing can be easily performed against possible misuse.

In non-urgent cases, the Web-based system offers new functions. Patients or their family members may search or browse for their desired physicians and hospitals. The MHCS may further help find appropriate hospitals or the clinics that meets the budget from the patients' insurance coverage. The MHCS can schedule examinations within the time duration as well as reduce waiting time in general.

For medical professionals, the MHCS also helps them in their time and schedule management anywhere anytime and helps them communicate with many other parties (such as the call center, hospitals, their own clinic, etc.) for support. In particular, the introduction of the AMS mechanism offers four important advantages. (1) It will make sure that an alert can reach the person who has to be notified. (2) The inclusion of multiple mobile devices and platforms helps both the medical professions and the patients. (3) The implementation of an urgency policy that uses concurrently multiple devices to communicate the alert can increase the probability to inform the person on time. (4) An automated alert can make sure that the information is passed accurately and completely. (5) The AMS allows the choice of received information, reception devices, and desired time slots.

As for adoption, a major problem in migration to the new system is that partner service providers may not be supporting Web Services or even computerization for some tasks. As our system architecture supports humans to be alerted, either the call center staff or personnel of the service provider can help enter information into the system through the interactive web-based *alert response forms* (cf. Figure 9). The worst scenario is that a call center staff is alerted to carry out manual work (e.g., calling a hospital through a phone to notify a patients' arrival) and record the deed through an alert response form.

As organizations are moving towards service-oriented models, service providers currently do not consider such computerization will eventually need to do so in order to enhance their competitiveness. In addition, they will eventually realize the value of such systems. Moreover, the proposed external Web Services interfaces are not complicated at all and can be easily programmed for alert reception and delivery. Moreover, such an AMS is light-weight, highly coherent, and loosely coupled with other sub-systems, enabling it to be plugged into any information system that needs such services. Besides routing alerts to external service providers, the AMS can also route alerts to other AMS within a large organization, such as a hospital. They are orchestrated by Web Services technology to work together seamlessly in the organization and even cross organization boundaries to partner service providers. This architecture is highly scalable and interoperable. Various healthcare partners operating call centers and therefore having similar objectives can therefore effectively form alliances for better services. As such, upgraded systems can provide alert support through an AMS gradually for adequate testing and streamlining the switch-over, which may otherwise be impossible involving a large number of service providers in a *service grid* (Gentzsch, 2002).

CONCLUSION AND FUTURE WORK

In this article, we have combined techniques from the different disciplines of computer science, marketing, and healthcare information systems to address a critical clinical service-based need as well as urgent policy-making challenge on the management of alerts. We have analyzed the requirements and proposed the conveying of alerts to the right service provider at the right time using Web Services and mobile devices, for service provision under urgency constraint. We have introduced a framework of an alert management system (AMS) supporting both human and Web Services providers. This framework supports a flexible alert conceptual model that allows users to specify tasks, alerts, roles, and their inter-relations. We further illustrate how alerts can capture requirements for both data integration and process integration requests. We have also presented our AMS architecture with an implementation outline based on Web Services and mobile technologies with the alert monitoring and routing mechanisms involved. We have demonstrated and discussed the applicability of the AMS in healthcare chain workflow management with a Medical House-call System, supporting both healthcare data and process integration. Because it is hard to promote radical changes to public healthcare services, our MHCS also serves as a pilot showcase for further deployment of AMS.

The main remarkable contribution of the AMS is that process and data integration requests to human service providers (including the physicians and nurses) as well as Web Service providers (such as contacting the hospital, ordering medicine for the patient from a pharmacy) can be uniformly modeled as alerts in this application framework and architecture. The logic for sending, routing, and monitoring these alerts is supported in the AMS and can be heavily reused. Thus application development can be much structured and streamlined.

In addition, because an AMS targets for urgent, asynchronous, unstructured, or even ad-hoc tasks (such as exception handling), it is complimentary to conventional workflow management systems (WFMS) that target at regular synchronous workflows. In fact, the motivation of AMS evolves from the exception handling and user-interface mechanisms of our ME-ADOME WFMS (Chiu et al., 2002), by factoring out and extending, in particular, urgency requirements. The physical execution of individual tasks of regular processes is outside the scope of the AMS and is captured in the application logic of individual information systems (as illustrated in Figure 3), which can be WFMSs as well.

To further evaluate our approach and the system prototype, we are scheduling life trials. In order to evaluate the performance of the system, we compare the service time to the existing practice. We also compare whether the costs are reduced for the patients. Using questionnaires, we also evaluate the patients' satisfaction with respect to the existing policies. We are also planning simulations for scalability and robustness as our future work.

We are incorporating the AMS under our ME-ADOME WMFS (Chiu et al., 2002), aiming to strengthen the support for alerts for general workflow and E-service management. We are also investigating in inter-relations among alerts. In particular, we are looking into alerts due to failure of commitments (Chiu et al., 2004b) and their relation to contract enforcement. We are also interested in further issues of collaborative workforce management, especially managing the diary of healthcare personnel with agents (Chiu et al., 2003). We are also interested in the impact of cancellations, other possible exceptions, tradeoff between quality and cost, and service negotiation (Chiu et al., 2004b). We are investigating in further legal, ethnical, security, and privacy requirements involved in cross-organizational patient record integration. The use of Semantic Web technologies for service composition (Wang & Cheung, 2004) and matching (Xu et al., 2004, Chiu et al., 1999) is also one of our theoretic research directions when we expand from a close system of medical partners to an open service grid in the future.

Bhavesh Shrestha
University of Massachusetts Dartmouth, USA

ABSTRACT

Multi-Agent System (MAS) is a suitable programming paradigm for simulating and modeling health care systems and applications, where resources, data, control and services are widely distributed. We have developed a multi-agent software prototype to simulate the activities and roles inside a health care system. The prototype is developed using a framework called Role-based Agent Development Environment (RADE). In this chapter, the authors present an integrated approach for modeling, designing and implementing a multi-agent health care simulation system using RADE. They describe the definition of role classes and agent classes, as well as the automatic agent generation process. The authors illustrate the coordination problem and present a rule-based coordination approach. In the end, they present a runtime scenario of this health care simulation system, which demonstrates that dynamic task allocation can be achieved through the creation of role instances and the mapping from role instances to agents. This scenario also explains how agents coordinate their activities given their local constraints and interdependence among distributed tasks.

INTRODUCTION

Multi-Agent System (MAS) is a suitable programming paradigm for simulating and modeling health care systems and applications, where resources, data, control and services are widely distributed. We have developed multi-agent software to simulate the activities and roles inside a health care system. Such software can be used to assist the collaborative scheduling of complex tasks that involve multiple personals and resources. In addition, it can be used

DOI: 10.4018/978-1-60566-772-0.ch006

to study the efficiency of the health care system and the influence of different policies.

However, the application of multi-agent system has been limited by the difficulty of developing agent-based systems, and considerable amount of time and highly experienced programmers are required to develop a multi-agent system. After such system is built, it is also difficult to test and maintain the system because of its complexity. The reusability of such system is low; it is unlikely to use an existing system for another application domain with little or minor change. In this chapter, we will describe a role-based approach to building multi-agent systems for health care simulation and modeling. With this approach, we are able to separate the concern on domain knowledge and the concern on intelligent problem-solving capabilities. In this approach, conceptual roles, such as physicians, nurses and patients are defined with the domain related knowledge including goals, permissions, organizational relationship, and interaction protocols, etc; where an agent is a concrete entity equipped with motivations, resources and problem-solving capabilities, which can be used to represent a real person in a health care system. Each agent can be configured based on different specifications according to the real person's situation and needs. Then the agent instance is dynamically generated for the real person who enters the system.

In this chapter, we will also describe an automated agent generation process, which utilizes the existing tools and mechanisms as much as possible. We propose to create agents using a drag-and-drop mechanism where the user can select components to plug into the agent depending on application requirements. We adopt a utility-driven agent architecture with quantitative reasoning capabilities. Besides the logical reasoning on the matching of motivations and the conflicts among different roles, we adapt a quantitative model of motivation named MQ (motivation quantities) framework. Based on the MQ framework, an agent can perform a quantitative reasoning on how important a role instance is, given its preference, its utility function and its current achievement. In the definition of a role, we introduce a formal language called RTÆMS (Role-based Task Analyzing, Environment Modeling, and Simulation) to represent the domain knowledge about how to achieve a goal. RTÆMS language is a hierarchical task network representation language with task interrelationships and quantitative descriptions of different alternatives to achieve a goal. The domain expert can specify how a complicated health service task should be performed with the collaboration of multiple roles inside the system. Each agent is also equipped with the capability for planning, scheduling and cooperation; hence, an agent can schedule its local activities with the consideration of the constraints from other agents. Meanwhile, a user of the system can choose different collaboration rules according to the organizational rules and the specific needs in the system.

In the rest of this chapter, we first discuss related work in several research areas. Afterwards, we describe how to construct a health care simulation system using the approach described above, and show how to define roles and their interrelationships, and how to define agent classes. Then, we present an automatic agent generation tool as well as a rule-based coordination approach. Finally, we use a runtime scenario to demonstrate how new role instances are created, how agents are taking new roles, planning and scheduling their tasks, and collaborating with each other to achieve a complex goal.

BACKGROUND

Researchers have studied a number of approaches for defining and developing autonomous agents and multi-agent system from different directions. Here we discuss related research work in four areas: agent development framework, role-based modeling of agent-based systems, specification of coordination rules, and model-driven development of multi-agent systems.

Agent Development Framework

DECAF (Graham, Decker & Mersic, 2003) and JADE (Bellifemine et. al, 2003) are examples of the frameworks that can be used to generate domain specific agents. DECAF (Distributed, Environment-Centered Agent Framework) developed in University of Delaware, is a toolkit to build multi-agent systems. The toolkit provides a stable platform to design, rapidly develop, and execute intelligent agents to achieve solutions in complex software systems. DECAF provides the necessary architectural services of an intelligent agent: communication, planning, scheduling, execution monitoring, coordination, and eventually learning and self-diagnosis. Plan editor is a GUI that provides the interface for control or programming of DECAF agents. In the Plan editor, executable actions are treated as basic building blocks, which can be chained together to achieve a larger and more complex goal in the style of a hierarchical task network. This provides a software component-style programming interface with desirable properties such as component reuse and some design-time error-checking. The chaining of activities can involve traditional looping and if-then-else constructs. This part of DECAF is an extension of the RETSINA (Williamson, Decker & Sycara, 1996) and TÆMS (Decker, 1996). task structure frameworks. Each action of an agent can also have a performance profile, which is used and updated internally by DECAF to provide real-time local scheduling services.

JADE (Java Agent Development Framework) (Bellifemine et. al, 2003) is a software framework fully implemented in Java language distributed by Telecom Italia. It simplifies the implementation of multi-agent systems through a middleware that complies with the FIPA specifications. The agent platform can be distributed across machines and the configuration can be controlled via a remote GUI. The configuration can be changed at runtime by moving agents from one machine to another, when required. The communication architecture offers flexible and efficient messaging, where JADE creates and manages a queue of incoming ACL messages, private to each agent; agents can access their queue via a combination of several modes: blocking, polling, timeout and pattern matching. JADE implements a full FIPA communication model, and its components have been clearly distinct and fully integrated: interaction protocols, envelope, ACL, content languages, encoding schemes, ontology, and finally, transport protocols. Most of the interaction protocols defined by FIPA are available and can be instantiated after defining the application-dependent behaviour of each state of the protocol. Agent management ontology has been implemented, as well as the support for user-defined content languages and ontology that can be implemented, registered with agents, and automatically used by the framework. JADE has also been integrated with JESS, a Java shell of CLIPS, in order to exploit its reasoning capabilities.

The goals of both these frameworks are to develop a modular platform to allow for rapid development of third-party domain agents, and provide a means to quickly develop complete multi-agent solutions using combinations of domain-specific agents and standard middle-agents. These frameworks specify agents in terms of roles they play, and assume that agents do not change their roles at run time. In contrast, we implemented an automated agent generation mechanism using the RADE framework. Using this framework, we can separate the domain knowledge and the intelligent problem solving capabilities. So an agent can be created with intelligent capabilities and motivations, and can take up different roles dynamically.

Role-Based Modeling

The related work in the second area is to propose role-based methodology for developing multi-agent systems. Approaches like Gaia (Wooldridge, Jenning, & Kinny, 2000; Zambonelli, Jennings & Wooldridge, 2003) and MaSE (DeLoach, Wood, & Sparkman, 2001) can be used to model multi-agent system societies in terms of organizations or groups composed of a collection of roles related to one another and participating in patterns of interactions with other roles. The agents are then specified in terms of a set of roles they play. These approaches explicitly assume that the inter-agent relationships and the abilities of agents do not change at run-time and that all the agents are explicitly designed to cooperatively achieve common goals.

The Gaia methodology can be used to model both the macro aspect and the micro aspect of a multi-agent system. It covers the analysis phase and the design phase. In the analysis phase, the role model and interaction model are constructed. Based on the analysis models, in the design phase, three models, the agent model, service model and acquaintance model are constructed during the initial design of the system, and then are refined during the detailed design phase using conventional object-oriented methodology. The later version of Gaia (Zambonelli, Jennings & Wooldridge, 2003) extends the former one in order to better suit to open multi-agent systems by introducing two new abstractions: (1) organizational rules (explicit identification of relationships and constraints between roles and protocols), and (2) organizational structures (explicit specification of organizations in terms of their topology and control regime).

The MaSE methodology is a specialization of more traditional software engineering methodologies (DeLoach, Wood, & Sparkman, 2001). During the analysis phase of the MaSE methodology, a set of roles are produced, which describes entities that perform some function within the system. In MaSE, each role is responsible for achieving or helping to achieve specific system goals and sub-goals. During the design phase, agent classes are created according to the roles defined in the analysis phase.

In our approach, the components of role instances and agent instances are loosely coupled, where agents can take or release role instances at runtime without knowing the internal structure of role instances. Thus, role classes and agent classes can be designed and implemented independently.

Coordination Rules

The related work in the third area is definition of coordination rules. Projects such as AgenTalk (Kuwabara, Ishida, & Osato, 1995) use scripts and finite state machine to define coordination rules. AgenTalk is a language for describing coordination protocols for multi-agent systems co-developed by NTT Communication Science Laboratories and Ishida Laboratory, Department of Information Science, Kyoto University. It provides an explicit state representation of a protocol, and a finite state machine that allows variables to be used as a basis to describe coordination protocols, called a script. Using this model, states of a protocol are explicitly defined, and actions of an agent can be defined for each state. Protocols can be defined incrementally by extending existing scripts. It provides a programming interface that specifies the portion of a state transition rule that needs to be customized for each agent. The AgenTalk has been implemented in Common Lisp.

In ROPE project (Becht et. al., 1999), cooperation process is built as a separated component from the concrete agents; the ROPE engine provides execution of the cooperation process, which is described as a high-level Petri net class. However, the implementation of ROPE engine is based on shared memory, which is not always feasible for agents that are widely distributed on different machines. Additionally, the cooperation process in ROPE is based on token and transition firing, which is not feasible enough to support more proactive cooperation and collaboration, i.e. agents are able to consider the cooperation and coordination needs when they are planning their own activities.

A set of domain-independent general collaboration mechanisms, Generalized Partial Global Planning (GPGP) (Lesser, et. al. 2004), based on TÆMS language (Decker, 1996) has been developed. We have reused some of GPGP similar mechanisms in RADE (Zhang & Xu, 2006) framework based on RTÆMS language. In framework such as AgenTalk, the emphasis is on the flow of messages and how the dialog between agents is structured. Such framework combines finite state machines with enhancements. In contrast, GPGP focuses on a domain independent and quantitative evaluation of the interactions among tasks and the dynamic formation of temporal constraints to resolve and to exploit these interactions. Our implementation gives a user the freedom to choose the appropriate coordination rule according to the application domain.

Model-Driven Development

Previous work on model-driven development of multi-agent systems can be summarized as follows. Gracanina, Boher and Hincey proposed a model-driven architecture framework as an extension to Cognitive Agent Architecture (COUGAAR) (Gracanin, Bohner & Hinchey, 2004). The Cognitive Agent Architecture is a distributed agent architecture that has been developed primarily for very large-scale, distributed applications that are characterized by hierarchical task decompositions, and as such, it is well suited for autonomic systems. The framework consists of two main parts, General COUGAAR Application Model (GCAM) and General Domain Application Model (GDAM). The GCAM provides representation in its model of the COUGAAR basic constructs, and the GDAM defines the requirements and the detailed design.

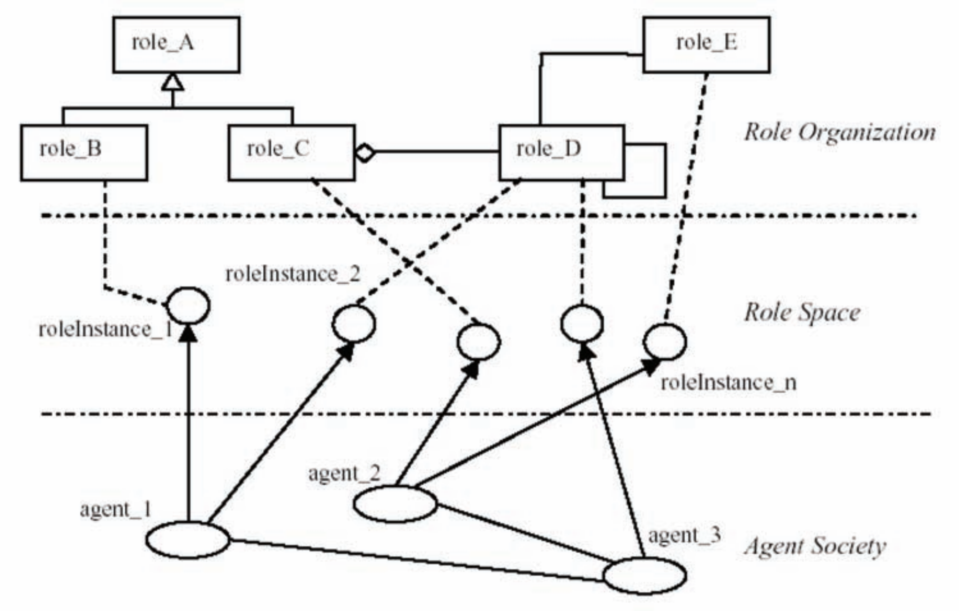
Maria, Silva and Lucena (2005) proposed an MDA-based approach to developing multi-agent systems. They first use MAS modeling language (MAS-ML) to model MAS by creating the platform independent models (PIM). Then the MAS-ML models are transformed into UML models using the ASF framework, which defines a set of object-oriented models for MAS entities specified in MAS-ML. The UML models are then transformed into code.

We have proposed three levels of models for developing role-based open multi-agent systems (Xu, Zhang & Patel, 2007), namely AIPIM (Application Independent Platform Independent Model), ASPIM (Application Specific Platform Independent Model), and ASPSM (Application Specific Platform Specific Model), as a refinement process. In each level of the models, role components and agent components are always separated and designed independently. Role instances and agent instances interact with each other only at runtime through an A-R (Agent-Role) mapping mechanism.

ROLE-BASE MODELING APPROACH

The basic idea of the role-based agent development environment (RADE) is illustrated in ***Figure 1***. The top level is the *role organization*, which defines the conceptual roles and their relationships such as inheritance, aggregation, association and incompatibility. In health care systems, conceptual roles represent all possible job titles in the system, such as *physician* and *nurse*. The relationships describe how these roles relate to each other. The second level is the *role space*, which consists of multiple role instances; each role instance is instantiated from a conceptual role dynamically. For example, whenever there is a need to cure a patient, a new physician role instance is created with the goal to cure a patient. A role instance

Figure 1. RADE Concept (© 2007, Journal of Computational Intelligence Theory and Practice. Used with permission.)



represents the task that needs to be accomplished in the system. The bottom level is the *agent society*, which consists of multiple agent entities. Agent can take or release role instances dynamically, where the mapping from role instances to agents is called A-R mapping, which represents that a real person takes a task in the system.

In an actual software system, agent instances are automatically generated based on the definition of agent classes. Each agent instance is a software entity that performs specific functions and also coordinates and communicates with other agent instances. On the contrary, role classes are defined to incorporate domain knowledge and organizational relationships. Each role class is associated with specific goals and detailed descriptions of how to achieve such goals. The relationships among different role classes also depict the organizational relationships among the real-world entities represented by these roles. Such information is expected to be provided by domain experts rather than software engineers. At system runtime, role instances are created dynamically either by a human user or by an agent when certain goals are needed to be realized. Those role instances mainly carry domain knowledge; however, they do not actually perform any actions like agents. When an agent takes a role instance, the agent uses the knowledge incorporated in the role instance in order to achieve the goals defined in it.

One major advantage of the RADE approach is that it supports the separation of domain knowledge and the agent framework for the simulation system. Any domain knowledge relates to the health care domain can be specified by domain experts through definition of roles and their interrelationships. On the other hand, software engineers are responsible to develop automatic agents that actually perform tasks in the simulation system.

DEFINING ROLES AND ROLE SPACE

The definition of a role class includes the following information:

1. A set of attributes, such as role name and identification.
2. A set of goals; each goal is associated with a plan tree, which is a hierarchal description of the alternatives to accomplish a goal.
3. A set of actions that can be performed by this role, i.e. a *Physician* role can perform an action of *Prescribe Medicine*.
4. Qualification: the requirement needed to take such a role.
5. The permission of this role, which specifies what information and resource are allowed to be access by this role. For instance, a *Physician* role has the permission to access the patient's medical record.
6. A set of protocols, which describe how this role should interact with other roles.

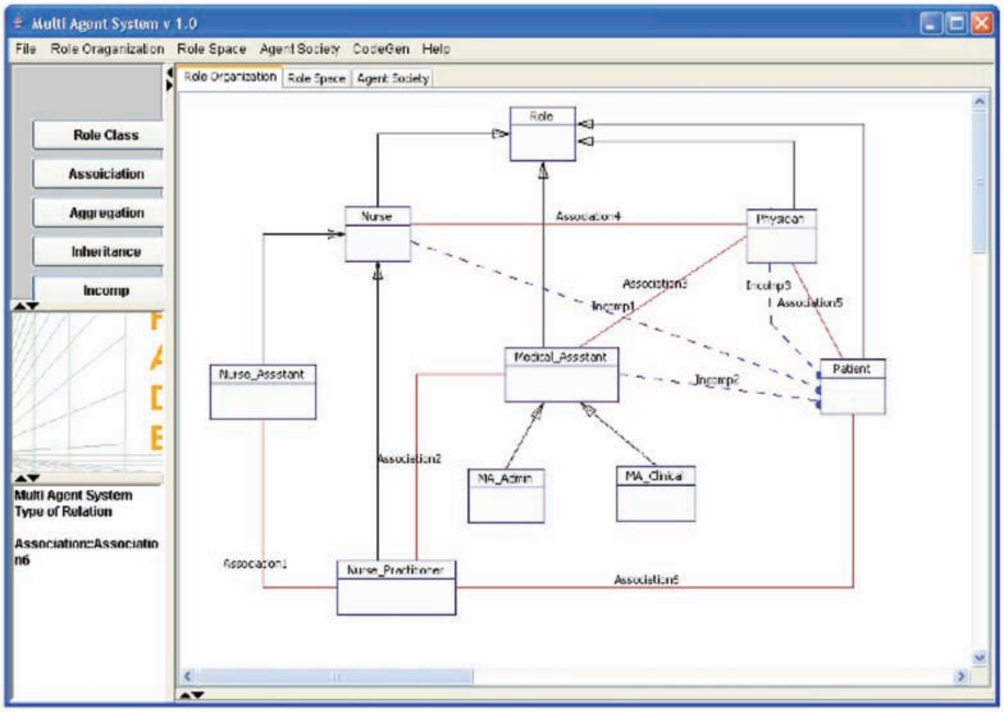
All above information is domain-dependent; hence an expert in health care domain who is familiar with all those rules and regulations can define those role classes. The formal definition of role class in Object-Z can be found in (Xu & Zhang 2005).

In the health care simulation system, we have defined the following role classes:

1. **Patient:** A person who seeks for health care.
2. **Physician:** A person who determines whether diagnostics are to be undertaken, provides prescriptions, performs medical and surgical interventions, has the ability to direct patient care and advance a patient to the next step of care.
3. **Medical Assistant:** A health care professional who performs a variety of clinical, clerical and administrative duties within a health care setting. There are two roles defined as subclasses of this role class:
    a. **Administrative Medical Assistant (MA Admin):** Medical assistant who performs the administrative job.
    b. **Clinical Medical Assistant (MA Clinical):** Medical assistant who performs the clinical job.
4. **Nurse:** There are two roles defined as subclasses of this role class:
    a. **Nurse Assistant:** a nurse who assesses the patient's medical problem, provides care and helps to set up laboratory specimen and medical instruments.
    b. **Nurse Practitioner:** a registered nurse who has completed an advanced training program in primary health care delivery, and may provide primary care for non-emergency patients, usually in an outpatient setting.

Figure 2 shows the RADE interface for a user to create role classes and define the interrelationships among role classes. In this example, the interrelationships include inheritance, association and incompatibility. An inheritance relationship describes the generalization/specification relationship between two role classes. For example, both *MA Admin* and *MA Clinical* inherit the *Medical Assistant* role class since they are specified medical assistants. Association is a very common relationship between role classes; it indicates that an instance of one role class may perform an action on an instance of another role class. Association relationships exist between *Physician* and *Nurse*, *Physician* and *Patient*, etc. Incompatibility relationship describes the constraints that the role instances of two role classes cannot be taken by the same agent in the same interaction scenario. For example, an agent cannot take a Physician role instance for treating a Patient role instance if the agent is already taking this Patient role instance; however, the agent can take another Physician role instance for treating another Patient role instance that is not taken by this agent. The definition of such relationships depends on the domain knowledge, so we feel that the domain experts are the best candidate to use this interface to define the role classes and their interrelationships.

Figure 2. RADE Interface for creating roles (© 2007, Journal of the Brazilian Computer Society. Used with permission)



In this example, Physician role is defined with a goal to provide cure. The plan tree provides domain knowledge of how to accomplish this goal. To represent the domain knowledge, we introduce RTÆMS (Role-Based Task Analyzing, environment Modeling, and Simulation) language as an extension of the TÆMS language (Decker, 1996). TÆMS is a hierarchical task representation language, which supports representation of relationships among goals and sub-goals, the quantitative description of the atomic approaches and uncertainties, and resources. We extend the TÆMS language by introducing a role attribute for task nodes that represent goals and sub-goals. The attribute role specifies what roles are needed to carry out this goal or sub-goal. ***Figure 3*** shows the plan tree for the goal 'Provide Cure', which includes two sub-goals: 'Examine Patient' and 'Provide Treatment'. The goal 'Provide Cure' is associated with a **min** quality accumulative function (**qaf**), which specifies the following relationship:

Quality(ProvideCure) = min(Quality(ExaminePatient), Quality(ProvideTreatment))

Each role is defined with a goal, a plan tree, a motivational quantity production set (MQPS), a certificate and other attributes. A goal represents a task that the role needs to accomplish, and the plan tree specifies the domain knowledge of how to accomplish the goal in terms of decomposing it as sub-goals. Consider the following role class.

ROLE: Physician

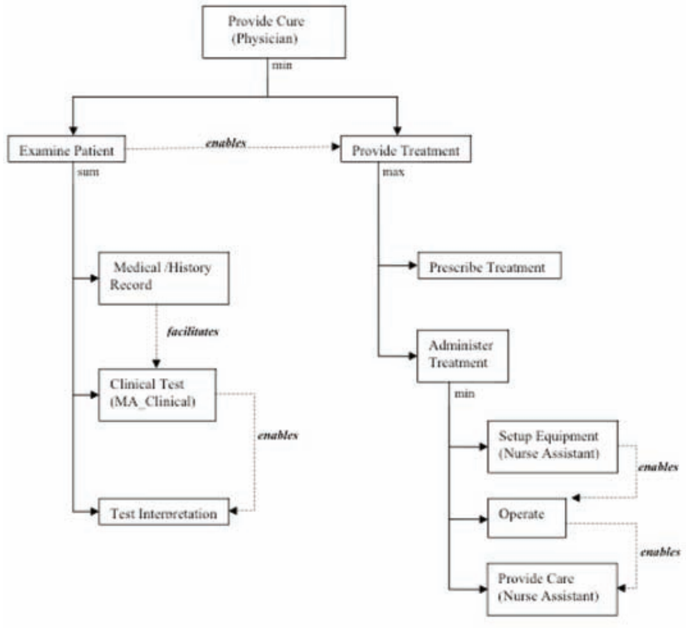
GOAL: Provide Cure

MQPS: (MQ_professional, p1), (MQ_moral, p2), (MQ_experience, p3)

CERTIFICATE: MD (Doctor of Medicine)

This min quality function associated with a

Figure 3. Plan tree for goal Provide Cure in RTÆMS representation (© 2007, Journal of the Brazilian Computer Society. Used with permission)



goal means that the success of this goal depends on the success of all of its sub-goals. Meanwhile, the use of max quality function specifies that there are several alternatives to achieve the goal. For instance, to 'Provide Treatment' for the patient, the Physician can choose either 'Prescribe Treatment' or 'Administer Treatment'. Other available quality accumulation functions in RTÆMS language are: *sum* and *seq_sum*.

Each sub-goal can be decomposed into smaller goals, i.e. 'Examine Patient' consists of three sub-goals: '(Read) Medical History Record', 'Clinical Test 'and 'Test Interpretation'. For those non-local goals, where the tasks need to be performed by other roles, the specification of other roles is included in the plan tree description. For example, 'Clinical Test' should be performed by a Clinical Medical Assistant (MA Clinical), and task 'Setup Equipment' and 'Provide Care' belongs to the Nurse Assistant role. The dash lines represent the interrelationship between goals/sub-goals. For example, 'Clinical Test', which enables 'Test Interpretation,' means that the first goal 'Clinical Test' needs to be achieved successfully before it is possible to implement the second goal 'Test Interpretation'. In addition, '(Read) Medical History Record' facilitates the 'Clinical Test' process because it can provide some useful information about the patient. Other types of interrelationships defined in TÆMS include *disables* and *hinders*. The primitive goal (lowest-level goal) in the TÆMS representation can be specified with more details in another plan tree that is associated with another role. For example, the plan tree for the sub-goal 'Provide Care ' is described in ***Figure 3***, this information belongs to the role Nurse Assistant. The plan tree represented in RTÆMS shows all possibilities to achieve a goal and the interrelationship among goals/sub-goals. It provides fundamental knowledge for agents to plan and schedule its local activities, and it also supports the collaboration and cooperation among agents. More details about the plan tree will be discussed later in the Section of Coordination.

Each goal is associated with a motivational quantity production set (***MQPS***): MQPS = {(MQi, qi), (MQj, qj), (MQk, qk)...}, which represents the success accomplishment of the goal that generates qi amount of MQi, qj amount of MQj, qk amount of MQk, etc. The MQPS describes how this goal contributes quantitatively to some higher-level goals (abstract goals), which are built in an agent's motivation. For instance, when an agent fulfills a goal 'Provide Cure', it collects p1 units of MQ_professional, p2 units of MQ_moral and p3 units of MQ_experience. The agent uses the MQPS specification in the goal definition and its motivation to determine whether it is interested in a role instance, and how interested it is.

The *Qualification* defined in a role class describes the requirements for a particular role. Only an agent who has the specified certificate can take a role instance of that role class. For example, Physician role is defined with a certificate of MD (Medical Doctor); only an agent with a MD certificate can take a Physician role instance.

DEFINING AND DEVELOPING AGENT CLASSES

Agents are the real programmed entities running in the system. In the health care simulation system, each agent represents a personal assistant for a human user in the real world. The agent is responsible for scheduling a user's daily tasks according to the user's preference and constraints. The agent is also responsible for coordinating with other agents when coordination is needed between its own user and other users. A formal definition of agent class in Object-Z can be found in (Zhang, Xu & Shrestha 2007). An agent class definition includes: a set of attributes, motivations, utility function, sensor data, a set of reasoning mechanisms, and execution mechanisms.

Agent attributes include agent names, user, identification, and other descriptive characteristics. The values of these attributes are set when an agent instance is instantiated from the agent class. Different agent instances have different attribute values.

Motivation is defined as "any desire or preference that can lead to the generation and adoption of goals, and which affects the outcome of the reasoning or behavioral task intended to satisfy those goals" (Luck & d'Inverno, 1995). Motivation is the key for an agent to decide which goals it should pursue and how to pursue a goal. We adopt a quantitative view of motivation in our practice. Motivation is defined as a set of motivation quantities (MQs) (Wagner & Lesser 2002).) that the agent tracks and accumulates. Each MQ is associated with a preference function and represents progresses towards an abstract goal. An abstract goal is a long-term commitment to make progress toward certain direction but not a concrete task with a specified plan. For example, a user creates an assistant agent

named Adam. The user specifies his preference on choosing tasks by defining the motivation of this agent as:

Motivation: {MQ_Professional, 0, 0; MQ_Moral, 1, 1; MQ_Experience, 2, 2}

The motivation specifies three long-term goals the user has: professional achievement, moral achievement and experience achievement, which are represented by three types of MQs due to the user's Physician role. The two numbers following the MQ name is the function index and the initial amount of this type of MQ. The function index specifies a utility function that maps a certain number of units of MQ of this type into the agent's local utility. Since the function could be a non-linear function and is also context sensitive, the initial amount of this type MQ is also important. The user also provides this agent his qualification MD, so this agent can be qualified for a Physician role.

Each agent collects sensor data from the environment. For software agents built in this system, sensor data refers to the messages and information the agent receives from the environment including other agents. Based on the sensor data it collects and its motivation, the agent uses its reasoning mechanisms to make decisions. The decisions are made at different levels: selection of roles, selection of goals, and selection of the approach to fulfilling the goals. The first issue is resolved by A-R mapping mechanisms, and the later two issues are inter-related, which are solved by planning /scheduling mechanisms. Given the formal definition of motivations, goals and the detailed description of alternatives to achieve a goal, it is possible to build some general, domain-independent reasoning mechanisms/toolkits. The user can select appropriate components from such toolkits and add them to the agent; the user can also customize these general mechanisms and toolkits by setting up certain parameters. These general mechanisms and toolkits are reusable for agents in different application domains.

Each agent is equipped with some execution mechanisms that can be used to generate the output, which changes the environment. For software agents, the execution mechanisms are the primitive actions to change the environment state. Some of these execution mechanisms are domain-dependent. For example, in our health care simulation system, an agent representing a hospital worker is built with an execution mechanism to set up medical equipment, which is an action the person can perform in real world. Other execution mechanisms could be application-independent, such as sending a message to another agent.

AUTOMATIC AGENT GENERATION PROCESS

After the user has defined role classes and agent classes, agent can be automatically created using a tool we developed. The basic idea of automatic generation of agents is to use component-based agent architecture, where the user can select the components to be included in this agent, and specify a set of attributes of the agent.

The designer or the user of the agent needs to decide what reasoning tool should be built in and select the appropriate execution tools for the agent according to the design purpose of the agent. It is assumed that there are a set of reasoning and execution mechanisms available in the toolkit, which can be selected and plugged into the agent seamlessly.

Based on the general agent architecture, we developed a tool to support the automatic agent generation process. This tool is created by extending the JAF framework (Vincent, Horling & Lesser, 2001) developed by MAS lab at University of Massachusetts, Amherst. This tool includes a graphic user interface (GUI), which can be used to create new agents, modify existing agents, run agents and delete agents. A screen shot of the graphic user interface is shown in ***Figure 4***.

The user also defines the agent's reasoning and execution mechanisms by selecting a number of ready-to-plug-in components such as: planning, scheduling, communication, etc. The user can select what coordination rule should be used by this agent. We will discuss more about the coordination rule in the next section. After an agent class is created, one or multiple agent instances (the executable programs) can be created from this class definition. Each agent instance is an independent program, and the agent is named after its class with a unique number ID. For example, when a user creates an agent class "X" and three agent instances of this class, the three agents are named as "X_1", "X_2" and "X_3," respectively. The user can run agents from this interface by clicking on the "RUN AGENT" menu box on the top, and selecting a number of agents to run from a list of agents that have already been created. Multiple agents can be created and run on difference machines. The user can choose to delete existing agents by clicking on the "DELETE AGENT" menu box. Finally, the user has an option to choose the coordination rules from three types of rules, namely simple rules, hard and soft relationships based rules, and priority based rules.

AGENT COORDINATION AND COOPERATION

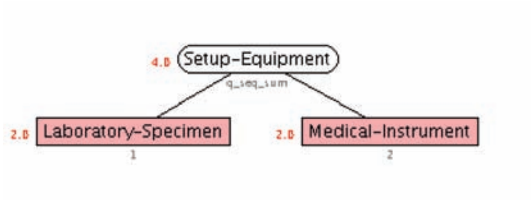
In a health care simulation system with complex activities, distributed information and resources, agents need to coordinate and cooperate on their actions. Efficient coordination and cooperation mechanisms are important for the performance of the system. An agent should coordinate its own actions with those of other agents when there are constraints and interdependencies among their actions.

The RTÆMS language supports collaborations and cooperation by specifying interrelationship among goals and sub-goals, so agents know when and with whom they need to collaborate and cooperate. A set of domain-independent general collaboration mechanisms (GPGP) based on TÆMS language (Lesser et. al., 2004), has been developed, where some of GPGP similar mechanisms are reused in RADE framework based on RTÆMS language. Agents can coordinate and cooperate with each other using the set of mechanisms according to the protocols defined in the role, which specify how the interaction between roles should proceed.

Figure 3 and ***Figure 5*** illustrate pictorially the information that are captured in a RTEAMS representation, which include:

1. Top-level goals that an agent intends to achieve including the deadline for their completion. In ***Figure 3***, 'Provide Cure' is the top-level goal that needs to be completed and in ***Figure 5***, 'Setup Equipment' is the top-level goal that needs to be completed.

Figure 5. Plan tree for 'Setup-Equipment' in RTÆMS representation

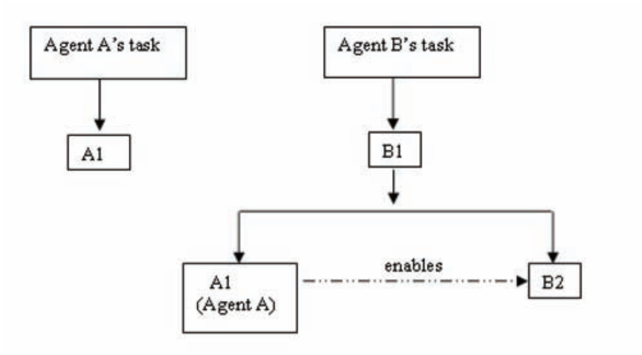


2. One or more of the possible ways of achieving goals is expressed as an abstraction hierarchy whose leaves are basic action instantiations, called methods. In ***Figure 5***, the top-level goal 'Setup Equipment' has sub-goals "Laboratory Specimen' and 'Medical Instrument', which are the methods. These sub-goals need to be completed before the top-level goal can be achieved.
3. Quantitative definition of the degree of achievement in terms of measurable characteristics, such as solution quality and time, is called the quality accumulation function (qaf). In ***Figure 5***, there exits a quality accumulation function *seq_sum* between the sub-goals "Laboratory Specimen' and 'Medical-Instrument'. The total quality of the goal "Setup Equipment" is the sum of the quality of its sub-goals "Laboratory Specimen' and 'Medical Instrument', and these two sub-goals need to be accomplished in a sequence order.
4. Task relationships indicate how basic actions or abstract task achievement affect task characteristics such as its quality and time, elsewhere in the task structure. In ***Figure 3***, there exits a "facilitates" relationship between the task 'Medical History Record' and 'Clinical Test'. A *facilitates* relationship indicates that if the task 'Medical History Record' is completed before the start of task 'Clinical Test', it will increase the quality, and reduce the cost and duration of task 'Clinical Test' by some value.

Task relationships represent a measure view of temporal constraints among activities as a result of information sharing relationships. An *enables* relationship is a hard relationship that essentially acts as a binary switch. In this case, the target method or task cannot accrue quality until the enabling interrelationship is active. A *disables* relationship indicates the exact converse of an *enables* relationship, which precludes the possibility of performing an activity when another activity is performed,. Both a *facilitates* and *hinders* relationship are soft relationships. When a 'facilitates' relationship is active, the targets' quality is increased by some quality power, and the duration and cost are reduced by the duration power and cost power, respectively. Similarly, when a 'hinders' relationship is active, the target's quality is reduced, while the duration and cost are increased. These relationships are called non-local effects if they are relationships between tasks situated in different agents for coordination. Relationships among tasks in the same agent are not of direct concern of the coordination component. The measured view of these relationships indicates how the quality of the information generated by an activity will affect the performance characteristics of the activity using this information, such as the length of its execution and the quality of its resulting solution.

There is a strong connection between the coordination module and a local scheduler module that is part of each agent's architecture. In our work, the agent's local optimization expert is the Design-to-Criteria Scheduler (DTC) (Wagner, Garvey & Lesser, 1998). During the coordination

Figure 6. Agent A and Agent B's initial task view with enables relationship



process, the coordination module queries the DTC scheduler repeatedly to explore the implications of constraints. The coordination and DTC module present in each agent can guide the agent's activities using knowledge of its own local situation and partial knowledge of the activities being carried by other agents. The coordination component in each agent also coordinates with that of other agents to generate constraints on local control that leads to more coherent agent activities.

Each agent starts its coordination component by constructing its own local view of the activities that the agent intends to pursue, as well as the relationships among these activities (Lesser et. al., 2004). The RTÆMS representation is used by the problem solving, coordination and scheduling components as a common communication language. The coordination component helps to construct a global view for an agent, and to recognize and respond to particular inter-agent task structure relationships by making commitments to other agents. The commitments result in coordinated behavior by affecting the tasks an agent executes and the results transmitted. The DTC scheduler, based on commitments, agent's goal, the local and non-local values of tasks, and other agent activity constraints, creates a schedule of activities for the agent, which must meet the real-time deadlines. The coordination component coordinates the activities of an agent through modulating its local control as a result of placing commitments and constraints on the local scheduler.

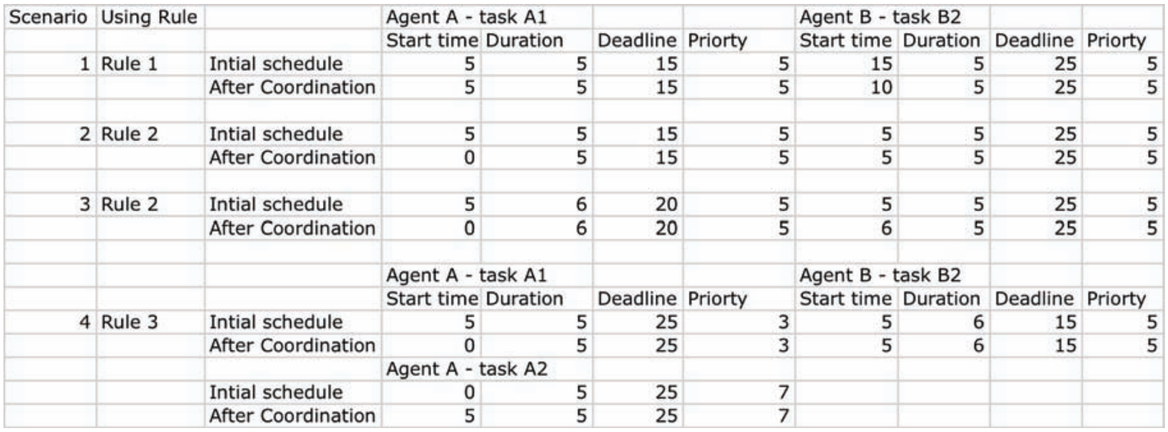
The coordination component uses the RTÆMS task structure representation to add an extension of local and non-local commitments to task achievement. The coordination includes the goals that the agent is currently pursuing, the goals it will likely pursue in the near future, the characteristics of the abstract tasks and basic actions available to achieve these goals, their relationships to other tasks, and the degree of achievement necessary for each goal.

A user can choose a coordination rule from three types of coordination rules, namely Rule1 (simple), Rule 2 (hard and soft relation), and Rule 3 (priority based). The coordination mechanism between agents depends on selection of a specific rule.

Suppose we have two agents A and B shown in ***Figure 6***. Agent B is performing task B1. Task B1 has subtask A1 and B2. Subtask A1 is performed by agent A and subtask B2 is performed by agent B itself. There is an 'enables' relationship from A1 to B2.

When a user selects Rule 1 (simple), the agents use a very simple coordination mechanism - they only consider the quality accumulation function but not the hard and soft relationships between the tasks. As shown in *Figure 6*, suppose there is a *seq_sum* quality accumulation function associated with task B1, agent B recognizes that the quality

Figure 7. Coordination scenarios using different rules



Scenario	Using Rule		Agent A - task A1				Agent B - task B2			
			Start time	Duration	Deadline	Priorty	Start time	Duration	Deadline	Priorty
1	Rule 1	Intial schedule	5	5	15	5	15	5	25	5
		After Coordination	5	5	15	5	10	5	25	5
2	Rule 2	Intial schedule	5	5	15	5	5	5	25	5
		After Coordination	0	5	15	5	5	5	25	5
3	Rule 2	Intial schedule	5	6	20	5	5	5	25	5
		After Coordination	0	6	20	5	6	5	25	5
			Agent A - task A1				Agent B - task B2			
			Start time	Duration	Deadline	Priorty	Start time	Duration	Deadline	Priorty
4	Rule 3	Intial schedule	5	5	25	3	5	6	15	5
		After Coordination	0	5	25	3	5	6	15	5
			Agent A - task A2							
		Intial schedule	0	5	25	7				
		After Coordination	5	5	25	7				

achievement of B1 depends on the accomplish of task A1 and it has to be performed before task B1, it then sends a message to agent A asking it to perform task A1 by a given deadline. Agent A replies with the start time and finish time for task A1 according to its local schedule. Upon receiving this message agent B reschedules the start time of its task B1 to the finish time of task A1. This is the Scenario 1 described in *Figure 7*.

Rule 2 deals with both hard and soft relationships together with the quality accumulation functions and non-local tasks. Hard relationships include the *enables* and *disables* relationship, and soft relationships include *facilitates* and *hinders* relationships.

As shown in ***Figure 6***, task A1 has *enables* relationship with task B2. Agent B sends a message to agent A saying that task B2 has an *enables* relationship with task A1 and should complete task A1 by a given deadline. Agent A checks the start time of task A1. If the start time of task A1 is less than or equal to the start time of task B2, then agent A makes a commitment to agent B that it can finish the task B2 by the given deadline. If the finish time of task A1 is greater than the start time of task B2, agent A then moves task A1's start time to task A1's earliest start time. Agent A sends the new start time and finish time of task A1 to agent B. If the finish time of task A1 proposed by agent A is less than or equal to the start time of task B2, agent B follows its normal schedule. Otherwise, agent B temporarily sets task B2's start time to the finish time of task A1 as proposed by agent A and calculates its new finish time for task B2. If the new finish time falls within the deadline of task B2, then agent B reschedules its task B2 with new values. Otherwise, task B2 is not performed.

Scenario 2 in *Figure 9* explains how agents coordinate with each other using Rule 2. In the initial schedule for task B2, the start time is 5. Agent A sets its start time to its earliest start time (0). Now the new finish time for task A1 is 5. Since the new finish time for task A1 is equal to the start time of task B2, the schedule for task B2 remains unchanged.

Scenario 3 shows a different case. In the initial schedule for task B2, the start time is 5. Agent A sets its start time to its earliest start time (0). Now the new finish time for task A1 is 6. Since the new finish time for task A1 is greater than the start time of task B2, rescheduling of task B2 is needed. Task B2 has a new start time as 6 after rescheduling.

Rule 3 is based upon priority of a task, which takes into consideration the hard and the soft relationships. Rule 3 is useful when an agent is performing more than one task. In the RTÆMS

	Laboratory-Specimen	26		29					
	Medical-Instrument	29		32					

representation, each task has a new attribute called "priority", with its value ranging from 1 (i.e., the highest priority) to 10 (i.e., the lowest priority).

Let us assume that agent A has two tasks A2 and A1. Task A1 has *enables* relationship with task B2. Agent B sends a message to agent A saying that task A1 has an *enables* relationship with task B2 and requires task A1 to be completed by a given deadline. Agent A checks the start time of task A1. If the start time of task A1 is less than or equal to the start time of task B2, agent A makes a commitment to agent B that it can finish the task B2 by the given deadline. If the finish time of task A1 is greater than the start time of task B2, agent A then checks the start time and finish time of task A2. If task A2 is performed before task A1, agent A compares the priority of task A1 and A2. If the priority of task A1 is higher than that of task A2, agent A reschedules task A1 to be performed before task A2, and the new start time and finish time of task A1 is sent to agent B. Otherwise, agent A sets the start time to task A1 to its earliest start time. Agent A sends its new start time and finish time to agent B. If the finish time of task A1 proposed by Agent A is less than the start time of task B2, agent B follows its normal schedule. If the proposed finish time of task A1 is greater, agent B temporarily sets B2's start time to A1's finish time and calculates the new finish time for task B2. If the new finish time is no later than the deadline of task B2, agent B reschedules its task B2 with new values; otherwise, task B2 is not performed.

Scenario 4 in Figure 8 shows how Rule 3 works. The initial start time of task B2 is 6 and agent A cannot complete the task A1 before 6. Hence, agent A compares the priority of task A2 and A1. Since priority of task A1 is higher, A1 is performed before A2, and the new schedule is sent to agent B.

Similarly, these coordination rules can be used to support other non-local relationships, including disables, facilitates and hinders.

RUNTIME SCENARIO

Now we present a runtime scenario for a hospital organization to describe how the health care simulation system works. The scenario demonstrates how the dynamic task allocation is accomplished through the A-R mapping mechanism, and how agents coordinate with each other in their activities. In this scenario, a special agent role space is first created. Role space agent is initially not taking any active role in the system; rather, it is mainly responsible for maintaining and managing the role instances in the system. The role space checks the plan tree of a role instance, when this role instance is taken by an agent, which recognizes the needs to create new role instances. The role space selects the appropriate agent for the role instance after verifying the qualification and consistency of the candidates.

When the system is initialized, the system administer creates several Patient role instances to express the expected service requirements from patients. The number of Patient role instances depends on the capability of the hospital. These patient role instances are posted in the role space and are not active until they are taken by some agents. When a (real) patient Bryan enters the hospital for services, a personal assistant agent named Bryan is created for this patient, and the agent takes one Patient role instance. In this case, Bryan uses the coordination Rule 3, which is specified when the user defines the Patient agent class.

When agent Bryan takes the Patient role instance, it has one goal to achieve: 'Get Cure'. The plan tree of this goal describes that two sub goals 'Assist Patient' and 'Provide Cure' must be achieved so that the goal 'Get Cure' can succeed. The goal 'Assist Patient' belongs to a MA Admin (Administrative Medical Assistant) role and the goal 'Provide Cure' belongs to a Physician role. Based on this information, a Physician role instance and an MA Admin role instance are created by the role space.

Four other agents, Adam, Cathy, Kevin and David that represent four medical professionals are also created and active in the system. Both agent Adam and the remaining agents are initialized with coordination Rule 3. They have been idle and sent requests to the role space for available role instances. When the MA Admin and Physician role instances are created in the role space, all three agents who are interested in taking any additional role instances receive a message for this update. After receiving the message, the agent checks the goal associated with the role instance, especially the MQPS, to see if it matches its own motivation. If the MQPS contains the same type of the agent's MQ in its motivation, the agent is said to be interested in taking that role instance.

For example, the Physician role instance has MQPS as: (MQ_professional, p1), (MQ_moral, p2), (MQ_experience, p3), all these three types MQ's belong to agent Adam's motivation. So Adam is interested in this role instance. How interested Adam is for this role instances depends on the actual values of p1, p2 and p3, the exact structures of the mapping functions with index 0, 1, and 2, and the current accumulation of these MQ's for agent Adam.

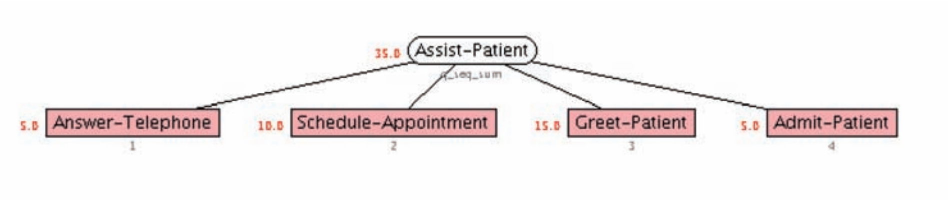
If agent Adam is interested in multiple role instance openings, it will compare the degree of interests in these role instances and select the most interested ones, and send requests to the role space. It is also possible that the role space receives requests from multiple agents for the same role instance. In this case, the role space verifies the qualification of each agent by matching the agent's qualification with the certificate requirement defined in the corresponding role class. For example, agent Adam is qualified for this role instance because it has a MD qualification that matches the certificate requirement of the Physician role class. The role space also checks if this role instance is compatible with other role instances the agent is taking right now. For instance, suppose agent Bryan has a MD qualification and it is also interested in this Physician role instance; however, according to the incompatibility relationship between the Physician role and the Patient role, agent Bryan cannot take this role instance because it takes the Patient role instance related to this Physician role instance.

After verifying the qualification and checking the consistency, the role space selects an appropriate agent (agent Cathy) for the MA Admin role instance, whose goal is to 'Assist Patient'. The role space then tells agent Cathy that the task 'Assist Patient' has an *enables* relationship with the task "Provide Cure'. The plan tree for the goal 'Assist Patient' consists of four sub goals: 'Greet Patient', 'Schedule Appointment', 'Admit Patient', and 'Answer Telephone'. All of these sub-goals can be performed by the same agent who takes the MA Admin role instance, so no new role instance has to be created.

After assigning the MA Admin role instance to agent Cathy, the role space assigns the Physician role instance to another appropriate agent - Adam, based on its qualification. The role space then tells agent Adam that task 'Assist Patient' enables its task 'Provide Cure'. The goal of taking the Physician role by agent Adam is to 'Provide Cure'. The role space reads the plan tree associated with the goal, and finds that in order to accomplish this goal, sub-goals 'Setup Equipment' and 'Provide Care' must be accomplished by other roles. In response to this need, new role instances Nurse Assistant and MA Clinical (Clinical Medical Assistant) are created. The role space then selects appropriate agents Kevin and David to take these role instances respectively. This process will continue until no more new role instance is needed, and all role instances have been taken. After a goal defined in a role instance is accomplished, the agent will collect the utility as defined in the MQPS of this role instance, and release the role instance, which will be further deleted by the role space.

After all role instances have been assigned to appropriate agents, the role space sends a table of roles to the agent who is performing that role, followed by a message to start the coordination.

Figure 10. Plan tree for 'Assist-Patient' in RTÆMS representation



The agents can now begin the coordination process. For example, as shown in *Figure 8*, Patient Bryan a goal to 'Get Cure", which has two non-local subtasks 'Assist Patient' and 'Provide Cure' performed by MA Admin Cathy and Physician Adam, respectively. Patient Bryan sends a message to both agents to ask them to complete the task within the deadline. Agents Cathy and Adam reply to Patient Bryan with their scheduled execution time. The Physician Adam coordinates with MA Admin Cathy using coordination Rule 3 to schedule the task 'Assist Patient' before 'Provide Cure'. There is a *facilitate*s relationship between task '(Read) Medical History Record' and task 'Clinical Test'. Since both tasks belong to the same agent, so the 'facilitates' relationship is taken care of by agent Cathy's local scheduler.

Since task 'Assist Patient' has an *enables* relationship with task 'Provide Cure', Physician Adam requests MA Admin Cathy to complete the task by 12. However, Cathy has another task 'Clean' that is scheduled for time 0 to 12, and the task 'Assist Patient' is scheduled for time 12 to 24. Cathy compares the priority of task 'Assist Patient' and task 'Clean': priority of task 'Assist Patient' is higher so this task is rescheduled before the task 'Clean'. Nurse Assistant Kevin can perform the task 'Provide Care' after task 'Operate' performed by Physician Adam. Similarly, Clinical MA David can perform the task 'Setup Equipment' before task 'Operate' and meet the deadline requested by Physician Adam. So no more rescheduling is necessary. The initial schedule for all tasks and new schedule for task 'Clean' are shown in *Figure 9*.

After the coordination is complete the agents can now begin execution, Patient Bryan can now begin executing its task 'Get Cure', which has subtasks 'Assist Patient' and 'Provide Cure'. The task 'Assist Patient' should be performed by MA Admin Cathy. Patient Bryan agent sends a message to MA Admin Cathy to begin the task 'Assist Patient'. MA Admin Cathy then begins executing the task 'Assist Patient', which has the subtasks 'Answer Telephone', 'Schedule Appointment', 'Greet Patient' and 'Admit Patient'. The quality of the task 'Assist Patient' is defined by the quality accumulative function "seq_sum", which is the total quality of all of its sub-tasks performed in sequence. Since MA Admin Cathy itself can perform all of the subtasks, it starts the execution immediately. After Cathy completes the task 'As-

Figure 11. Plan tree for updated 'Get-Cure' in RTÆMS representation

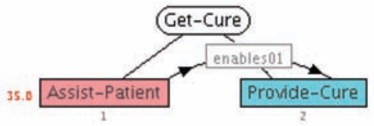


Figure 12. Plan tree for updated 'Provide Care' in RTÆMS representation.

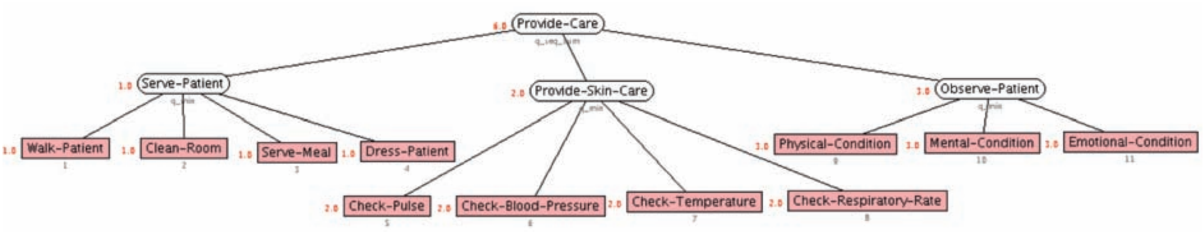

sist Patient', it collects the motivation quantities as defined in the MQPS of this role instance. (See Figures 10 and 11)

Upon receiving this message, patient Bryan updates its own task structure. MA Admin Cathy has rescheduled this task after the task 'Assist Patient'. So when Cathy completes the task 'Assist Patient', it begins executing the task 'Clean'. Now Patient Bryan can start executing the task 'Provide Cure'. Since the task 'Provide Cure' is performed by Physician Adam, so Patient Bryan sends a message to Physician Adam saying that it can start the execution. Physician Adam begins the execution of the task 'Provide Cure'. The task 'Provide Cure' has subtasks 'Examine Patient' and 'Provide Treatment' as shown in ***Figure 3***.

Physician Adam begins executing 'Examine Patient', which has subtasks '(Read) Medical History Record', 'Clinical Test' and 'Test Interpretation', which can all be performed by Physician Adam. After completion of these subtasks, it then begins executing task 'Provide Treatment', which has subtasks 'Prescribe Treatment' and 'Administer Treatment' with the quality accumulative function "max", which means only one of these two subtask needs to be accomplished.

If Physician Adam decides to perform the task 'Administer Treatment', then the three subtasks 'Setup Equipment', 'Operate' and 'Provide Care' need to be accomplished. The task 'Setup Equipment' is performed by MA Clinical agent David. So Physician Adam sends a request to Clinical MA David to perform the task 'Setup Equipment'. David starts executing the task 'Setup Equipment', which has subtasks 'Laboratory Specimen' and 'Medical Instrument'. After the completion, David sends a message to Physician Adam, saying that the task has been completed, together with the quality accumulated, cost accrued and the time taken. Upon receiving this message, physician Adam updates its task structure and begins executing 'Operation', which is performed by itself.

Similarly, the task 'Provide Care' is performed by Nurse Assistant Kevin. Physician Adam sends a request to Kevin to execute the task. Kevin begins executing the task 'Provide Care', which has the subtasks 'Serve Patient', 'Provide Skin Care' and 'Observe Patient'. Nurse Assistant Kevin itself can perform all of these subtasks. (See Figure 12)

After the completion of the task, Kevin sends a message to Physician Adam, saying that the task has been completed, together with the quality accumulated, cost accrued and time taken. Upon receiving this message, physician Adam updates its task structure. Since task 'Provide Cure' has now been completed, Adam sends a message to Patient Bryan that the task has been completed, together with the quality accumulated, cost accrued and time taken. Upon receiving this message, Patient Bryan updates its task structure.

FUTURE TRENDS

The future work includes further development of the system based on the current prototype. Especially, we are interested providing support for users to define interaction protocols in role classes, and integrating those domain-dependent protocols with domain-independent communication mechanisms in agents. We are also interested in experimenting with large systems, more complex scenario and analyzing the system performance.

CONCLUSION

In this chapter, we describe a multi-agent health care simulation system built using RADE framework. The integrated framework supports role-based design of multi-agent systems as well as implementation of utility-driven agents that can use a variety of existing agent reasoning and coordination mechanisms. We describe how the roles are defined, how agents are created, and how the role instances are mapped to agents. We also describe the rule-based coordination mechanisms and present a runtime scenario that shows how the simulation system works and how agents coordinate with each other to schedule their local activities. This work verifies the feasibility of modeling health care system with multi-agent approach and demonstrates the strength of automatic coordination, planning and scheduling.

Section III
Tools and Technologies

This section presents extensive coverage of the technology that informs and impacts health information systems. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support the emergence and advancement of health information systems. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Chapter 3.1

Capturing Data in Healthcare Using Patient-Centred Mobile Technology

ABSTRACT

This chapter outlines and discusses how an increasingly popular approach of incorporating patient perspectives and experience in research can be used to inform the development of user-centred technology in healthcare, with particular emphasis on hand-held mobile devices. The chapter draws on a programme of research and technological developments between an acute hospital trust and the Schools of Health Sciences and Social Care (SHSSC) and Information Systems, Computing and Mathematics (SISCM) at Brunel University in West London. The authors critically review existing literature and discuss the development of a new prototype mobile device for use by healthcare professionals in capturing patient information at the front end of hospital care.

INTRODUCTION

A three year research project, funded through the Knowledge Transfer Partnership (KTP), due for completion by the end of 2007, has focused upon evaluating patient and staff experiences in relation to the radical redesign of an acute district general hospital. A key aim of the research is to benefit these groups in an accident and emergency (A&E) environment, through the identification and development of technological tools designed to improve the patient journey which can be utilised by clinicians. Patients and staff have been observed in real-time field settings to establish positive outcomes, as well as areas that could be improved through the introduction of these evidence-based tools. The acute trust's redevelopment programme, recognised at national level, is a consequence of a forward thinking approach to developing and evaluating hospital services and is underpinned by current National Health Service (NHS) policy and reform.

Motivation for the research project is fuelled by the potential in disseminating the lessons learnt and benefits afforded by the tools across the NHS on a national basis. One key output has been the development of a prototype mobile device (in the form of a personal digital assistant (PDA)) for recording and sharing patient information in an emergency care environment. The impetus for this development arose out of the initial findings of the research that highlighted two key issues of concern to patients and staff: 'communication' and 'waiting times'. It was evident that the ways in which patient information and data were recorded during emergency consultations, and then relayed to staff who needed to use the information for clinical decision making could be problematic, thereby impacting on the patient journey. Hence, we have recommended a possible technological solution.

Rather than focusing on the detailed findings of the main research, this chapter is centred upon describing how the research is being used to feed into the technological development. The chapter begins with the political context surrounding the advent of patient-centred care and associated NHS reform. This leads into an account of the redevelopment programme at the hospital trust involved. The methodology employed in studying staff and patient perspectives at the hospital is presented, followed by a brief account of the key findings around collection and communication of patient information. The application of technology to address the identified issues is then proposed which includes a review of existing systems. The advantages of the utilisation of hand-held mobile technology with its flexibility of application, portability and potential for linking with other systems, steers direction for the subsequent proposal of the patient-centred PDA 'proof of concept'. The chapter concludes with a look towards future trends in the field.

NHS Policy and Reform

As healthcare has a strong political component, it is important to place the advent of patient-centred care and healthcare redevelopment in political context. The election of a new Labour Government in 1997 brought a pledge to alter perceived 'failures' in the NHS, and to build upon and learn from areas of success where they occurred (nhs.uk website). The Labour party had been particularly critical of the market approach of the previous Conservative administration. They aimed to remove competition but maintain the purchaser-provider spilt (Levitt et al., 1999). The approach by the new government to commit to bringing to an end internal markets was viewed as "eclectic and pragmatic." (Ham, 2004; p.54)

The 1997 White Paper, The New NHS: Modern, Dependable, set out the new political approach which was focused on partnership and integrated working, and was driven by performance (although these concepts and new ways of working were being established across certain organisations in health and social care before this time). This created the basis for further NHS reforms outlined in the NHS Plan (Department of Health 2000) and Delivering the NHS Plan (Department of Health 2001). It appeared that efforts were being made to give greater authority and decision making power to patients and frontline staff. Ham (2004) outlined how the policies to deliver the NHS Plan, whilst offering important differences, were to some extent "similar in a number of respects to those that lay behind the internal market (p.67), and this is particularly the case with offering greater patient choice" (Ham, 2004).

However, establishing the patient position at the centre of the NHS goes beyond simply offering greater choice in a healthcare environment. Not only the desire for patient involvement, but the general expectation of this participation has perceptibly intensified in the development and design of NHS services. This is both a political and social shift which is reflected not only by governmental approaches to policy and reform, but change programmes developed by certain public agencies and awareness raising by various user groups. The heart of the NHS Plan being presented as a vision of "a patient-centred service" (Department of Health, 2000 p.8) is a testament to this.

The evolution of thinking away from clinicians primarily holding the power and control over patient care, is in part a consequence of a number of well publicised NHS scandals. Kennedy (2001) in the Bristol Royal Infirmary Inquiry, a seminal report on certain failings surrounding children's heart surgery at the hospital, showed how NHS culture may directly impact on the patient experience, for better or worse. This report highlighted how cultures of nursing, medicine and management, for example, can be seen as traditionally distinct and internally closely-knit.

Kennedy (2001) surmises that his report is:

> *"an account of a hospital where there was a 'club culture'; an imbalance of power, with too much control in the hands of a few individuals. It is an account in which vulnerable children were not a priority, either in Bristol or throughout the NHS." (p.2)*

This statement is important as it clearly indicates that the issues identified were not unique to Bristol but may apply to the NHS as a whole. This does not necessarily mean that the majority of clinicians were not delivering good quality care to their patients, but the consequence of such a view is that patients are now being offered greater responsibility over their care.

The NHS Improvement Plan (Department of Health 2004), along with the plans presented in 2000-2003 outlined previously, proposed new targets centred upon increases in workforce and new structures within both the NHS and the Department of Health. This formed part of a 10 year reform process. The NHS Plan set out how increased funding and reform aimed to redress geographical inequalities, improve service standards and extend patient choice. It outlined a new delivery system for the NHS, as well as changes for social services and a range of professional groups.

The Healthcare Commission's statutory duty to assess the performance of healthcare providers and include the use of patient surveys further mirrors the importance placed upon patient involvement in national standards. The Healthcare Commission asserts that Patient Focus (a domain in its own right) should have the following specific outcome: "Healthcare is provided in partnership with patients, their carers and relatives, respecting their diverse needs, preferences and choices" (Healthcare Commission website, 2004).

Attempts have been made in the NHS to translate the principles around user-centred services and integrated working into front-line care. Change management models such as those under the umbrella of process redesign have become particularly popular (Iles & Sutherland, 2001, McNulty & Ferlie, 2002). Old professional cultural barriers are to be knocked down in favour of modernised services built around the patient. We focus here on one organisation that has attempted to put the rhetoric into practice.

The Acute Hospital Trust

Whilst it is becoming more common-place to find evidence within hospital trusts of involvement and consultation with patients in the design of services, it is less so the case that efforts are explicitly made from the outset to achieve an outcome which goes beyond the realms of the service provision itself. In this respect, the redevelopment programme presented in this chapter, and associated research project focusing on patient experience, may be unique in their end-point ambition. The project involves a trust that has gained a reputation for its clinically-led innovation (recognised in the NHS Plan) and has attempted to develop a transformational change model designed to be an 'exemplar' for modernising local hospitals

(Fig 1). With various external NHS pressures and changes in strategy aside, the trust is keen on using the research findings for further service innovation and the collaboration with the university is aimed at producing technological development that may be used more widely to improve staff working practices, care processes and patient care across the NHS.

The redevelopment programme has focused upon integration of hospital and community services, rapid throughput and expert teams. Ensuring more appropriate and timely referrals to the hospital from more highly trained general practitioners (GPs) and community services, is a key aim of the hospital model (which incorporates a smaller hospital bed base). This approach has been developed, at least in part, in conjunction with expert clinicians and public and patient groups via public feedback sessions and involvement of committees that include user representatives. These consultations have suggested that the desire expressed for patients to be cared for and treated in their own homes (where appropriate), would be medically more beneficial. Staff satisfaction levels and views towards the working environment are also expected to improve as a result of the changes taking place at the hospital. Our evaluation of the model will assess to what extent these aims are being fulfilled.

On a departmental level, the A&E model has introduced systems which revolve around specialist teams incorporating multi-skilled staff (e.g. nurse practitioners), with the aim to reduce unnecessary delays and improve the overall emergency service for patients. In addition, multi-disciplinary working is a central philosophy of the programme and we focus here on a key theme related to this: sharing of information between professionals.

RESEARCH METHODOLOGY

Nationally, research identifying patient and staff views relating to hospital services is mainly conducted through regular patient and staff surveys, the results of which are collated and published with free availability for all (e.g. Healthcare Commission surveys). The distinguishing feature which sets the current research aside from this bulk collection of data is the in-depth qualitative exploration of experiences and pathways within the hospital setting, from the patients' and staffs' perspectives. Appropriate NHS ethical approval has been granted for this ongoing project.

The various phases of data collection involved many hours of observations and tracing of patient pathways within the 'majors' A&E department. Researchers, in teams and individually, gradually built up a picture of the key elements of the patient pathway. Combining this with interviews with patients, who gave informed consent to participate, and staff views, it was possible to establish areas of concern which lent themselves to potential technological development.

Patients were traced whilst on the 'majors' section of the A&E department from the point of admission to either discharge home or onto a ward, where appropriate. Patient notes were also studied to establish aspects of patient care which may have been missed in patient interviews, or to confirm observations. The periods of observation began in 2003 and have been carried out during a number of updates leading to the present day. Current findings are based upon 73 patient maps conducted so far in the A&E department.

Where possible all elements of patient care were observed. This commonly included interactions between patients and a range of health professionals. In particular, we focused on the assessments made by staff of the patient's condition (known as 'clerking'); from nurses who carried out initial assessments to doctors taking histories and requesting further assessment. Patients were observed having cannulas fitted, drips topped up, blood samples taken, being referred to the x-ray room, waiting for test results, and exchanging information with doctors, nurses, healthcare assistants and porters. Doctors also were observed

Figure 1. Key hospital model objectives

A major drive for improved patient care and better health for the local population by providing services that deliver care to patients at the right time in the right place

Developing a 'whole systems' approach where effective health services can be provided locally by harmonising primary care, local hospital and more specialist services (e.g. chronic disease management) to prevent inefficiencies, gaps in provision, delays and duplication of effort

Staff, patients and the local community to be involved in the development, implementation and communication of the project

writing up patient notes and accessing previous assessment results.

CAPTURING PATIENT INFORMATION: THE PATIENT/ STAFF PERSPECTIVE

Through collation of observations and interviews to the point of 'saturation' (where we felt no new findings would emerge), key themes evolved regarding the A&E patient pathway. As mentioned previously, we are focusing here only on a limited number of initial findings that have been used by the research team to develop a technological prototype. The evaluation project is an ongoing process and further data collection is due to take place.

An understanding of the structure of staffing has been achieved as a result of the research. The A&E team consists of a nurse manager, nurse practitioners who may specialise in emergency care or surgery, and generic nursing staff. The A&E doctors are headed by a consultant (who is available for consultation) and also include higher level doctors such as registrars and staff grade doctors and junior doctors (Senior House Officers and House Officers). The junior doctors such as Senior House Officers (SHOs) working on the unit are typically on six month placements, rotating across specialities, whilst the senior doctors are more permanently based in A&E. The porters and administrators are the remaining staff component and critical to the smooth running of the service. The hospital model itself relies upon integration between this team of staff which makes up A&E and doctors from other specialties, such as medicine or surgery, who are referred to when necessary.

When doctors carry out the initial clerking of a patient this involves taking a full history and carrying out an examination, ordering tests and so forth (this procedure may last approximately 10 to 25 minutes depending on the individual patient). If a different speciality is required following a visit from the A&E doctor, the patient may be expected to repeat elements of the procedure which has already taken place. For example, the notes recorded by a junior doctor in A&E from an initial clerking procedure may be repeated by a doctor from the surgical team who requires the same information, perhaps with additional facts included.

All patients who enter A&E are issued with a hospital identification number. These numbers, along with basic information including a patient's name, address and date of birth, are printed onto a sheet of stickers which is placed within the patient file. The stickers are to be attached to patient notes and samples such as blood or urine which have been taken from the patient, as required. A trolley positioned in the centre of the majors department holds all patient notes and is located adjacent to the white board which tracks which bay a patient is in, their time of arrival and doctor/ nurse responsible for their care. This is particularly relevant in the context of the 4-hour governmental target for A&E outlined in the NHS Plan (2000) and implemented in 2004, as a means to manage waiting times.

As highlighted, a key philosophy of the hospital model is to integrate working, modernise the environment and enhance the patient journey. There is much evidence that these attempts are improving both staff and patient experiences (to be reported elsewhere). One area for improvement is that some patients have voiced some concerns with the clerking phase of their journey, and sharing of information between professionals. During this interaction between patient and clinician, observations were made by the researchers, and patients openly commented, that there was some repetition of questions asked and information requested from various professionals. This issue is known to be a general problem across the NHS and other health and social care systems. Being asked to repeat information resulted in patients experiencing frustration and some concern over the quality of their care, along with causing potentially unnecessary delay to the patient journey.

Following observations and discussions between the researchers and clinicians, the reasons suggested for such repetition became clear. Clinicians commented that some repetition was necessary in order to confirm certain clinical suspicions, but that due to poor note taking skills and/or a lack of communication between some of their colleagues, elements of clerking had, at times, to be unnecessarily repeated and notes re-written. In addition, the problem of lost notes was also raised as leading to delay and potential repetition for patients and staff.

TECHNOLOGICAL POSSIBILITIES

These findings led us to consider one of a number of possible technological outputs from our KTP project. In collaboration with colleagues from Brunel University and the trust, discussions took place to formulate a solution to the problems around recording and sharing clerking information as reported by patients and staff. Establishing a proof of concept to lead, ideally, to a handheld mobile prototype will be explored in the following sections.

Handheld Computer Systems in Healthcare

Problems and attempted solutions around capturing patient information have been addressed by others and are not unique to our project. The research described above, however, has uncovered a need to harness or develop a system that is more efficient at managing relevant information within a busy emergency scenario (i.e. during clerking). In this context, clinicians need quick and easy access to a system that can record and produce detailed data on an ongoing basis at the point of care. We have postulated that this could be achieved with the use of a Personal Digital Assistant (PDA). PDAs are often used in implementations within hospitals due to their user-friendly size, cost and ability to communicate via fixed and wireless networks. It is important to provide some context of previous work in this area to see how our developmental idea fits into the evidence base.

Using PDAs to Record Data

A typical example of such an application could be seen in the work of Oyama et al., (2002) in their implementation of a piece of software that enabled clinicians to enter historical and laboratory patient data at the point of care. Once entered onto the PDA's database, patient records would then be merged with a centralised patient record database located on a server, and could be printed to provide reports for inclusion in clinical notes (Oyama et al., 2002).

A slightly different approach was taken by Bird & Lane (2006), as their system was used with 12 first-year medical students in more controlled settings and with the aim of assessing whether or not the use of PDAs would result in benefits in emergency care, via improved access to procedural and patient documentation (Bird & Lane, 2006). PDAs were provided to all 12 of the students and criteria set for the recording of patient information. The trial was conducted over a three-year period and compared to a previous, totally paper-based trial that also lasted for three years. It was concluded that utilising PDAs did not alter emergency medicine procedures or patient resuscitation documentation, when compared to the equivalent paper-based trial.

Another system for documenting patient procedures and resuscitation information was developed by Rosenthal & Wolford (2000). They cited the limitations of many existing systems as being cumbersome or prone to data loss, and developed a piece of software for use with PDAs that allowed clinicians to enter basic demographic information (although evidence supporting an explanation of this claim was not wholly apparent). Clinicians typically entered their details onto the PDA in around one minute where the information was transferred to a desktop computer and onto a pre-existing database. The researchers concluded that the system presented a cost-efficient method of improved data capture, a reduction of burden upon secretaries and increased tracking capabilities (Rosenthal & Wolford, 2000).

Lapinsky et al., (2001) designed and implemented a system using PDAs for an Intensive Care Unit (ICU) team at Mount Sinai Hospital, Canada. It included hospital and medical reference materials and enabled patient details to be captured using the PDAs specialist application through the use of a customised template. The use of templates proved cumbersome as they merely provided an outline for the information to be entered and did not assist the user with data entry. Lapinsky et al., (2001) found that the lack of a network interface restricted the benefits of the system, as the information contained on the PDAs was isolated. Access to external data sources could have benefited both the patient records and reference applications.

The work of Serif et al., (2005) is also relevant to this discussion. This study involved the development of a system that enabled back pain data to be captured and visualised in mobile form through the use of a PDA. The system encapsulated pain drawings that allowed patients to locate the source of pain and also an appropriate scoring system for evaluating the degree of pain. The detailed documentation of the design, implementation and evaluation of the system showed that tried and tested methods of documenting patient conditions could be successfully digitised. The use of a wireless LAN also aided the usefulness of this system.

While some limitations have been identified, the above studies, in particular those by Oyama et al., (2002), Rosenthal & Wolford (2000) and Serif et al (2005) indicate the possibility that PDAs could be an effective way to enhance the capture of patient information in certain healthcare environments. However, despite being the closest set of examples to our development (particularly as they facilitated the entry of patient information at the point of care), the above devices mainly originated from outside the UK. Further, more development is required focusing on the clerking phase of the patient journey.

Using PDAs for Monitoring or Reference

The above examples illustrate how PDAs can be developed to assist the recording of patient data. However, it appears that these are rare and most developments centre around the use of PDAs mainly for monitoring and reference purposes.

Newlan et al., (2002) developed software for commercially available PDAs which displayed real time physiological outputs from a patient monitor. The software had the ability to display several waveforms at once and operated over a Wireless Local Area Network (WLAN) within a hospital or outside a hospital via the General Packet Radio Service (GPRS), thus allowing carers to monitor patients remotely. The software also had the ability to store the information being conveyed onto the PDA's removable memory. The implications of this with regard to patient confidentiality meant that security had to form a core part of the software. The authors described the use of hybrid public key cryptography for the encryption of data, of individual user logins in authenticating members of staff, and of firewalls to regulate access through the wireless network. This included handshake protocols and encryption algorithms to protect the transmission of usernames or passwords and to prevent data corruption or modification (Newlan et al., 2002).

The PDA-based reference system for clinicians developed at the Western General Hospital in Edinburgh used a WLAN that was constructed with particular attention paid to the implications such a network would have on sensitive medical equipment within the hospital. These PDAs were used to provide functions such as access to the hospital's patient database, x-ray and endoscopic images, medical reference materials and guidelines, papers and journals. Other features included note taking at the point of care, and the experimentation of digital note taking for speech recognition or transcription by secretaries, however the system did not enable details to be captured, only accessed (Turner et al., 2005). The use of off-the-shelf packages did not compromise the final system, as was initially expected by the authors. Usability problems were averted through the use of 'pick lists' to speed up data entry and standard interface widgets to aid familiarisation. Interference with hospital equipment was not an issue, nor was security with the use of Virtual Private Network (VPN) technology in establishing secure communication links.

The previous example is highly relevant given the nature of the research presented in this chapter, and the hospital context within which the developments would be employed. However, despite the authors' detailed account of the design and implementation of the system, their description of the evaluation of both the project and system lacked sufficient detail. Furthermore, the availability of detailed electronic medical information for use by any computer system is quite unique within a UK hospital. This was in part due to the sporadic development and procurement of hospital information systems within the UK NHS since its inception in the late 1940s.

The Mobile Medical Data (MOMEDA) system (Pattichis et al., 2002) provided both clinicians and patients with mobile access to information. Patients were able to access information regarding medical conditions and expected treatments both before and after hospital attendance (Pattichis et al., 2002). Clinicians were able to obtain medical records and images using a mobile phone, which meant that those who regularly travelled between different hospitals could still access patient details offsite using the mobile phone network. This is particularly relevant within the context of the hospital model we are focusing on where integration with community services and flexible, multi disciplinary working is fundamental.

The importance of the MOMEDA system is its ability to operate outside hospital premises using the commercial mobile phone network. Despite this being a highly attractive feature, particularly for mobile clinicians, the associated cost of transmitting detailed images across the mobile network would more than likely attract a high cost due to the volume of data that would need to be transmitted. Systems such as the PDA-based medical records system outlined by Turner et al. (2005) had a distinct advantage over systems such as MOMEDA, in that communication costs did not escalate as system usage increased, as the WLAN was a privately operated network.

Part of the work carried out by Sommers et al., (2001) at Virginia Commonwealth University (VCU) was in providing 15 medical students with PDAs for use as a reference tool. The results of the study indicated that students felt the PDAs had many benefits including accessing medical reference and documentation, treatment guidelines and patient monitoring (Sommers et al., 2001). This system was developed with the specific needs of a university hospital medical school in mind. The PDA software was heavily customised for use by students and designed and constructed in an entirely different way to the PDA-based system developed by Turner et al., (2005) at Edinburgh's Western General Hospital. Despite the evaluation highlighting the perceived usefulness of the system at VCU, caution should be exercised, as students are much more likely to be familiar with the use of mobile devices, removing the usability barrier typically encountered by researchers in such applications where user acceptance may be a more prominent obstacle.

The work carried out by Aziz et al., (2005) at St. Mary's Hospital, London looked at the possible use of PDAs to replace the current system of pagers used by a hospital surgical team. The study looked at efficiencies that could be gained in communication between team members, and assessed this through the length of time members took to respond to calls using PDAs compared to pagers. The PDAs used also functioned as mobile phones and provided access to the Internet and reference materials preloaded onto each of the PDAs. Results of the trial showed that the bi-directional PDA-mobile phones enabled faster communication between the team when compared to pagers. It was also found that initially there was some aversion from members of the team to embracing new technology and change (Aziz et al., 2005). This, in contrast with the results of the trial at VCU (Sommers et al., 2001), highlights the impact end-users can have on the system under development.

In summary, this section presents a comparative discussion of current PDA systems used to manage patient information in a healthcare context. Some studies have shown the potential for the use of handheld mobile devices in recording patient data. However, from studying the relevant literature, it appears these are rare developments. Most other applications of handheld technology within healthcare in the UK or abroad seem to facilitate monitoring procedures (e.g. patients' vital signs) or the provision of reference materials for clinicians often in terms of conveying specific clinical information. These studies, nonetheless, also provide an insight into the possibility of using PDAs in conjunction with wider data systems. This previous work has led us to begin developing a technology that may be applied to solve the problems around capturing patient information at the front end of care, and information that needs continually updating. How can clinicians record clear and valid patient information during clerking procedures that can be used in a busy and ever-changing emergency setting?

A TECHNOLOGICAL SOLUTION

As highlighted above, published findings suggest the use of PDAs in electronically capturing patient details is an emerging field, both within the UK and abroad, and is one which is conducive to further development. Most developments are related to non-UK contexts and capture only a small subset of patient information. Further, the systems may not be customisable to other areas of medicine, where often only patient resuscitation details are recorded (see, for example, Bird & Lane (2006), Rosenthal & Wolford (2000)). Many systems involve more primitive components and may not be accepted as industry standard, or particularly robust given the nature of each application.

This evidence has reinforced the aim of our research project to develop a piece of software to record patient information on attendance to the A&E department of an acute hospital, particularly during clerking phases. The software is intended to form part of a proof-of-concept that can be extended to other areas of healthcare by being customisable, robust in design, and above all, applicable to an NHS hospital where procedures and IT infrastructures often differ.

The need for this type of mobile technology is elicited directly from the experiences of the patients and staff in our study. The findings suggest that repetition of assessments may occur because previous assessments have not been recorded in the notes properly or communicated effectively. Further, doctors and nurses continually move around the hospital system, as do patients. For example, an attendance to A&E may result in patients being referred to an assessment area, then referred for investigations such as x-ray (where results need to be relayed to doctors quickly), and possibly being admitted to a ward. Further referrals may then follow (e.g. outpatient referrals, or discharged back to community care settings).

The PDA mobile device may not only have the capability of keeping up with changeable physical locations, but also benefit clinicians through immediate provision of and sharing of information between and within various services throughout the hospital (potentially throughout the UK, given the existence of the national electronic records programme). Note-taking problems as observed in some instances during our research such as illegibility and loss of documentation would also be overcome. Additionally, and most importantly in terms of clinical governance issues, having the ability to track which clinician has been responsible for clerking or treating a patient through a user sign-in feature when utilising the PDA, would be of significant benefit over the relatively fallible system currently in operation.

The proposed PDA solution is based upon the digitisation of the 'clerking form' (called the 'Adult Inpatient Assessment Protocol') currently used in the A&E department at the hospital. Clinicians complete the protocol following completion of a full history and examination of the patient. The protocol may not be completed in its entirety, as the latter part requires the recording of various test results and patient observations. During completion, the protocol is kept with the patient's notes in the A&E department. It is currently only available in paper form, and following patient discharge is stored in the hospital's archive together with other patient notes.

During development of the proof of concept, specific requirements were obtained from a combination of primary documentation used at the hospital and interviews undertaken with staff. The current IT developments within the trust were established with a meeting with the relevant Director of Information Management and Technology.

This technology addresses a number of key requirements:

- Mobility of device
- Ability to record patient information gathered during the clerking phase incorporating extended text-based notes and diagrams
- The ability to produce the equivalent paper-based records for inclusion in patient notes
- Consideration of appropriate security measures
- Adaptability in the device to allow for revisions to protocol and software

The PDA idea was developed using a simulation model on a computer where certain sections of the paper-based 'clerking protocol' were mapped onto the model to mirror the key stages of the clerking phase of the patient journey. When transformed to the PDA, it was envisaged that this process would guide the clinician through required fields and clarify the current stage of the patient journey while allowing the clinician to clearly record detailed relevant information. This illustrates the patient-centred nature of this proposed device. Figures 2 and 3 outline the process through which the PDA would operate in a hospital setting. An administrator would have access to the XML (Extensible Mark-up Language) document defining the appearance of the

Figure 2. Overall system architecture design

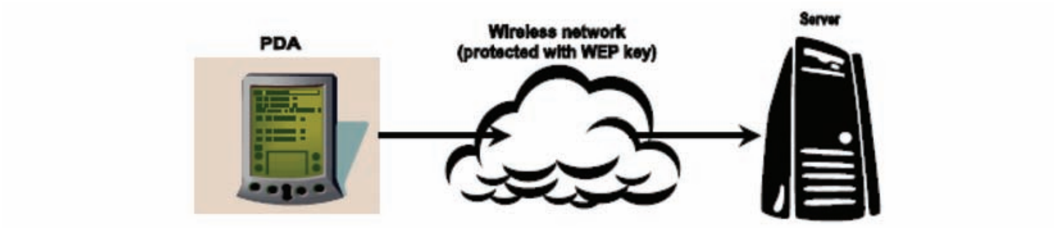

Figure 3. PDA use in context of hospital intranet

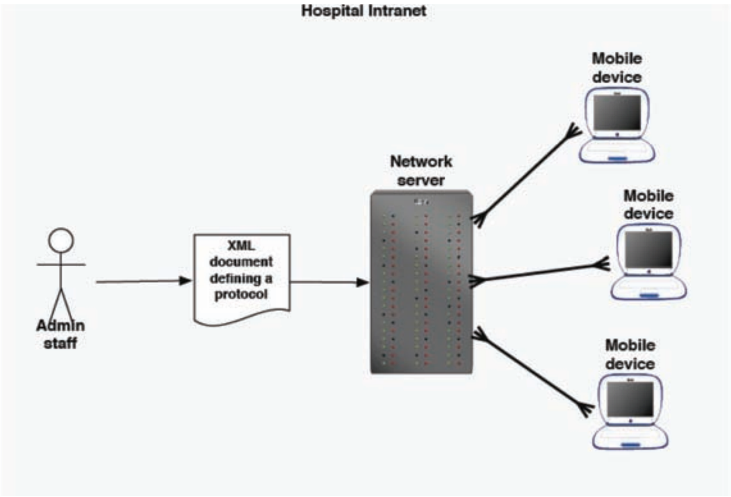

protocol (thus allowing alterations to be made). The hospital intranet would be used to link the system together.

PDA EVALUATION

With an outline system specification formulated from the original initial research findings (indicating patients have concerns with repetition, whilst clinicians are concerned with poor notes) further clarification was sought on these issues with the system's prospective end-users through direct observation at the hospital and interviews with relevant staff (n=7). This qualification was sought with full consideration being given to the pressures typically encountered each day by clinical staff. Outlining the PDA concept to staff also proved useful in determining the general opinion amongst clinicians in the application of technology to this area.

IT managers at the trust indicated that the development of modular, web-based systems would be the best option in future IT developments. It has been ascertained that the majority of patient data held by the trust is contained in information 'silos' on legacy systems, most of which were command line-based systems. Recent work focused on developing interfaces between a new web-based system and the existing data structures. The system would retrieve patient details from the underlying legacy systems and generate views of patient information. The extensible design of a new system, shortly due to go live at the time of writing, would be able to accommodate the inclusion of patient data from other sources. This therefore, would mean that any data captured by the new system could be successfully included in the trust's web-based system through the generation of an additional web page.

Clinicians interviewed reported a willingness to take on board the concept of shifting from paper based to the proposed electronic based clerking protocol. However, the issue of training for the use of the PDA was raised as being necessary for some staff and an issue which requires consideration in future development.

The utility of the PDA tool would be greater still if a barcode reading facility was able to record and check the details found on a patient identification sticker. This would be an added level of security in ensuring that the correct patient is being treated. In the context of the electronic patient record system, this would create a seamless link between clinician clerking and the generic patient record. Data protection issues also would need to be fully addressed, as in any new data collection system.

FUTURE TRENDS

The PDA developments discussed in this chapter may contribute to UK wide efforts to collect patient information and transfer patient records to an electronic format, although more research and testing is required. The National Programme for IT (Connecting for Health website, 2007) aims to modernise the current computer systems used within the NHS, thereby improving the flow of patient care and services. This, together with the aim of giving patients access to their personal health and care information, and an ambition to transform the way the NHS works, shows there is some clear synergy with the subject of this chapter.

The highly publicised financial constraints currently facing many parts of the NHS and current issues that have been cited in the media around the National Programme for IT clearly have significant implications for any IT programme which would require financial backing to be developed fully. However, it is important not to be overly short-sighted in perspective towards such a project. Despite initial costs to support the establishment of the use of a PDA, the long term potential for saving money may be substantial. The opportunity of a reduction in clinicians' need to repeat their colleagues' previous note taking, in conjunction with the reliability of a system which protects patients' notes from getting mislaid and the reduction in delays for patients, amongst other factors, may carry considerable financial benefits.

CONCLUSION

We have shown that patient experience research can uncover 'critical areas' in the patient journey where improvements are required (e.g. clerking phase in A&E), thereby providing scope and detail to develop patient-centred technology for use at the front end of care. The PDA software prototype described here for capturing patient data has the potential to reform the way hospital clinicians currently record and share patient clerking details. This may be a further step towards revolutionising healthcare systems within the field of hand-held mobile technology. More evaluation of the use of such a development and how it may link in with current and new hospital IT systems across the NHS is required, but the implications for staff working and patient experience have the potential to be far reaching. In the context of the national IT programme for electronic patient records and the political emphasis on patient-centred care, these observations are particularly salient.

FUTURE RESEARCH DIRECTIONS

There are many varied opportunities related to the work presented by the authors in this chapter for consideration as future research directions.

As the NHS continually evolves and hospital and healthcare services are further developed, opportunities for developing advanced technologies will continually present themselves.

Another focus of the authors' research is the organisational culture of hospital services, and in particular how cultures may vary between specialist and non-specialist areas within a hospital. Related to this is the role of the patient and the perceived control they have over their care and treatment. Traditional clinical boundaries are being challenged in this era of patient-centred modernisation and there is a need for providing healthcare professionals with tools for addressing the cultural shift. This is especially relevant in respect to hospital redevelopments, particularly as they often seek to build services around the patient journey. These insights, both from within our evaluation and across other studies, may enable the development of further technologies in a comparable way to the work described here. For example, computer-based interactive training tools focusing on optimum care pathways and multi-disciplinary working may be developed, where professionals can learn how to implement the best approaches and assess how various clinical scenarios may lead to different outcomes (such as in the case of 'simulation modelling').

In addition, with particular emphasis on the topic of this chapter, future research opportunities may relate to the potential for investigation of working towards an entirely paper-free environment within an accident and emergency department context. Support for the smooth integration of such a system may include elements such as bar code readers on PDAs which link together patient information in a more seamless manner. The addition of barcode scanners or other peripheral devices (depending on the intended application) may assist in data capture and help minimise clerical errors. The longer term implication might be for the majority of services across this and other UK hospitals to utilise electronic protocols, provided they were properly evaluated and proved successful. This could contribute to an evidence base that indicates the possibility of a hospital-wide paper-free environment.

Other important work may include the way in which data entered should be validated or verified. The challenge in this area is that although it should improve the accuracy of the data entered it should do so without compromising the dynamic and user-friendly way in which protocols are designed, deployed and displayed. Furthermore, future developments could include a simple tool for the quick and concise creation of new protocols for use with this system. Work could also focus on system integration issues, such as software metrics and security measures as both would assist the integration of such a system into existing information systems at other hospitals and health trusts.

The scope for the application of technology within healthcare is near limitless and changes occurring in the NHS today are cutting edge. In addition to the clear patient and staff benefits resulting from such applications, the potential financial considerations and commitments would also be substantial. As a consequence of this, research which either evaluates the potential efficacy of proposed devices or provides an increased evidence base for the success of existing tools is fundamental to the ongoing 'modernisation' of the NHS.

ACKNOWLEDGMENT

The authors would like to express their thanks to the following people who contributed to and supported this work: Professor Zahir Irani, Professor Ewan Ferlie, Professor Les Mayhew, Lynne Greenstreet, Paul Parkin, David Powell, Sir Graham Morgan, Mr Michael Burke, Dr John Riordan, Yvonne Slater, Dr Vincent Mak, Dr Alan Warnes, Dr Nicki Panoskaltsis, Dr David King, Doug Irish, Manil Chouhan, Pooja Goel, Harnaik Johal, Sajita Sachchithanantham, Rick Juniper and all the staff and patients who kindly took part in the research. We would also like to extend our appreciation to the Department of Health for funding the project through the Knowledge Transfer Partnership (KTP) scheme and NHS R&D Support Funding.

ABSTRACT

Incorporating healthcare information systems into clinical settings has been shown to reduce medication errors and improve the quality of work in general by improving medical decision making and by saving time. This chapter aims to demonstrate that mobile healthcare information system may also help physicians to communicate and collaborate as well as learn and share their experiences within their work community. Physicians' usage of a mobile system is analyzed through a knowledge management framework known as the 7C model. The data was collected through the Internet among all of the 352 users of the mobile system. The results indicate that frequent use of the system seemed to improve individual physicians' knowledge work as well as the collective intelligence of a work community. The guide for acute care, evidence-based medicine guidelines and information related to drug interactions supported the knowledge creation to a large extent. As such, mobile healthcare information systems may be capable of supporting the different sub-processes of knowledge creation and the knowledge work of individual physicians, and through this also improving the collective intelligence of the work community. Overall, knowledge management seems to be a prominent approach for

DOI: 10.4018/978-1-60566-332-6.ch006

studying healthcare information systems and their impact on the work of physicians.

INTRODUCTION

Personal digital assistants and mobile applications are promising tools for managing medical information and accessing it at the point of care (Ebell et al., 1997). They have been shown to assist in evidence-based practice in a clinical setting and support the educational needs of physicians, nurses and other clinical staff, while drug information, medical calculations, guideline information and administrative tasks have been identified as the most useful resources (Honeybourne et al., 2006). Topics such as e-prescribing (Kushniruk et al., 2005) and patient tracking (Lapinsky et al., 2001) have gained a lot of attention recently. On the other hand, access to medical literature and electronic pharmacopoeias, i.e. drug information, seem to be excellent tools for providing physicians with knowledge at the point of care (Fischer et al., 2003).

Incorporating healthcare information systems into clinical settings has been also shown to reduce medication errors (Grasso & Genest, 2001) and improve the quality of work in general by improving medical decision making and by saving time. Mobile versions of these systems are relatively easily incorporated into the workflow of the physicians (Rothschild et al., 2002) as they can be carried around and used when ever needed, for example during home visits or ward rounds.

In the information systems field the topic of knowledge management has received a lot of attention recently (for an excellent review on the subject, see (Alavi & Leidner, 2001)). Our view on knowledge management is through a conceptual framework known as the 7C model (Oinas-Kukkonen, 2004). It suggests that the seven Cs or knowledge creation sub-processes, namely Connection, Concurrency, Comprehension, Communication, Conceptualization, Collaboration, and Collective intelligence, play a central role in knowledge management. According to the 7C model, going through the key phases of Comprehension, Communication, Conceptualization and Collaboration repeatedly, in a seamless and spiral-like way leads into the growth of the organizational or social knowledge, i.e. Collective intelligence.

This paper focuses on mobile access to medical literature and electronic pharmacopoeias, aiming to demonstrate that these may help physicians to communicate and collaborate as well as learn and share their experiences within their user community. There are relatively few scientific studies on managing knowledge with mobile healthcare information systems. Moreover, only a small number of articles provide knowledge about the actual use of mobile medical applications (Fischer et al., 2003). We will present a case study among the users of Duodecim mobile healthcare information system. The data was collected through the Internet among all of the 352 physicians (with the response rate of 66.5%, n=234), who were users the case system.

The article is organized as follows. Chapter II describes the background for the study. Chapter III presents the 7C model for knowledge creation and management, Chapter IV introduces the case system, Chapter V discusses the results, and finally Chapter VI concludes the article.

BACKGROUND

Systematic processing of health-related data, information and knowledge focusing on the study of information processing principles and solutions in healthcare is referred to as *health informatics*, while the scientific discipline related to it is called medical informatics (Hasman et al., 1995). The terms are often used synonymously, even though some differences exist in their use between countries. For instance, medical informatics in Germany also includes nursing informatics and dental informatics, while in other countries medical informatics primarily focuses on solutions from the physicians' viewpoint (Hasman et al., 1996). In general, health informatics is often examined from different perspectives such as information technology or user needs.

A healthcare information system (HIS) is defined as an application of information technology in healthcare, encompassing a wide range of applications from disciplines such as medicine, computer science, management science and statistics (Raghupathi, 1997). Based on the interaction between the medical personnel and the patient, HISs may be categorized as customer supporting systems, interaction supporting systems, consultation systems, decision support systems, process supporting systems, economic systems, preparation tools and administrative tools (Suomi, 2001).

According to Siau (2003), *mobile healthcare information systems* are among the basic tools employed in the healthcare industry, the other two being Internet applications and enterprise systems. Mobile HISs offer two distinct advantages for the healthcare sector: firstly, they are important for the success of telemedicine, and secondly they enable physicians to access information whenever and wherever needed. Access to real-time information is important for physicians and hospitals because information is often needed immediately to enable accurate decision making (Siau, 2003).

Fischer et al. (2003) classify the main uses of mobile applications for medicine as: accessing medical literature, electronic pharmacopoeias, patient tracking, medical education, research data collection, e-prescribing, business management and specialty-specific applications. Other classifications have also been suggested, such as those ones by Adatia and Bedard (2003) and Embi (2001).

Providing *access to medical literature* increases the extent to which evidence will be sought and incorporated into patient care decisions (Sackett et al., 1998). The access to medical literature through a mobile application will allow decisions to be made by the bedside or at the point of care. This could further improve the decisions made by physicians (Sackett et al., 1998). Mobile devices containing decision-making tools and summaries of evidence may also improve learning in evidence-based medicine (Honeybourne et al., 2006) and reduce patients' length of stay in hospitals (Sintchenko et al., 2005). Usually, evidence-based information is presented in a guideline form to further support decision-making.

Pharmacopoeias are drug information databases and drug interaction guides. Drug information refers to information such as adult and paediatric dosing guidelines or common side effects, while drug interaction guides contain information about possible interactions that two or more drugs used together can have (e.g. drug A may influence the absorption of drug B). Access to drug information may reduce medication errors (Grasso and Genest, 2001) as it is impossible in practise to know all conceivable drug interactions by heart. Thus providing an easy manner to double-check these interactions should indeed help the work of physicians at the point of care. The survey conducted by Rothschild et al. (2002) with palmtop drug information guide users suggests that mobile systems may save time in information retrieval and improve drug-related decision making and can be relatively easily incorporated into the workflow of physicians. This is important, as it could improve technology acceptance and save time.

Patient tracking systems aid medical staff in ward rounds by keeping them informed about the patient's condition. Medical education applications are designed to help medical students in their studies, e.g. by monitoring their clinical experience or by finding gaps in their education. Mobile applications used for data collection have also been found promising for research purposes (Fischer et al., 2003). Using mobile applications for electronic prescribing has been found to decrease medication error rates (Grasso & Genest, 2001) and business management applications help the efficiency of hospitals, e.g. by improving coordination and billing (Fischer et al, 2003). Finally, different specialties (for example family medicine) have their own specific mobile applications.

Usually medical literature includes not only descriptions of treatment methods but also evidence supporting each method. This form of decision making is referred as *evidence-based medicine* and is defined as "the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients" (Sackett et al., 1996). For example, mobile decision support systems have contributed a significant reduction in antibiotic prescribing (Sintchenko et al., 2005), i.e. physicians' have been able to see better when to prescribe antibiotics and when not to.

There are two approaches to applying evidence to medicine (Eddy, 2005). The first approach is to use evidence-based guidelines. Twenty years ago medical guidelines were based on experts' consensus but over the years most of the guidelines have changed into evidence-based. Quite interestingly the new guidelines have been dramatically different than the previous ones (Eddy, 2005). The second approach is to apply evidence in individual decision making (Evidence-based Medicine Working Group, 1992). The difference to evidence-based guidelines is that this approach aims to "educating physicians to help them bring more research and evidence into their individual decisions about individual patients" (Eddy, 2005).

Knowledge management is "a business concept which includes concerted, coordinated and deliberate efforts to manage the organization's knowledge […] and applying it to enhance organizational performance" (Bose, 2003). Because of the growing costs of healthcare various knowledge management solutions have been applied in hospitals and medical centers to enhance performance and e.g. provide better care.

Yet the healthcare sector has been said to be data rich but knowledge poor (Abidi, 2001). That is to say different healthcare organizations generate huge amounts of data from hospital reports to clinical trials but not much of the data is transformed into strategic decision-support knowledge (Abidi, 2001).

Thus most of the knowledge management solutions in healthcare have been concentrating on transferring data into knowledge. One way of doing this is to utilize data mining (Fayyad et al., 1996). By using data mining we can find e.g. correlations or dependencies from the vast amounts of data available to us. This way the data could be transformed into a more usable form (i.e. knowledge) for e.g. evidence-based medicine. An example could be to use data mining to predict patients' length of stay in hospital (Kraft et al., 2003).

Clinical decision support systems (Teich & Wrinn, 2000) have also been used to utilize the data. Usually, they combine population statistics with existing knowledge to offer real-time information to support physicians' daily work (Teich & Wrinn, 2000). They can also facilitate evidence-based medicine (Jadad et al., 2000).

Recently, information systems focusing on the knowledge and relationships between patients and hospitals have also been introduced to healthcare settings. This solution is called patient relationship management (Siau, 2003) and through it healthcare unit can provide better care to patients by allowing the unit to get an increased understanding of patients' needs.

Besides the abovementioned the use of knowledge management based solutions on healthcare offers other benefits, too. For example if we had knowledge management based healthcare systems we could better analyze different types of knowledge found in healthcare organizations (e.g. clinical knowledge stored in repositories) as well as achieve significant organizational productivity improvements (Bose, 2003).

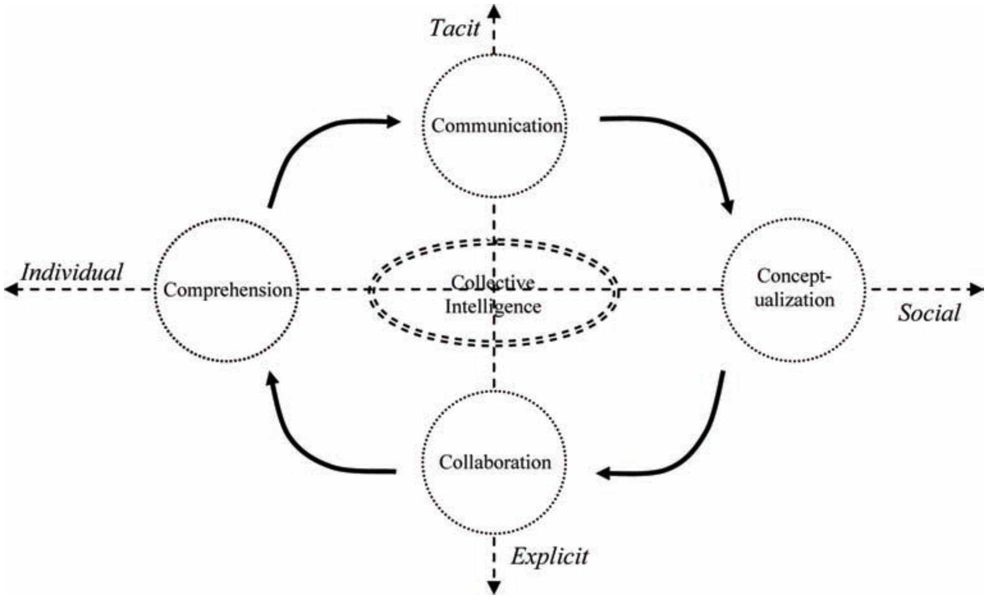
Our goal is not to define new ways to facilitate knowledge creation through healthcare information systems but rather to investigate knowledge reuse. Using the 7C model of knowledge creation and management we argue that over time through knowledge reuse healthcare organization do not only generate new knowledge but get better at their work, too. The next chapter will present the 7C model used in this study.

7C MODEL OF KNOWLEDGE CREATION AND MANAGEMENT

The *7C model* suggests that the following seven Cs play a critical role in the creation of organizational or social knowledge: Connectivity, Concurrency, Comprehension, Communication, Conceptualization, Collaboration, and Collective intelligence (Oinas-Kukkonen, 2004). The 7C model follows Nonaka and Takeuchi (Nonaka & Takeuchi, 1995) in that the integration of individual and social orientations (individual and organizational in their terminology) is emphasized, and that knowledge is assumed to be created through interaction between tacit and explicit knowledge. The model follows Engelbart (1992) in the outcomes of the Comprehension, Communication and Conceptualization sub-processes.

The framework assumes that *connectivity* of all stakeholders with the joint information space (the 1st C) and with people potentially *concurrently* (the 2nd C) is provided in a technologically sound manner, e.g. through the Web, Internet, wireless, mobile and other technologies. These may promote options and allow freedom of choice with contextual support, providing users with a rich environment for *comprehending* (the 3rd C) and *communicating* (the 4th C) the information they find. Knowledge is *conceptualized* (the 5th C) as artifacts, which serve as a vehicle for *collaboration* (the 6th C) through interaction between information producers and consumers, within a team of co-workers or among other stakeholders. All of these six preceding Cs contribute to the growth of "togetherness" or *collective intelligence* (the 7th C). The creation of organizational knowledge is

Figure 1. Knowledge creation sub-processes (Oinas-Kukkonen 2004)



not a linear process, but rather a multi-cycle spiral process (Oinas-Kukkonen, 2004). See Figure 1.

The four central sub-processes in knowledge creation are comprehension, communication, conceptualization and collaboration (Oinas-Kukkonen, 2004). *Comprehension* is a process of embodying explicit knowledge in tacit knowledge by surveying and interacting with the external environment on an ongoing basis in order to identify problems, needs and opportunities (e.g. learn by doing or re-experiencing).

Communication is a process of sharing experiences between people and thereby creating tacit knowledge in the form of mental models and technical skills, producing dialogue records which emphasize needs and opportunities, and integrating the dialogue and resulting decisions with other project knowledge on an ongoing basis.

Conceptualization is a collective reflection process articulating tacit knowledge to form explicit concepts and rationales and systematizing these into a knowledge system, which are iteratively and collaboratively developed, possibly including proposals, specifications, descriptions, work breakdown structures, etc., but rarely a one-shot effort.

Collaboration is a team interaction process of using the resulting conceptualizations within teamwork and other organizational and social processes.

Each of the sub-processes may also be regarded as the building of an artifact and reasoning over why it has been built in the way it has, i.e. capturing the knowledge rationale. Repeatedly going through these phases in a seamless and spiral-like way leads to the growth of *collective intelligence.* Support for capturing deep individual thinking and recording the dialogue between team members may help create truly innovative knowledge products. The learning involved in the comprehension and communication processes is closely related to the attitudes of the participants, i.e. whether they understand their weak points in the sense of individual learning styles, for example.

It is important to notice that the 7C model does not try to define how information systems should manage knowledge. Rather, it models the processes of how individuals interact with information and knowledge (and with each other) to increase the collective intelligence of the organization. In a hospital physicians and nurses can learn and understand new things (Comprehension) while they perform their daily work. They can then share their work related experiences with their colleagues (Communication). As they share they can collectively add to the knowledge of the group and create e.g. best practice guidelines (Conceptualization) to help them perform their work better in the future (Collaboration). Over time, as these processes go around over and over again the hospital unit could get better at providing care for its patients (Collective intelligence).

In spite of receiving a lot of attention recently among practitioners, relatively little knowledge management research has discussed the evaluation of the solutions suggested (Oinas-Kukkonen, 2005). This kind of evaluation may be carried out at the individual, work unit (group, team, or department), or overall organizational levels. The increase in the sharing and dissemination of information and the increase in varied interpretations are obvious and in any case by no means the most important measures of the success of knowledge management solutions. The truly important measure is the identification of underlying non-obvious, complex problems and issues (Oinas-Kukkonen, 2005).

Evaluation of the Comprehension and Communication sub-processes means, for instance, assessment of whether the following goals are achieved: better understanding of current and potential future customers, the key organizational business processes, the product portfolio, product features and potential future products and markets in general. Quite naturally, an improvement in any of these will lead to either an increase in new ideas or the achievement of better ideas for future business, and it may also help solve some of the problems that the organizations are faced with over time (by being more capable of defining the core processes and their key challenges) or even avoid some of the pitfalls they might suffer from. (Oinas-Kukkonen, 2004).

CASE DUODECIM

The *mobile healthcare information system* under investigation is evaluated at the individual and work unit levels. The system comprises a set of medical information and knowledge databases developed by Duodecim Publications Ltd (the Finnish Medical Society Duodecim is a scientific society with over 18,000 of Finnish doctors and medical students - almost 90% - as its members.). The system emphasizes the role of evidence-based medical guidelines (EBMG), i.e. a collection of clinical guidelines for primary care combined with the best available evidence. The collection includes almost 1,000 concise primary care practice guidelines covering a wide range of medical conditions and including both diagnosis and treatment, over 2,700 high-quality evidence summaries supporting the recommendations, a library of 900 high-quality photographs and images of all common and many rare dermatological conditions, electrocardiograms and eye pictures as well as abstracts from the Cochrane Library (which is a collection of databases in medicine and other healthcare specialties).

The system also contains the *pharmacology database Pharmaca Fennica* with a wireless update service for a complete medicine price list, a *drug interaction database* for drug-related decision making, the international diagnosis code guide known as The International Classification of Diseases ICD-10, an acute care guide, a medical dictionary of over 57,000 terms, and a comprehensive database of healthcare-related addresses and contact information for pharmacies, hospitals and health centres. The system is described in Table 1. It is typically used through smartphones and it is delivered to users as a memory card that includes a search engine, user interface software and the core databases.

The knowledge base is planned to support physicians in their day-to-day activities. It can be carried around and applied in the bedside or at the point of care. As physicians apply and reuse the knowledge they may be better equipped with the tasks at hand. This knowledge may also support their medical decision making as well as help them to learn new things. Some earlier studies of the system (see Han et al., 2004a, Han et al., 2005) have demonstrated that physicians have a positive perception of it and intend to use it, and that the most frequently requested mobile content entities were EBMG, Pharmaca Fennica and ICD-10.

Table 1. The Duodecim mobile HIS under study

Duodecim database	Description / functionality
Evidence-based medical guidelines	Search for evidence-based guidelines including literature references and abstracts from the Cochrane Library.
Pharmaca Fennica	Drug lists, adult and paediatric dosing guidelines, common side effects.
ICD-10	International Statistical Classification of Diseases and Related Health Problems. Codes for classifying diseases and a wide variety of signs and symptoms.
Acute Care Guide	Pathogenesis, causes, symptoms, differential diagnosis.
Drug Interaction Database	Possible interaction effects of selected drugs.
Medical Picture Database	Descriptions of symptoms and pictures.
Contact Information	Search for contact information on pharmacies, hospitals and health centres.

Data Collection

The data were collected through the Internet during a two-week period from January 23 to February 7, 2007. The key knowledge creation issues under investigation were Comprehension, Communication, Conceptualization, Collaboration and Collective Intelligence. The technological viewpoints of the 7C model (Connection and Concurrency) were omitted as they are beyond the scope of this research. Medical performance was not measured either. The questionnaire contained 18 questions. See Appendix 1. Five-point Likert scale from "Completely disagree" to "Completely agree" with the choice "I don't know" in the middle was utilized. Physicians were very familiar with this scale, as it had already been used in previous studies of the same system (cf. Han et al., 2004b, Han et al., 2006).

The respondents were approached by email with a link to the online questionnaire. The questionnaire was sent to all of the 352 users of the mobile system. They were all physicians who had a smartphone of their own and the software installed in it, donated by a large international medical company. It should be mentioned that while all of the users were members of the Finnish Medical Society Duodecim, they were not necessarily working at the same hospital. The response rate was 66.5% (n=234). Two responses were deleted from the data set because the respondents did not actually use the system, and one was deleted because the respondent did not answer any of the main questions related to this study. Thus the final data set consisted of 231 replies.

RESULTS

62.3% (n=144) of the respondents were men and 37.2% (n=86) women. 61.9% (n=143) were specialists, 27.3% (n=63) general practitioners, and 10.4% (n=24) researchers or working in administrative positions. Most of the respondents had more than 20 years of experience of working as a physician (55.8%, n=129), while 32.0% (n=74) had over ten years of experience and only 12.1% (n=28) had less. The majority of the physicians worked daily with patients (80.5%, n=186), nurses (86.6%, n=200) and other physicians (85.3%, n=197).

45.9% (n=106) of the physicians used the information system daily, 37.7% (n=87) several times a week, 11.7% (n=27) once a week, 3.9% (n=9) once a month and only two used it less often than once a month. The two most frequently used parts were Pharmaca Fennica drug information (96.5%) and EBMG (88.7%). The least used was the Picture Database (n=46, 19.9%). It was the most recent addition to the system and not all physicians had access to it yet which at least to some extent explains its low usage (the medical society estimated that about half of the users had the picture database installed). Besides using the mobile HIS, 27.7% (n=64) of the physicians read emails through the mobile device and 36.4% (n=84) used it for other Internet services. Quite naturally, the less experienced physicians more often felt that the system helped them to learn new things, and they also found it more useful to some extent than did the more experienced physicians (see Table 2).

Interestingly, there was a slight difference in how specialists and general practitioners felt about the system's ability to support learning of new things. 62.9% (n=39) of the general practitioners felt that the mobile HIS helped them to learn, while 47.9% (n=68) of the specialists felt that way (Chi-Square=3.902, p=0.048). The explanation may be simple fact that the specialists' area of expertise is more focused while general practitioners have to treat patients with wide variety of symptoms.

The four Cs of the knowledge creation spiral correlated with each other strongly. Interestingly, the highest correlations were between Comprehension and Communication, i.e. the individual side of the model (r=0.626) and Conceptualization and Collaboration, i.e. the social side of the model

Table 2. Experience affected the perceived usefulness and learning

Experience	**Learning** **(Chi-Square=15.445, p=0.000)**	**Usefulness** **(Chi-Square=7.459, p=0.024)**
under 10 y (n=28)	81.5%	92.9%
10-20 y (n=74)	58.1%	86.3%
over 20 y (n=129)	42.2%	74.2%

(r=0.675). This supports the individual-social dichotomy in the knowledge creation model. The next strongest correlation were between Communication and Conceptualization (r=0.554), Comprehension and Conceptualization (r=0.538), and Communication and Collaboration (r=0.534) while the lowest correlation was between Comprehension and Collaboration (r=0.514).

To investigate the *knowledge creation spiral* a sum variable was constructed, representing the Comprehension, Communication, Conceptualization and Collaboration sub-processes (referred to later simply as the "sum variable"). We used the sum approach as each of the 7C sub-processes may be treated equally important. Since five responses had one or more missing data items related to these, the missing data were replaced by means from similar respondents. The sum variable has a high reliability (Cronbach's α=0.841) and correlates strongly with Collective Intelligence (0.629). This seems to confirm the interplay among the four Cs, i.e. the spiral, indeed leads to the growth of Collective Intelligence.

A comparison between those who used the system daily and those who used it less frequently indicates that the daily use improves all *knowledge creation* sub-processes as well as the sum variable (see Figure 2). This seems to indicate that it actually helps physicians to perform their jobs better and it eventually may increase the Collec-

Figure 2. A mobile HIS may improve all key knowledge creation sub-processes

tive intelligence of the whole work community. This is an important finding and provides some empirical evidence for the usefulness of mobile information systems in healthcare in general. Thus, a mobile healthcare information system would be of benefit not only for patient safety (Honeybourne et al., 2006) but for the professional skills of the physicians as well.

We also analysed the different parts of the system to find out which functionalities had on effect on different knowledge creation sub-processes. As 96.5% of the physicians used the drug information (only eight did not use it) we could not compare users and non-users with it. The Independent Samples T-tests between those who used EBMG and those who did not suggest that *EMBG* use improves user perception on the mobile system's help to Communicate (F=1.813, p=0.001), Conceptualize (F=0.538, p=0.001) and Collaborate (F=0.035, p=0.001). See Figure 3. It improves the spiral (F=2.195, p=0.000), and to some extent it also affects Comprehension (F=4.949, p=0.022).

The ICD-10 improved Collective Intelligence (F=1.550, p=0.000) and the spiral (F=0.084, p=0.003). Whereas ICD-10 is packed with four-letter abbreviations of various diseases and it seems impossible for anyone to know all diseases and their codes by heart, it is surprising that there was no correlation with it and Comprehension. It may well be that these abbreviations are really used only for healthcare management and they do not involve diagnosing or modelling the groups of diseases.

Use of Acute Care Guide improved all knowledge creation sub-processes: Collaboration (F=10.312, p=0.000), Comprehension (F=6.067, p=0.000), Collective Intelligence (F=0.339, p=0.000), Communication (F=1.730, p=0.001), Conceptualization (F=0.001, p=0.008), as well as the sum variable (F=1.560, p=0.000). As such, the use of the Acute Care Guide seems to improve each of the knowledge creation sub-processes.

Table 3. Usage of the different parts of the system and their impact on the 7C processes

Duodecim database	Frequencies	CI	Comp	Comm	Conc	Coll	Sum var
Acute Care Guide	39.8%	X	X	X	X	X	X
Drug Interaction Database	54.5%	X	X		X	X	X
Evidence-based medical guidelines	88.7%			X	X	X	X
Contact Information	74.5%					X	X
ICD-10	57.6%	X					X
Medical Picture Database	19.9%						X
Pharmaca Fennica	96.5%						

Use of *Drug Interaction Database* improved Collaboration (F=1.218, p=0.000), Conceptualization (F=0.979, p=0.001), Comprehension (F=0.095, p=0.001), Collective Intelligence (F=0.073, p=0.010), as well as the sum variable (F=0.922, p=0.000). Quite interestingly, it did not affect Communication. Maybe the drug interaction information is useful in places where communication is not required, e.g. the physicians has already decided that he will prescribe drug A and he uses the system to check out possible interactions with existing medication.

Use of Medical Picture Database improved only the sum variable (F=0.000, p=0.009). The results concerning the Picture Database may be little inconclusive due to its low usage. Contact Information improved Collaboration (F=1.724, p=0.002) and the sum variable (F=0.025, p=0.004). Interestingly it did not improve Communication, even if it provided contact information.

Table 3 summarizes the correlations between parts of the system and knowledge creation subprocesses.

DISCUSSION

From the five Cs addressed in this study *Comprehension* was improved by the use of the Acute Care Guide and Drug Interaction Database. The Acute Care Guide was used slightly more often by the less experienced physicians, as 33.3% (n=43) of those who had more than 20 years of experience used it, compared with 48.0% (n=49) of the rest of the physicians (Chi-Square=5.140, p=0.023). Quite obviously, the less experienced physicians still have more to learn and comprehend. Maybe this is especially true in acute medical situations. The fact that Drub Interaction Database improves Comprehension seems feasible too, since there are a large number of different drugs and their combinations that it is practically impossible to know all of their interactions. Thus an easy way of checking these interactions should indeed help physicians and over time they may comprehend something new. Interestingly, EBMGs did not affect Comprehension. This might be because most of the physicians were experienced and thus familiar with the guideline information. On the other hand, most of the users (61.9%, n=143) had specialized in certain medical domains, which implies that their knowledge needs might have been more specialized than what is provided through the evidence-based medical guidelines.

Communication was improved by the EBMGs and the Acute Care Guide, which both are well-structured and evidence-based. Thus, they contain guideline information that is relatively easy to deliver. For example, all guidelines in the Acute care guide are organized in the same format, i.e. pathogenesis, causes, symptoms and differential diagnosis.

Conceptualization was improved by the EBMGs, Acute Care Guide and Drug Interaction

Database. Indeed, evidence-based information may help a group of physicians to reach a consensus in making medical decisions.

Collaboration was improved by the EBMGs, Acute Care Guide, Drug Interaction Database and Contact Information. It seems natural that guidelines help physicians to collaborate. Similarly providing Contact Information helps find the right people.

Collective Intelligence was improved by ICD-10, Acute Care Guide and Drug Interactions. Interestingly, 65.0% (n=93) of the specialists used ICD-10, but only 39.7% (n=25) of the general practitioners. This could mean that specialists have a greater need for the ICD-10 than general practitioners, but as such it does not explain why the use of ICD-10 improves Collective Intelligence. One reason for this could be that hospitals are very bureaucratic by nature and these classifications of diseases are needed in many situations, e.g. when a patient checks in, when a patient's treatments are entered into hospital records, or when a patient is discharged. The use of a mobile ICD-10 application can provide practical support in these situations.

From the different subsystems the Acute Care Guide improved all knowledge creation sub-processes. Mobile applications such as the Acute Care Guide combine the "any time, anywhere" possibilities of mobile applications with actual needs in acute medical situations, where knowledge must be acquired and applied swiftly. Thus, instead of concentrating on any time and anywhere mobile applications in knowledge work context might need to concentrate more on exact situations where knowledge is needed, e.g. in healthcare at the point of care.

Of the other subsystems *Evidence-Based Medical Guidelines* and *Drug Interactions* seem to support the knowledge creation sub-processes to a greater extent. Overall, guideline information seems to provide a good fit with knowledge creation. Guidelines contain information about diagnostic procedures that may be used with certain symptoms as well as suggestions for which drugs might work best for different illnesses. Physicians may also find them helpful when consulting other physicians, as the guideline information may provide a basis for communicating and collaborating. A general practitioner may first check the information found in the mobile HIS, for example, and then use it as a reference when consulting a specialist.

FUTURE RESEARCH

Future research should be directed towards empirical testing of the knowledge processes in more detail, e.g. what type of communication do the evidence-based medical guidelines really support and how can the transfer of tacit knowledge into explicit be better supported. Also multiple sources of data would help obtain deeper understanding.

We are also planning a longitudinal study on the case system described in this paper. With the longitudinal data we can see e.g. how the regular use of the system affects the 7C knowledge creation processes. For example the collective intelligence of the hospital units should increase over time.

We would also like to compare the case system to other ways of obtaining the same information and knowledge. For example, how does the usage of the mobile system compare to e.g. books or desktop information systems (Duodecim also has the desktop version of the case system). We are especially interested in finding out does the case system really offer better support at the point of care?

Another line of research we are interested in is what kind of features of functionalities would support the processes of the 7C model? We are especially interested in the comprehension and conceptualization processes as they have received less attention in the scientific literature than communication and collaboration.

CONCLUSION

This article discusses physicians' usage of a mobile healthcare information system. This was studied through the 7C knowledge management framework. The usage of the system seemed to improve the knowledge work of individual physicians as well as the collective intelligence of work community. The easiest sub-process to support through the system seemed to be collaboration between the physicians. Comprehension and, quite surprisingly, Communication were the most difficult aspects to support. All parts of the case system helped improve the knowledge creation spiral.

These findings go hand in hand with some of the previous findings (e.g. Ebell et al., 1997, Honeybourne et al., 2006) of the usefulness of healthcare information systems, especially in acute medical situations where decisions have to be made swiftly. The findings also hint that the daily use of such a system may indeed over time be of benefit not only for patient safety (Honeybourne et al., 2006) but for the professional skills of the physicians as well.

A limitation of our study is that we were not able to go deeper with studying the differences between experienced and less experienced physicians. Another limitation would be that the picture database was not in use by all of the physicians so the results concerning it are not conclusive. Also one limitation on our study could be that most of the physicians participating in the study had more than 20 years of work experience. It could be argued that the less experience the physician has, the more he has to learn and more he could benefit from the use of a mobile healthcare information system.

In sum, *knowledge management* seems to be a prominent approach for studying healthcare information systems and their impact on physicians' work.

Chapter 3.3

Personal Health Records Systems Go Mobile:
Defining Evaluation Components

Phillip Olla
Madonna University, USA

Joseph Tan
Wayne State University, USA

ABSTRACT

This chapter provides an overview of mobile personal health record (MPHR) systems. A Mobile personal health record is an eclectic application through which patients can access, manage, and share their health information from a mobile device in a private, confidential, and secure environment. Personal health records have evolved over the past three decades from a small card or booklet with immunizations recorded into fully functional mobile accessible portals, and it is the PHR evolution outside of the secure healthcare environment that is causing some concerns regarding privacy. Specifically, the chapter reviews the extant literature on critical evaluative components to be considered when assessing MPHR systems.

DOI: 10.4018/978-1-60566-332-6.ch003

INTRODUCTION

Information technology (IT) is dramatically transforming the delivery of healthcare services. This can be seen through the increased activity in Mobile Health (M-Health) and promotion of the Electronic Health Record (EHR) systems in the healthcare industry and the recent attention and increased activity in the adoption of Personal Health Record (PHR) systems. By distinction, PHR systems have not established a similar height of interest as the EHR (Tang, 2006), but this is changing as more government bodies such as the U.S. Secretary of Health and Human Services, the National Coordinator for Health Information Technology, and the Administrator of the Centres for Medicare and Medicaid Services (CMS) have all identified PHRs as a top priority. In addition to the government organizations involvement, standards organization such as Health Level Seven (HL7) have began the standard definition process to formalize a system model for PHRs.

PHR aims to allow individual health consumers the ability to monitor and manage their personal health information from multiple sources in a single repository. Research shows that maintaining a PHR encourages personal participation in healthcare and cultivates an increased emphasis on communication between the individual and the healthcare provider (Kupchunas, 2007). The use of a PHR provides the opportunity for healthcare providers to monitor and educate patients on health matters and lifestyle changes, and it also acts as a tool for enhancing health literacy. The PHR will eventually improve the decision making capabilities as the patients become more proficient at recording and monitoring vital health information (Lee, Delaney, & Moorhead, 2007). The goal of utilizing personal health records would be to enhance and optimize the healthcare practices while allowing patients to manage their own health care decision-making. For the caregivers, PHR technology can improve efficiency, cost-effectiveness, timeliness, safety, and efficacy of the care processes, whereas for the individual consumers, it can help improve their quality of life. Large organizations and government bodies have recently gained an interest in the PHR phenomenon; for example, Intel, Wal-Mart and BP have formed a consortium, called Dossia, to supply PHRs for their employees; Medicare and Medicaid Services are trialing PHR with Medicare claims; and Google and Microsoft have also entered this market with new products such as Microsoft Health Vault and Google Health. In addition, Verizon Communications in combination with WebMD now offers a password-protected site for PHR (Reese, 2007).

The PHR migration to the mobile platform offers immense benefits such as portability and convenience in the accessing and transmitting of personal health records from a single location, the empowerment of the health consumers to control, verify, and manage their own health information, and the potential enhancement of patient-caregiver relations. Unfortunately these benefits can be overshadowed by the concerns regarding security, privacy, mobile technology choice, and validity of information. This chapter will highlight the important evaluation components that need to be considered when the PHR is modified to support mobility.

The discussion is structured as follows. Following the introduction, the next section describes the history and background of PHRs. Against this backdrop, an overview of the literature and progress being made on PHR research will be highlighted. This will be followed by a discussion on the four categories of PHR systems, namely “individually maintained”, “tethered” to a health plan or employer, “comprehensive” or “Health 2.0”. Once the advantages and disadvantages of the various types of PHR systems have been presented, the discussion will converge on a framework for Mobile PHR systems evaluation, which is then followed by the review of three commercial Mobile PHR systems using components from the framework. The chapter will then conclude with a summary of thoughts on future growth and development in this area.

BACKGROUND AND HISTORY OF PHR

The Personal Heath Record (PHR) is not a completely new phenomenon; accordingly, one of the earliest references to a PHR can be found in an article by Okawa (1973) entitled, “A personal health record for young female students.” Several references to personal health records surfaced prominently as “paper records” up until the mid 1990’s, when the computerized version of the PHR appeared. With the diffusion and general use of computers, individuals became interested in maintaining an electric copy of their personal health information. Sittig (2002) conducted a search of available Internet-based PHR's and came up with 27 identified programs or usable tools; by April of 2003, only 7 of these tools were relevant and still accessible (Sittig, 2002). The demise of these Internet-based companies occurred with the meltdown of the dotcoms, poor business plans, inefficiency, and decreased value to the individual. (Personal Health Working Group, 2005). Even though the early PHR's were ultimately unsuccessful, they provided valuable insight into the next generation of PHR's by supporting the fact that by "adopting EMRs, providers and health care delivery systems can facilitate the development and implementation of PHR tools and PHR's should offer clear benefits to users and critical stakeholders." (Personal Health Working Group)

In summary, PHRs have evolved over the past three decades from a small card or booklet with immunizations recorded on it to a computerized application that stores an individual's personal health information. A report by the Markle Foundation, Connecting for Health (2003), defines PHR's specifically as

"An electric application through which individuals can access, manage and share their health information, and that of others for whom they are authorized, in a private secure, and confidential environment." Page 4

Imperative to the usefulness and functioning of the PHR is the establishment of a common data set. At the very least, it should contain information regarding items such as: allergies and adverse drug reactions, illness and hospitalizations, surgeries and procedures, vaccinations, lab test results, and family history. The National Committee on Vital and Health Statistics (NCVHS) reported in 2005 that it is not possible or even desirable to attempt a unitary definition of a PHR. The NCVHS did however state that it is possible and useful to characterize PHRs by their attributes. Attributes associated with PHRs are elements such as the nature of the PHR's content, the source or sources of information, and the functions that they offer (Sprague, 2006). In retrospect, the consumer and health care provider will be able to maintain this health care information in a way that is assessable to both parties.

More recently, President Bush and Secretary Leavitt brokered a plan that would allow patients and their health care providers the ability to access their personal health records through the use of technology (Gellman, 2008). Having this technological capability ensures that patient and health care provider can access healthcare information at any time when seeking medical care. As a result, in 2001, the National Committee on Vital and Health Statistics identified areas in deliverance of healthcare services that required improvements in systems in order to promote quality patient care services, continuity of care and beneficial treatment modalities. Technological systems were further explored in order to change the way personal health information was maintained by the patient and the health care provider.

The Hurricane Katrina saga in the USA has caused the healthcare industry to recognize the importance of seeking ways to secure personal health records. For years, people had collected, maintained and stored their health information on paper, in memory, and other manual means. During such disaster, all of the information kept by patients and health care providers became inaccessible. But with the advances in technology, consumers are provided with tools and mechanisms to maintain their own health records through the capability of computer-based applications. The consumer then has the ultimate responsibility of keeping track and updating their personal information so that their medical care is effective and efficient. Additional benefits of a PHR include access to health information, data collection, improved health, disease management and tracking, improved communication with health care providers, and although not well documented, it is also believed to lower costs related to chronic disease management and wellness programs (Tang, Ash, Bates, Overhage, & Sands, 2006) According to Kupchunas, "maintaining a PHR encourages increased personal participation in healthcare and fosters a greater emphasis on communication between the individual and the caregivers" (Kupchunas, 2007: pg 185).

PHR Literature Review

PHRs aim to enhance and optimize the healthcare practices while allowing patients to manage their own health care decision-making. On the side of healthcare practices, this would improve efficiency, effectiveness, timeliness, safety; on the side of the patients, it would help them to improve their quality of life. A comprehensive review of the extant literature published on issues related to PHRs using scropus tools (www.scropus.com) is now presented.

Scopus is the largest abstract and citation database of research literature and Web sources. Scropus contains over 33 million abstract and provides access to publications in 15,000 peer-reviewed journals and 200 book series from more than 4,000 publishers. The system also has access to over 1200 Open Access journals, 500 conference proceedings and 600 trade publications. The literature search undertaken not only investigated the bulk of the academic literature but also reviewed data from 386 million scientific Web pages and 22 million patent records from 5 patent offices. Even though our search criteria covered a period of 20 years, we have chosen to present data that are only from the last decade. The search excluded medical health records, electronic health records, and electronic medical records. This essentially directs the review to focus on system functionality of PHRs along with the unique elements associated with a PHR.

PHR FUNCTIONALITY AND COMPONENTS

There have been considerable research and investment into PHRs over the past decade. This is evident in the growing number of publications and patents registered in this area. Based on a review of the extant literature, the main areas of functionality are illustrated in Figure 1.

As shown in Figure 2, the functionality can be broken down into various aspects of consumer functionality (Denton, 2001). Two major aspects, which are considered to be among the most promising uses for PHR system, are the use of PHR for health education and for managing specific patients conditions(Arbogast & Dodrill, 1984; Bent, Bolsin, Creati, Patrick, & Colson, 2002; Bhuyan, 2004). Another aspect is linking the PHR to decision support. This is also a key research component with obvious benefits to the patients choosing and understanding a suitable treatment plan (Abidi & Goh, 2000; Ackerman, 2007). Other important aspects include consumer information (managing clinical and personal data) and the growing use of PHR systems to support and improve administrative support functions.

As issues relating to the area of privacy and security (Agrawal & C. Johnson, 2007; Alban, Feldmar, Gabbay, & Lefor, 2005; Albright, 2007; Alhaqbani & Fidge, 2008; Al-Salqan, Jagannathan, Davis, Zhang, & Reddy, 1995; Anderson, 1996; Armitage et al., 2008; Blobel, Pharow, Spiegel, Engel, & Engelbrecht, 2001) have now become more important than ever given the nature of the new generations of PHR systems, we will examine them separately and more closely in a later section of this chapter.

Although there seems to be a peak in academic research around 2006 (see Figure 1), this has not slowed down the commercial field. There is an increase in Web based activities and patent applications. This shows that as the research matures more commercial offerings are being launched. The industry-based publications are focusing on

Figure 1. Personal health records publications

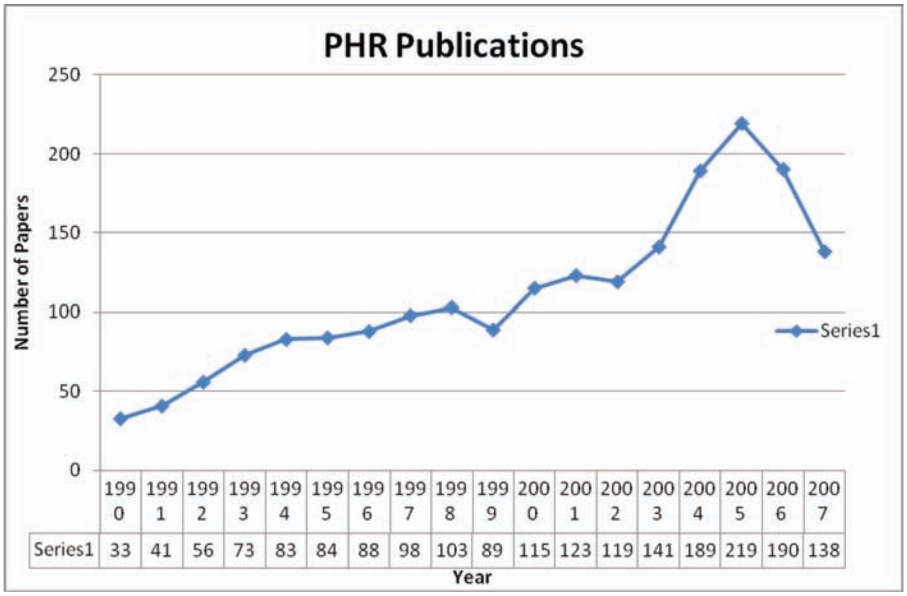

Figure 2. Concept map of personal health records research from literature

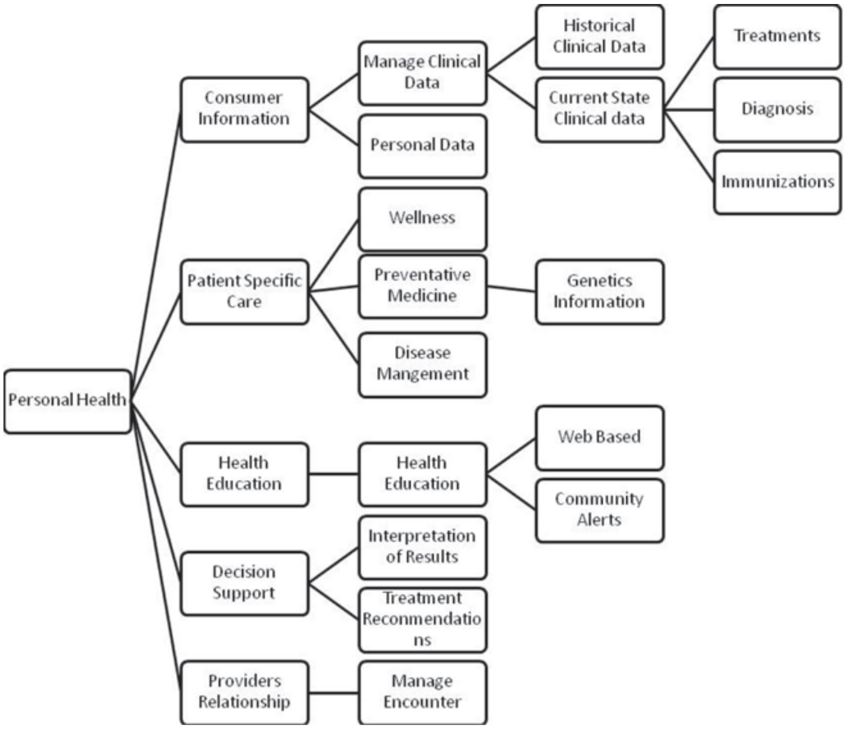


issues such as standards, interoperability, security and integration (Ball & Gold, 2006).

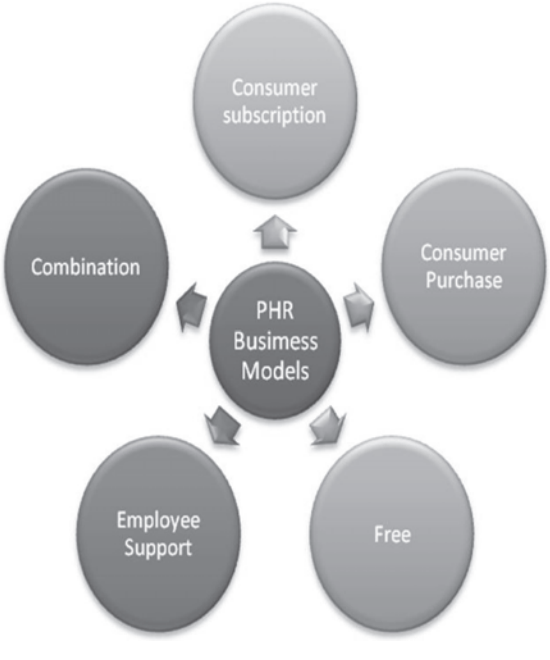
Personal health records are maturing rapidly and several diverse actors' have full-scale implementation of PHR systems - these actors include employer groups such as DOSSIA, and commercial vendors such as Google and Microsoft. The emergence of large organizations such as Google who already hold significant volumes of data about individuals is creating serious concerns. The concept map below provides a snapshot of the current work being undertaken in the field, the research covers a broad spectrum, which highlights the multidisciplinary approach to research in this field.

Business Models

A study by Adler, highlighted the fact that 74.6% of patients surveyed were willing to pay a small annual fee for one or more of the following online services: viewing parts of their medical record, messaging with their physician, medication refills, appointment requests, and billing inquiries (Adler, 2006). A variety of sources, such as healthcare providers, insurers, employer or commercial suppliers offer a wide range of products that are available to help you create your own PHR. Some PHRs include products that have free tools, others offer products for purchase, Figure 3 summarizes the various existing business models.

An array of complex business models exists in the PHR domain. However, from a general marketing perspective, these can be grouped into three commercial types – consumer purchase, consumer subscription, and a combination of the two (Gellman, R. 2008). For the purpose of this review, the business models have been classified into five categories:

Figure 3. Business model for personal health records



1. **Consumer subscription model:** The consumer is responsible for an ongoing service fee to access the data and related systems.
2. **Consumer purchase model:** With this approach the consumer pays a fixed fee to purchase the software that provides the core functionality of the PHR outright. This type is typically a desktop application. The subscriber may also have the option to purchase a support contact.
3. **Free model:** With this model the PHR is free to consumers because the service is supported by advertising.
4. **Employee support model:** With this model, an employer or health plan will contribute part or all the fees to run the service. This is seen as preventative medicine as there is strong evidence that they could save money on health care costs in the long run.
5. **Combination:** There is also the possibility that a combination of these various models could be in effect. For example a PHR service paid for by an employer or health plan may allow advertising.

Although these models may be the obvious source of revenues, there may be other elements in play such as affiliation models with informational Web sites, niche search engines, articles, surveys, software downloads, and a variety of products that are not directly associated with the PHR system.

Prices and formats vary widely, with diverse levels of technical abilities and functionality among the different product lines. From the perspective of Health Insurance Portability and Accountability Act (HIPPA), many of the PHR sites state in their guidelines that they 'comply with', or 'we voluntarily operate within the guidelines', but most mentioned nothing about HIPPA certification. Most sites stated they protect the privacy of personal health information (PHI) and will not share your PHI. A PHR privacy policy study in 2007 conducted by the Department of Health and Human Services (DHHS) stated that "only 3 percent, or one in 30, of PHR privacy policies stated that explicit consumer consent was necessary prior to the vendor sharing any of the data in the PHR" (Gellman, 2008, p. 7). Even though numerous PHRs are free to consumers, a PHR vendor is operating a business, in which revenues are generated primarily through advertising and marketing. Therefore, it is imperative that consumers educate themselves when sharing their information with PHR vendors.

Categorization of PHR Systems based on Ownership

There are many ways to categorize PHR systems, but for the purpose of this chapter, the concept of ownership is used. This approach was taken to highlight the potential issues that arise from transferring ownership. Most of the existing applications fall into three main categories: individually maintained, "tethered" to a health plan or employer, or comprehensive (Sprague, 2006).

A new category, which has also emerged recently and has been added for the purpose of this review, is called health 2.0. It is this new category of PHR applications that is providing serious concerns from a security and ethics perspective.

In order to assist readers attempting to compare and contrast among the different categories, we will also highlight the respective advantages and disadvantages associated with each category.

MOBILE HEALTH 2.0 PHRS

This category refers to the new generation of Web 2.0 healthcare applications that support mobility. Health 2.0 is just as difficult to define as the Web 2.0 concepts. The Health 2.0 conference definition focuses on user-generated aspects of Web2.0 within health care but not directly interacting with the mainstream health care system. The problem with this definition is that it is very difficult to separate the user generated and mainstream healthcare systems without generating duplication and redundancy. Given that there are several definitions, we have decided to share the approach taken by Scott Shreeve from CrossOver Healthcare due to the pragmatic nature of his definition of a Health 2.0 Company:

"Next generation health companies that leverage the principles of openness, standards, and transparency; utilize the technology tools of collaboration, information exchange, and knowledge transfer; and focus on delivering value added services that empower health participants (patients, physicians, providers, and payers) with freedom, choice, and accountability for health outcomes.

There is currently a lot of debate regarding this new concept. Some believe that the these companies are providing a wider movement to reform the entire US health care system, while others believe that these are merely tools and technologies to support the current system. There are considerable concerns when companies that are not within the health care industry take active roles in storing and maintaining personal health data. Most of the companies that operate in this domain are strong advocates for mobility and are keen to integrate mobile technology into their Web portal solutions.

Google is implementing a pilot at Cleveland Clinic hospital in Cleveland as the pilot site for a new personal health records initiative. Between 1,500 and 10,000 patients will partake in the project. Patients will have their current MyChart electronic health records migrated to their Google accounts. Once the PHRs, are shared with Google, patients will have the capability to access them outside of the Cleveland Clinic. Google is not the only technology giant looking to change the healthcare industry. AOL founder, Steve Case, has recently launched a new organization called Revolution Health (http://www.revolutionhealth.com/); InterActiveCorp has also invested in several health-related start-ups (http://www.healthcentral.com/); and Microsoft has been very active with a medical record service called HealthVault.

One of the ways that companies are providing customers with additional benefits is by providing secure access to the health records stored on the portals via a mobile device. At this point, we will highlight the respective advantages and disadvantages associated with the Health 2.0 category.

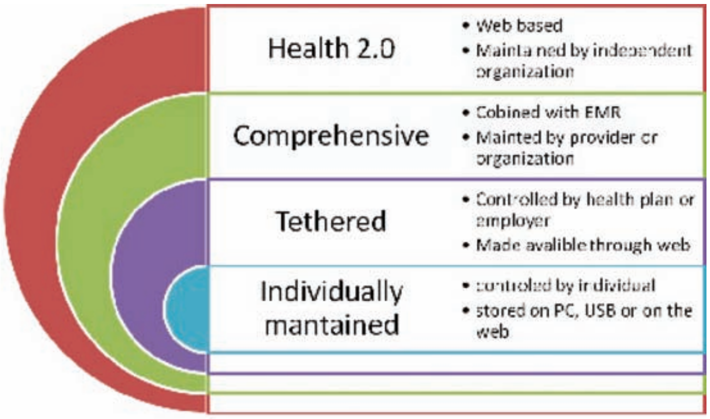
Advantages

- The data is available from anywhere
- Interoperability and the use of open interfaces mean that data can be imported directly from the healthcare provider in some cases.

Disadvantages

- This approach has already raised serious privacy concerns due to the migration of private data into the commercial domain, and critics of such projects have already begun to make themselves heard.
- These third-party PHR systems are not covered by the HIPPA, which has been in effect since 1996 and requires individuals to be notified when a party other than a patient's doctor wants to access confidential medical information.
- There will be some costs associated with the business model.
- Access to the Internet is required to access data via the mobile device.

Figure 4. Personal health records categories



INDIVIDUALLY MAINTAINED PHR

The simplest form of a PHR is one that is maintained by the individual. This sort of PHR is created, updated, and controlled strictly by the individual (Sprague, 2006). Such a PHR allows the individual to organize and retrieve their own health information and it captures the patient's concerns, symptoms, emergency contacts, and other relevant information (Endsley et al., 2006). This type of PHR can be software driven and may reside on a person's computer or be Web-based. The Wed-based format is maintained by a third-party. Other devices such as "smart cards," USB drives, and CDs can also be utilized for this type of PHR (Endsley et al., 2006).

Advantages

The individually maintained PHR has a limited number of advantages, aside from it being controlled by the individual; the security may be the biggest advantage of this type of PHR. The individual PHR provides more control over access to the data contained within the PHR (Tang et al., 2006).

Disadvantages

The question regarding the individual PHR is how often will the individual update their PHR? The individual PHR, as maintained by the individual, may not be updated as often as they should. Another disadvantage is that it may not be considered a trusted conduit for transmission of medical information among clinical offices or health care institutions. Another aspect is the fact that the individual PHR may not have enough back-up systems in place in case of any technical malfunction (Tang et al., 2006). As we discussed the back-up system, we need to also take into consideration the literacy of the individual. How well versed is the individual with regards to medical and technical information? Does the individual understand and comprehend the information and can they relay the information technically (Tang et al., 2006).

"TETHERED" TO A HEALTH PLAN OR EMPLOYER PHR

The "tethered" PHR, populated with claims data and typically available to the consumer through a secure Web portal, is created by a health plan or an employer Web.

Advantages

The main advantage of the "tethered" PHR is the fact that this type of integrated PHR can provide the patient with much more relevant data. It may also provide the patient with a better back-up system, due to the fact that the integrated PHRs have a larger back-up system (Sprague, 2006).

Disadvantages

A major disadvantage to the "tethered" PHR is the lack of portability; for example, the individual who changes jobs or insurance companies may lose access to the personal health information (Sprague et al., 2006). Other disadvantages include security and privacy issues and the question of standardized language (Tang et al., 2006).

COMPREHENSIVE PHR

A more sophisticated PHR is made available through the electronic health record (EHR). A care provider or organization, such as a hospital, physician, or an integrated delivery system, usually maintains the EHR. The EHR is designed to be a repository of clinical information on a patient and to accept information from a variety of sources. The sources of information may include physicians, laboratories, and consumers. The capability of this type of PHR allows the consumer access to some portion of his or her clinical data, under rules set by the provider; it may also allow secure e-mail messaging, access to condition-specific information, appointment scheduling, and many other functions (Sprague, 2006). Different organizations will maintain a range of somewhat differing policies and procedures with respect to availability, accessibility, portability, release and use of personal health information captured in the PHR.

Advantages

The biggest advantage is the access that patients will have to a wide array of credible health information, data, and knowledge (Tang et al., 2006). A secondary but still very important advantage is the potential to lower communication barriers between the patient and health care provider (Tang et al., 2006). Integrated or comprehensive PHRs provide an ongoing connection between patient and physician (Tang et al., 2006).

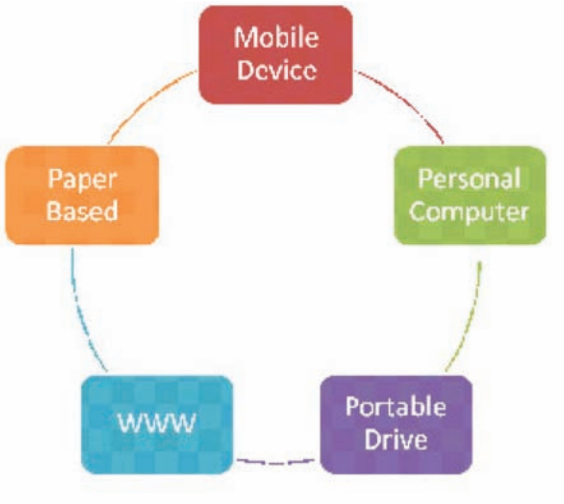
Disadvantages

Many of the disadvantages are the same for the comprehensive as for the "tethered" PHR. The issues of security and privacy and the use of standardized language are being raised with regards to the comprehensive PHR. The World Privacy Forum recently issues a report on why many PHRs can actually threaten security. The next section will discuss some of the important issues surrounding privacy and security of PHR systems

Categorization Based on Storage Medium

There are now organizations that collected, organized, summarized, and then make available electronically copies of all of the medical information. In some cases, the information is provided to user in a wallet or regular CD, or it could be accessed through the Internet. Typically an electronic PHR can be maintained in various formats including paper-based, PC, Internet or portable (flash drive, CDROM, DVD or smart card) or on mobile devices.

Figure 5. Categorization of PHRs based on storage medium



PHR ON THE PERSONAL COMPUTER

PHR products that involved health information residing on one's own computer is one of the most common types of PHR service. . The user typically uses a CD or downloads the PHR template from the Internet to the personal computer. Information about one's health would then be entered and maintained by the user on his or her computer.

PHR ON UNIVERSAL SERIAL BUS (USB) DRIVES

A USB, (Universal Serial Bus), also known as thumb drive or jump drive, is an inexpensive, portable, electronic device used to store information. The USB is a NAND flash device, with memory stored in chips. This architecture allows for low power consumption, fast speed of use, and high density, allowing for storage of large amounts of information (Axelson, 2006). Device memory is "nonvolatile", easily allowing the user to write and erase information. Moreover, these devices are designed to spread the write-erase cycles evenly across the components of the device in order to prolong the device life.

Advantages

Utilization of a USB device for storage of the PHR promotes an important goal, which is, encouraging individuals to become actively involved in their healthcare. With a USB device, the individual manages health information data input and storage (Ball, Smith, & Bakalar, 2007). Once health information is stored on a portable USB device, this information can be quickly accessed anywhere, a factor especially important during emergencies (Shetty, 2007). USB access is a standard feature on all computer systems, and the USB devices allow easy insertion and disconnection without interruption of the system (www.intel.com).

Individuals who advocate for development and utilization of PHRs stress that portability of the PHR is important as individuals move through the healthcare system. A USB would allow individuals to input and integrate data from many different sources, such as electronic health records, laboratories, radiology departments, and pharmacies. With increased consumer awareness of the importance of privacy, confidentiality and information security, a USB device that is individually carried and controlled can be an ideal solution (Ball et al., 2007). One design characteristic of USB devices that makes them desirable for information storage is durability, as the devices have no moving parts with the casing protecting the components (Axelson, 2006). Research of various USB vendors provided information on features available, including continuously increasing storage capacity, overwrite/modification prevention, display of remaining storage capacity, display of owner identity, and ability to perform on-line back up support. Security technology available includes encryption, password protection, requirements for complex passwords, password reset capability, biometric identification verification, and "lost and found" features.

Disadvantages

USB device issues that can be problematic for PHR utilization include potential for device damage and data corruption. In addition, the costs of USB devices increase as the technological and security features become more advanced and complex. Healthcare information is secure on the USB device when in possession of the owner, however, if the device is lost and data on the device is not encrypted or password protected, privacy can become jeopardized (Tang et al., 2006). While the goal of a PHR is to increase an individual's engagement in their own healthcare, those involved in the evaluation and promotion of PHRs question whether consumers are capable and willing to assume the tasks and costs involved in maintaining a stand-alone/USB PHR (National Committee on Vital and Health Statistics, 2006). The ongoing work involved in keeping the USB PHR up to date will most likely be seen as a burden to many consumers. Many providers would not likely see a PHR that contains information stored and maintained solely by individual consumers as a trusted or valid source. Similarly, providers may deem the information stored by consumers as "clinically irrelevant", and if the information were excessive, it would be overwhelming for providers to review (Tang et al., 2006). If providers decide that information contained in the PHR is unimportant, the value of the PHR is adversely affected (Ball et al., 2007). Finally, providers may be concerned with the legal issues involved in the utilization of PHR data, that is, when the treatment decisions they made are based on inaccurate or invalid patient-entered information (Tang et al., 2006).

While utilization of USB devices for PHRs promotes individual's engagement in their healthcare, the ability to interface and integrate healthcare information over time is a priority that an USB/stand-alone record cannot provide as the sole PHR source.

PHR ON THE WORLD WIDE WEB

Personal health records on the Internet are a growing phenomenon. These systems typically consist of a patient's personal health information on the Internet, entered by them and/or possibly by their caregivers. Patients can record their personal information, demographic information, emergency contacts, insurance, medications, allergies, immunizations, tests, hospitalizations, surgeries, advance directive, spiritual affiliation, and even their care plan (Colorafi, 2006). There are several Web sites on the Internet promoting personal health records. In 2001, if you performed a general search on the Internet for personal health records revealed over 19 sites, some of the examples found included Dr. I-Net, HealthCompass, MedicalEdge, MedicalRecord.com, MedicData, Medscape, AboutMyHealth, and many more (Kim, & Johnson, 2001), this number has grown significantly. The Web services begin with a registration process that involves the user choosing a username and password. Through a Web interface, users then complete information about their (or a family member's) health that is stored in a secure server maintained by the PHR company. Users can then access that information (and/or authorize access to others such as emergency contacts, physicians, or ER departments) by logging-in and providing their password.

At this point not too many patients are aware of personal health records. First, many of them are not computer savvy; or since some of the Web sites are subscription based. However, there are some companies that are willing to help out their employees, and are encouraging the use of a PHR. A number of U.S. companies are working together to develop "Dossia", a Web-based framework to assist employees and retirees to create and maintain lifelong personal health records, of themselves and their dependents.

Advantages

There are many advantages to having PHR on the Web for patients, physicians, employers, and pharmaceutical companies. "Technology can allow the use of personal health records that patients themselves can maintain, can allow and promote telehealth systems, and can actually enhance consumer choice" (Colorafi, 2006) Page 3. Several of these sites "allow patients and physicians to share patient-charted information and diagnostic test results. The benefit to the physician and office staff is that it enhances the physician's teaching efficiency and reduces communication bottlenecks when the telephone is the sole communication tool" (Smithline & Christenson, 2001). Another push towards the Internet for physicians is the ease of use with their handheld devices. They are able to research medications, diseases, treatments, as well as patient labs, test results, and even billing, coding, and dictation abilities. Electronic prescribing systems are also on the rise and a great advantage to the physician and patient. These systems increase patient safety and physician efficiency (Smithline & Christenson, 2001). There are many benefits to the use of the Internet and personal health record. "The most important benefit the Internet will bring to health care will be the integration of information" (Smithline & Christenson, 2001).

Disadvantages

1. With all the positive aspects of PHR and the Internet, some major disadvantages includecost and training. In addition, with the increased use of computers and the Internet, there is an increase of technical issues and system downtime.
2. Training staff can be tricky, especially since a large number of health care providers did not grow up with the internet or e-mail.
3. There will be a large cost for training staff in addition to hardware costs, software costs, implementation, maintenance, and productivity improvements (Colorafi, 2006).

PHRS ON MOBILE DEVICES

There is a new trend that is enabling patients to use their mobile devices to access details from their PHR. Patients can use the mobile device for a variety of functions including: maintaining a real-time health diary, and tracking vital health measures such as blood glucose levels, blood pressure, carbohydrate intake, height, weight. This approach can also be used to record and monitor physical activity such as diet, calorie intake or exercise. As people are becoming more reliant on mobile technology to organize and manage day to day routines, accessing and maintaining personal health information on wireless devices is a natural progression.

One approach taken by system developers is to provide functionality that will allow emergency details along with important data such as immunization records, insurance details, and allergy information from a PHR portal to be downloaded to a secure module within a mobile devices operating system. Another approach is to provide access to the PHR via Smartphones / mobile device using the Internet and the mobile network to view and update the records held in the PHR portal. The benefit of the latter approach is the ability to gain access to more detailed information such as clinical records, medical history and interventions.

Advantages

1. Patients can create and maintain comprehensive online PHR accounts via the mobile devices.
2. The mobile devices provide the capability to easily update and manage that PHR at any time, and from any location.
3. Easy and convenient to use for wellness and health monitoring.

Disadvantages

1. If the device is lost and the health data is stored on the mobile device, there could be serious security implications for the patient.
2. The screen for the mobile device may not display all the information clearly due to the size and those users who are not used to mobile displays may find it difficult to navigate and access information.
3. Only limited information can be viewed, while images and notes may be difficult to understand. The mobile version is not a replacement for the Web portal, and the role is to provide an interface to the portal.

Creating a Framework for Mobile PHR Systems Evaluation

The Mobile PHRS framework presented here has been inspired by the Personal Health Record System Functional Model (PHR-S FM), a model proposed by the Health Level Seven (HL7), along with the Evaluation model proposed by (Kim & K. Johnson, 2002). The approach by Kim (2002) provides a comprehensive view of the PHR functions, and identified five prospective functions of PHRs. The model outlined requirements for accurate entry of information and verification of reported test and study results. The criteria also outlined requirements for the provision of different routes of access, links to consumer health care information, functions to process and interpret information, and functions to provide secure communication between patients and providers. This evaluation was constrained by Web based criteria and does not take mobility into consideration. Another important element omitted from the Kim model is the data storage medium.

HL7 is a premier health care information technology standards development organization boasting an extensive national and international representation. The main purpose of the PHR-S FM is to define the set of functions that may be present in PHR systems. The PHR-S also presents a set of guidelines that "facilitate health information exchange among different PHR systems and between PHR and EHR (electronic health records) systems," The HL7 group advocates that "The PHR-S FM can be applied to specific PHR models (stand-alone, Internet-based, provider-based, payer-based, or employer-based models). At the same time, the Functional Model is flexible enough to encourage product innovation." The mobile model presented here also takes into consideration the mobility aspects. The model is currently not an American National Standards Institute (ANSI)-accredited standard. The ANSI accreditation process will take 2 years. This means that the PHR-S FM will become a U.S. standard for PHRs at around 2010. Once the PHR-S FM is finalized by HL7, it will ensure that standards are available to the health care industry and the general public for use in PHR development. There is currently a profusion of PHR systems in existence but there is a lack of a functional standard to which these systems should conform. HL7's PHR-S FM will be the first major industry standard to specify functionality for PHR systems. HL7 proclaims that the development of standardized, interoperable PHRs is a major component in the U.S[1]. DHHS plans, which is to make health information available electronically through a National Health Information Network (NHIN) by the year 2014.

Portability of Records: The HL7 EHR Technical Committee was created in 2005 by the PHR Working Group - the group has members from heathcare providers, consumers, vendors, and payers. The group recently announced that it had entered into a memorandum of understanding (MOU) with America's Health Insurance Plans (AHIP) and the Blue Cross and Blue Shield Association (BCBSA) to create a collaborative process for the maintenance of portability standards for PHRs. AHIP and the BCBSA have already developed an implementation guide (Implementation Guide for the Personal Health Record Data Transfer Between Health Plans) containing technical standards, a data dictionary, and operating rules for the transfer of PHR data elements between health insurance plans. Under the MOU, AHIP and the BCBSA have agreed to turn over the maintenance of the technical standards components of the Implementation Guide to HL7 and ASC X12 to ensure long-term maintenance of the standards.

With considerable research and investment into personal health records over the past decade, and the growing number of publications and patents registered in this areas, our review unveiled that the main areas of PHR functionality or concern can be grouped into four functional areas as illustrated in Figure 6 and Figure 7.

Personal health records are maturing rapidly and several diverse actors' have fullscale implementation of PHRs, - these groups include subscribers, employer groups such as DOSSIA, and commercial vendors such as Google. There are few Web based systems that are fully integrated into ambulatory or hospital-based EMR systems.

There are considerable challenges to implement the ideal PHR system, and there are important lessons that can be learned from the early adopters. A study by Halmaka et al (2008) identified a set of unique implementation issues and concerns from three case studies MyChart at Palo Alto Medical Foundation, PatientSite at Beth Israel Deaconess

Figure 6. Mobile personal health record functional overview

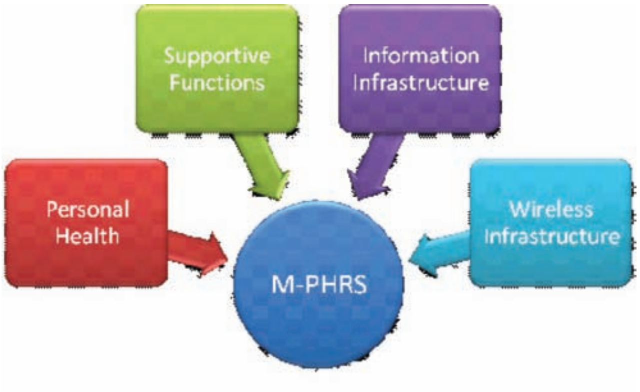


Figure 7. Mobile personal health record functionality

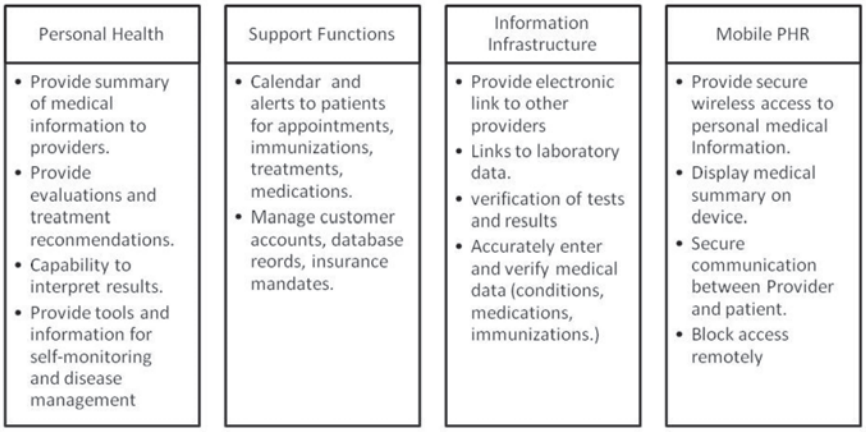


Personal Health	Support Functions	Information Infrastructure	Mobile PHR
• Provide summary of medical information to providers. • Provide evaluations and treatment reconmendations. • Capability to interpret results. • Provide tools and information for self-monitoring and disease management	• Calendar and alerts to patients for appointments, immunizations, treatments, medications. • Manage customer accounts, database reords, insurance mandates.	• Provide electronic link to other providers • Links to laboratory data. • verification of tests and results • Accurately enter and verify medical data (conditions, medications, immunizations.)	• Provide secure wireless access to personal medical Information. • Display medical summary on device. • Secure communication between Provider and patient. • Block access remotely

Medical Center, and Indivo at Children's Hospital Boston. They identified the following implementation challenges from 1999 to 2007, postulating that further challenges are likely to evolve over the next five years.

Current challenging questions facing implemented PHR systems include:

- Should the entire problem list be shared?
- Should the entire medication list and allergy list be shared?
- Should all laboratory and diagnostic test results be shared with the patient?
- Should clinical notes be shared with the patient?
- How should patients be authenticated to access the PHR?
- Should minors be able to have their own private PHR and should patients be able to share access to their PHR via proxies?
- Should PHR include secure clinician/patient messaging?

Future challenging questions that may arise in 2008 and Beyond include:

- PHRs are institution-based and patients will want a single PHR that works with all their sites of care – how can this be achieved?

- Should PHRs support electronic data input from outside institutions?
- How do you allow patients to integrate knowledge sources on the Internet with their PHRs?
- How do you connect patients using social networking tools? Patients with specific diseases may want to connect to communities of others with similar diagnoses
- Patients may wish to participate in clinical trials, post market pharmaceutical vigilance, or public health surveillance via their PHR – how is this possible without compromising security?
- How do you securely incorporate the concept of mobility in a PHR system?

The next section will discuss the wireless and information management element of the evaluation framework, which are important evaluation components of a mobile PHR.

Mobile PHR Information Infrastructure

There are no clear guarantees that the use of any IT applications in healthcare is going to be effective due to the technical complexity of Health IT systems. In the past healthcare software and hardware markets were considered to be less mature than other Industries and for medical technologies (Chiasson & Davidson, 2004). This notion is changing due to the development of new innovative software applications and availability of hardware specifically targeted to the growing healthcare market. The key to the growth in this area has been the launch of software that improves effectiveness by providing functionality to manage the administrative and support functions of healthcare.

It is important that any PHRS system should take into consideration Information Infrastructure from the following Dimensions.

1. **Interoperability:** Interconnectivity among systems is important and managing relationships with various healthcare providers in a seamless and efficient manner along with providing user-friendly processes and interfaces to perform administrative functions are key features that must be considered in the design of a PHR.
2. **Information management:** Question about how the data is to be stored, how often will it be backed up, and what storage medium is in place are key to successful information management.
3. **Record security:** A variety of options may be available such as password protection, biometrics, and encryption, but the challenge is to fit the best mechanism to the purpose and design of the PHRs.
4. **Audit capabilities:** With growing security and privacy concerns, measures must be in place to provide detailed audit of access to the records.

It is vital that any MPHRS is evaluated on the audit capabilities. Clear and comprehensive audit policies must be defined that describe the use of patient medical records within the system. The policies should not only aim to protect the confidentiality and integrity of data but also protect the patient. One of the important features of the new generation of PHR systems is their ability to interconnect electronically using predefined interfaces or XML based interfaces. All sub systems transferring data need to provide secure interconnection capabilities between the host systems and the PHR database. The data must be protected in terms of data integrity and patient privacy.

Security policies for personal health information must be carefully designed in order to limit the number of people, clinical physicians, insurance companies, nurses, and others, that can access the patient record, and to control the operations that may be applied to the record itself (Anderson 2006).

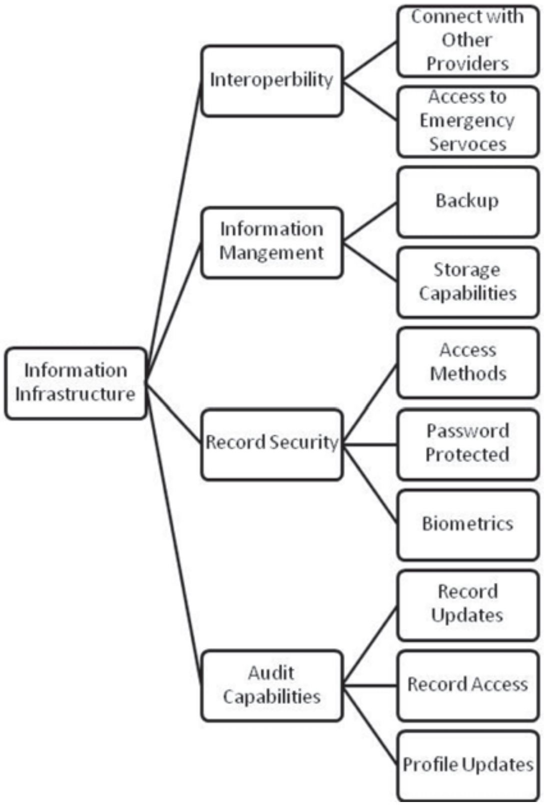
Jelena (2007) defines clear policies that are appropriate for wirless clinical information systems, these policies have been adapted to a PHR. These policies are discussed below as a number of security procedures:

- Each record must have an associated access control list - a list that restrict access to the records other than those individuals and groups identified on the access control list.
- There must be an individual on the access control list that must have administrator privileges and/or rights, i.e., the power to add other users to the access control list. It is critical that the administrator notifies the patient of any changes of names on the access control list to any part of the patient records.
- An audit log of usage activity must be presented to the user. Each time the record is accessed the following information must be presented - the name of the user performing the access, the date and time of access, and the manner of access (including records read, updated, stored, and/or deleted) - and has to be recorded.
- When the patient is incapacitated, the ownership of the records should belong with the legal guardian or another person with the appropriate power of attorney, not the person with the patients' mobile device.

WIRELESS NETWORK COMPONENTS

The adoption of mobile technologies in healthcare is on the increase and technologies such as Wireless Local Area Networks (WLAN) that use different protocols from the standard digital mobile technologies such as 2G, 2.5 and 3G technologies. A summary of these technologies are presented below along with the speeds and range covered.

Figure 8. Information infrastructure components



It is important to understand how the device will connect to the Internet to access private health information as some networks are more secure than others. The ease of access that wireless networks offer is matched by the security and privacy challenges presented by the networks.

One of the key concerns surrounding the implementation of Mobile PHRS is the issue of security. Moving a PHR into the mobile realm compounds these security fears. There are four types of security breaches that can occur.

1. **Data duplication:** PHRs raise the possibility of storing health data in multiple storage locations. For example in the EMR, Hospitals databases, and the PHR. In a mobile scenario this issue is compounded because the data may also exist on the mobile device.

2. **Data transmission issues:** Using open unsecured networks such as wireless local area networks (wifi) to transmit personal health information will leave users open to security vulnerabilities. The system must detect when using an unsecured network and prevent the release of information in that scenario.
3. **Lost devices:** If the device is lost, the data server must prevent that device from accessing medical information from that device. If the functionality is embedded within the SIM card the device must prevent the embedded functionality as well.
4. **Virus and malware:** There is a growing trend of Viruses being targeted at mobile devices due to the proliferation of mobile devices.

MOBILE PHR SYSTEMS REVIEW

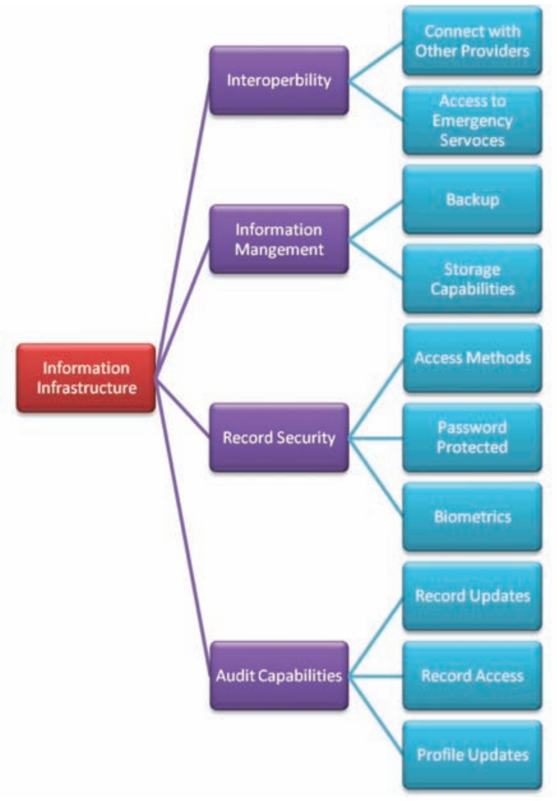
There are a variety of configurations that can be employed for a mobile PHR system. Each of the approaches provides a variety of benefits along with potential security vulnerabilities. The section will use the evaluation framework defined in the previous section to review three commercial PHR systems that support mobile phone access.

System 1: In Case of Emergency (ICE) PHR Mobile

This PHR product is a combination of CapMed products, icePHR and Microsoft HealthVault. The aim here is to make appropriate medical records freely available "In Case of Emergency (ICE)". The user has the capabilities to modify what pieces of their information will be accessible in an emergency situation by using a Web application. The full medical record resides within the HealthVault eco-system and is transferred into the icePHR. The icePHR emergency data are viewed by three methods.

1. displayed through a personalized icePHR Web site,
2. wallet-size emergency card,
3. Mobile client side wallet.

Figure 9. Wireless system components



The Wallet is the client-side portion of the application and resides on the mobile phone or personal computer. The personal health information located externally or privilege information is accessed right to the wallet. The mobile device would need to receive a software installation which can be delivered over-the-air. Vault Server: the Wallet communicates with the MobiSecure Vault Server for data synchronization and management. The role of Server-based software is to securely host, manage and retrieve personal user data from external data sources. The Personal Health record application must be hosted on the server side of the provider of the Vault Server software. The user

Table 1. Wireless networks

Networks	Speed	Range and Coverage	Main Issues for M-Health
2nd Generation GSM	9.6 kilobits per second (KBPS)	World wide coverage, dependent on network operators roaming agreements.	Bandwidth limitation, Interference.
High Speed Circuit Switched Data (HSCSD)	Between 28.8 KBPS and 57.6 KBPS.	Not global, only supported by service providers network.	Not widely available, scarcity of devices.
General Packet Radio Service (GPRS)	171.2 KBPS	Not global, only supported by service providers network.	Not widely available.
EDGE	384 KBPS	Not global, only supported by service providers network.	Not widely available, scarcity of devices
UMTS	144 KBPS - 2 MBPS depending on mobility	When fully implemented should offer interoperability between networks, global coverage.	Device battery life, operational costs.
Wireless Local Area	54 MBPS	30–50 m indoors and 100–500 m outdoors. Must be in the vicinity of hot spot.	Privacy, security.
Personal Area Networks – Bluetooth	400 KBPS symmetrically 150 -700 KBPS asymmetrically	10 – 100m	Privacy, security, low bandwidth.
Personal Area Networks – Zigbee	20 kb/s – 250 KBPS depending on band	30m	Security, privacy, low bandwidth.
WiMAX	Up to 70MBPS	Approx. 40m from base station.	Currently no devices and networks cards.
RFID	100 KBPS	1 m Non line-of-sight and contact less transfer of data between a tag and Reader.	Security, privacy.
Satellite Networks	400 to 512 KBPS new satellites have potential of 155MBPS.	Global coverage.	Data costs, shortage of devices with roaming capabilities. Bandwidth limitations.

has the capability to view, submit or send, via fax, email or SMS, the user's selected data.

IcePHR Mobile is a mobile device accessible software application that provides the capability to store and manage emergency medical information and contact numbers in a mobile phone. This product requires that the user subscribes to icePHR subscription. Mobile devices must meet the requirements of installing and running the custom icePHR Mobile application to allow the data to be stored on the phone negating the need for a data link connection. The application will allow subscribers the editing capability to insert, update and delete medical information directly on the icePHR server when Internet access is available.

The icePHR application is only supported on specified networks and on a number of certified handsets, which includes smartphone, blackberries and standard mobile phone handsets that run java Midlet.

The phones that do not incorporate the technology to install and run the icePHR Mobile™ application can use the WAP to view medical information stored on the server. To use WAP, the handset must have a built in Web browser such as Media Net. Unlike the Java icePHR Mobile application where medical data are stored on the device, using the WAP access method no information is stored on the device nor can the user edit the records over WAP.

Table 2. Evaluating three commercial MPHR Systems

Criteria	System 1	System 2	System 3
System Name	ICE PHR	No More Clipboard	allOne Mobile
System Description	software application that provides the capability to store and manage emergency medical information and contact numbers the a mobile phone.	Mobile Web based patient-controlled personal health record management system designed to consolidate medical information	All*One* Mobile cell phone-based application. to manage personal health information. Patient information
Network	2G or 3G Cellular requires data plan and SMS Plan	Access via mobile Internet browser using WiFi	Access via mobile Internet browser using WiFi
Device - OS	RIM 3.6, J2ME 1.1, Windows mobile for Pocket PC and Smart phone 2003+	Any device with Internet access	Blackberry RIM Java, Windows mobile for Pocket PC and Smart phone 2003+
Devise - Type	Mobile Phone (singular, sprint devices), Smartphone or PC	Any mobile device with Internet capabilities	Any mobile device with Internet capabilities
Information management	Application is downloaded and stored on the device	Application is run from the server. The user accesses the information via navigating to the home page on the mobile device	Application is downloaded and stored on the device
Data Storage	Stored on Device. (There is also an option to store data on server for non supported handsets	All the data is stored on the server	Data is stored on both the server and device
PHR Capabilities	Provided by ICEPHR and Microsoft Health Vault	Provided by Nomoreclipboard.com. Can integrate with Microsoft health vault	Integrates with online PHRs via community of Care (CCR) standards
Business Model	Add on to the ICE PHR subscription	Subscription only	Subscription only
Access technology	Uses WAP for non supported devices	Via mobile browser. Future enhancement will allow cellphone technology to access sever	Via mobile browser.

System 2: No More Clipboard M-PHR

NoMoreClipboard.com is an online, patient-controlled personal health record management system designed to consolidate medical information in one convenient and secure location for easy retrieval and updates. NoMoreClipboard.com provides Web-based solutions to maintain an online personal health record (PHR). The system also provides cell phone integration capabilities. Patients with Internet-enabled Smartphones such as the Palm Treo or Apple iPhone can interact with a PHR if they have an account with NoMoreClipboard. This approach requires the user to be connected to the Internet as no data is downloaded to the device. To gain access to the Web portal from a mobile device the users points their Smartphone browser to the PHR portal address and a version of the PHR application optimized for mobile devices is presented.

Future functionality will include the capability to send reminders, receive appointment alerts, medications reminders, or follow care plan directives. The Patients will also have the capability to capture pain levels or illness symptoms as they occur and insert this information directly into the PHR. Patients will also be able to capture and store images from their phone into their PHR. From a security perspective the site uses Secure Socket Layer (SSL) account security. Although the information is secured behind a firewall, accessing the information over non-secured network can lead to security vulnerabilities. An application under development that uses Binary Runtime Environment for Wireless (BREW) will allow patients with standard Code division multiple access (CDMA) based wireless devices to access their PHRs. A Short Messaging Service (SMS) interface is also being developed to enable communications between patients and the PHR system.

System 3: AllOne Mobile MPHR

All*One* Mobile cell phone-based application was created by the All*One* Health Group Inc. to manage personal health information. Patient information is stored behind a password-protected, encrypted channel using Diversinet wireless security application. All*One* Mobile uses mobile technology to facilitate the exchange of critical health information between individuals, providers, and health plans. This application downloads wirelessly a small application to the mobile device, which accesses the patients PHR stored securely on the Internet. The PHR system allows updates from the mobile device. The application supports all smartphones and the majority of non-business mobile consumer devices. The All*One* Mobile application supports the following features.

- Storage of confidential personal information, including provider and insurance information, allergies, immunizations, and medications
- Synchronize their mobile device with Web based PHR.
- Fax PHR information from a Mobile device
- Control access to receipt of relevant and timely communications on health care–related topics

All*One* Mobile integrates with existing health care information systems and applications, including existing online PHRs.

CONCLUSION

The goal of the MPHR system is to provide secure and controlled access to personal health informationat anytime via a mobile device to improve health outcomes. Mobile PHRs can provide patients with a variety of functions including: maintaining a real-time health diary, and tracking of vital health measures such as blood glucose levels, blood pressure, carbohydrate intake, height, weight.

This chapter presented a framework adapted from the HL7 PHR functional model and PHR literature.The purpose of the framework is to define the set of functions that may be present in Mobile PHR systems and to highlight important components that must be taken into consideration when evaluating Mobile PHR systems.

The growing number of large technology organizations entering the PHR landscape will eventually help the industry by driving standards forward, developing open interfaces and generating awareness of the products and implementing solutions that incorporate mobility on the one hand, and satisfying standards requirements and regulatory policies such as HIPAA privacy and security rulings on the other hand.

The key challenge that is likely to evolve from the influx of non healthcare organization delivering PHR systems runs parallel with Electronic Medical Records (EMR) and EHRs prior to HIPPA rules and regulations, enacted by the USA congress in 1996. These problems included the denial of health care coverage to individuals with chronic and genetic predispositions to diseases and the release of personal health information. Ultimately consumers must exercise extreme caution when utilizing and implementing a mobile or Web based PHR.

Chapter 3.4

Adoption of Mobile Technology by Public Healthcare Doctors:

A Developing Country Perspective

Nesaar Banderker
University of Cape Town, South Africa

Jean-Paul Van Belle
University of Cape Town, South Africa

ABSTRACT

South African doctors working in the public healthcare sector are faced with the unique resource constraints prevalent in a developing country. Mobile information and communication technologies (ICTs) hold the promise of improving the quality of healthcare, but this potential can only be unlocked if individuals decide to adopt the new technologies. Understanding the factors that influence the doctor's adoption of a technology is therefore vital. This article reports on an investigation into the factors influencing the adoption of mobile devices by doctors in the public healthcare sector in the Western Cape, South Africa. The research methodology was shaped by qualitative enquiry and described through thematic analysis. The authors confirmed the key adoption factors identified in prior research: job relevance, usefulness, perceived user resources and device characteristics. However, some additional adoption factors were uncovered in this research, namely patient influence, support structures from national government and hospital administration, and unease in respect of malpractice legal suits.

BACKGROUND

Healthcare in South Africa

Healthcare is a key component of South African society, socially and economically (Chiasson et al., 2004). Total healthcare spending in South Africa is 8.7% of GDP which is substantially above the norm of 5% recommended for developing countries by the WHO (Chetty, 2007). The *public* healthcare budget alone totalled R47.8 billion (approximately US$ 6.7 billion) in 2006, representing 4.27% of GDP. This represents a substantial growth compared with 1995 when it stood at only 1.84% of GDP. However, despite these efforts by the new democratically elected government, huge inequalities remain. The budget of the private sector, which services less than 8 million people, exceeds that of the public sector servicing 38 million (Chetty, 2007). Much of this remains a legacy of the pre-1994 apartheid era inequalities institutionalised through labour laws and highly unequal provision of services for different racial groups (Department of Health, 2004). There is still a movement of skilled resources from areas of poverty and low socio-economic development to more wealthy areas. Doctors who have recently qualified and completed their compulsory two years working for the public healthcare sector are either moving into private practice or leaving South Africa to work in other countries (Padarath et al., 2003). This results in a scarcity of skilled clinical resources in the public healthcare sector.

Although doctors working in the public healthcare sector are highly skilled, their available time is preciously sliced to try and diagnose and care for as many patients in a day as is possible. 80 to 85% of the South African population has access to public healthcare facilities only (Chetty, 2007). A doctor in the public day hospital environment is expected to diagnose, treat and manage about 40 patients during an 8–hour shift. This means that the doctor spends an average of only 12 minutes with each patient. Doctors in public healthcare also have to work extremely long shifts of sometimes more than 30 hours. Due to this extreme pressure, doctors can easily make an incorrect diagnosis or prescribe the incorrect patient management routine. Patients attending these public hospitals have to wait in long queues to be seen by the doctor. When they finally see the doctor, the visit is rushed. A full examination of the patient is not always possible and this could result in inadequate care of the patient.

ICTs offer tremendous potential in supporting the public healthcare function in the South African society. Although administrative healthcare information systems have been implemented, the shift to systems that support the clinical work performed by healthcare professionals directly has been slow to take off (Andersen, 1997). Better ICT support would, in turn, enable doctors to facilitate the provision of high quality, better informed and cost-effective public healthcare to all the citizens of South Africa.

Mobile Technologies in Healthcare

Mobile technologies can bring immense benefits to the healthcare environment (Varshney, 2006), because it is so information intensive (Li, Chang, Hung & Fu 2005). Doctors do most of their work at the point of care, which is the patient. This means that they move around between wards, outpatient clinics, diagnostic and therapeutic departments and operating theatres. This movement, together with the fact that most South African public hospitals usually only have one central computer terminal per ward, makes it extremely difficult to service all the needs of the doctor. The use of ICTs in support of this point of care activity of the doctor is what is relevant to this research. Mobile device technologies are quite suitable for supporting the doctor at the point of care. They are small, lightweight, can be carried around with the doctor and usually come with some form of networking protocol built into the device (Porn & Patrick, 2002). Mobile devices are also becoming more affordable and offer more processing power and storage capabilities (Varshney, 2006). Mobile technology ranges from cellular telephones, pagers and PDAs, to very sophisticated tablet computers. Key benefits, as summarized from a large number of studies, include a reduction in medical errors, time savings, better quality care and higher productivity (Lu, Xiao, Sears & Jacko, 2005).

A number of studies have looked at adoption of mobile computing devices. An excellent, systematic analysis of surveys of healthcare providers' PDA adoption is given by Garritty & Emam (2006) who found adoption rates in developed countries to vary between 45% and 85%. For instance, in a longitudinal study of mobile technology 33% of Canadian doctors reported use of a mobile device in their clinical practice in 2003, up from 19% in 2001 and 28% 2002 (Martin, 2003). By contrast, a similar study at selected healthcare institutions in Florida revealed that as many as 95% of the respondents to the survey owned a mobile computing device (Joy & Benrubi, 2004). The study also showed a pattern of perceived benefit for using the devices to maintain procedural statistic logs, pharmacology reference manuals and personal clinical protocols; but respondents did not perceive a massive time saving. Both studies also show quite a sharp increase in mobile device technology adoption by doctors.

Porn and Patrick (2002) and Hameed (2003) identify a number of healthcare applications that could be run successfully on a mobile device:

E-Prescription

This allows doctors to access basic patient information and check formulary compliance before writing the prescription. Potentially harmful drug interactions can be determined and often a patient's personal medication history is available. Prescriptions can be printed or transmitted directly to a pharmacy. The main benefits are a reduction in medication errors and less calls from pharmacies due to illegible handwriting (Berkowitz, 2002).

Charge Capture

This application allows a doctor to view schedules, capture patient charges and access or update patient information all at the point of care.

Order Entry

Applications to order certain tests could be scheduled, delivered to a central processing unit and acted upon. This will reduce errors due to misplacement of application forms.

Test Result Reporting

The results of the tests can be delivered directly to the mobile device. This will free doctors from having to refer to a specific PC workstation to retrieve test results.

Medical Information

Access to the latest medication formulary, disease description, symptoms and treatment as well as access to clinical procedures can be provided on a mobile device.

More technical descriptions of how mobile technologies can work in healthcare sector can be found in numerous sources, e.g. (Varshney, 2006)

Adoption Models and Healthcare

In order to realise the full potential and promise of healthcare information systems, technologies and applications, a better understanding of the organisational context as well as people and social issues is required. The adoption of mobile technologies in the healthcare sector involves both an organisational and an individual aspect. The organisational context or motivational factors that drive mobile ICT adoption is a relatively under-researched field; refer to Khoumbati & Themistocleous (2006) for an overview of relevant research and a comprehensive framework. The focus in this research is on the *individual factors* that drive mobile technology adoption in healthcare, with particularly focus on the doctors.

Because explaining human behaviour in all its complexity is quite a daunting task, a variety of models have been developed to explain and predict user behaviours and intentions. The most widely used of these models are the diffusion of innovation (DOI) theory published by Rogers (1995), the theory of reasoned action (TRA) (Ajzen & Fishbein, 1980), the theory of planned behaviour (TPB) (Ajzen, 1991) and the technology acceptance model (TAM) (Davis, 1989). These models have been well tested, validated and proven to be reliable when used in the evaluation of user acceptance in studies of business organisations, corporations and even students. However, there is less research evaluating technology adoption using TPB, TRA, DOI within a healthcare context.

In validating TAM and its extensions, researchers have determined some key factors that are of significance for use in general technology adoption models. These include perceived ease of use, perceived usefulness, perceived user resources, voluntariness, experience, subjective norm, image and computer self-efficacy. However, doctors are professionals who are particularly highly skilled, knowledgeable, autonomous and pragmatic decision makers. This impacts on the applicability of a number of constructs and causes some of the models not to behave in the way determined by prior research in other contexts. For instance, Hu & Chau & Tam (1999) found that the original TAM did not correlate well with doctor's intentions to use a new technology. When reviewing literature on the adoption of healthcare technologies by medical professionals the majority of the studies found apply to general healthcare systems such as telemedicine, internet health and clinical systems (Chau & Hu 2002, Chismar & Patton, 2003, Horan et al., 2004) while some studies were found that applied specifically to mobile healthcare (Wu, Wang, & Lin, 2005, Harkke, 2005; Li et al., 2005; Lu et al., 2005; Varshney, 2006; Wu, Wang & Lin, 2007).

Overall, however, researchers find the TAM-inspired models to be a successful approach to explaining the adoption of mobile technologies in the healthcare sector, with Wu et al., (2007) purporting to be able to explain up to 70% of the variance in behavioural intention to use mobile healthcare systems. These studies found the following factors to be of relevance when researching adoption in a healthcare setting:

- **Perceived usefulness/Job relevance:** A new technology needs to be useful to its user. Usefulness is defined as causing an increase in the doctor's productivity by being relevant to the doctor.
- **Perceived user resources:** The extent to which an individual believes that they have the personal and organisational support to use the device. This was validated by Horan et al. (2004) and Lu et al. (2005) whose research discovered that workplace compatibility played a more important role in predicting user intentions than the current TAM construct of perceived ease of use.
- **Subjective norm:** People who are close to the doctor could influence the doctor by their opinions of whether the device should be used or not.
- **Image:** Doctors will perceive the use of a mobile technology device as enhancing their status within their working environment. This was validated by Succi and Walter (1999) who state that doctors will more likely be influenced by the impact of the use of the new technology on their professional status. Further research has contested the idea that social processes of subjective norm and image would influence the decision to adopt. This is seen to be a result of the pragmatic nature of doctors in decision making, as well as a reliance on their own assessment rather than that of others. However, in the context of South Africa where being a medical doctor is often seen as a status symbol the two factors of subjective norm and image will

be retained to ascertain whether they would play a positively influencing role.

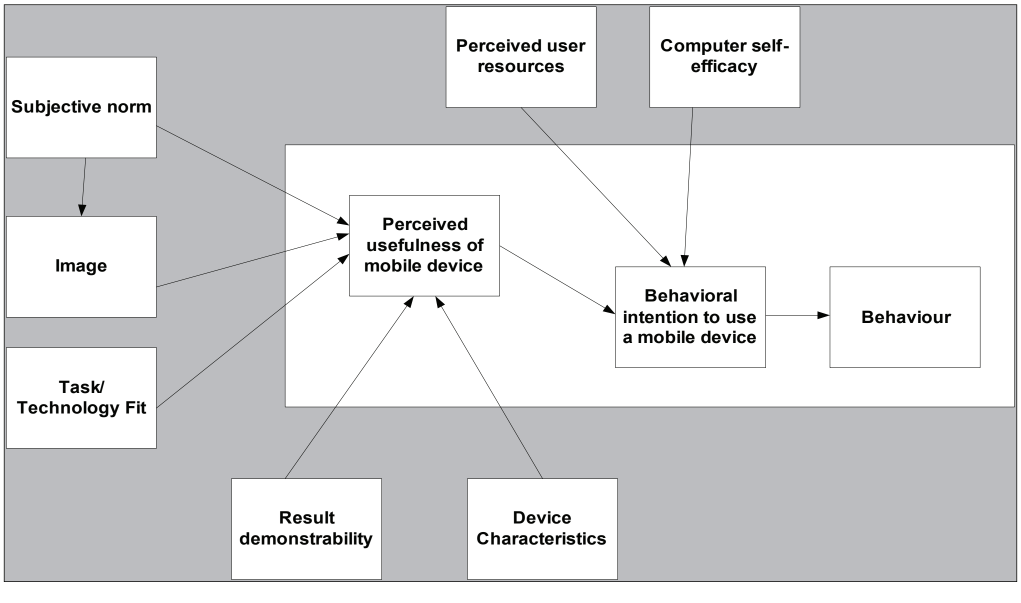
- **Task/technology fit:** A study by Chau & Hu (2002), added this factor – defined as alignment with current work practices – to TAM. It was thought that doctors would more likely adopt a new technology if it aligned closely with their current work practices.
- **Result demonstrability:** The technology should visibly improve the doctor's quality of care provided and enhance his effectiveness thus improving the quality of the doctor's work

Furthermore, in the evaluation of TAM2 (Venkatesh & Davis, 2000) by Chismar and Patton (2003), it was found that the construct of perceived ease of use showed an insignificant effect when used to predict intention of doctors. It has also been found that for technologies that are not mandated for use by the healthcare institutions, the construct of voluntariness can be removed from the model. In studies of a new technology the construct of experience can also be removed, since it was intended to measure the adoption of existing technologies. Due to the high intellectual and cognitive capacity of doctors, they appear to understand new technologies quicker. Doctors are therefore individuals with a high level of self-efficacy. This makes a good argument for the removal of the computer self-efficacy construct from the model. However, due to mobile technologies being relatively new to the South African market and not being widely diffused this factor will be included in the model developed.

The above research reduces the significant factors in the context of doctors' intention to use a mobile technology device to subjective norm, image, task/technology fit, result demonstrability, perceived user resources, computer self-efficacy and the technology device characteristics. These factors are summarized graphically in Figure 1.

The factors listed above formed the starting point for the research interviews.

Figure 1. Significant influencing factors



RESEARCH OBJECTIVE

Despite the purported advantages of mobile technology there is a distinct lack of adoption of this technology in the public healthcare sector in developing countries in general, and South Africa in particular. The public healthcare sector is recognized as having lagged behind other South African industries, such as the financial sector, in the use and adoption of new information technologies (Bower, 2005). ICTs encompass a wide range of technologies.

This research hopes to provide a better view as to *what* the significant factors influencing the adoption of innovative mobile technology solutions by public healthcare doctors to support them in their daily clinical activity are. More specifically, the objective of this research is to identify key factors that hinder or assist doctors' adoption of mobile technologies in healthcare.

Identifying these significant factors of influence will hopefully also provide an *insight* into how ICT solutions for healthcare should be developed, marketed, implemented and who the key stakeholders in the adoption process are. This research is particularly relevant because it cannot be assumed that research conducted in developed world contexts is applicable to developing countries.

RESEARCH METHODOLOGY

The factors identified in the literature (see figure 1) forms the basis for the framework that could be tested against public healthcare doctors. This section addresses the problems of *who* to test the framework against and *how* it will be tested.

Strategy

This research follows an exploratory qualitative research design strategy. It is exploratory since it is not directly involved with hypothesis testing and theory evaluation. It is more directly involved with laying a basic descriptive foundation to explain and understand the possible factors influencing adoption of a mobile technology device by doctors. A qualitative study was chosen over a quantitative one since the former allows for a better understanding of the people, and the social and cultural context in which the technology adoption can occur. Also, richer data sets from which factors influencing the possible adoption of mobile technologies can be obtained by discourse between people instead of having them complete a questionnaire. We believe that our specific qualitative approach complements the quantitative approach adopted by (Wu et al., 2007) who summarized a large number of quantitative adoption studies, and the evidence/opinion-based qualitative approach of (Lu et al., 2005) into adoption factors.

Site Selection and Sampling

The study was conducted in the two largest public healthcare facilities in Cape Town, namely the Groote Schuur Hospital (widely known because of the first heart transplant) and Tygerberg Hospital. These hospital are directly associated with the University of Cape Town and the University of Stellenbosch respectively. They are of similar size, offer very similar services, have similar administrative processes and are analogous to the rest of South Africa's academic public hospitals.

Due to time, resource and financial constraints as well as the limited time availability of doctors, a convenience sampling method was used. Possible doctors were identified by two doctors acting as the researcher's contacts in the hospitals and were selected based on their willingness to take part in the research since all participation was voluntary. Although a convenience sample allowed the researcher to skirt many of the resource issues mentioned, this did come at the expense of possibly compromising the generalisability and representativeness (Pare, 2004). In total, twelve doctors were interviewed. The interview sample was made up of doctors from each of the South African racial profiles.

Data Collection

Participant interviews were used as the primary source of gathering data. The interviews were semi-structured, with set questions as well as open-ended questions. Basic demographic data was also collected from the doctors. Key questions were developed around all the significant factors of influence identified during the literature review (Figure 1 above) with additional questions being derived from Chismar and Patton (2003). Questions were not necessarily asked in the order they were set out since the conversation dictated which question would be asked next. The complete list of the questions is available from the authors. A checklist was kept during the interview to ensure that all questions were asked. Interaction and discussion usually led to further follow-up questions of both explanatory and exploratory nature (Ritchie & Lewis, 2003).

The interview was recorded on an audio recording device, freeing up the interviewer to more closely observe the interviewee and possibly gain some further insight from the visual clues provided by the interviewee. A protocol for conducting the interview was established. This ensured that each interview process was consistent. It also helped ensure that standard items like obtaining consent, providing the interviewee with basic information about the research and informing them that the interview would be recorded, would not be forgotten.

As a departure point for starting the discussion, pictures of other mobile technology devices were shown to the interviewees. In addition, the interviewees were also shown a physical Nokia 9300 with a demonstration of some of the medical software obtained for the device, namely a drug formulary program, a fracture analysis program and a nutrition analysis program.

Data Analysis

There are many methods of analysis suggested for the interpretation of the data collected. These include Hermeneutics (Klein & Myers, 1999), Grounded Theory (Sarker & Wells, 2003), Semiotics – which includes content analysis, conversation analysis and discourse analysis – and thematic analysis (Ritchie & Lewis, 2003). However, these modes of analysis work to develop theory in most cases and fit closely with the interpretive paradigm (Fitzgerald & Howcroft, 1998). A thematic analysis of the textual data was performed, as recommended by Ritchie and Lewis (2003).

The analysis process that was followed can be described as follows:

- The recorded data from the interviews was listened to. While listening to the recording, reflective remarks about the interview and the data from the interview were made. This allowed for the visualization of the researcher's perceptions and ideas (Miles & Huberman, 1994).
- A coding scheme that is consistent with the theoretical propositions identified during the literature review was then developed (Hammersley & Atkinson, 1983). Additional codes were created for ideas presented by the interviewee that did not fit into the original coding scheme.
- The coding scheme was used to allow the segmentation of the data into units that are easily mapped to the theoretical propositions identified during the literature review. The scheme also allows for easier organization and retrieval of the data.
- These codes were then grouped together in logical units which formed higher order categories.
- For these categories a response from each interviewee was mapped. This formed the basis of a thematic chart. The visual nature of a thematic chart helped in discovering

connections between coded segments (Miles & Huberman, 1994).
- From this thematic chart, themes were developed by checking the occurrence of a certain idea and the language used by the interviewee.
- These themes were then used to answer the objectives of the study.

An important consideration in qualitative research is the reliability of the findings. Although a "mere count" of quotations or mentions is not necessarily an appropriate measure, a strong and consistent pattern across respondents does contribute towards a stronger confidence in the results. It was found that there was indeed a surprising degree of agreement between the various respondents and thus the table with the occurrence frequencies for the various factors has been included (Table 2 in the Appendix).

FINDINGS AND DISCUSSION

The results obtained by the analysis of the interview data as well as a discussion of these results are presented together in order to maintain a logical flow of information. Since the data analysis was done using a thematic analysis, the findings will be presented in the themes identified. These themes can also be referred to as the adoption factors identified.

Postulated Themes

Perceived Usefulness of a Mobile Device

The doctors agreed unanimously that the mobile technology device would be very useful and relevant to them. Two of the older doctors, however, could only conceptualise the device being useful by providing information to them. Even so, the information that they thought the device would be able to provide was of enough importance to warrant them stating that it would help in providing better medical care to their patients. "*I know I would be able to obtain electronic versions of certain reference manuals for such a device and I could use this as a source of information."*

This use as an information providing tool was confirmed when a doctor emphatically stated that he *"currently carr[ies] 2 to 3 management reference books around with me. I know that there is an electronic version of all 3 books available for the iPaq."*

The younger doctors could conceptualise many other exciting uses for the device. A few of the solutions that really excited the doctors are:

- Making paper records of patients obsolete: *Such a device could make the need for paper records obsolete. All patient information could be stored electronically and accessed from this device and not from the only PC assigned to an entire ward. This will make missing folders and folders not containing up-to-date patient information a thing of the past.*
- Not having to struggle with reading illegible notes and other information: *Doctors handwriting is generally quite poor and illegible. This device could make incorrect prescriptions due to bad writing a thing of the past.*
- Mobility: *Patient information could be delivered to such a device when you walk into the ward. This would alleviate the need to consult the slow, outdated PC assigned to the floor.*
- As a decision support tool: *I will have the latest available patient management information and with this can ensure that the patient is treated correctly.*

However the doctors did strongly indicate that the device would never be able to replace their skill and training and actually make the decision for them.

Most of the imagined uses envisaged by the doctors are a reality in more developed countries. Examples of mobile electronic patient record systems exist (Turisco & Case, 2001). E-prescriptions systems which make the "illegible" handwriting problem of doctors obsolete also exist (Berkowitz 2002). The transmission of real-time patient information using mobile devices and telecommunication infrastructure has been implemented in Sweden and the Netherlands (Wu, Wang, & Lin, 2005). There are also examples of medical reference material on mobile devices being useful in certain situations (Harkke, 2005).

Social Influences

A strong statement *against* the effect of social influences guiding a doctor's decision to use a mobile technology device was made. One of the older doctors hesitated when answering the questions regarding status. When clarifying her hesitation she stated: "*Indian doctors, especially the older ones, were usually recommended by their parents to become a doctor.*" This was usually for the prestige that came with being able to say that one's child is a doctor as well as the desire to have their children "be better off than the parents". This image of the medical profession being one of status was hard to totally avoid for an Indian doctor. The remainder of the doctors did not agree with the statement that status, image or peer influence will have some bearing on their decision to use the device. "*I would not at all be influenced to use this device by my peers nor would I think of it as increasing my status.*"

There was one softly conflicting statement of "*...as more doctors start using these devices you will become the odd one out for not using one…*" but when explored further it developed into the fact that doctors would only use the device when found to be useful and relevant to their daily clinical activity: "*If I see a colleague using such a device and he is able to provide better care to his patients I would most definitely be influenced to get one.*"

Perceived User Resources

When asking the interviewees questions around perceived user resources, they were quite emphatic that they did not believe they would obtain support for the use of a mobile technology device from within the public healthcare environment. There was a feeling of hopelessness when talking about the public hospitals IT support structures. One aspect of the lack of support related to the level of skills: "*I believe that the hospital IT department is not highly skilled and would take some time to adjust to support a more innovative device like this Nokia 9300.*" It was also felt that the hospital IT department was under-resourced and would not be able to cope with the added support required for the mobile technology device:

They barely cope with just running the daily activities of the hospital. How will they cope with the added support required for this device?

Even though doctors felt that public hospitals did not have the resources to support the use of such a device, they would not be negatively influenced by this:

The hospital might not support the device but that still will not stop me from using it.

The doctors also felt they had the necessary personal resources and skill to use the device.

The University [...] needed an online MMed program for family medicine. The university provided a very basic infrastructure to do this and the doctors lecturing in the department did all of the rest to provide this online program."

Computer Self-Efficacy

All the doctors interviewed considered themselves to be highly skilled professionals who had daily interaction with computers. "*I have an interaction with computers throughout my working day.*" The fact that 10 of the 12 doctors did not have much prior experience with mobile technology devices did not scare them away from using the device: "*As a highly skilled professional I think I am capable of learning to use a new technology from a user manual.*"

Device Characteristics

Ten doctors expressed an initial concern that the limited screen size of the handheld devices might make it less useful: "*Perhaps the screen on this device would not be able display information very legibly*" and "*I don't think a web page will display very nice on such a small screen*". However, some were quite surprised at the amount of information displayed with the drug formulary program on the Nokia 9300: "*That displays information in a very comprehensive manner and with one click of page down you can see the rest of the information.*"

There was a surprising request that the device be able to withstand small liquid chemical spills from the pathology doctors. This was due to the fact that they work with chemicals for most of their day and would probably leave the device lying around near chemicals. *"Would the device be able to withstand a chemical spill?"* The fact that it could not withstand substantial liquid spills and therefore liquid chemical spills even less did not detract from their eagerness to use the device. *"Ok, so it can't. I don't think that this will stop me using it"*

Both loss and theft of the device was also a major consideration for the doctors. "*I think such a device would easily be able to get feet.*" However, the two doctors who were high adopters of a mobile technology device said that doctors would have to learn to take care of the device in a similar manner in which they care for their stethoscopes.

The software demonstrated to the doctors was accepted with great enthusiasm. "*That could most definitely help me as a look up when I don't know what the drug does*" and "*You could look up side effects to make certain there will be no complications for the patient.*" The doctors were enthusiastic that the technology would be able to help them deliver better quality care. This is supported by the uses they conceptualised for the device. One of the doctors working in an emergency trauma unit, where rapid diagnosis and accurate patient management are essential, was sure that a mobile device could further ensure that patient management was in line with the diagnosis as well as being the most effective one and aiding in the fight for the patient's life.

Emerging Themes

A number of additional themes were identified during the analysis of the interview data. They do not form part of the original significant factors of influence identified during the literature review and appear to be specific to the healthcare environment.

Patient Influence

An addition to the social influences theme that was not part of the original significant factors was the patients' perceptions of the doctor if they should see the doctor using a mobile technology device. When talking about a patient's perception of the doctor if the patient should see the doctor using a mobile technology device to reference information from, there was a majority consensus that the patient's perception would *not* negatively influence their decision to use the device. This was conveyed strongly through statements like: "*It will help me improve the care and management provided to the patient and result in a much* *improved patient outcome*"; "*I will not mind at all to use the device to look up information in front of a patient*" or "*Patients should understand or be educated that having the latest information available as a reference tool will be of great benefit to them at the end of the day*".

However, two doctors did say that they would be hesitant to use the device while sitting with the patient: "*The patients might question my competence if they see me looking up information in front of them with this device. The same goes for looking up information from a book.*" However, that would not stop them from using the mobile device to look up information, just that they would not do it while the patient was sitting with them. "*I would most definitely use it when not in front of a patient*" or "*If I needed to look up information then and there I would go to another room and then come back.*"

By contrast, it was also mentioned by one of them that patients are starting to move away from the idea that a doctor should know everything. They are generally starting to ask more questions about the conditions they are diagnosed with. He did say that a mobile device might be useful in explaining conditions graphically to patients, as they would more readily be able to understand a picture than a wordy explanation. "*When patients ask questions about their medical condition, we could perhaps provide a clearer explanation to patients using such a device to display information graphically.*"

Malpractice Legal Suit

Another social influence factor was identified by the pattern of doctors wanting to use the mobile technology device as an information and decision support tool, reflecting the growing unease amongst the doctors of the increasing trend of malpractice legal suits being brought against doctors. This device could help doctors prevent such a situation from arising: "*This will help in action that could be taken against the doctor for incorrect treatment and management.*" If such a device could keep a history of the patient and all decisions made regarding diagnosis and treatment, it could help defend the doctor's decisions: "*An audit of patient information and history, patient management and drugs prescribed could be kept.*"

This unease of legal action being brought against the doctor was also discovered during the discussion on patient influence. So long as the patient knew that the device was being used to make 100% certain that the correct diagnosis and management of the patient takes place, doctors would use the device in front of a patient.

Management and Government Support

Even though these two factors of hospital administration and government help could form part of perceived user resources on a micro-scale it is the macro-scale that was being referred to by the doctors. They were referring to national government and healthcare management and the fact that healthcare could not escape the political reality it found itself in. This is why these two factors are regarded as separate from the de facto definition of perceived user resources.

Support from the managerial structures of the hospital evoked responses tainted with a lot of emotion: "*The people in hospital management have completely forgotten what it is like to be a doctor. They seem to be fighting for some of the wrong things.*" There was a unanimous agreement between all doctors interviewed that absolutely no support would be garnered from the management of public hospitals for the purchase of mobile technology devices: "*Even if we proved to them how useful such a device would be and how it would increase my productivity and improve patient outcomes, I really don't think they would spend money on it.*"

However, this stance is understandable in the context of South Africa as a developing country with more than 70% of working age adults being unemployed, 53% of the population living below the poverty line and 20% of the population being HIV positive (Department of Health, 2004). There are too many needs for the already thinly sliced portion of resources cake provided to the public healthcare sector by the South African government with problems of HIV, TB and inadequate resources deemed to receive more share of the healthcare budget: "*In a developing country like ours we have too many other health concerns to warrant healthcare budgetary expense on such a device*"; "*TB, HIV, infant mortality and cost of health services to the general public all take priority on already scarce financial resources*" and "*Our hospitals are overcrowded and you cannot spend money on a nice-to-have while you do not have beds for patients or doctors to service the patients.*"

When asked whether an external party would not be able to perhaps put some pressure on the hospital management to incorporate a mobile technology device into use in the public hospitals, there was mostly exasperation in the voices of the interviewees. It was said that no such external party exists. Not even the provincial or local government would be able to do this. They set out the budgets for each hospital and stipulate at a very high level what the money should be spent on:*"Government allocates the hospital budget for the year and they stipulate at a very high level where the money should be spent."*

Even then, these stipulations are guidelines and it is up to the hospital management to decide how this money is spent: *"It is up to the hospital management using the government guidelines to spend the money allocated to the hospital"* and *"They would not be able to say exactly on what the money should be spent. They will say that so and so an amount is allocated to information technology. It is up to the hospital management to decide what specific IT to spend the money on."*

This relative freedom to spend the money allocated results in a lot of political battles within the hospital management. This means that sometimes scarce resources are not properly allocated by the hospital management: *"They seem to be fighting for the wrong things"* or *"The management cannot collectively decide what the money should be spent on. This results in this one wanting this and that one wanting that."*

This results in poor administration of the hospital, as well as poor outdated equipment being used. This also results in poor working conditions for doctors, of which the patient has ultimately to bear the consequences.

These findings show that there is a clear statement being made by the doctors that no support would be given to them by the hospitals in the use of a mobile technology device. However, this lack of support for the adoption of a mobile technology device by the environment doctors find themselves in will not detract from there willingness to use the device. In fact 10 of the 12 said that they would purchase the device from their private funds as they could see many potential uses for the device: "*So long as it does not cost too much and the benefit it will add is quite visible, I will not mind paying for it*"; "*I don't think I would mind paying for such a device out of my own pocket if one can be found for about R3500*" (≈ US$500).

It was mentioned that if the use of the device was privately funded, hospital management would grab the opportunity to use the device in the hospital. "*If a company like HP came and privately funded such a device they would jump at the opportunity.*"

Patient-Doctor Relationship

Two of the doctors mentioned that they rarely worked directly with patients: *"I don't work directly with patients. I perform tests on blood samples from the patient."*

These doctors did therefore mention that they would not be influenced negatively in the use of a mobile technology device by patients' perception of them. They were also less worried about malpractice legal suits than their colleagues who worked directly with patients: *"Because I don't work with patients, I would be less worried about these legal suits. I would still worry but far less than my other colleagues."*

Another factor that distinguished these doctors from the ones that worked directly with patients was their perception of what the mobile device could offer them. They were less interested in using the device as an information or decision support tool and more interested in having the device act as a workstation for them. They wanted the device to be integrated into the hospital systems they used so that they were not tied down to a desk: *"If we could have the test results delivered directly to this device so I can report on it, it would help me greatly and I would not be tied down to my desk or my outdated computer."*

They did not however fully understand the intricacies of integrating such a device directly into the hospital systems even though they showed some understanding of security concerns that might be raised by this integration: *"I know that with such a device it will have to be very secure since we are dealing with confidential patient information."*

They did however understand that having the device fully integrated into all the hospital systems would be beneficial to them and make them more productive: *"They upgraded our result reporting application this year but to me it is more of a downgrade. This new application is not integrated into anything else. You cannot even export data to Excel and this makes life exceptionally difficult for us."*

SUMMARY AND CONCLUSION

The data analysis revealed that the factors of job relevance, usefulness, task/technology fit, result demonstrability, computer self-efficacy and device characteristics were in agreement with the findings of previous research on ICT adoption in healthcare. The more technically competent doctors are, the more likely their intention to use a mobile technology device. Where doctors found the device relevant and useful to their daily clinical activities, they would use the device. The better the device and its software could support them, the greater would be their intention to use such a device. Table 1 lists the adoption factors identified as significant during this research.

Could these factors form part of a generalised technology acceptance model for innovative technology in the South African public healthcare sector, along the same lines as (Wu, Wang & Lin, 2007)? We suggest that the hospitals from which participants were obtained are comparable to the rest of the South African public hospitals: doctors working in these hospitals face similar working conditions, challenges, administrative tasks and resource shortages. Their opinions could therefore be seen to be fairly representative for the South African public healthcare sector. This would mean that the factors identified could form a revised TAM for South African public hospitals; this could be researched using quantitative means.

In conclusion, the research shows that South African public healthcare doctors are eagerly looking for ways to support themselves in their daily clinical activities. They can conceptualise many uses for a mobile technology device, many of which are already a practical reality in countries like the USA, UK and many countries in Europe. Using the device as an information and decision support tool can be made a reality for public healthcare doctors in South Africa. This will not only provide much needed support to overworked doctors, it will also help improve healthcare outcomes for the majority of the South African public. The key stakeholders involved in the public healthcare function, the government, healthcare management and ICT industry, can help push the adoption of these devices. The ICT industry could get involved by developing strategic partnerships with the public healthcare sector. These partnerships can be used firstly for the showcasing the

Table 1. Adoption factors identified by the research

Factors	**Supports the literature?**	**Comments**
Perceived usefulness of a mobile device	Yes	In general a very positive perception of mobile technology devices by doctors was evident even though half of them had never come into contact with one before. They perceived the device being able to provide them with relevant information either via the internet or software for the device. They perceived the device as a reference tool, patient information tool and even contemplated its use as a decision support tool that could help in diagnosis and medication prescription.
Social influences	**No**	Doctors in public healthcare in the Western Cape display a professional maturity that does not allow factors like image or subjective norm to influence them.
Perceived user resources	**No**	Lack of resources to support their use of these devices by the hospitals did not negatively influence their intention to adopt. This could be attributed to the social circumstances South African doctors find themselves in, where they have learnt to cope with limited resources on a daily basis. Despite their extremely pressurised work environments, and poor hospital management and administration, patient care is uppermost in their minds.
Computer self-efficacy	Yes	Concurred with previous research (Chismar & Patton 2003), that due to the high self-efficacy beliefs of doctors this factor can be ignored even when researching an innovative technology in a South African context.
Device characteristics	Yes	Doctors would be negatively influenced by characteristics they regarded as being important for them.
Task/technology fit	Yes	The medical profession is a very information intensive one (Harkke 2005) and doctors realised that this device would be able to help keep abreast of the latest information.
Result demonstrability	Yes	Doctors believed that the technology would be able to help them deliver better quality care to their patients.
Patient influence	New	Doctors did not feel intimidated by possible patient perceptions on their doctor's use of the device. Most doctors did however expect that the patient perception would be positive anyway.
Fear of legal action	New	Underlying doctors' perceptions of the device as an information tool was an unease in respect of malpractice legal suits. It was thought that the technology could aid the decisions made. This could help reduce the possibility of incorrect diagnosis and treatment and perhaps legal action against the doctor.
Management and government support	New	Negative sentiments were expressed about the lack of national healthcare structures and government support for the use of such a device. Nevertheless this did not appear to influence their personal intention to adopt mobile technology. It was however felt that these structures should be providing more impetus for the use of these devices.
Doctor-patient relationship	New	Where doctors do not interact with patients, a number of the above factors are not applicable. Thus this can be seen as a moderating variable or factor on the other factors, especially patient influence and fear of legal action.

potential of mobile devices to the public healthcare sector. Once an interest is shown the partnerships can be used for the development of standards, infrastructure and solutions. Government can involve themselves through e-government initiatives and push the concept of mobile technology and healthcare. Hospital management can become involved by starting to support initiatives to help doctors provide better quality care to patients by using these devices as they have envisaged in this research, as a reference-, decision support- and record keeping tool.

The interpretation of the research results should take into account a number of limitations. Firstly, the sample was quite small and, to an extent, self-selected. Also, other stakeholders, especially hospital management and patients, were not interviewed. Finally, the perceptions of mobile technology are influenced by potential and actual use thus many responses could have been based on incorrect or incomplete conceptualisations of potential mobile technology application(s).

ACKNOWLEDGMENT

This article is a revised and updated version of a paper initially presented at the European Conference on Information Systems and later expanded into a chapter in the Handbook of Research on Advances in Health Informatics and Electronic Healthcare Applications. The feedback of the anonymous reviewers is hereby gratefully acknowledged.

APPENDIX: OVERVIEW OF RELATIVE SUPPORT FOR VARIOUS FACTORS

The following table summarizes the relative support for positively influencing factors (✓ = support, ✓✓ = strong support) or inhibiting factors (×). Blank cells indicate a lack of influence under current conditions.

Table 2. Consistency of support for influencing factors between respondents.

Influencing Factor	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12
Device usefulness	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
Job relevance	✓	✓✓	✓✓	✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
Status			✓✓									
Image												
Subjective norm				✓								
Perceived user resources												
Computer Literate	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
User Efficacy	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
Size of screen	×	×	×	×	×			×	×	×	×	×
Theft	×	×	×	×	×			×	×	×	×	×
Task/technology fit		✓✓	✓✓		✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
Patient Perception		×	×									
Fear of legal suit			✓✓		✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓	✓✓
Management support												
Government support												

As can be gleaned from the table, there generally seems to be a high degree of correspondence or agreement between doctors. This is therefore a fairly strong indication of the reliability of the research findings, despite the small sample.

ABSTRACT

The Wirhe project is an international collaborative study that focused on the future of healthcare needs, technology requirements and solutions for effective use of wireless technologies for health care delivery. This paper presents results of a Wirhe survey of 85 experts and individual interviews with 35 experts. Key findings include: 1) both notable quality improvements and process enhancements can be expected from effectively utilizing wireless technologies and mobile solutions, 2) integration of personal health monitoring and professional health management is a key issue to be addressed and 3) health promotion and illness prevention efforts can grow by utilizing mobile solutions. We propose a framework that can be used in developing wireless health care solutions for managing diseases and related health problems. This framework can also be used to structure and stratify the needs of technologies and solutions, and to estimate their market potential.

INTRODUCTION

Healthcare is a large industry that spends globally USD 6 trillion per year (in 2008). The US alone spent USD 2.3 trillion on health care in 2007, and spending is growing at a rate of 8 percent annually (Kalorama, 2007). An aging population, changes in environment such as global warming and industrial pollution, and infectious diseases that are non-responsive to treatment set major challenges to manage in human health and health care.

Many leading information technology companies like IBM, Intel, Microsoft, Google, HP and Cisco have started to focus on health care technology solutions. Online health record systems offer people the opportunity to input their health data including diagnostic and care history into forms, which they can share with their peers, nurses or doctors through the Internet. Kalorama's market study (2007) also shows rapid growth in IT; in particular, wireless technologies are seen to have big potential. They are expected to: improve patient care; reduce costs; streamline processes; help with regulatory compliance; and provide many other benefits. Healthcare professionals need real-time access to data at the point of care for improving their decision making and enhancing processes. Remote patient monitoring, e-prescription, asset management and tracking are also potential application areas of wireless technologies in health care.

The total market for wireless technologies in US health care in 2005 was USD 1.8 billion, expected to grow 33 percent annually until 2010, reaching a total market size of USD 7.3 billion.

Microsoft Health Vault is the first trial for a major generic commercial Personal Health Record (PHR). The dominance of Microsoft in personal computing makes this trial especially interesting. One big challenge is the connectivity throughout the health ecosystem and how users can browse their personal information in a wide range of health and wellness IT applications. Google emphasizes the continuity even more. They speak of a Continuity of Care Record (CCR). The health record system has to communicate both with people and machines, and simultaneously maintain the high privacy and security of people's health data.

An IBM research team (Adams et al., 2006) summarizes the challenges of the world's health care this way: "Change must be made; the choices left to the stakeholders of today's health care systems are when and how. If they wait too long to act or do not act decisively enough, their systems could 'hit the wall' – in other words, be unable to continue on the current path – and then, require immediate and major forced restructuring."

Among IBM's recommendations are that: health care providers enhance management of chronic diseases and prevention of illness; consumers take personal responsibility for their health and maximize the value they get from the health care system; societies make better decisions regarding lifestyle expectations; and governments provide the leadership and political will power needed for innovative, sustainable solutions. Three methods to improve health care systems are proposed: 1) transforming value, 2) transforming consumer responsibility and 3) transforming care delivery.

The same IBM research team also describes the major changes needed in typical successful U.S. health plans in 2015; one of them is that business processes should be greatly improved and enhanced with IT-related capabilities (Adams et al., 2007).

Intel's research team (Intel Health, 2007) proposes rethinking the disease management process, emphasizing development of IT solutions for chronic diseases. Patients with chronic conditions account for 83 % of US health care spending; 81 % of inpatient stays; 91 % of prescriptions; 76 % of physician visits; and 98 % of home health care visits (Anderson, 2004). New technical solutions could strengthen patients' long-term engagement in their care. Healthcare providers could get accurate, relevant and timely information from their patients. Patients could have intuitive, enjoyable and educational communication channels to their care team and their families. In addition to periodic mailings and phone calls, communication could occur by e-mail, videoconferences, SMS messages and other mobile services. Touch screen and other user-friendly technologies should serve people with little or no IT experience.

A UK report on wireless based disease management (Wireless Healthcare, 2007) argues that wireless technologies play a key role within disease monitoring and modeling applications for AIDS, diabetes and influenza which are, especially in developed countries, diseases that significantly impact health care providers and pharmaceutical companies.

The California Healthcare Foundation (CHCF) (Adler, 2007) categorizes wireless applications of health care in two ways: 1) Monitoring applications for cardiac, diabetic etc. functions which can use portable, wearable or implantable sensors and work automatically and 2) Patient communication and supporting applications which can provide patients with information and feedback directly, and encourage them to take an active role in managing their health.

Many applications have been developed, for example, for cardiac monitoring (http://medical-connectivity.com/), glucose monitoring (http://healthpia.us/, GlucoPhone, developed by HealthPia, South Korea), multiple vital signs monitoring (portable and wearable), and even implantable monitoring integrated in pacemakers (http://www.biotronik.de/, Cyclos DR-T, developed by Biotronik, Germany). There are also applications for appointment reminders, health education and promotion, public health alerts, compliance monitoring and other treatment support and engagement. BeWell's Asthma Assistant (http://www.bewellmobile.com/) is an example.

CHFC defines issues of adoption of wireless technology. The health industry issues are uncertainty in reimbursement; unproven benefits; incompatibility of the health system for wireless applications; and privacy and security issues. The technical issues are potential information overload; lack of standards; market issues; incomplete coverage; network fragmentation; and the mismatch between the vivid cell phone market and the slow health care market.

The Continua Health Alliance (http://www.continuaalliance.org/) promotes a promising cooperative strategy to achieve continuity in care from the developer point of view (Carroll et al., 2007). There are 177 members who develop architecture, create use cases and define standards for better integrated health care services (CHA, 2009). The three target areas are: 1) disease management - managing a chronic disease outside of a clinical setting, 2) aging independently - using technology and services to live in one's own home longer, and 3) health and fitness - expanding personal health and wellness to where people live and play.

Alberta Health Service's Capital Health (Rowe, 2008) is a good example of applying continuum of care with evidence based practice. The challenge is to cover even the most complex patients in the vast rural areas of Canada with 2700 beds in 13 hospitals and 29 000 staff members including 2400 physicians serving 1.7 million people. The operation serves 10 000 home care clients monthly and 635 000 calls for health advice. Annually they have 956 000 patient days in hospitals, 1.3 million ambulatory visits, 436 000 emergency visits, 93 000 surgical procedures, 13 900 births. The Canada Health Act outlines the rules that provinces and territories must follow to receive federal funding for health care; these are 1) public administration; 2) comprehensiveness; 3) universality; 4) portability; and 5) accessibility. In these conditions it is inevitable to focus on a technology supported continuum of care. (http://www.parl.gc.ca/information/library/PRBpubs/944-e.htm)

On the hospital side there are many indications that wireless technologies can support improved outcomes. Solovy (2007) lists ten lessons for hospitals and health systems to improve their outcome and quality including: 1) improve patient flow, 2) improve workflow, 3) improve whole processes,

4) measure results and 5) manage medication to drive quality to the bedside, 6) use smart alerts to improve care, 7) provide ubiquitous access to digital images, 8) do not forget the operating room, 9) plan for the worst and 10) remember that infrastructure is the key to the future.

There is much research and development work proceeding worldwide to save health care from financial crisis, including process reengineering, new service solutions development and new technology development. Wireless technologies offer interesting potential, but also face many challenges.

PRESENT STATUS OF WIRELESS IN HEALTH CARE

This analysis is based on an international survey and interviews which were carried out during the first half of 2008 in America, Asia and Europe as a part of the Wirhe project, where an international strategy and roadmap plan for cooperative development of wireless technologies and solutions for health care was planned (Alasaarela, 2008).

The Wirhe strategy and roadmap plan was seen as important for several reasons: to increase understanding of the changes needed in the health care industry worldwide and how wireless and mobile solutions can be applied to enhance and improve it; to draw a roadmap with essential milestones; to plan a set of activities and efforts needed to reach the goals; to raise awareness of big challenges; and to define gaps in the process where wireless technologies can provide the solution. The Wirhe strategy and roadmap was funded and published by Tekes (a public technology and innovation fund in Finland) in October 2008 (Alasaarela, 2008).

University of Oulu was chosen as the responsible operator for the Wirhe project. To get a wide scope of understanding for the Wirhe project we collaborated first with the University of California Berkeley in Berkeley, CA, and the Health Technology Center (HealthTech) in San Francisco, CA. Imperial College in London joined the project team to develop the idea of our wireless framework, especially for wireless management of diabetes (Alasaarela & Oliver, 2009). The University of Alberta, Canada, joined to work on defining wireless solutions in rehabilitation[1].

In the first part of the Wirhe project we collected information and expert opinions about drivers and challenges in developing and adopting wireless solutions in health care (Alasaarela, Nemana & DeMello, 2009). This study was carried out during HIMSS conference 2008, in Orlando, Florida, by interviewing 70 participants who are experts on hospital information management. The main findings show that on average the most attractive and credible application is wireless alarming and calling for help. The second and third are mobile access to patient health records and vital signs monitoring. The results also showed that process change challenges are remarkably more difficult than technical challenges. The process change from the doctors' point of view is particularly severe. Among technical challenges usability of the mobile user interface is seen as the most difficult. Also according to this study, security of patient data is no longer among the most severe challenges.

In the second part of the Wirhe project we interviewed 85 experts from 15 countries through an Internet survey. A ZEF analysis method (http://zefsolutions.com/en/) was used to collect opinions and comments and to produce a report of bases, needs, vision, challenges, risks etc. with 699 comments, ideas and proposals of experts. We also interviewed 35 experts face-to-face (15 of them were participants of the ZEF survey) to deepen the scope. In addition, we collected a Wireless in Healthcare database including 160 products or solutions, 193 concurrent scientific and technical articles, 149 news articles during 2007-2008 and 41 conferences and exhibitions during 2008-2009.

The ZEF Survey and Interviews

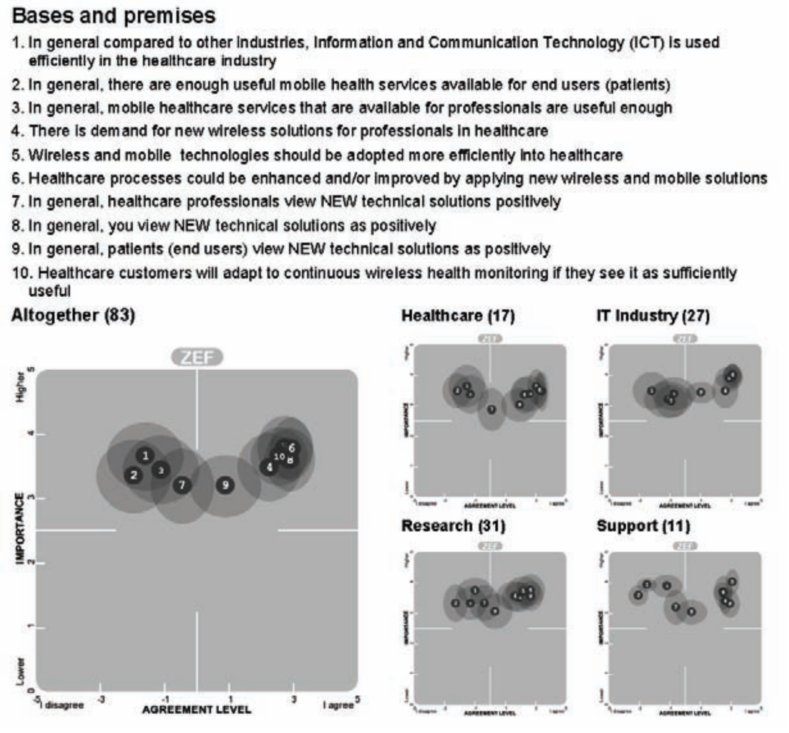
ZEF analysis is a two-dimensional graphical survey tool capable of z-score processing and is available on the Internet (http://zefsolutions.com/en). Examples of ZEF-charts can be seen in Figures 1-4. The respondents get an equivalent graphical survey form and work by pointing their evaluations on the answering field whose coordinates have been defined and indicated on the field axes.

The reports are calculated in the ZEF server as ZEF charts indicating the average points and deviation ellipses around them. The position of the numbers 1 to 10 on the charts in Figure 1, for example, reports averages and the height and width of the ellipses around the numbers are proportional to the deviation in the respective direction.

An absolute or z-scored method can be used in report processing. In the absolute process the original answers are used when processing the averages and deviations. In the z-scored process a normalization (z-scoring) method is used twice: first on each chart for each respondent's answers and second after averaging to the whole data chart by chart. The ZEF method gives full resolution to each respondent and also more accurate results than absolute processed charts. However, the normalized process can be used effectively only when finding comparative differences: better / worse, more / less attractive etc.

The ZEF survey content was planned by a small expert group[1] starting from the contents of our

Figure 1. Bases and premises according to 83 experts' answers to the 10 claims. Numbered spots are on their average points and the ellipses around are proportional to their standard deviations. Four small charts describe opinions of the same experts divided into groups that they represent. The ZEF method is a registered trademark of ZEF Solutions (http://zefsolutions.com/en)



Bases and premises

1. In general compared to other industries, Information and Communication Technology (ICT) is used efficiently in the healthcare industry
2. In general, there are enough useful mobile health services available for end users (patients)
3. In general, mobile healthcare services that are available for professionals are useful enough
4. There is demand for new wireless solutions for professionals in healthcare
5. Wireless and mobile technologies should be adopted more efficiently into healthcare
6. Healthcare processes could be enhanced and/or improved by applying new wireless and mobile solutions
7. In general, healthcare professionals view NEW technical solutions positively
8. In general, you view NEW technical solutions as positively
9. In general, patients (end users) view NEW technical solutions as positively
10. Healthcare customers will adapt to continuous wireless health monitoring if they see it as sufficiently useful

previous wireless strategy projects (Alasaarela, 2009). The question groups with the used dimensions (horizontal / vertical) are: A) Background questions (choice questions only); B) Bases and premises (Agreement level / Importance); C) Needs for development for inpatient use (Need 2012-14 / Need 2008-09); D) Needs for development for outpatient use (Need 2012-14/ Need 2008-09); E) Components of vision for 2014 (Attractiveness / Credibility); F) Threats and risks (Seriousness / Probability); G) Technical challenges (Degree of difficulty); H) Process development challenges (Degree of difficulty); I) Your message to the strategy team (Free text). In each question group there is at least one text box for writing free text comments and ideas.

The experts were invited via email and motivated by a raffle of a Nokia N95 8GB smart phone. They answered by clicking a link in their invitation mail to open their graphical ZEF survey form. Altogether 85 (46 %) experts of 187 invited responded to our ZEF survey. A total of 39 ZEF survey respondents represented USA; 20 Finland; 7 South Korea; 6 UK; and 13 other countries (including Canada, Spain, Belgium, Sweden, Norway, Estonia, Hungary, Japan, the Netherlands, Germany and Switzerland). The respondents represented all-important expert groups: 1) health care services (19), 2) IT industry (27), 3) research (32) and 4) supporting (11).

The number of respondents varies in the reported question groups since the ZEF system gave access to each respondent according to their expert areas that they had selected in the background questions.

Background Questions

In the background questions of the Wirhe study the experts were asked to define their primary responsibilities in their jobs. They were allowed to select one or more responsibilities. 31.8% selected "Management/coordination," 47.1% "Technical research & development," 16.5% "Technology planning, acquiring and/or maintenance," 10.6% "Marketing/sales," 12.9% "Medical diagnosis and care," 2.4% "Nursing/nursing science" and 22.4% "Something else".

Experts were also asked to rate their familiarity with IT technology. The agreement percentages were: 97.6% in "I use mobile phone daily," 89.4% "I use wireless network (WLAN, WiFi) when needed," 76.5% "I use Bluetooth links when needed," 51.8% "I use 3G services when needed," 69.5% "I use GPS navigation when needed," 63.5% "I know ZigBee technology," 51.8% "I know UWB technology," 45.9% "I use PDA device daily and 21.2% "I use wireless network to browse patient records".

Bases and Premises

In general the experts believe that "ICT is not used efficiently in the health care industry" and "there are not enough useful mobile solutions available for end users" (numbers 1 and 2 in Figure 1). In addition the "mobile health care services available for professionals are not useful enough" (3). All groups, people from health care services, IT industry, research and supporting agree on these negative statements. An example comment: "I have not seen an integrated total solution. There are lots of solutions tackling various different problems taking baby steps."

The same people agree that "there is demand for wireless solutions" (4) for professionals, "wireless and mobile solutions should be adopted more efficiently" (5) into health care, and they would "enhance and/or improve health care processes" (6). In addition the same experts believe that "customers would adapt even continuous wireless health monitoring" (10) if they saw it as sufficiently useful. It is interesting to note that the error bars for the responses to the bases and premises section of the ZEF questionnaire are the smallest of all the sections. This indicates that there is significant overall agreement on general principles between experts in wireless health care, regardless of background. The spread of responses and the size of the error bars increase for more specific sections of the ZEF survey, though it should be noted that the number of experts polled differs between sections.

Some of the experts are concerned about the health care processes themselves, which would require major changes. They would not like to grant technology too big a role. The majority of comments were positive, like this one: “Mobile solutions supported by privacy and security checks will be accepted as they will contribute to better, safer and more efficient care.”

Needs of Wireless for In-Hospital Use

The experts believe that in the short term the highest need is for “alarm buttons and systems” (number 11 in Figure 2). The highest needs both in the short and long term are “need for wireless networks” (1) themselves and “need for wireless access to an electronic patient record system” (4), “to an electronic prescription system” (5) and “to medical information” (6). In the long term “wireless sensor belts and wristbands” (10) are also needed.

The experts coming from health care services also stated a “need for wireless terminals” (2), and research experts estimate that the need with the greatest evolution over the forthcoming 5 years will be for “implantable sensors and care actuators” (9).

Patients would love to have services and information access through mobile and wireless devices.

Figure 2. Short and long term needs of wireless for in-hospital use according to 48 experts. The charts have been calculated by using a normalizing (z-scoring) method.

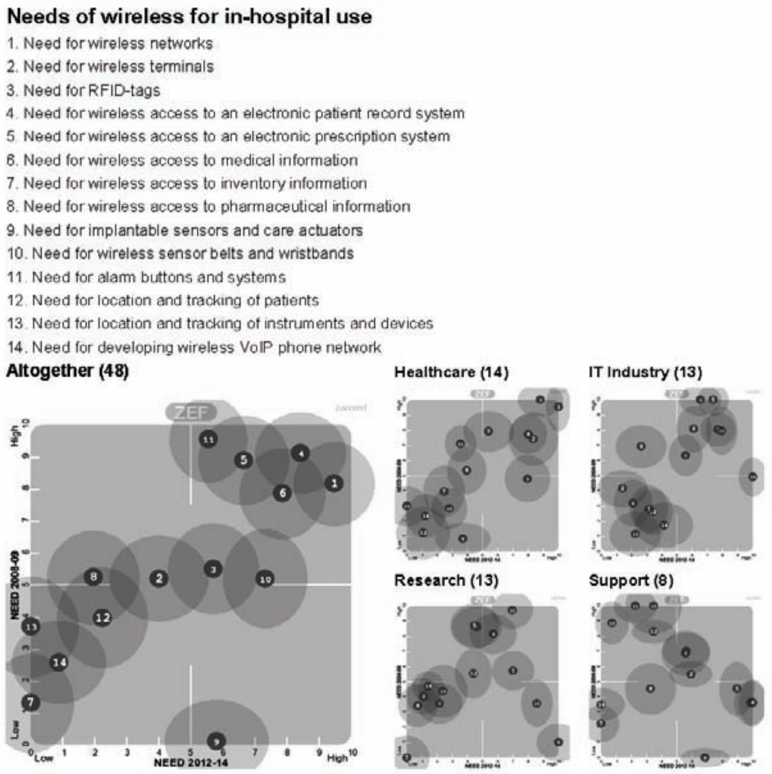


Figure 3. Short and long term needs of wireless for outpatient use according to 44 experts. The charts have been calculated by using a normalizing (z-scoring) method.

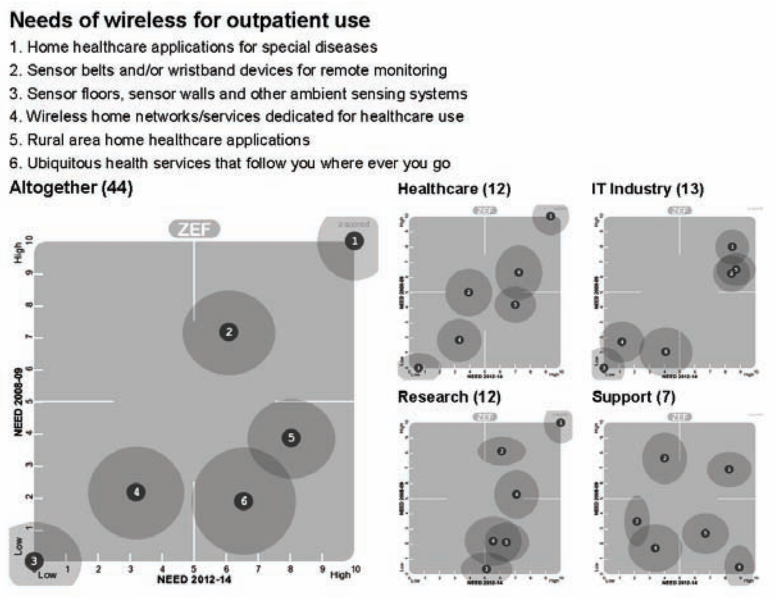


Needs of Wireless for Outpatient Use

One candidate is clearly higher than any other in our list of outpatient wireless needs, both short and long range: "home health care applications for special diseases" (1). The second is "sensor belts and/or wristband devices for remote monitoring" (2), especially, in the short term. Only experts from health care services raise "ubiquitous health services" (6) and "rural area home health care applications" (5) as more important long range. IT industry experts do not see ubiquitous health services as important as the three other mentioned above.

On the other hand these experts do not see any special "need for sensor floors, sensor walls or other ambient sensing systems" (3) which are usually seen as important in ubiquitous technology.

The text comments of the experts support the results above: "Near future: remote monitoring and tele-assistance. Far future: sensor implants, implants improving body functions (for example vision, pain relief), artificial limbs connected to neural system."

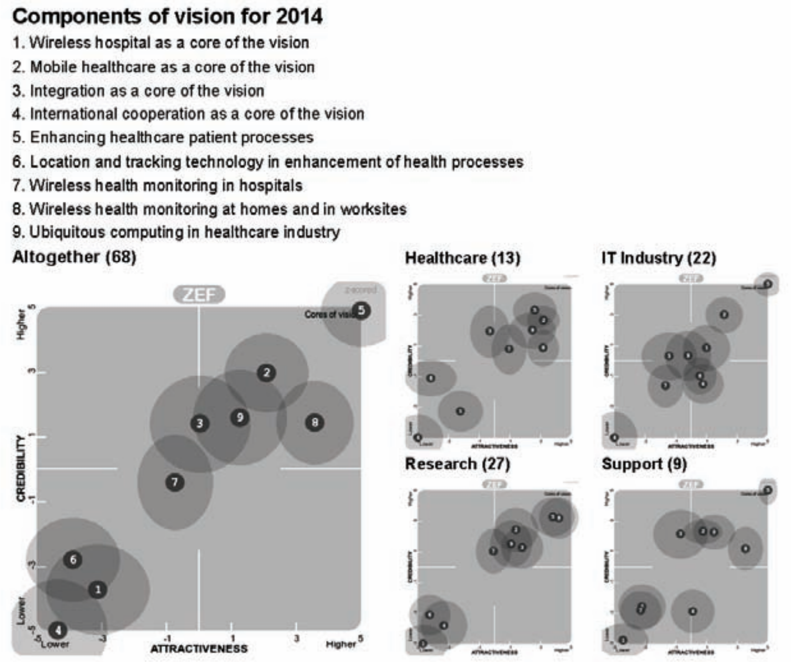
FUTURE OF WIRELESS IN HEALTHCARE

Vision and Goals for Future Development

In defining future vision and goals we used ZEF analysis to rate the attractiveness and credibility of questions or matters listed on a ZEF table. The thoroughly planned list of the asked choices for cores and components of vision can be seen in Figure 4. In the survey form each of them was described in greater detail.

In addition we asked the experts to write their comments and ideas about vision like: "Which objectives would be the most important to take into account?" and "Try to formulate your vision

Figure 4. The main summary of the ZEF analysis of the vision components calculated by using z-scoring to get relative results



for wireless solutions in health care. What are the key issues? What are the key technologies? What are the expected benefits?"

The result of the ZEF analysis can be seen in Figure 4. After numerous discussions with experts the results were as follows. "Enhancing health care patient processes" (5) is the most credible and attractive component of the vision. The second is "mobile health care as a core of the vision" (2). The next two are "wireless monitoring at homes and in worksites" (8) and "ubiquitous computing in health care industry" (9). Two more: "integration as a core of the vision" (3) and "wireless health monitoring in hospitals" (7) are highly credible and attractive, especially, according to experts from health care services and research.

Although most of the original average points (calculated without z-scoring) are situated in the upper right corner (representing attractive and credible elements), numbers 1, 4 and 6 are clearly lower both in attractiveness and credibility than the other. Thus the wireless hospital and wireless location and tracking cannot be core elements on average in the future according to these experts.

The "international cooperation" (4) is an interesting detail in this study. It is the least attractive and least credible component of vision. Why? Perhaps the health care systems are so national by their inherent character that the experts can foresee such severe national challenges that they cannot credit any possibility of international co-operation. This analysis reveals that we have an especially hard challenge to obtain international cooperation.

The two text questions generated 92 answers which strengthen and detail the interpretation. Here are two samples:

An informed and empowered consumer is more compliant. Wireless technology facilitates monitoring at home and work. Key issues relate to *privacy, security and reimbursement. The RFID, cell phones and ubiquitous technologies will continue to develop. This will produce significant cost savings to society as a result of better outcomes and fewer medical errors.*

Key issues: The application of wireless technologies in health care lags behind other areas. It is important to come up with a platform that can be easily integrated with the existing devices. An open platform will allow researchers to test and implement their technologies. Key technologies: PDA or smart phones enabled with wireless technology. Developing robust sensing technology. Software to provide patients and clinicians with feedback. Expected benefits: Tremendous reduction in health care costs. Increase in efficiency of clinicians. Convenience to patients.

Defined Vision 2014

According to the above studies and tens of face-to-face interviews of experts the vision 2014 was formulated as (Alasaarela, 2008):

Towards 2014 health care will become more mobilized and integrated – close to ubiquitous. The patient processes will be enhanced and supported by wireless monitoring and care services at homes and worksites as well as in hospitals. Wireless technologies and mobile solutions will be applied systematically to different disease groups according to a unified framework based on international development and standardization work.

The first part of the vision comes directly from the study results above. The second part –systematic application of wireless to different diseases - comes from discussions with experts. An estimation of prevalence and annual costs of some diseases in the USA can be seen in Table 1.

Major diseases compounded by aging and obesity problems form one of the biggest health care costs in the USA and even globally. Our hypothesis is that by utilizing wireless solutions we can manage these costs more effectively. The main aim of this study is to offer a framework that will reveal the exact points in the health service continuum where mobile solutions will bring the most significant outcomes and improve the quality of care. The unified framework can be used to manage planning of wireless solutions for each health problem systematically.

Table 1. The most expensive diseases in America (Herper, 2005)

Disease	*Annual costs*	**Patients in USA**
Heart conditions	$68 billion	20 million
Trauma	$58 billion	36 million
Mental Illness	$48 billion	31 million
Cancer	$48 billion	11 million
Respiratory Ailments	$45 billion	50 million
Hypertension	$33 billion	37 million
Arthritis and Joint Disorders	$32 billion	23 million
Diabetes	$28 billion	14 million
Back problems	$23 billion	18 million
Total	$383 billion	

Integration of Personal and Institutional Health Care

The future of wireless in health care can be viewed in four ways: 1) From the health professionals' point of view, how can health care processes be enhanced and improved by adopting wireless and mobile solutions? 2) From the patients' and citizens' point of view, how can disease and health management be enhanced, improved and better adapted to their daily lives? 3) From the providers' and governments' point of view, how can the whole health care industry be improved and made more efficient by promoting new wireless and mobile solutions? 4) From the engineers' technology point of view, how can modern wireless and mobile communication technologies be applied to solve problems in the health care industry?

In order to optimize the management of health care we need to combine the professionals' process-based thinking, the citizens' wellbeing, patients' disease-based thinking and the government and institutional return on investment (ROI) based thinking. This means integration of health care in a novel and fundamental way. Technologies are only tools to realize the solutions needed.

A health care process can be considered to be a chain of successive activities which health care professionals perform for the patient in a hospital or in the community. Broadly speaking, activities of the patient's own before coming to health services and after returning back home can also be considered to belong to this health care process. Therefore, wireless supported health care processes involve most of the same activities, which the patients receive in their wireless supported disease management programs.

The disease management concept is an entity, which comprises methods, systems, services, devices and products for diagnosing, caring for and monitoring a patient with a specific disease during the course of that disease. Mostly the term of disease management is attached to chronic illnesses, but now we broaden it to acute illness episodes as well. Perhaps, it would be better to speak of "health management concepts" or "healing support concepts".

Development of wireless supported disease management concepts requires a great deal of medical and nursing knowledge - much more than developing the devices and systems which are needed in only one phase of a health care process. This arises from a more holistic way of considering health processes.

By combining the three viewing angles we can formulate concepts to manage diseases with a wireless-supported continuum of care from preventive health management to care and rehabilitation services. This would lead to efficient, high quality care, financial savings and improved clinical outcomes which would not be possible without wireless and mobile solutions.

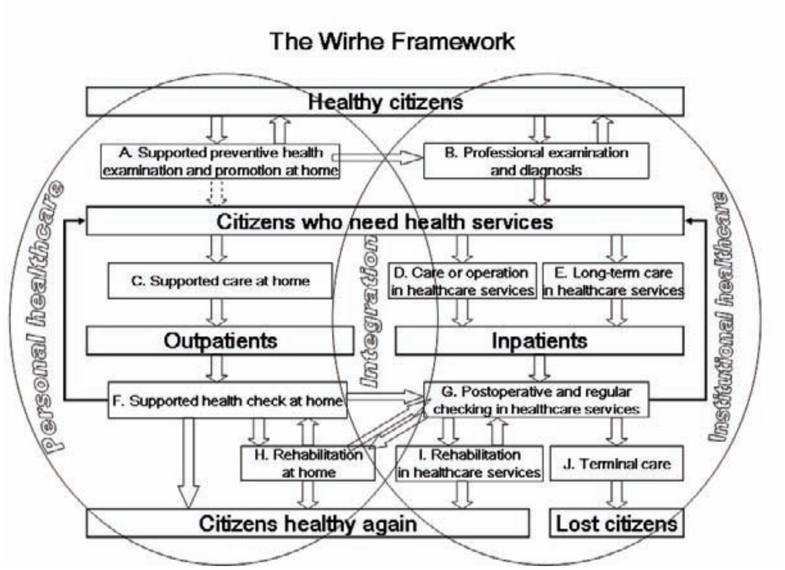
THE WIRHE FRAMEWORK FOR WIRELESS MANAGEMENT OF DISEASES

Each disease and health problem needs a specific diagnosing, caring and monitoring concept, comprising all-important phases starting from the first indicators of pathology and ending with no symptoms or indicators, demonstrating health. Disease prevention is also needed for specific risk groups (people with genetic or environmental risks).

Wireless support offers not only opportunities to manage diseases in a novel way, but also the opportunity to tailor the disease management concept individually for each patient, taking into account unique needs, wishes and lifestyles. The overall goal is that all patients continue their normal daily life despite their disease status and that wireless health care provides no additional burden to the patient.

Public, private and self-care can be seen as building blocks. They can be re-engineered to form a systematic framework (Figure 5) for developing the wireless supported health care. The

Figure 5. The Wirhe framework shows how the patient-driven disease management (left) and the professionals-driven health care processes (right) are integrated to form a unified service chain with many different paths for customers. Each text block refers to needs and solutions, both available and lacking. For example, supported care at home for a heart condition (arrhythmia) needs heart monitoring and requires a wireless ECG sensor with a means to transmit an alert and ECG sample to a professional health service unit as soon as abnormalities emerge in the data.



existing wireless and mobile solutions can now be placed on the Wirhe framework.

Wireless support may be very different for different diseases. It might also be tailored to meet individual patient's needs, particularly if the patient has two or more chronic diseases.

Important blocks in the Wirhe Framework are:

A. Supported preventive health examination and promotion at home
B. Professional examination and diagnosis
C. Supported care at home
D. Care or operation in health care services
E. Long-term care in health care services
F. Supported health check at home
G. Postoperative health check and regular (continuous or sampled) health monitoring in health care services
H. Rehabilitation at home
I. Rehabilitation in health care services
J. Terminal care

Wireless networks and access points are needed in hospitals, clinics, and health centers as well as at home. Therefore, they are needed in most of the blocks. Cisco (http://www.cisco.com/) and Philips (http://www.philips.com) are well known global providers of wireless networks solutions with access points, controllers, etc.

Aruba Wireless Networks (http://www.arubanetworks.com/) provides user-centric wireless networks to integrate adaptive wireless LANs, identity-based security, and application continuity services for health care campuses, clinics, physician and home-offices.

Flo Healthcare (http://www.flohealth care.com/) markets mobile clinical workstations, wireless access points and accessories specifically for the health care industry. Wireless connection to information helps clinicians stay better connected with their patients.

Cardinal Health (http://www.cardinal.com/) markets their Alaris solution including system manager and gateway units, a safety net module and a connectivity program for facilitating data flow between key technologies. Their customers are located on five continents and include hospitals, medical centers, retail and mail order pharmacies, clinics, physicians, pharmacists and other health care providers.

Nortel Networks (http://www.nortel.com/) provides affordable, scalable IP voice and wireless mobility solutions and other IP based clinical applications including asset tracking and management systems.

Motorola Remote Patient Monitoring Solutions (http://www.motorola.com/, earlier known as Symbol Technologies) combine WLAN enabled mobile computers, voice over WLAN, leading clinical IT and medical device applications to help improve the speed and quality of medical treatment.

Next we describe briefly each block and give examples of the kind of needs and wireless solutions there might be in each block. Some of the blocks are not needed in all of the diseases. For example, diabetes is a life-long disease. Therefore, rehabilitation is seldom needed for diabetes itself; it is more often needed due to its co-morbidities. In addition, diabetes itself is not fatal, although it may lead to fatal complications (Alasaarela & Oliver, 2009).

A. Supported Preventive Health Examination and Promotion at Home

Preventive care and health promotion are some of the most important needs in the future. Many changes in human life-style, working environment, eating habits, environmental pollution etc. set new challenges to our health. We need new solutions to measure and monitor our health to diagnose coming health problems as early as possible. We also need solutions to collect the right information at the right time about the right problem. In the future genetic information will become increasingly important.

In fact, if we are able to assess our genetic risks, follow daily what we eat and drink, monitor the gamut of our physical and mental exercise and measure regularly our bio signals, we will have a clearer risk assessment of what diseases and other health problems we should be concerned about. Is it possible to develop wireless solutions to offer these services? What are the most important means to start from?

There are already many technologies and platforms available for these needs. Heart rate monitors are well known; for example Polar Electro's products (http://www.polar.fi), who have also developed analysis software for fitness and weight monitoring. Firstbeat Technologies (http://www.firstbeat.fi) has developed an HRV (Heart rate variability) analyzing method and software which utilizes heart rate data to find latent diseases.

Cell phone networks working on the 3G level are effective platforms for preventive health solutions. Many mobile services for managing fitness, weigh, nutrition and lifestyle are under development. Wireless devices for monitoring vital signs and specific physiological parameters can also be used by healthy people, especially if they belong to a high-risk group. The monitoring could also be linked to health providers and call centers.

B. Professional Examination and Diagnosis

The professional examination happens mostly within health services (in health centers, hospitals or clinics). Therefore, some of the wireless technologies which are available for care are available also for examination.

As an example, LifeWatch Corp. (http://www.lifewatchinc.com/) offer wireless blood pressure meters, oxygen saturation monitors, weigh scales, PDA monitors with Bluetooth connection and services for integrated monitoring and analysis.

Medixine Ltd. (http://www.medixine.com/) offers an integrated monitor system via a Bluetooth connection for measuring devices such as blood pressure meters, scales and glucometers. The data are forwarded to the Medixine server either via a mobile phone or a Bluetooth hub.

C. Supported Care at Home

Home health care is a rapidly proliferating market. At Medica 2008 (http://www.medica.de/) visitors could see many comprehensive solutions for managing chronic patients at home. Wireless technology is important both for patient's freedom to move at home and for continuous connection and support from care providers.

Among the most utilized products in the home health care market are the Honeywell HomMed solutions. HomMed is one of the leaders in telehealth and remote patient monitoring solutions (http://www.hommed.com/) and over half a million patients are served by HomMed solutions. They are dedicated to improving the quality of patients' lives and reducing the cost of health care by providing integrated solutions for home care. The products of HomMed are the Centry and Genesis telehealth monitors with a wide variety of peripherals, medication reminders and a central station. The solutions can be used to collect heart rate, blood pressure, oxygen saturation and other vital signs data and to process and display it for diagnostic and care development use.

Philips Electronics (http://www.medical.philips.com/) offers among other products a TeleStation hub for the transmission of vital signs data collected from the wireless measurement devices at a patient's home. It is also a medium for interactive communication between care providers and patients at home. They also offer Intellivue Telemetry Systems for SpO2, ECG and improved tachycardia assessment, which uses so-called smart-hopping technology to maintain seamless connections between the central station and telemetry devices. Their Classic Pendant Personal help button gives patients at home access to fast assistance by a simple alert touch. Philips offers also many wireless products for hospital and other institutional use.

MedApps is an emerging company (http://www.medapps.net) which offers portable devices and a web-based monitoring application to deliver an end-to-end mobile, wireless, health monitoring system.

University of Alberta (a team lead by Dr. Masako Miyazaki) has developed a comprehensive home care solution, WWPM for chronic elderly patients (Miyazaki, 2008). The system was tested by a third party research team for a healthy population and clients' population in Capital Health. The system was spun off from the University of Alberta and is now available through Redengine Health (http:// www.redenginehealth.com).

eHIT Ltd (http://www.ehit.fi/) specializes in eHealth and eWellness solutions where end users actively participate in the maintenance of their own health. Their solutions include self-care, home care, and occupational health.

BeWell Mobile (http://www.bewellmobile.com/) is offered to advance engagement of conditions such as asthma and diabetes patients in three ways: via Web Portal, eDiaries by cell phones and Reminders by SMS.

ExmoCare (http://www.exmocare.com/) develops, produces and markets wireless health care, wellness and biosensor products. Its operations are focused around its line of wireless biosensor wristwatches and recurring monthly service plans for remote chronic care, weight management and eventually diabetes care.

BodyTel Scientific (http://www.bodytel.com/) specializes in telemedical monitoring and management systems for chronic diseases, particularly diabetes.

Visual Telecommunications Network (http://www.vitelnet.com/) offers ViTel Net solutions for home health monitoring, referral, consultation and emergency telemedicine.

Confidant (http://www.confidantinc.com/) has developed mobile phone solutions helping people suffering from chronic diseases manage their health easily while maintaining an active lifestyle.

D. Care or Operation in Health Care Services

Wireless networks are already in daily use in most of the hospitals in the western countries. For example, when physicians and nurses go on their rounds they have their laptops or tablet PCs to maintain access to patient record and medical information systems. In addition, there are many technologies available to apply WLAN, Bluetooth, RFID or other wireless connections.

Alien Technology (http://www.alientechnology.com/) provides RFID tags, RFID readers and related services.

InnerWireless (http://www.innerwireless.com/health care.asp) is a provider of comprehensive in-building wireless distribution systems, as well as wireless tracking and location solutions.

Medanets Oy (http://www.medanets.com/) offers a solution where the measurement data are transferred into the information system via a wireless network, either automatically or with one entry. The information is immediately available to all system users.

Allscripts (http://www.allscripts.com/) offers mobile TouchChart solutions for physicians to quickly prescribe, check for drug interactions, access medical histories and review drug reference information. Providers can connect directly to the pharmacy via electronic fax and electronically exchange prescription data.

CardioNet (http://www.cardionet.com/) offers a solution for arrhythmia patients. They wear three chest leads with a small sensor that detects heart rhythm and wirelessly transmits to the monitor. LifeWatch Corp. (http://www.lifewatchinc.com/) has a similar arrhythmia solution LifeStar, with a single lead ECG.

Audio Riders' (http://www.audioriders.fi/) Carerider collects information from wireless sensors placed in beds and nursing chairs, which is then integrated with the intelligent job control of the service.

CRF Inc (http://www.crfhealth.com/) is the leading global provider of eDiaries and wireless data collection solutions for the biopharmaceutical industry.

Emfit (http://www.emfit.com/) is specialized in developing and manufacturing networked, IP-based nurse call systems with assistive non-body-contact vitals and movements monitoring, fall and wander alarms, and epileptic seizure alarms.

Incode (http://www.incode.fi/) offers wireless technology for nurse calls etc.

Medictes (http://www.medictes.fi/) is focused on health care data systems by offering communication tools, applications and solutions. Their MobiiliSanelu allows clinicians to dictate ubiquitously by a web application or cell phone. The saved dictations are available for listening and unpacking in real-time.

A wireless, battery-free, fetal vital signs sensor which monitors baby's vital signs day and night has been developed in the National Children's Hospital. RF System Laboratory is in charge of product development. They have also been working with NASA to support astronauts during space flight (http://www.rfnokko.com/nokkop2.html)

E. Long-Term Care in Health Care Services

The applications of long-term care differ from basic hospital care. Their aim is to help patients to live with minimal intrusion while being monitored frequently enough to detect changes in health status. Many long-term patients have several chronic conditions and wear monitoring devices for years, increasing technology costs. However, in present care models, these patients use the vast majority of health care resources. Therefore, the expected savings of implementing wireless solutions are higher.

Televital (http://www.televital.com/) offers VitalWare VMS integrated Electronic Patient Medical Record and real-time telemedicine software modules with auto-recognition and configuration architecture that enables plug-and-play for a wide variety of medical devices from different manufacturers.

Sensitron (http://www.sensitron.net/) has developed careTrends solution, which is an enterprise software and wireless vital signs collection and dissemination system, to improve patient quality of care and decrease health care costs.

IST International Security Technology (http://www.istsec.fi/) offers automatic personal security systems monitoring and analyzing users´ activity levels. Their Vivago wristtop monitor consists of sensors and algorithms that allow body signals to be monitored and analyzed automatically and continuously.

Medtronic (http://www.medtronic.com/) is a manufacturer of medical technology solutions for people with chronic disease. Each year, 6 million patients utilize Medtronic's technology, used to treat conditions such as diabetes, heart disease, neurological disorders, and vascular illnesses. Their Minimed Paradigm system integrates an insulin pump with real-time continuous glucose monitoring and sends blood sugar test results wirelessly to an insulin pump – making integration of glucose and insulin data easier.

Toumaz Technology (http://www.toumaz.com/) is a specialist in ultra low power sensing technology. Their Sensium is a sensor interface and transceiver platform for a wide range of applications in health care, not only for chronic diseases but also for lifestyle management. The device includes a reconfigurable sensor interface, digital block with 8051 processor and an RF transceiver block.

F. Supported Health Check at Home

Patients may acquire some home devices and services to monitor their important health parameters, blood pressure, blood glucose, weight, temperature etc. An example of a chronic disease with a need for regular self-checking is diabetes. Most diabetics should measure their blood glucose several times per day using portable glucometers. Some of these glucometers have wireless capability to transmit data to personal computers for later review.

ProWellness (http://www.prowellness.com/indexEN.html) has developed a mobile system for diabetics to monitor their health at home. Similar solutions are available from eHIT, Medapps etc.

G. Postoperative and Continuous Checking in Health Care Services

Many patient monitors are available with wireless connections. When intensive monitoring is not needed it is better to have a light minimally invasive or non-invasive patient monitor and move the patient into an area where costs are lower. Light patient monitors are available from many companies.

For example, Welch Allyn (http://www.welchallyn.com/) offers Spot Vital Signs Lxi monitors which use a barcode scanner, and a wireless radio to capture and transfer patient vital signs quickly thus bringing wireless vital signs transmission capability from the bedside.

H. Rehabilitation at Home

There are wide range of technologies that have been used to provide remote delivery of rehabilitation by Occupational Therapists, Physical Therapists, Speech Pathologist and Audiologists The most widely used modalities, as of 2008, are webcams, videophones, and websites containing health information. There are telecommunication infrastructure challenges depending on where you reside. If your clients are living in a remote community in Canada, your access to high speed Internet would provide TV type broadcasting for patients with chronic illness and provide education just in time. The majority of rehabilitation services can be augmented if therapists and clients can access necessary equipment. For example, Occupational Therapists at the Glenrose Hospital, Edmonton incorporates the Wii fit (NINTENDO) game for head injury patients' balance, cognitive and endurance building. Providing readily commercially available wireless games enhances patients' recoveries. Many aspects of rehabilitation practice can be enhanced with objective measurement tools such as 3D motion analysis for Occupational Therapy and Physical Therapy, instead of goniometry and manual muscle testing which are susceptible to error in measurement.

Two important areas of telerehabilitation research are (1) demonstrating equivalence of assessment and therapy to in-person assessment and therapy, and (2) building new data collection systems to digitize information that a therapist can use in practice. Groundbreaking research in telehaptics (the sense of touch) and virtual reality may broaden the scope of telerehabilitation practice, in the future. (http://en.wikipedia.org/wiki/Telerehabilitation)

I. Rehabilitation in Health Care Services

It is obvious that health care and being healthy do not have any clear boundaries. It is a continuum of care throughout our life inside and outside of institutions. One way to look at this is the level of care you need or level of productivity you have accomplished. You may need a small device to help you to get back to work or need a wheelchair to get around. Institutional rehabilitation service can be augmented by having a secure wireless LAN so that health care providers can access clients' data at the point of care. There is a serious need to evaluate all the wireless products which are used in an institution so that industries can provide the equipment clients' needs without interfering with other wireless medical devices.

J. Terminal Care

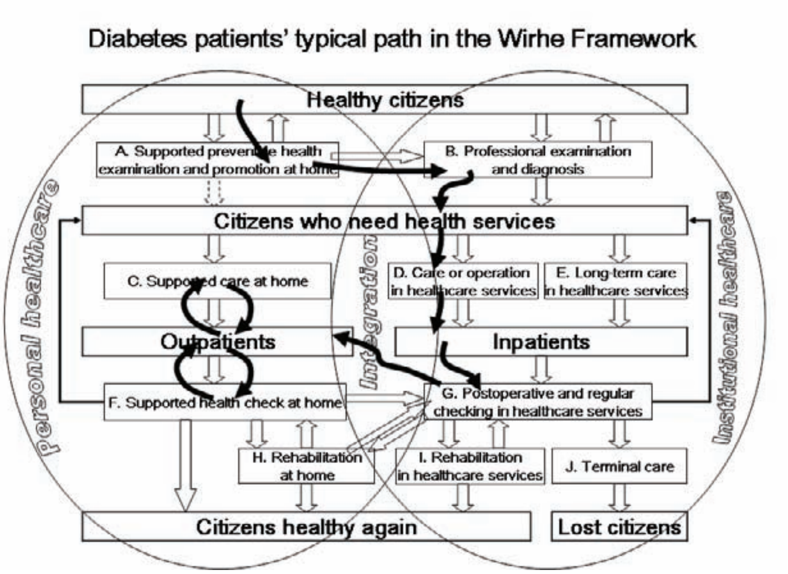
In terminal care there are only few wireless solutions available. If the patient is immobile, wires are not disruptive and the advantages of wireless data are reduced. However, terminal care should be planned for future utilization of wireless technologies due to potential improvements in cost efficiency.

Hoana Medical (http://www.hoana.com/) markets a special bed solution (LifeBed™ System) which could work in terminal care. Patient vigilance system provides a solution for continuous observation of patient conditions. Unlike conventional monitoring systems no physical contact or connections are needed. Wireless solutions for palliation of symptoms in the dying patient might include pain monitoring, consciousness monitoring and analgesic or hypnotic drug delivery.

PATHS OF PATIENTS IN THE WIRHE FRAMEWORK

In Figure 6 we can see an example of a path followed by a patient in the Wirhe framework. The individual with no symptoms of diabetes uses only preventive services. However, if the process of home monitoring and preventive care reveals signs of diabetes he/she goes on to professional examination. If diabetes is not diagnosed he/she returns back to use only preventive services. If the diagnosis is made, he/she progresses through the framework to care in a clinic. After a satisfactory review in the hospital he/she returns home to use supported care services with supported health monitoring at home. This loop continues until there is a need to go to a professional health

Figure 6. A typical path of diabetes patients when they proceed in health care services from healthy citizens to outpatient loop (Alasaarela & Oliver, 2009)



check, at which stage he/she can access inpatient or outpatient hospital care and his/her care will describe an alternative loop in the Framework until resolution.

If the patient can use the same mobile user interface to access the service systems at home, in the workplace and in health care organizations, he/she will not need to carry different devices with him/her. Suitable devices are smart phones, PDA devices and mini-PCs. One interface system means a big advantage to the patient user. The same would be useful to doctors and nurses as well, although not so remarkable as for patients. In many cases the professionals benefits more from a big screen interface when they work in or close to their office and a mobile device when they go into the field.

Integration can be built on electronic health record (EHR) systems. Mobility means wireless access to patients' health records when and where needed and automatic (sometimes manual but mobile) wireless collection of health information from patients. If all products and services (mobile or fixed) are built around the EHR system, the integration comes through the operating system of the EHR. Therefore, it would be ideal if all EHR systems were to use the same architecture and interface policies (such as HL7 – Health Level Seven). Standardization is a key factor in both national and international integration.

The Continua Health Alliance (CHA) is developing health standards, protocols and practices. Integration between health institutions and systems is a severe problem not only in diabetes but widely in global health systems. Healthcare IT systems have been developed mostly by companies who compete against each other to maintain their customers. Alliances like CHA help companies to cooperate rather than compete.

DISCUSSION AND CONCLUSION

Wireless technology is a cost-efficient way to respond to the challenges for public health care systems posed by inevitable structural changes. Due to demographic changes, the amount of patients will increase in upcoming years, while the relative amount of health care professionals is going to decrease. Despite these financial challenges, high quality treatment and organizational integrity must be maintained. An inevitable structural change is happening already.

The public health care systems are challenged to operate according to business requirements. The business baselines in developing health care systems are cost efficiency, patient-orientation, high quality at all operational levels and accessibility of services.

All these baselines can be improved by bringing real-time functions into health care systems accessed by wireless technologies. As human resources are decreased, a leading strategy is to develop technological solutions and preventive health care. Wireless technology is a relatively small, but strategically vitally important part of required IT solutions.

In the Wirhe Framework the viewpoints of health care professionals, citizens and government have been integrated to form a mutual fight against diseases and health problems. Now the wireless technologies and mobile solutions can be applied, in practice, according to the Wirhe framework. This allows a cost-efficient use of existing technologies; therefore, the focus can be shifted towards the development of unavailable products and services and unmet needs.

Wireless technologies can play a critical role in maintaining the independence of our elderly population, through support of safety monitoring (both within the home as well as tracking via GPS); assessment of gait (to predict the likelihood of falls); monitoring and transmission of vital signs and specific biological parameters (such as glucose levels); and the capability of triggering emergency alerts.

Alzheimer's patients would benefit from a wireless "safety net" that constantly tracks their location, assesses their level of cognitive awareness and capacity, and notifies family members and caregivers of behaviors or events.

Wireless support of food intake monitoring, tracking of dietary patterns, timely education and alerts, and even data support for meal services (using body chemistry and eating history to determine and order prepared meals) are all valuable applications to support those with obesity problems.

Even a small productivity increase in service processes will pay wireless technology investments back rapidly. For example, in diabetes alone, a USD 3 billion savings could be achieved if only 10% of patients adopt wireless treatment process, according to the Wirhe framework, resulting in a 20 % resource savings. The very reasonable payback time for investments is only 2 years (Alasaarela & Oliver, 2009).

Real-time, wireless health care will benefit patients in numerous ways. Also the motivation and efficiency of health care professionals will improve markedly, as they can focus on care giving instead of bureaucracy. The main benefit will be faster, better and more efficient treatment processes, which will be of higher quality. Accordingly, waiting lists for treatment will shorten. In the future, wireless technology will improve productivity in health monitoring, outpatient activities and hospital activities.

In fact, wireless technology can be an important enabler of the structural change of public health care worldwide.

ACKNOWLEDGMENT

The authors would like to thank Riku Mäkelä, Tekes, Finland, for his great contribution in planning and practical implementation of the Wirhe project. In addition, they send their warmest thanks to the 105 experts, who gave their valuable contributions by participating in interviews and queries.

Chapter 3.6

Confirmatory Factor Analysis to Establish Determinants of Wireless Technology in the Indian Healthcare

Raj Gururajan
University of Southern Queensland, Australia

Tiana Gurney
University of Southern Queensland, Australia

Abdul Hafeez-Baig
University of Southern Queensland, Australia

ABSTRACT

This study reports the determinants of wireless technology in the Indian healthcare validated by a second order regression model. In order to assert the determinants, a qualitative study was conducted with 30 physicians using interviews to arrive at a set of barriers and drivers. Further analysis of the qualitative data indicated that there is a third component emerging, namely, clinical influence. The interview data was used to develop a survey instrument and this was administered on the Indian clinicians with 200 completed surveys. This data was used to establish the sub-components of the three major determinants as identified in the qualitative study. This is reported in this article.

INTRODUCTION

In the last few years, high expectations, technological developments, and effective and efficient services have been shown to be prerequisites for improvements in the healthcare domain (Rogoski, 2005; Versel, 2008). Latest trends in the healthcare sector include the design of more flexible and efficient service provider frameworks aimed at providing health services to all stakeholders. In order to implement such frameworks, wireless technology is increasingly being used in the healthcare sector. A decrease in the cost of wireless devices and improved awareness of the benefits by using related wireless applications are two of the contributing factors towards the increased use of wireless technology in this sector (Gururajan, Quaddus, Fink, Vuori, & Soar, 2005; R. Gururajan, Hafeez-Baig, & Gururjan, 2008). Even though the future of this technology and its usability is promising, its adoption is still in its infancy, which is attributed to the complex and critical nature of the healthcare environment. In the current competitive and complex business environment, technology developments have played a critical role in delivering high quality of care (Reinecke, 2004). However, there is limited knowledge and empirical research on the effectiveness and adoption of wireless technology in general, and in the Indian healthcare system in particular.

Recent research has established that investment in emerging Information Technology (IT), including Information Systems (IS), can lead to productivity gains only if they are accepted and effectively used by respective stakeholders. Consequently, acceptance and utilization of IT/IS in the healthcare environment have been central themes in the information systems literature. Therefore, the fundamental focus of this research is to investigate and examine the influence of internal and external determinants on the usefulness of wireless technology. Further, this research also assesses how its acceptance contributes to the adoption of wireless technology. We believe that this research is the first of its kind attempted in the Indian healthcare domain and it employs empirical evidence to explore the impact of wireless technology and its usefulness in the Indian healthcare system. The Indian healthcare domain is at the forefront in adopting the latest medical technologies and applications, as evidenced by media reports and, as such, it constitutes an excellent context for validating existing adoption theories and extending them.

The main contribution of this research includes the identification of a set of drivers and barriers to using wireless technology in a given Indian healthcare setting. In addition to this, for the first time, a set of clinical factors influencing the adoption of wireless technology has been identified and validated using a second order regression model.

LITERATURE REVIEW

The concept of wireless technology in healthcare is discussed in many studies (Dyer, 2003; Hu, Chau, & Sheng, 2002; Sausser, 2003; Simpson, 2003; Siracuse, Pharm, & Sowell, 2008; Versel, 2008; Wisnicki, 2002; Wu & Wu, 2007; Zhang, 2007). For example, Wisnicki (2002) provides details of how broadband technology, an essential component of wireless technology, can be used in healthcare. While prior studies agree that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such applications (Gururajan, Toleman, & Soar, 2004; Gururajan, Moloney, & Kerr, 2005). In general, the majority of the works reviewed are descriptive about the benefits of wireless handheld devices in healthcare in general, and medicine in particular. There are only a small number of studies that provide evidence-based information concerning these devices in healthcare (Fischer et al., 2003; Sax et al., 2005)(Hafeez-Baig, 2007). Furthermore, five major studies in the area of healthcare (evaluated by (Spil & Schuring, 2006) testing the Technology Acceptance Model (TAM) produced findings which were inconsistent with the body of knowledge in non-healthcare settings. With 'Perceived Ease of Use' and 'Perceived Usefulness' as the major TAM attributes, these studies found that in the health environment, 'Perceived Usefulness' is an important attribute in technology adoption, while 'Perceived Ease of Use' was found to have no effect (Spil & Schuring, 2006). This is different to findings reported in non-health IS studies, where both attributes were found to be reliable technology adoption predictors. Therefore, further empirical investigation is required to explain the reasons why this variation exists in healthcare. In addition, there is a need to explore if further attributes exist which may influence the adoption of wireless applications in the healthcare environment.

TECHNOLOGY ADOPTION IN HEALTHCARE CONTEXT

In healthcare literature, the discussion on wireless technology falls into three periods. For example, studies prior to and including 2000 discussed the status of wireless technology and the possible role the technology can play in healthcare. Studies between 2000 and 2003 discussed how wireless technology can be deployed in healthcare and the potential benefits the technology can bring to healthcare. It should be noted that these studies were only 'discussion' type studies. Majority of these studies did not provide any empirical evidence as to the use or acceptance of wireless technology in healthcare domains. Studies from 2004 till current date have collected data to establish the usefulness of wireless technology in healthcare. These studies, to some extent have focussed on the PDAs as these devices have been found to be useful in nursing domain for clinical data management.

The studies between 2000 and 2003 discussed a number of potentials of wireless technology in clinical domains. For example, how broadband technology can be used in healthcare was discussed by (Wisnicki, 2002), ability to address prevailing healthcare staff crisis by adopting intelligent solutions using agent and wireless technology that can identify the need and match the need with available resources in a timely and efficient manner was outlined by (Davis, 2002), better compliance with the rigorous regulatory framework was highlighted by (Wisnicki, 2002), reduction in medication errors and hence the benefits that can be realised was discussed by (Turisco, 2000), provision for greater flexibility and mobility of healthcare workers in performing their work was portrayed by (Athey & Stern, 2002), effective management of the increasingly complex information challenges and improved access to those information from anywhere at anytime was discussed by (Stuart & Bawany, 2001). Our review clearly identified that all these studies were only implying the potential of wireless technology and did not provide any empirical evidence.

While prior studies agreed that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such wireless applications in order to establish the adoption of technology in a given healthcare context (Gururajan et al., 2004; Gururajan et al., 2005). During the period of 2004 – 2006, studies emerged in the area of technology acceptance, specifically focussing on the acceptance of wireless technology in healthcare domains. These studies were empirical in nature and were testing the available models of technology acceptance or a variation in order to ascertain whether previous models hold good for a new technology in a specific domain . These studies were reported in a book titled 'E-Health Systems Diffusion and Use', published by Idea Group Publishing in 2006 (Spil & Schuring, 2006). These studies are summarised below:

Predicting Internet Use: Applying the Extended Technology Acceptance Model to the Healthcare Environment (Chismar & Wiley-Patton, 2006) – This study empirically established that only perceived usefulness is significant and ease of use was not significant.

The dynamics of IT adoption in a major change process in health delivery (Lapointe, Lamothe, & Fortin, 2006) – This study established that TAM as devised by (Davies, Bagozzi, & Warshaw, 1989) is not adequate for health systems because adoption/resistance factors may be group related as opposed to the fundamental basis of TAM which is individualistic, influence of intra and inter organisational factors, linkages to cultures, environmental factors as well as the complexity of the environment.

Introducing electronic patient records to hospitals: Innovation adoption paths (Suomi, 2006) – This study found that relative advantage, strong network externalities available, rich availability of information through different communication channels are key factors for innovation and adoption. It should be noted that these are not discussed in the TAM models.

User acceptance and diffusion of innovations summarised (Spil & Schuring, 2006) – This summary established that perceived usefulness is a predictor of technology acceptance in healthcare. Ease of use was not found to be significant.

Understanding physicians' use of online systems: an empirical assessment of an electronic disability evaluation system (Horan, Tule, & Hilton, 2006) – This study found that in order to diffuse technology in an organisation, it is important to ascertain physicians' behaviour, their workflow practices and their perceptions regarding the value of specific information systems.

In essence, the recent studies appear to be indicating that the current models of technology acceptance or its derivatives are not suitable to predict the adoption factors of wireless technology in healthcare environment. Strong support can also be derived from three specific studies that have tested TAM models in healthcare. The first study conducted by (Jayasuriya, 1998) established that ease of use was not significant in a clinical domain. The second study by (Chau & Hu, 2002) echoed similar sentiments. The third study by Hu et al. (Hu, Chau, & Tam, 1999) also found similar findings.

Further, recent studies conducted by (Howard, Gururajan, Hafeez-Baig, & Howard, 2006) also established that ease of use was not significant while determining factors of adoption in a clinical domain in regard to wireless technology. Further, (Ivers & Gururajan, 2006) also found that there are other factors beyond the TAM models influencing the acceptance of technology (Versel, 2008).

Interviews conducted with Queensland nursing staff members in Australia (Gururajan, Moloney, & D. Kerr, 2005) revealed that clinical usefulness of wireless technology is far more significant than ease of use factor as established in TAM. Another focus group discussion with the Western Australian senior health managers (R. Gururajan, M. Quaddus et al., 2005) also indicated that aspects of clinical usefulness such as integration of clinical data may be a significant factor than the ease of use factor. (Howard et al., 2006) also identified clinical usefulness is far more influencing than the ease of use factor while determining factors of adoption of wireless technology in the Indian healthcare domain.

However, the recent findings that the ease of use factor not showing strong significance in healthcare domain while determining wireless technology adoption warrants explanation as this is different to many other reported studies in the generic IS domain where both attributes (ease of use and perceived usefulness) were reported to be reliable predictors.

This variation requires further empirical investigation in order to explain the reason behind this variation specific to healthcare. Therefore, there is a need to identify attributes that assist in the adoption of wireless applications in healthcare environment. We argue that the initial validity of many technology acceptance models was predominantly established by testing the model with students as surrogates in a generic software application domain. This environment is very different to the healthcare environment, where the skills are at different levels. Further, the healthcare environment is complex, sensitive and time critical. These could be some of the reasons why TAM did not perform as expected in healthcare settings.

In addition, in the recent variant of technology acceptance, namely, UTAUT, (Venkatesh, Morris, Davis, & Davis, 2003) reviewed eight prominent models of user acceptance and managed to create a unified view. The unified model comprised of seven constructs. The first four – performance expectancy, effort expectancy, social influence and facilitating conditions – were theorised to be direct determinants. The last three – attitude towards technology, self efficacy and anxiety – were theorised to be indirect. All the seven constructs were found to be significant determinants of technology usage by Venkatesh et al ((Venkatesh et al., 2003).

In terms of attitude, Venkatesh et al. (Venkatesh et al., 2003) defined it as an individual's overall affective reaction to using a system. The model depicts four constructs relating to this determinant – attitude towards behaviour, intrinsic motivation, affect towards use and affect. (Spil & Schuring, 2006) verified that in three cases the relation between attitude and behavioural intention is significant. Therefore, this determinant cannot be indirect. If there is significance between attitude and behaviour intention, then there is a direct relationship.

Therefore, there appears to be a basis to identify factors that contribute to the adoption of technologies in healthcare settings. Given that wireless technologies have started making in-roads in healthcare, the overarching purpose of the research is to identify the factors that influence the adoption of wireless technology in the Indian healthcare system. The rationale of the purpose is justified by the fact that India is a leader in software technologies, especially medical applications. Further, India is emerging as 'health tourism', due to the advancement in medical technology and reduction in cost in offering high quality health services—as highlighted by various print media. However, our initial review of available literature indicated that this area is under-researched. Collectively, these aspects led to the following research question:

- What are the determinants for the adoption of wireless technology by physicians in the Indian healthcare system?

The first stage of this study is focused on answering the research question qualitatively and the second stage on answering the research question quantitatively. Details as to how the research question was answered are provided in the research methodology section below.

METHODOLOGY

An examination of existing IS studies indicated that there is a necessity for a suitable research method. Most of the reviewed studies follow a quantitative approach which involves an instrument being administered onto a domain with perhaps a lesser understanding of the domain issues. For this study it was felt that if technology issues are to be studied with respect to a specific domain, then user involvement with the technology issues forms a major part in establishing the adoption (or inhibiting) factors. By necessity, this would occur prior to administering quantitative instruments (e.g. survey). This, in turn, requires an understanding of research philosophy, values of inquiry that would guide the study, and the choice of relevant research techniques required to conduct the investigation in order to answer the research questions.

Further, there appears to be limited information available in the Indian IS domain to guide the principles of this study. This study is relatively new and, hence, requires a rigorous justification as to the choice of research methods employed. We also believe that due to aspects associated with various regulatory issues impacting the Indian health system, unique factors of technology acceptance, as well as usefulness, may emerge. Our initial meetings with Indian physicians also suggested that there is a divide in terms of technology usage between private and public hospitals, where private hospitals are rich in technology use and public hospitals are not. On the other hand, in many traditional studies in IS, either quantitative or, to some lesser extent, qualitative methods are used—but not both. In recent years this has been cited as a weakness (see (Mingers, 2001) for a detailed argument on this). Taking this into account, this study investigates the suitability of both approaches in order to answer the research question.

We recognise that the foundation for any research will be grounded on the researcher's fundamental philosophical view of the world (Myers, 1997). The choice of tools, including research techniques, instruments, and methods such as qualitative and quantitative, are not inherently linked to a particular philosophical position, as these positions are generic in nature. It is the contextual framework within which they are applied that provides consistency to an inquiry. While the choice of tools and methods are not linked to the philosophical view, the articulation—which is commonly the process of explaining choices of research methods and its related choice of research instruments—helps determine the philosophical disposition. This is usually achieved by asking questions on the beliefs, perceptions, experiences, advantages and disadvantages in order to determine this disposition. This may even include a researcher's personal experience within that domain, or their expertise in explicating the information using any approach that may be suitable to that domain. This has prompted us to follow a qualitative approach as the first phase of the study. We argue that this approach facilitates direction to the second phase of the study where quantitative evidence can be collected to establish causality between the dependent and the independent variables.

The research question dictates the need for quantitative research methods, while the behavioural component of the same investigation dictates qualitative research methods. The rationale for this approach is based on the notion that behavioural components require a thorough understanding of how users apply wireless technology in a given setting in order to understand behavioural issues. To extract 'tacit' aspects, this is best accomplished by applying a qualitative approach. A quantitative instrument can then be developed to extract the quantitative aspects, such as the opinion scores.

Health professionals view the term 'wireless technology' in different ways, either as a product or a process. The combined domain of wireless technology and healthcare is relatively new in the Indian IS domain. While IS studies have discussed the impact of Information & Communication Technology (ICT) tools and associated behavioural intentions on healthcare users, limited information can be found as to how the combination of wireless technology and healthcare settings would influence users who are already conversant with novel and advanced medical technologies (Spil & Schuring, 2006). The workplace or organizational factors that influence such combinations are yet to be explored in detail. Such an exploration has close association with the choice of research method as these methods pave the way for proper inquiry into the factors that determine technology acceptance in a given setting. On this basis, the suitability of one research method over another has to be carefully weighed. Consequently, this study identified an exploratory approach to be suitable for the initial investigation. This approach is particularly favourable in confirming the direction of the study, variables chosen for the study, and in helping refine the literature. The exploratory study can also possibly eliminate some variables, while providing opportunities for including emerging variables.

Qualitative Data Collection

As argued, for the first stage of this research the investigators used a qualitative approach to collect initial sets of themes for the adoption of wireless technology in the Indian healthcare system. For this purpose, 30 physicians operating in Indian healthcare were identified randomly. These physicians were interviewed by an independent member (external to the team) who identified the attributes for the adoption of wireless technology by physicians in the Indian healthcare system. This approach was deliberate to address criticisms of 'bias' in the interview process. Further, due to linguistic issues, we required a person with proficiency in both Indian language and English. The interview questions were derived from existing literature. The first stage of the data collection concentrated on Indian hospitals with some form of wireless technology already in use. The physicians were also chosen based on their wireless technology awareness or working experience. They were drawn from both private and government hospitals. The interviews were conducted over a 45-60 minute period and recorded using a digital recorder. Once they were recorded, the interviews were transcribed.

Quantitative Data Collection

This study developed a survey instrument from the interview data. The main reason for this digressed attitude was that previously tested instruments in the technology domain were not relevant to healthcare setting and were found to be inadequate in answering the research question. The data from the interviews were used to develop specific ranges of questions to gather a more detailed view from the wider population. This survey instrument was pilot tested to capture the information reflecting the perceptions and practice of those adopting the wireless technology in the Indian healthcare system. Particularly, it focussed on what internal and external environmental factors affect the adoption of wireless technology and the extent of this influence. The survey was then distributed to over 300 physicians randomly chosen from the telephone book and a total of 200 responses were received. The survey responses were then entered into a spreadsheet file. A Visual Basic interface was written to generate numerical codes for various elements of the survey for data analysis using SPSS. The coded spreadsheet file was then copied onto a SPSS file format.

DATA ANALYSIS

Qualitative data was analysed using the NVivo (version 7) application, which helped identify the initial themes from the interviews. Quantitative data were analysed using SPSS, which helped identify the factors and their correlation for the adoption of wireless technology in the Indian healthcare setting.

Qualitative Data Analysis

Qualitative data was manually coded to extract themes that had an impact on wireless technology acceptance as stated by the physicians. In total, 63 themes were extracted from the interviews. The initial themes include awareness, cost factors,

Table 1. The factors driving and inhibiting wireless technology adoption in healthcare

Drivers	Barriers
Save-time Improve-clinical-workflow Efficiency-in-communication Delivery-of-high-qual-info Better-quality-of-service Save-effort Improve-clinical-performance More-contact-time-with-patients Improved-delivery-of-information Reduce-overall-cost Positive-impact-on-patient-safety Reduce-inaccuracies Improve-public-image Reduce-medical-errors Easy-access-to-data Attract-more-practitioners Reduce-workload	Legal barriers Administrative purpose Communication with physicians Patient education Communication with colleagues Obtain lab results Note taking Electronic medical records Device usage barrier Benefit evaluation barrier Resource barrier Electronic prescribing

advantages and disadvantages, medical errors, information sharing, current state of technology, usefulness and role of wireless technology, and technology awareness. On the basis of the interviews and the literature review, the themes were classified into drivers and inhibitors as shown in the following table. This list of drivers and inhibitors was expected to provide a direction for the development of the survey instrument for the collection of quantitative data to capture the wider community views and to generalize the outcome of the research. This grouping is presented in Table 1.

The content of the Table 1 is consistent with findings of previous studies conducted by Gururajan et al. (2004; 2005). This prompted conducting a quantitative study in order to establish causality among dependent and independent variables, as well as external validity and generalisability.

Quantitative Data Analyses

In order to ensure statistical reliability, suitable tests were run on the entire instrument, as well as selected group of variables. For example, the reliability test returned a Cronbach alpha value of 0.965 for the instrument indicating high reliability (Zikmund, 1994). We ran this test because the instrument was generated from the interview data and, hence, it was necessary to establish statistical reliability. In addition, reliability tests were also run for three factor groupings, namely, drivers, inhibitors of adoption and other technology factors. The reliability tests returned values of 0.941,

Table 2. The factors driving and inhibiting wireless technology adoption in healthcare from data analysis of survey result

Drivers	Loading values	Barriers	Loading values
Improve-clinical-workflow	.798	Poor technology barrier	.605
Tech-support	.764	Time for training barrier	.572

Org-culture	.464		

0.447 and 0.536, respectively, indicating that the data were suitable for factor analysis testing.

As a second step, survey data were analysed for factor analysis using SPSS. It is evident from the table below that two factor component matrix identified drivers and the barriers for the adoption of wireless technology in the Indian healthcare setting. This finding is consistent and aligned with the findings of the qualitative data collection stage (i.e. first stage) of this research.

The drivers were further tested for factor groupings. The analysis resulted in Table 3.

The driving factors of adoption yielded three categories of factors, namely, 'organisational', 'management' and 'clinical'. The organisational components include wireless technology drivers that can generate specific benefits for organisations. The management components represent the benefits that healthcare managers can realise using wireless technology. The clinical components encompass clinical drivers of using wireless technology.

A similar factor model was generated for the inhibitors. The model resulted in Table 4.

Similar to the drivers, the inhibitors also resulted in three specific categories. The 'technology' category includes technology factors that inhibit wireless adoption in the Indian healthcare. The 'resource' category encompasses resource barriers that are currently being encountered in the healthcare setting. Finally the 'usage' category is comprised of inhibiting factors, which are associated with usage issues.

In addition to the two factor groups, namely drivers and inhibitors, we also identified a third. We named this 'clinical usefulness' and its components are shown in Table 5 below.

This factor group yielded three components. The first component deals with the general communication aspects facilitated by wireless technology in healthcare settings. The second component refers to clinical communication using wireless technology. The third component is specific to records management. In summary, the data analyses yielded three specific categories of factors which can affect the adoption of wireless technologies in the healthcare setting. These comprise adoption drivers, inhibitors, and clinical usefulness.

Hypotheses Formulation and Testing

Based on the evidence collected, the three sets of factors, namely, drivers, barriers and clinical usefulness, contribute to the acceptance of wireless technology in healthcare. We hypothesise that the drivers positively impact clinical usefulness,

Table 3. The factors driving wireless technology adoption in healthcare from data analysis of survey result

whereas the barriers have a negative impact on it. While the drivers and barriers include factors beyond the technology aspects, their respective influences are restricted to the clinical domain as this is where the usefulness of wireless technology can be experienced. Therefore, the following two hypotheses were generated for testing:

H1: *Drivers of wireless technology positively impact clinical usefulness.*

H2: *Barriers to wireless technology negatively impact clinical usefulness.*

A "Structural Equaction Modeling (SEM) model was developed in order to test the hypotheses. The rationale for using SEM includes: SEM is used for confirmatory factor analysis (CFA); the pattern of loadings of items on the latent constructs is explicit; SEM provides strong convergent and discriminant validity; p-value of t-value is significant (over 0.50

level) for constructs; and measurement items load highly on theoretically assigned factors and not highly on other factors.

SEM MODEL DEVELOPMENT

In order to develop the SEM model, an AMOS version 16 was used. Initially, the individual drivers, barriers and clinical usefulness were tested for CFA (Confirmatory Factor Analysis) scores and these were found to be reliable. When the CFA was found to be satisfactory, a model was built with clinical influences as dependent variable on drivers and barriers. The final outcome is shown in figure below.

Figure 8 shows that the factor loading (the number on the path: for example, for the construct Drivers, has 0.16, 0.21, and .48). The drivers and clinical usefulness load highly (over 0.8 for most of the items), indicating a high reliability. Further, all variables have a t-value of over 2.0 to indicate high convergent validity.

Upon construct validation, a simple SEM (consolidated) model was developed to test the hypotheses. The model consists of clinical usefulness as the dependent variable, and drivers ("Organizational" (O), "Clinical" (C), and "Management" (M)) and barriers ("Usage" (U), "Technology" (T), and "Resources" (R)" (M) as independent variables. The model was run with AMOS Graph program and the screenshot shown in Figure 2 displays the values along the link from Drivers to Clinical Usefulness, and Barriers to Clinical Usefulness.

According to (Holmes-Smith, 2000) to analyse a model for the data fit, the following five measurements need to be analysed carefully:

- Chi-square (X^2 acceptable fit: $p > 0.05$)
- Normed Chi-square (X^2/df acceptable fit $1 < X^2/df < 2$)
- Goodness-of-fit index (GFI- acceptable fit value, $0.95<GFI<1$, reasonable fit value would be $0.90<GFI<0.95$)
- Tucker-Lewis Index (TLI- acceptable value; $TLI>0.95$; reasonable value of fit $0.9<TLI<0.95$ and lack of model parsimony would be $TLI>1$)
- RootMean-Square Error of Approximation (RMSEA- acceptable fit value: $RMSEA<0.05$; reasonable level of: $0.05<RMSEA<0.08$)

Above criteria was used to analyse the data fit for each of the construct before computing the composite variables. Figures below show the values of each variable separately for initial model and the improved acceptable model for each of the composite model.

Data Reduction and Technique for Compatibility Variable

Diagram 1, 2 and 3 above shows the data fit for the improve model. This was achieved by ap-

propriate after the analysis of the suggestions provided "Modification Indies" provided by SEM along with the analysis of the adequate theoretical support. Objective was to achieve the improved measure of data fit for the empirical data while keeping integrity of the theoretical support. Results shows that changes in the model has resulted all the five indicator showed that empirical data fitted the improve measurement model.

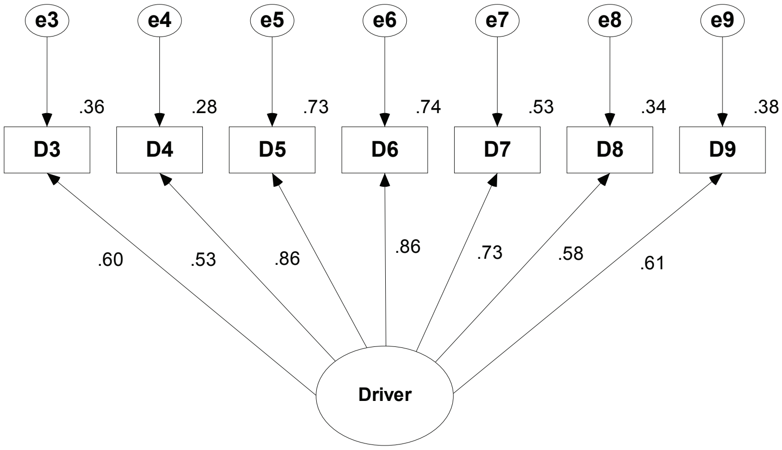
Once the data reduction techniques was used to individual variables and data was found to fit as per (Holmes-Smith, 2000) incies, we draw the initial SEM model with Barriers (B) and Drivers (D) as an independent variables and "clinical Usefulness (CU) as dependent variable in the model.

As can been seen from the above Figure 4 above five of the popular measured provided by (Holmes-Smith, 2000) is provided under the diagram. First two values (Chi-square, and Normed Chi-square) were not at acceptable level, however values of other three (Goodness-of-fit index, Tucker-Lewis Index, and RootMean-Square Error of Approximation) were not at acceptable level. It was concluded that the data did not adequately fit the model.

Diagram 5 above shows the data fit for the improve model. This was achieved by appropriate after the analysis of the suggestions provided "Modification Indies" provided by SEM along with the analysis of the adequate theoretical support. Objective was to achieve the improved measure of data fit for the empirical data while keeping integrity of the theoretical support. Results shows that changes in the model has resulted all the five indicator showed that empirical data fitted the improve measurement model.

The diagram in the above figure provide the visual results of aggregating the items of the measurement model of stage two of the process, which provided the evidence for the data fit the model for the empirical data. As a result we produced a composite variable for "Drivers", "Barriers", and

Figure 2. Drivers: $X^2 = 27.5$, $df = 14$, $p = 0.017$, $X^2/df = 1.964$, *GFI = 0.961, TLI = .963*



RMSEA = 0.070 (Data fit the improved model)

Figure 3. Drivers: $X^2 = 37.3$, $df = 25$, $p = 0.054$, $X^2/df = 1.492$, *GFI = 0.959, TLI = .900, RMSEA = 0.050 (Data fit the improved model)*

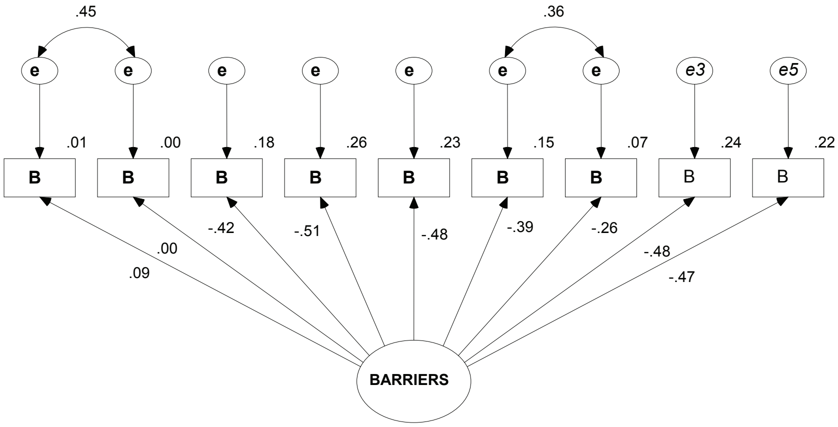


Figure 4. Clinical Usefulness: X² = 30.8, df = 12, p = 0.054, X²/df = 1.492, GFI = 0.959, TLI = .900, RMSEA = 0.050 (Data fit the improved model)

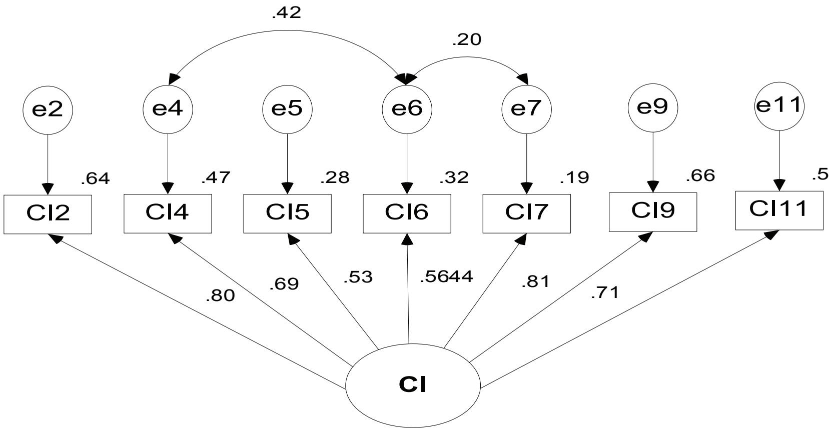

Figure 5. Clinical Usefulness: X² = 9.0, df = 7, p = 0.252, X²/df = 1.28, GFI = 0.986, TLI = .992, RMSEA = 0.038 (Data fit the improved model)

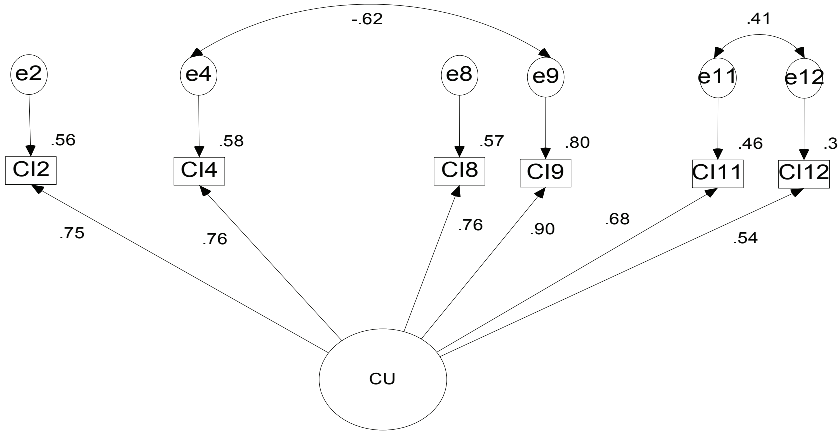

"Clinical Influences" in the complete model for the existing data in order to analyse the influence of drivers and barriers on the clinical influences. Data fit of the model and the indices measures are X² = 41.6, df = 23, p = 0.010, X²/df = 1.810, GFI = 0.955, TLI = .932, and RMSEA = 0.065.

In the above diagram, the latent variable "Clinical Influences" (CI), set of possible predictors, "Usage" (U), "Technology" (T), "Resources" (R), "Organizational" (O), "Clinical" (C), and "Management" (M) are the observed variables. CI is itself indicated by three items, "Technological Management" (TM), "Clinical Communication" (CC), and "General Communication" (GC). As can be seen, the overall structural model fit was good. Criteria used to determined: X² = 41.6, with 23 df, X²/df = 1.810, CFI = , AIC = , GFI = 0.955, TLI = .932, and RMSEA = 0.065, . Based on these results we proceeded to test the two hypothesis mentioned above (H1, and H2) previously proposed. These hypotheses stated that drivers have positive impact and barrier have negative impact on the clinical usefulness. The result supported theses hypothesis, for example in the case of drivers, "Organizational, (t=1.56, p > 0.01)", "Clinical, (t=2.14, p < 0.01)", and "Management, (t=4.4, p < 0.01)" shows that clinical and management drivers are positively contributing to the clinical usefulness, where as the contribution of organizational is not significant. Whereas barrier have vary limited scope, “Usage, (t= -1.98, p > 0.01)”, “Technology, (t=3.13, p < 0.01)”, and “Resources, (t= -0.685, p > 0.01)”. Drivers and barriers are the predictive of the clinical usefulness; results indicate that drivers have stronger influence on the clinical usefulness of the wireless technology than the barrier.

Figure 6. SEM Initial Model: X² = 548.0, df = 202, p = 0.000, X²/df = 2.713, GFI = 0.817, TLI = .755, RMSEA = 0.094 (Data did not fit the improved model)

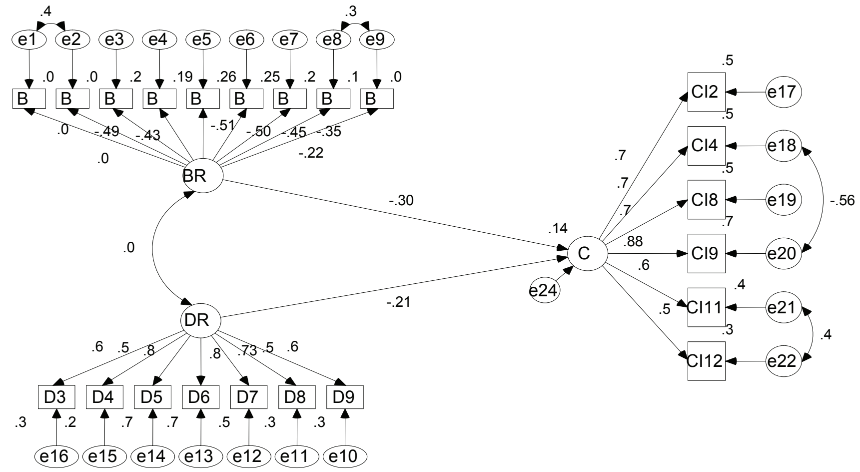

Figure 7. SEM Model: X² = 78.9, df = 50, p = 0.006, X²/df = 1.577, GFI = 0.939, TLI = .910, RMSEA = 0.055 (Data fit the improved model)

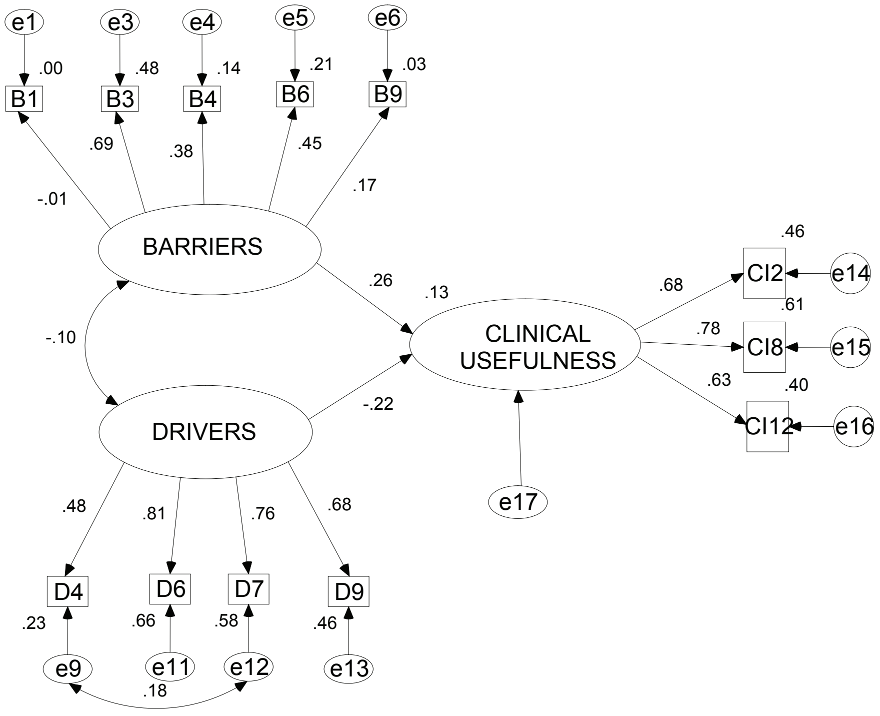

Figure 8. SEM Model: $X^2 = 41.6$, $df = 23$, $p = 0.010$, $X^2/df = 1.810$, $GFI = 0.955$, $TLI = .932$, $RMSEA = 0.065$ *(Data fit the improved model)*

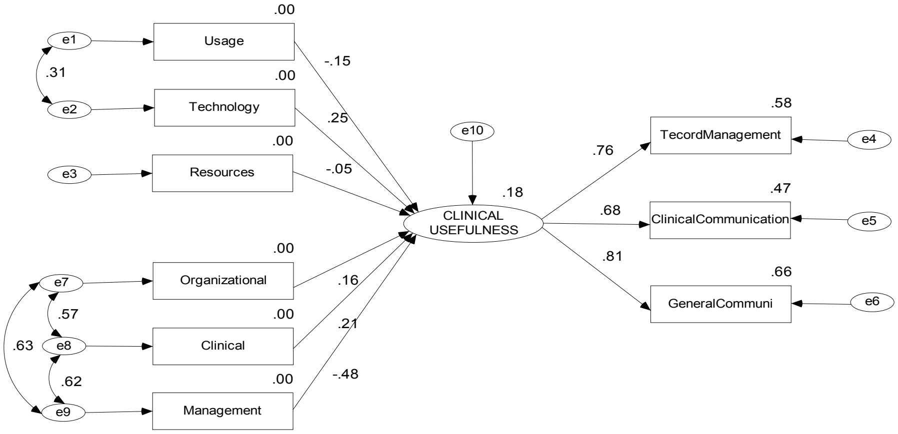

DISCUSSIONS

The Confirmatory Factor Analysis agrees with the outcomes derived from the interview qualitative data in that the set of drivers, barriers and clinical influences are indeed the determinants of wireless technology in the Indian healthcare. Within these three determinants, we are able to identify usage, technology and resources influencing the clinical usefulness. The predictor 'usage' is influenced by the usefulness of technology as identified in recent studies. This study also conforms to the notion that 'ease of use' is not a major influence on technology adoption in the Indian healthcare.

In terms of clinical usefulness, we are able to assert that record management, clinical communication and general communication to be the three major aspects. Our qualitative study had already given us some indication to these predictors. Our interviews revealed that the greatest benefits of wireless technology in clinical settings would be records management because it is possible for clinicians to access patient data at the point of care. We also understood that it is possible to use smart phone type technology to send patient conditions to other clinicians in order to get advice. In terms of general communication, our interview transcripts indicate that it is now possible to provide patient education using the wireless technology.

Thus, wireless technology can be used to facilitate access to clinical information and communications between clinicians, maximise clinician time, increase patient safety, and accomplish the strategic and business goals of health organisations. Taken together, these factors have a direct impact on clinical usefulness and its effectiveness. However, achieving clinical usefulness with wireless handheld devices can be a challenge and has several implications.

Firstly, the highest security standards must be achieved. This includes direct end-to-end data encryption, authentication, authorisation, maintenance of audit logs and session management (Chen et al. 2004). While high security standards are essential, their implementation is likely to affect usability. For example, the download and encryption of patient information from the server where it is stored into a wireless handheld device may not be prompt. Sax et al. (2005) argue that clinicians may experience increasingly longer time lags when they carry out increasingly more complex procedures. This is likely to adversely affect clinical usefulness and, hence, decrease user acceptance.

Closely associated with security is also the issue of patient confidentiality, which is of significant importance and concern. Although wireless handheld devices have locking security features and password protection functions which activate during periods of inactivity, the frequent use of these functions during the clinicians' busy daily schedules may have an impact on clinical usefulness.

A crucial lesson learnt in this study was in the use of qualitative and quantitative components. We approached the healthcare professionals to seek their opinions on the benefits of using wireless technology. This stage was followed up with a survey instrument. We conducted a first order regression analysis to regress the 90 or so factors explored into a set of manageable factors. The lesson was quite valuable because as outsiders (coming from an Information Systems background), we were able to appreciate the complexities of healthcare information systems. Similarly, our open minded approach enabled healthcare professionals to appreciate IS related aspects. We also found out through our informal discussions that the study would have been a stereo-type study had we approached a quan-qual type mixed method because we would have been restricted by what was available in the literature to derive our quan part and this would have restricted our qual part.

To our own surprise, we found both IS and health literature to be limited in catching up with wireless technology related attitude and perception data. While the technology literature such as the IEEE provided us with the technical knowledge, human aspects have not yet been discussed in IS and healthcare literature. The results established through a second order regression are consistent with what we found for the Australian Healthcare (published elsewhere).

We measured only perceptions and attitudes in this study. While there is sufficient information available through interviews on the type of savings and benefits that can be attained by using wireless technology in healthcare, it is still not clear as to the exact quantification of these. Therefore, it would be useful to measure this by employing a wireless technology in a clinical setting and then collecting some evidence as to the savings and benefits.

ABSTRACT

In the last years, much work has been done to create a complete solution in m-Health environments. The problem can be summarized as follows: any health professional (medical specialist, sport trainer, nutritionist, etc.) should be able to control a series of measurements related to a person's health. The characteristics of these people vary from those patients with limited knowledge of the control processes and low mobility to sportsmen highly involved in the process and great mobility in the moment the measurements take place. This wide set of characteristics raises two basic challenges: the use of measurement equipment easily adaptable to the control system and the necessity of adding mobility support mechanisms to the design. This chapter focuses on studying these two challenges, illustrates them with several use cases and contributes to the mobility support problem with a new algorithm.

INTRODUCTION

Telecommunications and advanced information technologies have increasingly been used for clinical activities and research to improve healthcare delivery. The design of these e-Health systems has boosted many evolutions in the last years towards integrated solutions and new application environments. Thus, Medical Devices (MDs) and Vital Sensors (VSs) at the Point of Care (PoC) end are now part of very diverse environments: home telemonitoring, mobile solutions (m-Health) for teleemergencies, or on-line follow up while patients

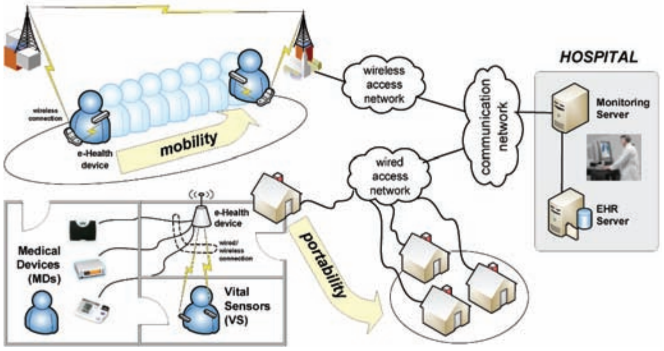
DOI: 10.4018/978-1-60566-046-2.ch027

carry out their daily living activities (Ruiz, Viruete, Hernández, Alesanco, Fernández, Valdovinos, Istepanian & García, 2006). These devices and sensors acquire huge amounts of very valuable information, without the need for manually writing down each measurement, contributing to the generation of the Electronic Healthcare Record (EHR). Moreover, as different manufacturers use their own software and communication protocols (building proprietary solutions that can only work alone or inside a single-vendor system), an important interoperability problem emerges, leading to the need of communication standards (Galarraga, Serrano, Martinez & Toledo, 2005), and their further adaptation to new wireless (Bluetooth, Zigbee, or WiFi) and wired (USB or Ethernet) communication technologies. Some of these standards are EN13606, the European standard for EHR communication (EN13606, 2007); and ISO/IEEE11073 PoC-MDC, the European CEN/TC251 family of standards for PoC-MD Communications also known as X73 (IEEE11073, 2007). Thus, this need for developing open sensor networks in healthcare environments has fostered the development of standard-based specific solutions (Martínez, Fernández, Galarrage, Serrano, Toledo & García, 2007) that allow transparent integration and interoperability inside e-Health systems with monitoring medical devices. Furthermore, the use of standards provides plug-and-play capabilities and auto-configuration features with the lowest level of user intervention, also taking into account users with no technical knowledge (the end user, without the support of a technician, should also be able to substitute or add a device in case of failure or due to a change in the follow-up design).

From this scenario, and in order to propose global e-Health solutions, all this interoperability effort must be integrated in a design scheme to support a network of compatible devices from different patients in different locations (see Figure 1). Thus, information data acquired from the different MDs and VSs is transmitted in a standards-compliant mode to a compatible e-Health device that acts as a gateway. This compatible e-Health device in each PoC connects to the monitoring server to manage different e-Health services, and its design must adapt to the new relevant scenarios in addition to those based on traditional fixed networking. Thus, the e-Health device design must support two additional connection modes: portable (in supervised environments but with changing requirements), and mobile (with changing both environments and requirements). First, in a portable networking scenario, the device design requires allowing intra-network connections and communications to any access network, in order not to depend on the specific requirements related to each fixed location. However, the design does not require continuing the ongoing communication between communicating peers during movements. In a complementary way, a mobile networking scenario requires services to continue ongoing communications while roaming, preferably without interruption or the degradation of communication quality. In fact, the first scenario can be regarded as a special case of the second scenario. Likewise, devices must adapt to the available (wired and wireless) connection technologies, and be able to communicate to several access technologies and seamlessly move between them in an Internet Protocol (IP) environment. These requirements involve the integration between heterogeneous networks, known as 'all-IP,' including mechanisms to provide mobility support for roaming devices and efficient seamless vertical handoff (or handover) schemes to enhance Quality of Service (QoS) and provide flawless mobility (Le, Fu & Hogrefe, 2006).

Today many things have changed in the traditional TCP/IP networks with the deployment of mobile devices, in particular in relation to the scenarios previously described and their service requirements when a mobile device moves across wireless networks. In this situation, its location may change frequently and, therefore, its IP address may change accordingly. Due to the changes of IP address, the ongoing connections of

Figure 1. Network environment for interoperable devices including portability and mobility



a mobile host can be broken and peer nodes may have difficulty to locate a mobile host. Therefore, two key issues for mobility support in wireless IP networks are: how to maintain the continuity of ongoing connections and how to provide location management. To date, many mobility management schemes have been proposed to address these two issues. Many of them have been designed and implemented, and some of them are starting to be deployed. Nevertheless, they demonstrate both pros and cons in dealing with mobility support in terms of efficiency, functionality, security, and so forth. Le et al. (2006) reviews previous works that have developed different mobility solutions, discusses the strengths and weaknesses of implementing mobility at three different layers of the TCP/IP stack, and compares them on various aspects like performance, security, deployment, scalability, robustness properties, and so forth.

In addition, handoff schemes are required to preserve connectivity as devices move about, and at the same time curtail disturbance to ongoing transfers. Consequently, seamless handoff, with low delay and minimal packet loss, has become a crucial factor for mobile users who wish to receive continuous and reliable services. One of the key issues that aid in providing seamless handoffs is the ability to correctly decide whether or not to carry out vertical handoff at any given time. This could be accomplished by taking into consideration two aspects: connection maintenance and network conditions for vertical handoff decisions. These two schemes need to be tightly coupled in order to move seamlessly across different network interfaces. To attain a positive vertical handoff, the network state ought to be constantly measured by means of a suitable handoff metric. In multinetwork environments, this is very challenging and hard to achieve, as there is not a single factor that could provide a clear idea of when to hand off. Signal strength and available resources in the target cell, the main metrics in horizontal handoffs, cannot be utilized for vertical handoff decisions due to the overlay nature of heterogeneous networks and the different physical techniques used by each network. In vertical handoffs, many network characteristics have an effect on whether or not a handoff should take place. Thus, transmission rates, error rates, and other QoS parameters can be measured in order to decide which network can provide improved service levels. The cost of the different services to the user or risks in any wireless technology could sometimes be the decisive factor in the choice of a network.

The previous discussion leads to ask which IP mobility support mechanisms should be chosen for the e-Health device – monitoring server communication, and what specific characteristics should be considered in the handoff decision. Several relevant use cases as home telemonitoring (fixed or portable), and chronics and athletes' follow-up (portable or mobile) have been selected in order to define the specific requirements for the e-Health device – monitoring server communication. They will permit to choose the most suitable solutions for mobility support, propose the characteristics which are particularly important for vertical handoff decisions, and define the most appropriate algorithms for each use case. This methodology deals with the possible future integration of medical standards (X73 and EN13606) in systems provided with IP connectivity and mobility. IP mobility is responsible for carrying out the change between technologies in a transparent way to upper architectural levels, which is often denoted as Media Independent Handover (MIH) (IEEE802.21, 2007). In order to achieve that objective, an algorithm for IP connectivity and mobility management will be presented. It permits to maintain medical and vital data communications in spite of any possible changes in the available IP technologies of the e-Health device.

Thus, this chapter explains initially the requirements needed for Internet mobility support and reviews existing solutions in different layers. Then, it presents fixed/portable and portable/mobile use cases to define the specific requirements for the e-Health device—monitoring server communication. Furthermore, it classifies the characteristics for vertical handoff decision and categorizes them depending on their relevance and applicability. Finally, it defines an algorithm optimized for different e-Health use cases.

MOBILITY SUPPORT IN 4G HETEROGENEOUS NETWORKS

This section presents a summary of the primary aspects of mobility support. The different requirements and solutions for IP mobility are explained first. Vertical handoffs are needed when dealing with heterogeneous networks; therefore the desirable features of the vertical handoff decision are presented in the end.

Requirements and Solutions for IP Mobility

As mentioned, the traditional TCP/IP networks were originally designed for communications between fixed devices and are not appropriate for Internet mobility support. The original situation based on using only well-known single persistent IP addresses is no longer a viable solution. This address orientation was valid when four issues were considered invariants (Nikander, 2001): an address received was the address sent, addresses were stationary, source and destination were reversible, and all hosts knew to which address they should send packets to reach the wanted host. These assumptions cause four fundamental problems in the network layer (Henderson, Ahrenholz & Kim, 2003). The first concerns addressing: mobile hosts usually have an incorrect interface address when they attach to a new network. Second, when changing networks, the mobile host may become unreachable to the rest of the network unless the new address is somehow mediated to other nodes. The third problem is related to session management: as the current transport protocols use the IP address as part of the connection identifier, the change of address breaks active connections. Finally, mobile hosts must be able to authenticate themselves to their peers upon moving and maintain or re-establish network level security associations.

The main issue to be resolved in the current Internet addressing scheme is the separation of address and identifier concepts. Currently, devices connected to the network are identified by their IP addresses. When the mobile device moves between networks, its IP address changes and so does its identifier. The device has two choices to continue the ongoing communication with its peer: the new identifier is mediated to the peer or, alternatively, the device makes itself reachable via the original identifier. Therefore, in order to provide Internet mobility support, a number of fundamental issues arise, which can be summarized as the following functional requirements for Internet mobility support (Le et al. 2006):

- **Handover management.** The most important function needed to support mobility is to keep the ongoing communication alive while a Mobile Node (MN) moves and changes its point of attachment to the Internet. The main objective of handover management is to minimize service disruption during handover.
- **Location management.** Another important function needed to support mobility is the reliable and timely notification of the MN's current location to those other nodes that need it. Location management involves identifying the current location of the MN and also keeping track of their location changes as it moves on.
- **Multihoming.** The future mobile environment will be characterized by diverse wireless access networks, and the MN will be equipped with multiple interfaces supporting different wireless techniques. Thus, it is necessary to require multihoming support by which the MN can access the Internet through multiple links simultaneously and select and switch dynamic links while moving.
- **Applications.** The mobility management mechanism should be transparent, without requiring changes to current services and applications.
- **Security.** Any mobility solution must protect itself against misuses of the mobility features and mechanism.

While developing an Internet mobility solution, the performance metrics also deserve special attention. Some of the most relevant performance metrics for Internet mobility are the following:

- Handover Latency. It refers to the time elapsed from the last packet received through the old network to the arrival of the first packet along the new network during a handover.
- Packet Loss. It is defined as the number of packets lost while maintaining communication during a handover.
- Signalling Overhead. It is defined as the number of messages for the handover and location procedures.
- Throughput. It is the amount of data transmitted over a mobile Internet in a given period of time.

In addition to functional and performance requirements, there are some considerations to take into account for deploying a mobility mechanism in the Internet:

- Minimum changes to the applications. It is desirable not having to change every application when the mobility mechanism is applied in the Internet.
- Avoid adding third-party devices. Adding a third-party device into the network usually generates additional management overhead and security vulnerabilities, and should be avoided if possible.
- Easy integration into the existing infrastructure. Changes to allow integration into the existing infrastructure should be kept simple, as a well-deployed infrastructure implies a significant amount of investment, operational, and administrative/maintenance efforts if it is necessary to make updates to software or hardware in routers.

To date, many mobility management schemes have been proposed, in different layers for extending TCP/IP to support mobility. Because IP is the internetworking layer for the Internet, mobility solutions that build on the existing network layer are considered a natural approach. Mobile IP (MIPv4 and MIPv6) (Johnson, Perkins & Arkko, 2004; Perkins, 2002) and various enhancements to their performance (Gustafsson, Jonsson & Perkins, 2004; Jung et al., 2004; Koodli, 2005; Malki, 2005; Ramjee et al., 1999; Soliman et al., 2005; Valko, 1999) have represented "classic" means for supporting mobility. The Location Independent Network Architecture for IPv6 (LIN6) (Teraoka, Ishiyama & Kunishi, 2003) provides an alternative to mobility support to MIPv6. These protocols apply techniques such as proxies and tunnelling to deal with mobility. MIPv4 provides network-layer mobility and transparency to the higher layers. However, this solution introduces higher latency, extra overhead to the network, and it is vulnerable to single point of failure. Although many enhanced techniques and micro-mobility protocols can improve MIPv4 performance, MIPv4 still has weakness in terms of efficiency and complexity. MIPv6 has the advantages of inherent mobility, security support, and routing optimization compared to MIPv4. However, as in MIPv4, MIPv6 has the same problem of failure probability of communication and it has additional header overhead. Micro-mobility solutions improve the performance by minimizing signalling overhead, packet loss, and handover latency; but their scalability and complexity are a concern. In comparison with MIPv4/MIPv6, LIN6 is more tolerant to errors and it has less overhead due to its avoidance of the extension header and tunnelling.

As the transport layer is subject to the impact of mobility, much work has been carried out over the past few years on TCP performance improvement and mobility enhancement (Bakre & Badrinath, 1995; Caceres & Iftode, 1995; Funato, Yasuda & Tokuda, 1997; Haas, 1997; Maltz & Bhagwat, 1998; Snoeren & Balakrishnan, 2000; Yavatkar & Bhagawat, 1994), including efforts to enhance UDP for mobile environments (Brown & Singh, 1996). More recently, the mobility support for the new transport layer protocols of Stream Control Transmission Protocol (SCTP) (Stewart, Xie & Morneault, 2000) and the Datagram Congestion Control Protocol (DCCP) (Kohler, 2004) have been proposed. The basic idea of enabling transport-layer mobility is to remove network-layer dependences by using indirection, migration, tunnelling, multihoming techniques, and do forth. The TCP extensions proposed for improving transport performance on the mobile Internet cannot deal well with mobility on their own. Their main purpose is merely to minimize degradation of transport performance. Stewart et al. (2000) provides an alternative solution in the transport layer with Mobile SCTP (mSCTP). It can support seamless handover and improve transport performance. However, the current mSCTP proposal only illustrates the basic requirements for Internet mobility. Some essential issues are open to further study. However, mSCTP by itself does not handle location management. Thus, Koh & Xie (2004) proposes reusing MIP for location management in mSCTP. Similarly, the current specification of DCCP is at its primitive stage.

Because the traditional TCP/IP protocols are already heavily loaded down with functionalities, adding new functionalities to support mobility is very difficult. A new idea for mobility support is to introduce a new layer where Internet mobility is deployed. Thus, Host Identity Protocol (HIP) (Moskowitz & Nikander, 2005) can be considered as a layer 3.5 solution for mobility. It decouples network and transport layers by introducing a statistically global unique host identity. In this way, the transport connections are bound to host identity, not IP address. Therefore, the mobility issue can be solved by mapping different IP addresses to the unchanged host identities. However, it is not very simple to add a new layer since the functioning of the network and transport layers is in a way optimized to work together.

Due to the fact that applications can provide mobility support without any modifications of lower-layer protocols, different attempts have also been made at this layer. For example, Session

Initiation Protocol (SIP) (Rosenberg et al., 2002) can be extended to support mobility by resending the INVITE message to the peer to re-establish a session when the IP address of a mobile host changes. Nonetheless, it is adverse to real-time applications since considerable handover latency and overload occur with certain procedures (address renewal, location registration, etc.).

There is no single perfect solution so far; mobility support may require some rethinking of the Internet architecture. Network-layer solutions are based on routing mechanisms, so they require changes to the endpoints and routers for address binding. In addition, they need a third device of agents for packet forwarding and location management. Transport-layer solutions are based on an end-to-end model, so they require no change to intermediate routers, and they are absent from location management by themselves, so there is no need to deploy a third device. Therefore, transport-layer solutions require very little infrastructure change. New layer solutions need modifications of the endpoints and the addition of a third device. In addition, the introduction of a new protocol layer also destroys the traditional TCP/IP infrastructure. Similarly, the application solution of SIP employs a proxy server to relay flows and redirect servers to locate the MN; it also needs to add a third device and change the endpoint.

Vertical Handoff Decision: Desirable Features

All solutions for IP mobility require a handoff algorithm to change the location of a node as it moves or when its current performance degrades. But there are more characteristics that a properly designed handoff algorithm must take into account. These various desirable features depend on the context and, in general, the most relevant features of a handoff algorithm are the following:

- **Reliability.** This characteristic refers to the call quality after handoff. The handoff algorithm should improve, or at least maintain, call quality.
- **Seamless.** Calls should not suffer any kind of interruption or service degradation due to the handoff process. In this sense, the speed of the handoff algorithm is a critical point.
- Interference prevention. A properly-designed handoff algorithm should avoid causing interference to other devices and systems.
- **Load balancing.** The handoff algorithm should be able to balance traffic between different technologies or even cells of the same technology, paying special attention to the trade-off between cost and performance.
- **Improving performance.** The number of handoffs should be kept minimum to avoid heavy handoff loads and to minimize the risk of poor call quality.

Before a handoff takes place, the first phase carried out is the handoff decision phase. Handoff decisions in fourth generation handoffs take many aspects into account:

- **Quality of service.** One of the most desirable metrics of a handoff decision is QoS. If the handoff algorithm is provided with quality of service information from all of the possible target networks of the handoff, the decision process can select the network with better conditions and higher performance to achieve the best service level.
- **Cost of service.** The monetary cost of using the different networks is usually a key metric in the handoff decision process. The handoff decision process should balance performance vs. cost to try to obtain the best performance at the lowest possible cost.

- **Security.** Nowadays, given the availability of wireless networks, security risks are a main concern. Information transmitted can also be very sensible, so the handoff decision process should take security into account.
- **Power.** Power consumption due to handoffs should be kept at minimum. Wireless devices operate on limited battery power and the number of handoffs carried out should cause a minimal impact on the normal operation of the device.
- **Velocity.** Moving devices at high speeds discourage the use of handoffs because it could be necessary to handoff back to the original network in a short time. The handoff decision should take the velocity factor into account.

USE CASES

The ongoing increase of elderly people and chronic diseases in developed countries makes it necessary to extend patient follow-up from hospitals to home and mobile scenarios. Moreover, e-Health applications with high-quality features focused in athletes' control, sport centres, and so forth, are more extended in developed countries. Therefore, new solutions should be adopted to afford the need of assisted living and remote healthcare. In these e-Health scenarios, new use cases emerge and they may require specific analysis. In this section several use cases are proposed in order to constitute the start point to the analysis of the needs in these scenarios, and also imply a contribution to the standards evolution and mobility support. These use cases include home telemonitoring (fixed or portable communication), and chronics and athletes' follow-up (portable or mobile communication). This work allows foreseeing some possible ideal future scenarios far from today's state of the art in telemonitoring and mobility. In summary, scenarios that bring up advantages in interoperability, network transparency, scalability, costs, comfort, and system usability for the patients.

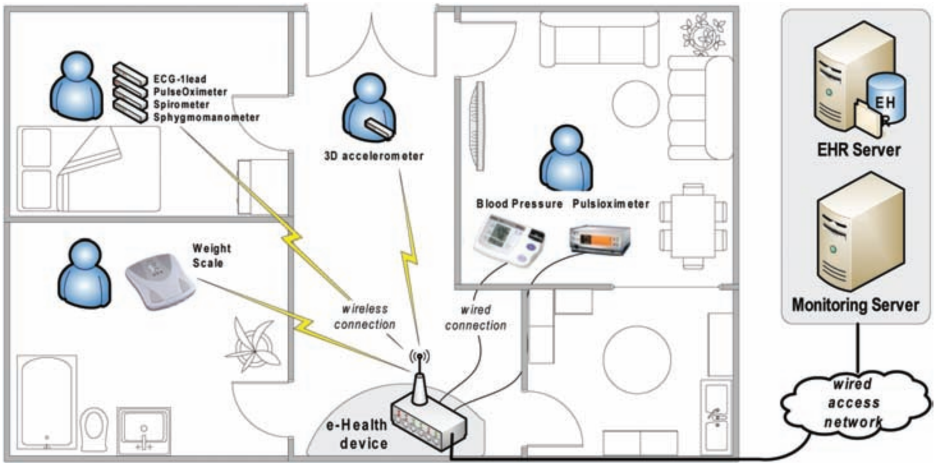
Fixed/Portable Use Case: Home Telemonitoring

This first Use Case (UC1) relates to patients located at home (controlled environments), which monitor different parameters several times a day and send the results to a monitoring server in store-and-forward mode in order to store all this information in the EHR of the hospital (see Figure 2). The MDs considered in this UC1 usually are: blood-pressure, pulse-oximeter, and weight scale. The connections from MDs to the healthcare gateway are usually fixed (wired or wireless). However, a standard-based design that includes plug-and-play and interoperability features must be independent of the particular characteristics related to every location (network access, transmission quality, number of multiplexed MDs in the CE, amount of data flow, etc.) in order to allow its portability obtaining an ubiquity solution. The main requirements for their involved connection technologies and access communication networks are summarized in Table I. Moreover, the healthcare context implies several working requirements to be taken into account (see Table I): remote management of MDs status (no batteries, device not connected or not working properly, warnings via SMS, beeper call, e-mail, Web page, etc.), measurements range in abnormal levels, system's malfunction, absence of patient data after a pre-established period (in order to call to the case manager or social worker for a visit), and so forth.

Portable/Mobile Use Case: Chronics and Athletes' Follow-Up

This second Use Case (UC2) relates to patients with a chronic illness that have to self-monitor their vital signs in order to follow-up: spirometry and pulse-oximetry (for chronic respiratory con-

Figure 2. Design scheme for fixed/portable use case focused on home telemonitoring



dition), non-invasive blood pressure, ECG, and weight (for cardiac diseases), or blood glucose levels (for diabetes); and answers to a symptoms questionnaire. Additionally, the physical activity of the user is estimated using as MD a wearable wireless 3D accelerometer (allowing activity monitoring), which records patient movements during all day, detects falls, and provides a summary of activity level. The case manager provides the patient with the required MDs and a wireless healthcare gateway (i.e., a mobile phone) to allow ambulatory operation and patient comfort. As the patient is continuously moving, the proposed solution must be portable or mobile. Data transmission could be store-and-forward (not time-critical) and being sent within the same day. Case manager could check patient's status daily (pull mode) and receive alarms triggered by the system. The service is supervised by technical staff from the service provider which takes care of the equipment.

An interesting variant of this UC2 include real-time transmission for continuous monitoring: for example, in sport centres of high efficiency for athletes' control (see Figure 3). These situations imply more restrictions in the technical requirements (very low delay, low packet loss, and suitable available bandwidth), and need guaranteeing mobility support (see Table 1).

In summary, each UC requires different desirable features to include in the design of a handoff mechanism. UC1 needs selecting the best access technology (regarding to cost of the service, QoS parameters, etc.) in every moment for providing portability. In this UC the handover is not necessary, but guarantying a suitable buffering capacity according to the maximum number of simultaneous MD is a key point. These portable characteristics are similar for chronic patient's follow-up (UC2). But, on the other hand, the variant of UC2 related to athletes' follow-up requires full mobility, reliability, seamless, and strict conditions of traffic requirements for guaranteeing QoS in real-time communications.

All these considerations have been taken into account in the design proposal of a handoff algorithm that it is detailed in the Solutions section.

SOLUTIONS

Mobility Support

No ideal solution exists to provide with mobility fulfilling all requirements of any situation. However, mobility solutions can be summarized

Figure 3. Design scheme for mobile use case focused on athletes' follow-up

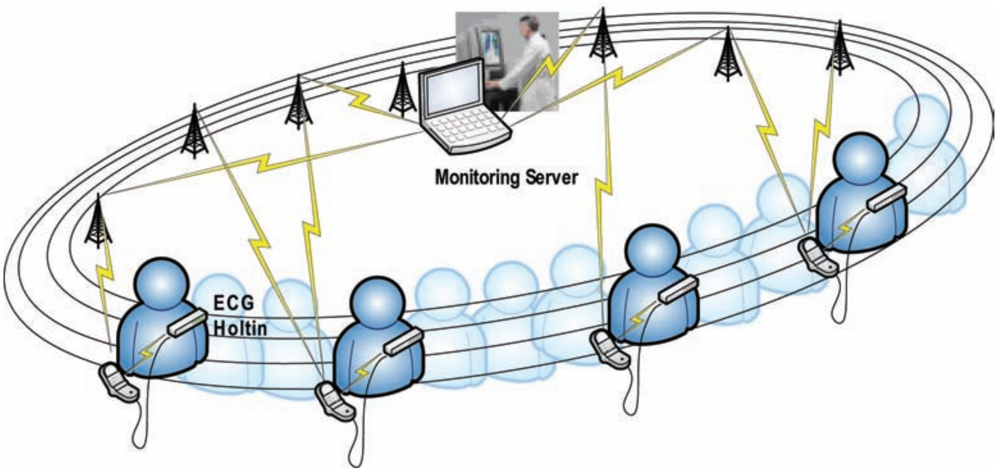


Table 1. Main characteristics and technical requirements for the use cases of this study

Characteristics/requirements	UC1. Home telemonitoring	UC2. Chronics and athletes' follow-up
Related patients	elderly people, post-operatory	chronic diseases, athletes
Acquired vital signs (related MDs)	blood-pressure, pulse-rate, weight scale, pulse-oximetry	blood-pressure, pulse-rate, weight scale, pulse-oximetry, ECG, spirometry, blood glucose, 3D accelerometry.
Service management	user and malfunction warnings, battery status control	user and malfunction warnings, battery status control
Connection mode	fixed/portable	portable/mobile
Connection technologies	wired (USB/RS-232/LAN) wireless (Bluetooth, IrDA, WLAN)	—— wireless (Bluetooth, ZigBee, WLAN)
Access mode	periodic (several times a day)	event-driven or continuous data
Access technologies	wired (xDSL, ISDN, Ethernet)	wireless (GPRS, UMTS, WiFi, WiMax)
Quality of Service thresholds	suitable buffering capacity suitable bandwidth suitable simultaneous MDs number	very low delay suitable bandwidth low packet loss
Other features to guarantee	security, portability, plug-and-play, high multiplexation level	security, mobility, selection of access technology, device location, handover

and compared based on different requirements: handover management, location management, multihoming, security and applications.

Regarding security, most solutions address it to some extent, although some paradigms are not very secure. For example, mSCTP suggests using IPSec or TLS, but does not specify the details, and DCCP does not provide cryptographic security guarantees. MIPv6 has also security problems, but HIP, on the other hand, has been specifically designed with security in mind. However, HIP uses cryptographic methods that require heavy computations that can cause problems in mobile devices with limited CPU power.

Handover management is a critical aspect due to the fact that handovers at the network layer cause high handover latency and packet losses (even inside the network caused by proxies and the lack of support for multihoming). This problem can be alleviated with the use of techniques as make-before-break or anticipated handovers. On the other hand, transport-layer mobility has also advantages: route optimization, multihoming support, and so forth, which facilitate seamless handover and minimize packet loss. The addition of a new layer (like in HIP) might add time to the total handover latency and packet loss due to the use of location management.

Algorithm

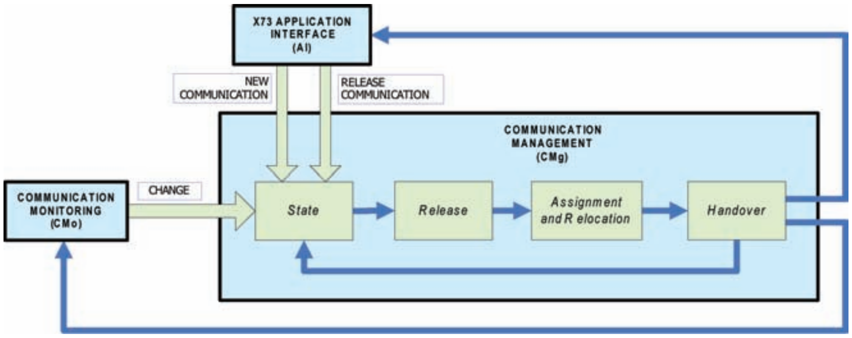
To conclude, an algorithm devised to implement a solid mobility support mechanism is presented next. IP mobility is responsible for carrying out the change between technologies in a transparent way to upper architectural levels, which is often denoted as Media Independent Handover (MIH) (IEEE802.21, 2007). In order to achieve this objective, an algorithm for IP connectivity and mobility management has been designed. It permits to maintain medical and vital data communications in spite of any possible changes in the available IP technologies of the healthcare gateway and is divided into three main blocks (see Figure 4): Communication Management (CMg), Application Interface (AI) and Connection Monitoring (CMo).

CMg is responsible for checking the state of all the TCP/UDP communications and for establishing, maintaining and releasing them, assigning each communication to a proper physical connection. AI requests the establishment of new communications and the release of finished ones to CMg. CMo checks gateway connectivity and the technical characteristics associated to the different IP connections periodically, informing to CMg of any change.

When AI requests the establishment of a new communication to CMg, it informs about the different required parameters: desired priority, communication traffic model, needed capacity, delay, jitter, and so forth. CMg, once the communication has been properly established, sends the confirmation feedback, together with a communication identifier to AI. In parallel, CMo periodically sends the parameters of all the available connections to CMg: capacity, available bandwidth, delay, jitter, packet loss rate, and so forth. In this manner, CMg can release or assign and relocate (through the handover process) the different communications in the available connections depending on their priorities and their required QoS) levels. This information is transmitted in the beginning of the process and every time a change is detected. As feedback information closing the loop, CMg informs to CMo about the assignment state of the parameters to the communications, so that the latter could calculate available bandwidth more easily.

Due to functionality reasons, CMg is divided

Figure 4. IP connectivity and mobility algorithm



into four processes that execute sequentially: *State*, *Release*, *Assignment and Relocation*, and *Handover* (see Figure 4). *State* is the process that receives the establishment, release and change events, and the most up to date information about all the currently established and the available connections from the *Handover* process. The next step carried out (*Release* process) is to release any communications requested to do so, with the aim of offering the next process the maximum available space to assign and relocate communications. Next, in case of new establishment requests, the new communications are assigned to the available connections depending on their current characteristics. If there are not enough available resources, communications have to be relocated depending on their priority and the QoS they require (*Assignment and Relocation* process). Once the proper decisions have been taken in the previous processes (*Release*, and *Assignment and Relocation*), the *Handover* process executes them. There are multiple proposals to carry out its implementation (Nasser, Hasswa & Hassaneim, 2006) but we would like to highlight those under study in the IEEE 802.21 working group (IEEE802.21, 2007). Finally, the *Handover* process returns to *State* process, sending the most up to date information about all the currently established and the available connections, closing the loop. This block diagram in Figure 4 illustrates the behaviour of the algorithm.

CONCLUSION

This chapter has presented an overview of the problem of designing a complete solution for m-Health scenarios. The wide range of characteristics involved in these scenarios regarding patients' knowledge of the system, very diverse VSs and the different mobility situations poses challenges in two directions: new standards are required for the interoperability of medical devices and mobility support mechanisms must provide adequate solutions for any possible mobility situation.

Regarding interoperability, some of the most recent standards are EN13606, the European standard for EHR communication, and ISO/IEEE11073 PoC-MDC, the European CEN/TC251 family of standards for PoC-MD Communications also known as X73. Thus, the need for developing open sensor networks in healthcare environments has fostered the development of standard-based specific solutions that allow transparent integration and interoperability inside e-Health systems with monitoring medical devices. Furthermore, the use of standards provides plug-and-play capabilities and auto-configuration features with the lowest level of user intervention.

In this sense, the chapter has presented different real scenarios (Use Cases) in the assistance area, which require communications standards, but also mobility support. Those scenarios can be classified into fixed/portable and mobile, where the first one can be considered as a particular case of the second. The different solutions to the problems faced in this context have been shown and studied, which lead to the vertical handoff decision. Finally, the solution has been formalized: a complete algorithm is proposed to give response to the mobility situations faced.

KEY TERMS

Handoff: Handoff (or handover) is the process used in cellular systems to transfer a call between base stations when link quality decreases due to the mobility of cellular phones to obtain a better service.

Horizontal Handoff: A horizontal handoff (or horizontal handover) is a handoff between two network access points that use the same network technology.

IP Mobility: IP mobility refers to the set of mechanisms that allow an IP mobile node to move freely between different IP networks (possibly with different underlying technologies) while maintaining IP connectivity in a transparent way to upper layers. One of the most desirable features of IP mobility mechanisms is the ability of maintaining connectivity without interrupting ongoing communications. Other desirable features include location tracking and quality of service maintenance.

m-Health: Mobile Health is an emerging area of telemedicine in which the recent developments in mobile networks and telemedicine applications converge. M-Health involves the exploitation of mobile telecommunication and multimedia technologies and their integration into new mobile healthcare delivery systems. M-Health systems take advantage of the new possibilities that wireless and mobile networks offer thanks to the wide coverage provided by cellular networks and the possibility of serving moving vehicles.

Vertical Handoff: Vertical handoff (or vertical handover) generalizes the term "handover" to the transference of calls between different network technologies. Vertical handover denotes the transference of a call between two different network technologies with the purpose of obtaining a better service. Node mobility (e.g., cellular phones, laptops, sensors, etc.) can cause link quality to degrade. If a new network technology is available in the node's coverage area and can provide a better quality, the node's current communications are transferred to this technology, preferably without interruption. This process is called vertical handover.

Chapter 3.8

Exploring the Technology Adoption Needs of Patients Using E-Health

Linda M. Gallant

Gloria M. Boone
Suffolk University, USA

ABSTRACT

An extended version of the technology acceptance model (TAM) is applied to study hospital Web sites, one specific area of e-health. In a review of literature, five significant factors from TAM research are identified that are logically related to e-health sites from the user's perspective: usefulness, ease of use, trust, privacy, and personalization. All five factors emerged in the data analysis of 30 participants using a hospital Web site. We discuss the implications of this study for guiding development of effective patient-centered e-health

INTRODUCTION

To design e-health that meets the needs and wants of users, we should consider technology adoption research and user-centered design (UCD) principles. Research in these areas can help e-health producers and providers to develop a successful UCD strategy. In general, producing high quality, functional, and usable Web sites is a goal for all businesses and services on the Internet, but particular industries and disciplines must develop Web site design strategies that encompass the specific needs and concern of their specific users. Currently, businesses are searching for successful e-commerce models (Noteberg, Christiaanse, & Wallage, 2003). In this chapter, we investigate what user-centered design strategies can be applied to develop effective e-health, using the specific example of a hospital Web site. We review the basic premises of the technology acceptance model (TAM) (Davis, 1989) and some of its extensions (e.g., Gefen, Karahanna, & Straub, 2003; Gefen & Straub, 2000; Perea y Monsuwe, Dellaert, & Ruyter, 2004; Wang, Wang, Lin, & Tang, 2003) and apply this to the research in e-health. In synthesizing these two bodies of literature, we develop an approach of experience design for e-health.

DOI: 10.4018/978-1-60566-016-5.ch015

"Eighty percent of American Internet users, or some 113 million adults, have searched for information on at least one of seventeen health topics ... Most health seekers are pleased about what they find online, but some are frustrated or confused," (Fox, 2006, pp. ii). Specifically, 22% felt frustrated during their health searches, and 18% felt confused by the information they found online (Fox, 2006). Another study indicates that significant barriers to use of the Internet to find healthcare information remain for some elements of the population, such as those age 60 and older, people with 12 or fewer years of education, and residents of rural communities (Licciardone, Smith-Barbaro, & Coleridge, 2001). To increase the social and practical value of e-health, research needs to first produce answers as to what basic elements make e-health successful to its users.

What are the basic features that individuals search for on the Web? They want to find information and retrieve information easily. They want tailored health information. They want to trust the information. What is a successful e-health model? Using the technology acceptance model (TAM) as a framework, we propose to identify key factors leading to adoption of e-health. Past TAM research (Gefen et al., 2003; Gefen & Straub, 2000; Perea y Monsuwe et al., 2004; Wang, et al., 2003) gives us a starting point to shed light on the role of trust, privacy, credibility, and user perceptions of technology in the dynamic exchange between patients and provider-delivered e-health. In reviewing past research on TAM and UCD, we identified five relevant factors to explore in a case study of 30 participants using a hospital Web site. The five factors are usefulness, ease of use, trust, privacy, and personalization. These are used as sensitizing concepts in a case study to identify why potential users adopt e-health.

PRIOR RESEARCH

Using proven research approaches such as TAM and UCD to investigate patients' adoption of e-health can provide important insights. "The TAM postulates that user adoption of a new information system is determined by their intention to use the system, which in turn is determined by their beliefs about the system" (Wang, 2003, pp.335). In online technology adoption, the TAM model highlights the importance of trust, usefulness, and ease of use from the user's point of view (Gefen et al., 2003; Gefen & Straub, 2000; Perea y Monsuwe et al., 2004; Wang et al., 2003). More specifically, research using TAM in e-commerce has found that trust, privacy, and user perceptions of technology are central elements of online technology adoption (Gefen et al., 2003; Gefen & Straub, 2000; Perea y Monsuwe et al., 2004; Wang et al., 2003).

Popularity of e-health is growing. While the design and development of e-health is not well researched (Ketchum, 2005), searching the Internet for health and medical information is known to be one of the most common activities for e-health users (Akerkar & Bichile, 2004; Fox, 2006). Given that the Internet has altered the way people gain access to health information (Akerkar & Bichile, 2004; Kreps, 2003; Neuhauser & Kreps, 2003), health professionals need to understand how to design e-health using strategies that meet the needs and expectation of Internet users. In this vein, e-health has the potential to produce innovative care models in healthcare (Nash & Gremillion, 2004).

We propose that four TAM-related factors (perceived usefulness, perceived ease of use, trust, and privacy) are highly relevant to the context of e-health. An additional factor, personalization, has been found by UCD research to be a key driver of adoption and use of hospital Web sites, a form of e-health (Gallant, Irizarry, & Kreps, 2007). We review the literature relating to each of these factors in the following sections.

Usefulness

Perceived usefulness is the chief reason why people intend to use technology systems (Gefen & Straub, 2000). In TAM, usefulness is the most important source of user acceptance of new technologies (Perea y Monsuwe et al., 2004).

Perceived usefulness is defined as the extent to which a person believes that using a particular system will enhance his or her job performance, while perceived ease of use is defined as the extent to which a person believes that using a particular system will be free of effort (Wang et al., 2003, pp. 503).

Perceived usefulness is a major predictor of intended use of online technologies (Gefen et al., 2003), including e-health (Wilson & Lankton, 2004).

Ease of Use

In the sphere of the Internet, Gefen and Straub (2000) found that perceived ease of use influences individuals' intention to use an e-commerce system. Their research indicates that perceived ease of use is dependent on the tasks or types of use people expect to perform. In particular, when users perceive an intrinsic system task as easy to perform, this has a positive influence on the adoption of a technology. In the e-health context, a main task of users is searching for accurate health and medical information, which Wilson and Lankton (2004) found to be significantly correlated with patients' perceived ease of use.

Trust

Trust has been found to be a multidimensional construct invested with consumer beliefs in integrity, benevolence, ability, and predictability of the vendor (Gefen & Straub, 2004).

High levels of consumer trust encourage e-commerce, however, the appropriate conceptualization of trust has been much debated in online research, with trust levels of users being associated with personal propensity to trust (McKnight, & Chervany, 2001), perceived severity of user health problems (Fruhling, 2003; Fruhling & Lee, 2006), and Web site design factors (Shanker, Urban, & Sultan, 2005). In response, there has been a call for online trust transactions to be studied in more context and application specificity (Riegelsberger, Sasse, & McCarthy, 2005). Studying trust is important as "understanding how online trust is created and maintained can lead to improved Web sites, sales revenues, profitability, and ultimately shareholder value" (Shanker et al., 2005, pp. 326). In the context of e-health, trust is both situational and context dependent (Noteberg et al., 2003). Users provide personal information that can carry significant privacy risk (Culnan & Armstrong, 1999).

Online trust has been described as an association of networked relationships which depend on the degree of trust between the parties involved (Durkan, Durkin, & Gillen, 2003). All partners in this known network must be seen as trustworthy for members to willingly assume risk. The networking of trust extends to e-health. In the exchange between a patient and his or her healthcare provider, the provider's e-health system can provide structural assurance that the online technology environment, even with network partners, is safe and under control. This type of assurance helps to build a trusted reputation for all parties involved (Hsiao, 2003). Online interactions "include different types and levels of risk, and they are only possible if users trust each other and the systems they use to meet, communicate and transact–as well as the organizations that provide them." (Riegelsberger et al., 2005, pp. 382).

Branding is another area impacting online trust. Online trust rests in part upon the perception of a vendor's credibility. Research has shown that brand recognition can influence trust of online vendors. Durkan et al. write "Often a recognized brand name will provide a measure of credibility and thus stimulate consumer trust" (2003, pp. 99). Endorsements can also work to increase trust by decreasing uncertainty in online transaction (Noteberg et al., 2003).

Privacy

Culnan and Armstrong (1999) identify two major risks to privacy in online transactions. Once users provide personal information, they may be unable to control and protect it. Secondly, personal information could be used in other ways than were intended. Institutions must strike an appropriate balance between the personal privacy and business needs, noting that concern for privacy can be mediated by expected benefits. People will provide personal information online when an economic or social benefit can be expected (Culnan & Armstrong, 1999; Durkan et al., 2003).

Given the high sensitivity of personal health and medical information, advancement of e-health could be obstructed if users fear that their privacy is at risk. Fear of revealing personal information "to third parties without their knowledge or permission" provides a development and design challenge to e-health adoption (Wang, 2003, pp.339). Privacy is a fundamental right in most democracies (Basu, 2004), and the loss of personal privacy is a major concern of consumers in e-commerce (Noteberg et al., 2003).

Personalization

The goal of personalized care is to provide "the right information, to the right person, at the right time" (Hesse & Schneidermann, 2007, pp. 7). Hawkins, Pingree, Shaw, Gustafson, Gatzke, McDowell, and Tryon-Petith (2006) point out that the efficacy of tailored health messages has been supported across a variety of general health education domains. Other research has demonstrated that personalized or tailored information is viewed by users as more relevant and thus, more likely to be valued (Oenema, Brug & Lechner, 2001). In their study of a hospital Web site, Gallant et al. note that "users want personalized information geared to their health needs presented in a seamless and easy-to-use manner" (2007, pp. 20). While this point may seem intuitive, it is important to remember that not all e-health interfaces are designed with user goals in mind. Rigorous human-centered testing is essential for effective and useful personalization strategies.

Personalization of e-health holds much potential for preventative medicine and patient-centered care. Applying personalization strategies to e-health Web sites provides the capacity for online technologies to act in the tradition of telehealth, which has been used successfully to implement tailored healthcare management of chronic diseases, such as diabetes and asthma, and risk factors, such as high cholesterol.

METHOD

Through systematic investigation, qualitative research traditions answer questions of process, understanding, social meaning, and human action. Since we are inquiring about a process of knowledge production arising from human actions that infer meanings from product use, a qualitative research design is most appropriate. We use a case study method. Typically in qualitative case work, data is prerecorded (Stake, 2005, pp. 450). Our data was transcribed from the prerecorded usability tests and interviews. The data was analyzed for classification and pattern recognition. We conceived participant users as evaluators. From this point of view, we analyze the user data in accordance with the five sensitizing concepts described in our review of prior research. This analysis method is in accordance with an instrumental case study approach.

"…the methods of instrumental case study draw the researcher toward illustrating how the concerns of researchers and theorists are manifest in the case. Because the critical issues are more likely to be known in advance and to follow disciplinary expectations, such a design can take greater advantage of already-developed instruments and preconceived coding schemes," (Stake, 2005, pp. 450).

Participants

The 30 participants were recruited for the usability testing of a hospital Web site redesign project. Participants were paid $85.00 for up to 90 minutes of their time. Participants were selected to have a group mixed in demographics in age, gender, education, and income. See Appendix A for a breakdown of participants' demographics. All selection criteria were based on the hospital's typical patient demographic. Gender of participants was split evenly with 15 female participants, and 15 male participants. The age of participants was classified into three categories. For education, there were three categories. All participants were able to name their primary care hospital. A professional recruiting firm was hired to screen and recruit participants. The testing was done in a professional usability lab during five consecutive days of testing.

Data Collection

A high fidelity prototype of a working Web site for a Northeastern hospital was tested in a traditional usability lab. Study participants performed a task on the prototype that was accessed over the Internet from the hospital's servers. There were 34 task scenarios performed by 30 participants using a think-aloud protocol. There are three sections of the usability test designed for measuring the medical center's typical user profile. The task script was pretested on three pretest participants and minor wording changes were made. Participants had the option of reading the task along with the task being read aloud by the test facilitator.

Think-aloud protocol. This produces a verbal text of user participants' performance of task scenarios. Usability testing falls into the category of "natural techniques" in the knowledge acquisition process (Shadbolt & Milton, 1999, pp. 314). The traditional usability data collection technique of think-aloud is a process tracing method with its root in decision making research. Process tracing endeavors to let researchers observe the "natural" decision making process that participants engage in when given a task. With a think-aloud protocol, researchers gain participants' verbal utterances without interjecting any interaction that would cause a change in the participants' actions.

In-Depth Interview and Adaptive Questioning. Layering the think-aloud protocol with in-depth interviewing produces a text that provides observable and knowledge-centered data. After a participant finishes the task, the facilitator uses probing questions to elicit the user's understandings and meanings of the task, design, and overall system. As the task being performed comes to an end, the research method data collection process using interviewing becomes a codiscovery process between the participant user and test facilitator. This adaptive usability technique allows system testers the traditional behavioral measures while further providing user-centered knowledge concerning how potential customers perceive a product and its use. The latter data can be valuable to business teams across the organization.

Interviewing is a method of data collection that is well matched in the collection of information and processes "that cannot be observed effectively by other means" (Lindlof & Taylor, 2002, pp.174). Enhancing data collection with in-depth questioning at the end of tasks produces an interview procedure aimed at capturing user evaluations and knowledge of product uses and meanings. Unlike the task scenarios, the in-depth questions and probes are not predetermined. The task facilitator turns to an interviewing format that constructs a conversational environment producing questions and probes that are based on participant users' task experiences. Two trained facilitators conferred on how to approach the testing process for layering the technique of traditional think-aloud with interpretive questioning and probing, adaptive usability testing. Thus, the facilitator must adapt the post-task environment to an interviewing format. This acts as a summary of users' experiences, opinions, and evaluations of products.

Data Analysis Procedures

There were 34 task scenarios designed to measure important interaction dimensions of the Web site. The task list was developed by the lead researcher along with the hospital's marketing department team, which was responsible for the Web site development and upkeep. Tasks were divided into sections such as homepage usage, navigation, patient resources, employment, and health information. In the first part of the current investigation, a content analysis is used to measure usability problems. Measurements of the think-aloud analysis model should distinguish whether or not the usability problem was detected by observation or participant verbalization before developing a categorization of usability problems (Van Den Haak, Jong, & Schellens, 2003). The second part of the analysis seeks to learn what types of data arise from participants' responses in the post-task interviewing situation. A grounded theory approach is used. This approach is sometimes referred to as a constant-comparative method (Lindlof & Taylor, 2002, pp. 218). The analysis by the researcher is grounded in analyzing the data by aptly naming categories, making data comparisons, and overall extracting "an innovative, integrated, realistic scheme from masses of unorganized raw data" (Strauss & Corbin, 1998, pp. 13).

Traditional Analysis of Think-Aloud Data

Think-aloud protocols have been used in a variety of ways. Boren and Ramey (2000) identify that the practice of think-aloud protocols in usability testing diverge from its theoretical basis proposed by Ericsson and Simon's (1984) three-level model of verbalizations. This model in usability testing is used to identify system deficiencies (Boren & Ramey, 2000). This traditional concurrent cognitive verbalization model favors level one verbalization. Here verbalizations are not cognitively transformed before thinking aloud during a task performance (Boren & Ramey, 2000). At level two, more complex cognitive processing occurs before verbalization. Concepts such as images must be transformed into words. Level three produces the greatest amount of cognitive processing and is the least desired according to Ericsson and Simon's (1984) three-level model. Instead of simple verbalization, participants engaged in cognitive processes at level three go beyond direct task performance and verbalizing.

Analysis of Adaptive Usability and Knowledge Centered Data

At level three verbalizations, information retrieval from participants' memories is called upon to verbalize a response. Knowledge of how people perceive the usefulness of a product in their work or private life comes to bear. Knowledge management literature suggests that conversation is the key to sharing knowledge (McInerney, 2002, pp.1012). Gaining user knowledge on products is the goal of adaptive usability testing. In a qualitative interpretive methodology, talking and eliciting information can be the basis of data collection. As such, talk between the user and researcher is not a biasing factor. Using speech communication as a basis for analysis is a promising approach to usability testing.

> *[S]peakers cannot ignore listeners, even silent ones. Speakers expect that listeners will react to what they say, and that listeners' actions (or interactions) are reflective of that response…if we accept the view of human communication, the issue in usability testing becomes not one of disappearing from participants, but rather one of creating a highly asymmetrical speaker/listener relationship, one which maximizes the speakership of the participant and minimizes the speakership of the usability practitioner. (Boren & Ramey, 2000, pp. 268)*

DATA ANALYSIS

Data used for content categories should "provide useful evidence for testing hypotheses or answering research questions," as well as "communication," an understanding of a subject (White & Marsh, 2006, pp. 27). This analysis allows participants' descriptions and opinions about hospital Web site to be communicated. It allows users' knowledge to be known.

Using five analytic constructs (usefulness, ease-of-use, trust, privacy, and personalization) drawn from TAM and UCD research, an analysis was performed on 1,800 pages of data transcripts. The five descriptive codes can also be referred to as analytic constructs. Descriptive codes "entail little interpretation" in "attributing a class of phenomena to a segment of text" (Miles & Huberman, 1994, pp. 57). Descriptive codes are more denotative in attaching face value meanings to participants' discursive text than with interpretive coding that is more connotative given a constant comparative analysis process between the developing codes and the text.

The lead author performed and initial coding analysis and developed a description of each code for hospital Web site use; participant statements that matched any category of the five codes were tagged. Appendices B through F present representative supporting quotes for each descriptive code. Based upon the set of quotes for each code set, a more precise conceptual structure for the use of hospital Web sites was defined. As a validity check, both co-authors next independently read the conceptual codes and representative quotes to compare these with the raw textual data. The coding, definition, and quotes were found to be valid and credible in transferability, dependability, and conformability.

RESULTS

The results of our analysis relating to each of the constructs we studied are reported below.

Usefulness

The usefulness of the hospital Web site as an e-health artifact centers on obtaining information about personal and family health matters, physicians, diseases, insurance plan acceptance, medical specialties, and types of medical procedures offered at the facility.

Ease of Use

Having information organized in a logical and familiar arrangement provides users a sense of flow. Especially important in this e-health context is the user's sense of timely interaction with health appointment scheduling. Participants stated the importance of having a direct sense of communicating with a medical professional instead of interacting with a nonhuman information system. Participants also emphasized the need for appropriately labeling sections and their content so that Web site users can easily find information that they need. A search function on the Web site was seen as an important user tool for finding information.

Trust

Trust was viewed as the standard of medical care associated with the reputations and specialties of physicians at the healthcare facilities. Participants wanted to view physicians' background information, including medical degrees, years of practice, and even lawsuits.

Privacy

Privacy was a concern among participants with sensitive medical conditions. Additionally, participants were more apprehensive of trusting an automated information system to properly make appointments. Participant responses suggest that as users get to know and trust a system, they feel more secure with it.

Personalization

Participants foresee an ongoing interest in acquiring tailored and up-to-date healthcare and medical information. Many participants have particular health conditions and diseases for which they are interested in obtaining targeted health information and news updates. Participants wanted to be able to access their medical records online and make appointments online.

DISCUSSION

Using an illustrative case study of a hospital Web site, we found usefulness, ease of use, trust, privacy, and personalization to hold considerable importance for participants. The finding of our case study corroborates prior research on technology adoption and suggests that these five factors should be considered when designing and building e-health systems.

Since the usefulness of new technology is a primary motivator for adoption (Perea y Monsuwe et al., 2004), people will most likely adopt e-health systems that are situationally useful in relation to illnesses, health problems, or past medical histories. This phenomenon was seen in participant quotes that show usefulness as having an easy-to-navigate hierarchy. For example, within a topology of illnesses, some users verbally distinguish aspects such as medical condition, visitor, patient, and medical professional. For others, usefulness merged with perception of ease of use. This included easy viewing and clear navigation on the Web site. Participants wanted pages that are easy to read, have large font sizes, and organize information into small segments. Factors related to navigation included a global search function, a clear primary and secondary navigation, and clear organizational principles such as alphabetical or chronological ordering. Participants wanted clear directions on how to complete forms relating to healthcare, insurance, contact information, selecting doctors, and making appointments. They wanted to be able to quickly retrieve information on financial and insurance aspects of their healthcare. Participants wondered, for example, if they could go to specific doctors with their insurance or get prescriptions filled.

While the role of trust in e-commerce has been studied by numerous researchers, proposed strategies may not be adequate to understand trust in the context of e-health (Fruhling, 2003). Yet, a mainstay of healthcare organizations' relationships with their patients and other stakeholders is trust (Hesse, Nelson, Kreps, Croyle, Arora, & Rimer, 2005). Internet users' trust of health information Web sites has also been growing (Rosenvinge, Laugerud, & Hjortdahl, 2003), with personal doctors, medical universities, and the federal government being seen as the most trusted sources of online health information (Dutta-Bergman, 2003; Kind, Wheeler, Robinson, & Cabana, 2004). This issue is prominent in our data. Participants want to search for doctors' credentials to judge whether or not the information presented and the institution owning the Web site are credible.

Online healthcare information needs to be seen as credible by users before they trust it (Rosenvinge et al., 2003). The stakes are high because use of health information can impact people's health positively or negatively (Al-Bahrani & Plusa, 2004; Luo & Najdawi, 2004; Williams, Nicholas, Huntington, McLean, 2002). A component of trust is credibility. In general, perceived credibility of an online technology attracts users (Wang et al., 2003). Our findings are in agreement with past research (Eysenbach & Kohler, 2002; & Luo & Najdawi, 2004), in that participants view e-health Web sites as more credible when source and ownership are disclosed. Trust is part of the name and reputation of the institution. Trust is also a consideration when selecting doctors as our findings suggest prospective patients want to see the biography of the doctor including specifics on education, specialties, and years of experience.

We find perceptions of online trust and privacy are contrasted to other communication methods. Participants compared the Web site functions with traditional ways of accomplishing tasks. For example, they would search to make an online appointment until they felt it was easier to fall back on the traditional communication method of making an appointment by telephone. Participants would often compare the online task to what they would do in a face-to-face interaction with a hospital employee. Thus, e-health should try to support communicative interactions people expect to have within traditional telephone and face-to-face communication with administrative and medical staff in the healthcare process. Web site users should be able to have a choice to leave the Web site to interact by telephone or in person. This would be especially helpful with users who are low in trust of general Web transactions. While some evidence in the data suggests that placing sensitive personal information on a Web site for healthcare users is an Internet privacy concern, our research design did not allow us to explore this research dimension. Future research should be undertaken to provide more insight into e-health privacy and security concerns of users.

Personalization can have impacts on issues of privacy, ease of use (usability), and usefulness. To meet the diversity needs of users, e-health Web sites can employ a personalization strategy. This process presents tailored information to users based on their personalized profile. Knowledge about a user can be used in a dynamic Web site that can specifically target information, content, and services to individual users (Adomavicius & Tuzhilin, 2005). Personalization of e-health can solve usability problems relating to user characteristics, such as disabilities and illiteracy (Denny, Ginsberg, Papp, Browne, Morgan, Kushins, & Solina, 2002). Further, the strategy of personalizing Web sites as individualized patient portals can be a useful tool for patients to gain greater access to personal health information and make better informed decisions for their health (Nguyen, Carrieri-Kohlman, Rankin, Slaughter, & Stulbarg, 2004). Personalization strategies are especially pertinent given that patients are increasingly using electronic personal health records to manage their own health (Lorbach & Detmer, 2007). Our case study data suggests that people with particular health concerns such as diabetes want to find up-to-date information on their medical conditions. People search for health information upon being diagnosed or having a family member diagnosed with a medical condition. In addition, personalization appears to enhance the expectation of usefulness. For example, personalization can allow e-health users to access RSS feeds that enable them to select useful topics, sources or information channels to access the health information.

CONCLUSION

Through analyzing several factors drawn from TAM and UCD from the user's perspective, we were able to identify a number of implications for developers of patient-centered e-health. As

Hesse & Shneiderman, (2007) observed, many elegant theoretical interfaces have failed when used in real-world settings because they fail to take user needs into account. A patient-centered design focus can avoid these problems, providing e-health that is both effective for healthcare providers and empowering to patients.

APPENDIX A

Demographic	Categories	Number (percentage)

APPENDIX B

Usefulness
User 2: "Primary – wait a minute, primary – Finding a primary care physician. I definitely would be interested in that to see where would I go for daily checkups. And finding out the type of physician that I would want for me. And I'd probably click here to find that information out…I have a child as well and I would be interested in – especially if I'm in another healthcare, like I'm in Tufts, I'd be interested in would I have to switch doctors, especially for my son where he already has a doctor. And if I switch to [hospital name], would that same doctor be there, would be offered for me to go to that same doctor. And I would click here for that information."
User 3: "Oh, for someone like me, the most important thing would be uh – oh, let me go back to it – would be – seems like the healthcare information because this is for me, I'm trying to learn about trying to find a doctor. If I wanted to become a patient or a member, I have to – I need to know all this information. So, healthcare information."
User 7: "Maybe they would list the physicians that are affiliated with the [hospital name] and then what I would have to do is – now if my personal doctor, for example, from Watertown, I'd have to see if he's listed there. If I didn't want to bother to call his office, I'd look to see if he's affiliated with [hospital name], if I could have procedures done there, whatever. Or maybe you're looking up the names of some physicians that maybe – Maybe some information about their specialties or whatever.
User 10: "Personally? What I would use it for? I probably would – knowing me, I would probably be looking up diseases and getting information, just a general overview of it. And specifically, the type of service that's offered for that particular disease. I'm sure they don't cover everything, but I find it, what little I've moved around in it, it's very informative, so that. And I think the obvious with the patient, with the patient information, I know that with Tufts that I have a book, I don't believe there's a Web site that you can search for doctors."
User 17: "Depending on the most important to me is looking for a PCP [Primary Care Physician] that meets in my plan because if he doesn't meet your plan, I can't go to him."
User 23: "For example, my situation now, I had pain in my back, couldn't walk, my leg and so on. I want to know what was wrong, and who could treat it…So I would look for back, for example, or spinal or neurosurgery. I want to know who the doctors are, who neurosurgeons are, and how good they are. And the backgrounds they have. Their bios."

APPENDIX C

Ease of Use
User 5: "But a lot of times that's what I do. I just go to the search part of some Web sites unless it shoots out at me right away."
User 7: "Oh, I – oh, patient pharmacy. I would never think to look under there. Again I'm thinking little specialty shops. I want to get a gift. I want to get dinner. I want to get flowers or something. I would never put that together."
User 9: "This takes three days to make an appointment. If I thought it was very important, I would call up myself…This was good for – to get information. If I was going to make an appointment, I would try to do it this way if I didn't have to have it right away…I find that when I call at least the people I deal with, if they say well, can't see the doctor for two or three weeks, I'd try to speak to the doctor himself if I'm a patient of his. And tell him what my problem is and I'd tell him I need to see him sooner than three weeks. But you're on the computer, you have nobody to talk to."
User 13: "Just – it [specialty shops] could be anything. It could be a place where you just get – go buy a newspaper or you can get gifts and things like that. Flower shops or something like that. That's what I would associate it with… outpatient pharmacy, OK. Wow, I never would have looked there. Never would have looked there… Just too – not – it's more something you were going to shop for."

Ease of Use
User 15: "You know what I'm finding, that patient service is an awfully large and important button. In fact, I would suspect that for patients or patients who are going to be referred there, that may even have to be broken out. And I can think of something here. Healthcare information divided between in-house physicians, nursing services. Something that they would like on their homepage, but for their own information. And patient related or just for newbies. People new to Lahey Clinic. The great unwashed plus patients. And I'm not saying that you have to dummy it down. But you need to make that – for example. It's nice. Medical research at Lahey, residencies and fellowships. But I'm new here. Where would I go, and it seems that oftentimes we're going through this patient service center."
User 18: "And there'd be a roster of all the physicians. And what they do and all that. After physicians, they'd do it by specialties and then the more you click on them and then get a list of the roster there. That's how I would logically go about it...And I'm sure they all link, because if you go under the disease, and then I'm sure there'll be something on the page of whatever say, kidney, that would have the physicians that would – clearly, I would think it would connect you right into the physicians, too, so there'd be a link, whether you went in one way or the other."
User 20: "OK. Specialty shops and services … I wouldn't put it with shops because as soon as shops comes into my brain, I'm seeing gift shops…And services, well, I don't know. Send a telegram. I don't know. But it doesn't say pharmacy to me."

APPENDIX D

Trust
User 2: "I'm going to scroll down to see…. Physician finder. Maybe I should look him up first before the appointment…OK, let's see. OK, so here we find him right here, residency. So I'd probably want to read a little about him."
User 6: "And then I think for – one thing that sort of provides security for patients is just seeing a little bit, like what each medical background is, like where they got their medical degree, where they've studied. You know."
User 11: "And you want to find out information like where she graduated, and her medical school, and everything … I want to know about this doctor's background…I thought it was very important when you were getting a physician finder, to be able to pull up that physician and find out – maybe that physician went to a school that you heard was really awful…I thought that was really important."
User 12: "If someone's going to [hospital name], they're going to go to [hospital name] for whatever reason, the doctors, their doctor's there, or they're good for their specific condition. No one's going to look at it [the Web site] and go oh my God what a fabulous Web site. I'm going to that hospital. Or, oh my God, this is ridiculous. I'm not going to that hell-hole."
User 20: "And I've also learned once I find that person's name, I may not be able to get it through here but, I forget now, but someone told me how to look up that person, see whether there have been lawsuits against him or things like that. It's a very helpful thing to know. I think I would definitely go to here."
User 23: "To me the most important thing is the staff, who is there, what their specialties are. Where can I get my condition treated the best. The best facilities and the best people doing it. One of the things I always look for – we're looking for a family doctor now. Our family doctor retired. We loved him and we can't find a replacement… We're looking for a family doctor, my wife and me. Internal medicine. I'm looking for somebody who is not too old, is not too young. And what I find at [hospital name], for example, is that most of the – most of the long, long lists of people in Internal Medicine, most of them got out of school in 2000, 1999, 1998. They're probably very sharp but I want somebody who said Oh, yeah, I had a case like this 12 years ago….And I like to see people who are board certified. So that page on the whatever – whatever [hospital name] is doing is very, very important to me."

APPENDIX E

Privacy
User 2: "OK at this point, honestly, at this point I'd pick up the telephone. You know? I – I use the computer a lot for information. Even when I hear some of my customers talk about – yeah, we're going on a cruise, we went through the computer to get the tickets –I go to Orbitz and (inaudible) tickets cheaper. - I'm always leery of it. I'd rather talk – after talking to all the answering machine messages, the mechanical stuff, when you finally get a hold of a human being to make an appointment, to make sure that there's no mix-up…If I was familiar with the Web site I would do that. But if I'm unfamiliar with something, I would just get on the phone and make the phone call."

Privacy
User 12: "Well, I'm thinking I guess to make an appointment I've got to fill out some forms. And they're telling me about the security, that it's OK…it's not totally important to me but depending on what I'm using this for, but I could see a person that might have a problem with it, like maybe has AIDS and doesn't really need the whole world to know, or there's certain privacy issues. I always assume if it's a hospital that they have to put that here, but I am maybe naively assume that it's safe…but maybe it makes them feel good to see security but if you just saw a link I think you'd feel good knowing oh, it must be secure"
User 28: "Initially I would think to click it, to keep going, but I think it has to do with the privacy statement. So if I click on it, I think I'd probably get that click on thing…Because it's blue and it says read the privacy statement right there under it, but this made me think, keep going…But initially, that's what I want to know. You think oh, no I want to read more about the privacy statement."

APPENDIX F

Personalization
User 1: "That's what I would look for. There's very specific information about that hospital, or that organization like how to reach me, how to make an appt… If I were a regular customer with the ability to get into my records… to the extent that that's allowed, I might be able to use my SSN or some other access code to check on one big thing."
User 6: "Right, because I'm diabetic…So that's why I go online, most of the time, is to find out current news about treatments for diabetes like if there's anything new about diets, you know, for diabetics, so – you know, and not every – not every hospital or clinic treats diabetes, you know, in that sort of way, so I'd look for something. Plus I always go and look at who the doctors are, who the care – medical care givers."
User 15: "Read health information. Health information. Now that's an interesting one. Is this one the disease of the day? Can I scan, or can I search according to what I think I have, and is there information on that."
User 21: "I think it would break down into three things. An existing patient, and then what does an existing patient want to do?...Make an appointment. Check out doctors that they'd been referred to. Learn more about conditions."
User 23: "If I pop that, that's what I would expect to happen. Request an appointment – I think this would take me to some central appointment office, not to any particular doctor, and tell him who I wanted, Dr. Ollie, and I'd like an appointment for this, and that central office would somehow have available to them his free times. That's been my experience I think."
User 24: "Primarily for research, that's why I go to the other medical Web sites that I do, just for my own edification or just out of curiosity if there's something in the news, I'll just check different Web sites and plug into just, like, the general search and see what articles come up."
User 25: "I guess more articles. Articles, articles. You know, articles regarding health…Yeah, health topics….will I see news here. Sometimes – I guess…Sometimes if you're – I don't think I'd design anything – other Web sites, anyway, but – I'm just saying, sometimes, if you're in a Web site, then it'd be pretty good if it had news, you know, up-to-date news."
User 28: "Yes, see this is what – this isn't really going to help me get an appointment. I'd have to call and talk with someone. So up until this point, it's like good to use the Web site, to get the information but there's no appointment schedule that I see right away, so I would just get the phone."

Chapter 3.9

Technology Enablers for Context-Aware Healthcare Applications

Filipe Meneses
Universidade do Minho, Portugal

Adriano Moreira
Universidade do Minho, Portugal

ABSTRACT

The increasing availability of mobile devices and wireless networks, and the tendency for them to become ubiquitous in our daily lives, creates a favourable technological environment for the emergence of new, simple, and added-value applications for healthcare. This chapter focuses on how context and location can be used in innovative applications and how to use a set of solutions and technologies that enable the development of innovative context and location-aware solutions for healthcare area. It shows how a mobile phone can be used to compute the level of familiarity of the user with the surrounding environment and how the familiarity level can be used in a number of situations.

DOI: 10.4018/978-1-60566-332-6.ch013

INTRODUCTION

"The most profound technologies are those that disappear. They weave themselves into the fabric of everyday life until they are indistinguishable from it." (Weiser, 91)

In 1991, Mark Weiser had a vision that still inspires many researchers in the ubiquitous and pervasive computing area. In a perfect world people needs would be detected and fulfilled by a set of devices that would act in the background to provide the means or data necessary to the users' activities. Current technology does not allow to entirely fulfilling the Weiser vision but allows realizing many aspects of this pioneer vision.

Continuous monitoring of the health condition of people has been desired for many years, in particular for impaired persons or for people requiring special health treatments. In certain cases, these requirements for continuous monitoring force people to stay at the hospital facilities for a few days, such as when monitoring cerebral activity, or force them to visit the hospital every few days for downloading data from portable monitoring equipment to a server, such as when monitoring the hearth rate.

The increasing availability of mobile devices and wireless networks, and the tendency for them to become ubiquitous in our dally lives, creates a favourable technological environment for the emergence of new, simple, and added-value applications for healthcare.

One major opportunity resulting from this technological evolution is that electronic health assistants can now be used by everyone, independently of their health condition.

The technological evolution achieved during the lasts years lead to more sophisticated environments. We have more sophisticated users in the sense that more people use more technology in their living and have their lives controlled by technology, and also because more technological devices exist to assist people that search for healthcare services. WLAN, Bluetooth, mobile phones, digital diaries are among some of the most popular technologies used today by many people. Others technologies control peoples' life individually or collectively, many times without people noticing it, like remote video surveillance or remote traffic control systems.

To explore and take advantage of these new technologies it is necessary to solve a set of technical, ethical and legal problems. Pervasive and ubiquitous computing devices can be very useful to people, providing important information and establishing an infrastructure that enables the emergence of a new kind of applications and services: the context-aware services and applications.

In context-aware computing, applications adapt their behaviour accordingly to the context of its users. The context is all the information that characterizes the user in a specific moment. It may include the location, position, a list of nearby objects (e.g. people), the user's activity, the available resources, some user's vital signals, and even the familiarity of the user with his/hers surroundings.

Among the technical problems that need to be worked out are the notion of context and the context management. Until today, many location-based and context-aware services and applications were built based on specific solutions, where location or other data was directly used from the sensors.

Context management should be done through an open and generic entity capable of supporting virtually any sensor or positioning service, without imposing a specific space model and by being capable to support a context based on multiple dimensions.

Context is all the dimensions (all the information) that characterize a user in a specific moment. Some basic dimensions of a context may be obtained directly from physical sensors, while some others may be calculated from raw data or may even be estimated from the information provided by other dimensions.

Location and position have been the most used dimensions when creating context-aware applications and services because there are more sensors and services capable of provide this kind of data than any other dimension. Moreover, position and location are among the dimensions that, in fact, influences a lot the interaction of people with computing devices. Context-aware applications that rely primarily on location are known as location-aware. Location-aware applications provide to mobile users the possibility to access services and information that are relevant to the user in a specific moment and location.

A number of technologies can be used to acquire the user's position and location, inside and outside buildings. In the last decade, research in context and location-aware computing produced frameworks and solutions that enable the easy development of context-aware applications. In particular, several developments in context management frameworks provided the tools for programmers to access the context of users without the need to deal directly with the low-level technical details of the sensors used to acquire the context, and allowing the use of several technologies simultaneously to provide position and location with more precision and in more places. For example, the Place Lab system (LaMarca, 2005) exploits the beacons broadcasted by many wireless networks to estimate the geographic position of mobile users.

Many of these technologies enable the development of new solutions for healthcare, improving the cares with people in a hospital, for sick persons that are at home, for an accident victim, for the doctors and for those who rescue the victims of accidents. In this chapter we discuss how context and location can be used in innovative applications and how to use a set of solutions and technologies that enable the development of innovative context and location-aware solutions for the healthcare area.

This chapter is organized as follows: section 2 presents what is a user' context and how it should be managed. Section 3 presents some technologies that can be used to acquire some of the user' context dimensions. Section 4 shows how an ordinary mobile phone can be used to detect the user movement and the data collected by the phone can be used to create a personal space model and to infer the familiarity of the user with a place. The last section presents the conclusions of this chapter.

CONTEXT AND CONTEXT MANAGEMENT

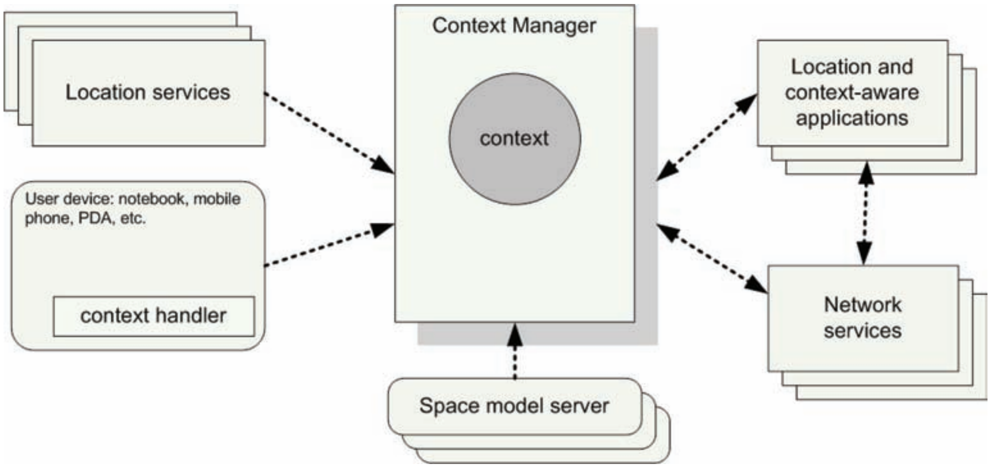
Considering that a user' context is something very wide, that can contain a considerable and variable number of dimensions, we sustain that context should be represented by an unbound and dynamic list of attributes, represented by standardized and non-standardized data structures, with mandatory and optional attributes. Context is a cumulative storage of knowledge, being able to describe the current situation of a person and also remember past experiences.

Context management should be done by a pervasive universal service, capable of dealing with any number of context sources. In (Meneses, 2004) we proposed a generic context manager capable of receiving data from virtually any sensor or location service, that provides an interface that allow authorized client applications to access to user' context represented by a XML stream. The developed solution also allows some other functionalities like the use of space model servers to complete the context information and a publish-subscribe mechanism that allow applications to request to be notified by the context manager when the context (or a specific dimension of the context) changes. Figure 1 shows the context manager and the main entities that interact with it.

The context manager holds and manages the context object which contains the user' context. It receives contextual information from location services that can exist on the infrastructures (like, for example, a positioning mechanism on a wireless network or soft sensor that detects the presence of the user mobile phone nearby an Bluetooth access point) and from context handlers that run on a user device. An example of a simple context handler, to be run on the user device, is a software that detects and updates the context with the BSSID of the WiFi networks detected or a software that updates the context with the geographic coordinates that retrieves from a GPS receiver. Data received by the context manager is integrated into the user context becoming available to be used by applications and services that can run on the user device or in the network.

The context manager, besides integrating the data received from sensors, can also improve

Figure 1. The context manager that manages the context and interacts with a set of external entities



the user' context using some external services capable of providing additional information about the collected data, and can also execute inference algorithms that supply new contextual dimensions. For example, the context manager can execute an algorithm that by processing the GPS coordinates is able to automatically determine if the user is at home or at his/her workplace (Moreira, 2005). Other example is the possibility of using data available at GSM phones to automatically infer high level information about the current situation of a user.

AVAILABLE TECHNOLOGIES AND SOLUTIONS

Today, there are a wide number of technologies that can be used to acquire the user' location and position. Some of those technologies, like the Active Badge (Want, 1992) or Active Bat (Ward, 1997), were specifically developed to acquire the user' location or position inside buildings. Other technologies, like WiFi networks or Bluetooth access points, were initially developed for a different proposes but can also be used to locate a user.

The lack of a universal pervasive solution for location/position is one of the main problems that block the bootstrap of location-based services and applications. Even GPS receivers, that become popular in the last years, are not a universal solution because it only works in open areas and not everybody has a receiver.

What is necessary is a solution that can be deployed by anyone, everywhere, and pervasive enough to not interfere on people's life. Currently, the best possible solution is to use mobile phones. If we look to a person on the street, at home, at work, going out with friends, etc., we observe that a mobile phone is the technological device that is always present and always turned on. Unlike a laptop that only some people have and it is only turned on when it is needed, or a GPS receiver that people use mainly in car, mobile phones are almost universal (ubiquitous): almost everybody has one, it is kept turned on most of the time and the user takes it everywhere.

Several mechanisms were developed to acquire the mobile phones' position. Angle of Arrival (AOA), Time Difference-Of-Arrival (TDOA) and Enhanced-Observed Time Difference (EOTD) are some of the solutions developed to acquire the location of mobile devices in GSM cellular networks.

These technologies provide the positioning data of mobile phones to network operators which usually do not make this information accessible to applications running outside their backbones. Hopefully, there is a basic position mechanism, known as cell-ID positioning, that is done at the mobile terminal by identifying the network cell being used in that moment by the handset. The accuracy of cell-ID method is reduced when compared with the others mechanisms but has the advantage of being possible to be done on the user handset, without depending on any network service.

GSM networks are made of cells with each cell covering an area. In rural areas, with fewer users per square kilometre the cells are usually bigger, covering a wide area. In contrast, in urban areas cells are usually smaller. Each cell supports a limited number of users thus in urban areas the cells are usually smaller with more cells covering the same area in order to support the communications requirements of all the users.

Each cell has a numeric unique identifier, generically called cell-id. Mapping each cell-id into a geographic position would allow finding the location of the user in a well known referential. However, this mapping is a difficult task because network operators do not make their network configuration or base station positions public. Mapping each cell manually would be a big effort considering that new cells and changes in the network configuration would have to be detected in order to keep the service updated.

Medical equipment with network connectivity is also becoming available, enabling the development of integrated systems where the patient's data is available and monitored remotely. Moreover, automatic collection of data from medical devices allows more complete patient medical histories (with less mistakes introduced by manually collecting data and with more data – data collected more often). Reasoning algorithms that process this data can detect and foresee health problems based on the user history or simply remember or automatically instruct medical devices to apply certain drugs.

Users' history and scientific knowledge can be joined in data mining and machine learning algorithms to create knowledge and predict the user medical evolution.

Current technology allow to locate doctors inside an hospital, access patients records automatically when a doctors gets near a patient or to locate a patient that may suffer from memory problems and get lost on a street, etc. However, smarter applications can be developed.

Some health services and equipments already provide medical records in an electronic format. The next stage of the technological development should be the integration of the records into the user context. The integration would allow to simultaneous access to the medical records and to other dimensions of the user context which could benefit the user and medical staff. Information like the familiarity of the user with the surrounding environment or the user location can help medical rescue services. Information about the presence of familiars or friends nearby can provide valuable information that benefit the medical staff and also the patient, allowing to have information about what happened to the patient before the lost of conscience or to find out if any other person would be with the injured patient at the moment of a accident and it is still missing. Having a user' context that keeps memory of the user movements will help to know easily where the user was before and to find and contact the persons that were with the ill person.

IMPROVING CONTEXT WITH TODAY'S TECHNOLOGY

If a person is involved in a medical emergency situation, the attitude changes according to the place where the emergency occurs, whatever the person is the victim or the rescuer that provide assistance to injured persons. A certain health problem can be less critical if the person is in a familiar place and surrounded by friends in contrast to a situation where the victim is alone in an unfamiliar place. A context management system can provide such a support for this kind of applications.

The user's context is valuable information in case of emergency because it can include the user's position and location and also provide additional valuable information like the familiarity level with the current place, the presence of nearby friends and relatives or information about the user medical history and known problems. The context of the user can even include information that may suggest the causes of the emergency if it is feed by temperature or acceleration sensors. The ubiquity of mobile phones and networks provide a particularly rich technological environment to gather such information and enable assistance applications for the health care mass market. Most of these applications can rely on the phone's hardware only and be easily deployed in the majority of the current mobile phones. Therefore, all the conditions for a fast dissemination of these applications are fulfilled.

Mobile phones are small and people take them to everywhere, being common the presence of a mobile phone on every people's pocket (including injured victims). Just by using the cell phone it is possible to infer when the user is moving or visiting a place and compute a familiarity level with the user's current location. This kind of information can be computed on the mobile phone and does not need to use any network services.

Detecting the User Movement

When turned on, a GSM phone is linked to a cell - the active cell - which is selected among the cells available in a certain place. The handset movement can not be detected just by analysing the changes in the cell-id because the handset changes from a cell to another when fluctuation occurs in the radio signal level, when it becomes weaker or because the user moves to another place. Thus, even if a terminal stays for a long period in a single place it may change several times the active cell. While remaining in the same place, sometimes a handset stays for hours in one cell while in other occasions it stays only some seconds or minutes in each of the available cells.

By analysing the changes of the active cell during a period of time it is possible to detect the movements. When the terminal is stopped in a certain place it will change between the set of cells available on that place. When the terminal moves to a new place, new cells will become available and will be used. Thus, when the user is moving we observe the use of different cells and faster variations in the active cell.

Computing a Mobility Distance and a Mobility Index makes it possible to detect the user movement (Meneses, 2006). Considering that a record has the identification of a cell being used in a certain moment and that instant timestamp, the Mobility Distance measures the distance between two records. If the user in both moments is in the same cell then the distance is zero. If not, the distance is the inverse of the time spent on each cell. For a list of records, the Mobility Index gives the sum of the mobility distance between each record and all the previous ones. Thus, the Mobility Index allows to estimate the user movement, computing the index from the current time instant back to a certain amount of time back.

CREATING A PERSONAL SPACE MODEL

Considering always the last cells used by a mobile phone it is possible to find out if the user is moving or not, computing the Mobility Index of the records collected during the last minutes (the used cells). When the user is not moving it is possible to characterize the place based on the set of cells used during that time. The place is characterized by the set of cells used and by the percentage of time spent on each cell. The characterization allows create "an image" of the GSM network in that place: we call it a fingerprint.

If the user visits the same place several times then a fingerprints is created in each visit to that place. Several visits to a place result in several fingerprints, which are not necessarily equal because the user' handset spends different amounts of time on each of the available cells (the percentage of time spent on each cell is different). Although different, the fingerprints have some similarity because they were created on the same place served by the same subset of cells.

By clustering similar fingerprints it is possible to group fingerprints, creating a cluster for each place. A cluster is created by the union of fingerprints (that are created based on the cellID) and represents a place visited by a user. To measure the similarity between fingerprints and clusters two functions are used. The first function calculates the percentage of cells in a fingerprint that are also member of a cluster. This function ignores the cells of the fingerprint with less than 1% of time because so small amount of time is not representative of a place. The second function calculates the absolute difference between the percentage of time spent in that cell in each fingerprint (or in a fingerprint and a cluster).

Based on the total distance the system can join a fingerprint to a cluster or create a new one. A new clustering algorithm was created to deal with this data. The new clustering algorithm deal with symbolic data (the fingerprints), supports an endless number of fingerprints and can be applied as the data becomes available. The clustering process allows to create clusters that are continuous changing as new data (new fingerprints) are generated by the user movement.

Inferring the Familiarity of a User with a Place

A cluster contains the same basic information that a fingerprint has. It allows to know which cells exist in the place represented by the cluster and the exact moment (timestamp) the user arrived and leaved the place. Using timestamp data it is possible to know the total amount of time spent in a cluster (place) and the time elapsed since the last visit to that place. Based on the total amount of time spent in a place it is possible to estimate how well a user knows that place – the places best know are the places where a person spends more time. The Knowledge Index represents the knowledge the user has about a place based on the total time spent in it.

Places change as time goes by, with the construction of new buildings, new roads, etc. If a person does not visit a place for a long period then when he/she goes back to that place the changes will be noticed and the person will not feel so familiar with the place. Based on the time elapsed since the last time the user visited a place it is possible to calculate a Forget Index. Combining the Forget Index and Knowledge Index it is possible to obtain a Familiarity Index.

The Familiarity Index expresses the familiarity with the current place and can be very useful to a number of applications. It allows applications to adapt themselves according to the familiarity of the user. For example, in a very familiar place a user will not need help from a GPS guidance (navigation) application – the user knowledge should be enough to know which direction take to go to another place. On the opposite situation, in a completely unfamiliar place, the familiarity index can be useful to trigger an application that guides a user based on GPS coordinates, or an application that provides information about local attractions or about where to get a hotel or a restaurant in the surrounding area. An injured people, in a familiar place, will fell more comfortable and eventually more capable to request help and provide information about his location or get help from a relative. In contrast, an injured people in an unfamiliar place with the anxiety of get medical help will probably fell lost and be much less capable to provide his/her location or other information describing the current situation.

Table 1. Results achieved by the three users

	User A		User B		User C	
Visits to different places	59		123		147	
Visits correctly detected	53	(89,8%)	95	(77,2%)	121	**(82,3%)**
Clustering errors	3	(5,1%)	12	(9,8%)	4	**(2,7%)**
Partially well detected	0	(0%)	11	(8,9%)	9	**(6,1%)**
Faults	3	(5,1%)	5	(4,1%)	13	**(8,9%)**
False Positives	31		10		11	

Results

The technology described in the previous section was tested by three different users, clients of two different GSM networks, during several consecutive weeks. The users kept their normal life and manually registered their activities in a diary. The computed results were them compared with the user's diary (ground truth) to access the quality of the results achieved.

The system was tested considering the cells used by the phone during the last 10 minutes, considering the user was immobile when the Mobility Index was less than 6. Results show that the user movements were well detected in most of the occasions. Table 1 summarizes the results achieved considering all the visits made by the users to the different places that took at least twenty minutes.

Between 78% and 90% of the visits made to the several places were correctly detected. The amount of errors is small and a detailed analysis of the data show that those errors occur in very specific situations or places. False positives occur when the user is moving and the system classifies the user as visiting a place while clustering errors represent visits that were correctly detected but the clustering process joined the fingerprint to a cluster that represents other place. Generally the results are very good, considering that two of the users live and work inside cities and visited places very near. If we consider also the visits that takes less than twenty minutes the results range from 70% of visits correctly detected to user B to 86% to user A.

The main problem with the proposed solution are the places visited for very short period of times that sometimes are not detected and places that are very near each other that not always are distinguished. However, even some of the places geographically near and places visited for short periods of time were detected and correctly clustered.

An analysis of data allows explain most of the errors detected. User A lives inside a big city and works in another city located 35 km away from his house. Everyday, he goes to work by car, crossing a rural area, travelling in a narrow and sinuous road. Analysing the user data we see that false positives are the most common error in user A data and always occur when the user is going to work. Because he drives in relative slow speed in a rural area (where the number of GSM cells is small and each one covers a wide area) then he uses the same set of cells for several minutes. The use of the same set of cells makes the mobility index to decrease below the threshold that defines the boundary between considering the user moving or not moving. Thus, the system considers the user is visiting a place when, in fact, he is travelling. Although this is a false positive, it is not a completely mistake because in fact the user knows the area has he travels by that road everyday.

Many of false positive registered for the others users can also be explained by analysing data detailed. For example, false positives occur when user B is travelling with the family and when user C travels in a natural park, in an inhabited area. User B diary shows that the users travelled, by car, near the sea. Considering the distance and the amount of time the trip took, it is possible to conclude that the user travelled very slowly and/or stopped to visit a place. User B does not remember exactly what he has done on that afternoon but admitted that stopped visiting some beaches in the shore. User C travelling in a natural park with narrow and twisted roads experimented the some problem that occurred to user A: he drove even more slowly and for a long time inside the same cell (being an inhabited area it has only one or two GMS cells). Thus, by an analysing data it is possible to explain many of the errors.

In (Maitland, 2006) it is presented a solution to detect the users' daily activity, through the use of am unmodified mobile phone. The solution is based on an application that works detecting patterns in signal strength fluctuation and changes in the active GSM cell to infer whether the user is sitting still, walking or travelling by car.

Although not completely accurate in the inference of the user' activity and in the detection of the amount of exercises done by the users, the study shows that people are willing to accept applications that do not produce 100% accurate results. Running on a mobile phone (which is a device originally developed for communications proposes) the application has the merit to also encouraged people to do more exercise which brings recognized benefits for people health. Even having knowledge of the accuracy of the application results people felt motivated to do exercise in order to be healthier (and achieve higher values in the application). In (Tsai, 2006) it is presented another solution based on mobile phone which allows users to self-monitor caloric balance in real time.

There is a big set of new technologies can be applied to help patients and emergency personnel. However, apply technologies to complex, stressed and emergency situations imply some constrains. Data networks can fail, wireless systems are even more unreliable and in stressful situation the interfaces and systems must be simple and reliable. Medical and emergency equipment does no comply with unreliable, inaccurate and not easy to use systems.

Location based on GSM cell-ID is not the most accurate positioning system but still produces very valuable data for the user context, which can be useful in many circumstances, including emergency situations. We do not propose a medical system based on cell-id but the use of position data to improve the context and enable a new set of applications that can use the familiarity level.

All information related to an ill person is important to emergency services and, sometimes, as the result of panic or stressful situation people are not capable of provide detailed and complete information. The presented solution can be valuable for users in many circumstances, including injured people, victims of accidents or sudden illness.

A simple alarm application that is executed in a mobile phone by pressing a button can trigger medical assistance providing valuable information about the user context to rescuers. By pressing the button, the user activates an application that collects information about the current situation/environment and sends an alert message based on the detected situation. The alert message can transmit information like the location of the user (available in the user context), the user familiarity with the surrounding environment, the identification of the user (which could allow access to his medical records by the emergency services) or even some dimensions of the user context that express the user medical history.

CONCLUSION

The existent technology allows create a new class of applications that explores the rich technological environment that today exist almost everywhere. The pervasive and ubiquitous technologies present everywhere and the use of inference techniques enables the creation of innovative applications in the healthcare domain. The solution presented in the previous section is just an example of these inference techniques. Although it has not been tested in any specific case in the healthcare domain, we foresee that the application of the proposed system can bring important benefits to this domain.

Chapter 3.10

Electronic Patient Monitoring in Mental Health Services

Werner G. K. Stritzke

Andrew C. Page
University of Western Australia, Australia

ABSTRACT

This chapter reviews advances in electronic patient monitoring in mental health service delivery. The first part focuses on interactive-voice-response (IVR) technology and its dual role of enhancing the efficient and reliable access to vital patient information and reducing the need for human resources in using that information to guide patient care. Future directions for IVR-mediated mental healthcare are outlined and challenges to dissemination and routine implementation are discussed. The second part of the chapter focuses on touch screen technology as a clinical tool for continuing, flexible treatment planning in mental health inpatient clinics. It reports on a successful trial of linking an innovative mental health 'well-being thermometer' to a touch screen interface for keeping electronic patient reported outcome data at the clinician's finger tips. The authors argue that the field needs to move beyond feasibility studies and identify the drivers of and barriers to routine implementation.

INTRODUCTION

In this chapter we review innovative uses of two emerging technologies in mental health service delivery. The first part of the chapter focuses on interactive-voice-response (IVR) technology and its dual role of enhancing the efficient and reliable access to vital patient information and reducing the need for human resources in using that information to guide patient care. The second part of the chapter will focus on touchscreen technology as a clinical tool for continuing, flexible treatment planning in mental health inpatient clinics.

INTERACTIVE VOICE RESPONSE (IVR) TECHNOLOGY EXTENDS THE REACH OF MENTAL HEALTH OUTPATIENT CARE

Information captured directly from patients using electronic methods is known as electronic patient reported outcome data. In developed countries almost every patient owns or has access to a telephone, making it a potentially ubiquitous portal for interactive data exchange and feedback between mental health service providers and patients. Interactive Voice Response (IVR) is a mode of data collection that uses an automated telephone interview, where a computer controls the administration of pre-recorded questions, and the respondents indicate their answers by pressing one of the keys on their telephone key pad or, as voice-recognition technologies become increasingly sophisticated, by saying out aloud the number corresponding to their answer. Such automated consumer-provider interactions are already commonplace in many business and service applications (e.g., phone banking, airline flight information). The scope of automated information exchange is very flexible. IVR systems for mental health care can be programmed to collect information in three basic modes: interval contingent (e.g., having patients report daily the frequency and intensity of symptoms of a presenting problem), signal contingent (e.g., calling patients on multiple occasions to elicit patient reports for those specific points in time), and event contingent (e.g., patients initiate calls to the system to report their acute status at the moment a particular target event occurs). Conditional branching of IVR administered questions based on decision algorithms acting on patient input can be adapted for many clinical applications such as diagnostic screening, aftercare monitoring, and triggering system-initiated proactive support mechanisms (e.g., automated voice and email messages describing coping strategies). If a patient fails to call the system at the expected times, automated reminder calls can be sent and treatment providers can be electronically notified to asses the need for an in-person follow-up. Likewise, clinicians can be alerted by the system if changes in patient status trigger programmed thresholds for stepped-up risk management or treatment intensity.

There are several advantages of IVR systems that are particularly relevant to mental health care applications. Patient-initiated calls can be recorded and processed at any time of day or night. Provider-initiated calls reach patients in their home without requiring an office visit. IVR systems are ideally suited for providing continuing care to hard-to-reach groups such as the homeless and drug users, or patients living in remote locations. Previous reviews of IVR studies (e.g., Corkrey & Parkinson, 2002) noted that the privacy afforded by interacting with automated, standardized interview protocols facilitates the accurate and honest reporting of potentially stigmatizing behaviors such as drug use or sexually risky behaviors. The automated patient-provider interface and standardization of interviewing formats eliminates interviewer bias and other unintended observer effects (Shaw & Verma, 2007). The verbal nature of IVR-based interviewing benefits patients with low levels of reading ability, including children. Children especially appreciate the high level of confidentiality in IVR communications, because questions presented by the IVR system cannot be overhead by others even within earshot, and the children's responses are keyed in unobtrusively via the touch-tone telephone (Stritzke, Dandy, Durkin, & Houghton, 2005).

Despite these potential advantages of IVR technology in enhancing mental health service delivery, the routine integration of IVR systems in mental health care is yet to be realized. In a review of first-generation IVR studies published in the decade prior to the year 2001, Corkrey & Parkinson (2002) concluded that most patient monitoring studies were uncontrolled and intervention trials produced mostly nonsignificant results. Yet, these reviewers were optimistic that IVR technology would eventually prove its value as an economical and flexible tool in the provision of quality mental health services. More recently, there are promising signs that research in this area is slowly moving from a preponderance of studies demonstrating only feasibility and acceptability of this technology to controlled trials evaluating the efficacy of psychological interventions incorporating IVR protocols (e.g., Brendryen & Kraft, 2008; Mahoney, Tarlow, & Jones, 2003; Mundt, Moore, & Bean, 2006; Greist et al., 2002; Reid, Pipe, Quinlan, & Oda, 2007). While there is still some way to go, there can be little doubt that IVR systems are one of a suite of emerging technologies that will reduce the burden of unrecognized and untreated psychological disorders at the level of primary care (Kobak et al., 1997), while simultaneously increasing the capacity for delivering preventative services. For example, in the U.S., there is a huge gap between the one minute that primary care providers consider the realistic average amount of time they can devote to prevention during a typical office visit, and the 7.5 hours each day they would have to spend on prevention if they delivered all the preventative services recommended by practice guidelines (Glasgow, Bull, Piette, & Steiner, 2004). IVR technology is a partial solution to closing that gap. Just as accurate diagnosis is the cornerstone of effective treatment, reliable monitoring of treatment progress is the foundation of iterative treatment planning and accountability for outcomes (Page & Stritzke, 2006). A number of recent studies demonstrate that IVR systems can be successfully incorporated in (a) assessment and diagnosis of mental disorders, (b) monitoring of behaviors and symptoms during treatment and aftercare, and (c) initiating referral pathways and delivering interventions.

Assessment and Diagnosis

IVR systems can be used prior to the clinic visit to initiate the assessment process. In an early study, Kobak et al. (1997) showed that an IVR version of a standard structured clinical interview administered in primary care settings yielded high diagnostic correspondence between the IVR- and clinician-administered versions. Recent studies have confirmed the feasibility of collecting diagnostic information via IVR technology in community settings. For example, Brody and colleagues (Brody, Rosen, Brodey, Sheetz, & Unutzer, 2005) explored the reliability of an IVR version of the Brief Symptom Inventory (BSI) in a community health centre serving low-income populations including English- and Spanish speaking groups. Results showed that IVR-generated responses on the BSI were not significantly different from a paper-and-pencil version, had high test-retest reliability ($\alpha = .95$), and patients reported similar satisfaction with both modalities. Thus, IVR is well suited to administer standard diagnostic tools of broad psychiatric functioning.

The reliability and validity of IVR versions of specific psychiatric symptom scales have also been examined. For example, a comparison of clinician-administered and IVR-administered versions of the Montgomery-Asberg Depression Scale (MADRS) yielded comparable reliability measures (Mundt et al, 2006), and symptom severity was equivalent for nine of the ten individual items. An interesting feature of the IVR version was that after providing an initial rating for each item of the scale, the system responded with a gender-matched voice to provide the anchoring description of the numerical severity rating spoken in an affective intonation that reflected the severity of the rating provided by the respondents. Patients were allowed to adjust their ratings up or down based on the auditory feedback until they felt the affective tone of the voice matched their own feeling. Whether such features improve the reliability or predictive validity of the rating was not tested in this study. Assessment systems using IVR technology to screen for depressive symptoms have also been used extensively in clinical trials of antidepressant medications (Moore et al., 2006).

Few studies have examined IVR assessment protocols in non-adult samples. A notable exception is a comparison between IVR- and clinician-administered versions of the Teen-Addiction Severity Index (Brodey et al, 2005). The authors reported that reliability indices of the IVR version were equal or superior to those obtained by interview, and IVR-generated responses were reasonable convergent across a range of symptom domains. Importantly, participants claimed that their responses would be more honest using automated systems than during face-to-face assessments, although they preferred an Internet version over the IVR version. However, because this sample was recruited from a highly structured inpatient setting, it is unclear if IVR assessment of addiction severity would yield comparable results in outpatient settings.

IVR assessment protocols have also been evaluated for neuropsychological testing. Mundt and colleagues (Mundt, Kinoshita, Hsu, Yesavage, & Greist, 2007) monitored longitudinally cognitive functioning in three groups of community-dwelling elderly participants, who were either cognitively normal, had mild cognitive impairment, or had mild dementia. Results were promising and showed that the IVR-administered test battery reliably and validly discriminated cognitive functioning between the three groups. However, the reliance on touch-tone inputs proved somewhat difficult for participants with mild dementia, indicating that the generalizability of IVR assessments in this format may be constrained by the severity of cognitive impairments in respondents (Mundt et al., 2007; cf. Block, Bates, & Hall, 2003). This limitation may be overcome in the future as automated speech recognition can provide an alternative to manually keyed-in responses. There is also some preliminary evidence that it may be feasible to use IVR for the administration of *objective* measures of neuropsychological functioning such as choice reaction time tasks (Mundt, Geralts, & Moore, 2006). However, reliability of these measures can be poor as design and functional constraints of the telephone interfaces are still extremely variable posing problems for the standardization of testing conditions (Mundt et al., 2006).

In sum, there is considerable evidence that IVR-administered assessments of psychiatric symptoms can yield reliable and valid diagnostic impressions. In most studies, though, participants received compensation for their participation. It is unclear what the uptake of IVR assessment protocols would be among patients not receiving monetary incentives.

Monitoring

IVR systems are especially well suited for the frequent monitoring of clinically relevant behaviors, thoughts, and feelings over time while keeping reporting burdens at a minimum. For example, daily IVR assessments have been used in a randomized controlled trial to monitor the effect of medication on patients' ratings of emotional and painful symptoms associated with depression (Moore et al., 2007). The daily reporting regimen via IVR was able to show that a dose-related improvement in symptoms was already evident after the first day of treatment. IVR has also been shown to be a valid tool in monitoring the side effects or complications associated with medication. In one recent study examining the onset and chronology of antidepressant-induced sexual dysfunction, assessments of participants at home using IVR identified onset of sexual dysfunction well before it was detected during scheduled office visits (Dunn, Arakawa, Greist, & Clayton, 2007). Thus, frequent assessments via IVR enables more precise evaluation of changes in symptom patterns.

Frequent monitoring of problem behaviors is especially important for chronic, relapsing disorders such as substance use disorders. In two recent studies, Toll and colleagues (Toll Cooney, McKee, & O'Malley, 2005; 2006) compared reports from recently quit smokers on their cigarette and alcohol consumption over a 7-day period using either an IVR system or the traditional timeline follow-up (TLFB) method. Although both methods yielded largely comparable reports, compliance with the IVR system was quite poor despite participants earning extra compensation for completing the telephone questionnaire. As with studies using IVR to collect assessment and diagnostic information discussed earlier, monitoring studies also typically offer a fair amount of monetary incentives to enhance compliance. Little is known about the motivation required for IVR users to bear the burden of frequent interactions with an IVR system under conditions where no monetary incentives are provided. Some have argued, though, that lower rates of IVR reported data entry which is verified by date and time stamping is preferable over higher, but unverifiable, compliance rates achieved with alternative methods (Collins, Kashdan, & Gollnisch, 2003). Moreover, IVR monitoring is superior to other methods in contiguously exploring triggers and contextual variables of problem behaviors. For example, IVR studies have examined the relationship between mood and gambling behavior in real time (Gee, Coventry, & Birkenhead, 2005), environmental and internal triggers of cigarette smoking (Krukowski, Solomon, & Naud, 2005), contextual variables of drinking and abstinence for up to 128 days in resolved untreated community problem drinkers (Tucker, Foushee, Black, & Roth, 2007), changes in alcohol use and comorbid symptoms (Simpson, Kivlahan, Bush, & McFall, 2005), and links between alcohol use and stress (Anderson, Gordh, & Berglund, 2007) and victimization (Neal et al., 2006).

Although the feasibility of IVR monitoring in adult samples is well documented, there is a relative neglect of IVR monitoring research with adolescent samples and children. The feasibility and acceptability of daily IVR monitoring of predictors of alcohol use was recently explored in a small pilot study of adolescents treated for alcohol use disorders (Kaminer, Litt, Burke, & Burleson, 2006). Results were encouraging, but compliance over a 14-day period was moderate (72%) and may have been contingent on the use of generous incentives (up to $100) which are typically not available in general clinical practice. In contrast, in the first studies to investigate the feasibility of using IVR in community samples of children (Ns = 74 and 662; aged 9 – 13 years), compliance rates with daily monitoring of alcohol and tobacco related behaviors and attitudes were high (91% and 92%), with reporting periods of up to 8 weeks and a comparatively modest amount of incentives of up to $15 (Stritzke et al., 2005). Yet, the potential of IVR technology in health promotion and research with non-adult populations still remains largely untapped.

Intervention

Perhaps the greatest clinical utility of IVR technology lies in its capacity to integrate IVR diagnostic and monitoring functions with automated clinical decision-making tools. Systems can be configured for initiating differential referral pathways, delivering brief interventions, enhancing risk management, assessing the need for stepped-up or stepped-down follow-up care, and providing tailored relapse prevention assistance.

In several non-controlled studies, IVR systems have been used for pre-visit screening to direct patients into appropriate referral pathways and interventions. For example, IVR technology has been used to screen for tobacco use prior to scheduled primary care visits in two inner-city clinics (McDaniel, Benson, & Martindale, 2005). Just over half of the patients contacted completed the automated survey, and 39% of those were identified as smokers. Survey information was linked (albeit via manual entry) with the electronic medical record system to generate reminders to primary care providers to initiate smoking cessation interventions. Unfortunately, almost one in three patients reported in a post-visit interview that they did not receive an automated call prior to their appointment, and less than half of the smokers had discussed smoking cessation with their provider. This raises concern about the reliability of the IVR-initiated screening and the utilization of IVR-generated feedback to prompt clinician-guided behavior change. Future refinements of automated patient-provider interfaces need to take into account the potential for "reminder fatigue" in medical personnel (McDaniel et al., 2005), especially if IVR systems do not also incorporate automated brief intervention features that can lessen the response burden on medical staff. The feasibility of IVR screening to initiate referral pathways has also been explored for large, state-wide dementia screening (Mundt, Moore, & Greist, 2005), as well as for automated depression screening of a small convenience sample of disadvantaged pregnant women in an urban obstetric clinic (Kim, Bracha, & Tipnis, 2007). In those studies, of the callers who received a positive screen, 34% to 57% indicated a desire to speak with a health care provider or accessed further information about referral options. These results are encouraging and demonstrate the feasibility of IVR applications in facilitating the automated transfer of patients receiving positive screens into appropriate referral pathways.

Beyond the initiation of referral pathways, feedback from an IVR patient-provider interface can be used to directly prompt the delivery of interventions. In one recent randomized-controlled trial, IVR technology was tested for following and triaging smokers after discharge from a busy tertiary care hospital following treatment for coronary heart disease (Reid et al., 2007). Patients were automatically contacted via telephone to check their smoking status for up to 30 days after discharge. A decision-making algorithm prompted the IVR system to flag any patients who had resumed smoking but were motivated to make another quit attempt. These patients then received additional assistance via three telephone sessions over an 8-week period conducted by the nurse-specialist. The odds of being smoke-free at the 12-month follow-up were more than two-fold for the IVR group compared to a usual care group. Another randomized controlled trial examined outcomes of a 12-month IVR-mediated intervention designed to assist family caregivers managing persons with disruptive behaviors related to Alzheimer's disease (Mahoney et al., 2003). Caregivers were monitored weekly by the automated system and, if distress levels exceeded programmed thresholds, were offered automated assistance. If problems persisted, additional coping strategies were made available, as well as options for stepping up care which allowed caregivers to seek support from an expert panel or other caregivers via personal voice-mail linkage. Caregivers with low levels of mastery and high anxiety at baseline showed a significant intervention effect at 12-months follow-up, reporting reduced distress, depression, and anxiety compared to controls. IVR-mediated positive treatment effects have also been demonstrated in randomized controlled trials of computerized cognitive-behavior therapy for obsessive-compulsive disorder (Tumur, Kaltenthaler, Ferriter, Beverley, & Parry, 2007), and some of these systems have gained approval by government regulatory bodies (Baer, Greist, & Marks, 2007). It appears that randomized controlled trials of systems that combine automated features with some options for clinician-guided care, whether in person or via telephone contacts, show superior treatment outcomes and clinical utility compared to trials of systems where patient contact is limited to the machine (e.g., Mundt, Moore, & Bean, 2006). However, as IVR systems mature and start to utilize 100% automated patient-machine interfaces in *multiple* media, such as text, voice, and graphical images, which are capable of providing real-time feedback and iterative case management, the need for human resources to achieve long-term efficacy of IVR-mediated treatment outcomes may diminish (Brendryen & Kraft, 2008).

Perhaps the greatest advantage of the 24-hour availability of IVR-controlled "duty managers" in mental health case management is its tremendous potential for extending the reach of risk management protocols for outpatients, and thereby improving the safety of patients. For example, IVR systems have been successfully used for detecting, monitoring, and managing suicidality risk in home monitoring programs for patients with chronic illness (Turvey, Willyard, Hickman, Klein, & Kukoyi, 2006), and in large clinical trials involving vulnerable populations of depressed outpatients (Nierenberg et al., 2004).

Similar to diagnostic and monitoring applications of IVR technology, there is almost no research evaluating IVR-based applications to interventions with adolescents, let alone children. A promising start is a recent encouraging report on the feasibility and acceptability of an IVR-controlled behavioral aftercare intervention for youths following a 9-week treatment program for alcohol use disorder (Burleson & Kaminer, 2007).

Future Directions for IVR-Mediated Mental Health Care

The modal conclusion in published reports of IVR applications in mental health service delivery to date is that they are "feasible", and that they are "acceptable" to patients, when compared to alternative methods of information exchange between patients and providers. If the promising potential of IVR technology is to be fully realized in the routine care of mental health patients, future research needs to move beyond simply demonstrating feasibility and attend to several important issues. First, there is a need to extend the body of randomized controlled trials that test the long-term clinical outcomes of IVR-mediated interventions. Second, it is important that such trials are carried out by investigators that do not have a commercial stake in the intervention (Tumur et al., 2007). Third, not only improvements in psychological functioning and well-being are of interest. Equally important is to increase the evidence for cost effectiveness, cost offsets, and reductions in health care utilization associated with IVR-mediated care (e.g., McCrone et al., 2007). Fourth, the dissemination and wide-spread implementation of these innovative treatment tools is likely to require the advocacy and funding infrastructure from macrosystems such as large health care organizations, practice networks, and payers (Glasgow et al., 2004). Fifth, there is a dearth of studies investigating IVR-based interventions in children and adolescents. Given that today's technology-savvy youth in the developed world are born with a 'digital spoon' in their mouth, they are likely to be tomorrow's primary consumers of mobile telephone based interfaces for mental health services delivery. Sixth, compliance with IVR protocols requiring frequent patient-initiated contact with the machine has ranged from very good to poor, and published compliance rates typically were achieved by offering incentives for IVR users. Evaluation data are needed to establish the reliability of the uptake of IVR technology in routine care in the absence of monetary incentives for patients. Finally, medicolegal and ethical challenges associated with automated mental health services require further scrutiny (Koocher, 2007), and there need to be safeguards for monitoring the automated monitors. Especially if interoperation of independent IVR database systems between members of service networks occurs, it is important to ensure that data sources are allowed to interoperate and make their data available to external user interfaces without compromising their autonomy and security (Dawson, Qian, & Samarati, 2000). One can also be safe in the prediction that IVR technology is going to be only one of many drivers of modern mental health service communication interfaces, and it will be seamlessly integrated with other innovations in automated processing of electronic patient reported outcome data. One of these is the use of touchscreen technology to provide treatment staff with a platform to access on demand up-to-date data on a patient's treatment progress and mental health well-being.

TOUCHSCREEN TECHNOLOGY CAN KEEP A MENTAL HEALTH "WELL-BEING THERMOMETER" AT THE CLINICIAN'S FINGER TIPS

The humble thermometer is one of a suite of excellent tools for monitoring a person's health. The measurement is quick, reliable, and elevated temperatures alert staff to the presence of pathology. In contrast to physical medicine, clinical psychological services have lacked a "thermometer" to monitor client progress in real time. There is a need for a mental health measuring instrument that is rapid, reliable, sensitive to change, and can assist clinical decision making in mental health. Fortunately, developments in computing have facilitated rapid and efficient data collection, storage, and management. When this computing power is combined with a valid and psychometrically sound instrument, the promise of being able to provide real-time feedback on progress in treatment becomes a reality. The remainder of the chapter will briefly review the current status of data collection in psychotherapy and describe efforts to automate the real-time data collection in a mental health context. The ultimate aim is that when mental health "thermometers" are available and widely used, positive treatment responses will be identifiable to prevent unnecessarily long service delivery, and potential negative responses will be flagged in a timely manner to trigger a review of treatment options or activation of safety protocols.

The Rationale for a Mental Health Well-Being Thermometer

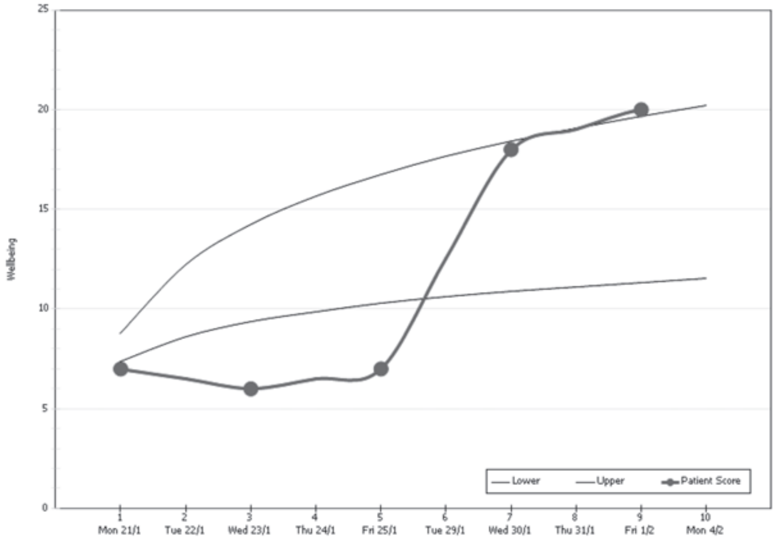
The logic behind the clinical use of a mental health thermometer is straightforward. First, it is necessary to identify and distinguish normal and abnormal 'temperature' readings. In the second step, once cut-off scores are identified, client trajectories can be monitored as they move from the abnormal range and shift towards normal by post-treatment. Clients who fail to follow the anticipated trajectory of improvement can be identified and remedial action instituted. Clients who reach the normal range faster than expected, can be discharged safely from treatment thereby saving on therapy time. The final step is the efficient assimilation into the workflow of a system of data collection and feedback that interferes as little as possible with the core business of therapy.

In psychotherapy, the concept of "clinical significance" was developed to achieve the twin functions of identifying when a change in mental health outcomes was statistically reliable and when it was clinically meaningful. The most commonly used metric (Ogles, Lunnen, & Bonesteel, 2001) is that developed by Jacobson and colleagues (Jacobson, Follette, & Revenstorf, 1984). The Jacobson and Truax (JT) method comprises two components, the first of which is the Reliable Change Index (RCI). The RCI expresses the pre to post difference in standardized units. The units are based on the reliability of the index and conceptually the RCI can be used to determine if the pre-post change is reliable (i.e., beyond that associated with measurement error). The second component assumes that client scores are drawn from one ("unhealthy") population and non-client scores are drawn from another ("healthy") population. A cut-off is established to estimate if a client's post-treatment score has moved from the unhealthy range into that of the healthy population range. Consequently, a client with a post-treatment score that is not reliably different from their pre-treatment score can be classified as "unchanged." Someone who has reliably improved, but failed to move into the healthy range will be classified as "improved" whereas someone who has reliably improved and moved into the healthy range can be classified as "recovered." Finally, clients who exhibit a reliable change in the opposite direction can be classified as "deteriorated." Such a classification allows clinicians to identify a benchmark against which mental health outcomes can be compared (e.g., Newnham, Harwood, & Page, 2007).

In terms of the thermometer analogy, these classifications permit discrimination between 'normal' and 'abnormal' scores on a psychometric instrument. It is then possible to interpret the trajectories of clients as they progress through treatment. Ideally, a client who begins in the abnormal or dysfunctional range will proceed towards the normal or functional range by the end of treatment. When symptom severity is plotted as a function of time in treatment, the average of client trajectories tends to follow a negatively accelerating function. That is, rapid initial progress gives way to a slower progress, which ends in the progress curve reaching an asymptote (Howard, Lueger, Martinovich, & Lutz, 1999; Lutz, Lowry, Kopta, Einstein, & Howard, 2001).

The expected progress trajectories can be used as a benchmark against which to compare each individual's progress. Minimally, clients can be compared against the average score of all clients. Alternatively, rather than a single trajectory, an estimate of measurement error can be placed around the trajectory to acknowledge the variability expected around the average course (Lambert & Archer, 2006). Initial symptom severity can be used to generate a suite of trajectories, so that the expected course of improvement will be different for different clients (Lutz et al., 2006). In addition, different methods of calculating the trajectory and the difference of a client's score from the trajectory can be used (Lutz et al., 2005). However, the common theme is that the progress of an individual client through treatment is evaluated against an expected trajectory. When a desired level of improvement has been achieved or exceeded, client and clinician can begin a discussion about the termination of treatment as well as planning for discharge and relapse prevention. Alternatively, if a client fails to make sufficient progress, a dialogue with the clinician can be initiated and the issues addressed (Harmon, Hawkins, Lambert, Slade, & Whipple, 2005). For instance, in Figure 1, the

Figure 1. An example of a client's scores during treatment being plotted against an expected trajectory (i.e., the area between the upper and lower curves)



client's trajectory, on an instrument where high scores are associated with improvement, shows that the person is failing to improve across the first five days of the inpatient treatment program. The area between the upper and lower curves is the expected trajectory of improvement for a patient with this level of severity. Thus, it was possible to discuss the absence of improvement. In this case, reasons were identified and a remedial plan was able to be put into operation over the weekend. By the Monday, the patient had been able to put into operation the treatment plan and move into the expected course of recovery, and into the healthy range by the end of treatment. Thus, real-time monitoring allowed for a timely adjustment to the treatment plan, which in turn resulted in a rapid improvement in patient well-being over the next couple of days (see Figure 1).

Monitoring Well-Being Trajectories

Lambert (2005) described the development of a monitoring regime within an outpatient setting using a 45-item instrument called the Outcomes Questionnaire (OQ-45). Following the analogy of the thermometer given earlier, Lambert's team repeatedly administered the instrument during treatment. Once sufficient data had been collected, typical expected treatment trajectories could be generated, and ultimately, actual progress could be benchmarked against expected improvement. In outpatient settings, providing staff with feedback from the OQ-45 increased treatment efficiency and effectiveness (e.g., Hannan et al., 2005; e.g., Hawkins, Lambert, Vermeersch, Slade, & Tuttle, 2004; Lambert et al., 2001; Whipple et al., 2003). Specifically, clients who were 'on track' could be treated in fewer sessions when feedback was provided. In contrast, clients who were 'not on track' received more sessions than when feedback was not provided. Since the clients who were 'not on track' were in the minority, there was a net reduction in the amount of treatment. This is a desirable outcome. The consumer is satisfied because they receive an appropriate level of care, and the provider is satisfied because costs are reduced and their time is used efficiently. Furthermore, by predicting treatment outcomes and alerting therapists to clients deemed likely to demonstrate poor outcomes at the termination of treatment, it was possible to halve the number of clients who deteriorated (Lambert et al., 2005).

There are a variety of other questionnaires that are appropriate for evaluating client outcomes (e.g., Miller, Duncan, Sorrell, & Brown, 2005). The Clinical Outcomes in Routine Evaluation (CORE) is a suite of instruments that vary in length (Barkham et al., 2001) from the 18-item short form (Cahill et al., 2006) to the 34-item Outcome Measure. Like the OQ-45, the CORE is able to identify patterns of change and then use these to predict different treatment outcomes and durations (Stulz, Lutz, Leach, Lucock, & Barkham, 2007). However, these initiatives were largely focussed on outpatient settings (where treatment duration is measured in weeks) rather than inpatient settings (where duration is measured in days). The difficulty is that the questionnaires being used in outpatient settings refer to "long" time periods (e.g., the past week). Therefore, we needed to identify a measure potentially suitable for briefer time periods.

Searching for a brief measure that could be administered rapidly and repeatedly, we identified the World Health Organization's 5-item Well-Being Index (WHO-5). It measures psychological health and is suitable in physical (Bech, Gudex, & Staehr Johansen, 1996a, 1996b) and mental health (Henkel et al., 2003). It has high sensitivity and good specificity in identifying health status and good negative predictive value (Henkel et al., 2003). In her doctoral thesis Elizabeth Newnham has shown that the WHO-5 is a valid, highly reliable and sensitive measure when used in a psychiatric setting. Positive correlations between the WHO-5 and various symptom measures suggest it has strong convergent validity. In concert, these findings suggest that the WHO-5 is an appropriate measure of wellbeing in psychiatric settings.

Given that the psychometric properties of the WHO-5 remained strong among inpatient psychiatric samples it appeared a good candidate for monitoring change trajectories in inpatients. Since our purpose was to monitor well-being, we modified the wording to measure well-being over the past day, rather than the past two weeks as it was previously designed. Despite this change, the reliability and validity of the WHO-5 remained high and predictive of future outcome. Previous research (Lambert et al., 2003) revealed that early progress is indicative of final outcome and our results support this view. However, having an appropriate instrument is only one element to the issue of monitoring progress. The second component is a process for the efficient input, processing, and output of the data from each patient. To illustrate, we will describe the process adopted at Perth Clinic; a private psychiatric hospital in Western Australia, funded in part by the health insurer Medibank Private.

Linking the Well-Being Thermometer to a Touchscreen Interface

To address the issues associated with the input of data, it was necessary to find a process that was simple for patients to use, did not place a burden on nursing or administrative staff, minimized data transcription errors, and was readily accessible. To this end touchscreens were introduced into the treatment rooms and quickly adopted into the daily routine. This permitted data collection from both inpatients and daypatients at any time of the day. The touchscreens were acceptable to patients and provided an easy method of completing the questionnaire.

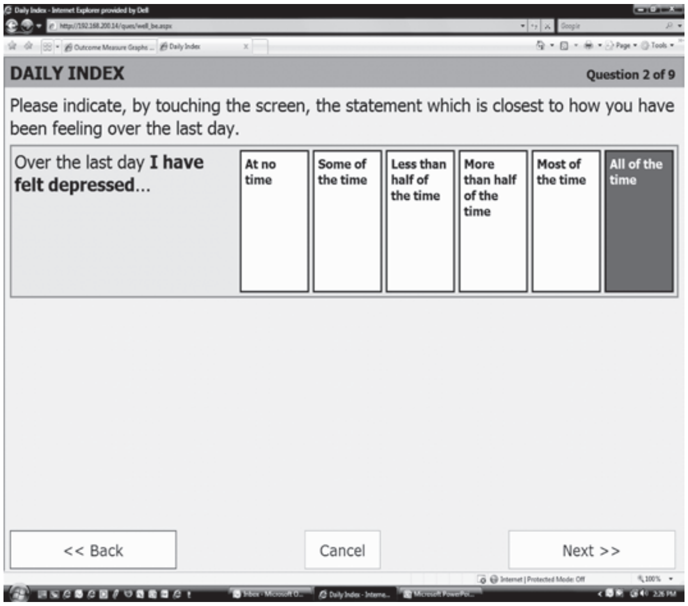
The next problem that needed a solution involved security. First, there was the issue of patient confidentiality. It was necessary to link the patient data to other data within the existing data base without providing a data entry system that disclosed the confidentiality of each person. Second, there was the issue of security of the existing patient data (i.e., it was imperative that people could not use the data entry hardware to access any confidential data held by the hospital). Third, there was the issue of security of the hardware itself. A hospital environment is a busy one and there is a risk of both theft and accidental damage.

Patient confidentiality was assured by requiring each user to enter their initials and date of birth into an entry screen. If a match was found with the hospital database, then patients were asked to confirm that the first name and suburb being used was correct. The patient could then proceed to enter their data (and in the future, view their treatment trajectory plotted against an expected trajectory).

The security of existing data held in the hospital's database was protected by the use of a Wyse "thin client" terminal. A thin client is a computer that relies on a central server for processing activities. They typically are solid state and do not have a hard drive. The hardware is sufficient to manage input and output and may include embedded software with a Web browser. In our context the thin client links to a web page that displays the questionnaire to the screen. Logging on opens a session and as patients enter their data, these are transferred to the server (for an example of a touchscreen data entry page, see Figure 2). Since no application data reside on the thin client, patient data is secure against loss or theft.

A variety of other benefits accrue from the adoption of a thin client to manage the data entry rather than a personal computer. The absence of moving parts and dependence on the remote server mean that the thin client is sufficiently robust to function in a busy ward environment. Since the thin client has no moving parts, overheating is less of a problem and so the hardware could be mounted securely and safely in a cabinet. From the perspective of the hospital's IT Department, the programming (in .NET) was relatively straightforward and thin clients are efficient because software upgrades and modifications can be made centrally on the server.

Figure 2. A screenshot of the touchscreen of the "well-being thermometer"



DAILY INDEX

Question 2 of 9

Please indicate, by touching the screen, the statement which is closest to how you have been feeling over the last day.

Over the last day **I have felt depressed**...

In sum, we have found that the development of a "wellbeing thermometer" has been well-received by patients and staff. To date, the responses from patients to the touchscreen technology has been anecdotal, and more systematic evaluations of this novel patient-provider interface are needed. They indicate that they are willing to participate because they can see that their data are relevant to their treatment progress. The main limitation seems to be that some level of management is required to oversee the process to ensure that patients are compliant with the data entry. In the past, when paper-and-pencil versions were used, it was obvious to staff which patients had been provided with and completed the questionnaires but now these data are stored on a central database. Therefore, a feedback process is required to alert staff which patients needed to be invited to complete the questionnaire on a given day. Nonetheless, these difficulties seem to be offset by the advantage that missing data (which occurred with paper-and-pencil versions) no longer occur, because progress through the questionnaire requires completion of previous items. Thus, the use of touchscreens to manage data entry (and ultimately feedback) has been achieved in a cost-effective manner that permits timely monitoring of mental health well-being in a psychiatric in-patient setting by providing relevant data to the clinical staff.

CONCLUSION

Among the emerging technologies in mental health service delivery, IVR and touchscreen technologies are poised to change the way mental health practitioners interact with their patients and deliver services. There is consistent evidence that these technologies can produce reliable patient reported outcome data, and level of acceptance of these innovations among patients is satisfactory. More controlled studies are needed to bolster the evidence base for the long-term efficacy of IVR- and touchscreen-mediated interventions. There is little doubt, though, that integrating these technologies in mental health care is feasible and holds great potential for improving the quality of care. However, routine and wide-spread adoption of automated patient-provider interfaces has significant implications for the funding infrastructure of mental health services and poses considerable challenges for the training of veteran and new members of the mental health work force. To the extent that these challenges are successfully met, the impact of IVR- and touchscreen-mediated interventions on the quality, continuity, and responsiveness of mental health care will be immense.

INTRODUCTION

The adoption and diffusion of e-health and the application of IT in healthcare is increasing at a rapid rate. Both European and U.S. governments are making e-health a priority on their agendas. The technical infrastructure required to support initiatives such as community healthcare integrated networks (CHINs) and telemedicine efforts is often dependent upon connecting different types of computer networks, each running on different types of technologies so as to present to the user the image of a single virtual electronic health highway. It is generally agreed that current software development technology cannot deliver this due to limitations of restricted scalability, fragmented management, and inflexibility in providing business support.

One of the potential solutions may be the use of Object Oriented (OO) technology. This article explores the feasibility of combining OO technologies with healthcare based workflow management systems (WFMS). We introduce the concept of workflow technologies and discuss the main advantages and limitations of WFMS. We detail the circumstances in which the use of WFMS could be considered and the technological factors necessary for its successful implementation.

DOI: 10.4018/978-1-59904-889-5.ch168

We also present an Object Management Group (OMG) model, analysing it in the context of the support offered for WFMS. The main advantages and disadvantages of the model are discussed. A workflow management coalition (WFMC) model is then contrasted with the OMG management model in order to identify the architectural differences between them. We focus on the relationship between workflow concepts and the position of the two reference models (WFMC and OMG) and on the use of UML in the design of information systems. We conclude by summarizing our findings on the extent to which OO technology can be used to build collaborative applications in healthcare and medical information systems.

BACKGROUND

During his State of the Union Address in January 2004, President George Bush affirmed the intention of the government to emphasize the role of technology in administration and delivery of healthcare in the United States (Bush, 2004). Similar sentiments have been voiced by the European leaders (Global Medical Forum Foundation, 2005; The Oslo Declaration on Health, 2003), and the World health organization ("E-Health in Eastern Mediterranean," 2005; A Health Telematics Policy, 1997). Both European and U.S. authorities define their initiatives primarily in terms of medical information technology centering on computerized patient record (CPR) or, in more acceptable parlance, the electronic health record (EHR). See Brailer and Terasawa (2003).

WHO's platform statement (A Health Telematics Policy, 1997) speaks of "health telematics policy," an all inclusive term that incorporates not only EHR but essentially all healthcare services provided at a distance and based on the use IT.

While implementation of these concepts is preeminently realistic in the context of EU and the U.S.A., the WHO plan appears, for many reasons, a combination of a list of good ideas and delineation of significant obstacles that make the good ideas seem almost futuristic. In response to the inefficiency of the highly fragmented programs to address even the most urgent aspects of healthcare across the globe, a demand for the development of a new rule set (Banjeri, 2004; Barnett, 2004; Olutimayin, 2002; Onen, 2004) governing the future actions began to emerge—the quest for the "doctrine of global health."

To address this void, von Lubitz and Wickramasinghe developed the doctrine of "networkcentric healthcare" (von Lubitz & Wickramasinghe, 2006a, 2006b, 2006c), which calls for the development of interconnected information grids that, together, constitute a powerful and well-structured network that facilitates information sharing among all participants within the operational continuum (Cebrowski & Garstka, 1998; Stein, 1998). Consequent to improved information sharing is the enhancement of its quality and integrity which, in turn, escalates the level of situational awareness that is the foundation for efficient, real-time collaboration among the involved entities, their self-synchronization, and operational sustainability which leads to a dramatic increase in mission effectiveness (Cebrowski & Garstka, 1998).

As described by von Lubitz and Wickramasinghe (2006a, 2006b, 2006c), networkcentric healthcare operations must be conducted within the intersecting territory of three mutually interconnected and functionally related domains (Garstka, 2000):

- The *physical domain* which encompasses the structure of the entire environment healthcare operations intend to influence directly or indirectly, for example, elimination of disease, fiscal operations, political environment, patient and personnel education, and so forth.
- The *information domain* which contains all elements required for generation, storage, manipulation, dissemination/sharing of information, and its transformation and

dissemination/sharing as knowledge in all its forms. It is here that all aspects of command and control are communicated and all sensory inputs gathered.

- The *cognitive domain* relates to all human factors that affect operations, such as education, training, experience, political inclinations, personal engagement (motivation), "open-mindedness," or even intuition of individuals involved in the relevant activities. Difficulties in metrics relevant to the cognitive domain notwithstanding, a body of experimental studies begins to emerge that will, ultimately, provide close quantitative relationships to other domains that govern healthcare operations space (Abel-Smith, 1989; Back & Oppenheim, 2001; Bodner et al., 1986; Newby, 2001; Roberts & Clifton, 1992; Wetherell et al., 2002).

The essential and enabling technology element of NCHO is the Worldwide Healthcare Information Grid (WHIG) that allows full and unhindered sharing of information among individual domains, their constituents, and among constituents across the domains (von Lubitz & Wickramasinghe, 2006a, 2006b, 2006c). In order to perform such a function, the WHIG must consist of an interconnected matrix of ICT systems and capabilities (including communication platforms, data collection, storage, manipulation/dissemination, and sharing), associated processes (such as information and knowledge storage and retrieval, management and their dissemination/sharing), people (e.g., healthcare providers/investigators, administrators, economists, politicians, lawyers, ICT personnel), and agencies (governmental and Non-Governmental Organizations or NGSs) at local/national/international level.

However, von Lubitz and Wickramasinghe have not detailed the technological make up of the WHIG which is the backbone of NCHO. We contend that the ultimate use of Object Oriented (OO) technologies as we discuss in this article will be to provide the technological backbone to such initiatives as NCHO or smaller scale initiatives such as community healthcare integrated networks (CHINs) or e-health and telemedicine applications. To fully appreciate the power and benefits that OO technologies bring to effecting superior healthcare delivery, it is necessary first to understand the evolution of IT applications in healthcare and the key challenges to date.

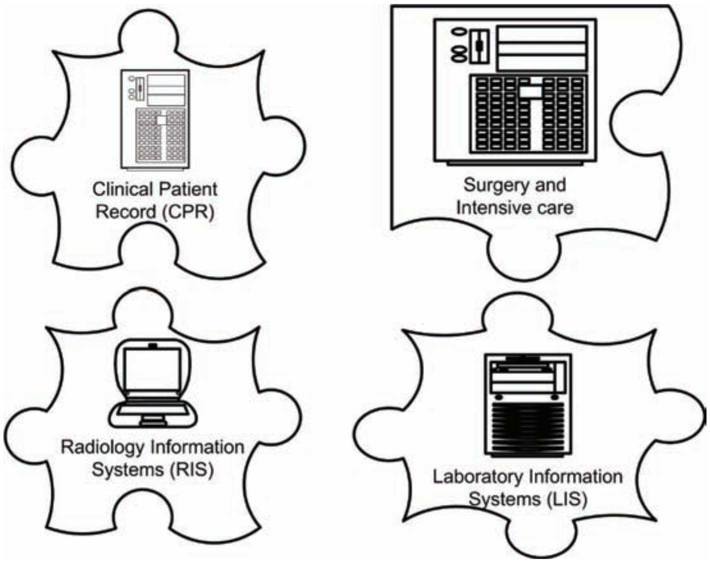
EVOLUTION OF IT APPLICATIONS IN HEALTHCARE

In the 1970s, the focus of IT applications in healthcare was to facilitate better healthcare administration, particularly in routine administrative tasks such as the calculation of patient charges for reimbursement . In the 1980s, the focus shifted to the development of clinical systems to aid in patient diagnosis and treatment (Johns, 1997; Rao, 2001). This trend continued until the late 1990s. A distinguishing feature of this trend was that most of the IT applications in healthcare were developed for very specific uses such as standalone software applications (Rao, 2001). This lack of interoperability has today become a significant challenge for the healthcare sector.

Simultaneously, in the last 40 years, there has been a significant evolution in system architectures that form the substrate of IT applications. Organizations have evolved from a centralised to a distributed computing architecture (Ganti & Brayman, 1995). This change of emphasis in system architectures has been accompanied by the emergence of client/server and object oriented (OO) technologies. By the 1990s, these two technologies had signalled the coming of age of the distributed computing architecture (Ganti & Brayman, 1995).

Modern IT applications have evolved to provide basic support for services to aid knowledge processing, problem-solving, and coordination by incorporating concepts such as intelligent design

Figure 1. Limited interfaces between IT healthcare apps



systems, workflow management, and intelligent agents (Ganti & Brayman, 1995). These changes (i.e., evolution from a centralised to a distributed computing architecture technologies) have had implications on the healthcare sector. Even IT applications in healthcare have undergone a drastic change (Ohe, 1998; Pollard & Hammond, 1998; Rao, 2001).

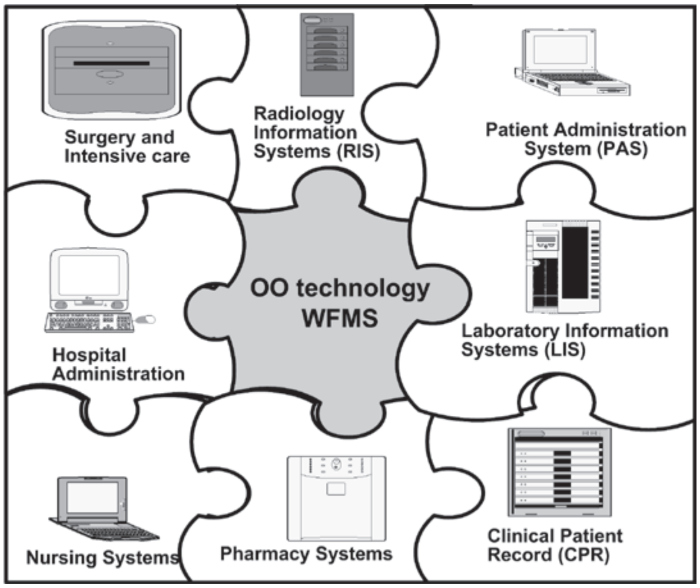
In the centralised computing architecture, IT applications in healthcare were characterised by being written in a proprietary language, specifically made to function on a particular hardware platform, and, most importantly, had very limited interfaces (connections, ability to communicate) with other healthcare information systems (clinical, diagnostic, etc.) (see Figure 1). Moreover, they did not have to ability to interconnect with common desktop applications (word processing, etc.).

This lack of interoperability between different but related healthcare systems (see Figure 1) has been cited as one of the main challenges facing the healthcare sector (Ferrara, 1998; Greenberg & Welcker, 1998; Harrington, 1993). This problem has been further aggravated by the advent of modern IT applications in healthcare that are centred on the power of the Internet (Egger, 2000; Weber, 1999).

The use of OO technologies in conjunction with protocols such as the HyperText Transport Protocol (HTTP) and the Wireless Application Protocol (WAP), with devices such as Personal Digital Assistant (PDA), have allowed patients and doctors to remain in close contact (Dwivedi, Bali, James, & Naguib, 2001; Farkas, 1999; Pollard & Hammond, 1998). These new technologies (OO, HTTP, and WAP) have collectively triggered the connectivity revolution in healthcare. Simultaneously, these new technologies have been accompanied by a revolution in medical electronics and human genome research. It is estimated that in the next 10 years, more then 100,000 medical devices will be launched in the healthcare sector (Egger, 2000).

Advances in the application of computer technology have largely driven the biomedicine revolution in the healthcare industry. As a result of the above revolution, modern day healthcare industry is witnessing "the emergence and proliferation of entire new scientific disciplines—

Figure 2. Vision of an integrated healthcare system in the new millennium



molecular biology, economics, bioinformatics and proteomics—which are revealing the secrets of genes, proteins and their functions" (Watanabe, 1999, p. 27). This has implications for the healthcare process.

Advances in pharmaceutical developments will in turn be driven largely by these new scientific disciplines. Our understanding of the human genome could result in the discovery of new treatments based on new pharmaceutical compounds. It has been estimated that in the near future new pharmaceutical compounds could replace 50% of today's in-patient services (Egger, 2000). It is clear that the healthcare system of the new millennium will be computing based and would revolve around Information Technology (Egger, 2000).

The benchmark for survival for healthcare institutions in the future will shift from the current emphasis on "facilities, range of services,or clinicians associated with the organization" to the "experience that the healthcare institution has in providing that care" (Egger, 2000, p. 22), which in turn would require an effective integration of all the different systems associated with healthcare treatment, diagnosis, and delivery. The vision of the healthcare system of the new millennium is one where all the different information systems relating to healthcare delivery are connected seamlessly and appear to the user as a virtual system, see Figure 2 (Johns, 1997; Mercer, 2001).

Object Oriented Technology (OOT) and Workflow Management Systems (WFMS) are the two most promising technologies that stand out from the entire set of all the technologies that can provide a seamless integration for a virtual healthcare system for the future (see Figure 2). We contend that these two technologies, in combination, hold the potential of transforming the vision of the healthcare system of the new millennium into a reality. As mentioned earlier, one of the biggest paradigm shifts in computing was the evolution of system architectures from centralised computing architecture to a distributed computing architecture. This paradigm shift brought out to the forefront the enabling power of client/server computing (Khanna, 1994).

Table 1. Evolution of client/server with OOT

<tr><td></td><td></td><td colspan="2">Groupware</td><td></td></tr>
<tr><td>Third Wave</td><td></td><td></td><td></td><td colspan="2">Distributed Objects</td></tr>
</table>

EVOLUTION OF OOT

One of the main reasons for the popularity of the client/server revolution is the sharing of data, applications, and the processing power between different clients and the server, thereby improving the efficiency of the system. OOT, and in particular distributed objects, are likely to be the driving force that will transform the vision of an integrated distributed computing architecture into reality; see Table 1 (Orfali, Harkey, & Edwards, 1996).

OOT is a software development methodology that uses a commonly accepted body of knowledge that includes notation diagrams to represent the design of a software application. One of the main advantages of adopting the OO methodology is that it reduces the software development cycle; it offers support in extending the application further by allowing reuse of existent software components.

In addition to the above, OO methodology offers more flexibility in building and interfacing the proposed /existing application with other applications. This not only makes it easier to maintain software applications produced under the OO methodology, but also substantially reduces the cost of software development (Athwall & Moreton, 1995).

Prior to the mid 1980s, all the major types of Hospital Information Systems (HIS) were based on the centralized computing architecture (Khanna, 1994; Ohe, 1998). These legacy HIS used to consist of a number of powerful mainframes which were linked to a very large number of dumb terminals (Ohe, 1998).

One of the main problems in the 1990s was how to utilise these legacy systems with the modern HIS. This gave impetus to the need for having a computing architecture that enabled coordination between different resources (hardware and software) that was available on a network, and the concept of the distributed computing architecture that could enable the above to become a reality (Khanna, 1994).

DISTRIBUTED COMPUTING BASED CLIENT/SERVER ARCHITECTURE

One of the main disadvantages of early client/server technologies was that there was a clear separation between the two, resulting in the creation of two monoliths instead of one (Orfali et al., 1996). Any vision of a healthcare system in the new millennium would feature knowledge-intensive applications. These applications would evolve from a convergence of digital and multimedia technologies and all of which are likely to run a large number of heterogeneous, autonomous, and distributed information systems (Tsiknakis, Chronaki, Kapidakis, Nikolaoul, & Orphanoudakis, 1997).

This poses severe limitations for existing client/server applications, most of which are based on old technologies (see Table 1). Distributed objects are being regarded as a technology that holds a lot of potential in empowering client/server applications to deal with the challenge of repeatedly integrating a large amount of multimedia clinical data from a wide number of heterogeneous, autonomous, and distributed HIS within a very limited time span (Orfali et al., 1996; Tsiknakis et al., 1997).

Distributed objects through the use of components can achieve the above by subdividing today's monolithic client/server applications into self-managing components that can interact with each other and move across networks and operating systems (Orfali et al., 1996). Distributed objects take full advantage of having the data and business logic which is encapsulated within them to interact with other (old) legacy applications via object wrappers (Orfali et al., 1996). This makes the system more flexible as it takes full advantage of the concept of modularity in software development.

DEFINITION AND INTERRELATIONSHIP BETWEEN DISTRIBUTED OBJECTS AND COMPONENTS

Distributed objects can be defined as an independent piece of created code that is visible to other remote clients irrespective of the language and compiler used to create it. It has the ability to be accessed by other remote clients via method invocation. To put it in simple terms, a distributed object is a blob of intelligence that can live anywhere on the network and which can message each other transparently (Orfali et al., 1996).

There is no precise definition of the term component as it represents diverse features depending upon the perspective taken. However, any definition of components must include the fact that it is a reusable piece of software that is independent of any application (Orfali et al., 1996). Components can be a black box (i.e., they support polymorphism and encapsulation but not inheritance) or white box that supports all three mentioned concepts of traditional objects (Orfali et al., 1996).

A broad overview of the relationship between components and objects could be verbalised to state that each component is an object that is not bound to a particular program, computer language, or implementation (Orfali et al., 1996). The interrelationship between distributed objects and components is that all distributed objects are components but not all components are objects or distributed objects, for example, OLE and black box components (Orfali et al., 1996). This is because components have synergistically evolved from three paradigms (1) the distributed computing architecture, (2) the client/server revolution, and (3) the OO revolution.

Components are different from traditional objects in the sense that components are standalone objects that can plug-and-play across networks, applications, languages, tools, and operating systems (Orfali et al., 1996). As each component has its own intelligence and data, the use of components would allow developers and users to create applications on the fly very easily. Moreover, by using components based on distributed objects on a client/server platform, it is possible to very simply build a large number of customised software applications. The use of components represents the ultimate form of client/server distribution and in the near future almost all desktops would be using client/server distribution (Orfali et al., 1996).

If we look at the evolution of database management systems (DBMS) in the context of their suitability for multi-user support whilst handling complex data types, the following picture emerges (see Table 2) (Connolly & Begg, 1998).

A previous study has noted that almost all modern day HIS are based on traditional relational database systems. However, it has been acknowledged that relational database systems cannot deal with the large volumes of clinical data that come in different formats (audio, video, images, and multimedia) (Farkas, 1999). This study examined both extended relational and object relational databases (see Table 2) and on their ability to

Table 2. Evolution of DBMS

Search capabilities/multi-user support.	Relational DBMS	Object Relational DBMS
	File Systems	Object Oriented DBMS
	Data complexity/ extensibility	

store and access clinical data that is multimedia in nature, and come to the conclusion that in a HIS context, object-oriented databases is the best solution (Farkas, 1999). All the existing HIS use client/server technology with the server running a traditional relational database that cannot store and supply multimedia data (X-ray images, etc.) effectively, while their client side often uses peculiar user interfaces that are difficult to govern and are usually not platform independent (Farkas, 1999). The main rationale behind a relational database application is that it establishes modularity between data—modularity which is not established not because it is an essential requisite, but only because it makes the system easier to implement and manage (Farkas, 1999).

WFMS

A Workflow Management System (WFMS) is an ideal software application that assists in the processing of tasks. At a basic level, workflow can be thought of as a series of actions that help in the automation of tasks.

Since workflow refers to a series of tasks, it implicitly refers to scheduling or routing (i.e., which is the best possible way of performing a particular group of tasks). Since it refers to tasks which have to be performed, it would require responsibility at a basic level. Thus a workflow model can be thought to be a value adding process which is carried out in an efficient and effective manner with clear responsibilities for each of the participants in the process (Workflow Management Coalition, 1995). The WFMS uses process instances to instantiate each business process, and each process instantiation represents a workflow. This gives the WFMS the facility of having several workflows of the identical business process, at the same time. This means that each of them (each process instantiation) can act in a different manner. The advantages here are comparable to the advantages given by multitasking and object orientation (Workflow Management Coalition, 1999).

The Workflow Management Coalition (WFMC) (1995) have provided a Workflow Reference Model (WRM) that has the following five main interfaces:

1. **Process definition tools:** This interface provides specifications for process definition data and interchange.
2. **Other workflow enhancement services:** This interface provides support for interoperability between different workflow systems.
3. **Invoked applications:** This interface provides support for interaction with a variety of IT application types.
4. **Workflow client applications:** This interface provides support for interaction with the user via desktop functions.
5. **Administration and specifications for process definition and data interchange:** This interface provides support for system monitoring and metric functions to facilitate the management of composite workflow application environments.

One of the main weaknesses of the WRM model recommended by the WFMC is that it does not support workflow implementation "across a heterogeneous, distributed infrastructure" (Santanu, Edwin, & Jarir, 2001).

This drawback forces the workflow system architecture to be a client/server system architecture where all the main workflow services are run from the workflow server and, as such, it becomes "monolithic" and "centralised." The main disadvantage of the centralised workflow system architecture is that it "does not address the needs of distributed workflows on a WAN" and thereby prevents the workflow to function in a distributed manner (Santanu et al., 2001). This is a very serious drawback, particularly considering that the future of workflows is connected with the Web or, at minimum, across multiple sites.

The Object Management Group (OMG) is an international body whose objective is "to promote the theory and practice of OOT" by establishing industry standards (Athwall & Moreton, 1995). OMG has challenged the WRM by providing its own version of workflow systems.

The OMG architecture uses CORBA as middleware (a software that helps in assuring client/server communications) that enables distributed objects to cooperate. The OMG architecture uses Object Request Brokers (ORBs) to provide the basic functionality for establishing communication between objects.

This is achieved via two interfaces: (1) the application specific interface and/or (2) the Domain interface. All the CORBA facilities given by the OMG can be classified into: (1) Object services (OSs), which are families of system services, that are universal and have standardised interfaces, and (2) Common Facilities (CFs), which specify the specific services for a particular application domain (e.g., healthcare) (Pollard & Hammond, 1998). In the OMG model, workflow is a part of its CORBA facilities and falls under common facilities (Leymann & Roller, 2000).

The main difference between these two models is that, under the WFMC model, the workflow engine has a centralist character, while in the OMG architecture workflows are just objects. The WFMC model uses five interfaces whilst the OMG model uses just objects, thus fully exploiting the CORBA facilities (both object services and common facilities).

FUTURE TRENDS

Modern day healthcare organizations have realised that in the future their survival would depend upon their ability to give the caregiver access to such information that would enable the caregiver to deliver personalised clinical diagnosis and treatment in real-time in very specific clinical contexts (a process termed as Information Therapy). Information therapy is defined as the "prescription of specific, evidence-based medical information to a specific patient, caregiver, or consumer just in time to help someone make a specific health decision or behaviour change" (Kemper & Mettler, 2002, p. 17). This vision has been translated into concepts like Integrated Delivery System (IDS) and Community Health Information Networks (CHIN) (Lang, 1997; Mercer, 2001; Morrissey, 2000).

IDS refers to a HIS that is a business model based on computing technologies such as OO "to share key data, with partners and providers, that will allow faster and more accurate decision making… to deliver care to a broader population with fewer requirements for expensive and scarce resources" (Lang, 1997, p. 18). CHINs are integrated HIS based upon a combination of different technology platforms that are connected to enable support for data sharing amongst different healthcare providers (Mercer, 2001).

Both IDS and CHIN are very similar in nature and both refer to an integrated network for allowing the delivery of personalised healthcare. We argue that in the near future component technology would be the driving force behind all HIS as it would support new ways of combing islands of knowledge, and present the knowledge acquired to the user as an integrated whole. In addition to the above, component technology would also provide support for the use of modern computer techniques (such as Intelligent Data Mining tools, WFMS) to discovering previously undiscovered patterns on a case-to-case basis, thereby bringing to the fore a truly integrated healthcare system that supports delivery of personalised healthcare.

On a grander, global scale, such component technology and the integral role for the OO-platform we have discussed is essential in supporting networkcentric healthcare operations (NCHO) as outlined by von Lubitz and Wickramasinghe (2006a, 2006b, 2006c). The constructing of NCHO is clearly a large task that requires to coordination of several players at a global level. However, the WHIG (as discussed earlier), the world healthcare information grid and backbone of NCHO, cannot be constructed without utilising these component technologies and OO platform. To date actualising the structure of the WHIG has not been discussed.

We contend that the ultimate use of Object Oriented technologies for healthcare as we have discussed in this article will be to provide the technological backbone to such initiatives as NCHO. NCHO represents the new paradigm for healthcare delivery while the OO technologies coupled with the WFMC model is an essential enabling criterion and critical success factor fore realising superior healthcare delivery.

CONCLUSION

Old legacy HIS were predominantly used to allow computerization of information to aid in providing financial information and to assist the healthcare managers in having centralized control over different healthcare activities (Lang, 1997).

Healthcare institutions in the 1990s have realized that the old model does not work as the nature of information required is different. Contemporary healthcare institutions are under ever-increasing pressure to find new ways of reducing healthcare costs whilst simultaneously increasing administrative and clinical efficiency to provide a superior level of quality relating to patient care (Carlos & Comaford, 1998). Modern day HIS have a number of clinical information systems each of which is committed to diverse healthcare providers (nurses, doctors, etc.) in different clinical disciplines (radiology, surgery, etc.) to effectively ensure coordination among these necessitates the integration of hospital-wide available information (Tsiknakis et al., 1997).

There is an increasing realization that an integrated HIS is an infrastructure prerequisite if healthcare institutions are to successfully meet the above mentioned challenge (Farkas, 1999; Ohe, 1998; Pollard & Hammond, 1998; Tsiknakis et al., 1997). The old model of HIS cannot meet the above challenge as the old legacy HIS running monolithic computing applications based upon centralized computing architecture cannot ensure an integrated HIS (Lang, 1997; Tsiknakis et al., 1997).

The distributed computing architecture is the only means of providing the integration between different heterogeneous systems that are autonomous and distributed (Lang, 1997; Pollard & Hammond, 1998; Tsiknakis et al., 1997). Another factor which holds a lot of potential in ensuring that the vision of an integrated HIS becomes a reality is the Unified Modelling Language (UML). Developed by the OMG, UML is a graphical and object-oriented notation methodology for describing processes in a form that helps both developers and users (Botelho, 2000a, 2000b). The advent and acceptance of UML as the defacto industry standard has made possible a standard way to depict graphically the design of an information system that can be understood by all the stakeholders at any stage of the software development cycle (Botelho, 2000b). Despite being of OMG specification, UML is independent of any middleware technology, that is, OMG's-CORBA, Microsoft's Component Object Model (COM), and Sun's Enterprises JavaBeans (EJB) (Sutherland, 1998). It is clear that, in the new millennium, an innovative approach would have to be adopted to ensure that the vision of a virtual integrated HIS becomes a reality. We conclude by reiterating that the current gap between different islands of heterogeneous HIS can be bridged if the technologies discussed above (OO, Component Technology, Distributed Computing, WFMS, and UML) are concurrently adopted.

Chapter 3.12

Collaborative Virtual Environments and Multimedia Communication Technologies in Healthcare

Maria Andréia F. Rodrigues
Universidade de Fortaleza, Brazil

Raimir Holanda Filho
Universidade de Fortaleza, Brazil

ABSTRACT

This chapter shows how recent computing technologies such as collaborative virtual environments, high speed networks and mobile devices can be used for training and learning in healthcare providing an environment with security and quality of service. A number of studies have been conducted so far in these research areas. However, the development of integrated care has proven to be a difficult task. Therefore, we aim also to discuss the promising directions of the current work and growing importance on these subjects. This includes comparative analysis of the most relevant computer systems and applications developed so far that integrate modern computing technologies and health care. We believe this work is considered to be primarily for the benefit of those who are working in the field of computer science and health care, as well academic community, practitioners, and those involved in the development, implementation and study of integrated care using new computing technologies.

DOI: 10.4018/978-1-60566-002-8.ch028

INTRODUCTION

In this chapter, we investigate how recent computing technologies such as collaborative virtual environments (CVEs), high speed networks and mobile devices can be used for training and learning in healthcare providing an environment with security and quality of service (QoS).

In our view, there is a considerable gap between the promises that the new computing technologies hold, and the expectations that they cause in the medical area, particularly, in the simulation and training of surgical procedures. The evidences indicate that these expectations should be fulfilled in the next few years. This partnership will require the improvement of several computational technologies (storage devices, high-speed networks, distributed systems for mobile environments, etc), as well as changes in the background of health professionals before their routine adoption. New areas of interdisciplinary research can emerge, such as multimedia surgical support, interventional radiology, and even less invasive surgical procedures. The development of system architectures utilizing new computing technologies that support interactive computer graphics and CVEs is another growing necessity. Examples are computer systems developed to support virtual training and learning, which are becoming more and more realistic (Blezek et al., 2000; Hosseini & Geordanas, 2001; Dev et al., 2002; Gunn et al., 2005a; DiMaio & Salcudean, 2005; Lee et al., 2006; Rodrigues et al., 2007). Some of these systems are used to construct a virtual world where users (trainer and trainees) can interact with one another and the environment in which they preside when performing training exercises.

Nowadays, geographically distributed computing technologies can be interconnected to create an integrated computing environment. Healthcare professionals in different places can collaborate using this environment. Collaborative virtual environments involve several participants working in a network, using a shared virtual environment to analyze the same object from different points of view, and in which the action of any participant is viewed by all others sharing the environment. In order to make communications more realistic the environment must supply voice, video and data multimedia applications. This will favor comprehension of the actual intent of each participant, thus improving the collaborative environment.

Networked computers and corresponding applications facilitate collaboration activities through a constellation of various tools (such as shared spaces, whiteboards, etc) having appropriate approaches to collaboration and social interactions. A World Wide Web tem proporcionado uma plataforma comum para que pessoas em qualquer parte do mundo possam interagir. Com o incremento do uso de dispositivos móveis, abre-se um vasto campo para novas pesquisas especialmente nas áreas de redes sem fio e colaboração distribuída. O aumento da disponibilidade de facilidades de comunicação tem provocado uma mudança no conceito de utilização de inúmeras aplicações, uma vez que dispositivos móveis possuem um comportamento diferente e oferecem possibilidades de interação diferentes, dependendo do contexto em que a aplicação está sendo usada. Para analisar estes diferentes cenários, muito esforço tem sido direcionado em pesquisas para mitigar possíveis ataques e para prover padrões mínimos de qualidade de serviço.

The World Wide Web has provided a collective platform where people in any part of the globe can interact. The increasing number of mobile devices in use has opened a vast field for new research, especially in the areas of wireless networks and distributed collaboration. The increase in availability of communications facilities has brought about changes in the concept of use of many applications, considering that mobile devices have a different behavior and offer different possibilities of interaction, depending on the context in which the application is being used. In order to analyze these different settings, a lot of effort has been directed to researches in mitigating possible attacks, and providing minimum standards of QoS.

Our discussion will also focus on recent wireless network technologies (Sharma & Nakamura, 2004) and mobility facilities (Pesch et al., 2007) that are highly recommended for the development of CVEs. One of the benefits of wireless data communication is the possibility of exchanging real-time messages among patients and medical staff. Wireless handhelds are becoming simple, direct and efficient communication paths with great potential for facilitating the access and flow of information. These new computing technologies are also important to be taken into account to provide better working conditions in the health area.

Finally, as consequence of the use of patient data, further attention is important to provide a secure network environment, specifically in the cases where wireless connections are used. In this scenario, authentication, authorization and cryptography procedures (Stallings, 2005) are mandatory to mitigate unauthorized users to get access to information, and to hinder data capture in promiscuous mode. Another relevant topic is to supply a network environment with minimum QoS guarantees for voice and video traffic (Ash, 2006). In this case, some network parameters such as delay and jitter are very important to assure QoS. Moreover, the traffic of huge image files should also be controlled in order not to affect real-time traffic classes.

Hence, the key to achieving all these requirements on current technology is to pay more attention to applications that aim at assisting in bridging the gap between theoretical workers in the medical field and those scientists involved in handling and simulating true life problems. In so doing, the former should be able to better identify the objective towards which future developments should be directed, and the latter will be provided with an insight of the possibilities and limitations of existing theoretical work. Our utmost interest is then to investigate the extent to which present computer technologies can contribute to training and learning in healthcare.

CVES IN HEALTHCARE

Although no attempt was made to be comprehensive, we have investigated the CVEs developed so far for training and learning in healthcare.

Many researchers have reported that Virtual Reality (VR) technology has proved to be an invaluable approach in Computer Graphics to represent real life problems within an interactive three-dimensional representation of an environment. Based upon these grounds, we can consider that VR technology is increasingly becoming an important component for simulation in surgical training, although it brings with it educational issues and practical implications. Further, qualitative findings reported in the literature, present that simulators can provide safe, realistic learning environments for repeated practice, underpinned by feedback and objective metrics of performance (Kneebone, 2003).

Some researchers have concentrated on the development of CVEs that have proved beneficial when groups or individuals need to share visual (graphics) or textual information. The most representative simulation-oriented learning environments support interaction, collaboration, and active learning. In general, the topics of training and learning are anatomy and basic surgical manipulations which involve a visual-haptic-audio experience. According to Dev et al. (2002), "while books, lectures, and multimedia are important routes to learning, the acts of touching, feeling, and cutting are believed to be essential in the training of surgeons". Therefore, simulated environments that deliver this experience with simultaneous viewing of the virtual world by all users are expected to form the next generation of technology-enhanced training and learning environments.

In some CVEs, haptic feedback devices are also used to improve the perceived virtual presence in these environments. In fact, they have been useful in building realistic computer based training systems in which users interact with virtual objects. In these systems, Web-based technology can be used to set the model parameters and run the simulation on a remote machine, while visualizing results on a low cost local machine. A library of objects, such as patients and medical devices, can then be created, and used to provide the component parts for a variety of virtual environments (VEs) that may be shared, simulated, analyzed, touched, and visualized by the virtual world of trainee and instructor.

In the last few years, implementation of shared virtual environments has been particularly active.

As a result, distributed, multi-user simulations have been implemented, which generally allow the interactions of users with the virtual scenario by clicking on objects to carry out functions to reproduce typical tasks and conditions commonly available in a physical training environment (e.g., a surgical) or educational environment (e.g., a classroom). These actions can be shared and transmitted through the Internet to other participants to have the impression of being involved in a training exercise. One example is the work presented in (Gunn et al., 2005b).

Essentially, the main focus in implementing shared VEs that use haptic devices is to reduce delay in processing force information. Actually, touch is central in expertise in surgery. During surgery procedures, the surgeon should have the feeling in his hands of directly holding the medical instruments interacting with the patient. In addition, the integration of VR technologies and experiences with VR-based approaches for clinical assessment, treatment and rehabilitation offers powerful options that could revolutionize standard practices in these fields (Rose et al., 2005; Rizzo et al., 2006). There is a series of studies involving haptic devices which can display virtual textures, which are useful to perceive objects (tactile sensing). The haptic devices have potential for simulating real world objects and helping in the navigation of VEs, mainly for simulating minimally invasive procedures (to operate remotely and interactively) and assisting people with disabilities. The great importance of minimally invasive surgery resides in the fact that it has revolutionized many surgical procedures over the last few decades (Basdogan et al., 2004). One of the most important aspects of surgical simulation is to provide the user with estimated reaction forces that arise from surgical instrument and soft tissue interactions.

The advantages of using VR in the medical area through simulations (that could replace the process of building physical mock-ups of functional environments needed for human performance testing, training, and learning) have already been recognized by many research groups. These joint efforts point to a promising future for CVEs. As the field of VR matures, our expectations are indeed that CVEs can deliver substantial benefits to the healthcare area.

MOBILITY

CVEs in healthcare increase the needs for privacy of data. This is tightly linked to security. If data about patients are to be processed, the level of security should match the sensibility of the data with personal information (e.g. address, phone number etc.) calling for lower security, and secret information (like names, exams, test results, etc) requiring highest security and more access restrictions. Enhanced privacy and security furthermore result in added trust in the system. This should in turn increase usage and acceptance, whereas low security will almost certainly have detrimental effects.

Hence, the system needs to be secure. The necessity and the level of security depend on the data processed. Patient images and other medical content could be secured in a way that only authorized users (health staff) have access to them. This might be desirable from a medical point of view when the documents should not be widely distributed, for example, because they contain confidential information.

Recently, security concerns have been emphasized due to mobility issues, and due to access through wireless networks. Introduction of these new technologies have associated greater difficulties to these kinds of communications, demanding mechanisms, for example, to prevent attacks.

In order to provide mobility, wireless network technologies have expanded rapidly in the past few years, becoming accessible to the ordinary user, which may revolutionize the computing and learning environments. This concept affords the emergence of numerous possibilities, like the development of real-time, distributed collaborative applications in mobile devices.

The concept of mobility in CVEs is not entirely new. For example, a system was proposed in Satchel (Lamming et al., 2000) to provide access to any document, at any time from anywhere. Although this is not a Mobile-CVE, it requires sharing of resources from anywhere at any time. The scenario proposed in Satchel involved a worker outside his workplace, who needed remote access to documents, but couldn't do so effectively due to the high transmission times provoked by mobility. Satchel's scenario (Lamming et al., 2000) demonstrates the importance of resource (e.g. documents) sharing during the mobile process, and that it is even more important to diffuse the collaboration of not only resources, but also of information in the more ample sense of the word (such as chats, messages, etc.).

The new "computing anywhere, at any time" paradigm is generating a movement towards mobile services. In this case the concepts of e-commerce are being extended to m-commerce, and e-learning now includes m-learning. With mobility, advantages in the quality of education, and improved results in learning are both expected. M-learning is, therefore, the next step in the evolution of e-learning.

The need for mobile users to use mobile devices for collaborative purposes does not arise from the fact that they are mobile, but from the implication of mobility, that is, they do not have access to conventional means of collaboration through their desktop computers. As mobile devices and access networks become more adequate and trustworthy, people feel increasingly attracted to use collaborative computing on several types of platforms. These changes have brought about a transition from the traditional model of computing to an ubiquitous one, which enables the entire environment to be available to the user from wherever it may be required.

The use of mobile devices is also justified in emergency situations, where a worker (or team of workers) must be located to establish collaboration, but is presently outside the normal work environment, and therefore unable to access his (their) desktop computers. Therefore, it is necessary to evaluate the impact of transferring the use of a desktop computer to a mobile device, mainly in the issues related to QoS (quality of service) and security. Now we present some situations in the medical field where mobile devices can be employed: requests for a second opinion, remote attendance of surgical procedures, and the transmission of warnings concerning the state of patients.

New computing technologies have provided some tools to overcome some limitations, creating virtual environments that can bring people closer together. A fairly common procedure, nowadays, is the concept of a "second opinion". This procedure has progressed from the use of asynchronous communications (e-mails) to synchronous communications, by means of instant messages to relay information. More recently, this communication has progressed even further with the development of CVEs that allow healthcare workers to interact in real time with audio, video and data transfer based on Web standard interfaces. All of these concepts may obviously be available also in PDA (Personal Digital Assistant) type mobile devices, and the collaborators can be located anywhere, at any time. This has been made possible through the creation of an access infrastructure based on wireless networks. It was recently established that part of the resistance of healthcare professionals to working in remote areas originates from the feeling of isolation and not being able to share diagnoses.

In the case of transmission of patient data warnings, the idea is not limited to the use of Short Message Services (SMS) provided by cellular phone networks, but also the transmission of a warning followed by the relay of information that can be monitored at a given moment, allowing a physician to evaluate the gravity of the warning and issue procedures adequate for each case.

QUALITY OF SERVICE AND STABILITY

Present Internet network architecture was designed to relay information using a Best Effort service model, with no guarantees concerning QoS (quality of service) requirements. In the event of a congestion packets are discarded and there is a certain downgrade in the transmission rate, which does not guarantee that the application will be executed effectively. These problems result from the increase of traffic over the Internet, and the type of information carried over the network.

QoS is defined as a set of techniques used to provide differentiated treatments to the flow of data, according to the application. The requirements for each flow can be characterized by four main parameters: Delay – the time necessary for a packet to travel through he network, measured from the moment of transmission to the moment of arrival; Jitter - is the variation in delay, and is defined by consecutive pairs of packets (if D_i is the delay of the i_{th} packet, then the jitter of the pair of packets is defined as $D_i - D_{(i-1)}$); Reliability - is associated to the packet loss rate, which is the relation between the number of packets lost and the number transmitted, measured at the receiving end (this loss occurs when the router buffer is overloaded and no longer allows storage of packets); Bandwidth – represents the speed of the environment, in other words, the maximum transmission rate available at a given moment for communication between two knots of the network (Ash, 2006).

In a multimedia environment different types of traffic (viedo, voice, data, etc.) compete for the use of the same resources. Therefore it is important to understand the network requirements needed to provide satisfactory QoS performance. The introduction of QoS management mechanisms is necessary, as a measure to guarantee that applications sensitive to delay, jitter and packet loss are not affected.

Furthermore, to guarantee the continuous use of a mobile system, stability must be a premise. Stability, in the technical sense, means that the services must be carried out obeying parameters of speed and availability. This is a fundamental point when the link to the mobile device has low speed. Instability, in this case, such as connection losses and application interruptions, will cause loss of user data. If the system is functioning devoid of interesting information, users will lose interest in the system. Lastly, stability is also connected to maintenance. Programming errors may never be fully solved, thus the need for someone who is responsible for receiving bug reports and suggestions that should be incorporated to the system, in order to guarantee good acceptance.

MOBILE LEARNING

The premise of Mobile-education is based on the idea by Pascoe et al. (2000): “Using While Moving”, which is basically what users need from a mobile computer system. Mobile-education affords distributed collaboration over wireless devices to generate learning opportunities. This is, therefore, a new approach that uses a virtual wireless community to facilitate learning activities through collaboration in a distributed environment. Mobile-Education is significantly different from traditional learning systems. In this new model collaborative activities are based on virtual communities, and offer a wide range of collaboration opportunities, such as synchronous and asynchronous peer-to-peer interactivity, allowing data visualization. All of this interaction will be possible from handheld devices.

MAIN CHALLENGES

Some challenges facing the CVEs and Multimedia Communication Technologies are briefly outlined in this section.

High performance computing and networking technology promise to offer great potential to link many medical centers and universities to each other. An interesting point to note regarding this fact, is that virtual anatomical models of the human body will be able then to be shared and used systematically, for various surgical simulation and learning applications through the Web. As a result, we believe that these applications will be able to generate immersive and highly adaptable VEs that will allow individual participants or teams to train and learn simultaneously. However, we need also to take into account the fact that CVEs are typically associated with high-performance computers and specialized input/output haptic devices, with high costs involved, which make operating them on a large scale still prohibitively expensive. Also, related to this issue is the problem of ensuring that each participant sharing an entity in the CVE has a consistent view of the environment. The consequences of differing state can be detrimental to the application as each user's perception of the interaction being performed would differ, thus, leading to a breakdown in the collaboration (Glencross & Chalmers, 2005).

Other important issues in typical CVEs are the most complex types of interactions possible, which are collisions (detection and response) and touch. Collisions are often the bottleneck of simulation applications in terms of calculation time, directly related to the geometric complexity of the VE, and sometimes involves a huge number of geometrical tests for determining which elements are colliding (Ericson, 2005). Colliding virtual bodies can be deformable or rigid. During their movements, a point located anywhere in space (centre of rotation) is associated with the surfaces. Rotational and translational velocities around that point define the instantaneous motion. These velocities are integrated forward in time to define the motion of the surfaces. It is appropriate to certify always during the collisions whether the surfaces are still both physically continuous and topologically contiguous. From a rendering point of view, for graphical display of VEs that support interactions between objects, such as collisions, one of the most important considerations is maintaining suitably high frame rates to guarantee the quality of the simulation.

In some CVEs, participants may change attributes of entities (with complex behavior), which have physical characteristics allowing them to deform or flow (Glencross & Chalmers, 2005). This type of interaction impacts upon the values provided to the algorithms used to compute the state and/or the geometric structure of the entities. Haptic feedback is one of the important stimuli that can be used to provide richer response for physical interaction with VEs by touch. However, simply adding haptic feedback to CVEs does not lead to usable medical applications. It is also essential to consider how to combine suitable force models to support correct perception of surface details (e.g, textures), entity-entity collisions, and motion during interactions.

As medical devices are becoming increasingly networked, ensuring the same level of existing health safety become crucial (Lee et al., 2006), especially considering that interactions in VEs still suffer from problems of accuracy. In addition, networked virtual reality (NVR) services with integrated multimedia components (and perceived "real-time" interactivity) impose certain QoS requirements at the user/application level as well on the underlying network (Skorin-Kapov et al., 2004).

IP technology, in its original conception, does not offer any type of guarantee of QoS. Also, in order for an IP network to support voice services with strict delay and jitter requirements, it is necessary to implement some functionalities to this protocol. The IETF (Internet Engineering Task Force) standardized two specific architectures to supply QoS in the IP environment: IntServ – Integrated Services, and DiffServ – Differentiated Services. The big challenge, however, consists of implementing an infrastructure capable of supporting these architectures.

Further, as devices become increasingly smaller in physical terms, but larger in software terms, they bring capabilities that are sufficient to provide the basis for mobile use. Equipped with small health applications these PDAs can be given out to a number of health agents, thus providing a higher coverage by giving many agents access to a computing device. Therefore, as mobility in collaboration is emerging as a research topic in itself, it is imperative that researchers in this field explore new methods of interaction and novel applications (Perry et al., 2001).

The type of device which can be used for a service is basically unrestricted as long as it is wireless. However, wireless does not mean that a constant connection to a server or network is required. A PDA that holds notes which were transmitted during synchronization using a personal computer is a mobile device just as is a mobile phone with a Wireless Application Protocol (WAP) browser, or a PDA with a Wireless Local Area Network (WLAN) connection.

The need for privacy and confidentiality is giving rise to increased expectations about data storage and transmission security, as data on demand emerges as a viable concept in healthcare. Regarding security, it is important to emphasize that unrestricted admittance is only possible with a valid user identity, which is controlled by the system. Adequate security is ensured by encrypting all data at 128 bit. For mobile admittance the user has to enter an identifier. When the infrastructure supports Wireless Identification Module (WIM), additional security can be established by unambiguously identifying a user.

CONCLUSION AND FUTURE WORK

The medical field has been one of the most appealing areas for computer graphics and VR research. Further, we believe that CVEs can provide novice physicians, residents and students with a natural training and learning environment that may increase understanding of the anatomic relationships of the human body and improve healthcare, minimizing the risks to patients, thereby their ultimate safety. The advantage is that the novice, for example, will be introduced to uncommon conditions that would only arise rarely in clinical practice.

We also observe that while a range of VR medical applications do contain simulation and rich behavior to varying degrees, it is still very hard to quantify the realism of the computer models, since the human body is a system of complex interactions between organs and tissues. These interactions are particularly intricate in the case of soft tissues (very little information is currently known regarding their deformable behavior). In addition, there are ethical problems involved and the need of volunteers. Last, but not least, there is still the fact that collecting medical data takes time. Beyond these issues are also the psychological and sociological barriers to implementation that any new technology should overcome. Crossing these barriers among professionals in Education, Training, Healthcare Delivery, Engineering, and Computer Science will require an integrated and collaborative approach. Actually, over the past few years, a movement characterized by increased collaboration among these professionals has started to take shape.

QoS makes it possible to offer better guarantees and security for Internet applications, once the traffic of advanced applications (such as voice, videoconference, etc.) is being given greater priority, while users of traditional applications continue to use the Best Effort approach.

Finally, we hope that CVEs and recent computer technologies can contribute not only to the advance and improvement of healthcare delivery, but also to do it more safely.

ACKNOWLEDGMENT

The research was partly supported by The National Council for Scientific and Technological Development of Brazil (CNPq) under grant No. 303046/2006-6.

KEY TERMS

Collaborative Virtual Environments (CVEs): CVEs are used to construct a virtual world where users can interact with one another and the environment in which they preside in order to perform, for example, a training exercise.

Distributed Collaboration: VR has been employed to allow geographically distributed people to do more than simply hear and see each other. For instance, VR technology is being used to develop highly interactive shared virtual environments, graphically orientated, for local and distance training and learning.

Haptics: It refers to technology which interfaces the user via the sense of touch by applying forces, vibrations and/or motions to the user.

Haptic Feedback: A crucial sensorial modality in VR applications. Haptics means both *force feedback* (simulating object hardness, weight, inertia, etc) and *tactile feedback* (simulating surface contact geometry, smoothness, slippage, and temperature) (Burdea, 1999).

Mobility: It is the ability of mobile devices to move or change the position.

Quality of Service (QoS): QoS refers to control mechanisms that can provide different priority to different users or data flows, or guarantee a certain level of performance to a data flow in accordance with requests from the application program.

Security: It is the practice of protecting and preserving private resources and information on the network from unauthorized modification or destruction.

Virtual Reality (VR): VR entails the use of advanced technologies, including computers and multimedia peripherals, to produce "virtual" environments that users perceive as comparable to real world objects. It offers great potential as a technology for computer-based training and simulation. It may be delivered to the user via a variety of input/output devices such as screen monitors, head-mounted displays, data gloves, etc.

Virtual Environments (VEs): VEs can be used to simulate aspects of the real world which are not physically available to the users of the application.

Wireless: Communication or transfer of information over a distance without the use of wires. It is generally used for mobile devices.

Chapter 3.13

HealthGrids in Health Informatics:

A Taxonomy

Lampros K. Stergioulas
Brunel University, UK

ABSTRACT

Healthcare is a vast domain encapsulating not only multiple sub-domains or sub-sectors but also many diverse operations and logistics within each sub-sector. This diversity needs to be handled in a systematic and well-characterized manner in order to maintain consistency of various healthcare tasks. Integration of health information systems within each healthcare sub-sectors is crucial for ubiquitous access and sharing of information. The emerging technology of HealthGrids holds the promise to successfully integrate health information systems and various healthcare entities onto a common, globally shared and easily accessible platform. Many different types of HealthGrids exist but there lacks a taxonomy to classify them into a hierarchical order. This chapter presents a well-characterized taxonomy of different types of HealthGrid and classifies them into four major types, namely BioGrid, MediGrid, PharmaGrid and CareGrid. Each of these HealthGrids possesses dedicated features and functionalities. The proposed taxonomy serves to better understand the realtionship among various HealthGrid types and would lay a basis for future research.

DOI: 10.4018/978-1-60566-030-1.ch008

INTRODUCTION

Healthcare is currently going through a series of technological advancements and modifications. Health information has always been of great importance to society and has a strong impact on various social aspects. Due to its nature, health information has to be dealt with great care and confidentiality. At the same time, it has to be shared and exchanged across various organizations or individuals to provide improved healthcare service. Two of the most important disciplines in Health Informatics today are bioinformatics and medical informatics. As Computer Science and Biotechnology communities join forces to create new technologies for the advancement of medical science and improvement of medical service delivery (Stewart, 2004), this might prove to be promising for enabling people to lead normal, healthy lives.

It is widely recognised today that the healthcare industry requires customized solutions with respect to information integration. The information sharing techniques currently available are not sufficient to meet the requirements of an integrated health care system. The state of electronic information integration in healthcare lags noticeably behind other business domains such as banking, insurance and electronic commerce (Bilykh et al., 2003). There is a need for health information systems to be fully integrated with each other and provide interoperability across various organizational domains for ubiquitous access and sharing. Moreover, due to rapid progress of biotechnology an increasing number of life science databases are becoming available that are being operated and managed individually (Tohsato et al., 2005). Many existing solutions still do not offer the desired levels of utility/functionality or sophistication that a health information system demands.

The emerging Grid technologies hold out the promise of a global information channel that is far more powerful and uniquely distinct from the existing internet framework (Naseer and Stergioulas, 2006b). By definition:

"Grid is a large-scale, high-performance, always-on and dynamic, although geographically distributed yet networked, infrastructure that comprises and seamlessly unifies a variety of autonomous, heterogeneous components such as processes, resources, network layers, interfaces, protocols and services, with strong, consistent and controlled relationships among them." (Naseer and Stergioulas, 2006b)

HealthGrid is a Grid used in the context of healthcare. HealthGrids are expected to successfully integrate health information systems and various healthcare entities, including humans and non-humans, such as scientists, scientific tools, medical instruments, physicians, patients and all types of healthcare data or medical information, onto a common (global) platform that would be shared and easily accessible (Breton et al., 2005). In such a scenario, each health information system is composed of various distinct components, which are integrated in a way that each component has its well-defined semantics and ontology and is well-aware of all other components.

Considering the vast nature of the heathcare domain (Alexopoulos et al., 2007), it can not be assumed that only one HealthGrid would be sufficient for the entire healthcare domain. However, many small HealthGrids could be combined together to form a giant HealthGrid infrastructure in order to facilitate collaborative work and resource sharing. There are several existing medical classifications, terminologies and taxonomies (Alexopoulos et al., 2007) but such a taxonomy that illustrates how the various HealthGrids could be classified does not exist yet. Therefore a taxonomy is needed that classifies various types of HealthGrids and lays-out a hierarchical structure that is simple to understand but is yet systematic & well-characterized. Such a taxonomy would be beneficial for understanding, in detail, the realtionship among various HealthGrid types and would lay a basis for the future research.

This chapter offers a systematic taxonomy of the HealthGrids. It first outlines the characteristic features and functionalities of HealthGrids, and reflects on the need for Grid technology in healthcare. The taxonomy of HealthGrids is proposed, based on their functionality, purpose, and application area. Finally, this chapter reflects on the future of HealthGrids in Health Informatics and draws some conclusions.

HEALTHCARE NEEDS GRID TECHNOLOGY

The case for the use of Grid technology in healthcare arises mainly from the need to improve, safeguard and effectively exploit the available *life-significant medical information*, the need to protect the privacy of *personal, life-sensitive health information*, and the need to provide *integrated healthcare services* and have in place effective, global *channels of collaboration*.

Health-related information is important for the well-being of society and has to be accurate and consistent. Medical information provided over the internet often suffers from ambiguity and contradiction that would increase the complexity and confusion of medical issues instead of solving them. Moreover, anyone can publish or post material of their choice over the internet without any peer review or checking, which makes open internet an unreliable source of healthcare information.

Information available on HealthGrids can initially be peer reviewed once before uploading, but even more importantly, it can be constantly and continuously checked and revised appropriately, thus making HealthGrids an accurate and reliable source of health information that can be accessed any time from any place.

Blake and Bult (2006) stated: "One of the major challenges faced by the biomedical research community is how to access, analyse, and visualize heterogeneous data in ways that lead to novel insights into biological processes or that lead to the formulation of a hypothesis that can be tested experimentally". In order to exploit effectively the wealth of medical information, there is an urgent need to *integrate, manipulate, process, and analyse* huge heterogeneous datasets from disparate sources. More systematic use of Grid technology in healthcare will not only help meet the current needs for data processing, but will ensure that future demand for even more capacity to deal with far larger volumes of data can be met (Breton et al., 2005).

Moreover, whenever *confidential medical information* is shared among health organizations, security and privacy are critical issues (Bilykh et al., 2003), since HealthGrids contain 'life sensitive data'. The information content in a healthcare system is related to various entities, such as hospitals and their staff, stakeholder organisations and their members, medical equipment/devices, medicines, diseases, patient information records and healthcare operations (pathways). Amongst all the entities, the *patient record* is the most prominent, since it encapsulates information on most other entities (some of which is personal, and should be kept private to the patient).

On another level, HealthGrids can prove to be an *effective channel for international collaborations* where the world's scientific minds can collectively work, such as to conduct a group-wise analysis, and might produce solutions that would effectively address complex medical problems (for instance, a disease or remedy).

There are many *other reasons* why the healthcare industry needs Grid technology, such as to:

1. provide more computational power
2. make network resources readily available
3. better utilise system resources, and reduce wastage by eliminating idle resources
4. create new business opportunities and exploit economies of scale
5. enable faster problem solving
6. support multiple operations by concurrent and ubiquitous access
7. provide the massive data storage spaces required in healthcare
8. make healthcare solutions/systems more efficient
9. facilitate collaborations and integration among various healthcare resources and stakeholders

All of the above and many more emerging issues demand to be addressed in a sophisticated manner by an advanced and reliable solution and a systematic, well-characterized taxonomy of different types of HealthGrids is expected to facilitate these operations. A study by Estrella et al. (2007) discusses that Grid computing holds the promise of harnessing extensive computing resources located at geographically dispersed locations that can be used by a dynamically configured group of collaborating institutions. It defines a suitable platform on which distributed medical informatics applications could be based. Particularly, HealthGrids are expected to address issues such as data distribution, data processing, data analysis, data sharing, data security, resource heterogeneity and interoperability.

HealthGrids might prove to be a good way to address these needs and provide reasonable solutions the challenges of modern healthcare. A study by Piggott et al. (2004) explores the potential use of Grid technology in Healthcare, such as integration of heterogeneous data sets from multiple diverse sources systems. Thus, if successfully implemented, the HealthGrid will have a high impact towards lower costs and greater benefits for healthcare in the long run. In this respect, the HealthGrid could be the driver of Health Informatics and which is the next generation of healthcare IT and a taxonomy of various HealthGrid types would be of significance at this stage in order to have a better idea of how the various types are classified in order of their hierarchy.

TAXONOMY OF HEALTHGRIDS TYPES

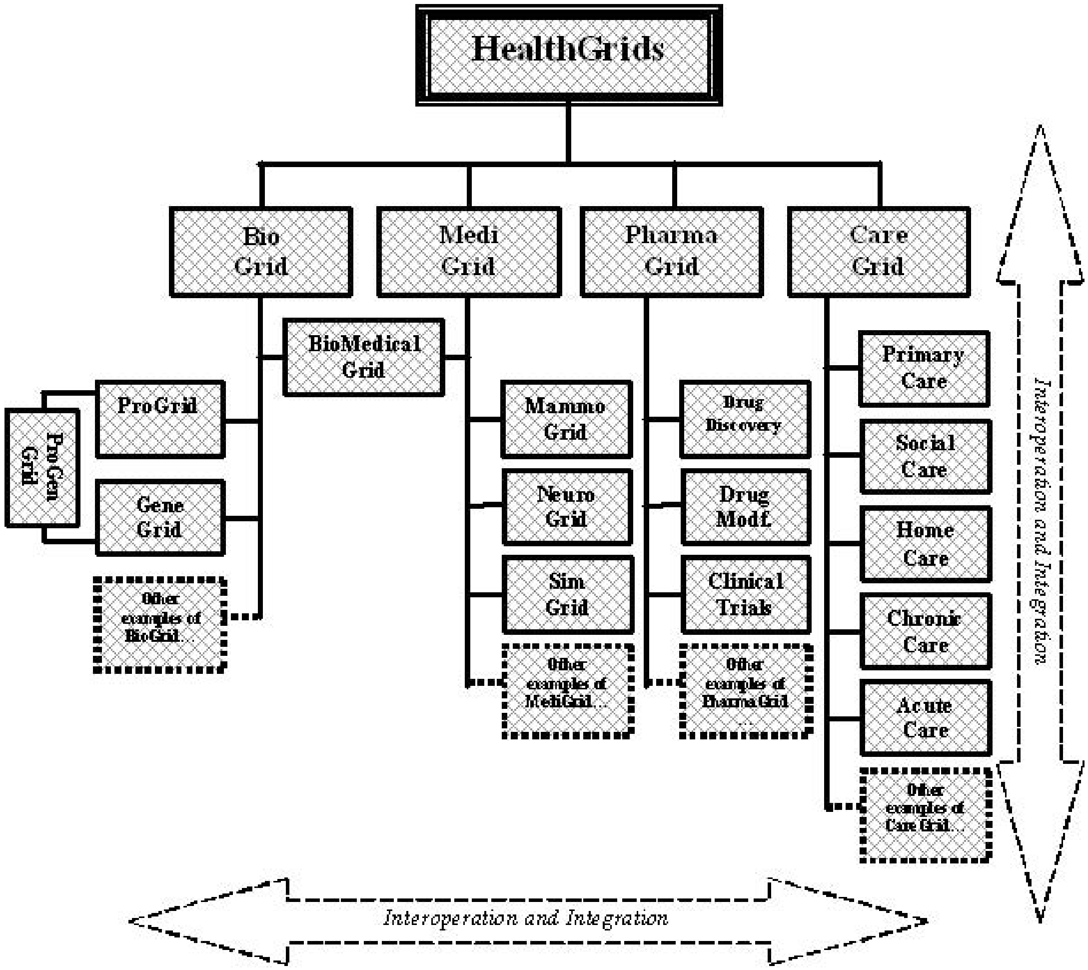
There are various types of HealthGrids defined in the healthcare sector. Each has been devised for a dedicated purpose, so as to provide special services and to support the performance monitoring of specialized tasks in a particular healthcare sector. A taxonomy of HealthGrids types is proposed based on their functionality, purpose, and application area. This must be kept in mind that all HealthGrids are mainly DataGrids.

Considering the vast nature of the heathcare domain (Alexopoulos et al., 2007), it can not be assumed that only one HealthGrid would be sufficient for the entire healthcare domain. However, many small HealthGrids could be combined together to form a giant HealthGrid infrastructure in order to facilitate collaborative work and resource sharing. There are several existing medical classifications, terminologies and taxonomies (Alexopoulos et al., 2007) but such a taxonomy that illustrates how various HealthGrids could be classified doesnot exist yet.

This chapter presents a taxonomy of HealthGrids (Figure 1) and classifies them into four major types, namely BioGrid, MediGrid, PharmaGrid and CareGrid, where the BioGrid and the MediGrid merge into the BioMedicalGrid, which combines the features and functionalities of both Bio and Medi Grids. The BioGrid is sub-categorized into representative examples such as ProGrid for Proteomics and GeneGrid for Genomics, both of which merge into the ProGenGrid. The MediGrid is also further sub-categorized into typical implementations, such as Medical Imaging (Visual) grids (e.g. MammoGrid) for the management and processing of medical images, scans or DICOM (Digital Imaging and Communications in Medicine) files, NeuroGrid for neurologists and SimGrid for medical simulations and modelling (another example of a Visual Grid). There is a need for the HealthGrids to be integrated and possess strong interactions among themselves in order to facilitate data sharing. For example, although GeneGrid does not have a direct link with the CareGrid as shown in Figure 1, however, data from both these domains could be made available for accessing & sharing over these Grids, if needed.

The various types of HealthGrids, along with characteristic applications, are examined and discussed further in this section. Each of the HealthGrids described in this section is effectively a DataGrid and could also be a SemanticGrid (Semantic grid project, 2007) if it is based on semantic principles. For example, in a similar fashion to NeuroGrid, there can be a dedicated HealthGrid for each medical domain, such as Car-

Figure 1. **Taxonomy of HealthGrids types**



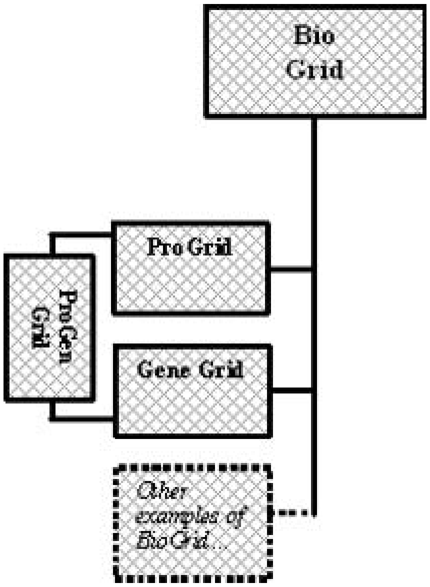
dioGrid, OptiGrid, OrthoGrid, GynaecologyGrid or OtolaryngologyGrid and many others.

BioGrid

BioGrid is a type of HealthGrid designed specifically for accessing and sharing biological information, often around the globe, by authorized individuals and/or organizations. Information related to biological components at the molecular level such as genes, proteins, DNA, RNA, chromosomes and other molecular biological structures need to be critically analysed for further biological research purposes. BioGrids are increasingly important in the development of new computing applications for the life sciences and in providing immediate medical benefits to individual patients. They have significant potential to support the offering of personalised medical care and to be able to target only those at risk (Ellisman et al., 2004). Examples of BioGrid are shown in Figure 2.

OGSA-DAI (Open Grid Service Architecture Data Access and Integration) have been used in ChemBioGrid by bringing Data Management tools into collaborative environment. The mechanism has been studied, for supporting Digital Libraries in High-Performance Computing environment based on Grid technology. OGSA-DAI have been

Figure 2. Examples of BioGrid



implemented to provide abilities to assemble heterogeneous data from distributed sources into integrated virtual collections (Zhuchkov et al., 2006). The BioGrid is sub-categorized into the ProGrid and the GeneGrid, which are also the applicable examples of BioGrids and are described below:

a. ProGrid

ProGrid is a practical example of BioGrid that is specialized in the management of all types of information related to proteins, such as proteomic and proteo-type data, protein structures, protein identification, protein analysis, protein expression level, protein mutation, protein screening and classification.

The human body is incredibly complex and consists of roughly 50 trillion cells, each consisting of an enormous number of components (of the order of 10^{13}), many of which are proteins. It normally takes months on a Peta-flop class computer (one capable of performing 10^{15} calculations per second) to simulate the activity of a single protein, taking into account each atom in the protein. No such computer systems exist today, and designing one remains a formidable challenge (Stewart, 2004).

The ProGrid will be able to address this issue by making available enormous computation resources for highly complex computational operations. A recent study (Cannataro et al., 2005) presents MS-Analyzer, a tool for the management processing and analysis of proteomic Mass Spectrometry data. It is a specialized version of PROTEUS (Cannataro et al., 2004), which is a Grid-based Problem Solving Environment for bioinformatics applications that uses (a) domain ontologies to design complex in silico experiments by modelling basic software tools, data sources and workflow techniques and (b) data mining software tools to provide proteomics facilities. Its main requirements include interfacing with proteomics facilities, storing and managing proteomic Mass Spectrometry data, and interfacing with off-the-shelf data mining and visualization software tools.

An architecture combining the use of OGSA-DAI, Grid distributed querying (OGSA-DQP) and data integration software tools to support distributed data analysis has been proposed (Zamboulis et al., 2006), for the integration of several autonomous proteomics data resources.

b. GeneGrid

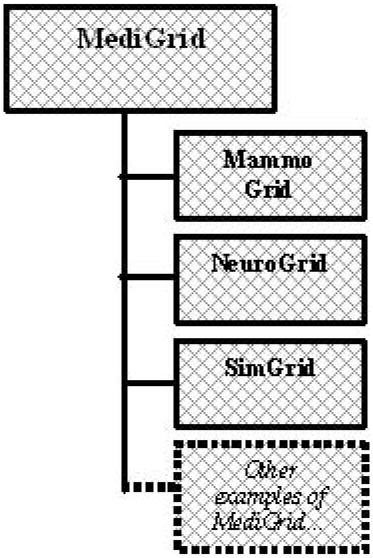
GeneGrid is another practical example of BioGrid that is specialized in the management of all types of information related to genes and of relevance to genomic studies, such as information on genomes & genotype, genetic structures, genetic sequences, genetic mutations, genetic diseases, genetic epidemiology, gene therapy, gene naming, genetic analysis, gene screening, genetic variation and genetic classification. For the purposes of genetic epidemiology GeneGrid can support the unified naming of phenotypes and standardised acquisition and recording of clinical parameters. In genetic epidemiology studies, a clinical annotation service is one of the central services in a Grid for clinical phenotype descriptions (Breton et al., 2005). The GeneGrid project (Jithesh et al., 2005) integrates numerous bioinformatics programs and databases available on different resources across various sites allowing scientists to easily access the diverse applications and data sources without having to visit many web servers. This reduces the overall time for executing the experiment. The Grid services developed in the GeneGrid project are based on the Open Grid Services Architecture (Foster et al. 2003) and provide scheduled access to resources, data, and applications, using XML-based messages.

The need to have a dedicated GeneGrid arises due to the ever-increasing volumes of genomic data and ever more demanding complex computations for genetic operations.

c. ProGenGrid

The ProGrid and GeneGrid merge into the ProGenGrid which is dedicated to perform management of data related to the sequence and structure of both the genome and proteins. Operations carried out on a ProGenGrid could include the aggregation, selection, retrieval, analysis, filtration and sharing of proteomic and genomic data for concurrent access and collaboration. The ProGenGrid, developed at the University of Lecce (Aloisio et al., 2005a), is intended to provide a practical solution to specific HealthGrid problems. This Grid aims at providing a virtual laboratory where e-scientists can simulate biological experiments, compose existing analysis and visualization tools, monitor their execution, store the intermediate and final output and finally save the model of the experiment for updating or reproducing it. Another study (Aloisio et al., 2005b) introduces the ProGenGrid workflow that comprises a semantic editor for discovering, selecting and composing bioinformatics tools available in a Grid environment, and a workflow scheduler for running the composed applications. The workflow editor uses an ontology of tools for the bioinformatics domain and employs the Unified Modeling Language (UML) for modelling the workflow. The UML graphical notation is stored as an XML file. On running the application, the workflow scheduler takes activities from the XML file and runs them, taking into account the state and availability of Grid resources and relevant bioinformatics tools. The system also allows monitoring of the job flows.

Figure 3. Examples of MediGrid



MediGrid

The MediGrid (Medical Grid) is a type of HealthGrid designed specifically for accessing and sharing medical information around the globe by authorized individuals/organizations. Examples of MediGrid are shown in Figure 3.

It is expected to contain all levels of medical information from tissue, organ, and patient to population and public health, including various types of scans, mammograms, simulations and models of different body organs and other medical domains. All this information needs to be shared and critically analysed for further medical research purposes. A paper proposes a MediGrid (Boccia et al., 2005) which has been designed specifically for the aggregation and integration, analysis and visualization, and processing and management of biomedical images for nuclear doctors. It is a distributed, user friendly GUI-based application that uses the First In First Out (FIFO) algorithm for job scheduling and follows the Grid Application Development Software (GrADs) Project workflow (Berman et al., 2001), (Vadhiyar and Dongarra, 2005). It focuses on complex Grid-enabling parallel algorithms for the examination of medical images.

Amongst others, the MediGrid can be subcategorized in terms of its practical application; representative examples include the MammoGrid, the NeuroGrid and the SimGrid, which are next described:

a. MammoGrid

The MammoGrid (Mammography Grid) (MammoGrid, 2007) is one of the most important practical examples of a MediGrid designed particularly for the access, storage, retrieval, analysis, management, manipulation and sharing of various types of digital images, medical scans, or DICOM (Digital Imaging and Communications in Medicine) files. Some computationally intensive image analysis algorithms often devised to assist clinicians to make decisions in diagnosis and therapy are known to produce better results, but are not used in practice due to the lack of computing power (Breton et al., 2005). The MammoGrid is expected to provide enormous computing and storage resources so as to make feasible and to support distributed image analysis.

A recent study (Scheres et al., 2005) presents an interface between Grid computing middleware and a three-dimensional electron microscopy (3D-EM) image processing package ("Xmipp") (Sorzano et al., 2004). Results showed clearly that 3D-EM image processing can greatly benefit from the resources offered by Grid computing. Another study (Glatard et al., 2005) produced a generic, Grid-enabled workflow framework, to be deployed on the computational Grid infrastructure provided by the EGEE European project (EGEE, 2008). It encompasses image registration algorithms wrapped in standard Web-Services, a Grid enabled workflow manager, and Grid middleware for performing the distributed computations. The framework developed could easily be adapted to a wide variety of medical applications. However, one of the limitations stems from the *stateless nature* of Web Services.

e-Diamond, a UK e-Science project (Brady et al., 2003), is a Grid-enabled prototype system (medical image database) that aims at supporting breast cancer screening by maintaining a national database for digital mammograms. In the development of e-Diamond, an object-relational approach to the storage of DICOM files has been taken (Power et al., 2004). Other work carried out within the context of the e-Diamond research project (Power et al., 2005), (Simpson et al., 2005) addresses the challenges of patients' data security and confidentiality via employing query modification. Query modification is also used in GIMI (Simpson et al., 2005) to restrict access to the data in Grid-enabled medical research databases for the sake of patients' data security.

A MIP-Grid (Grid-enabled Medical Image Processing Application System) is presented (Huang et al., 2006), that is based on OGSA-DAI middleware. It aims at providing high performance medical image process services in a large distributed grid computing environment. OGSA-DAI allow uniform access to and integration of data held in heterogeneous data resources.

b. NeuroGrid

The NeuroGrid (Neurology Grid) is another example of a MediGrid that is designed to support neurologists worldwide in their collaborative work. A recent study (Geddes et al., 2005) has proposed the implementation of a NeuroGrid, i.e. a Grid dedicated to neuro-scientific studies. It is intended to be built on the experience of other UK e-science projects aiming to assemble a Grid infrastructure, and apply this to three exemplar areas: (a) stroke, (b) dementia and psychosis, and (c) generic collaborative neuroscience research. Grid-enabled sharing of data, experience and expertise will facilitate the archiving, curation, retrieval and analysis of imaging data from multiple sites and enable large-scale clinical studies in neurology. To achieve this goal, the NeuroGrid seems to be built upon existing Grid technologies and tools (developed within the UK e-Science programme), aiming to integrate image acquisition, storage and analysis, and to support collaborative working within and between neuro-imaging medical centres. Moreover, the Biomedical Information Research Network (BIRN) (Ellisman and Peltier, 2004) is devoted to neurology and is exploring the use of Virtual Data Grid (VDG) to support multiscale brain mapping. BIRN currently participates in three testbed projects; namely Function BIRN, Morphometry BIRN and Mouse BIRN (Stewart, 2004).

In the not too distant future, a dedicated NeuroGrid will address the need to support the computation and monitoring of various neurological functions, for both humans and animals, such as brain histology, MRI (Magnetic Resonance Imaging), neurological disorders, electron microscopy and brain imaging.

c. SimGrid

The SimGrid (Simulation Grid) is also an example of MediGrid designed specifically for providing special simulation and modelling services for various types of medical treatments and analysis such as surgery, radiotherapy, chemotherapy, endoscopy, electrocardiography, osteotomy and bio-fluids simulation. Thus SimGrid encapsulates all simulation levels from Proteomics and Genomics up to overall body-level simulation. The SimGrid can be of importance not only in planning surgeries but also in training surgeons (Breton et al., 2005). The simulation process is quite time consuming and might require millions (or even billions) of computation cycles and terabytes of storage space, depending upon the nature of the specific simulation task. However, using Grids for this purpose could resolve the problem of computation speed to a considerable extent.

A recent study (Gonzalez-Velez and Gonzalez-Velez, 2005) presents a stochastic simulation of L-type Ca^{2+} current assuming thousands of calcium channels on the membrane of a spherical cell. The simulation runs on a dedicated Grid and employs structured parallelism techniques. Results showed hours of time saved using a computational Grid for simulation (compared to single-machine simulation runs).

GEMSS (Grid-enabled Medical Simulation Services) (Jones et al. 2004), (Benkner et al. 2005) that is concerned with the Grid-provision of advanced medical simulation applications and aims to provide a transparently accessible health computing resource suited to solving problems of large magnitude. The viability of this approach is currently being evaluated through six diverse medical applications, including maxillo-facial surgery planning, neuro-surgery support, medical image reconstruction, radiosurgery planning and fluid simulation of the airways and cardiovascular system. Without using a Grid, an accurate nonlinear simulation takes a considerably longer time (up to several hours), whereas, by allowing access to high performance computing through the Grid, the simulation time can be reduced to a level acceptable for clinical implementation (less than one hour), with the potential to improve the outcome of the surgical procedure. The GEMSS Grid infrastructure is based on standard Web Services technology with an anticipated future transition path towards the OGSA (Foster et al. 2003) standard proposed by the Global Grid Forum.

A new execution and simulation procedure for two dental applications, namely Computational Fluid Dynamics (CFD) and Computational Aero Acoustics (CAA) is proposed in (Nozaki et al., 2005), which can reduce the implementation time via Grid-enabled parallel processing. The study also reports on the design, implementation and performance evaluation of the optimal CPU resource allocation based on the total computation time of the dental application, which combines CFD and CAA as a part of a DentGrid system. The data for both the simulations is obtained by Magnetic Resonance Imaging (MRI). This DentGrid system aims to be a computation and storage power supplier for dental clinics and hospitals. Simulating dentistry operations is highly beneficial, in the sense that dentists can examine visually the post-effects of dental surgery.

The modelling of individuals is an ongoing research topic and involves the complete simulation of the human body, which is a computationally intensive task. In the field of modelling and simulation, Grid computing has the capability to accelerate the pace of the analysis/discovery process and to deliver the new results quickly and efficiently to the medical user community (Berti et al., 2003).

The application of OGSA-DAI in Simulation Grids has been discussed (Xing et al., 2006), to address the issues of integrating, controlling and accessing the different types of distributed data resources in the simulation. The databases in the simulation grid system supported the dynamic distribution of the data and model resources in the simulation environment.

OGSA-DAI has been used also as a middleware in the BioSimGrid project (Wu et al., 2004), that aims to exploit the Grid infrastructure to enable comparative analysis of the results of biomolecular simulations.

BioMedicalGrid

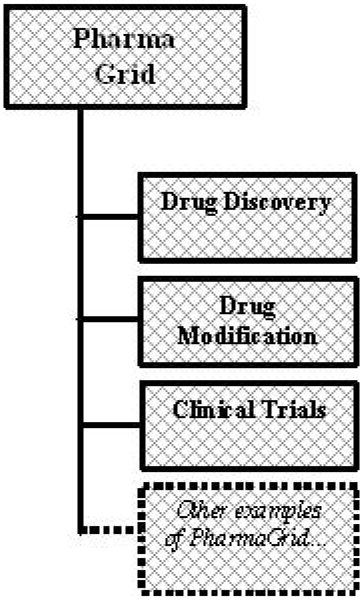
The BioGrid and MediGrid merge into the BioMedicalGrid which encapsulates features of both the Bio and Medi Grids. The main challenge faced in biomedical informatics is the development and maintenance of an infrastructure for the storage, access, transfer and simulation of biomedical information and processes. Moreover, BiomedicalGrids must be able to produce, use and deploy knowledge as a basic element of advanced applications and to achieve this, they are mainly based on Knowledge Grids and Semantic Grids (Breton et al., 2005). BiomedicalGrids will thus provide a universally accessible platform for the sharing of ever-increasing biomedical data pertaining to all the levels of healthcare such as molecule, cell, tissue, organ, patient and public health. They are expected to provide interoperability and sharing/collaboration to both the Biological and Medical domains of healthcare.

Recent research (Tirado-Ramos et al., 2005) has used *on-line application monitoring* for improved computational resource selection and application optimization. A number of user-defined performance metrics within the European CrossGrid Project's G-PM tool (CrossGrid.org, 2008), (Stevens et al., 2004) have been used to run a blood flow simulation application (solver) based on the lattice Boltzmann method for fluid dynamics. Results showed that online monitoring gives a more accurate view of computational resource status than the regular resource information provided by standard information services to resource brokers. Moreover, on-line monitoring has good potential for optimizing biomedical applications for more efficient computational runs. Other work (Alonso et al., 2005), (Tirado-Ramos et al., 2005) has shown how a BioMedicalGrid can enhance the processing of a biomedical application as well as the respective image analysis. The integration of a bio-physical model into a clinical augmented reality system is another challenging task, where Grid technology could be the key (Breton et al., 2005).

PharmaGrid

Another important type of HealthGrid is the PharmaGrid (Pharmaceutical Grid), which focuses on the management and sharing of drug-related data to support operations such as clinical trials, dose

Figure 4. Examples of PharmaGrid



computation, drug discovery, drug development, drug interactions, pathology and genomics that could be carried out in a collaborative environment to advance the quality of healthcare. Examples of PharmaGrid are shown in Figure 4.

The pharmaceutical industry is a distinct domain with specific operations and processes, and is currently faced with many challenges. There is an increasing need for more innovative products that can target more effectively today's critical diseases. At the same time, there is a growing pressure for personalised medication (by using both phenotype and genotype), a move which will increase both the effectiveness and safety of medicines, but which will eventually shrink the scale of economy and create a much more fragmented market. Furthermore, the data produced by the pharmaceutical industry is of the order of terabytes or petabytes in size and needs massive storage capacity. Moreover, various operations to do with the manufacturing of drugs and the dissemination of drug information need huge numbers of computational cycles. The results obtained from various drug experiments and clinical trials are of crucial importance and need to be delivered in a consistent and timely manner to the healthcare professionals and patients.

One of the key challenges of the pharmaceutical sector today is to manage, share and understand the medicines information in a way that facilitates and accelerates the Research & Development process. This progress suffers from poor information management due to inflexible, closed, heterogeneous, unconnected and segregated sources of information. It has now been widely recognised that Grid technology holds out the promise for a more effective means of sharing and managing information and enhancing knowledge-based processes in the Pharma R&D environment. The emerging PharmaGrid is a powerful new technology set to revolutionise the way medicines-related ("Pharma") information is used. The PharmaGrid has the potential to address the "information" problem, with many benefits for the industry, in terms of boosting innovation in drug discovery, shaping clinical trials, reducing time to market, and reducing costs. (see Figure 4)

Furthermore, Grid technologies have the potential to provide transparency and integration of information, break communication barriers, enhance communication and collaboration between the various actors (industry, regulators, healthcare and insurance providers, doctors and patients), and as a result to accelerate a large number of healthcare processes to do with pharmaceutical therapies.

Other benefits from the use of PharmaGrids include (Houghton, 2002):

- substitution of in silico for in vitro and in vivo testing;
- operation and management of clinical trials;
- monitoring post-launch usage and outcomes;
- marketing and distribution of medicines;
- e-commerce and total quality management in healthcare supplies and procurement;

- regulatory and watchdog activities;
- financial planning and cost efficiency in healthcare;
- health information services for all stakeholders;
- electronic prescription and clinical decision support tools.

Even more crucially, the Pharma industry and researchers are faced with a continuously growing amount of distributed heterogeneous information, a real explosion of experimental data, documents, article, patents, with rapidly changing terminology and analysis approaches. In order to adequately fulfil such requirements, the PharmaGrids have to meet the following challenges:

- Intelligent middleware that facilitates the user transparent access to many services and execution tasks
- High quality security features, enabling large databases to be accessed via Grid solutions
- Sophisticated semantic and contextual systems to enable diverse sources of data to be related to knowledge discovery

Thus PharmaGrids are expected to deal with all types of drug-related information such as drug features, design specifications, safety, success rate, purpose and usage, and complex operations such as clinical trials, evaluation process, experimental results, treatment, and effective trails. This information should be shared across various organizational boundaries and manipulated online.

The development of PharmaGrids is instrumental in meeting the current industry challenges, as it will provide an efficient way of exchanging and managing knowledge in a shared environment in the areas of discovery, development, manufacturing, marketing and sales of new drug therapies. Grid infrastructures are currently built upon different architectures, designs, technologies, open standards, and operating systems. PharmaGrid development is a highly complex and technically challenging activity and it should address many different problems to do with Pharma information, including knowledge-representation and integration, distributed architectures, search and access controls, data mining and knowledge management, real-time modelling and simulations, algorithm development and computational complexity. PharmaGrids will need to be scale-independent/scalable, adaptive, secure and dependable Grid infrastructures that enable the management of large networked distributed resources across different platforms of stakeholders, such as pharmaceutical companies, policy makers, R&D development companies. The required enabling technologies include amongst others semantic web and agent-mediated approaches, peer-to-peer technologies and self-organising architectures.

PharmaGrids can be part of or closely integrated with other HealthGrids. For reasons of competitiveness and intellectual property protection, PharmaGrids are predominantly private, enterprise IntraGrids with strict access and authentication controls, but there is a recognised need for cross-industry platforms (InterGrids), whereby the resulting integration will lead to more efficient coordination of activities.

Moreover, PharmaGrids open up the perspective of cheaper and faster drug development and may enable parallel processes in drug development, away from the traditional approach where the full cycle of target discovery, target validation, lead discovery, lead optimization and transition to development takes on average 12 years (Breton et al., 2005). PharmaGrids hold the promise to provide improved and efficient drug design and better control of diseases and to improve *patient safety* and *quality of healthcare*. Examples of PharmaGrids could include dedicated Grids for Drug Discovery, Drug Modification, Management and/or Running of Clinical Trials.

Another study (Tohsato et al., 2005), uses Globus Toolkit 3 and OGSA-DAI, for the federation of heterogeneous databases, for supporting a drug discovery process. Due to the rapid progress of biotechnology, there are an increasing number of life sciences databases, which need to be shared in order to conduct research collaborations, and OGSA-DAI could make this feasible.

CareGrid

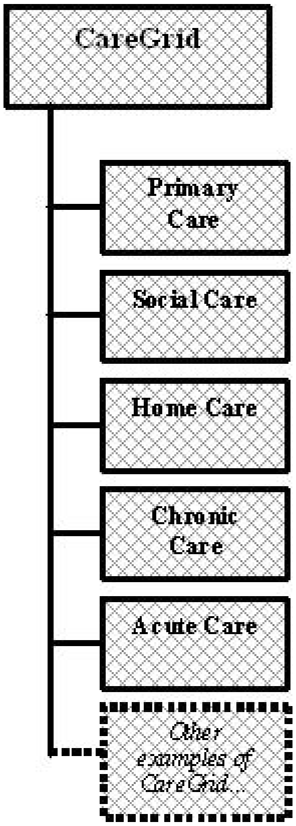
The CareGrid is designed specifically for the general public healthcare services such as patient-centred or virtual healthcare services, dose computation, self-assessment, and online health management. Services on the CareGrid could be customized according to the individual patient needs so as to provide personalized healthcare services. Moreover, the CareGrid aims to provide data management facilities and improved diagnosis.

A typical example of CareGrid is a recently implemented prototype for HealthInfoGrid (Bilykh et al., 2003). The HealthInfoGrid can also be viewed as a Service Grid and its services are designed for sharing and distributing medical information, at times of critical importance and under strict privacy and security regulations. Formalization of the interaction semantics of the HealthInfoGrid components is based on coloured Petri-nets (Jensen 1997). HealthInfoGrid has various components such as organization, staging area, initiator, translator, and merger/adder. Examples of CareGrid are shown in Figure 5.

CareGrids represent a new facet of advanced and improved healthcare that can provide personalized healthcare services at a cost-effective price. Patients can access the CareGrid to retrieve information about their own health, such as clinical tests and diagnosis, dose composition and recommendation, precautions and preventions. This would save them the time and effort spent in waiting to book appointments and all the hassle that goes with such processes.

Examples of CareGrids could include dedicated Grids for Primary Care, Social Care, Home Care, and Chronic Care.

Figure 5. Examples of CareGrid



WHAT'S NEXT IN HEALTH INFORMATICS WITH HEALTHGRIDS?

As we have seen, HealthGrids can be used to support many kinds of healthcare operations and tasks. As such, they can be made to adapt to the lifestyle choices of the patients. Patients should be more and more able to choose their living styles, keeping in mind their persistent health conditions. The future of Health Informatics with HealthGrids implementations would allow patients to take control of their own health by personalized healthcare or illness management programs, thus improving healthcare provisioning quality while lowering the costs. Particularly, future HealthGrid applications will:

- provide secure access to medical data/information distributed globally
- free-up doctors' time and provide healthcare to patients at their doorsteps
- enhance the use of various health monitoring devices, which can be plugged together via Grids to provide better quality of care
- provide active interoperability & collaboration among the various healthcare stakeholders, which is needed for the success of Health Informatics
- facilitate resource sharing

The main problems with medical information or healthcare data are that it is:

- difficult to access
- not always available
- lacks integrity & interoperability
- difficult to understand or data being obscure
- lacks sharing of distributed resources (including healthcare data)

These problems are magnified due to the dynamic nature of healthcare data which is always being modified, and changes to one part are not updated or reflected onto other parts of the system. Moreover, in Health Informatics massive datasets and heavy computation make things even more complicated. Also the health information systems need to be inter-connected. As HealthGrids are mainly DataGrids, they provide platform for data integration and facilitate interoperability among various healthcare data sources. Thus changes to one would automatically be reflected in other and healthcare information would be accessed in a timely and seamless manner.

The case for the use of Grid technology in healthcare arises mainly from the need to improve, safeguard and effectively exploit the available *life-significant medical information*, the need to protect the privacy of *personal, life-sensitive health information*, and the need to provide *integrated healthcare services* and have in place effective, global *channels of collaboration*. To do all this effectively, different types (the most suitable ones) of HealthGrids should be employed to perform different dedicated tasks with specialized features and functionalities and for this purpose a taxonomy of various HealthGrid types, described earlier in this chapter, would prove to be very useful. For long-term future, there is a need for designing various Grid-enabled applications specifically for HealthGrids. Moreover, there is a diverse range of many other services (Naseer and Stergioulas, 2006a), which can be provided on HealthGrids.

Future of Health Informatics lies in the integration, not only among various types of HealthGrids but also among the various healthcare stakeholders, in order to conduct collaborative research. It also lies in constructing new types of specialized HealthGrids, i.e. HealthGrids dedicated for specialized tasks such as anatomy, morphology, and epidemiology. Integration among various HealthGrids would allow information sharing at an advanced level where information related to one classified domain would be accessible by other domains. Future trends also follow that Grid technologies get tightly integrated with Web Services technologies (Naseer and Stergioulas, 2007).

However, the case for HealthGrid implementation in Health Informatics is not that obvious. Learning new Grid-enabled techniques, procedures, and know how about the HealthGrids applications and confidentiality of the medical data remains a challenge. Thus, if HealthGrids can take-on this challenge and provide easy and secure accessibility to the physically distributed heterogeneous data sources with simple user-friendly interfaces, then the future of Health Informatics is secure and very promising through the implementation of specialized HealthGrids.

CONCLUSION

In order to fully benefit from Health Informatics there is a need for the Healthcare data to be available, accessible, readable, understandable and most importantly reliable. Moreover, Healthcare information needs to be interoperable and shared by integrated channels of collaboration and healthcare stakeholders.

This chapter has reviewed current implementations of HealthGrids, and offered a systematic taxonomy of the HealthGrids. It has outlined the characteristic features and functionalities of HealthGrids and reflected on the need for Grid technology in healthcare. Based on their functionality, purpose, and application area, a taxonomy of HealthGrid types has been proposed constituting of four major categories. It has been shown that each serves a dedicated purpose, so as to provide the required services and to support the performance monitoring of the specified/desired tasks. Furthermore, the various types of HealthGrids have been examined on an individual basis and their representative implementations have been reviewed. In summary, this chapter gives some suggestions about the future of Health Informatics with HealthGrids.

To exploit effectively the wealth of medical information, there is an urgent need to integrate, manipulate, process, and analyse huge heterogeneous datasets from disparate sources. More systematic use of Grid technology in healthcare will not only help meet the current needs for data processing, but will ensure that future demand for even more capacity to deal with far larger volumes of data can be met.

Data security is another major issue, as healthcare data has to be protected through ethical firewalls to ensure the privacy, confidentiality and integrity of patients' data. HealthGrids deal with 'life sensitive data' and patient record is the most sensitive data resource that encompasses many critical elements related to personalized healthcare. As patient record encapsulates instances of various other entities, HealthGrids can help achieve the required levels of robustness and consistency of the patient record by provision of secure access to:

- patient's medical history
- medical images (e.g. mammograms)
- library of examples for training & diagnosis
- health support services
- drug details & clinical trials
- health information systems
- standard formats of files & information for comparative analysis

As HealthGrids can also serve as an effective channel for international collaborations, in order to incur long-term economic benefits from the implementation of HealthGrids, there is a need for interoperation and integration among various HealthGrids as shown in Figure 1. Also constructing new types of specialized HealthGrids dedicated for specific tasks would strengthen the future implementation of Health Informatics. Moreover, it has been witnessed from the study that contemporary Grid technologies such as OGSA-DAI and can prove to be a candidate solution to the problem of data federation or integration. However, work is still going on and efforts are being made towards a modernized facet of future healthcare by using HealthGrids as depicted in a prognosis for year 2013 (Silva and Ball, 2002).

As a final remark, HealthGrids hold the promise to offer accurate and reliable sources of health information that can be accessed at any time and from any place. They can and should become a major driver in the race towards successful e-Health and an important ingredient of Health Informatics which is the next generation of healthcare IT. A successfully implemented HealthGrid infrastructure could support all the facets of healthcare sector, and help realise the vision of personalized healthcare. Successful implementation of HealthGrids will have a high impact towards lower costs and greater benefits for healthcare in the long run, thus facilitating the provision of quality healthcare services cost-effectively.

KEY TERMS AND DEFINITIONS

Grid: a large-scale, high-performance, always-on and dynamic, although geographically distributed yet networked, infrastructure that comprises and seamlessly unifies a variety of autonomous, heterogeneous components such as processes, resources, network layers, interfaces, protocols and services, with strong, consistent and controlled relationships among them

Grid Services: a type of Grid resource (service resource) with special capabilities and features to get tasks successfully accomplished on Grid networks. These are used to access other types of Grid resources

HealthGrid: a type of Grid. It is a Grid infrastructure dedicated to the management of healthcare resources that encompasses and integrates the various Grid components and healthcare components with consistent, compatible and meaningful coordination among them, to facilitate provision of the healthcare services

Heterogeneity: a difference in format, platform, semantics or ontology

Integration or Interoperability: a link or connection that enables communication among two or more resource types

OGSA-DAI: Open Grid Service Architecture Data Access and Integration, it is a powerful technology that possesses strong features for providing interfaces to heterogeneous data sources on Grids in order to integrate them

Resource or Grid Resource: a Grid resource can be any real or conceptual object that is needed to be accessed by other entities, such as human users of the system or programmes that generate requests for accessing particular resources

Taxonomy: a classification

Web Services: considered as the most efficient and reliable communicators of messages from one place to another regardless of geographical or technological heterogeneity

ABSTRACT

The main features of RFID are the ability to identify objects without a line of sight between reader and tag, read/write capability and ability of readers to read many tags at the same time. The read/write capability allows information to be stored in the tags embedded in the objects as it travels through a system. Some applications require information to be stored in the tag and be retrieved by the readers. This paper discusses the security and privacy challenges involve in such applications and how the proposed and implemented prototype system Authentication Processing Framework (APF) would be a solution to protect hospital patient data. The deployment of the APF provides mutual authentication for both tags and readers and the mutual authentication process in the APF provides security for the information stored in the tags. A prototype solution for hospital patient data protection for information stored on RFID bracelets is offered.

INTRODUCTION

Radio Frequency Identification (RFID) refers to an Auto-Identification system comprised of RFID tags, RFID readers and the requisite RFID middleware that interprets tag information and communicates it to the application software. RFID tags contain specific object information in their memory, accessed via radio signal of an RFID reader. RFID tags contain a microchip capable of holding stored information, plus a small coiled antenna or transponder (Psion, 2004).

In the APF (Authentication Processing Framework) implementation (Ayoade 2005) an Omron's RFID tag "V720S-D13P01" was used. It is a passive tag that has read and write tag memory capability. The memory capacity of this tag is 112 bytes (user area). This means it has EEPROM/RAM memory capability. The reader used was manufactured by FEIG electronic (ID ISC MR 100). It has a frequency of 13.56 MHZ. This type of RFID system was used because its frequency has the widest application scope and it is the most widely available high frequency tag world-wide. Its typical read range is approximately 1m.

APF is a system that could allow many readers to read from and write to the RFID tags and it prevents unauthorized readers from reading information from the tags without the knowledge of the tags.

In a nutshell, APF prevents privacy violation of information in the RFID system. The APF system was developed based on the existing typical RFID system and will therefore work with the existing system.

In the RFID system, many proposals have been presented to solve common privacy and security problems, however, these proposals face one disadvantage or another, making them insufficient to completely address the problems in question. We agreed that a simple approach for dealing with the problem of privacy is to prevent readers from receiving data coming from tags (Avoine, 2004). However, as mentioned earlier, all the propositions to date have one disadvantage or another.

RFID technology can be used to collect a lot of data related to persons, objects or animals, thus there are data protection concerns. The first type of risks arises when the deployment of RFID is used to collect information that is directly or indirectly linked to personal data. In a digital world, collecting and analyzing personal data is a task that computers and agents can do diligently. This is an issue connected to ICT in general, rather than to RFID specifically. It is mainly the widespread use of RFID, and its use in mobile situations accompanying persons that could lead to unpredictable situations – and thus unpredictable threats (ECISM 2006).

A second type of privacy implication arises where personal data is stored in RFID tags. Examples of this type of use can be found in passports or RFID-based health records. The relative openness of the area where the application is deployed will greatly influence the options to illicitly access the data (ECISM 2006).

A third type of data protection implication arises from uses of RFID technology which entail individual tracking. As soon as a RFID-profile is known (because the tags are linked to personal data) the comings and goings of people could be followed. This is possible for company-level applications (e.g. by using access cards), but could theoretically also be used in tracking where you are. This could be in your car (if the car or clothes are tagged, as also indicated in the example), or in person, in public locations (ECISM, 2006). This could have implications for people who could come to harm if their health records were to be accessed such as in the case of HIV/AIDS, mental illness, past medical history or even pregnancy.

THE PROPOSED CONCEPT OF THE AUTHENTICATION PROCESSING FRAMEWORK

A framework that will authenticate readers before they can access the information stored in tags was proposed in (Ayoade, 2004). The proposed procedure is called Authentication Processing Framework - APF. The main concept of this framework is that tags and readers will register with the APF database which will authenticate readers prior to reading data stored on RFID tag. Implementing this kind of framework in the RFID system will alleviate security and privacy concerns.

Overview of the APF System

The APF was proposed to deter the data security problem in the RFID system.

APF is a framework that makes it compulsory for readers to authenticate themselves with the APF database before they can read the information in the registered tags.

Figure 1, shows that APF system comprises of four application segments:

i. The Tag Writer's (writer application) is the part of the APF that encrypts the information in the tag and produces the decryption key which will be submitted along with its identification number, to the APF database.
ii. The Reader's Application queries the tag and registers readers' identification number with the APF database. This is also the part of the system that uses the decryption key to decrypt the information after it has been authenticated by the APF database.
iii. The Authentication's Application is the part of the system that integrates both the reader application and the APF database maintenance application.
iv. The Maintenance's Application is the part of the system that maintains the APF database.

APF System Operation and Methods

The tag writer (writer application) subsystem reads tags in its vicinity and then generates a randomized encryption key. The next step is to input and encrypt the information into the tag for security purposes. The next paragraph explains how the authentic tag reader (reader application) subsystem reads the encrypted information in the tag.

The reader subsystem sends a "challenge" command to the tag in its vicinity (just as any typical RFID reader will read the information in the tag within its vicinity) and the tag responds with its unique identification and the content of the information in it. However, in case of the APF system, the content of the information stored in the tags is encrypted. This means the reader can not decrypt the information in the tag without the decryption key which is kept in the APF database system.

The next stage of the operation is that the reader will submit its ID to the APF database subsystem. Then, the APF key inquiry subsystem will check whether or not the reader is authorised to be granted the decryption key to have access to a particular tag. If it is authorised, the decryption

Figure 1. The functional diagram of the APF

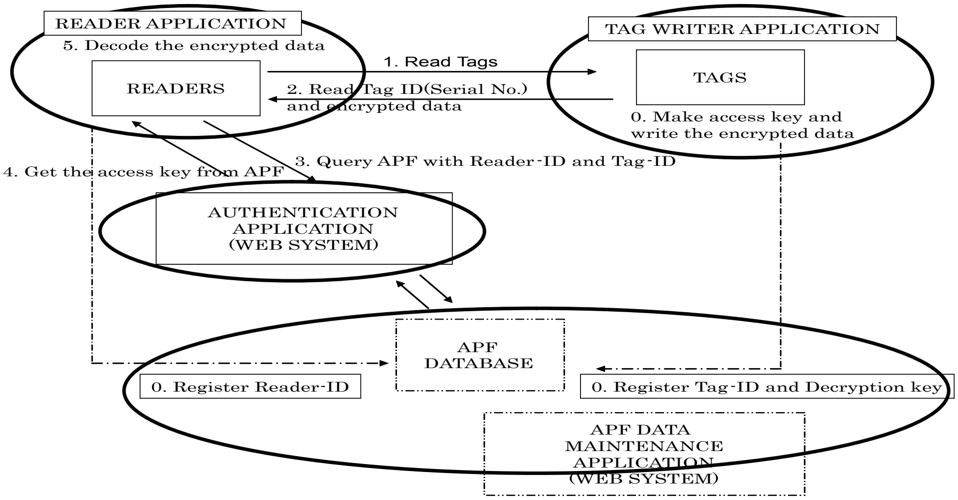

Figure 2. The flowchart of the APF

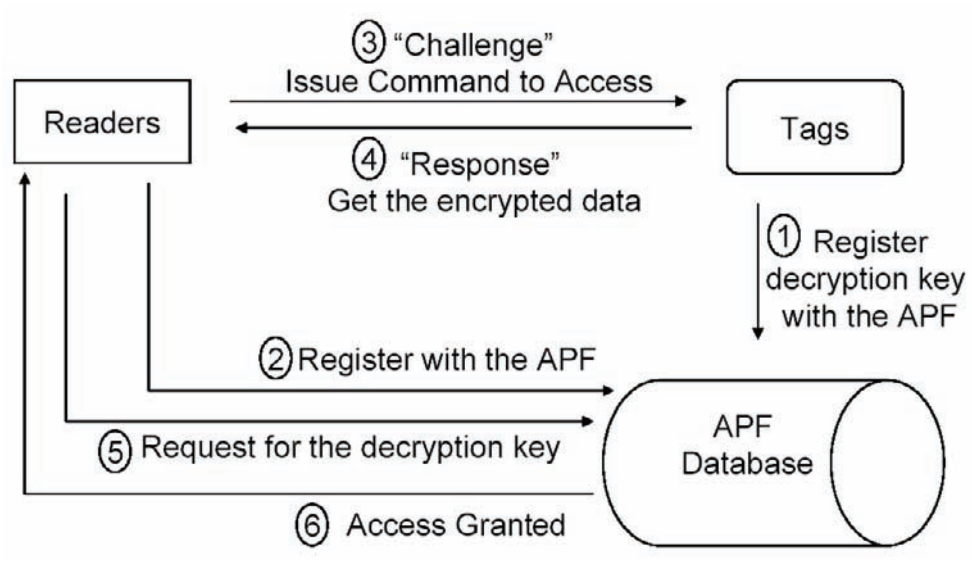

key will be granted and the reader will be granted access and if not, the decryption key will be denied and the reader will not be able to decrypt the information stored in the tag.

The Methodology of the APF System

Figure 2 is the step by step representation of the APF. Initially, tags will register their identification numbers and the decryption keys with the APF database. Also, readers will register their identification numbers with the APF database. Normally, readers will send a "challenge" command in order to access the information in the tags. However, with the APF protocol, tags will send a "response" command consisting of the tags' identification numbers and the encrypted data to the readers. The response message from the tag will instruct the reader to get the decryption key from the APF database in order to decrypt and read the data in the tag. Since, authenticating readers would have registered with the APF database then, only authenticating readers would be given the decryption key to decrypt the encrypted data in the tags.

In order to prevent illegal access to the information stored in the tags there should be a procedure for access control to the information stored in the tags. As shown in Figure 3, and discussed above, each tag will register its unique ID and decryption key with the APF database. This is necessary for the protection of tags from unscrupulous readers that may have ulterior intentions. Once a tag registers its unique identity and decryption key with the APF, it will be difficult for unregistered readers to have access to the data in the tag without possessing the decryption key to the tag. This means every registered reader will be authenticated prior to getting the decryption key to access stored data in the tag.

In the next paragraph we discuss how the authenticated reader would have access to stored data in the tag.

Every reader will register its identification number with the APF in order for it to be authenticated prior to the time the reader will request the decryption key to access the data in the tag. In a nutshell, every reader will register its unique identification number with the APF and this will be confirmed by the APF before releasing the

decryption key to the reader in order to read the encrypted data in the specific tag.

Figure 4 shows that every reader registers its unique identification number with the APF. However, since both readers and tags register their identification numbers with the APF, this serves as mutual authentication and it protects the information in the tags from malicious readers which is one of the concerns users have. This means that unauthorized access to the tag will be almost impossible if the APF system is correctly implemented. In the next paragraph the authors of this paper discuss the registration and access control of readers to the APF.

In the previous paragraphs, the authors of this paper discuss the registration of the tags' unique ID and the decryption key with the APF. Also, we discuss the registration of readers with the APF prior to accessing the information in the tags. When the reader sends a "read" command to the tag, it replies with its identification number and encrypted data. In this case the data is encrypted and the reader registered with the APF will be able to get the decryption key in order to decrypt the data. Once the key is received the data in the tag will be readable. In this framework there are two important processes: first, mutual authentication is carried out by the APF because it authenticates the reader and the tag; secondly, privacy is guaranteed because the data stored in the tag is protected from malicious readers. Since, the information the reader obtained from the tag is encrypted, it can only be read after the decryption key needed to access the information is received from the APF.

APPLICATION OF THE APF

The APF described in this paper has many applications. For example, it can be deployed in the supply chain management, or in granting or in restricting access to information for certain groups of people in a hospital. This has been a major concern in many large hospitals (RFIDGazette, 2004). The APF could help to control these security concerns. Take for example, in a hospital where the RFID system is used. The APF will guarantee total data security of the information in the tag from malicious readers because every authentic reader will register its ID with the APF prior to reading the information in the tags and all tags that will be read by those readers will register with the APF. This means that there will be mutual authentication and the information in the tags will be secure.

One of the areas in which the APF could be deployed in a hospital is for the protection of medical records.

In (Patient Tracking, 2005), the implementation of a RFID system for hospital asset management was discussed. Such RFID systems may be used to track patients, doctors and expensive equipment in hospitals. The RFID tags can be attached to the ID bracelets of all patients, or just patients requiring special attention, so their location can be monitored continuously.

One of the benefits of the above mentioned system is the use of the patient's RFID tag to access a patient's information for review and update via hand-held computer or PDA (Patient Tracking, 2005). In such applications there is a tendency for unauthorized readers to access the information stored in a patient's tag. This is obviously of great concern to patients. In order to prevent this kind of problem, the APF would offer secure solutions.

Hospital patient data is not easily protected by the currently available security measures already discussed. The Kill Command would not work because the data does not have a finite life as products on a shop shelf do. The Faraday Cage

Approach would not be practical as a metal mesh or foil container would make an RFID bracelet very difficult to work with and to wear. Active Jamming would be dangerous and would interfere with other systems in a hospital environment. Similarly, the Blocker tag method would interfere with other systems in the hospital environment. Therefore, hospital patient data is a good case study for the APF because conventional privacy and security measures are not appropriate for application and the problem is hindering the development of RFID patient care systems in hospitals.

The APF Case Study

This experimental case study was carried out to test the possibility of deploying the APF to deter illegal access by unauthorized readers to RFID tags containing medical records of patients. Figure 6 is a screenshot of the tag writer (writer application) application and it shows the practical possibility of using RFID tags for storing the medical record of patients in the hospital. However, patients will not want their medical record accessed by an unauthorised person because they want their privacy protected from others except their doctor.

Moreover, with a typical RFID system anybody who has a reader can access the information in the tag within its read or write vicinity. This means that any patient that has their confidential information stored in the tag is prone to abuse and invasion of privacy.

However, using the APF, the information stored in the tag will be encrypted in order to secure it from unauthorized readers. This is the underline text shown in Figure 6. As Figure 6 shows the APF tag writer (writer application) subsystem reads the Tag ID in its vicinity, then generates a random encryption key. The encryption key is used to encrypt the plaintext information about the patient about to be written to the tag. After the encryption of the information, the encrypted text will be written into the tag. This information will be secured from unauthorized readers, unlike a typical RFID system.

Figure 7 shows that readers have to be registered. This means that, only readers registered in APF database can access the information in the tag. In this case study it was demonstrated that readers unregistered in the APF database would not be able to access the medical records stored in the tag. Once an authenticating reader is opened, then the tag reader (reader application), has to obtain the decryption key of the encrypted information stored in the tag. However, prior to that it needs to send its ID to the APF database and the APF database will check whether or not it is an authenticating reader and once that is confirmed the decryption key will be released for it to access the encrypted information stored in the tag, provided it is an authentic reader. However, if it is not an authenticating reader, the reader will be denied access to the stored information. This is shown in Figure 8.

In this case study, the authors assumed that the patient's doctor alone will be in control of the three application subsystems that is: the tag writer (writer application), the tag reader (reader application), and the APF protected application software.

Thus, the patient whose information is stored within the APF protected system can rest assured that their confidential medical information stored in their tag are secure from violation of unauthorized readers.

There are a number of well-established RFID security and privacy threats:

i. **Sniffing:** RFID tags are designed to be read by any compliant reading device. Tag reading may happen without the knowledge of the tag bearer or from a far distance from the bearer of the tag (Rieback, 2006). In the APF system, sniffing threat is considered to be very difficult because with the deployment of the APF system every reader that will be part of the system will register and be

```

ISO E004010001AD7AC1

mutually authenticated before such reader could be functional or carry out any operation. In essence, it will be impossible for just any reader to function within the APF system and that will make sniffing threat to be difficult.

ii. **Tracking:** RFID readers in strategic locations can record sightings of unique tag identifiers (or "constellations" of non-unique tag IDs), which are then associated with personal identities. The problem arises when individuals are tracked involuntarily. Subjects may be conscious of the unwanted tracking (i.e. school kids, senior citizens, and company employees), but that is not always necessarily the case (Rieback 2006). The purpose and goal of the architectural framework design of the APF system is to protect and secure the data content stored in the tag and therefore the focus is not to protect the tracking threat that is possible through the readers associating personal identities with the tag ID's.

iii. **Spoofing:** Attackers can create "authentic" RFID tags by writing properly formatted tag data on blank or rewritable RFID transponders. One notable spoofing attack was performed by researchers from John Hopkins University and RSA Security (Rieback 2006). Spoofing will be difficult or almost impossible because even if the tag ID is spoofed the content of the tag is encrypted and that means without the decryption key from the APF system the content of the tag will not be readable. Therefore, without the mutual authentication between the authenticated reader and the APF system, the content of the spoofed tag is useless.

iv. **Replay attacks:** Attackers can intercept and retransmit RFID queries using RFID replay devices. These transmissions can fool digital passport readers, contactless payment systems, and building access control stations. Fortunately, implementing challenge response authentication between the RFID tags and back-end middleware improves the situation (Rieback 2006). Replay attack will be difficult with the deployment of the APF system because the APF system employs mutual authentication process between the tags and the readers.

v. **Denial of Service:** is when RFID systems are prevented from functioning properly. Tag reading can be hindered by Faraday cage or "signal jamming", both of which prevent

Note: Authenticating reader declares its ID and accesses the decrypted information. Also, an unregistered reader declares its ID and is denied access to the information

radio waves from reaching RFID tagged objects. Denial of Service (DoS) can be disastrous in some situations, such as when trying to read medical data from VeriMed subdermal RFID chips in the trauma ward at the hospital (Rieback, 2006). The DoS is a difficult threat to handle most especially when it is through "signal jamming".

Furthermore, an attacker can spy out data in a situation in which he uses his own reader to read data from the tags. The device can be installed in a hidden place, or it can be used in a mobile manner (Oertel 2004). In case of the APF system mutual authentication is required between the reader and the tag and this made it difficult for attacker to falsify the identity of the reader because every reader has its unique identity number. Also, the attacker can change the contents of the tag but not the ID (serial number) of an existing tag. This is only possible if the data associated with the ID are stored on the tags themselves (and not in the backend). In this kind of scenario, deployment of the APF secures the application from attackers because the information stored in the data is encrypted.

We will briefly describe some of the approaches and their adverse effects:

a. **The Kill Command:** The standard mode of operation proposed by the AutoID Center is for tags to be "killed" upon purchase of the tagged product. With their proposed tag design, a tag can be killed by sending it a special "kill" command. However, there are many environments in which simple measures like this are undesirable for privacy enforcement. For example, consumers may wish RFID tags to remain operative while in their possession (Liu 2003).
b. **Faraday Cage Approach:** An RFID tag may be shielded from scrutiny using what is known as a Faraday Cage - a container made of metal mesh or foil which is impenetrable to radio signals (of certain frequencies). There have been reports that some thieves have been using foil-lined bags in retail shops to prevent shoplifting-detection mechanisms (Liu 2003).
c. **Active Jamming:** An active jamming approach is a physical means of shielding tags from view. In this approach, the user could use a radio frequency device which actively sends radio signals so as to block the operation of any nearby RFID readers. However, this approach could be illegal for example if the broadcast power is too high it could disrupt all nearby RFID systems. It could also be dangerous and cause problems in restricted areas like hospitals (Juels 2003).
d. **The Blocker tag:** The blocker tag is the tag that replies with simulated signals when queried by reader so that the reader can not trust the received signals. Like active jamming, however, it may affect other legal tags (Juels 2003).

All these approaches could have been effective solutions to the privacy problem but the disadvantages make them unacceptable. In this paper, we propose that a good authentication procedure will be the best option to tackle this problem. The reason is that our proposed solution - APF - provides solutions to the privacy problem and enhances the security of RFID systems. However, in this paper we identified the specific area of application in which the APF system could be used.

THE SCENARIO OF THE AUTHENTICATION PROCESSING FRAMEWORK IN THE HOSPITAL

According to (Parkinson, 2007) hospital patients are used to wearing wristbands, but now those bands have gone high-tech. At the Birmingham Heartlands hospital patients wear RFID wristbands that carry personal data embedded. When they arrive they have a digital photo taken and loaded on to an electronic tag contained in a wristband worn throughout their stay. Staff dealing with the tagged patients has access to PDAs with which they can scan the bands and also access patient details, via wifi, from a secure area on the hospital's central computer system. A 'traffic light' system flashes up when a patient is ready for their operation, and as they go through the theater's doors, a sensor reads the bar code on their wrist and their details are displayed on the theater's computer screen (Parkinson, 2007).

This is the type of RFID application scenario in the hospital which requires the APF systems implementation. The information stored in the wristbands of the patients needs to be protected from various potential security threats. The authors of this paper believe the deployment of the APF system will serve as a deterrent and countermeasures to such security vulnerabilities. From the above scenario, without necessary security countermeasures such as the one APF system will be providing, it means anybody with the PDA that has a reader can read the information stored in the tag about the tagged patients within or around the hospital without the consent or awareness of the patients.

In the APF system every reader will be an authenticating reader which means any other reader will not be able to access the data in the tags associated with the APF system.

CONCLUSION

The potential applications of the RFID system may be identified in virtually every sector of industry, commerce and services where data is to be managed. However, RFID systems have faced widespread resistance due to lack of privacy (Kumar, 2003). This calls for a prompt and concrete solution for the full realization of the RFID system's potential.

This research focuses on an experimental prototype system that uses fictitious data. Future research will seek to implement and test a small implementation with live data and applications as proof of concept. Rigorous testing could investigate whether this system can in fact stand up to the security and privacy threats established earlier in this paper such as sniffing, tracking, spoofing and denial of service attacks.

Future development might also include expansion beyond hospital patient data. For example, where RFID tags might implanted into human flesh for every day use to access property and vehicles. This will open up the RFID market place to longer range RFID tags and readers to replace the current short range (7-10cm) equipment.

Regarding the issue of scalability, the APF system will register only tags and readers that are necessary for a particular application. It will not register tags and readers that are not related to that particular application.

Furthermore, the traffic flows of steps ⑤ and ⑥ in Figure 2 will be encrypted by a secure sockets layer in order to protect the information decrypted by the authenticating reader from being exploited maliciously.

The authors are convinced that the APF system will go a long way to defuse the fears and concerns that consumers have regarding the present lack of privacy in the RFID system. Moreover, in the prototype system the authors extended his research to employ Secure-HTTP and SSL protocols for the protection of the APF database. The authors further their research work on how the APF database will be protected from various malicious attacks.

In summary, the application of the APF system for securing patients medical records in hospitals will be a secure system that will prevent the invasion and abuse of a patient's confidential information. It is believed that the deployment of the RFID system for the management of medical records in hospitals will enhance the efficiency and accuracy of medical treatment. However, without employing effective privacy and security protection for the confidential information stored in the tag, privacy problems will negate the benefits that RFID offers. In conclusion, the authors believe that the application of the APF system is an effective solution to patients' privacy concerns regarding their confidential information stored and has a wide range of other potential applications.

ABSTRACT

This article proposes a workflow and reliability model for surgery patient identification using RFID (Radio Frequency Identification). Certain types of mistakes may be prevented by automatically identifying the patient before surgery. The proposed workflow is designed to ensure that both the correct site and patient are engaged in the surgical process. The reliability model can be used to assess improvements in patients' safety during this process. A proof-of-concept system is developed to understand the information flow and to use information in RFID-based patient identification. Reliability model indicates the occurrences of patient identification error can be reduced from 90 to as low as 0.89 per 10,000 surgeries using the proposed RFID based workflow.

INTRODUCTION

Improvement in patient safety in medical care continues to be a very important issue in the medical care community. According to an Institute of Medicine (IOM) report, 44,000 to 98,000 people die each year as a result of preventable medical errors (Kohn, Corrigan, & Donaldson, 1999). The percentage of hospital inpatient admissions experiencing adverse events has been estimated at 3.7% in the U.S., 16.6% in Australia, and 10% in the UK (MF & JD, 2004). Various types of medical errors occur during the course of healthcare delivery, such as improper transfusions, wrong-site surgery, and mistaken patient identities. High error rates with serious consequences are most likely to occur in intensive care units, such as operating rooms and emergency departments ("What an unbelievable surgery!-Perform an operation with exchanged charts", 2006). Many of these medical errors are due mainly to avoidable human errors that can be potentially eliminated by proper design and error-proofing of the associated workflow. Surgery generally involves the execution of many complex tasks and each task is composed of multiple steps. The most common human error in the medical process is unintentional omission of one or more steps, especially when there are a large number of steps (Reason, 2002).

Patient identification is one of the necessary processes performed prior to anesthesia and surgery. Errors in this process can lead to unrecoverable medical accidents and there are numerous such accidents reported ("What an unbelievable surgery!-Perform an operation with exchanged charts", 2006). One instance of such an error involved intake nurses and surgery doctors: two patients—one with thyroid cancer and one with stomach cancer—had their identities exchanged in the surgery. As a result, the thyroid of the patient with stomach cancer was removed and the stomach of the patient with thyroid cancer was removed. There are other instances where medical doctors have reported performing invasive procedures on the wrong patients (Mark R. Chassin & Elise C. Becher, 2002).

The IOM report revealed that the majority of medical errors are not caused by individual recklessness or the actions of a particular group (Kohn, Corrigan, & Donaldson, 1999). More commonly, faulty systems, processes, and conditions lead people to make mistakes or fail to prevent them. Therefore there is a need to design and error-proof workflow systems that render human error essentially impossible or at least extremely difficult (Etchells, O'Neill, & Bernstein, 2003). Barcode system such as the Global Service Relation Number (GSRN) from GS1, which is used to identify patients and the services provided to them, may be helpful in addressing some of these needs (http://www.gs1.org/docs/patient_safety). However, use of such a barcode system may impose awkward constraints on the surgery team because a bar code must be within the line of sight of the scanner. Ideally, patient identification technology should be simple and reliable so that the overall activities and associated workflow of the surgical team is smooth and efficient. In this context, RFID technology offers an attractive solution because it does not need a line of sight and its reading range is greater than that involved with a barcode system. RFID technology is one potential solution in resolving occurrences of patient misidentification (Fisher, 2006; MF & JD, 2004).

We suggest a model that applies RFID technology to the patient identification process prior to entry into the operating room, and a prototype system for the application model. Automatic recognition eliminates the possibility of misidentification error by displaying the patient's identification information on the computer monitor of the operating room as s/he is being rolled into the room. A reliability model is used to show that the probability of patient identification error can be reduced by the proposed RFID based workflow. The next section provides a literature review on the RFID application in medicine and an overview of current costs. In the third section a typical workflow process for identifying a surgery patient is described and a process involving the RFID identification system is suggested. The suggested process is evaluated according to workflow process reliability model. Lastly, the prototype system developed to serve as a proof-of-concept of the proposed workflow process is discussed.

RFID TECHNOLOGY IN THE MEDICAL AREA

RFID technology may dramatically improve an organization's capability to obtain real-time information on the location and properties of tagged moving objects, such as people, materials, or equipment. It has been utilized in many areas, such as luggage tracking, security keys, toll collection, and supply chain management (SCM) (Angeles, 2005; Srivastava, 2004). The healthcare area is regarded as promising application area for RFID technology (Ericson, 2004;, "RFID in the Hospital", 2004).

A limited number of hospitals are reportedly testing RFID. Most began with tracking and managing equipment. One hospital installed an RFID equipment tracking system to monitor 12,000 pieces of medical equipment. The hospital estimated that it had gained a $200,000 benefit per year over and above the cost of the RFID system's installation and maintenance costs ("Patient Safety Applications of Bar Code and RFID Technologies"). Another hospital utilized inventory RFID tags, cutting inventory losses in half ("Patient Safety Applications of Bar Code and RFID Technologies"). RFID technology has also been used in tracking sponges in surgery (Alex Macario, Dean Morris, & Sharon Morris, 2007; Schwaitzberg, 2006). Tagging equipment or materials may be simpler than tagging people as proven in its uses in the manufacturing and retail sectors.

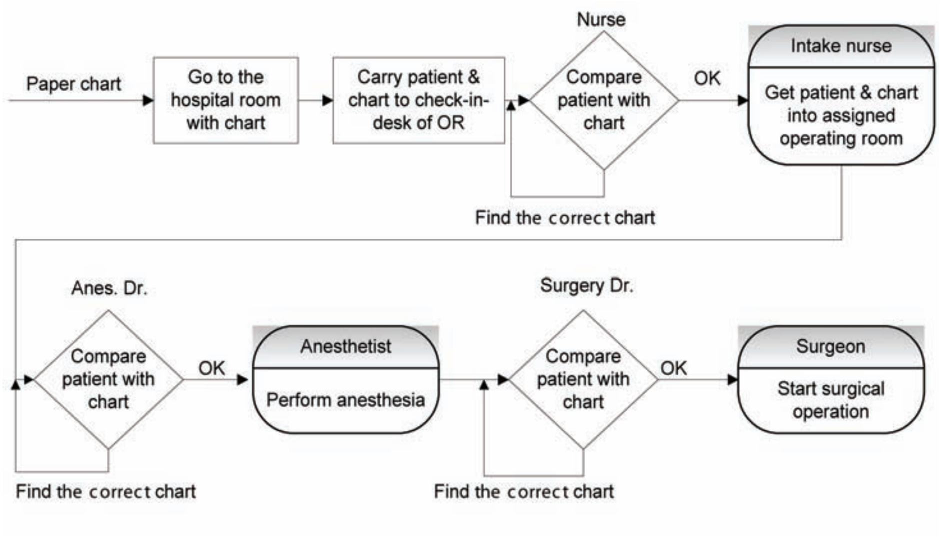
RFID technology has rarely been used in tracking and managing people, such as patients, physicians and nurses. A location-based Medicare service project with a hospital-wide RFID system was conducted in a university hospital in Taiwan (Wang, Chen, Ong, Liu, & Chuang, 2006). Two Singaporean hospitals implemented a RFID system for tracking visitors, patients and staff in the Accident and Emergency Department. These systems were used to identify and trace the contact history of Severe Acute Respiratory Syndrome (SARS) infected patients ("Singapore Fights SARS with RFID", 2003).

Tagging people, however, is more challenging and requires more circumspection because of other technical and organizational problems. Many medical electronic devices use radio waves in a hospital. The presence of these devices raises the possibility of interference with RFID radio waves. Although the range of its operating frequency is restricted to free ISM (industrial, scientific, medical) bands, these frequencies can be a source of interference, too, and can interfere with RFID devices (Srivastava, 2004). Cost issues are another major obstacle to hospital-wide use of RFID technology. An RFID company estimated that it could cost between $500 and $2,000 per hospital bed to install its RFID system ("Health Care RFID Startup Scores $9 Million in Venture Funding", 2004). Like most electronic devices, even though RFID unit cost has fallen dramatically over the past few years, it is still too expensive for hospital-wide use. Unless these obstacles, such as unit price and device interference issues are resolved, application of RFID is likely to be limited to restricted areas of the hospital. Thus, it may be more efficient to deploy the RFID system in a specific area and for a specific function, such as patient identification in operating rooms. Such targeted uses may help to eliminate the possibility of unrecoverable and serious medical errors, such as performance of surgery on the wrong patient or at the wrong site.

RFID FOR SURGERY PATIENT IDENTIFICATION

A medical doctor decides to perform surgery on in- or outpatients, based upon the results of the patient's medical examination. A patient's surgery schedule is usually developed according to the schedule of the surgery doctor in charge. The patient, if an outpatient, is required to check into the hospital one day prior to the operating day if the operating schedule has been set. An operating room and an anesthetist are assigned to the patient on the previous afternoon of the operating day. The preoperative setting for the next day's operation usually begins in an operating room after finishing the scheduled surgical operations for the day. The anesthetist in charge checks the medical status and physical constitution of the patient during rounds and determines the anesthetic method to be used in the next day's opera-

Figure 1. The original workflow diagram



tion. The results of the anesthetic round must be recorded on the patient's chart and the hospital's information system. The workflow process involving the movement and identification of a surgery patient begins after completion of the necessary preoperative setting.

Figure 1 describes the typical workflow process around the movement of a surgery patient who is scheduled for an operation, focusing on consultation of a paper chart on the day of the surgery. A nurse or commensurate employee brings the patient to the designated surgery according to the surgery schedule. The worker takes the patient to the check-in desk in the operating room and turns him and the paper chart over to a nurse in charge. At that time, patient identification is confirmed by the nurse and the worker who brought the patient in. The nurse could ask for the name and compare it on the wristband and chart of the patient. After confirming the identity of the patient and presence of the correct chart, the patient moves into the assigned operating room. The nurse and anesthetist in charge of the operation confirm again identify of the patient and the chart before performing anesthesia. The surgeon then checks the identification of the patient by comparing the wristband and the chart of the patient before beginning the operation.

In order to eliminate the possibility of human errors in confirming the patient's identification, it is necessary for any automatic error-free process to be introduced in parallel to the current confirmation process relied upon by a surgical team. We suggest a workflow process that prevents human error by deploying the characteristics of an RFID system. Figure 2 contains a conceptual diagram for an automatic identification system using RFID technology. RFID antennae may be placed at the entrance of each operating room and check-in room. An RFID reader may be connected to the existing information system through an RFID server. An RFID tag is attached to a surgery patient's wristband. The hospital information system is used in tandem with the prototype described in this article. We assume the existence of a hospital information system and ability to retrieve necessary information from the system using the patient's ID.

Figure 3 shows a diagram of the suggested workflow process for identifying a surgery patient using an RFID reader in each confirming step of the current identification process. The possibility of human error in the confirmation process

Figure 2. Conceptual diagram of an operating room with RFID system

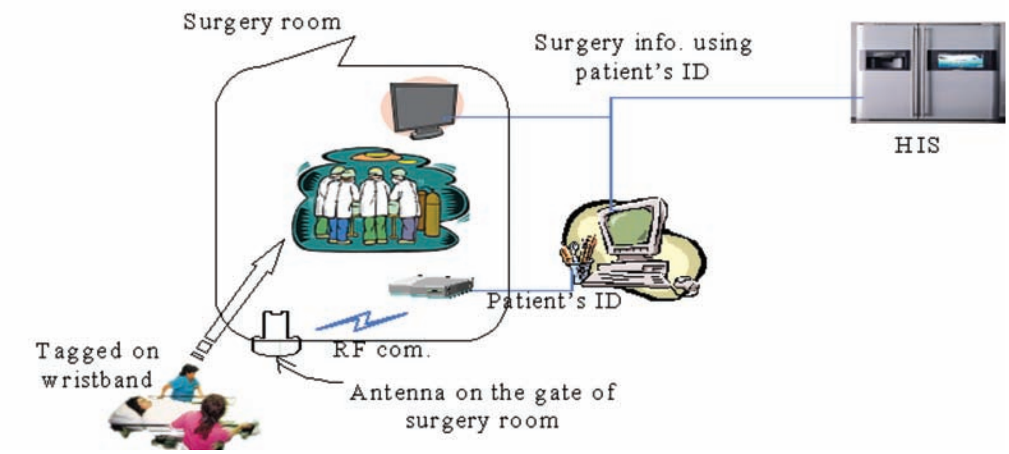


Figure 3. New workflow diagram using RFID in patient identification

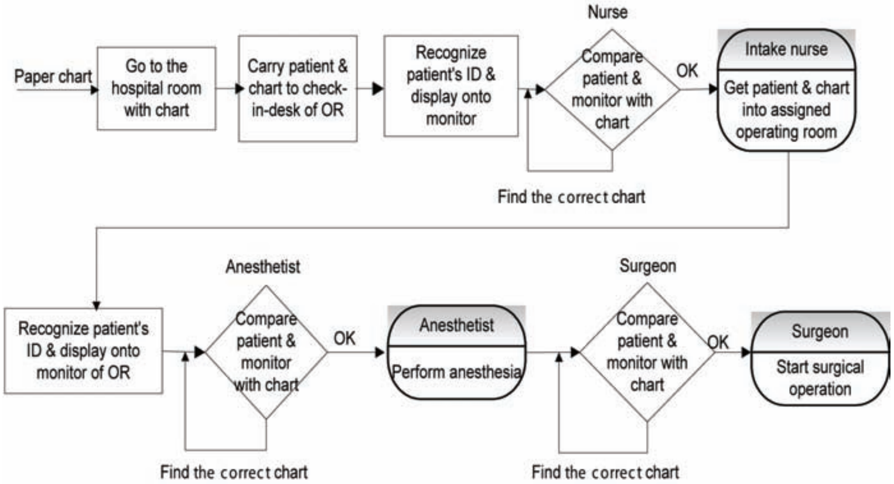


may be reduced by adapting RFID technology to identification of a moving object. In the proposed process, a patient is wearing a wristband with an RFID tag on his wrist. The surgeon confirms the patient's identity during rounds the morning of the surgery. When the patient is brought to the check-in area of the operating room, the identification is confirmed by the intake nurse and the worker who took the patient into the operating room. At this time, the patient's identification information is recognized by an RFID reader and displayed on a computer screen, allowing the intake nurse to again compare the displayed patient's name to the name on the paper chart. After the confirmation and check-in processes are complete, the patient is rolled into the surgery. As he passes through the entrance of the surgery, an RFID antenna at the entrance reads the RFID tag within the wristband and uploads information into the computer system in the operating room. The computer immediately queries the scheduling system about surgical operation to confirm that the patient is indeed scheduled to be in that specific operating room and then uploads the patient's identification information and other necessary information from the electronic medical record, including allergies, blood type, and laboratory reports, including laterality from radiology studies. If the RFID system indicates that the wrong patient has entered the room, a warning is provided (e.g., beeping sound) and a warning sign is displayed on the monitor. At the instant the patient wearing an RFID tag enters the operating room, the computer system confirms that the right surgeon and right patient are in the right place before the surgical procedure begins.

Although the RFID technology contributes to patient safety and traceability, it may increase the complexity of processes and decrease hospital performance. In the next section, we analyze the reliability of the workflow process and compare it with a paper-based process.

ANALYSIS OF PROCESS RELIABILITY

The reliability models can be applied in this case to evaluate error probability (Kuo & Zuo, 2002). Let x_i indicate the error probability of component i for $1 \le i \le n$. Then, vector $x = (x_1, x_2, ..., x_n)$ represents the state of all components and is called the component error vector. Let $R(x)$ represent the reliability of system x.

Serial system:

The reliability function of a serial is given by (Figure 4):

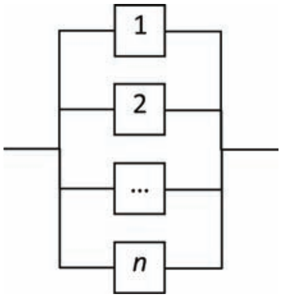
$$R(x) = \prod_{i=1}^{n}(1 - x_i)$$

Parallel system:

The reliability function of a parallel is given by (Figure 5):

Figure 4. Structure of serial system

Figure 5. Structure of parallel system



$$R(x) = 1 - \prod_{i=1}^{n}(x_i)$$

Serial-Parallel System:

A serial-parallel system includes an *m* disjoint module connected in a series and module (Figure 6).

The single module is:

$$R_i(x) = 1 - \prod_{j=1}^{n_i}(x_{ij}) \ , \qquad R_i(x) = 1 - \prod_{j=1}^{n_i}(x_{ij})$$

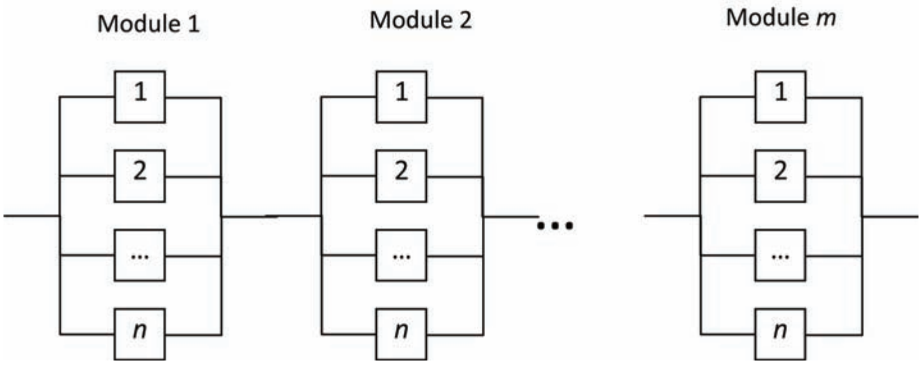
$$i = 1,2,...m\ ,\ i = 1,2,...m$$

The reliability function of a serial-parallel is given by:

$$R(x) = \prod_{i=1}^{m} R_i(x) = \prod_{i=1}^{m}\left(1 - \prod_{j=1}^{n_i}(x_{ij})\right)$$

Surgical processes contain many steps and tasks. Usually, the error rate for a process may increases as the number of steps in the process increases. Unfortunately, any empirical or experimental data about human error rate or error possibility in medical area has not been reported even though various types of medical accidents based on human error occur in healthcare. The incidences of incorrect surgery on patients are

Figure 6. Structure of serial-parallel system



due to errors in the checking process and may be regarded as a kind of human error of omission. Since any kind of omission error rate has not been reported in healthcare area, we use the error probability of omission in similar situations to show how much the error rate may be reduced by RFID applications in the patient identification process in the operating room. General human errors of omission, those in which the items being omitted are embedded in a procedure, have an error probability of 99.7% (Park, 1997). Such studies have also been proposed for identifying human error in general anesthesia administration (Blatt, 2007). On the other hand, the accurate rate of RFID reader is more than 99.9% in an area of 0-5m (Yoo et al., 2007) that is, the probability of misidentification error is at most 0.001 in the case of RFID.

As shown in Figure 2, a nurse, an anesthesiologist, and a surgeon must compare a surgery patient with his paper chart. This procedure follows a serial procedure in which each component has an error probability of 0.003, with reliability r=0.997, as shown in Figure 7(a). The reliability of the total patient identification system involving a series of three components is R=.991027 (99.10%). Use of an RFID warning system as a parallel component in the series, as shown in Figure 7(b), increases the reliability of the total system to R=0.999991 (99.99%). In other words, this can be expressed to reduce the occurrences of error from 90 per 10,000 times to 0.089 per 10,000 times. On the other hand, if manual operations are eliminated and the patient identification procedures are relied on then the RFID warning system as a serial component in the series, as shown in Figure 7(c), the reliability of the total system can still reach R=0.997003 (99.70%). In this case we assume that the probability of missing an RFID warning is the same as that of errors in the procedure followed to check a patient's medical chart. Thus, RFID warnings via either beeping or display on a computer monitor dramatically reduce misidentification errors to nearly zero.

DEVELOPMENT OF A PROOF-OF-CONCEPT RFID SYSTEM

Design of the Proof-of-Concept System

We developed a prototype system to show that an RFID system can be used in the identification process of a surgery patient. The hardware component of the RFID system is an RFID tool kit, manufactured by Alien, which includes ALR-9800 Enterprise RFID reader and ALR-9610-BC antenna. The ALR-9800 model uses an electromagnetic wave of 900MHz band and the ALR-9610-BC model has a standard antenna. We experimented to investigate the identification ratio of this RFID

Figure 7. Human reliability model before and after using RFID

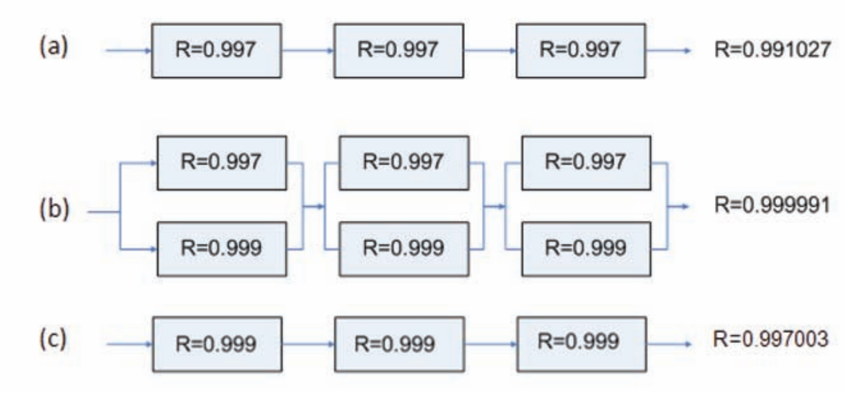


Figure 8. Process flow with two modules

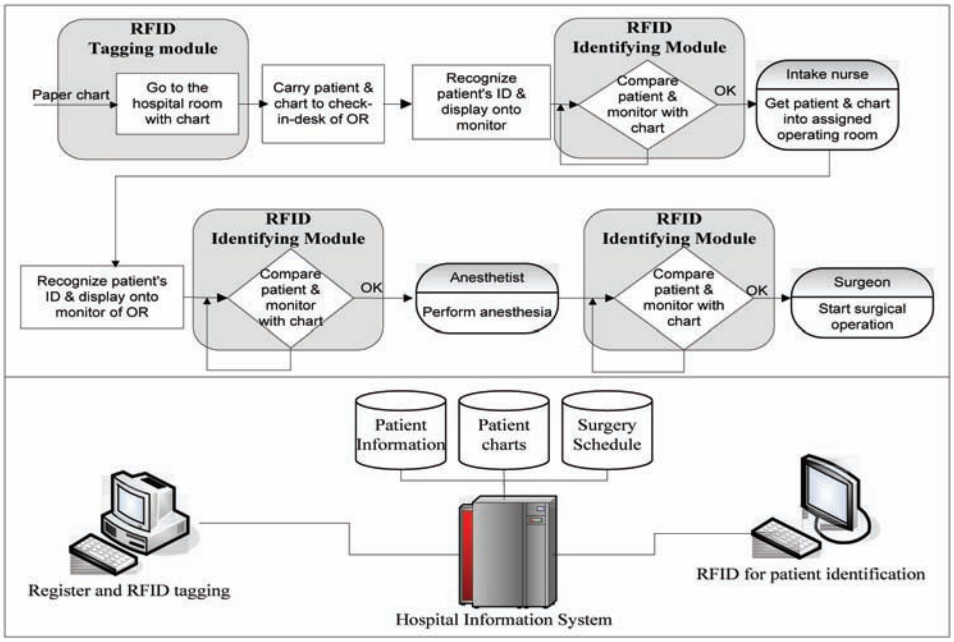
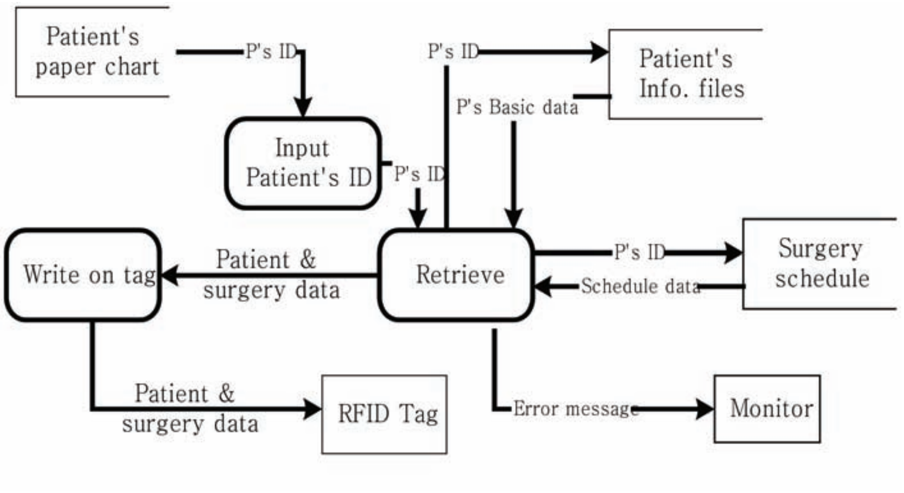


system. The experiment was performed in open space with an object moving at working speed. The results revealed an identification ratio of 99.9% within a 4-meter distance, and may correspond to a reliability prediction model.

Figure 8 shows a tagging module and an identifying module required in the prototype system. The first one is used to write a patient's basic information to a tag attached to a wristband to be worn by the patient. The function of the other module is to recognize the patient's basic information from the tag on the patient's wristband and to display it on the monitor in the room where the surgery will be performed. These modules can be easily connected to a legacy system to retrieve detailed information on the patient and surgery.

Figure 9 shows a data flow diagram of the tagging module. The module retrieves basic

Figure 9. DFD for tagging



information, such as the patient's ID, name, diagnostic department, hospital room number and surgery room number, from the legacy database and records the information on the RFID tag that is attached to the wristband. The data flow diagram for the identification module is shown in Figure 10. As a patient is rolled into the operating room, the RFID antenna on the door frame of each operating room recognizes the tag information on the patient's wristband and uploads it into the RFID identification module in the specific operating room into which the patient is being transported. The module immediately queries the surgery's scheduling module in the legacy system to confirm that the patient is indeed scheduled to be in the operating room and then uploads information about the electronic medical record from the legacy database. The system confirms that the right patient is in the right room before the surgery procedure begins.

Implementation of the Prototype

We developed a prototype module for middleware that may be used to enable an information interchange between the RFID module and the legacy system. The prototype system involves a tagging module, recognition module and tag manager module. Figure 11 shows the screen of the tagging module. Once a patient's surgical schedule has been finalized, the patient is hospitalized in preparation for preliminary procedures and a wristband with RFID tag is attached to his wrist. At this time, the tag information is assigned to the patient. Figure 11 shows a tagging form that is used to match a patient's identification information with the information on the tag on his wristband. A nurse presses the search button and types the patient's name onto a search screen. If the screen reveals the patient's name in the surgery schedule in the legacy database, the nurse highlights and double-clicks on the name. The basic information on the patient is loaded into the tagging form as shown in Figure 11 and the tagging information is recorded into a tag by pressing the save button.

Figure 12 shows a form that may be used to display information for a patient who is being rolled into an operating room. An RFID antenna that sends radio waves continually communicates whether a patient with an RFID tag is approaching or not. If a patient passes through the entrance of an operating room, the RFID reader recognizes the patient's tag and displays basic information on the operating room monitor. The information may be retrieved from the hospital's legacy system using the tag information recognized by the RFID

	RFID-based automated process	5 min	100%

system. Surgical team members, such as surgery doctors and nurses in charge of the operation, may then again confirm whether this is the right patient by comparing the patient's name on the PC monitor and paper chart while the patient is under anesthetic. This prototype system displays only basic information on the patient as recognized on the RFID system. In real applications, however, other important medical information required for an operation may be easily retrieved through the existing hospital information system.

Preliminary Evaluation

In order to examine the impact of RFID in information accuracy and productivity improvements by reducing the keyboard entry, we had a preliminary evaluation in three scenarios. Each scenario contains two tests, user entry from the keyboard and RFID-based data collection. The user entry data mix with different data type including text, numerical, and date. The average length of a single record input data is 6.56 characters. Table 1 presents the preliminary evaluation result. The detail of the experiment is studied in (Cheng & Prabhu, 2007). Based on three-scenario evaluation processes, the accuracy of RFID data collection enables the end-to-end process automation that reduces the processing time and eliminates potential data entry errors. The evaluation result shows we can improve the accuracy of data acquisition, which is the main objective in this study.

CONCLUSION

In this article a workflow model is suggested that utilizes RFID technology to improve patients' safety during a surgical operation. A workflow process that involves RFID technology in the identification process is proposed and a prototype system for RFID middleware is developed here. Some obstacles to RFID use remain hospital-wide, but it is becoming a promising option for some areas in healthcare. Furthermore, the suggested process offers the potential to reduce human errors by reducing/eliminating data entry. The proposal mathematical model indicates that such error can be reduced from 90 to as low as 0.89 per 10,000 surgeries using the proposed RFID based workflow. In conclusion, this article shows that using RFID can be expected to reduce patient identification errors significantly, thereby reducing potential harm to patients in terms of injury or death. A major caveat is that these results are theoretical and must be considered preliminary therefore no assertions can be made about eventual reductions in injuries or deaths with further research. Experimental research can also be used for assessing some of the technical challenges such as interference of RFID and other medical instruments, and assessing changes in workflow complexity caused by introduction of RFID. Future work could also consider changes in the workflow complexity by introducing RFID technology and applying RFID for monitoring patient flow through healthcare systems.

Chapter 3.16

Internet as a Source of Health Information and Its Perceived Influence on Personal Empowerment

ABSTRACT

The primary aim of this study is twofold. First, the authors seek to identify the factors that influence members of the general public to conduct Internet searches for health information. Their second intent is to explore the influence such Internet use has on three types of personal empowerment. In the summer of 2007 the authors conducted a household sample survey of a population of Canadian adults. A total of 261 self-administered questionnaires were returned to the researchers. Our findings indicate that use of the Internet as a source of health information is directly realted to three main factors: sex, age and the individual's perceived ability to understand, interpret and use the medical information available online. Further, their results lend support to the notion that using the Internet to search for information about health issues represents a more consumer-based and participative approach to health care. This study is one of the first to relate Internet use to various forms of personal empowerment. This area appears to have great potential as a means by which consumers can become more empowered in managing personal health issues.

INTRODUCTION

A number of studies have confirmed growing use of the Internet to find information on personal health issues. For example, it has been estimated that of the 15 million Canadians who had Internet access in the home in 2005, 58%, or 8.7 million, used it to search for health information (Underhill & McKeown, 2008). The majority of these users said that they had searched for information about a specific ailment or about lifestyle issues such as nutrition, diet or exercise. More recent data from the United States have shown that in 2007, 71% of adults turned to the Internet for health information. This percentage stood at 61% in 2006 and 53% in 2005 (Harris Interactive, 2007).

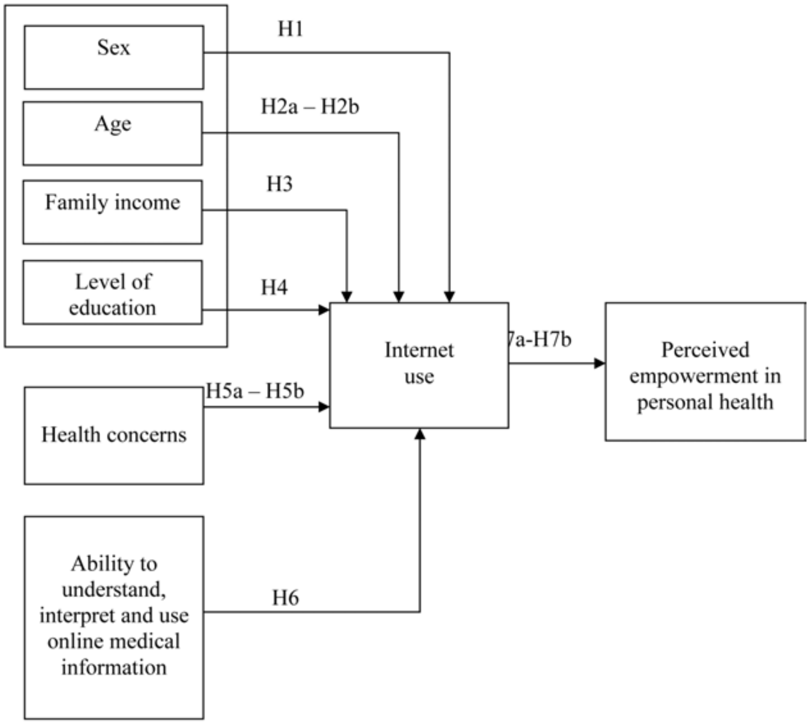
Increased use of the Internet by the general public is transforming people's relationships with their health. By providing wide access to information, advice and health services, the Internet is increasingly seen as a powerful lever for personal empowerment (Wilson, 2001). These opportunities therefore deserve a closer examination. In recent years, various studies have shed light on the opportunities provided by the Internet with regard to personal empowerment in health. These studies have been based on different visions of the construct, which is generally defined as the development of the individual's involvement in responsibility to their health care. According to Lemire et al. (2008), studies on this subject have focused on the impact of Internet use on the development of one of three forms of personal empowerment: *professional* empowerment, which is focused on the individual's self-actualization for approaches more consistent with expert knowledge (Fox et al., 2005; Henwood et al., 2003); *consumerist* empowerment, which is focused on choices based on personal judgement and resources (Kalichman et al., 2002); and *community* empowerment, which is focused on better social inclusion in a group or community (Radin, 2006; Hsiung 2000; Burrows et al., 2000).

However, there are two main reasons why only limited generalizations can be made from past studies. First, the data was collected from very specific groups. For example, the samples consisted of people who had serious illnesses (e.g., Kalichman et al., 2002; Radin, 2006), who were using a specific drug (e.g., Henwood et al., 2003) who had similar health concerns (e.g., Fox et al., 2005), or who relied on the same Web site as the main source of their health information (e.g., Fox et al., 2005; Radin, 2006; Hsiung, 2000). Second, the data were often collected without trying to understand the development of personal empowerment in relation to past research on searches for information on the Internet and to the specific nature of how online health information is consulted. To our knowledge, the study by Lemire et al. (2008) is the only one that has examined simultaneous development of the three forms of empowerment mentioned above. Our research is an extension of their study, inasmuch as it tries to extend the reach of its theoretical and practical contributions. More specifically, instead of analyzing the three forms of user empowerment on a single Web site, we shall examine opinions and points of view expressed by a sample of the general public. In other words, in order to sidestep the above-mentioned limitations, the present study sought to identify the factors that influence members of the general public to conduct Internet searches for health information and explore the influence of Internet use on three types of personal empowerment.

RESEARCH MODEL

The research model presented in Figure 1 links previous research on Internet use as a source of health information to its impact on the empowerment or self-empowerment of individuals in how they manage personal health issues.

Figure 1. Research model



Prior Research on Using the Internet as a Source of Health Information

Previous studies have shown that some demographic factors influence whether or not an Internet user conducts searches for health information. According to a Statistics Canada survey, Internet users who are women are twice as likely as their male counterparts to be concerned with health issues (Underhill & McKeown, 2008). It is now well established that women are more likely to get involved in the decision-making process in personal health issues (Barrett et al., 2003; Nease & Brooks, 1995); they are therefore more inclined than men to turn to the Internet for health information (Pew Internet and American Life Report, 2006; Rice, 2006; Nicholas et al., 2003; Cotton and Gupta, 2004). This may be explained by the traditional role of women in the family, expressed by a sense of responsibility for the health of all the other members of the family (Hibbard et al., 1999; Dolan et al., 2004). This result seems consistent with the fact that men are more reticent than women to consult a health professional and seek professional help when it is needed (Broom, 2005). According to Pandey et al. (2003), women use the Internet more for disease prevention and health promotion. We therefore arrived at the following hypothesis:

Hypothesis 1: Women use the Internet more than men to search for health information, mainly for preventive purposes.

Age is another factor presented in the literature as a possible antecedent of belonging to the group of users concerned with health. In contrast to the results on sex, the findings associated with age are contradictory. Several studies have found a negative association between age and using the Internet as a source of health information (e.g., Cotton & Gupta, 2004; Pandey et al., 2003; Anderson, 2004; Licciardone et al., 2001; Laurence & Park, 2006). On the other hand, Nicholas and al. (2003) found a positive link between age and Internet use, while other investigators found no significant relationship between the frequency of Internet use for health purposes and user age (e.g., Underhill & McKeown, 2008; Lemire et al., 2008).

A recent Statistics Canada study (Underhill & McKeown, 2008) revealed that it is the type or nature of the information sought by Internet users that varies by age group. Their study found that a greater percentage of people in the 18 to 44 age group were looking for information about lifestyle and the health care system (for preventive purposes), while an even greater percentage of people 45 years and over were looking for information on specific illnesses and drugs (for curative purposes). Given these results, we made the following hypotheses:

Hypothesis 2a: Age is positively associated with frequency of Internet use for curative purposes.

Hypothesis 2b: Age is negatively associated with frequency of Internet use for preventive purposes.

In a recent study, Reddick (2006) demonstrated that among households with Internet access in the home, those reporting an annual income under $75,000 were less likely to consult the Internet for health information than those with an annual income of over $75,000. These results have been confirmed in a review of the literature (Renahy & Chauvin, 2006) and by recent data from Statistics Canada (Underhill & McKeown, 2008). The data indicate that Internet users seeking health information have higher income levels than those who do not.

Hypothesis 3: Household income is positively associated with using the Internet to search for health information.

Level of education is also considered a factor positively associated with using the Internet to search for information on personal interests. Studies have shown that Internet users concerned with health issues are better educated than other users (e.g., Cotton & Gupta, 2004; Reddick, 2006; Renahy & Chauvin, 2006). It would therefore appear that education is one of the main predictors of whether the Internet is used to search for health information.

Hypothesis 4: Level of education is positively associated with the frequency of online searches for health information.

In addition to the four socio-demographic factors presented above, it would appear that an individual's concern for their own state of health also has an impact on whether they will use the Internet to obtain health information. Several studies have shown that people who are ill or handicapped or who consider themselves in poor health more frequently search for health information online (e.g., Rice, 2006; Goldner, 2006; Baker et al., 2003). A recent study has also found that 86% of Internet users who are chronically ill search the Internet for health information on a regular basis, as compared to 79% of users who do not suffer from serious illnesses (Pew Internet and American Life Report, 2007). On the other hand, Cotten and Gupta (2004) found that individuals who actively searched the Internet for health information considered themselves in better health than people who did not. Since contradictory results have been obtained and age seems to be closely associated with concern for personal health, we made the following hypotheses:

Hypothesis 5a: Frequent use of the Internet for curative purposes is positively associated with level of concern for personal health.

Hypothesis 5b: Frequent use of the Internet for preventive purposes is negatively associated with level of concern for personal health.

Finally, in a study commissioned by EuroHealthNet—the European network for public health, health promotion and illness prevention—Christmann (2005) examined people's capacity to understand, interpret and use medical information properly. In a recent article, Norman and Skinner

Table 1. Contact, acceptance and response rates

	N	Rates
Homes visited	1 439	-
Contact established	619	Contact rate = 43%
Individuals willing to participate	368	Acceptance rate = 59%
Returned questionnaires	261	Response rate = 71%
Completed questionnaires	255	-

(2006) raised the same idea, indicating that the health information that is available online is not widely consulted due to Internet users' lack of knowledge or skills in health matters. The two articles raise the issue of e-health literacy. Based on this work, we made the following hypothesis:

Hypothesis 6: Use of the Internet as a source of information on health is positively influenced by an individual's ability to understand, interpret and properly use the medical information that is available online.

Influence of Internet Use on Perceived Empowerment in Health

Using the Internet for health purposes includes various goals or motivations; identifying them could shed light on their relationship with the concept of empowerment in personal health. According to Lemire et al. (2008), what motivates Internet users to seek health information could be closely linked to their perception of the resulting personal empowerment. More specifically, the authors found that individuals who believed that they could follow prescriptions, according to the medical model, used the Internet mainly to gain a better understanding of a problem or illness, while those who relied more on their ability to make personal choices were seeking alternate views from those associated with traditional medicine. Again according to these authors, information searches based on social motivations (e.g., participating in online forums or helping a loved one who is ill) were found to be more closely associated with the community logic of empowerment described above. We therefore made the following hypotheses:

Hypothesis 7a: Frequent use of the Internet for curative purposes fosters the development of the professional logic of empowerment in personal health.

Hypothesis 7b: Frequent use of the Internet for preventive purposes fosters the development of the consumerist logic of empowerment in personal health.

Hypothesis 7c: Frequent use of the Internet for social or community purposes fosters the development of the community logic of empowerment in personal health.

METHODS

Applying a methodological approach proposed by d'Astous (2005), in the summer of 2007 we conducted a household sample survey using a self-administered questionnaire addressed to an adult Canadian population. This method is akin to a mail survey, except that the questionnaires are administered in the respondent's home. One of the researchers left the questionnaires with the individuals willing to participate and made arrangements to pick them up once completed. In terms of the sampling, this method has four advantages: there is no need to have a list of all the addresses corresponding to the targeted population; an efficient selection can be made randomly using a city map and targeting streets in pre-selected residential neighbourhoods according to the needs of the study; the personal contact with respondents has a positive impact on the response rate; the quality of data is generally higher than that from mail surveys; and the home selection process is relatively flexible and corresponds to the needs of the study.

The study was conducted in Montreal, Canada, the world's second largest French-speaking city on the basis of the number of inhabitants whose mother tongue is French. The city is also the second largest city in Canada and North America's only French-speaking metropolis. Boroughs were identified for questionnaire distribution by consulting the Internet portal of the City of Montreal's municipal services.[1] This allowed us identify two predominantly French-speaking boroughs with different socio-demographic profiles: Outremont and Montreal North. Outremont represented the borough with the highest percentage of people with university degrees and the highest average income. In contrast, Montreal North offered the lowest percentage of people with a university degree and one of the lowest average levels of family income.

A random selection algorithm was used to determine which streets to visit in each borough. To avoid any bias, we eliminated streets neighbouring one of the city's four universities. These neighbourhoods usually have a large student population made up of young people with low incomes and high levels of education.

The specific nature of our methodological approach required a particular interpretation of the response rate. Clear distinctions had to be made between the contact rate, the acceptance rate and the response rate (d'Astous, 2005). The contact rate refers to the percentage of the homes that were visited in which contact was established with a resident; the acceptance rate indicates the percentage of individuals who were contacted and who agreed to participate in the study; and the response rate provides the percentage of individuals who agreed to take part in the study and who returned the questionnaire. As shown in Table 1, contacts were not established in more than half of the homes visited. Residents in these homes either were away (e.g., for vacation, work) at the time when the interviewer attempted to make contact or they just did not want to open the door to an unfamiliar person. Among those residents with whom we established a contact, nearly 60% agreed to participate in our survey. Refusals generally result from apathy, fear of invasion of privacy or any number of reasons. Finally, a total of 261 questionnaires were returned, for a response rate of 71%. Six of the 261 returned questionnaires were incomplete and had to be discarded from the database. The final sample came to 255 respondents.

Operationalization of the Variables

The variables associated with the respondents' socio-demographic profiles—sex, age, income level and level of education—were all measured with a single item. Concerns with personal health (continuous variable) were measured with two items adapted from work by Lemire et al. (2008). On the other hand, the variable associated with the concept of e-health literacy was measured using the seven items suggested by Norman and Skinner (Christmann, 2005). The three categories of motivations underlying Internet use for health purposes (curative, preventive and social) were measured with two items. Finally, the dependent variable corresponding to the three logics of empowerment was adapted from Lemire et al. (2008). Some of the items needed to be reworded in order to compare empowerment levels among individuals interested in health information (the only population targeted by Lemire's study) with that of other users. The measure distinguished between skills and sense of control based on professional expertise, those that were based on personal judgement, and those generated by exchanges in support and discussion groups (five items each). All the items included in the questionnaire (except those associated with socio-demographic variables) are listed in the Appendix.

Pre-Testing

Questionnaires need to be pre-tested in order to ensure that the items included in the instrument are reliable. This pre-testing is crucial since, as pointed out by Kumar (2005), respondents to self-administered questionnaires generally do not ask for clarifications and will respond according to what they understand in the statements. Clear, well-phrased statements can reduce the risk associated with misinterpretation. A total of 10 individuals with different socio-demographic profiles were selected from the researchers' networks of contacts. Based on their comments, minor changes were made to some items and some of the text was edited to improve readability.

RESULTS

This section presents the profile of the respondents who participated in this study, the psychometrics of the measures used, and the results of the hypothesis testing.

Respondent Profiles

As indicated in Table 2, our sample included an equal number of men and women, and no significant difference was found between the two boroughs as far as this variable was concerned (p=.353). A significant difference was found between the two boroughs in terms of the average age of respondents. The Outremont respondents were, in general, older than the respondents in Montreal North. Respondents 39 years of age or younger made up 63% of the Montreal North sample as compared to 43% of the Outremont sample. In Outremont, respondents aged 50-59 represented 21% of the sample, compared to only 7% in Montreal North. Given these demographics, it is not surprising that the Outremont respondents reported more concern about their health than those in Montreal North. In terms of education, a significant difference was again found between the two boroughs.

The respondents who participated in the study were relatively well educated, and 68% of them had completed a university degree. As expected, however, the respondents from Montreal North were less educated than those in Outremont. While 77% of Outremont respondents had a university degree, the rate fell to 57% in Montreal North. In terms of average family income, another significant difference was found between the two boroughs. As expected, the average family income of respondents was higher in Outremont than in Montreal North. Finally, the percentage of respondents who never used the Internet was low and not significantly different between the two boroughs.

Psychometric Qualities of Measures

We examined the reliability as well as the convergent and discriminatory validity of the measures used. Reliability refers to the precision and internal consistency of a measure. It was measured using Cronbach's alpha (α) with a minimum acceptable threshold of 0.7 (Nunnally, 1978). Convergent validity preserves the unidimensionality of each variable (Usunier et al., 2000), which is usually attained when only one factor emerges from a factorial analysis that includes all the items associated with the same construct. Finally, the discriminative validity of a variable is confirmed when the square root of the variance it shares with its own items is greater than its inter-correlations with the research model's other variables.

The results of the reliability analysis led to the removal of 2 of the 15 items associated with the three forms of empowerment in personal health (item 2, associated with professional empowerment, and item 3, associated with consumerist empowerment). We were also obliged to remove the variable associated with Internet use for social or community purposes. Both of the items associated with this variable gave a Cronbach's alpha of 0.48, a level markedly below the required minimal threshold. Therefore Hypothesis 7c of

Table 2. Respondent profile

		Complete Sample (n=255)	**Comparisons Between Boroughs**

	No	13%	10%	15%	
Concerns about personal health (1 to 10)		7.3	7.4	6.7	*t* = 2.0 p = .04

the research model could not be tested. Finally, analyses aimed at testing the convergent validity of each construct led to the removal of a second item associated with the professional form of empowerment (item 5).

Tables 3 and 4 present the psychometric qualities associated with the measures used to test the model's hypotheses, excluding the four socio-demographic variables.

Hypothesis Testing

To ensure consistency in the results presented below, respondents who indicated that they never used the Internet for personal purposes were removed from the sample. They represented 13% of all respondents, leaving 222 respondents in the sample.

Before testing the model's hypotheses, we examined the relative importance of the Internet as a source of health information. Respondents were asked to indicate the frequency of use of each source of information about personal health presented in Table 5. The results corroborated the findings of earlier studies (e.g., McMullan, 2006; Dumitru et al., 2007; Hesse et al., 2005), which suggested that health professionals and especially physicians are still the preferred source of information on personal health issues, and that the Internet represents a complementary source of information, such as information from friends,

relatives and the print media. Our data also reveal that Internet users turn to this source mainly for curative rather than preventive purposes (t=-11.5; $p < .001$).

A *t*-test was then used to verify the influence of sex on turning to the Internet for issues of personal health (H1). The results which are presented in Table 6 suggest that women consult the Internet more often than men for preventive and curative purposes. However, this difference was only statistically significant for Internet use for preventive purposes, supporting Hypothesis 1.

Under Hypothesis 2, age is positively associated with frequency of Internet use for curative purposes (H2a) and negatively associated with Internet use for preventive purposes (H2b). To test this hypothesis, we broke the sample down into three age groups: 18-29 (young adults), 30-49 (adults) and 50 and over (mature adults). The results from the variance analysis (presented in Table 7) suggest that young adults turn to the Internet more often for preventive and curative purposes than adults in the other two age groups. As with sex, this difference was statistically significant only when the Internet was used for

Table 4. Descriptive statistics and discriminant validity

The ratios in bold on the diagonal correspond to the square root shared by each of the variables and their respective items. The ratios appearing under the diagonal correspond to the correlations between variables.								

Table 5. Sources of information on personal health issues

Sources of Information	Mean [1 to 10]	Standard Deviation
Health professionals	7.7	2.3
Friends and relatives	5.6	2.6
Internet	5.0	2.8
Print media (books, magazines)	4.7	2.7
Support groups	1.7	1.6

Table 6. Results associated with sex

		N	Mean	Standard Deviation	*t*	*P*
Frequency of Internet use for preventive purposes	Women	106	3.9	2.4	2.7	.05
	Men	107	3.1	2.3		
Frequency of Internet use for curative purposes	Women	106	5.7	2.8	1.9	.07
	Men	107	4.9	2.8		

preventive purposes. The results therefore only support Hypothesis 2a.

The next hypothesis states that Internet users interested in health issues would be found to have a higher average annual income than other users (H3). To test the hypothesis, we divided our sample into two groups of similar size: respondents whose family income was lower than $50,000 and those with a family income over $50,000. Results from the *t*-test, presented in Table 8, clearly indicate that family income does not appear to be associated with the frequency of Internet use for issues of personal health.

The fourth socio-demographic variable included in our research model was level of education. Hypothesis 4 states that level of education would be found to be positively associated with using the Internet to search for health information for curative or preventive purposes. To test it, respondents were divided into two groups: those

Table 7. Results associated with age

		N	Mean	Standard Deviation	*F*	*P*
Frequency of Internet use for preventive purposes	18-29	76	3.8	2.5	3.4	.04
	30-49	89	3.2	2.2		
	50+	48	2.8	2.1		
Frequency of Internet use for curative purposes	18-29	76	5.6	2.7	1.7	.18
	30-49	89	5.5	2.8		
	50+	48	4.7	2.9		

with a university degree and those without. As indicated in Table 9, our results do not support a link between level of education and use of the Internet for personal health.

In addition to the socio-demographic profile, two more variables were hypothetically associated with the frequency of Internet use for health purposes: individual's concerns about their own health (H5) and their capacity to understand, interpret, and use available medical information on the Internet (H6). Correlation analyses were used to test both hypotheses. As shown in Table 4, only the ability to understand, interpret and use online medical information is positively correlated to Internet use for health purposes. This link was stronger in the case of Internet use for curative purposes as compared with preventive purposes. The data could not support Hypothesis H5. Based on our sample, there does not appear to be a significant relationship between the level of concern for one's health and frequency of Internet use for preventive and curative purposes.

The final two hypotheses state that what motivates the Internet user to search for health information online is closely linked to the different forms of empowerment. Before testing these hypotheses, we wanted to capture our respondents' perceived level of empowerment with respect to their own health. It should be recalled that empowerment related to professional logic involves a self-empowerment process, through which the individual learns about expert knowledge and how to use it. This allows them to be proactive in dealing with personal health issues. This logic as-

Table 8. Results associated with average annual household income

		N	Mean	Standard Deviation	*t*	*P*
Frequency of Internet use for preventive purposes	< $50,000	119	3.1	2.3	0.3	.76
	> $50,000	114	3.2	2.4		
Frequency of Internet use for curative purposes	< $50,000	119	4.6	2.9	0.8	.45
	> $50,000	114	4.9	3.0		

Table 9. Results associated with level of education

		N	Mean	Standard Deviation	*t*	*P*

	College or high school diploma	103	5.4	2.7		

sumes that the individual becomes an active agent in the prevention, care or management of their illness and condition, but nevertheless agrees with the prescriptive vision of the biomedical model, under which the health professional is a legitimate expert. Consumerist empowerment, on the other hand, is seen as a demonstration of individual freedom of choice based on personal judgement and resources. This form of empowerment is seen when the individual develops their personal autonomy by identifying options, choosing from among these different options and managing the consequences of such choices. The data in Table 10 suggests that our respondents perceive that they have developed skills and a sense of control over their personal health. However, these skills belong mainly to the professional logic, which means that they are aligned with the views of health professionals (t=8.5; p < .001).

As far as our hypotheses are concerned, it should be recalled that the work of Lemire et al. (2008) reveals that a search for information associated with typically curative motivations is more likely to foster the development of empowerment under the biomedical perspective, as suggested by the professional logic (H7a), while a search for information associated with typically preventive motivations falls under the consumerist logic (H7b). Interestingly, as indicated in Table 11, the data only supported Hypothesis H7b. It would appear that the use of health professionals, and not the Internet, is positively associated with professional empowerment. Frequent use of the Internet as a source of information is more closely associated with an approach aimed at making informed choices on the basis of personal judgement, i.e. the consumerist logic.

DISCUSSION

Our results support the idea that the Internet represents a complementary source of information and that health professionals (and especially physicians) remain by far the main source of information used by individuals in matters of personal health.

In terms of the testing of our hypotheses, our study has confirmed the results of prior research that found that women are more inclined than men to search for health information online. Like Pandey et al. (2003), we observed that women use the Internet more often, especially to consult medical information for preventive purposes. As mentioned above, one explanation may be found in the traditional role of women, who often feel responsible for the health and well-being of other family members.

Our results contradict those of Cotten and Gupta (2004), suggesting that young adults represent the group which makes the most use of the Internet as a source of information for preventive purposes. Contrary to what we may have expected, older Internet users appear not to consult the Internet for curative purposes more often than young adults. There may be several explanations for these results. For one thing, it is well known that young people are the most active users of the Internet and that they connect to the world and to information largely through this technology. It is therefore not surprising to see a significant difference between young adults and older adults when it comes to their perceived capacity to understand, interpret and use the medical information that is readily available on the Internet (t=2.2; p=.04). On the other hand, it

Table 10. Levels of empowerment in personal health

Form of Empowerment	Mean (1 to 10)	Standard Deviation
Professional	8.0	1.8
Consumerist	6.6	1.9

Table 11. Relationship between Internet use and forms of empowerment

	N	Professional Empowerment	Consumerist Empowerment
Frequency of Internet use for preventive purposes	217	.10 p = .16	.19 p = .006
Frequency of Internet use for curative purposes	211	.10 p = .15	.25 p < .001
Frequency of use of health professionals	220	.48 p < .001	.10 p = .15

seems simpler to obtain easy-to-interpret information about lifestyle for preventive purposes than it is to obtain personalized information on illnesses for curative purposes. Finally, older adults' concerns with respect to health are greater, are may be more urgent. They do not have the same level of comfort or knowledge using the Internet as younger people, so they are less likely to use it, relying instead on their physicians.

Existing literature on the subject inspired us to hypothesize that income and education levels would be positively associated with use of the Internet as a source of health information. Like Lemire et al. (2008), we could not support these findings and found no significant association between frequency of use of the Internet and these two sociodemographic variables.

As for the link between perceived health status and use of the Internet as a source of health information, the existing literature provides contradictory evidence. As mentioned above, some studies have shown that people who feel that they are in poorer health or who are concerned about their health consult the Internet the most, while other studies have found the opposite: that the people who actively look for health information online are the ones who worry the least about their health. Our results confirm those studies which suggested a negative association between health concerns and use of the Internet as a source of information.

Our results also confirm an idea introduced by Norman and Skinner (2006): that the health information available online is underutilized due to Internet users' lack of knowledge and/or skills in health matters. We found a significant, positive association between an individual's ability to understand, interpret and use the medical information available online and the frequency with which an individual uses the Internet as a source of information on personal health issues. It should be recalled that, for our respondents, the Internet represents the third most important source of information, after health professionals and family and friends.

Use of the Internet for personal health information is not necessarily associated with a personal self-empowerment strategy aimed at acheiving greater compliance with the vision of physicians and other health professionals (the professional logic). It is more clearly associated with a desire to make more informed decisions by exercising personal judgment (the consumerist logic). These results depart from Lemire et al. (2008), who demonstrated that these two empowerment logics coexist in the users of a widely admired health information site and that the perception of empowerment was stronger among Internet users who subscribed to the professional logic. In this study we observed that it is the use of physicians and other health professionals, rather than use of the Internet, that is positively associated with a professional logic of empowerment. This may be explained by differences in the populations targeted by the two studies (the general public vs. the well-informed users of a health portal) and certain differences in the operationalization of the measures.

A large percentage of our respondents therefore feel that their use of the Internet mainly allows them to be better decision makers. More specifically, they perceive Internet allows them to make better personal health decisions based on personal judgement. These results provide some support to authors who have seen the growth in Internet use as evidence of a more participative and consumer-oriented approach to health care (Kalichman et al., 2002). Our results express this willingness, present among many Internet users, to more or less free themselves from medical authority and adopt an approach that is more centered on themselves, their preferences and their decision-making autonomy. Other empirical studies have provided a complementary illustration of this phenomenon, including Nicholas et al. (2003), who suggested that using the Internet to gain access to health information is accompanied by changes in behaviour, such as better eating habits, physical exercise, relaxation and the consumption of vitamins and supplements. This trend reflects a questioning of the classical approach to health, which has essentially been based on medical authority and passive patient obedience (Lewis, 2006).

To summarize, our results indicate that using the Internet as one's source of health information is directly associated with three main factors. First, women, who accounted for close to half of our sample, use the Internet for health information more often than men and, more specifically, they use it for preventive purposes. Second, young adults tend to consult the Internet more than older adults, and they use the information mostly for preventive purposes. Finally, using the Internet as one's source of information is strongly associated with an individual's perceived ability to understand, interpret and use the medical information that is available online. In addition, this study is one of the first to have explored the influence of Internet use on multiple forms of empowerment. This development appears to have significant potential, particularly in terms of the general public's decision-making autonomy.

Given the small size of our sample and the inherent limits of transversal surveys, we believe that caution should be exercised when interpreting these results. In addition, we collected the opinions and points of view of the residents of a single region that has its own characteristics. Future research should therefore see if these results can be validated in a larger sample of Internet users in other parts of the world.

APPENDIX: QUESTIONNAIRE ITEMS

Item	Description
Professional_logic_1	I always follow the instructions of the physician and the other health professionals that I consult.
Professional_logic_2	I make my own decisions about my health, without necessarily ignoring instructions from the physician that I consult. (removed item)
Professional_logic_3	I always apply instructions from the physician or the other health professionals that I consult.
Professional_logic_4	I have a good understanding of my medical condition because of the knowledge and advice I receive from my physician and the other health professionals I consult.
Professional_logic_5	I play an active role in my relationships with the physician and the other health professionals that I consult. (removed item)
Consumerist_logic_1	The sources of information that I consult (magazines, the Internet, health professionals, etc.) give me a better understanding of my medical condition through my own ability to analyze what is relevant or not.
Consumerist_logic_2	The sources of information that I consult (magazines, the Internet, health professionals, etc.) help me feel better able to choose on my own which treatments or drugs I feel best meet my needs.
Consumerist_logic_3	I make decisions on my health based on my preferences and means rather than just following instructions from my physician or the other health professionals I consult. (removed item)
Consumerist_logic_4	Generally speaking, I trust my decisions about possible treatments and drugs.
Consumerist_logic_5	I am very well informed about the treatments or drugs recommended to me.
Community_logic_1	I make decisions about my health based on the experience and opinions of people I know (friends, family, colleagues, etc.)
Community_logic_2	The sources of information I consult (magazines, the Internet, health professionals, etc.) are useful when I discuss my health with the people I know (friends, family, colleagues, etc.)
Community_logic_3	Based on the sources of information that I consult (magazines, the Internet, health professionals, etc.), I feel more confident when talking with the people I know (friends, family, colleagues, etc.).
Community_logic_4	I have a very good understanding of my medical condition due to the support groups and focus groups that I belong to.
Community_logic_5	I know a lot about the opinions of people in a state of health similar to my own.
Preventive_use_1	I often consult the Internet to learn how to prevent disease by adopting a healthy lifestyle.
Preventive_use_2	I often consult the Internet to obtain points of view that are different from those in traditional medicine.
Curative_use_1	I often consult the Internet to better understand a health problem or a disease.
Curative_use_2	I often consult the Internet to find a specific solution or treatment for a health problem.
Social_use_1	I often participate in online discussions about health. (removed item)
Social_use_2	I often consult the Internet in order to help a friend or family member who is ill. (removed item)
e-Health_literacy_1	I know how to find useful information about health on the Internet.

Chapter 3.17

A Software Tool for Biomedical Information Extraction (And Beyond)

Burr Settles
University of Wisconsin-Madison, USA

ABSTRACT

ABNER (A Biomedical Named Entity Recognizer) is an open-source software tool for text mining in the molecular biology literature. It processes unstructured biomedical documents in order to discover and annotate mentions of genes, proteins, cell types, and other entities of interest. This task, known as named entity recognition (NER), is an important first step for many larger information management goals in biomedicine, namely extraction of biochemical relationships, document classification, information retrieval, and the like. To accomplish this task, ABNER uses state-of-the-art machine learning models for sequence labeling called conditional random fields (CRFs). The software distribution comes bundled with two models that are pre-trained on standard evaluation corpora. ABNER can run as a stand-alone application with a graphical user interface, or be accessed as a Java API allowing it to be re-trained with new labeled corpora and incorporated into other, higher-level applications. This chapter describes the software and its features, presents an overview of the underlying technology, and provides a discussion of some of the more advanced natural language processing systems for which ABNER has been used as a component. ABNER is open-source and freely available from http://pages.cs.wisc.edu/~bsettles/abner/

DOI: 10.4018/978-1-60566-274-9.ch017

INTRODUCTION

Efforts to organize the wealth of biomedical knowledge in the primary literature have resulted in hundreds of databases and other resources (Bateman, 2008), providing scientists with access to structured biological information. However, with nearly half a million new research articles added to PubMed annually (Soteriades & Falagas, 2005), the sheer volume of publications and complexity of the knowledge to be extracted is beyond the means of most manual database curation efforts. As a result, many of these resources struggle to remain current. Automated *information extraction* (IE), or at least automated assistance for such extraction tasks, seems a natural way to overcome these information management bottlenecks.

Named entity recognition (NER) is a subtask of IE, focused on finding mentions of various *entities* that belong to semantic classes of interest. In the biomedical domain, entities of interest are usually references to genes, proteins, cell types, and the like. Accurate NER systems are an important first step for many larger information management goals, such as automatic extraction of biologically relevant relationships (e.g., protein-protein interactions or sub-cellular location of gene products), biomedical document classification and retrieval, and ultimately the automatic maintenance of biomedical databases.

In order to facilitate and encourage research in the area of biomedical NER, several "bake-off" style competitions have been organized, in particular the NLPBA shared task (Kim et al., 2004) and the BioCreative challenge (Yeh et al., 2005). For these events, several research teams rapidly design, build, and submit results for machine learning systems using benchmark annotated text collections. The challenges showcase a variety of approaches to the problem, and provide a wealth of insights into what sorts of models and features are most effective. However, few of the resulting systems have been made publicly available for researchers working in related areas of natural language processing (NLP) in biomedicine.

I first released ABNER (Settles, 2005) in July 2004 as a demonstrational graphical user interface (GUI) for the system I developed as part of the NLPBA shared task challenge (Settles, 2004). In March 2005, a revised, open-source version of the software was released with some performance improvements and a new Java application programming interface (API). The goal is to encourage others to write custom interfaces to the core NER software, allowing it to be integrated into other, more sophisticated biomedical information management systems. ABNER also supports training new models on corpora labeled for different knowledge domains (e.g., particular organisms, since gene naming conventions vary from species to species).

Figure 1 shows a screenshot of the intuitive GUI when ABNER is run as a stand-alone application. Text can be typed in manually or loaded from a file (top window), and then automatically tagged for multiple entities in real time (bottom window). Each entity type is highlighted with a unique color for easy visual reference, and tagged documents can be saved in a variety of annotated file formats. The application also has options for processing plain text documents on the file system in batch mode offline.

ABNER has built-in functionality for tokenization and sentence segmentation, which are fairly robust to line breaks and biomedical abbreviations (users can choose to bypass these features in favor of their own text preprocessing as well). The bundled ABNER application is implemented in Java and is therefore platform-independent, and has been tested on Linux, Solaris, Mac OS X, and Windows.

The basic ABNER distribution includes two built-in entity-tagging models trained on the NLPBA (Kim et al., 2004) and BioCreative (Yeh et al., 2005) corpora. The first is a modified version of the GENIA corpus (Kim et al., 2003), contain-

ing five entity types labeled for 18,546 training sentences and 3,856 evaluation sentences. The latter corpus contains only one entity type that subsumes both genes and gene products (proteins, RNA, etc.) labeled for 7,500 training sentences and 2,500 evaluation sentences. Evaluation of NER systems is typically done in terms of recall $R = tp/(tp+fn)$, precision $P = tp/(tp+fp)$, and the harmonic mean as a summary statistic, $F_1 = (2 \times R \times P)/(R+P)$, where tp means true positives, fn means false negatives, and fp means false positives. Table 1 presents results for the two built-in models, trained and evaluated on the designated train/evaluation splits for these corpora.

ABNER's accuracy is still roughly state-of-the-art. To my knowledge, only two systems with published results have outperformed ABNER on the NLPBA corpus (Zhou & Su, 2004; Friedrich et al., 2006), and neither is freely available. Comparisons to published results on the BioCreative

Table 1. Evaluation results for ABNER's two built-in tagging models

Corpus	Recall	Precision	F1
NLPBA (all entities)	0.720	0.691	0.705
protein	0.778	0.681	0.726

RNA	0.619	0.613	0.616
cell line	0.582	0.539	0.560
cell type	0.656	0.798	0.720
BioCreative (gene)	0.659	0.745	0.699

corpus are more difficult to interpret, as the figures in Table 1 reflect only perfectly accurate entity predictions (i.e., exact word-boundary matches), and official BioCreative evaluation gives some "partial credit" to incomplete entity extractions (Yeh et al., 2005). When adjusted for this, ABNER is competitive with the leading systems on this corpus as well, and is again the only freely available open-source system among them.

Third-party research also indicates that ABNER is among the most accurate publicly available NER tools for biomedical text. Kabiljo et al. (2007) performed a comparative analysis of three systems: ABNER (using the BioCreative model), GAPSCORE (Chang et al., 2004), and NLProt (Mika & Rost, 2004) on a new benchmark corpus called ProSpecTome, which is a subset of NLPBA re-annotated with more stringent labeling conventions. They found ABNER to be the most accurate on this new corpus by a significant margin. Lam et al. (2006) also conducted an informal comparison of ABNER (using the NLPBA model) to PowerBioNE (Zhou et al., 2004) when deciding which to use as a component in their automated database maintenance system, and found ABNER to be consistently the best. Furthermore, most other systems are only available as web services or platform-specific compiled binaries, whereas ABNER is designed to be portable, flexible, and integrated into third-party biomedical NLP applications.

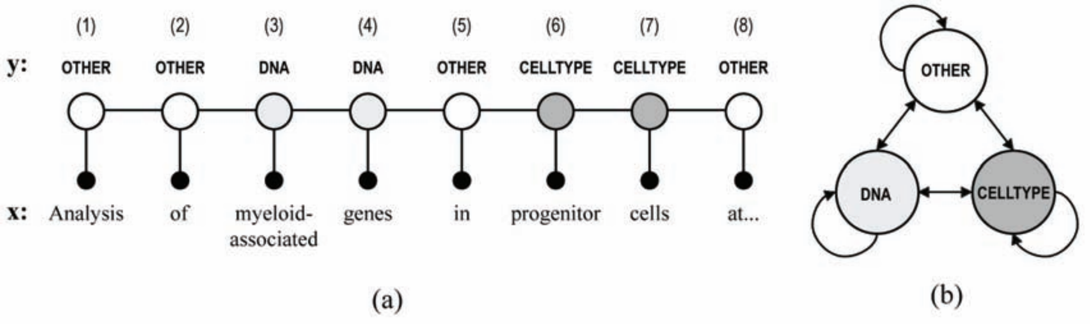
BACKGROUND AND TECHNOLOGY

The NER problem can be thought of as a *sequence-labeling task*: each word is a *token* in a sequence to be assigned a *label* (which corresponds to an entity class of interest). Once upon a time *hidden Markov models* (HMMs), which are statistical finite-state machines (Rabiner, 1989), were the machine learning method of choice for sequence labeling, such as part-of-speech tagging. However, more complex problems like NER tend to require larger, more sophisticated sets of features (e.g., words, prefixes or suffixes, capitalization patterns, neighboring words within a certain window of distance, etc.) which are certainly not independent, and can present difficulties for generative models like HMMs if the dependencies are not modeled explicitly. As a result, some researchers opt to use simple discriminative classifiers (which are more robust to such independence violations) to label each word separately, in lieu of graphical sequence models altogether (Kudoh & Matsumoto, 2000; Kazama et al., 2002).

However, *conditional random fields* (CRFs) have emerged as a sort of "best-of-both-worlds" solution (Lafferty et al., 2001). CRFs are undirected statistical graphical models (a special case of which is a linear chain, corresponding to a statistical finite-state machine), but they are also conditionally trained in a way that overcomes feature independence and other shortcomings of HMMs. After being shown effective for other NLP sequence labeling tasks like part-of-speech tagging (Lafferty et al., 2001), phrase chunking (Sha & Pereira, 2003), and named entity recognition for newswire text (McCallum & Li, 2003), they naturally became a popular candidate for solving the biomedical NER problem as well (Settles, 2004; McDonald & Pereira, 2004; Settles, 2005; Friedrich et al., 2006).

Let $\mathbf{x} = \langle x_1, x_2, \ldots, x_T \rangle$ be a sequence of observed words (i.e., a sentence) of length T, and let $\mathbf{y} = \langle y_1, y_2, \ldots, y_T \rangle$ be a sequence of labels that are assigned to the words in the input sequence $\mathbf{x}$. Figure 2(a) illustrates an example sentence and how it might be labeled. The labels in $\mathbf{y}$ represent the entities of interest (e.g., DNA, cell type, other), which also correspond to states in a statistical finite state machine, such as the one in Figure 2(b). A first-order linear-chain CRF defines the conditional probability of a label sequence $\mathbf{y}$ given an input sequence $\mathbf{x}$ to be:

Figure 2. Example CRF graphs for (a) a labeled input sequence, and (b) the structure of a corresponding finite-state machine.



(a) (b)

$$P(\mathbf{y} \mid \mathbf{x}) = \frac{1}{Z(\mathbf{x})} \exp\left(\sum_{t=1}^{T} \sum_{k=1}^{K} \theta_k f_k(y_{t-1}, y_t, \mathbf{x}_t) \right),$$

where $Z(\mathbf{x})$ is a normalization factor over all possible label sequences, f_k is one of K binary functions describing a features that characterize position t in sequence $\mathbf{x}$, and θ_k is the weight for that feature. For example, f_k might be the feature WORD=*myeloid-associated* and have value 1 at position t=3 in the sequence from Figure 2(a). Other features that are set to 1 for this position might be HASDASH, SUFFIX=*ated*, and NEXTWORD=*genes*. The weight θ_k for each feature should be positive for a feature correlated with the target label, negative for a feature that is anti-correlated, and near zero for a relatively uninformative feature. One can think of CRFs as a sequence-based generalization of maximum entropy (also known in the literature as multinomial logistic regression) classifiers (Nigam et al., 1999). In order to learn these weights properly, we can use gradient ascent to maximize the conditional log likelihood of N labeled sequences in a training set $D = \{\langle \mathbf{x}, \mathbf{y} \rangle_{(1)}, \ldots, \langle \mathbf{x}, \mathbf{y} \rangle_{(N)}\}$:

$$LL(D) = \sum_{n=1}^{N} \log\left(P(\mathbf{y}_{(n)} \mid \mathbf{x}_{(n)}) \right) - \sum_{k=1}^{K} \frac{\theta_k^2}{2\sigma^2},$$

where the second term is simply a Gaussian prior over feature weights to help to prevent over-fitting due to sparsity in D. If the training sequences are fully labeled, the objective function $LL(D)$ is convex and the model is guaranteed to converge to an optimal set of feature weights. New sequences can then be labeled using an inference algorithm such as Viterbi. For more information on CRFs, their typical training procedures, and their relationship with other graphical models, see Sutton & McCallum (2006) for a good introduction.

ABNER uses a first-order CRF with a default feature set comprised of orthographic and contextual features, mostly based on regular expressions, prefixes or suffixes, and neighboring tokens. The full feature set is viewable (and editable) in the ABNER distribution source code. Some research indicates that additional features like part-of-speech tags and lexicon (dictionary) membership can improve accuracy, however ABNER does not have native support for such features at this time. My own research indicates that the gains of such features for ABNER are only slight, and pose several software engineering challenges at the expense of its currently robust, portable, and fast performance.

ABNER is written entirely in Java using graphical window objects from the Swing library. The CRF models are implemented with the MALLET toolkit (http://mallet.cs.umass.edu), which uses a quasi-Newton method called L-BFGS (Nocedal &

Wright, 1999) to learn the optimal feature weights efficiently. ABNER conducts its built-in tokenization using a deterministic finite-state lexical scanner built with JLex (http://www.cs.princeton.edu/~appel/modern/java/JLex/).

BEYOND NAMED ENTITIES

As stated earlier, accurate NER systems are an important first step for many larger information management goals. This section briefly discusses some more recent work by other researchers who are using ABNER as a component in larger biomedical text processing systems. These applications generally fall into three main categories: higher-level information extraction, document categorization and information retrieval, and the automatic maintenance or curation of biological databases.

Higher-Level Information Extraction

NER is a basic subtask of information extraction (IE), focused only on finding *entity* mentions in text. Naturally, the next step in IE is identifying the *relationships* among such entities directly from text. For example, in mining the biomedical literature this can mean extracting protein-protein interactions or identifying the sub-cellular localization of gene products.

Madkour et al. (2007) developed an extraction system for protein-protein interactions that employs ABNER in the protein identification phase. After proteins are annotated, the articles are mined using an unsupervised mutual reinforcement algorithm to rank textual patterns indicating an interaction relationship. They report an F_1 score of 0.55 on a corpus of MEDLINE abstracts, which appears to be near the current state-of-the-art for this formulation of the problem. To facilitate further progress in the area of extracting protein-protein interactions, a few variants of the task were proposed as part of the BioCreative2 challenge, and ABNER was also chosen as an NER component in at least four of the competing approaches (Abi-Haidar et al., 2007; Figueroa & Neumann, 2007; Gonzalez et al., 2007; Huang et al., 2007). Results from this evaluation are somewhat mixed, however, and substantially lower than those reported by Madkour et al.

Bethard et al., (2008) propose another interesting IE task that involves extracting semantic role arguments for protein transport predicates. Consider the following sentence: “IRS-3 expression blocked glucose/IGF-1 induced IRS-2 translocation from the cytosol to the plasma membrane.” They developed a system that attempts to automatically extract relational predicate records like TRANSLOCATION(*IRS-2*, *cytosol*, *plasma membrane*) from such passages of the biomedical literature. The extracted predicate name represents the type of protein transport, and the arguments correspond to the target protein and the sub-cellular source and destination locations of the transport action, respectively. The authors employ ABNER’s protein predictions as part of the predicate extraction system, resulting in an F_1 score of 0.792 (compared to 0.841 if protein mentions are already perfectly known).

Document Categorization and Information Retrieval

Most information retrieval (IR) systems aim to retrieve documents that are relevant to the user’s particular information needs. Recently, however, interest has grown in developing systems that combine IR (particularly in the biomedical domain) with text categorization and information extraction, attempting to answer user questions or put them in context, while providing supplementary information and linking to the original sources (Hersh et al., 2007).

Several researchers who work on these more sophisticated IR systems have found that utilizing named entity predictions can improve their accuracy. For example, Tari et al. (2007) employ

ABNER to process query topics in a Q&A-style document retrieval system. The extracted entities are then matched against synonym lists in gene databases as part of a query-expansion step to improve recall. Another task, part of the Text Retrieval Conference (TREC) 2005 genomics track, involves filtering a set of documents for those which are appropriate for manual curation in four different biological databases. Several systems developed to solve this task (Yang et al., 2006; Yu et al., 2006; Li et al., 2007) use ABNER's entity predictions to enhance the feature set in this classification problem. Similarly, ABNER is used effectively by IR systems designed to filter passages of text for mentions of protein-protein interactions (Abi-Haidar et al., 2007; Figueroa & Neumann, 2007; Huang et al., 2007).

Automatic Maintenance of Biological Databases

Biological researchers often rely on specialist databases to maintain an in-depth repository of domain knowledge. For example, a database may only catalog information on a single, organism-specific genome, or functionally classified toxins and other chemicals. However, as indicated in the introduction, the rate of growth for new information to be mined from the primary literature or filtered from larger, general-purpose databases each year far eclipses the ability of curators to keep things up-to-date manually, even with a focused and specialized scope of interest.

Lam et al. (2006) present a novel system to address some of these issues, combining ABNER with a protein sequence motif extractor to automatically update special-interest databases. Entities are extracted from the textual fields of target database records (e.g., titles and abstracts or reference articles), and motifs are likewise extracted from the protein sequence fields (i.e., the actual amino acid sequences). The entity keywords and sequence motifs are then combined to generate queries for more general-purpose databases in the public domain, such as GenBank or SwissProt. The idea is to filter the records from these broader interest databases and automatically extract the records that are relevant to the special-interest resources at hand. Their experiments in automatically maintaining a snake venom database achieve an F_1 score of 0.80 using both ABNER keywords and sequence motifs (as opposed to 0.045 and 0.41, respectively, using either one in isolation).

Cakmak & Ozsoyoglu (2007) present another system that uses ABNER to extract gene mentions from the literature, and infer new function annotations from the Gene Ontology (GO Consortium, 2004) that may have been overlooked. The GO is a standardized vocabulary for molecular function of gene products used in most model organism genome databases. The resulting GO annotations can be appended to the extracted genes' database records automatically. They report F_1 scores of 0.66, 0.66, and 0.64 for the Biological Process, Molecular Function, and Cellular Component sub-ontologies, respectively.

CONCLUSION

ABNER is an efficient, accurate, cross-platform software tool for finding named entities in biomedical text. It has been demonstrated to perform at or near the state-of-the-art on multiple benchmark corpora, and remains one of the few high-accuracy NER systems available freely and under an open-source license at the time of this writing. It also ships with its own API, allowing users to re-train the underlying machine learning system for specific tasks, or to integrate it into larger, more sophisticated information management systems. So far, ABNER has been used as a vital component in several such systems, including applications for higher-level information extraction, document classification and retrieval, and the automatic maintenance of biological databases.

ACKNOWLEDGMENT

I would like to thank Mark Craven for his guidance and support of this project. Research related to the software was supported by NLM grant 5T15LM007359 and NIH grant R01-LM07050.

Section IV
Utilization and Application

This section introduces and discusses the utilization and application of health information systems. These particular selections highlight, among other topics, challenges in electronic medical record system adoption, wireless technology adoption in healthcare, and current practices in healthcare systems. Contributions included in this section provide excellent coverage of today's online environment and insight into how health information systems impact the fabric of our present-day global village.

Chapter 4.1

Challenges with Adoption of Electronic Medical Record Systems

Jigish Zaveri
Morgan State University, USA

INTRODUCTION

Among health care information systems, past research has credited Electronic Medical Records (EMR) systems with offering the greatest potential for improving quality within health care environments. Benefits range from reducing errors to cutting overall health care costs. For instance, the utility of an EMR system will allow physicians' enterprise wide access to a patient's entire medical chart, monitor patients' care for possible drug interaction, proactively prompt doctor(s) with recommended treatment, provide clinical decision support, simplify record keeping, e-prescription, documented referrals, and reminders to patients and health care providers.

Despite these benefits and a defined movement to integrate EMR systems in medical outfits, adoption of EMR systems by health care professionals has been very slow (Audet, Doty, Peugh, Shamasdin, Zapert, & Schoenbaum, 2004; Burt, Hing, & Woodwell, 2005; Miller & Sim, 2004; Simon & Simon, 2006). According to the National Ambulatory Medical Care Survey Report (2005) only 25% of office-based physicians are recorded as partial or fully using EMR systems. Nevertheless, interest to adopt EMR systems continues to be significant (Miller & Sim, 2004).

What accounts for the slow adoption of EMR systems? To answer, we must identify and address challenges associated with this process. A review of the recent practitioners, academic health informatics literature, and provisions of HIPPA Act of 1996 (Adler & Edsall, 2005; Audet et al., 2004;

DOI: 10.4018/978-1-59904-889-5.ch027

Baharozian, 2005; Edsall & Adler, 2005; Hough, Chen, & Lin, 2005; Lenhart, Loomis, Criswell, & Meggs, 2000; Miller & Sim, 2004; Retchin, Wenzel, &, 1999; Swartz, 2005; Valdes, Kibbe, Tolleson, Kunik, & Petersen, 2004) cite several barriers faced with the adoption process. Further analysis also suggests that the promises of successful EMR deployment will not be fully realized unless concerns linked to the EMR implementation process are alleviated. We investigated EMR adoption by conducting open ended interviews with EMR managers, vendors, and physicians to explore their experiences with their EMR implementation.

In this article, we present the results from our study. The next section highlights challenges associated with EMR adoption and use. We conclude by suggesting solutions geared towards lessening these challenges thereby clearing the path for successful EMR adoption and use.

CHALLENGES

Our meta-analysis identified several barriers experienced by professionals regarding EMR adoption and use. These challenges include: cost, difficulty in calculating return on investment, lack of education, physicians' and staff concerns, technology related concerns, inadequate complementary changes to organizational processes, lack of IT support, and lack of incentives.

Costs

EMR systems are costly. Many health care institutions cite cost as a primary prohibitive factor with adoption of EMR. There are high up-front installation costs and recurring expenses for operation and maintenance. During our interviews, the interviewees clarified that up-front costs range from $15,000-$60,000 per physician. Initial set-up costs include purchase cost of hardware, software, network infrastructure, trainin, and workflow reorganization. Operation and maintenance costs include data conversion, ongoing training, hardware and software, and specialized IT support staff.

With such exorbitant costs and uncertainty regarding return on investments, we can assume that small companies may not find adoption of EMR systems feasible thus prohibiting implementation (Audet et al., 2004; Miller & Sim, 2004; Retchin et al., 1999; Winn, 2002).

Additional expenses are incurred during the EMR transition period due to physicians attending to fewer patients translating to decreased revenue.

Difficulty in Calculating Return on Investment

One of the major concerns with new projects for upper level management is financial payoff. Is this worth the investment? As mentioned earlier, the level of initial investment is high. There is an uncertainty over the size of financial benefits that may accrue over time (Audet et al., 2004; Miller & Sim, 2004).

Benefits obtained from EMR can be complex to measure with long pay back period. Most health care institutions lack the financial and operational analysis tools for an "uninformed" EMR buyer to make a competent decision on behalf of their organization.

Lack of Education

Most health care institutions lack knowledgeable personnel capable of evaluating and managing implementation EMR system for their organizations. EMR systems are complex with several modules and requiring special expertise.

During the implementation phase there is a need for a champion. The literature states projects without a champion are most likely to fail. A champion is one that promotes the benefits of EMR within the organization. He or she is a person capable of aligning the systems' functions with the needs of the health care organization. A champion can properly assist in defining the scope, allocating resources and preparing the organization for the transition that will come with EMR implementation.

Concerns of Physicians and Staff

The concerns of physicians and staff to use and manage EMR systems remain another major challenge. Physicians are very reluctant to adopt and use EMR systems. Physicians view their role primarily about patients, with automation secondary. Many fear the use of EMR systems will take them away from their primary duties.

Physicians and nurses also fear that managers could measure, compare, and evaluate the amount of time each professional spends on each task. Physicians and other medical staff are apprehensive that they may be reprimanded for "slacking off" or deviating from predetermined practice sequence. These concerns act as an impediment for adoption and use of EMR systems (Bar-Lev & Harrison, 2006). During our interviews, however, this factor did not emerge as one of the areas of concerns.

Physicians and staff are also reluctant to use EMR because they need to take time off their schedule for training on coding, documentation, and e-prescription capabilities of EMR systems (Berkowitz, 1997; Lenhart et al., 2000). Training requirements erode the initial enthusiasm for use among some users. During our interviews, a few physicians expressed that they spent a significant amount of time meeting the training requirements.

Physicians are also resentful with receiving clinical recommendations from EMR. They believe that after years of medical training, accepting recommendations from a computer information system is demeaning and a threat to their independent thinking.

Technology Related Concerns

There are several concerns related to EMR technology.

Technophobia

There are people within the health care clinics that are intimidated by technology. They simply panic when interacting with technology. Fears range from care providers perceiving that their jobs are at stake (EMR will replace or outperform them) to "what if I hit an incorrect key stoke and erase critical data from the system?" Such fears have crippling effects on EMR implementation.

Other Technology Concerns

Interoperability is another major concern. Interoperability refers to the ability of EMR system to facilitate exchange of patients' medical records across medical institutions such as hospitals, polyclinics, independent testing labs, and medical centers. This factor is important because there are more than 264 different software programs currently used in the U.S. and most of these programs are not compatible with each other (Retchin et al., 1999; Valdes et al., 2004). Poor interoperability results in poor electronic data exchange across institutions. Support staff and physicians get frustrated as they are forced to spend more time to manually enter data from external systems.

System difficulty is another technology related concern. This issue pertains to the difficulty associated with conversion of old paper based documents into electronic medical records (Berkowitz, 1997; Retchin et al., 1999). This factor need to be considered because many documents involve extensive handwritten content, some of which may have been generated by different health care professionals over the life span of the patient and some of the content is illegible for conversion. Moreover, the digital scanning process involved in conversion of these physical records to electronic documents is an expensive, time-consuming process, which must be done to exacting standards to ensure exact capture of the content.

Usability remains as a major concern. There are multiple screens, options, and navigational aids in the EMR system. Problems with EMR usability, especially documenting progress notes cause physicians to spend extra time learning effective ways to use the EMR (Audet et al., 2004; Miller & Sim, 2004). This issue is compounded by the fact that smaller medical institutions often lack financial resources to train physicians on usability.

Health care information is sensitive. There are concerns pertaining to data security and privacy (Baharozian, 2005; Rind & Safran, 1993). HIPPA Act (1996) mandates that all health care providers adhere to national standards while conducting electronic exchange of health data and emphasis should be laid on the security and privacy of health data. Even though it is recognized that EMR systems are better than paper based systems in terms of data security and privacy, these concerns still persist (Baharozian, 2005; Hsieh & Lin, 2006). There is a persistent fear that hackers can destroy sensitive patients' records.

Inadequate IT Support

With the implementation of any major information system as EMR, there is a need for IT support. Factors range from hardware, software, or network ongoing issues to training. EMR is also considered a reengineered process. Most professionals found in health care environments are medical professions with limited technology expertise. Many care providers express being more at ease using the system with IT support close by.

Inadequate Complementary Changes to Organizational Processes

EMR hardware and software cannot simply be used as "out of box" to reap superior business value. As Wade and Hulland (2004) point out, managers should effectively use outside-in and spanning resources such as IT management practices, IT change management, business systems thinking together with inside-out IT resources such as basic IT infrastructure and IT technical manpower. This simply means that information technology innovations and organizational process changes in tandem. Complementary changes needs to be done to the hospital processes such as patient registration, diagnosis, medical/surgical process, prescription generation and billing, and so forth. These complementary changes exact a great deal of time from physicians, nurses, front-office staff, and hospital managers. Physicians have to redesign their workflows (i.e., how they work in the exam room). Managers and support staff have to redesign office workflows. Practitioners' literature (Miller & Sim, 2004) point out that office-based physicians and solo physicians do not spend enough time in redesigning workflows. It is well known that hospitals that install sophisticated EMR systems before they have done the necessary organizational process changes are not going reap benefits from EMR investments. In our interviews, EMR managers agreed that extensive changes are needed in the management of work flow while trying to implement EMR systems.

Lack of Incentives

It is agreed upon that EMR systems are expensive and most medical professionals require extensive training to reap full benefits. The evidence from the literature suggests that given a choice many physicians will not use EMR systems. They view use of this system as time consuming and distracting from their primary duties. Without incentives by their institutions or government many health care professionals will not implement EMR systems.

SOLUTIONS

There are no simple anecdotes to overcome the challenges referenced above. We therefore propose a multifaceted solution. To expedite the process of EMR implementation, barriers experienced by health care professionals must be addressed at the individual, organization and governmental levels. On one hand we have risks feared by health care professionals and institutions. On the other hand we have a lack of incentives to entice businesses to adopt EMR.

We believe that interventions at the governmental and institutional levels can play a role in stimulating the adoption process. Each intervention increases the attractiveness of EMR use by hospitals and medical institutions.

Governmental Level Interventions

Certain interventions could be undertaken at the governmental level in order to spur the EMR adoption and use.

a. Federal and state governments could provide financial incentives, subsidies, and tax breaks to hospitals and medical institutions that adopt and use EMR systems. As we mentioned before, lack of financial resources is one of the major challenges faced by medical institutions and hospitals. This scheme of providing financial incentives would promote medical institutions and hospitals to invest and effectively use EMR systems. Audet et al. (2004) report that in European countries such as the UK and Sweden, physicians who invest in EMR systems receive government subsidies, which has spurred adoption of EMR systems. Such policies could be adopted by the U.S. federal government also. This scheme would also benefit the patients as EMR systems improve the overall efficiency of health care service providers.

b. As we mentioned before, system interoperability is one of the major technology related concerns. In order to address this concern, the U.S. Department of Health and Human Services could develop a process to harmonize EMR system applications and create industry-wide standards for operation and maintenance of EMR systems and exchange of health data. Vendors who sell EMR systems would be forced to come up with software applications that are compatible with each other. This would promote better standardization of the product, interoperability of EMR systems and information sharing of health records across medical institutions, hospitals and testing centers. This scheme would in turn promote usage of EMR systems. Miller and Sim (2004) report that the government has initiated some data exchange standards such as HL7, LOINC, and provisions of HIPPA Act of 1996 also mandate use of data exchange standards. We hope that more organizations use these data exchange standards so as to improve system interoperability.

Institutional Level Interventions

Hospitals and medical institutions could undertake the following interventions in order to promote adoption and effective usage of EMR systems by physicians and other staff.

a. **Provide performance incentives to physicians and other staff:** Hospitals and medical institutions could consider providing performance improvement based financial incentives to physicians and other staff. As mentioned before, many hospitals and clinics have reported that EMR systems have improved the throughput for diagnosis, treatment, and consultation, reduced the time taken for delivery of services, improved the speed and accuracy of medical insurance claims registration, reduced the number of medical coding and transcription errors, and improved the data integrity of patient's medical records and the institution's overall responsiveness to patient's needs. Hospitals could come up with a set of process based metrics (such as diagnosis throughput, number of medical errors, number of correct insurance claims registered, etc.) and evaluate the performance improvements associated with the use of EMR systems. Based on the extent of performance improvements achieved, physicians and other staff could be provided extra financial incentives. This would motivate the physicians and other staff to use EMR systems.

b. **Consider temporal aspect of technology payoff:** As IT business value studies (Brynjolfsson & Hitt, 2000; Devaraj & Kohli, 2000, 2003) suggest, top management of hospitals and medical institutions should consider the temporal aspect of technology payoff; that is, payoffs may not be realized instantaneously, but only after certain periods of time, which is usually 2-3 years. Hence it becomes important for top management to consider the lag effect when they conduct cost-benefit analysis of EMR systems.

c. **Top management support for use of advanced capabilities of EMR systems:** As mentioned before, the capability of EMR to document progress notes and facilitate audit trails create fear in the minds of physicians and nurses that managers could measure, compare and evaluate the amount of time each professional spent on each task. Physicians and other medical staff also fear that they might be reprimanded for "slacking off" or deviating from predetermined practice sequence. These fears act as an impediment for usage of EMR systems. Top management should lend its support to physicians and work to alleviate these fears. Top management should develop strong channels of communication and co-operatively work with physicians and other staff members. Also, physicians should be made to understand that coding, documentation, and audit trail capabilities should be viewed as positive features as they provide the required checks and balances in the health care delivery system.

d. **Increase thrust on training:** In order to work around technology usability issue, hospital management should place increased emphasis on training of system users (i.e., physicians and other office staff). Users should be given time off their regular work schedules so that they can be trained to use EMR systems effectively.

e. **Emphasize complementary process changes:** Managers and physicians should stop viewing EMR as a "mere technology." To derive value out of EMR, it has to be viewed as "Joint EMR- organization" endeavor. It is important to recognize that information technologies such as EMR interact with key organizational processes in order to bring about business value. Swanson (1994) calls such a joint endeavor as Type III innovation (Swanson, 1994). Complementary changes needs to be done to hospital processes such as patient registration, diagnosis, medical/surgical process, prescription generation and billing, and so forth.

f. **IT support:** Technical support is critical when implementing complex computer information systems. Problems can arise from hardware, software, network or user initiated failure. The provision of adequate IT support is essential to achieving maximum results of EMR with minimal downtime. Medical personnel also report feeling more comfortable transitioning to EMR when IT support is available. Health care institutions should never underestimate the value of IT support. During IT planning, institutions should consider acquiring IT support from

EMR vendors and independent consultants, as well as establishing an in house support center.

CONCLUSION

Implementation of EMR systems can be a daunting task. Many health care advocates as well as the government are promoting EMR to become a standard in health care. The promised benefits of EMR are enticing. This process is also accelerated by changes in health care and reporting demands from the influx of managed care plans. We reviewed the existing literature as well as conducted our own study to unearth key barriers that affect EMR adoption. In this article, we highlighted these challenges and proposed solutions.

We urge researchers to continue this line of research. Several interesting topics still need to be explored. Is cost really the main inhibitor of EMR adoption? What organizational factors affect the success or failure of EMR adoption? Initial evidence suggests that the size of a practice matters with EMR; more work is needed to confirm this. What demographics data affect EMR adoption; for instance, does age or medical school education of physicians affect EMR adoption/use. The literature reports that many of the benefits of EMR will be realized later. As such, this gives us a need to conduct longitudinal studies at health care organizations.

Additionally, researchers should seek to evaluate EMR adoption research with the theoretical lenses of transaction cost economics, resource based view, social network theory, digital options theory, diffusion of innovation, and other grounded IT adoption theories.

KEY TERMS

Electronic Medical Records System: An interorganizational information system that captures the essential components of a patient's medical encounter with the medical provider, including storage and retrieval of subjective, objective patient information, assessment, and plans for patient care (Lenhart et al., 2000).

EMR Challenges: Any factor that would impede the adoption and use of EMR.

Health Care Information System: An arrangement of information technology, people, data, and processes that interact to gather, process, store, and disseminate health care information (adapted from Whitten & Bentley, 2007).

IS Adoption: The deployment of information systems within an organization.

ABSTRACT

This chapter introduces a multi-level, multi-dimensional meta-framework for successful implementations of EHR in healthcare organizations. Existing implementation frameworks do not explain many features experienced and reported by implementers and have not helped to make health information technology implementation any more successful. To close this gap, we have developed an EHR implementation framework that integrates multiple conceptual frameworks in an overarching, yet pragmatic meta-framework to explain factors which lead to successful EHR implementation, in order to provide more quantitative insight into EHR implementations. Our meta-framework captures the dynamic nature of an EHR implementation through their function, interactivity with other factors and phases, and iterative nature.

DOI: 10.4018/978-1-59904-792-8.ch007

INTRODUCTION: OVERVIEW OF THE ISSUE AND THE CHALLENGES

Advances in healthcare technology and the explosion of new therapies have outpaced the ability of healthcare systems, organizations, and professionals to cope. Healthcare costs have spiraled. Medical errors cause thousands of deaths each year and under-treatment is rampant (Institute of Medicine, 2001). Innovations take over 17 years to get from bench to bedside. Although information technology, such as electronic medical records (EMR), electronic health records (EHR) and computerized physician order entry (CPOE) systems, continue to evolve as technologies for use in clinical practice and show great promise, they are fraught with high implementation failure rates and sometimes cause even greater harm than previous paper systems (Koppel, Metlay, Cohen et al., 2005).

Typically, most of the investment of system implementation is born up-front both in terms of finances, and in time and energy. With increasing fiscal restraint and a greater demand by all stakeholders for demonstrated value, it is important to ensure that health information technology implementations are successful, yet, in spite of over three decades of experience with EHR implementation, the penetration of the EHR is still less than 20% in the United States and in Canada (Duke Clinical Research Institute, 2005). The failure rates of EHR and CPOE implementations are also consistently high at close to 50% (Centre for Health Policy and Research, 2006). As experience with implementations of technology in medical practice increases, new knowledge is gained on how to make those implementations more successful. The acceleration of EHR adoption and increasing success may depend in part on better understanding of the factors that influence the success and failure of EHR implementations (Studer, 2005). The existing empirical literature is beginning to reflect this knowledge in a series of case studies, limited randomized controlled trials, review articles and numerous qualitative studies exploring various factors and frameworks aimed at explaining how to best implement health record and information systems to achieve a successful outcome (Ash et al., 2003; Berg, 2001; Collins, 1998; Curtis et al., 1995; Golden & Martin, 2004; Rogers, 1995).

Existing implementation frameworks do not explain many features experienced and reported by users and have not helped to make health information technology implementation any more successful. To close this gap, we have developed an EHR implementation meta-framework that integrates the experiences of actual implementations and underpins those experiences using multiple conceptual frameworks from a variety of theoretical perspectives from the information technology (IT), business and EHR implementation literatures. This meta-framework is an overarching, yet pragmatic framework to explain the factors which are important in EHR implementations and how they interact in a dynamic and mutually reshaping manner which leads to successful EHR implementation.

BRIEF LITERATURE REVIEW

As experience with implementations of technology in medical practice increases, a cumulative literature of empirical support, in the form of case studies, limited randomized controlled trials, and numerous qualitative studies, has begun to emerge (Ash, 2003; Berg, 2001; Collins, 1998). The high failure rates seen in information systems implementation calls for a better understanding of the critical success factors necessary for EHR implementation (Somers et al., 2000). Listing ‘success factors’ has been the most popular approach in the literature for describing implementation approaches (Chiang & Starren, 2002, Chin, 2004; Saleem et al., 2005; Smith, 2003; Tape & Campbell, 2003; Weir et al., 1995), but has not been fully explanatory and predictive of success or failure (Kukafka et al., 2003; Studer, 2005). The factor approach however is too static to account for the evolving nature of EHR implementation experienced by implementers. Development of a more comprehensive framework which takes into account the dynamic, iterative and interactive aspects of EHR implementations is necessary to provide a sounder theoretical basis to underpin practical EHR implementations. Kukafka et al.

(2003) confirm in their systematic review of the healthcare IT implementation literature that the integrative impact of multiple factors on implementations and indeed the development of multi-dimensional interventions is lacking (Kukafka et al., 2003). Several different factors and frameworks have been put forward in the literature for explaining how to best implement the EHR to achieve a successful outcome and to improve EHR diffusion and uptake. These include Rogers' diffusion of innovations model (Rogers, 1995), Collins' risk mitigation model (Collins, 1998) and Ash et al's success factor matrix model (Ash et al., 2003). More recently, Berg has described the socio-technical model (Berg, 2001) and Heeks describes a 'design-reality' gap model (Heeks, 2006). The technology acceptance model (TAM) of Davis and Wilder (1998) provides understanding of human behavior relative to potential technology uptake. However, most models explain only a small component of the complex interplay of factors that are inherent in an EHR implementation. Only Ash et al. (2003) take a comprehensive view of IT implementations, but they do not explain how the various factors interact nor do they underpin their framework with a theoretical base.

The success of information systems implementation and utilization depends on the integration of the information technology (IT) into an often complex organizational setting (Golden & Martin, 2004). In this context, EHR implementation should be understood in a much more complex framework (Curtis et al., 1995). Without addressing the full range of factors in an implementation framework, EHR implementers run the risk of being ineffective because they fail to recognize the interdependencies between individual, organizational and technological factors (Kukafka et al., 2003). There are several features of EHR implementations that require frameworks from organization behavior and IT literature to fully explain what implementers observe and experience during an implementation. Golden's systems theory approach using his Strategic Star Model (Golden & Martin, 2004) provides a framework for organizational change which is rooted in the organizational behavior literature. The people-capability maturity model (P-CMM), which utilizes the people, process, and technology model (Curtis et al., 1995), is rooted in the IT literature. Kotter's model of change management which addresses change agent issues, change leadership, and change management is rooted in the business literature (Kotter, 1995).

DEVELOPMENT OF AN INTEGRATED BEST PRACTICES EHR IMPLEMENTATION FRAMEWORK

We integrated multiple conceptual frameworks from the EHR implementation, information technology, business and organizational behavior literatures in the process of developing our EHR implementation meta-framework. The EHR implementation meta-framework was developed through an iterative process of reading primary descriptions of implementations, identifying implementation-relevant factors and iteratively mapping those factors to the various conceptual frameworks we identified earlier. In this manner, we identified and filled gaps in the existing EHR implementation models and used the additional models to label new issues arising from the EHR implementation literature to create our meta-framework. Finally, we developed operational definitions for the factors in our implementation framework. This multi-theoretical, meta-framework for EHR implementation was recently presented and published in a conference proceeding (Keshavjee et al., 2006).

We applied our EHR implementation meta-framework retrospectively to 47 articles, which were primary descriptions of the experiences of EHR implementers obtained through a systematic search of the literature (Keshavjee et al., 2006). Each article was reviewed independently by two authors for whether a factor existed, whether it was correctly implemented and whether that factor had an impact, positive or negative, on the final outcome. Each author also provided a global outcome score for the article. Inter-rater reliability of the factors within the framework and use of the framework to analyze actual implementations will be reported elsewhere. All scores were resolved through consensus and the final scores were analyzed using logistic regression. Odds-ratios reported in this chapter are from this logistic regression analysis. Greater explanation of the methodology will be reported elsewhere and is out of the scope of the current article. This chapter takes a more pragmatic approach and presents a more nuanced discussion on the human and social aspects of EHR implementations.

INTEGRATED FRAMEWORK FOR EHR AND INFORMATION SYSTEMS

Figure 1 illustrates the meta-framework that integrates the theoretical frameworks and factors and is intended to guide multi-level EHR implementations. Key to this framework is its comprehensive and integrative nature for including various thematic threads such as people, process, and technology-related factors. In addition, our framework describes the implementation process as the journey of an EHR implementation through the healthcare system over time with respect to strategic and operational levels. The meta-framework describes three phases over which EMR implementations occur: pre-implementation, implementation and post-implementation phases. Each phase has its specific conceptual 'tasks' or sets of activities that need to be done and 'deliverables' or outcomes that are expected before it can move on to the next phase.

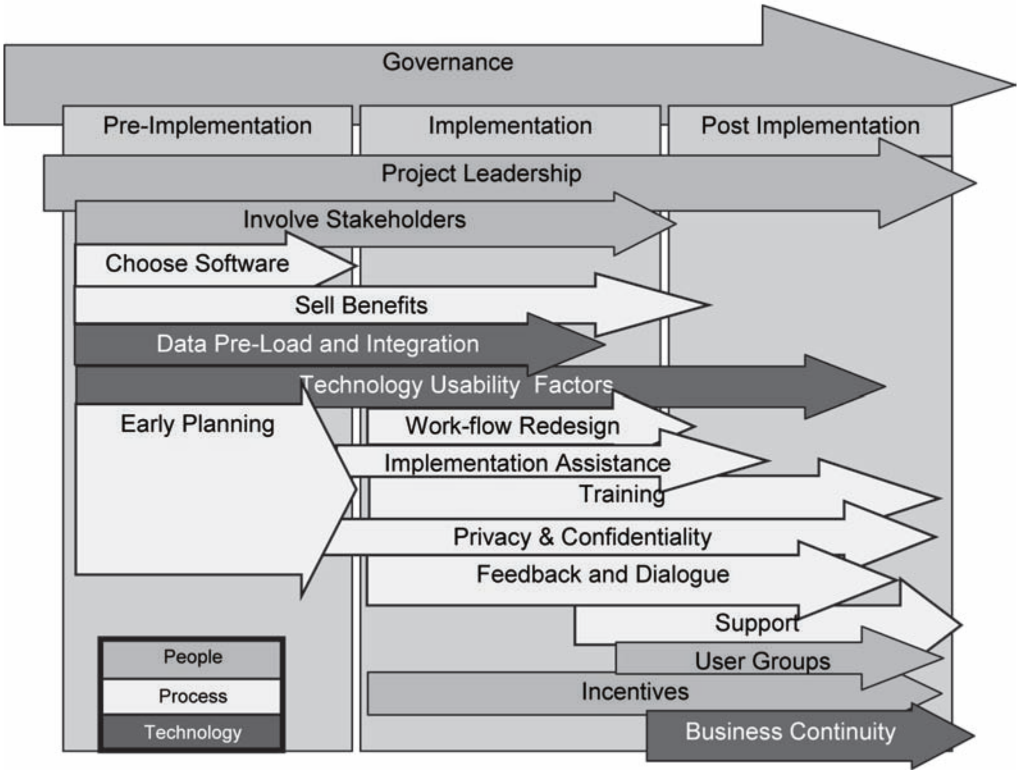
People-Process-Technology

An implementation of a new information systems results in a complex set of interacting forces (Clegg et al., 1997). People and tasks in an organization undergo significant change, learning, adaptation and growth in response to the introduction of information technology (IT). The changes are often drastic and cause intra-organizational tensions (Kuruppuarachchi et al., 2002). For the success of the healthcare delivery institution, an integrated approach to organizational and technical change must be adapted. Our literature review has established that there are many factors influential to understanding the successful EHR implementation in an effective healthcare delivery organization. For these reasons, we have concluded that human factors as well as technology factors need to be taken into consideration. The conceptual bridge between human and technology sides, "process," also has an important contribution. It is the process components of an implementation that allow the people and technology factors to mutually influence and shape each other—the end-users changing and adapting as they learn about the technology and how it will impact their work and the technology changing as vendors and developers better understand the goals and needs of end-users. People, process, and technological issues have to be seen as inextricably linked as a triad for successful change to take place. The people-process-technology triad in each phase has its important tasks which, correctly implemented, lead to appropriate deliverables—both in terms of technology being ready to be implemented and in terms of readiness of people to move on to the next phase.

People

People are one of the most important elements of healthcare delivery systems (Ash et al., 2003). Workforce knowledge and skills are related concepts in explaining the effectiveness of EHR implementation. Human resources of the healthcare delivery organizations include decision makers, such as executives or managers; end users, such as physicians or nurses; and information technology

Figure 1. Integrated meta framework



specialists, such as systems or software related subordinates. Additionally, project leaders have a crucial role during the implementation efforts. We identify four groups of important people in an EHR implementation: (a) senior management, (b) project managers and project champions, (c) end users, (d) information technology specialists and/or vendors.

a. **Senior management:** Initiating an EHR implementation effort is a strategic decision for most organizations. It requires significant investment of organizational resources and energy and it commits the organization to a particular direction. Leadership, commitment, and participation of senior management are prerequisites for EHR implementations (Davis & Wilder, 1998; Laughlin, 1999; Oden et al., 1993; Sherrard, 1998). Senior management is responsible for analyzing and rethinking existing business directions and deciding on future directions for the organization. They also have to weigh integration of a new information technology system against other organization priorities and need to have a keen understanding of the benefits and risks of EHR in terms of operational costs, human resource capabilities and retraining and return on investment (Krupp, 1998; Umble et al., 2003).

b. **Project managers and project champions:** Successful information systems implementation requires skilled and experienced project management (Rosario, 2000). This includes a clear definition of objectives which are congruent with the strategic direction and vision of the organization, a work plan that tracks utilization of resources, continuous monitoring of project progress and management of risks (Bingi et al., 1999; Buckhout et al., 1999; Sumner, 1999). Initially, the scope of the project must be framed accurately, since the project will affect overall business processes (Holland et al., 1999; Rosario, 2000; Umble et al., 2003). Project leadership encompasses two distinct roles: that of a project manager who has skills and experience in managing complex project implementations (Collins, 1998) and that of a project champion who has organizational credibility with clinicians (Ash et al., 2003; Chiang & Starren, 2002; Chin, 2004). Project leaders are responsible for all these planning and managing issues and play key role in successful management of the project. They bridge the strategic needs of senior management and the operational and tactical needs of end users by matching activities to strategic goals, creating an agreeable working climate, solving conflicts, coordinating and enhancing internal communication, managing risk and coordinating users and training of human resource of the organization.

c. **End users:** End-users have a crucial role in EHR system development, specifically in identifying and clearly articulating their needs and requirements and participating actively in designing and implementing new systems (Clegg et al., 1997). Although end-users are very important in implementation, they are rarely influential in designing new systems. End-user participation is usually limited in influencing the design of the technology and their participation is usually poorly managed. End-users need to have a much greater voice in implementations for them to achieve greater success (Clegg et al., 1997). In many cases, system developers are still seen as the `owners' of new technologies, where in reality, end-users are the real customers—those who will actually use the systems. The reason for this is believed to be technical orientation of system developers and the widespread failure to address human and organizational factors when designing technology (Clegg et al., 1997; Kuruppuarachchi et al., 2002).

d. **Information technology specialists and/or vendors:** Assistance to clinicians or primary users by detecting, solving and following up on problems that arise during implementation is essential for the success of the EMR experience. Continuous improvements and/or modifications of the system are important to achieve the expected outcomes. Changes may need to be made to applications for such components as basic configurations and workflows, custom templates, forms and shortcuts (Miller & Sim, 2004), to hardware and network components that are not functioning properly or to network architectures. In many cases, implementations have failed simply because of hardware problems that plagued implementers who had not planned for them; a simple recurring hardware problem that is not solved quickly can create havoc in a production environment and cause healthcare providers to quickly lose confidence in the technology. Vendors and technical support play a key role to assist in implementation. The assistance team, both vendor and technical support, needs to provide rapid and efficient service, or clinical users will stop calling and find some other way to access and record data (Keshavjee, et al. 2001). Implementation assistance should be available on-site initially (Aydin & Forsythe, 1997; Smith, 2003; Tonnesen, et al., 1999) and should be easily accessed throughout the implementation phase. Technical support also has a "bridger" role between end users and vendor (Chin, 2004).

Process

Organizational determinants such as complexity or connectedness to other organizations have a direct impact on the outcome of the implementation. The structure of the organization and existing operational processes also impact outcomes. If poorly handled, they can create significant conflict within the organization. Organizational complexity, which may be regarded as a basis for conflict, is related to the technology used within the organization (Killing, 1988). Healthcare is growing increasingly complex (Bates & Atul, 2003) and complex tasks can be a hindrance to the quality of healthcare delivery outputs.

In our meta-model, process is the arena and mechanism through which people engage with technology and through which each shapes the other along a journey toward a successful transformation of the organization. This is much clearer today than it has been in the past (Aarts & Berg, 2004).

Technology

Enormous improvements have been made in recent years in healthcare delivery technology. Although technological change has been very beneficial in various ways, it also causes many new problems that need to be addressed. These include redistribution of power, new types of errors and requirements for new skills and competencies and new scopes of practice; many of these are human resource, policy and regulatory issues which create friction within and outside the organization and manifest as resistance to change (Ash et al., 2006). In some cases, there is a mismatch between technology and organizational and end-user needs (Lawler, 1993; Massaro, 1993; Tonessen et al., 1999). The scale of health information and the complexity of using it properly make technology another important element for EHR implementations, especially since it is seen to be the vehicle through which the organization will meet its strategic goals.

The increasingly complex technology, task scope, intensity and the number of tasks performed simultaneously by healthcare workers push organizations toward a requirement for coordination and integration and use of information technology (Hage, 1980; Schumaker, 2002). Paradoxically, it is precisely this task complexity and organizational complexity which makes implementation of technology so difficult and prone to failure.

BEST PRACTICES FOR EHR AND INFORMATION SYSTEMS IMPLEMENTATIONS

Implementation of the EHR is not only a technology application at the operational level, but also a major change in the business processes, organizational structure and organizational culture, which are directly related to the mission and vision of an institution. In this context, the decision of transferring the overall system of the healthcare setting from a paper-based environment to a new information system happens at the strategic level, which is followed by operative level management and execution activities (Poskela et al., 2005).

A key aspect of our meta-framework is that it models the time perspective which brings out the dynamic and interactive nature of EHR implementations. The time frame element is modeled as three major operational phases of an EHR implementation: pre-implementation phase, implementation phase and post-implementation phase activities. In each phase, related tasks or factors aggregate together due to similar time courses, functions, and outcomes. A factor can begin in one phase and end in another, but may spend most of its lifetime in a specific phase. It is to this phase that we allocated its primary relevance for the purposes of this framework. However, the strategic level is beyond these phases; the time frame of the strategic level activities starts before these operational phases and goes as long as EHR lives in that setting.

Strategic Level

The meta-framework factor ***governance*** speaks to senior management's activities or substantive personal interventions in the EHR implementation. It is concerned with mission, vision and senior management's behaviors related to pre-implementation, implementation and post-implementation phases of the EHR. Senior management support is a must for EHR implementation (Bingi et al., 1999; Buckhout et al., 1999; Fui-Hoon Nah et al., 2001; Sumner, 1999) and EHR must have a plausible chance of helping attain the strategic business goals (Sumner, 1999). Senior management must allocate valuable resources to the implementation efforts (Holland et al., 1999), including providing the needed people for the implementation (Roberts & Barrar, 1992). Management needs to announce the new system and structures regarding EHR implementation, provide the compelling rationale for taking the EHR pathway and support the key champions and project managers who will communicate the strategy and tactics for EHR implementation throughout the organization (Kotter, 1995). Senior management must create a sense of "urgency" for change, inspiring people to act, think, and make objectives real and relevant (Kotter, 1995). New roles and responsibilities should be established and policies should be set by senior management to suit the new systems in the company (Roberts & Barrar, 1992).

Top-down organizational support is one of the dominant factors associated with successful implementation of EHR. Project leadership must be "empowered to act" by removing obstacles and enabling support from senior management (Kotter, 1995). Our analysis indicates that implementations that had good governance were 6 [95% CI 1.3 to 27, p= 0.025] times more likely to succeed than implementations that had poor governance. Without real commitment from the top, stresses experienced during implementation can easily hinder EHR development (Townes et al., 2000). In some implementations which experienced failure, EHR implementation was either not sanctioned by senior management (Chiang & Starren, 2002; Townes et al., 2000) or senior management was diverted by other organizational priorities (Tonessen et al., 1999) at a crucial time in the EHR implementation. Without top level support, implementations, which hit a snag that requires additional resources to resolve, will quickly die on the vine.

Operational Level

Pre-Implementation Phase

The initial or pre-implementation phase is relatively the most important part of any IT initiative and should focus on activities that facilitate project success, such as goal setting, planning, and communication. Pre-implementation activities set the tone for all other phases of an IT implementation project, and it is important to recognize any potential progress impediments and be prepared to proactively address them (Rosenthal, 2002). The key outcomes of the pre-implementation phase are a consensus within the organization on which technology it will implement, that the technology is the right one for the organization and a willingness and excitement amongst clinician end-users to implement the technology.

Our factor ***project leadership*** combines two important roles in the EHR implementation. This factor runs through the entire implementation, from pre-implementation to post-implementation phases. The first role is that of the experienced and skilled project management. Much has been written about project management and we will not repeat it here. In an EHR implementation, the role of the project manager is to use the process factors of the implementation meta-framework as a series of activities that over time bring about the desired change within end-users and technology for a successful implementation to occur. Successful implementations also need champions who are able to influence operational level activities

(Hauschildt, 1999). Physician champions are central in all phases of an implementation, acting as enabling advocates, selling benefits and engaging in a 'web' of communications with other clinician end-users. Championship, defined as the persistent and persuasive communication between strategic and operational levels, is a crucial instrument for senior management and appears to be an important middle management function (Floyd & Wooldridge, 1992). Our findings show its strong impact, with a 26-fold [95% CI 3 to 234, p = 0.004] increase in likelihood of success with strong project champions and experienced project managers working together to manage the people, process and technology aspects of an implementation.

One of the key activities in the pre-implementation phase is the software selection process, our factor *choose software carefully.* All of the pre-implementation activities and outcomes revolve around this process. It is the process through which end-users buy-in to the needs of the organization, the need for a software solution and the appropriateness of a particular technology to meet organizational needs. Project leaders, both project managers and project champions, need to help stakeholders within the organization to galvanize their commitment to the particular pathway chosen by senior management to achieve its strategic objectives and to put their own stamp on the implementation through participation in the selection process; after all, they will be the ones to live with the day to day consequences of their choices. Project managers also need to hold vendors and system developers accountable to meeting the needs of end-users. This factor is the key mechanism through which the mutual reshaping of end-users and technology takes place. Implementations which correctly implemented this process were 17 [95% CI 2-152, p = 0.011] times more likely to succeed than those that executed it incorrectly or did not use this process at all. User friendliness of the software and meeting users' requirements are important for user acceptance of the system and human related issues. The flexibility of the software and matches with the norms and values of the organization makes this factor crucial in terms of processes. In this context, choosing the software is a central activity that can unite an organization and generate excitement and a shared vision or can create deep divisions. Successful project managers and project champions are able to use a series of pre-planned activities to guide the organization and end-users toward a shared vision and a commitment to the EHR pathway. Unsuccessful project managers were more likely to have embarked on a journey to develop their own software after finding out that they couldn't find a suitable one on the market (Chiang & Starren, 2002) or followed a good process and then sabotaged it at the end because a 'new and improved' software came along "at the 11th hour" (Goddard, 2000).

Involvement of end users was one of the key factors mentioned by implementers as being essential for the implementation. It facilitates creating a better system that is integrated with the existing one and promotes user ownership (Clegg et al., 1997). This factor appears to provide a 4.5-fold [95% CI 0.98 to 20.5, p = 0.054] improvement in success. Although this factor did not achieve statistical significance in our study, a larger sample size might have allowed us to detect statistical significance. It is likely that the ***choosing software carefully*** incorporates this factor. Many failed implementations that did not involve end-users also did not choose their software carefully (Lawler, 1993; Massaro, 1993; Tonesson et al., 1999; Wager et al., 2001).

Selling benefits and addressing barriers leads to a 14-fold [95% CI 1.54 to 119, p=0.019] increase in the likelihood of the success. By selling benefits, the organization and actors of the system are prepared for change by identifying core values, understanding the broader organizational context and stakeholder concerns, understanding end-user needs, creating a vision and compelling need for change, and being sensitive and responsive to organizational stresses resulting from change (Kotter, 1995; Lorenzi & Riley, 1995). Physicians, nurses, and staff need to be constantly reminded of the benefits of EHR and need to feel confident that obstacles and barriers are being addressed. It is quite common for clinicians to misinterpret the chaos of implementation as incompetence of implementers and a sign of things going awry. End-users need to experience early and quick wins to maintain their confidence in the implementation process. Implementations that failed due to incorrect execution of this factor were more likely to assume that the benefits were self-evident and did not need to be sold or project champions were entirely absent from the implementation process (Chiang & Starren, 2002).

Early planning strategies encompasses early and extensive planning on how computers will be introduced and implemented into the organization. It is concerned with foreseeing and predictive risks and problems that may arise and planning for them. Plans for acquiring appropriate experts and support personnel to field concerns, anticipation of problems and development of plans to solve them, plans for process and workflow redesign, training plans and planning for the technology deployment are all required to ensure a successful implementation. Use of *early planning strategies* increases the likelihood of success by 10-fold [95% CI 1.8 to 56, p = 0.009]. Given the large number of factors that need to go right in the implementation phase and given that those factors are also potential points of failure, *early planning strategies* are crucial to the successful implementation of an EHR into actual practice. Unsuccessful project managers did not plan for unexpected contingencies. Given the fast-paced, mission critical environment of healthcare, there is typically very little time or patience to deal with technology problems. Successful project managers made sure that a multi-disciplinary team was on-site or readily available during the early weeks of implementation to quickly manage problems that arose. Problems that arise during implementation are likely to span multiple disciplines, such as a hardware problem that exacerbates an existing process problem, causing chaos to ensue. If the problem is not fixed quickly, users are forced to go back to their old processes. If this is allowed to last too long, clinicians lose confidence in the implementers and will not go back to using the new technology (Chiang & Starren, 2002; Lawler, 1993). Quick, on-site support is crucial at these junctures.

Technology usability appears to be a very important factor, with a 96-fold [95% CI 9 to 999, $p < 0.00001$] increase in likelihood of success for overall system design including hardware and software and the system selection at the outset. Conversely, technology usability issues are ostensibly blamed for most failures, partial failures or even hiccoughs in implementation. This is likely to be an over-estimate of the actual impact of technology fit to the organization as it is easy for an organization to blame the system instead of pointing to themselves as the cause of implementation problems, but clearly the perception of its importance is high. New EHR technology will be implemented better if it is easy to use thereby helping derive its purported benefit, especially if it's real benefit closely fits end-user expectations. Essentially the EHR must perform as advertised and be a good match to the needs of the organization, without disrupting workflow and time to complete task expectations, and organizational culture so much that the organization cannot adapt to this change (Ash et al., 2003; Berg, 2001; Delone et al., 2003; Heeks, 2006; Kushniruk & Patel, 2004). The technology usability factor has two aspects to it. Initially, it is the organization's and stakeholder's perception of how usable the technology is and whether it will meet the needs of the end-users. This is modeled in Davis' technology acceptance model (TAM) (Davis & Wilder, 1998). Later, as the technology is implemented, the actual usability and fit within the organization becomes a crucial factor. Many implementations failed to make the transition from perceived usability to actual usability (Lawler, 1993; Massaro, 1993; Tonnesen et al., 1999). Most partial failures languish in a situation where the technology only partially supports the strategic and operational requirements of the organization—stuck in a limbo not of their own making (Aarts & Berg, 2004; Chiang & Starren, 2002; Poon et al., 2003; Tonessen et al., 1999; Wager et al., 2001; Williams, 2002). The reasons for failure in this factor can be attributed to: (1) a flawed EHR selection process that did not engage the appropriate stakeholders whose input was crucial to ensuring a good fit of technology to users (Massaro, 1993); (2) poor mapping between functionality of the software and needs of the organization (Aarts & Berg, 2004) and; (3) poor understanding that flaws in acquired technology requires organizational capacity to overcome them (Lawler, 1993).

Data pre-load and integration plays an important part in achieving success with EHR implementations (Ash et al., 2003; Smith, 2003; Townes et al., 2000). Data-preload and integration of systems before providers start to use the system decreases the requirement for initial data entry from previous documentation and from other systems. Getting data from other systems makes it easier for physicians to get started and decreases their on-going charting efforts. Digitization of paper charts into the new system is an example of decreasing the gap between the technology reality ("we allow you to document all encounters, as long as you do it our way") and expectation of end-users ("we need previous records to be easily accessible when we use the system") (Heeks, 2006), resulting in a better fit of the technology to the expectations of the organization. Previously used database formats from legacy systems can be imported into the new system. Effective integration with other systems containing billing, lab results, reporting, scheduling, diagnostic imaging, referrals and reference sources can be achieved (Chin, 2004). Consideration can be given to scanning parts of the previous paper-based record provided the information can be effectively indexed for later retrieval. These integration and pre-load activities increase end user satisfaction and user acceptance of the new system.

Lack of data pre-load and integration can lead to duplicate paper and electronic documentation which leads to inefficiency, risk to patient safety and a cognitive burden which is difficult to overcome for most clinicians (Keshavjee et al., 2001).

In summary, the goals of the pre-implementation phase are to assist the clinicians within the organization to make the necessary mental and attitudinal changes to implement the EHR technology. This phase uses the EHR selection process as the central activity through which the transformation occurs and which leads to the selection of a particular software solution which will be implemented. At the end of this phase, the organization and its users are confident that the technology is usable and that it will meet their needs, they have a clear understanding of the risks and benefits associated with their choice of EHR software and have begun the planning process to take the organization into the implementation phase.

Implementation Phase

In the implementation phase the work of EHR activation begins. This is the true test of an organization's preparations made in the pre-implementation phase, and of the overall match of these success factors to the nature of its EHR implementation.

Workflow redesign speaks to the relationship between human factors, how people work, and technology. Critical to successful implementation is the fit of staff and physician work flow to that of the EHR functionality and usability design constrictions (Smith, 2003). If the EHR software fits into clinician workflow then it is more likely to be accepted (Wager et al., 2001). It is well documented that redesign of business process is important for technology to deliver on its promise. Automation of poor workflows only leads to faster chaos—an undesirable outcome (Keshavjee et al., 2001). Workflow redesign is a highly specialized field and requires skilled practitioners to guide clinicians in a process through which they can achieve superior productivity in their work. It is the role of the technology to support and enable the new, more efficient workflows to be implemented. Implementers who correctly executed *workflow redesign* experienced 36-fold [95% CI 4 to 333, p = 0.002] increases in the success of their implementations.

Training, implementation assistance and *feedback and dialogue*, all had relatively modest impacts on the success of implementations of between five and nine-fold. Proper *training* (nine-fold increase [95% CI 1.6 to 48, p = 0.013]) supports the smooth transition to a paperless patient care system. Hands on training sessions immediately prior to going live has great significance for accelerating the implementation and user acceptance of the new system (Halley et al., 1996; Swanson et al., 1997; Wager et al., 2001). Training of the end users on EHR should be both initial and on-going, as it is not possible to learn all the features of the EHR software during initial training. Many functions of an EHR are only used once a physician has climbed up the steep learning curve of using an EHR.

A successful implementation requires comprehensive *implementation assistance* (five-fold increase [95% CI 1.1 to 23, p = 0.037]) to be responsive to solving technical problems quickly. In addition, end-users need assistance in making system improvements and modifications and making necessary changes such as developing custom templates, forms and shortcuts (Miller & Sim, 2004; Swanson et al., 1997). Quick and competent support can come from a variety of resources. A strong vendor partnership (Swanson et al., 1997), the presence of "super-users" (Chin, 2004; Keshavjee et al., 2001; Pizziferri et al., 2005; Wager et al., 2001) and "bridgers" (Chin, 2004) and on-site technical teams can contribute significantly to provide proper assistance on time. EHR implementations are dynamic processes which evolve as learning occurs and new problems and opportunities are discovered. End-users who are learning while continuing to provide patient care require additional support to ensure a smooth transition to using technology in their practices.

Feedback and dialogue (nine-fold increase [95% CI 1.6 to 48, p = 0.013]) is essential for supporting the dynamic EHR implementation process by providing opportunities to end-users for discussing issues and problems, to vent their frustrations, to share problems they are experiencing and to recommend changes to the software or to workflows. This process gives project managers and project champions an opportunity to monitor and track the progress of the implementation and detect and resolve problems before they get out of hand (Ash et al., 2003; Chin, 2004; Swanson et al., 1997; Townes et al., 2000).

EHR implementations must meet requirements for *privacy and confidentiality*. Although this is usually stated as a 'top 3' requirement for clinicians and is an important component of information systems management, it did not achieve statistical significance as being a factor for implementation success (4.70-fold increase [95% CI 0.53 to 42, p=0.165]). It is easy to see that although privacy and confidentiality is unlikely to be a driver of success, its absence could be a factor which prevents success or hastens failure. In any case, no discussion of implementation can be considered complete without mention of privacy and confidentiality.

In summary, the goals of the implementation phase are to assist physicians in making a successful transition from existing paper-based processes to the new electronic process. Barriers to the transition must be quickly resolved lest users revert to previous practices. Ensuring that new workflows are logical and streamlined, that appropriate training has been provided, that users have a forum in which to provide feedback and that they get support in a timely manner is crucial for successful navigation through the implementation phase.

Post Implementation Phase

The goals of the post-implementation phase are to consolidate the gains of the implementation phase and to start the organization along the journey toward meeting the real goals of the organization: improved efficiency and improved patient care. This is done through providing incentives and support to clinicians and providing them with a forum in which to share best-practices and enhance their use of the system.

The post-implementation phase is the culminating activity of an IT implementation initiative (Rosenthal, 2002), but also the start of a new journey toward newer implementation activities (Chin, 2004). Despite very limited discussion in the literature on importance of ***incentives*** in the EHR literature, in our analysis implementation efforts that offer incentives to users were 70 times more likely to succeed [95% CI 7 to 705, $p < 0.001$). The identified benefits of an EHR including improved patient safety (Berner et al., 2006; Hippisley-Cox et al., 2003; Mekhjian et al., 2002), increased income and decreased costs (Cooper, 2004), increased efficiency of care (Hippisley-Cox et al., 2003; Mekhjian et al., 2002; Nordyke & Klikowski, 1998), faster access to clinical information at the point of care and more efficient outcomes assessment (Nordyke & Klikowski, 1998) need to be demonstrated to all users. Most incentives were professional and work related incentives—increased efficiency, better patient care and more professional satisfaction, rather than monetary incentives.

Users groups and *business continuity plans* are two post-implementation phase factors that did not achieve statistical significance as drivers of implementation success. However, as with privacy and confidentiality, they can be interpreted as barriers to success rather than as a driver. Structured interactions of the users by scheduling meetings, *users groups* or discussion platforms provides a forum for ongoing training and facilitates a cooperative dynamic where end users can solve technical problems, write templates, and teach each other about software features (Berner et al., 2006). User groups can produce a greater user acceptance and satisfaction (Smith, 2003). A business continuity plan is also essential where there is provision for data protection and disaster recovery (Swanson et al., 1997).

EHR users require significant amounts of *support*, especially in the early phases after implementation. Myriad questions and issues arise which can lead to disenchantment and disillusionment if not handled appropriately (Keil et al., 1998; Massaro, 1993; Miller & Sim, 2004). *Support* did show some impact on the success of implementation; however the sample size was too small to reliably detect the magnitude of the impact.

Requirements of the new system and structures tend to change continuously even after the completion of the implementation phase. In this context, post-implementation activities are critical for the acceptance of new systems (Kuruppuarachchi et al., 2002) and for allowing the organization to grow and achieve its mission.

Overall, it appears that much of the success of EHR implementations can be explained by activities in the pre-implementation and implementation phase. Only the provision of incentives in the post-implementation phase has a large impact on success of implementations. However, the role of user groups and support should not be underestimated, as these are required for clinicians to meet higher order goals such as chronic disease management, preventive maintenance care and more evidence-based care. Although these higher order clinical goals may not be important to the ‘technological success’ of the project, they are important to help the organization meet its strategic goals for which it implemented the technology in the first place!

CONCLUSION

Despite remarkable advances in EHR, many systems still fall short of performance expectations (Centre for Health Policy and Research, 2006). A growing share of these implementation failures are due to non-technical factors (Clegg et al., 1997). This study has attempted to combine a large and diverse literature into a multi-level multi-dimensional meta-framework of successful implementations of EHR in healthcare organizations. Our meta-framework provides a comprehensive set of factors for assessing the EHR implementation literature. Our systematic review of the literature has provided support for this meta-framework by assessing impact on EHR implementation success.

The limitations of our research come from the relatively poor quality of case reports on EHR implementations. Most articles are written by implementers, not academics, who were probably asked to write about their experiences after a successful implementation. These articles are mostly experience reports, are generally incomplete and probably suffer from recall bias. There is also a publication bias in that the number of articles describing failed implementations is under-represented. Of the 47 articles we reviewed, only 10 described failures. Given the prevalence of failed implementations, we should expect to see many more articles describing failures. In addition, implementations in smaller clinic settings are presently under-represented in the literature and need to be examined and reported upon.

Research aimed at validating this framework should include prospective usage of these factors in an EHR implementation and establishing key outcome measures of overall EHR success.

FUTURE RESEARCH DIRECTIONS

Although, our review affirmed well-described success factors in the literature, they add additional components which model the dynamic and evolving nature of EHR implementations. The complexity and multi-dimensional nature of EHR implementation makes it difficult to match a factor tightly to the phenomena in a real EHR implementation (Berg, 2001). Also, a gold standard model to assess and rate EHR implementations is still needed. We believe that our meta-framework can be used iteratively in future research efforts to refine these matches and design a more standardized framework to evaluate the success of implementations prospectively. Future research could benefit from improved data collection through more precise operational definitions and generation of checklists in an attempt to more precisely identify the presence of certain factors or concepts. Improved hypothesis generation could be achieved again by defining more precise operational definitions of success factors and further identifying component concepts that might be successful and unsuccessful. Further definition could be done of the weighting of different factors as they contribute to implementation success. Finally, knowledge translation and controlled trial research needs to be conducted to translate findings from this study into practical advice for project managers and project champions. The factors identified in this study need to be validated in actual implementations through systematic collection of data on a prospective basis from actual implementations.

ACKNOWLEDGMENT

The authors wish to acknowledge the generous support of CIHR and the CHPSTP project in providing funding and infrastructure to accomplish this research.

Chapter 4.3

Electronic Medical Records:

TAM, UTAUT, and Culture

ABSTRACT

Many policymakers, industry experts, and medical practitioners contend that the U.S. health care system—in both the public and private sectors—is in crisis. Among the numerous policy issues associated with the provision of US healthcare is the call for increased adoption and use of health care information technology (HIT) to address structural inefficiencies and care quality issues [11, p. 33]. This paper reports the first steps in a multi-phased research effort into Electronic Medical Records system adoption. The first two phases of our research applies the Unified Theory of Acceptance and Use of Technology as a lens to interpret the responses of physicians completing their Residency in Family Medicine and the third phase examines the role of organizational culture as a critical variable for effective strategy implementation in the same setting

INTRODUCTION

The 2005 Government Accountability Office (GAO) (2005) report, 21st Century Challenges: Reexamining the Base of the Federal Government, was intended to identify critical issues and potential options for addressing key fiscal challenges facing the federal government; the GAO identified healthcare as one of the most critical issues facing federal policy makers. Among the numerous policy issues associated with the provision of US healthcare is the call for increased adoption and use of health care information technology (HIT) to address structural inefficiencies and care quality issues plaguing the US health care industry (GAO, 2005). Multiple clinical and administrative benefits have been identified with the adoption of HIT generally and EMR systems specifically. Yet the health care industry remains a laggard in IT adoption relative to other industries (Burke, D. E., & Menachemi, N., 2004).

The United States federal government is actively encouraging the development of "a nationwide interoperable health information technology infrastructure that:

a. Ensures that appropriate information to guide medical decisions is available at the time and place of care;
b. Improves health care quality, reduces medical errors, and advances the delivery of appropriate, evidence-based medical care;
c. Reduces health care costs resulting from inefficiency, medical errors, inappropriate care, and incomplete information;
d. Promotes a more effective marketplace, greater competition, and increased choice through the wider availability of accurate information on health care costs, quality, and outcomes;
e. Improves the coordination of care and information among hospitals, laboratories, physician offices, and other ambulatory care providers through an effective infrastructure for the secure and authorized exchange of health care information; and
f. Ensures that patients' individually identifiable health information is secure and protected.

Thus, a key objective of federal policy is to achieve widespread adoption of EMR within the next 10 years (Department of Health and Human Services, 2004).

This paper reports the first steps in a multi-phased research effort seeking to:

- Assess new physician residents' beliefs, attitudes and perceived group norms concerning EMR use within their residency, using UTAUT (Venkatesh, V., Morris, M. G., Davis, G. B., & Davis, F. D, 2003)..
- Identify HIT related education and training provided by medical schools and residency programs, and its impact on future career choices.
- Evaluate the role of culture as a value added support strategy in assessing the match between mission and vision, and organization priorities.
- We employed both qualitative and quantitative data collection and analysis to provide what we believe to be a richer understanding of the role of the Unified Theory of Acceptance and Use of Technology (UTAUT) and the role of culture in the adoption of HIT.

THEORETICAL FRAMEWORKS

The Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT)

TAM has been the dominant theoretical approach for studying individual IT adoption and use and has spawned an incredibly rich and widely cited stream of theoretical and empirical research (Lucas Jr., H. C., Swanson, E. B., & Zmud, R. E., 2007; Benbaset, I., & Barki, H., 2007; Straub Jr., D. W., & Burton-Jones, A., 2007). TAM is an information systems theory that models how users come to accept and use technology: the main dependent constructs are behavior intention to use and system usage. The model suggests that when users are presented with a new technology, a number of factors influence their decision about how and when they will use it, specifically Percieved usefulness and Perceived ease of use (Wikipedia, 2008). TAM is is a derivation of Ajzen and Fishbein's Theory of Reasoned Action (TRA) and assumes that "when someone forms an intention to act, that they will be free to act without limitation (Bagozzi, R. P., Davis, F. D.,

& Warshaw, P. R., 1992). Because new technologies are complex an element of uncertainty exists in the minds of potential users. Attitudes and intentions are formed and these attitudes may be positive or negative about technology use in general and the usefulness and ease of use of a specific technology. Thus, in the real world, there are many constraints that might limit a potential users' freedom to act upon their initial intentions (Bagozzi, R. P. et al., 1992).

The Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh, V., Morris, M. G., Davis, G. B., & Davis, F. D., 2003) is a comprehensive synthesis of TAM and serves as a theoretical lens regarding strategic implementation and adoption of EMR. UTAUT proposes a set of variables that directly influence the outcome variables of Behavioral Intent and Usage of Technology. The theory holds that four independent constructs (performance expectancy, effort expectancy, social influence, and facilitating conditions) are direct determinants of usage intention and behavior (Venkatesh, V., 2003). In addition, each of the direct determinants is mediated by one or more of a set of demographic variables such as, gender, age, experience, and voluntariness of use. Validation of UTAUT in a longitudinal study found it to account for 70% of the variance in usage intention (Venkatesh, V., 2003).

Employing a qualitative research design in the first phase of our research, our objective was to identify key TAM-related beliefs and factors concerning perceived usefulness and perceived ease of use in such a manner as to obtain greater insight into the formation of perceptions or beliefs such that subsequent recommendations (or hypotheses) for design changes for both the IT artifact or the work processes in which the IT artifact is employed might be generated.

Recent studies have highlighted the criticality of physician attitudes and the importance of their support with respect to the effective adoption and use of HIT (Illie, V., Courtney, J. F., & Van Slyke, C., 2007; Lapointe, L., & Rivard, S., 2005; Snyder, K. D., Paulson, P., & McGrath, P., 2005; Kohli, R., & Kettinger, W. J., 2004; Daar, A., Harrison, M. I., Shakked, L., & Shalom, N., 2003; Hu, P. J., Chau, P. Y. K., & Sheng, O. R. L., 2002; Treister, N. W., 1998). Physician resistance to technology adoption is not necessarily unwarranted. Snyder, Paulson and McGrath report that while the time required to perform the tasks of medical technicians may decrease, "the doctor is faced with an increase in his or her workload" (Miles, M. B., & Huberman, A. A., 1994, p. 90). Darr, Harrison, Shakked and Shalom (2003) identified six domains of concern: "managerial implications of the EMR, limits on professional autonomy, impact on communications with colleagues, facilitation of research, legal defense, and influence on the professional hierarchy within the hospital"(2004, p. 353). Kerr, McGlynn, Adams, Keesey and Asch (2004) raised many of the same issues particularly highlighting concerns regarding the impact of technology, i.e., data entry, on the quality of doctor-patient interaction, as well as problems with various perceived restrictions imposed by the system.

Thus the second phase of our inquiry into the adoption of EMR is UTAUT driven. This research's primary focus is on one specific mediating factor of the UTAUT theory: prior experience with EMR. Commonly accepted knowledge posits that "Many medical schools and residency programs do not currently employ or train future physicians to use EMR; training the future medical workforce to rely on EMR… can only serve to accelerate universal EMR adoption" (2004). While it may seem intuitive that prior experience would be positively correlated with use, UTAUT does not predict such a simple, positive, linear relationship. Thus, with UTAUT as our theory base, this quantitative second research step scrutinized the impact of physicians' prior experience with EMR.

Culture as a Value Adding Social Influence

UTAUT posits that social influence is one of the four direct determinants of usage intention and usage behavior. We suggest that culture may be the among the strongest social influences in an organization. "Culture acts as a silent governor" (Wenzel, F. J., 2005, p. 54). When new strategies, such as the implementation and use of new technology, are introduced, the cultural component merits consideration. Most often, one of three tactics are employed: 1) attempts may be made to change the existing organizational culture to match the new strategy, 2) the existing culture may remain and the strategic initiatives try to manage around it, or 3) the strategies may present a good fit with the existing culture (2005).

To elaborate, one way of understanding the culture in a specific health service organization may be made possible by how physicians, managers, and staff answer questions regarding organizational mission and value prioritization (Swayne, L. E., Duncan, W. J., & Ginter, P. M., 2006). The mission of the organization refers to why the organization operates the way it does.

- What is the mission of the organization?
- What are the values associated with the organization?
- What are the high and low priorities within the organization? High priorities are those activities that are in concert with the organizational values and mission. Actions that offer good fit should receive higher priority.

Along with the mission, values, and prioritization in the organization, successful "stories" are repeated to underscore the culture.

The telling of such stories also serves to educate others who work in the organization about its culture. And, through the telling of these successful stories, it becomes part of the cultural history of the organization. The story itself becomes meaningful to the staff members who work there (Higgins, J. M., & McAllaster, C., 2003). Hence, such stories serve as a value adding support strategy and, as a result, encourage additional buy-in from other staff members to continue the culture of quality, and in this specific case, the use of EMR.

Swayne, Duncan and Ginter (2006) propose that a strategic thinking map for value adding support strategies may identify matches (or mismatches) of culture and strategy. The construction of the map is subjective and offers direction during strategic planning; the process offers a way to examine if strategic initiatives are good fits for organizational strategy. In the construction of a strategic map, culture is assessed in terms of its assumptions, values, behavior and norms of the organization (see Figure 1).

The third phase of our inquiry into the adoption of EMR, then, employs a qualitative examination of the social influence of culture. Organizational culture permeates throughout an organization (Swayne, L. E. et al., 2006; McConnell, C. R., 2006; Wenzel, F. J., 2005). This concept of culture influences the way people in an organization do their work, and we suggest, it impacts the an organization's intention to use, and the actual use of, EMR.

THE SITE AND THE THREE PHASES OF RESEARCH

The primary site of all three phases of our work is a Family Medicine clinic (FMED) in the Intermountain West region of the United States. The clinic resides in one of the larger population centers in the state, having a metropolitan area less than 75,000 persons.

The Centricity Physician Office EMR product was obtained via grant funding and data were preloaded into it in Fall, 2004 with initial patients seen using the EMR starting in December, 2004. All patients were seen using the EMR by Spring,

*Figure 1. Strategic thinking map for value adding support strategies for FMED**

Strategy Initiatives: EMR initiative and Quality and Culture Project

Characteristics/Attributes			**Evaluations**	**Support Strategy**
Value adding support strategy	Results of Internal Analysis—What is the Culture at FMED?	Requirements of Selected Strategy (IT Implementation and The Quality as Culture Project)	Comparisons Made Between Strategy and Cultural Fits	Guidance, Ideas Offered
Organizational Culture *Mission* *Values* *Behavior* *Norms*	*Strong culture, focused on technological innovation, effective primary care for the underserved rural population.* *Strong culture, focused on the education of family practice physicians* *Strong culture, focused on learning in University environment.*	*Culture reflects probable IT adoption and use by physicians; continuous learning efforts to be employed; and introduction of projects designed for cutting edge healthcare efforts*	*Culture offers good match. The values and norms need to be maintained for successful implementation.*	*IT—Emphasis on readiness and ability for training efforts; emphasis on listening to physician users' ideas and input regarding EMR* *Leaders—Emphasis on visible communication and behavior supportive of strategy*

**[Adapted from Swayne, Duncan, and Ginter (2006) Strategic Thinking Map Exhibit, p. 411]*

2005, and e-prescribing became available in December 2006. Data are accessible at the clinic via a wireless network and all attendant physicians are provided with notebook computers while on call. The data are also accessible from the nearby hospital, and through secure remote access, off-site. In addition, Laboratory Tests, Radiology, and Pharmacy, including E-Prescriptions, are accessible through the network.

There are eight physicians on the staff at FMED clinic who are also Faculty in the College of Health Professions, Department of Family Medicine at the University with which FMED is affiliated. The FMED practice is structured with physicians functioning as director and associate director, and a Pharm.D. as Director of Research.

The Family Medicine Residency Program is designed to train physicians for successful rural family practice. Six Residents are admitted into the program annually, resulting in eighteen Residents in training each year during the three year program. "Residency is a stage of postgraduate medical training in North America and leads to eligibility for board certification in a primary care or referral specialty. It is filled by a resident physician who has received a medical degree (M.D. or D.O.) and is composed almost entirely of the care of hospitalized or clinic patients, mostly with direct supervision by more senior physicians." (Wikipedia, 2007).

Open Ended Face-to-Face Interviews

To assess residents' beliefs, attitudes and perceived group norms concerning EMR use within their residency, open ended interviews were conducted during Winter 2007, with 7of the 18 residents in the Family Medicine Residency program. We were pleased to achieve a 39% level of participation given the intensive nature of our research interview and the tremendously busy schedule of resident physicians.

Three residents were in their third and final year of residency and two were in each of the first and second years. Three of the residents were female and four were male, two were in their late twenties and 5 were 30 years of age or older, three were international. Four of the residents had no experience with either paper or electronic medical records prior to their admission into the Family Residency program. Two of the residents had previously worked with an EMR. In addition, two of the residents had significant information systems backgrounds, both having worked in support functions prior to obtaining their MDs.

Prior Use Survey

The next phase of this work was a written survey project that was conducted during spring, 2008. Both residents and faculty from the residency described above, and from a sister family practice residency program from across the state, were invited to participate. Questions included in the survey were guided by the findings from the face-to-face interviews discussed above. One hundred percent (100%) of the 15 faculty surveys and seventeen (37%) of the resident surveys were returned. Fourteen of the participants were female, 18 were male, 26 were MDs, 4 were DOs, and 2 indicated they were PAs.

The Quality of Care Project

The Quality as Culture Project was initiated independently by FMED. Each resident is required to partake in a quality project before they leave the residency and to on to their first practice site. The Quality as Culture project reported here focused on documenting and assessing Adult Diabetes Clinical Performance Measures from the Physician Consortium for Performance Improvement (PQRI). This project could not have been undertaken without the use of EMR.

Qualis Health, a private, nonprofit healthcare quality improvement organization with national reputation, recognized FMED in 2008 with its Award of Excellence in Healthcare Quality for its demonstrated leadership and innovation in improving healthcare practices. Qualis Health specifically noted FMED as one of the few clinics in the nation that could readily generate reliable clinic data.

FINDINGS

2007 Face-to-Face Interviews

Performance Expectancy

"Performance expectancy is defined as the degree to which an individual believes that using the system will help him or her to attain gains in job performance" (Venkatesh, V., 2003 p. 447). The seven residents were unanimous in their expectation that adoption of an EMR would enhance their ability to provide medical care. Although we found variance in how each resident used EMR with patients, they consistently commented on the value of having the patient's data available at any time, from either the clinic or hospital.

In addition, residents commented on the value of having standardized data elements in the system as a component of their performance expectation. Although 60% of the patients at FMED see a regular physician, the inherent turnover of residents imposes instability on a long-term physician-patient relationship. Having data standardized facilitates patient care by providing consistent history, diagnosis and treatment information for each patient.

Effort Expectancy

"Effort expectancy is defined as the degree of ease associated with the use of the system." (Venkatesh, V., 2003, p. 450), The seven residents unanimously commented about the accuracy of patient documentation, and the ability to easily locate data. Easy access to lab work, medications, prior visits, history and conditions were all discussed as being benefits of the system, in addition to the data being readable. Electronic prescriptions had recently been added to the functionality of the system and were also mentioned as a system benefit.

Overall, data input was the major problem with the EMR cited by residents. One third year resident commented that "the time it takes to enter all the data makes it difficult to see more patients." Another Resident commented that it "takes too long to wrap-up…there are too many tabs…it would be helpful to enter necessary data on one sheet." Navigation of the system was mentioned as a problem by another of the third year residents. Similar comments were echoed by all the residents, with the exception of a technology savvy resident who had prior experience in systems support and development. This third year Resident commented that he was "adept at the EMR."

Additional drawbacks mentioned included system efficiency and the cumbersome nature of many screens, with some including multiple tabs for basic procedures. Because the residents ideally completed their paperwork between appointments, interruptions were also cited as system drawbacks.

Thus from these face-to-face interviews we found strong evidence in support of TAM. The TAM model positis that performance expectancy and effort expectancy predict behavior intention to use and system usage. The construct of performance expectancy was high for these residents; all agreed that the EMR would enhance the care they provided, primarily because of the increased access to patient data. We also found amply evidence of TAM's other construct, effort expectancy; the residents' primary complaints were about the amount of effort it took to enter information, to navigate the system, and to work through all the tabs when closing one patient's record and moving on to the next.

UTAUT is somewhat more complex in the independent variables that it proposes impact the same dependent variables as TAM: Behavioral Intention and Usage of Technology. The theory holds that four independent constructs (performance expectancy, effort expectancy, social influence, and facilitating conditions) are direct determinants of usage intention and behavior (Venkatesh, V., 2003). In addition, each of the direct determinants is mediated by one or more of a set of demographic variables such as, gender, age, experience, and voluntariness of use.

Social Influence

"Social influence is defined as the degree to which an individual perceives that important others believe he or she should use the new system." (Venkatesh, V., 2003, p. 451). At FMED, the organizational culture indicated an expectation that all residents use the EMR system.

When discussing peer influence, residents consistently stated that some of their peers didn't like the system. It was also discussed that some of the residents take more advantage of the system and were rather proficient with the EMR. The residents commented that peer influence was encouraged regarding screen modifications. One of the 'tech savvy' residents stated that "peers had a big influence on what templates were used".

Facilitating Conditions: Gender, Age, Experience, and Voluntariness of Use

"Facilitating conditions are defined as the degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system" (Venkatesh, V., 2003, p. 453). Broad facilitating conditions existed to access the EMR at FMED. First, all residents had a lightweight portable device with a full screen and touch screen technology, not dissimilar to a clipboard. Second, a wireless network provided access to the system while at either FMED or the adjacent hospital. This allowed them to input data not only in the vicinity of the visitation room, but also anywhere within the facility, at any time. Third, the FMED IT staff provided support services at the home of each Resident to configure them for remote access to the EMR.

We did not observe any significant differences in performance expectations by either gender or age in our 2007 interviews. In addition, we had little variation in the ages of our residents as most were in their late 20s to mid 30s, thus are unable to comment on age as a mediating variable

Technical experience had a definite influence on effort expected and behavioral intention of system use in this study. The two 'tech savvy' residents endeavored to master the system and realized that they had to learn the system either through training or on their own. Because training was mentioned frequently by the residents when discussing their intentions of using the system, it seems that the level and nature of training provided to the residents was a facilitating factor.

Use of the EMR was not voluntary for the residents in this study. There was no other option, therefore all residents, as well as faculty at FMED, used the EMR.

2008 Survey of Residents' Experience with EMR and Future Employment Decisions

This second phase of our research stream is primary focused on one specific mediating factor of the UTAUT theory: prior experience with EMR. Commonly accepted knowledge posits that "Many medical schools and residency programs do not currently employ or train future physicians to use EMR; training the future medical workforce to rely on EMR…can only serve to accelerate universal EMR adoption" Kerr, E. A., 2004). While it may seem intuitive that prior experience would be positively correlated with use, UTAUT does not necessarily predict such a simple, positive, linear relationship.

Use of EMR in Medical School

43.8% of the participants in the 2008 survey process reported using EMR while in Medical School. When broken out between faculty and residents, only one out of the 15 faculty participants (7%) used EMR in Medical School; 13 of the 17 residents (76.5%) used EMR while in Medical School. When asked if the presence or non-presence of EMR had a bearing on their choice of residency programs, 7 of the 13 residents who used EMR in medical school (53.8%) indicated that EMR did influence their choice of residency, all indicating their preference had been for a residency with EMR.

Use of EMR in Family Practice Residency Programs

61.3% of the aggregate used EMR in their residency program. As the residency programs chosen for this pilot study both have adopted EMR, 100% of the resident participants in this study indicated they use EMR in their residency. In comparison, only two of the faculty used EMR while in their residency programs. Of the 19 respondents who indicated that they use, or did use, EMR in their residency programs, 11 (57.9%) report that their residency EMR was very or somewhat user friendly, 2 (10.5%)said it was neither friendly or unfriendly, and 8 (42.1%) indicated their residency EMR was somewhat or very non-user friendly.

Choice of Practice Sites

When asked if the presence or non-presence of EMR had or would influence their choice of first practice sites, 12 in the aggregate (37.5%), nine of which were residents (52.9%) and 3 of which were faculty (20%), indicated that EMR did or would have a bearing on first practices sites. Eleven of these physicians said they preferred practices with EMR, one preferred a practice without EMR. Twenty of the aggregate (62.5%), 8 residents (47%) and 12 faculty (80%), indicated that EMR had, or would have, no impact on choice of first practice sites.

Thus, our 2008 survey of residents and faculty found that though UTAUT predicts a positive relationship between experience with EMR and intention to adopt this technology, for 62.5% of the physicians in this study, that positive relationship may not exist.

The Impact of Culture

Mission, Values, and Priorities

When new strategies are introduced, such as the implementation of EMR or the Quality of Culture initiative at FMED, organization culture must be considered. The success of the use of EMR in the Quality of Culture Project is due, in large part, to its good fit and alignment with FMED's existing organizational culture.

An organization's mission statement embodies the intent and self image of the organization. It delineates the highest goals of the hospital and serves as a road map for strategic direction. Mission and value statements reflect the character, strategic direction, and priorities of the organization (Wiggins, C., Hatzenbuehler, L. C., & Peterson, T., 2008). In specific reference to FMED:

- What is the mission of the organization? FMED's mission is to provide a collegial learning experience through which residents become mature, competent and compassionate family physicians. In an environment characterized by academic, technological and clinical innovation, each learner and teacher is encouraged to pursue a path of individual professional growth and leadership. From public policy advocacy to cutting edge information technology to high-quality, multidisciplinary care for the underserved, we seek and encourage the best in family medicine. At FMED, the mission is to train physicians for successful rural family practice.

- What are the values associated with the organization? FMED's values focus on its being identified as a place where training and learning help to produce a competent and compassionate family physician. Thus, its core activities support the focus on education, learning, and patient centeredness.
- What are the high and low priorities within the organization? High priorities are those activities that are in concert with the organizational values and mission. Actions that offer good fit should receive higher priority. Thus, EMR implementation and quality initiatives offer a good fit with the organizational values at FMED precisely because of its focus on technological innovation to serve patients better. EMR use was mandatory: when the paper file room was cleaned out and changed into office space, it illustrated the high priority placed upon EMR use by FMED.

Organizational Stories

In addition to mission, values, and prioritization, told and retold stories of successes and failures, heroes and villains, underscore culture.

FMED's experiences and the stories that evolved focused on positive patient impacts. FMED physicians commented on the value of EMR adoption in both the 2007 interviews and the 2008 survey. Specifically, the reduction of patient error via e-prescribing, cross checking availability regarding prescription drug behaviors, and the physicians' ability to access patient information from remote computing sites were the most common value added components noted.

FMED physicians interviewed in 2007 and faculty members and residents surveyed in 2008 noted factors that did not add value. These include comments that the software was not user friendly, it was not easy for the physicians to enter data, and that the laptop and the process of data entry created intrusions with patient interaction.

Despite these concerns, nearly unanimous recognition of EMR's value resulted after EMR use was proven to have direct benefits upon patient safety and quality of care. As a case in point, the EMR allowed residents to assess how many female diabetic patients of childbearing age were prescribed potentially teratogenic medications that had high potential for causing birth defects, without documentation of contraceptive counseling. Further, 22% of the population who were prescribed these potentially dangerous medications had been prescribed by a physician outside of FMED. FMED sent a certified letter to these patients strongly recommending that they discontinue the medication and contact their primary care provider. In addition, FMED contacted the primary care providers of these patients and alerted them of the situation.

This story entwined the EMR with FMED's Quality of Culture and was direct evidence that patients' lives were made better because of the EMR and the Quality Project's initiatives. It is important to note that this success story could not have occurred without both the EMR and the Quality project working in tandem.

Leadership Support

Critical to the success of the EMR implementation and the Quality as Culture Project was the role of FMED leaders' support to maintain the culture. To maintain culture, leaders focus on consistent communication, behavior, and evaluation (Swayne, L. E. et al., 2006). At FMED, frequent communication of its priorities existed through IT training efforts and verbal and written communications that underscored the importance of IT implementation for improved patient outcomes. The message was clear: FMED leadership supported the efforts—the IT implementation and Quality as Culture Project were important at FMED.

Strategic Thinking Map

Swayne, Duncan and Ginter's strategic thinking map of value adding support strategies identifies matches (or mismatches) of culture and strategy (Swayne, L. E. et al., 2006).

In the case of FMED, the strategic map was not developed during the strategic planning stage. Rather, we adapted Swayne, Duncan, and Ginter's map to illustrate the match between culture and strategy at FMED. This allows us a method to discuss the importance of culture for strategic success.

FMED's strong organizational culture focused on innovation, effective primary care for the rural patient population, and the education of family practice physicians. EMR implementation and the Quality as Culture Project offered a good fit with the way FMED customarily went about conducting work. Grants were secured to support innovative technological developments such as the EMR; FMED is housed within the University which is a site of continued educational efforts and projects designed for cutting edge efforts. Support strategies and tangential activities that helped ensure success included continuous IT support regarding training and one-on-one guidance. IT personnel paid attention to physician input regarding the set up of forms and data entry. Leaders underscored the importance of the project through behavior that supported the strategy, such as the reduction in patient scheduling for a limited time.

The organizational culture that existed at FMED influenced effective strategic implementation. EMR adoption and The Quality as Culture Project were in sync with the mission and values of FMED.

CONCLUSION

Using UTAUT as a framework for the interpretation of our initial 2007 interview responses from residents provides a lens through which we assessed broad underlying factors for the adoption of EMRs by family practice residents. Residents readily and unanimously agreed that EMRs are beneficial in providing enhanced medical care. The overriding concern voiced by residents, however, was the unfriendliness of the system, represented by requirements to enter excess data and click through multiple forms and screens.

When the respondents of the 2008 survey were asked if the existence of an EMR had or would influence their choice of first practice sites, only 37.5% indicated that EMR did or would have a bearing on first practice sites with eleven of these physicians reporting they preferred practices with EMR, one preferred a practice without EMR. 62.5% indicated that EMR had, or would have, no impact on choice of first practice sites.

Thus, this second phase of our research stream found that though UTAUT predicts a positive relationship between experience with EMR and intention to adopt this technology, for 62.5% of the physicians in this study, that positive relationship may not exist.

Using the concept of organizational culture and assessing its match with strategy, our third phase of research assessing EMR implementation and the Quality of Culture Project at FMED were indeed found to have a good fit with FMED's culture. FMED adopted a three year Quality as Culture Project that focused on the usage of an electronic medical records system that helped create a forum for practice measurement and improvement. The project resulted in FMED's receiving the Award of Excellence from Qualis Health in 2008 as one of the few clinics in the nation that could readily generate reliable clinic data. The match of organizational culture with FMED's mission, values and goals was key for successful strategic achievement.

The residents and EMR at FMED provide an interesting set of conditions that perhaps influence, and certainly warrant, further research. The residents are essentially a cohort group, enabling group dynamics of social influence to impact behavioral intention. In addition, the combination of an organizational culture of quality encouraged and supported EMR implementation and the outcomes evidenced to the residents that they could provide a higher quality of medical care because of the information available with the EMR.

FUTURE RESEARCH

These findings are from the first 3 stages of an on-going stream of research. We find it interesting to note the generally more positive attitudes toward EMRs expressed by this study's participants relative to those presented in others' work. We acknowledge these more positive attitudes may result in part from the fact that EMR capabilities are improving over time, technical competency of several of the respondents, and the degree of participation residents had in configuring the system. Further, the experience of working in an organizational culture that supported HIT may have also added to this positive stance.

TAM and UTAUT have been widely used to study physician's intentions to adopt and use EMR. One of the mediating factors in UTAUT is experience. Our work found that although UTAUT predicted a positive relationship between experience with EMR and intention to adopt this technology, for the population in this study, that positive relationship may not exist. This somewhat unexpected finding requires further investigation in different settings and among different specialties of physicians before any conclusions can be drawn regarding the usefulness or validity of UTAUT and EMR.

Finally, all three phases of our work thus far have been based on one residency and a small sample of family practice residents: caution must be used in generalizing our results to other physicians and other settings. In particular it is important to note that one of UTAUT's mediating variables, voluntariness of use, is not a true variable in our work, in the sense that it is not allowed to vary among our subjects or our research sites. EMR use is required of all residents in all three phases of our research. Indeed, the US federal government intends to require that all healthcare practitioners and facilities use EMR within the next decade, thus any research employing UTAUT to investigate the adoption and use of EMR will soon have the same limitation.

Chapter 4.4

Perceptions of an Organizing Vision for Electronic Medical Records by Independent Physician Practices

John L. Reardon
University of Hawaii, USA

ABSTRACT

Adoption and usage rates of healthcare information technology (HIT) in general and electronic medical records (EMR) in particular are below expectations even though both show potential to help solve pressing problems plaguing the U.S. healthcare system. This research explores the role an organizing vision (OV) (Ramiller & Swanson, 2003) plays in shaping independent physician practices' (IPP) perceptions of EMRs and hence their interest in adopting and using the technology. This paper reports on an OV for EMRs by using a mail survey of IPPs and uses factor analysis to examine structural properties and content of the OV among the practices. Contributions to theory include exploring the applicability of Ramiller and Swanson's (Ramiller & Swanson, 2003) OV on HIT innovations in healthcare research. Contributions to practice include empowering HIT decision makers with a model for addressing the introduction of a technology innovation (EMR) into an independent physician practice.

INTRODUCTION

The Advanced Technology Program (ATP) of the National Institute of Standards and Technology (NIST) promotes using information technology (IT) systems in the healthcare industry as a means to deliver substantial cost savings, to improve the quality of healthcare, and to capture global market share of new and improved products and services (NIST, 2005); the Institute of Medicine (IOM) highlighted IT as integral to improving healthcare (IOM, 2001); and, the U.S. Government in general has promoted increased use of health information technology (HIT) (WHSOU, 2008, 2007) and in particular has outlined a plan that seeks to ensure that most Americans have electronic health records (EHR) by the year 2014 (WHSOU, 2006, 2005, 2004). In addition, Health and Human Services (HHS) Secretary Mike Leavitt recently described how electronic medical records (EMR) can help change the macroeconomics of the way small physician practices are reimbursed thereby facilitating improvement in the delivery of healthcare (Burda, 2008).

Despite these high expectations for the value of IT in healthcare, HIT use in the U.S. is low in the sheer number of adopters as well as in the extent of actual use (Poon et al., 2006; Johnson, Pan, & Middleton, 2002). Studies from the Center for Studying Health System Change (HSC) show wide variation in IT adoption across physician practices, particularly by physician practice setting, size, and specialty. That is, in the 2004 to 2005 timeframe, U.S. physicians in traditional practice settings i.e., primarily solo or relatively small group practices where the vast majority of Americans receive care, reported that their practice generally confined IT use to five clinical function areas: obtaining treatment guidelines (65%), accessing patient notes (50%), writing prescriptions (22%), exchanging clinical data with other physicians (50%), and exchanging information with hospitals (66%) (Cory & Grossman, 2007). Since only those physicians with access to IT for all five of these clinical activities are considered to have an EMR the issue of adopting an EMR based on lack of support is an important issue for small practices. That is, typically the highest levels of IT support for patient care are found in staff- and group-model health maintenance organization (HMO) practices, followed by medical school faculty and large group practices (Johnson, Pan, & Middleton, 2002).

In particular, the adoption and use of EMRs by independent physician practices is well below expectations. For example, in a random survey of nonfederal, office-based physicians providing direct patient care, Burt et al. (2007) found that just 24% of physicians used EMRs in their office-based practices; in a survey of primary care physicians, Menachemi and Brooks (2006) found that 24% overall reported electronic health record (EHR) use in the office; and, in a national, representational survey of physician practices Gans et al. (2005) found that just 14% of practices overall used EMRs. In addition, whereas recent estimates of EMR adoption indicate that the actual number of adoptions has increased from about 105,000 physicians to 130,000 physicians, this increase still represents just approximately 20% of the overall general physician population (iHealthBeat, 2005).

This apparent variation in IT adoption in general and low EMR adoption in particular across the community of independent physician practices, provides a fertile opportunity for research, from both theoretical and practical perspectives. This paper thus reports on a survey of the perceptions of EMRs by independent physician practices by extending the theoretical model of organizing visions as developed by Ramiller and Swanson (2003). That is, Swanson and Ramiller (1997) posit that a diverse inter-organizational community creates and employs an organizing vision of an information system innovation that is central to its early, as well as later, diffusion. In this context, an organizing vision is a 'focal community idea for the application of information technology in organizations' (Swanson & Ramiller, 1997, p. 460). By utilizing the theoretic concept of an organizing vision for IT innovations (Ramiller & Swanson, 2003; Swanson & Ramiller, 2004, 1997) this paper analyzes how small physician organizations perceive the discourse surrounding EMRs in terms of interpretability, plausibility, importance, and discontinuity with existing clinical and administrative practices and technologies. In the next sections of this paper the organizing vision concept and its applicability to EMR adoption is outlined. Next, survey method and findings are described. Finally, a discussion of the implications and future steps in this research are presented.

LITERATURE REVIEW

Electronic Medical Record

In terms of managing information resources in healthcare, the U.S. Health and Human Services Department defines health information technology (HIT) as the comprehensive management of medical information and its secure exchange between health care consumers and providers (HHS, 2008). An electronic medical record (EMR) is a specific example of a HIT that is a computer-based record containing health care information (Tang & McDonald, 2001). This record may contain some, but not necessarily all, of the information that is in an individual's paper-based medical record. Although EMR is the term used signifying the artifact in this study, the concept of a computer-based (or electronic-based) record to manage healthcare information comes by many names depending on specific functional components. In addition, all comprehensive EMR's share several common traits: they all contain large data dictionaries that define their contents; all data are stamped with time and date so that the record becomes a permanent chronological history of the patient's care; the systems have the capability to display data in flexible ways, such as flow sheets and graphical views; and, they have a query tool for research and other purposes (Dick, Steen, & Dether, 1997).

Study Rationale and Significance

There are few theory-based research studies in the area of IT in healthcare (Chiasson & Davidson, 2005) and virtually no theory-based research studies on the process of adoption and assimilation of complex IT in the small organization setting (Lee & Xia, 2006). In addition, most HIT studies, theory based or otherwise, have examined large organizations such as hospitals (Garrets & Davis, 2006; Ash, Gorman, Seshadri, & Hersh, 2002; Doolan & Bates, 2002; Schubart & Einbinder, 2000) or have examined perceptions and use of HIT at the individual-level (Dykes, 2006; Blumenthal et al., 2006; Chau & Hu, 2002). A review of the literature indicates that there are virtually no theory based HIT studies at the small physician organization level. It is thus unclear if theories developed at the large organizational level or at the individual level apply equally well at the small organizational level.

Prominent specific factors contributing to low EMR adoption rates in small, independent physician practices include cost, lack of financial incentives, and an immature EMR software market (Ash & Bates, 2005). Likewise, beyond the apparent adoption of EMRs, actual use of EMRs in clinical practice is of concern because little is known about why some physician practices ultimately use an EMR successfully, despite high barriers to adoption and assimilation, while others do not (Ash & Bates, 2005). It is evident that unless IT applications are effectively assimilated into small physician practices in ways that improve overall healthcare, benefits such as decrease in errors, increase in cost savings, and better results in clinical outcomes will be limited to mere incremental, automation improvements (Broder, 2005). Therefore, a better understanding of those factors that facilitate or hinder the adoption and assimilation of EMRs in physician practices is a key to achieving substantial healthcare improvement though HIT.

The issue here is to select those theories or models that enhance our understanding of EMR adoption and assimilation patterns. To that end, the unit of analysis in this study is the independent physician practice as an organization and not the physician as an individual adopting a technology innovation. As such, an individual-based method of analysis such as the Technology Acceptance Model (TAM) (Venkatesh, Morris, Davis, & Davis, 2003) would be less useful than an organizational-based one as an EMR is an organization-wide system. That is, although the physician-owner of a practice may serve as the key decision-maker in the adoption of IT, it is not feasible that this one individual would adopt and use an EMR but associated professional and administrative staff would not, or visa versa. Therefore, the adoption and use of an EMR is best considered an organization-based decision and not an individual-based one.

The problem here is that determining just how an organization i.e., independent physician practice, goes about developing a collective understanding of an IT innovation such as an EMR is not an easy task to accomplish. An organization requires help in reconciling different interpretations and conceptualizations of the innovation that may be held by members of the organization. It is suggested that by employing the theoretical model of an organizing vision (Ramiller & Swanson, 2003), a relatively small, independent physician practice may reconcile the varied individual meanings and invented or contrived ideas surrounding an innovation. The physician organization can then better position itself to decide if adoption and use of the innovation is truly in the organization's best interests.

Organizing Visions of IT Innovation

Individuals and organizations often first learn about an innovation such as an EMR through a community-wide discussion and discourse before an adoption and use decision is made. Swanson and Ramiller (1997) posit that a diverse, inter-organizational community creates an organizing vision (OV) of an information system innovation through its community-wide discussion and discourse, and that this vision is important to early, and late diffusion of the information system. Furthermore, Swanson and Ramiller (1997) define an OV as the focal community idea for the application of information technology in organizations. This focal community coalesces in the inter-organizational field. As such, the OV becomes the community's vision for organizing in a way that embeds and utilizes new IT in organizational structures and processes (Swanson & Ramiller, 1997).

The concept of an OV thus helps to explain how information system innovations originate, develop, and diffuse over time, across firms and industries. This vision serves key functions in interpretation, legitimation, and the organization and mobilization of economic roles and exchanges. In essence, a community's discourse serves as the developmental engine for an OV. Within this community additional factors such as business commerce, the IS practitioners' world view, the motivating business problem or objective, the core technology, and material processes of adoption and diffusion help to provide the discourse with its content, structure, motivation, and direction.

A key aspect of an OV is that it has a "career" over which it varies substantially in visibility, prominence, and influence. For example, previous OV research was used to identify and characterize new types of information systems such as application services provisioning (ASP) and customer relationship management (CRM). To illustrate, Currie (2004) found that over time the initial discourse surrounding the OV of ASP was replaced by skepticism and distrust as powerful institutional interests in the form of leading technology firms, industry analysts, and IT consultancies were ultimately unsuccessful in their attempts to disseminate ASP across wider business and not-for-profit IS user communities. Currie's research indicates that a process-oriented analysis of how OVs are interpreted, legitimized, and mobilized is critical to understanding and explaining how underdevelopment of an OV at an early stage may inhibit its later adoption and institutionalization. Likewise, Firth (2001) used the analysis of the OV as a tool to trace the diffusion of a CRM system as an IS innovation and found that by creating, participating, and being influenced by the CRM discourse, managers do not operate in a vacuum when they consider whether to adopt and implement a CRM system. These studies are of value because they illustrate that even as an OV helps shape how managers think about the future application and practice in their field, the OV nonetheless still struggles to achieve ascendancy in the overall community (Swanson & Ramiller, 1997).

Swanson and Ramiller (2004) address this struggle to achieve ascendancy by positing that different types of organizations will respond differently to an OV. For example, some organizations respond "mindlessly" to join the "bandwagon" to adopt an innovation whereas other organizations more purposefully evaluate the innovation's appropriateness for their own situation. Swanson and Ramiller (2004) also suggest organizations respond differently at different stages in the OV "career." That is, organizations may be more inclined to accept an innovation uncritically in the early stages, when little is known about the innovation, especially so if the OV is powerfully presented in the discourse community. To illustrate, in an exploratory study of the structural aspects of organizing visions, Ramiller and Swanson (2003) investigated how information systems (IS) executives responded to OVs that are in different career stages. By using field interviews and a survey Ramiller and Swanson identified four dimensions of executive response that focused on an organizing vision's *interpretability*, *plausibility*, *importance*, and *discontinuity*.

Interpretability reflects how intelligible and informative the executive found the representations of the OV in its associated public discourse. Interpretability revolves around such aspects as clarity, consistency, richness, and balance. *Plausibility* focuses on distortions in the discourse, emphasizing in particular the burdening of the OV with misunderstandings, exaggerations, and misplaced claims. Items contributing to plausibility are suggestive, on one hand, of honest confusion and basic lack of knowledge and, on the other hand, of the calculative and even deceptive exploitation of the OV. *Importance* brings together a diverse set of judgments. That is, importance implies the power of influencing or the quality of having evident value either generally or in a particular relation and often by merely existing. Importance is further categorized into three sub-dimensions *business benefit*, *practical acceptance*, and *market interest*. Business benefit concerns a "bottom line" understanding i.e., to what extent does the innovation contribute to a value chain or return on investment? Practical acceptance concerns an innovation that may be characterized more by technology push, than by need pull. That is, whether the innovative concept transfers well to practical application may still be an open question thus undermining the sense of its basic importance. As such, the vision may be a "hard sell" to management, and its practical acceptance may be weak. Market interest concerns the extent to which market signals are substantively informative such that a relative lack of market interest may reflect real and persistent problems of practical acceptance. In essence, the notion that an innovation is or is not worthy of the community's interest, and accordingly its attention, is fundamentally tied to the vision's received importance. Finally, *Discontinuity* consists of two concepts: conceptual discontinuity i.e., how great a departure from existing ideas and notions of existing technologies does the OV pose; and structural discontinuity i.e., how much difficulty is entailed in implementing the new innovation. These four dimensions thus form the underlying structure of an OV and are examined in this study.

By taking a comparative approach, Ramiller and Swanson's (2003) study offers several grounded conjectures concerning the career dynamics of an OV. For example, Conjecture 5 states: "Supporters and detractors will not differ from the community's majority, on the average, in their evaluation of the discontinuity of the organizing vision" (Ramiller & Swanson, 2003, p.36). This is of value because for a managerial decision maker, an IS executive in their case, the findings point the way to a more proactive, systematic, and critical stance toward innovations that can place the executive in a better position to make informed adoption decisions. Likewise, an understanding of the OV surrounding EMR technology may help place the physician practice in a better position to make informed EMR adoption and use decisions. Also, if policy makers such as government officials, professional associations, and healthcare organizations who want to promote EMR adoption understand how physicians perceive the OV surrounding EMRs, they can then take steps such as general education and directed continuing medical education (CME) to better effect such promotion. In addition to policy makers vendors can also better understand how to promote products. Additional resources such as consultants and implementation guides that are mobilized through the OV may similarly provide substantial benefit from which organizations may draw as they undertake adoption and assimilation of the complex organizational technology.

The potential benefits of EMR adoption, there is some common knowledge and trade press level coverage of purported barriers to EMR adoption such as initial cost of investment, return on investment, and decrease in productivity (Havenstein, 2006), but much less scientific examination into those barriers. Since adopting and assimilating EMR technology in an independent physician practice is an important undertaking, it is imperative that the decision to adopt adequately address such issues as investment costs, operational and procedural changes, and market support. When the innovation is new, or when the adopter population is not familiar with the innovation, community-level discourse about the innovation serves an important role in informing and persuading potential adopters on such issues. In the case of EMRs, although the technology has been available for some time the rate of adoption remains low among small independent physician practices (Callahan, 2007). This paper suggests that the OV for EMRs also contributes to the low rate of adoption. As a first step in investigating this possibility, this study explores organizational decision-makers' perceptions of the EMR OV using Ramiller and Swanson's (2003) institutional reception variables of interpretability, plausibility, importance, and discontinuity in independent physician practices.

RESEARCH METHOD

To empirically evaluate independent physician practices' reception of the OV for EMRs, a mailed survey following procedures outlined in Dillman (2000) was conducted to include the following major steps: a brief pre-notice letter; an initial questionnaire; a thank you and reminder postcard; a replacement questionnaire; and, a final contact. The mailing list for an independent physicians association with approximately 780 physician members was used. The endorsement of the association's leadership and their sponsorship of the survey helped assure a good response rate as physicians are typically noncompliant to surveys (Olson, Schneiderman, & Armstrong, 1993). The unit of analysis in this study is the physician organization; therefore it was determined that although the association is overwhelmingly made up of solo practitioners the 780 individual physician members were grouped into 567 separate independent practices (organizations). To determine which physicians practice together as a single organization, information in the practice association databases (for example, the same address and phone number), online sources of licensing information, and calls to office staff to verify practice arrangements were used. Membership in these 567 clearly distinct and separate physician practices ranged from a minimum of just one physician to a maximum of 18 physicians with an average practice size of two physicians. Overall practice sizes (consisting of physicians and staff members) ranged from a minimum of two (just the physician and a staff member) to a maximum of 54 (physicians and staff members) with an average overall size of six members. As surveys were uniquely addressed to the practice and each physician member was identified as belonging to just one unique practice organization there were no cases of double counting of results.

Over the course of mailings to the 567 physician organizations, 302 or 53% were not returned, 54 or 10% were returned but respondents declined to participate, 32 or 6% were marked by the U.S. Post Office as "return to sender" (due to reasons such as retired, deceased, moved out of state etc.), and 179 or 32% were returned apparently complete to use for analysis. Out of the 179 returned and apparently complete 15 were deleted due to partial responses, ambiguous responses, or other reasons. The resulting 164 responses or 29% were utilized for this analysis in a confirmatory factor analysis to determine the extent to which the OV perceptions of interpretability, plausibility, importance, and discontinuity affect the perceptions of EMR technology by small, independent physician practices.

Of the physicians responding to the survey, the majority (63%) of physicians operates an urban practice (in Honolulu), 26% operate suburban practices, and 11% operate rural practices (on neighbor islands or rural parts of Oahu). About 23% operate more than one office location or work in a clinic as well as in their own office(s). The majority (57%) have patient panels of less than 4000, indicating both the small size of practices and the predominance of solo practices. Respondents covered a wide range of medical specialties with most in general practice, family practice, internal medicine, or pediatrics. This distribution of practice demographics is consistent with the overall make-up of the independent physician association membership.

The OV items used in this study were adapted from Ramiller and Swanson (2003) by placing them in the context of healthcare in general and EMR technology in particular. A draft of the survey was discussed with a number of healthcare experts to elicit feedback on wording and format. The healthcare experts included the executive director of the independent physicians association; the Chair, Care Improvement Committee of the independent physicians association; members of the Health Information Management Systems Society (HIMSS), Hawaii Chapter; a registered nurse familiar with HIT and EMRs; and, a colleague who had prior research and publication experience in HIT and EMRs. Comments and suggestions from these individuals contributed to updating the survey with respect to improving survey question wording and formatting issues. A comparison of questions as originally used in the Ramiller and Swanson (2003) factor analysis and as adapted for this paper is illustrated in the Appendix.

A copy of the updated draft of the survey was subsequently administered to two practicing independent physicians (results from these two physicians were not included in the survey results) where additional feedback was obtained to include the approximate time to complete the survey. In particular, the two physicians were asked to help support the development of the survey by accomplishing the following:

Complete the survey as they would if the answers affected their unique independent practice (not as an individual and not as a staff member of a Hospital or other large scale healthcare institution);

Identify any questions that were so ambiguous or nebulous that they needed rewording;

Write-in questions or comments that they felt were important to include but were not addressed in the given survey question format;

Provide feedback with respect to the overall appropriateness of the types of questions, number of questions, and approximate survey length i.e., time to complete the survey

Feedback from the individuals identified above were subsequently incorporated into the final version of the survey

FINDINGS

In this section the results of the survey of physicians' perceptions of the EMR organizing vision and findings from a confirmatory factor analysis are presented. In addition, content validity was maximized using an iterative process in developing the questionnaire. Prior use of the OV dimensions and subsequent experts' opinions in the development stage of the survey helped to refine the questionnaire. Also, validity and reliability were strengthened by using an extensive literature review of surveys in healthcare in general and prior OV research in particular to help develop the wording of the questionnaire and by perfecting the questionnaire using feedback from the two physicians identified earlier. For example, previously validated instruments concerning various aspects of EMR adoption and use were reviewed such as: attitudes toward implementation of an EMR (Jacob, 2003); effects on patient care (Marshall & Chin, 1998); measurement of physicians' use of, knowledge about, and attitudes toward computers (Cork, Detmer, & Friedman, 1998); EMR use and outpatient encounters (Gadd & Penrod, 2001, 2000; Penrod & Gadd, 2001); users vs. nonusers of EMRs (Loomis, Ries, Saywell, & Thakker, 2002); and, family practice residents perspective on use of EMRs (Aaronson, Murphy-Cullen, Chop, & Frey, 2001). Reviewing these previously validated instruments helped with rewording the original questions used by Swanson and Ramiller (2003) to the wording of the questions used in this study (see Appendix).

Factor Analysis

Confirmatory factor analysis (CFA) requires *a priori* designation of plausible factor patterns from previous theoretical or empirical work. These plausible alternative models are then explicitly tested statistically against sample data (Comrey & Lee, 1992). As such, following prior exploratory factor analysis work of Ramiller and Swanson (2003) and using communality estimates of one, a principal axis factor analysis was run using SPSS (version 14) to determine the legitimacy of the underlying structure of the OV model based on eighteen OV items. Responses to items 2, 4, 6, 7, 11, and 13 were reverse-coded (rc) prior to conducting the factor analysis so that the item under study would contribute in a consistent positive way to the survey coding category with which it was initially associated.

Table 1 presents the detailed results of the factor analysis. Anti-image, KMO, Bartlett's test of sphericity, and a scree plot were obtained and Varimax was used for the group method. These selections were used to produce a solution using principal axis factoring extraction, which was then given a Varimax rotation. Eigenvalues of the correlation matrix were obtained in both table and scree plot form. Consistent with the research model and prior OV research by Ramiller and Swanson (2003), a four factor solution was chosen for analysis. The Kaiser-Meyer-Olkin Measure of Sampling Adequacy measured 0.829, relatively high, so a factor analysis is indeed useful with the data. Bartlett's test of sphericity in this case was Sig. = 0.000, so the variables in this study are related and therefore suitable for structure detection.

In this analysis four factors in the initial solution have eigenvalues greater than 1 and together accounted for almost 56% of the variability in the original variables and this indicates that four latent influences are associated with the data. The Extraction Sums of Squared Loadings indicates the variance explained by the extracted factors before rotation such that the cumulative variability explained by the requested four factors in the extracted solution is about 44%, a difference of 12% from the initial solution. Thus, 12% of the variation explained by the initial solution is lost due to latent factors unique to the original variables and variability that simply cannot be explained by the proposed factor model. Cronbach's alpha in

this study measured 0.698 and is considered acceptable at the general level of 0.70 (rounded).

Interpretation of Factors

In essence, a factor analysis seeks to answer two basic questions: How many underlying variables, or factors, are there? What are the factors? (Kerlinger & Lee, 2000, p. 828). In general the data analyzed here support the findings outlined in Ramiller and Swanson (2003) of four factors. In particular, in selecting a threshold value of 0.600 for factor loading criterion, *Interpretability* reflects how intelligible and informative the independent physician practice finds the representations of the OV. As Table 1 indicates, *interpretability* seems to correlate with Factor 4 and with item 1 with factor pattern coefficient of 0.679.

Plausibility complements interpretability. That is, both support qualities of the community discourse that builds and sustains the OV. The difference is that interpretability concerns the intelligibility and informativeness of the discourse whereas plausibility focuses on distortions in the discourse. Plausibility further emphasizes the burdening of the OV with misunderstandings, exaggerations, and misplaced claims. As Table 1 indicates, *plausibility* seams to correlate with Factor 2 and with item 6 with factor pattern coefficients of 0.630.

Importance brings together a diverse set of judgments exemplified by the three sub-dimensions of *business benefit*, *practical acceptance*, and *market interest*. As Table 1 indicates, *importance* seams to correlate with Factor 1 and with items 8, 9, 10, and 12 with factor pattern coefficients of 0.791, 0.692, 0.722, and 0.601, respectively.

Discontinuity consists of two dimensions. *Conceptual Discontinuity* indicates how great a conceptual departure does the OV pose to the independent physician practice whereas *Structural Discontinuity* indicates how difficult would it be for the independent physician practice to actually implement the technology. As Table 1 indicates, *discontinuity* seams to correlate with Factor 3 with items 16 and 17 with factor pattern coefficients of -0.675 and -0.697.

In general, a simple or clean factor structure is evident when each item in a factor analysis loads highly on one factor and lowly on other factors. Discounting for the 0.600 threshold value for factor loading criterion and utilizing a 0.400 threshold, clearly the data here suggest that the OV construct of *interpretability* appears to load on both Factors 2 and 5; *plausibility* appears to load on both Factors 1 and 2; *importance* appears to load on Factors 1, 2, and 3; and, *discontinuity* appears still to load on just Factor 3. This less than pure factor structure may be explained by the fact that this survey was the first attempt at applying the OV to a healthcare information technology innovation. As such, subsequent research may yield a simpler, or cleaner, factor structure.

Descriptive Analysis of the Survey

For each of the 18 OV Likert scale-based items (Babbie, 2005) used in the survey, the corresponding OV dimension, number, and percent of respondents are indicated in Tables 2 thru 5.

Table 2. Survey items on Interpretability **(***numbers vs. % where 1=strongly disagree vs. 7=strongly agree and status with respect to basic premise of the item i.e., disagree, neutral, or agree)*

That is, item number 1 “Useful information on what EMRs can do is easy to come by” falls under the Interpretability OV dimension. This OV item yielded 42 or 26% of respondents indicating neither disagreement nor agreement and 38 or 23% indicating somewhat agree. In addition, Tables 2 thru 5 also indicate an overall general summary measurement of respondents’ status with respect to the basic premise of the item i.e., disagree, neutral, or agree. To illustrate, with respect to item number 1 under interpretability, respondents generally disagree that useful information on what EMRs can do is easy to come by. That is, discounting the 42 neutral responses of choice #4, there were 65 disagree responses (sum of choices #1, #2, and #3) versus 57 agree responses (sum of choices #5, #6, and #7) yielding a slight overall disagreement with the premise of item number 1. Likewise, for item number 2, respondents agree that finding a good balance of information on the pros and cons of EMRs is difficult; for item number 3 respondents disagree that key players in physician professional associations (AMA, AAFP, etc) have been heard loud & clear concerning EMRs; and, for item number 4, respondents agree that there are aspects of EMRs that you cannot easily grasp. These results are important because they are consistent with prior research in that physician practices identified the following variables as sources of information when conceptualizing the EMR: relying on a uniform set of sources to obtain information on EMRs; reviewing the literature; attending conferences or trade shows; consulting respective specialty societies (e.g., AAFP); speaking with peers and colleagues; and visiting independent or reference sites (Rippen, 2006).

With respect to plausibility, respondents generally disagree that EMRs will be adopted and used by independent physician practices faster than many people seem to think; agree that a lot of what they've heard about EMRs seems like exaggerated claims; and agree that what EMRs really consist of is widely debated. These results are consistent with prior research in that physician practices identified a lack of robust empirically derived evidence on the costs and benefits associated EMR adoption and existing cost-benefit studies based on simulation models that rely on expert opinion and extrapolation from literature sources as reasons to doubt the plausibility of EMR success (Rippen, 2006).

With respect to the business benefit of importance, respondents to this survey agree that in theory EMRs offer a tremendous opportunity to deliver value to a practice, that EMRs make doable some wonderful things that were previously only dreamed of, and that a practice that waits too long to use an EMR is going to fall behind its peers. These results are of value because they are consistent with prior research in terms of perceptions of business variables in the adoption and implementation of EMRs. For example, Rippen (2006) found that for small physician offices, major perceived barriers to EMR implementation include lack of capital investment, maintenance costs, complex contracts, and lack of time whereas major perceived benefits to EMR implementation include improved charge capture, reduced transcription costs, reduced staff expenses, and increased revenues. With respect to practical acceptance of importance, respondents to this survey agree that the push for EMRs comes mainly from parties with something to sell. However, respondents are neutral about EMRs as solutions that have found the right problems to solve and their transfer to the "real world." These results are significant because they are consistent with prior research in terms of experience in actual practice with respect to EMR adoption. For example, Cimono et al. (1999) identified issues of cognitive overload, disorientation, and blind acceptance of information and recommendations from an EMR as barriers to effective adoption. With respect to the market interest of importance, respondents to this survey agree that the health care market still has a considerable interest in EMRs. This result is important because it is consistent with prior research as indicated by the level of general interest in the physician community in wireless access to EMRs. That is, a Medical Records Institute survey indicates increased use of WiFi, WWAN (digital and analog), and WPAN wireless connectivity, with WiFi most used (Medical Records Institute, 2007).

With respect to discontinuity, respondents agree that EMRs call for a fundamentally different way of thinking about a private practice from clinical perspectives and that EMRs seem to require some kind of health information technology wizard to get it all to work out but disagree that using EMRs basically turns a private practice upside down or that complexity of running a private practice decreases significantly when an EMR is implemented. These findings are supported by prior research that indicates that the combination of increasingly sophisticated functionality, including improved user-interfaces, increasing numbers of successful implementations, growing consumer expectations for information accessible via computer-based systems, and increased physician (i.e., end-user) awareness of functionality and benefits must occur before more widespread adoption of EMRs will take place (Meinert, 2005).

Interpretation of Survey Items

With respect to interpretability, item responses indicate that stakeholders (i.e., governmental agencies, insurance companies, software vendors, training companies, and professional organizations etc.) need to do a better job at presenting the representations of the EMR before an independent physician practice would find the OV clear, consistent, rich, and balanced enough to adopt an EMR.

For example, the U.S. Government could provide more support to the independent physician practice other than merely stating that by computerizing health records, dangerous medical mistakes can be avoided, costs can be reduced, and care can be improved (WHSOU, 2004). Likewise, insurance companies could do more to better present the overall benefit to physicians of using an EMR as many physicians perceive the practical benefits of using an EMR favor insurance companies and not the physician practice (Guadagnino, 2005).

Results also indicate that stakeholders need to do a better job at communicating the apparent validity (plausibility) of the EMR concept before a practice would find the misunderstandings and exaggerations of the OV minimized enough to adopt an EMR. Whereas results indicate that physician practices basically find the OV influential (important), results are some-what mixed on discontinuity. That is, the OV poses a significant conceptual departure from existing mental schemas, and respondents are split on how much difficulty the OV suggests in actually adopting an EMR.

Additionally, although the physician practices surveyed appear to find EMRs important, stakeholders need to do a better job increasing physician practice perceptions of interpretability and plausibility while decreasing discontinuity. That is, a key aspect of an OV is the career over which it varies substantially in visibility, prominence, and influence. The data here suggest that the concept of an OV is still in the process of shaping the opinions of the key IT decision maker in independent physician practice organizations. That said the data do help to clarify the extent to which an OV on EMR technology has attained importance in this physician community. In fact, it is suggested that as the career of the OV progresses to a point of strongly positive perceptions held by physician practices then many of the apparent barriers to adoption and assimilation of EMRs would dissipate and more physician practices would ultimately adopt and use an EMR.

LIMITATIONS OF CURRENT RESEARCH

Dillman (2000) cites four sources of survey error: measurement, sampling, coverage, and nonresponse. Measurement error is the result of poor question wording or questions presented in a way that either inaccurate or un-interpretable answers are obtained. By obtaining feedback on survey questions from professionals in the field such as physicians and other healthcare professionals it is believed that the potential for measurement error has been reduced.

Sampling error is the result of surveying only some, but not all, elements of the survey population. The unit of analysis in this research was the independent physician practice in one state in the United States. Physicians in Hawaii may differ in significant ways from physicians in other states, such as ethnic makeup of the population and percentage of small practices. The state has approximately 4,000 practicing physicians. Approximately 780 of these physicians belong to the independent physicians association (IPA) surveyed. This IPA is not representative of all physicians in Hawaii, but it is believed that this group is typical of the adopter population in this study.

Coverage error is the result of not allowing all members of the survey population to have an equal or known nonzero chance of being sampled for participation in the survey. All IPA member contact information was available for use and given that only 32 out of 567 surveys, or 6%, were returned by the U.S. Postal Service as “return to sender” it is believed this return rate limits the potential for coverage error.

Non-response error is the result of individuals who respond to the survey who are different from sampled individuals who did not respond, in a way relevant to the study. It was not possible to assess demographic differences within the practice association among respondents and non-respondents. The rate of EMR adoption reported by the respondents (24%) suggests a slight bias towards EMR adopters, compared to national surveys of EMR adoption rates. Thus, the data may present a more positive reception for the EMR OV.

In addition, the survey asked that the physician most responsible for making decisions concerning the IT used in the practice complete the survey. At the end of the survey a question asked who actually completed the survey. Response categories and corresponding number of respondents are: physician (149), nurse (1), office manager (9), office staff member (2), IT staff member (1), and other (2). Following up with those practices where a practice member other than a physician completed the survey, responses indicated that each such practice discussed the survey with the physician members so the responses on the survey are considered representative of the views of the physician members and hence the organizations. In addition, in no instance were multiple surveys submitted by a single practice as each individual member and each practice grouping were clearly identified prior to mailing of the survey and each survey was numbered to indicate recipient. Finally, confirmatory factor analysis results should be taken with a grain of salt (Dillman, 2000) as the criteria used to evaluate overall goodness-of-fit and model design are relative, not absolute--there simply are really no well-defined cutoff values for evaluating model data fit or even the existence of higher-order constructs.

FURTHER RESEARCH

It is suggested that the OV for EMRs is a work in progress in motivating the physicians sampled in this study to overcome their hesitance to adopt in the face of very practical barriers like up-front investment costs (Groves, 2007). The 18 item survey developed in this research may be useful for additional assessments of physicians' perceptions of EMR technology and to evaluate whether the "career" of the EMR OV is progressing towards greater acceptance or is declining towards skepticism i.e., as measured by degree of agreement or disagreement with the various OV questions. In addition, further refinement of the questions may be needed to produce a more factorially pure model. That is, the questions used for this survey were adapted from Ramiller and Swanson (2003) as the Appendix illustrates. Those original questions were developed by Swanson and Ramiller for information technology managers and general information technologies i.e., computer-aided software engineering (CASE), client-server computing, and electronic commerce. As the present survey concerns a health information technology, the EMR, and as the present survey was directed at non-information technology managers i.e., physician practices, it is suggested that perhaps some of the questions may not translate very well to the healthcare setting. It could turn out that questions concerning cost to include acquisition and on-going maintenance, workflow performance, and treatment outcomes might weigh more heavily than those questions as posed in the current research. Further exploration of these issues might yield a better crafted survey in which to elicit perceptions of an OV for EMRs by physician practices.

Despite some shortcomings in the survey items themselves, overall survey results are expected to be useful in the next steps of investigating the adoption and assimilation of EMRs by small independent physician practices. That is, a logical next step is to consider whether the physicians' reception of the EMR OV predicts the likelihood of actually adopting an EMR. This may be accomplished in two ways. First, an analysis indicating if a positive perception along any of the OV dimensions is significantly associated with the organization's decision to adopt an EMR. Further research could indicate if there is a significant relationship between an OV dimension and a practice's adoption of an EMR. Second, further analysis may reveal if any of the OV dimensions is associated with the physician's stage of assimilation i.e., actual use, of an EMR. To illustrate, assimilation may be defined as a scale from awareness, thru interest, active investigation, and preliminary adoption, to full assimilation (Fichman & Kemerer, 1997; Cooper & Zmud 1990; Meyer & Goes, 1988; Ettlie, 1980). Identifying a scale of assimilation is important because one needs to differentiate between the mere adoption of a technology and the actual use of that technology. For example, Fichman and Kemerer (1999) developed a general operational measure derived from the difference between cumulative IT acquisition and deployment patterns to introduce the concept of *assimilation gap* i.e., the difference between mere IT acquisition and actual deployment of that IT. Fichman and Kemerer observed that cumulative adoption patterns vary depending on which event in the assimilation process, acquisition or deployment is considered the actual adoption event. This concept of assimilation gap suggests that although 20% of the overall general physician population in the U.S. may have indicated they have acquired EMRs (iHealthBeat, 2005), this does not necessarily imply widespread assimilation as there is no research (theory-based or otherwise) indicating to what extent actual deployment of EMRs has occurred. Therefore, the concept of assimilation gap is of value because there is the danger that mere EMR adoption statistics might equate to deployment thereby yielding an incorrect and inaccurate picture of overall EMR system usage.

Finally, although this research suggests that the analysis of the perception of the EMR OV provides useful insight into the perceptions of EMRs among small physician practices, it is recognized that many other factors are also influential. For example, additional research may investigate whether small practices differ significantly in terms of their ability to overcome the learning barriers that EMR adoption represents, and if so, whether the development of community resources can assist physician practices that are not as adept as the minority of practices that have successfully integrated EMR use into their clinical practices. It is believed that the EMR OV may play a role in this process, as the community discourse represents an important resource of composite learning and experience with EMR implementation developed within the discourse community.

CONCLUSION

In the U.S., there is increasing regulatory and economic pressure on healthcare providers to adopt health information technologies to address such issues as cost, quality and access to healthcare. It is believed that the adoption of health information technology in general and electronic medical records in particular by small physician practices is a key step to achieving such goals. However, potential adopters have been slow to embrace EMRs (Havenstein, 2006; Loomis, 2002). This research used a survey of physician members of an independent physicians association. The target sample was representative of independent physician practices in the state. Individuals from this group responded to a questionnaire adapted from prior organizing vision research (Ramiller and Swanson, 2003). Confirmatory factor analysis was applied to the resulting data set and yielded a four factor model consisting of interpretability, plausibility, importance, and discontinuity and results are consistent with prior organizing vision research by Ramiller and Swanson (2003). A descriptive analysis of these four constructs indicates that the organizing vision for EMRs is still working its way through the target population. That is, for interpretability, although respondents agree that finding a good balance of information on the pros and cons of EMRs is difficult and that there are aspects of EMRs that you cannot easily grasp, respondents disagree that useful information on what EMRs can do is easy to come by and that key players in physician professional associations (AMA, AAFP, etc) have been heard loud & clear concerning EMRs. For plausibility, respondents agree that a lot of what has been heard about EMRs seems like exaggerated claims and that what EMRs really consist of is widely debated, respondents disagree that EMRs will be adopted and used by independent physician practices faster than many people seem to think. For importance, although respondents agree that EMRs offer a tremendous opportunity to deliver value to a practice, that EMRs make doable some wonderful things that were previously only dreamed of, that a practice that waits too long to use an EMR is going to fall behind its peers, that the health care market still has a considerable interest in EMRs, and that the push for EMRs comes mainly from parties with something to sell, respondents are neutral that EMRs are solutions that have found the right problems to solve and that EMRs don't transfer well to the real world. For discontinuity, although respondents agree that EMRs call for a fundamentally different way of thinking about a private practice from clinical perspectives and that EMRs seem to require some kind of health information technology wizard to get it all to work out, respondents disagree that using EMRs basically turns a private practice upside down and that complexity of running a private practice decreases significantly when an EMR is implemented. Overall, results are significant because they illustrate that the perceptions of the organizing vision for EMRs are not quite yet fixed. That is, the notion that an organizing vision's career is by turns ascendant and descendant is tied to the level and tenor of the discourse surrounding it. In addition, an organizing vision's career is tied to a particular level of maturity i.e., a youthful and undeveloped vision may or may not achieve ascendance, whereas a older and established vision, once having achieved ascendance, ultimately faces decline. Against this broader life cycle, an organizing vision may also undergo smaller fluctuations in prominence i.e., multiple ups and downs, over its career (Ramiller & Swanson, 2003, p. 16).

In essence, results from this study address one aspect of the ways in which small physician practices respond to a community discourse, or organizing vision, related to EMRs. Empirical findings suggest that, among physicians surveyed, EMRs are now perceived as an important innovation for physician practices, but questions about the interpretability, plausibility and discontinuity of this innovation remain. It is hoped that this research contributes in practical ways to the effective utilization of IT in healthcare settings and to the refinement of theory-based information systems research applied in the healthcare industry.

APPENDIX: COMPARISON OF SURVEY QUESTION CONSTRUCTION

Ramiller & Swanson (2003)	**Survey**
Interpretability	
1 Good information on ___ is hard to come by.	1 Useful information on what EMRs can do is easy to come by.
2 Finding a good balance of different perspectives on the ___ concept has proven difficult.	2 Finding a good balance of information on the pros and cons of EMRs is difficult. [rc]
3 Key players in the industry are yet to be heard from concerning ___.	3 Key players in physician professional associations (AMA, AAFP, etc) have been heard loud & clear concerning EMRs.
4 There are aspects of ___ that you can't really get your fingers on.	4 There are aspects of EMRs that you cannot easily grasp. [rc]
Plausibility	
5 ___ is not going to happen as fast as many people seem to think.	5 EMRs will be adopted and used by independent physician practices faster than many people seem to think.
6 A lot of what I've heard about ___ seems like hype.	6 A lot of what I've heard about EMRs seems like exaggerated claims. [rc]
7 What ___ really consist of is widely debated.	7 What EMRs really consist of is widely debated. [rc]
Importance	
8 ___ offer a tremendous opportunity to deliver business value.	8 EMRs offer a tremendous opportunity to deliver value to a practice.
9 ___ make do-able some wonderful things that were previously only dreamed of.	9 EMRs make doable some wonderful things that were previously only dreamed of.
10 The company that waits to do ___ is going to fall dangerously behind.	10 A practice that waits too long to use an EMR is going to fall behind its peers.
11 The push for ___ is coming mainly from parties with something to sell.	11 The push for EMRs comes mainly from parties with something to sell. [rc]
12 ___ is a solution still looking for the right problems to solve.	12 EMRs are solutions that have found the right problems to solve.
13 ___ doesn't transfer well to the real world.	13 EMRs don't transfer well to the real world. [rc]
14 The market has lost interest in ___.	14 The health care market still has a considerable interest in EMRs.
Discontinuity	
15 ___ calls for a fundamentally different way of thinking.	15 EMRs call for a fundamentally different way of thinking about a private practice from clinical perspectives.
16 ___ seems to require some kind of wizard to get it all to work out.	16 EMRs seem to require some kind of health information technology wizard to get it all to work out. [rc]
17 Doing ___ basically turns an organization upside down.	17 Using EMRs basically turns a private practice upside down.
18 Complexity increases significantly when you undertake ___.	18 Complexity of running a private practice decreases significantly when an EMR is implemented.

Note: Under the Ramiller & Swanson questions the "___" represents the following IT: CASE, client-server, and E-commerce.

ABSTRACT

The role of information technology (IT) in managing disasters is increasingly being recognized. The Healing Touch project was started after the tsunami disaster in Tamilnadu to address the healthcare needs of the survivors through IT. Specifically, it provided mental health support to the victims near their place of residence. This project has been different from other telemedicine projects because:

- It was sponsored and managed entirely by NGOs.
- The local community and local NGOs were directly trained to manage there own health problems after the natural disaster.
- Success was linked to the intensive pre and post execution work done.

We believe that preparation and involvement of people is the key to success in most IT projects. Some problems we faced were related to a general lack of awareness and nonpenetration of IT in the community we served. If people are using IT in their day to day work, adoption of telemedicine and other e-services will be far simpler after a disaster.

BACKGROUND

"E-Health will completely change health care," says Kendall Ho, who heads the U21 committee (http://www.innovations-report.com/html/reports/medicine_health/report-50033.html) for e-health. "It is one of the fastest-growing fields of health care today, giving undreamt-of opportunities for us to spread our medical knowledge to the whole world."

SATHI is a nongovernment organization (NGO) based in New Delhi and consists of experts from the fields of health, IT, and telecommunications. They provide consultancy services in the fields of telemedicine and healthcare informatics. Their members (see Acknowledgments for a list of the key persons) contribute to the projects on a voluntary basis, whereby SATHI tries to reimburse the actual costs incurred in managing the project. The idea of such varied professionals joining together was mooted in the realization that, at least in India, current practices and efforts in promoting telehealth and related services had not been very successful. SATHI felt that such technology showed great promise, but was providing less than desired outcomes. Important related aspects to this technology such as change management and capacity building and so forth were lacking. Probably a different approach was required.

SATHI was registered in 2004. The current report pertains to the very first project assignment of SATHI. It was named Healing Touch (Gogia & Surwade, 2006)

The Technology

The dictionary definition of *telemedicine* is the use of telecommunications technology to provide, enhance, or expedite healthcare services, as by accessing off-site databases, linking clinics or physicians' offices to central hospitals, or transmitting x-rays or other diagnostic images for examination at another site. *E-health*, however is a much more encompassing term. This has been defined by World Health Organization (WHO) as:

> *The delivery of healthcare services, where distance is a critical factor, by all healthcare professionals using information and communication technologies for the exchange of valid information for diagnosis, treatment and prevention of disease and injuries, research and evaluation, and for the continuing education of healthcare providers, all in the interests of advancing the health of individuals and their communities.*

Telemedicine was initially conceived to provide healthcare to space travelers, thereafter to extending healthcare facilities for the geographically hard-to-reach and the underserved, literally providing a virtual doctor to places where a physical presence is a problem. With time, telemedicine is becoming more widespread, less costly, and new applications are emerging. The technology has moved from expensive room-sized systems to the desktop personal computer, and now further to the Internet, as well as mobile phones and palm tops.

Healthcare in India

India, with its large population (1029 million in 2001), has vastly varied terrains. The range consists of deserts, coastal regions, tropical jungles, islands, and mountains (CIA, 2001). Roads and physical reach are a problem in many areas. 72.2% of India's population is rural (United Nations Economic and Social Commission for Asia and the Pacific, 2000), and this population is supplied by less than 30% of medical professionals. The ratio for specialized medical care is worse with less than 4% of specialists serving in rural areas.

Even while healthcare in India is free and the responsibility of the state, over 70% of the population prefers to pay for treatment as the actual availability of the facilities leaves much to be desired. To service this demand, rural areas are filled with healthcare workers without adequate training as most doctors having better qualification are unwilling to work in such places. There is a lack of adequate facilities for them to satisfactorily practice to the level of training imparted to them. Good schools for their children as well as social and entertainment facilities matching the standards of living which they are used to are also lacking.

While actual healthcare expenditure in India constitutes 5.2% of GDP (gross development product), as compared with 2.7% in China (WHO World Health Report, 2000), it is widely believed that it can go up to 15% of the budget of most families. In rural areas, much of the expenditure is wasted on the transportation to the nearest healthcare facility. Bringing down transportation costs, including the time wasted for travel, is the real boon which telemedicine can provide. Traditionally, in India any sick person is accompanied by three or four persons when he goes to a hospital. Thus, the time off work for them is an additional hidden cost.

Though not widely publicized, we have come to know that China has been doing teleconsultations for a long time mostly through telephone as well as other means using experts in the cities and a wide network of less qualified barefoot doctors present in the community (Dr. B.S. Bedi, personal communication, 2006). Telemedicine as a concept was designed to take care of health problems of space travelers (Garshnek, 1991) and first applied in a disaster situation after the Mexico earthquake (Garshnek & Burkle, 1999).

Setting the Stage

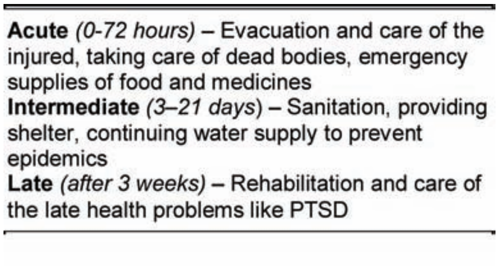
Telemedicine is a generic term but comes in various streams:

- **Between patient and doctor** which generally means a direct virtual consultation by the patient or his relative through e-mail or telephone.
- **Between a general practitioner** or any healthcare provider which could be an untrained village health practitioner or nurse (as the setting in this case) *and an expert*/specialist who happens to know more about a particular problem (see below).
- **Between specialists**. These are online discussion forums and user groups. The Association of Plastic Surgeons of India (APSI) runs an active discussion group (plastic_surgery@yahoogroup.com) where difficult and interesting cases are presented and the ensuing discussion helps the members to manage the patients with similar problems better.
- **Through e-learning programs**. Training and skill upgrading of healthcare workers can be provided online. Joshi (in press) cites that his organization provides education and training to parents on how to take care of spastic as well as disabled children.
- **Through home telemedicine**. Many gadgets are available which can monitor the elderly and infirm for problems and provide timely reminders for taking medicines.
- **By telerobotic surgery**, and so on,

The stream with the most relevance to developing countries is through improving the skills of any local healthcare practitioner with the expert. The average individual goes to her nearest medicine man whenever unwell. Generally, in India, for persons in rural areas and other far-flung places, the healthcare provider would be untrained and practicing medicine as per the family occupation or after working as an apprentice with a doctor for some time in a town.

80–90% of diseases are known to be self limiting or treatable by simple measures. However, since one would have taken advice, credit is provided to the health provider from whom the advice was taken, irrespective of whether the improvement was a result of, or in spite of, the advice. Thus, over time, faith, respect, and fame of varying degrees is achieved by any healthcare service provider whatever the qualification. Ensuring a licensing regime for such untrained persons is difficult to achieve due to the lack of suitable alternatives. However, in such a scenario, persons who have a genuine problem will suffer due to a delay in treatment and, occasionally, inappropriate treatment. A consultancy with the trained persons can help the local practitioner decide on what is to be done: Is local treatment possible?, its specifics, and if not, where and how to shift (Gogia, 2002). Each teleconsultation becomes an opportunity to interact with the specialist to learn more about the problem at hand and upgrading one's knowledge.

Figure 1. Phases of healthcare response after disasters; Use of IT can improve the outcome in all three.



Acute *(0-72 hours)* – Evacuation and care of the injured, taking care of dead bodies, emergency supplies of food and medicines
Intermediate *(3–21 days)* – Sanitation, providing shelter, continuing water supply to prevent epidemics
Late *(after 3 weeks)* – Rehabilitation and care of the late health problems like PTSD

The Tsunami Disaster

The worldwide response to the tsunami disaster on December 26, 2004 resulted in a massive outpouring of personnel, materials, and funds. Healthcare was felt as a primary need for the survivors.

Management of disasters is broadly categorized into four phases: preparedness, mitigation, response, and recovery (Warfield, 2007). The phase immediate after the disaster is the response phase which can be further subclassified (see Figure 1).

After any natural or man-made disaster, supplies, food, and so forth can be moved to the affected area, but disease and healthcare needs require specialized care which in most cases mean a reverse transfer.

Citing his experience after the Kashmir Earthquake of 2005, Patoli (2006) found telemedicine to be an effective method of helping the healthcare aspects of disasters. It can provide the specialists virtually to the affected area(s), overcoming time and geographical barriers. However, most studies in telemedicine in general and specifically in disasters have concentrated on the technology rather than the implementation. Shifting from a normal physical healthcare provision to a virtual availability is a significant change. This requires following change management principles and the key to SATHI's approach to this project.

Schiesser (2002) defines Change Management as "a process to control and coordinate all changes to an IT production environment."

Box 1. Telemedicine processes

There are two main forms of teleconsultations, the most common called **Store and Forward** technology.

In this, all medical records are stored electronically in a local database. On need for opinion, patients' records with all images and reports are transmitted normally during the night or hours of low telecommunication demand, although with current available technology of high speeds, such a restriction may be superfluous.

The other type is **Real Time** where dynamic active video conferencing or live data transfer takes place.

In a normal teleconsultation, a combination is used per need. Data are transferred beforehand and appointment set for a live session. In this, speech and eye contact for the patient provided online and reports are reviewed. Some questions are asked for clarification or even a possible online clinical examination may be done. Examples would be skin lesions sent through a digital or the VC camera, listening to heart sounds by using a digital stethoscope, asking the patient to walk, and so forth.

Thereafter, the patient may be asked to do some tasks as explained by the specialist or further tests may be requested. After that, the patient maybe provided a prescription online.

A referring doctor or the patient is then informed on what to do. Telecounseling, especially for psychiatric cases, is possible through VC.

Sometimes the patient may be asked to come to the expert center for a procedure. An appointment is given and problems and means of transfer explained. In emergency situations, preparations are made for receiving the patient.

According to Wikipedia (2007), change management is responsible for managing change process involving:

- Hardware
- Communications equipment and software
- System software
- All documentation and procedures associated with the running, support, and maintenance of live systems.

As will be shown later, this was the route SATHI followed and some of the problems faced were due to lack of maintenance support, failing hardware and software as well absent communication links—factors which were beyond our control or not managed well due to our inexperience in properly dealing with vendors, and so on.

Telemedicine is yet to be regarded as a primary tool in the management of disasters. However, many e-health experts (e.g., Mathew, 2004) have emphasized that IT will and can help disaster management, but much preparatory work is required.

While worldwide telemedicine programs have increased in number in hospitals, academic departments, managed care organizations, homes, schools, prisons, and so on, in India most efforts were limited to government organizations, the most prominent being ISRO (Indian Space Research Organization). Most of these efforts were to provide teleconsultations to persons in far-flung places However, the rural community, the one desperately in need of quality care, has so far been unable to reap the benefits. A perusal of the above Web site has shown that most linkages are

Box 2. List of activities performed by SATHI (further details in full text)

- **Preliminary planning** and design of project.

- Preliminary visit to the project area consisting of a **needs assessment survey**. This helped to identify the health problems faced by the survivors. An evaluation of the existing health system was also done for adequacy and possible areas of reinforcement.

A personal visit and interview of the identified NGOs who were potential partners, both in periphery as well as expert end, was done alongside with discussions with government functionaries.

These interviews were accompanied with **concept marketing and orientation** of the persons interviewed. A look into connectivity needs and how they could be fulfilled. Based on the visit report, the project was redesigned and a formal order the systems (hardware and software) was placed.

- **Create MOUs**. These were between the various identified partners of the project meaning OXFAM, SCARF, and other local NGOs.

- **Install the systems** in the identified locations. **Training** of the local persons who will manage the sessions, on how identifying the problem cases, running the systems, conducting the sessions, troubleshooting, and so on. Test sessions were held before a formal launch under SATHI's supervision as well as an engineering representative from the vendor.

- **Streamlining** of the project included setting and fine tuning protocols for identified problems and setting up the time table for the consultations, which was called TCS (telemedicine consultation session) time table.

- **Feedback** was obtained on a regular basis with reporting mechanisms in place.

- Outcome analysis, done by an outside agency, was planned at the outset as this was to be a pilot.

between district hospitals with referral hospitals. The tsunami had affected areas largely at the village and block level where any health services let alone technology was simply unavailable.

The tsunami disaster spurred SATHI, like many other organizations, to reach out to help those affected. With a basic guiding principle that "More people die of after-effects of natural disaster than the disaster itself," SATHI felt that telemedicine can and should provide a solution to control the "disaster after the disaster" through efficiency and greater reach of the health services on offer. SATHI offered its services to various organizations, stating that SATHI could provide data collection services as well as help in improving the health status in a sustainable manner. It received support from OXFAM Trust India, the Indian branch of OXFAM International wherein the SATHI would be providing consultancy to manage healthcare in the relief centres run by OXFAM and its sister organizations. OXFAM was also concerned with the mental affects of disasters having experienced during their rehabilitation efforts in previous disasters (Sharma, 2002).

SATHI was fortunate to get funding for the project with a relatively free hand. The project was to be treated as pilot which could show sustainability of telemedicine along with providing some immediate gains to the tsunami victims, an attempt to showcase the use of IT in healthcare after disasters.

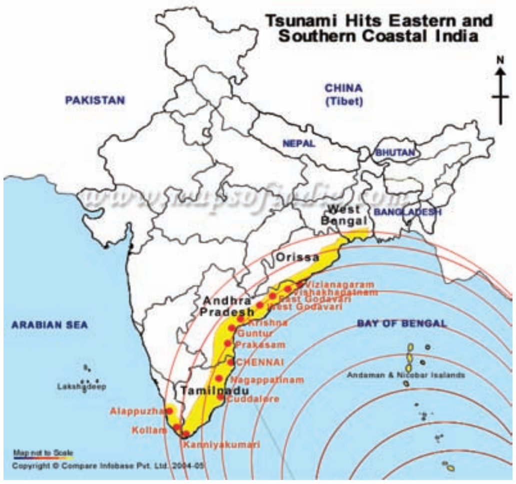
CASE DESCRIPTION

A summary of the procedures that follows is listed in Box 3.

Once the MOU was signed, a detailed plan to execute the project was drawn out. Preliminary discussions were done between OXFAM as well as the possible vendors of the hardware and software. BSNL (Bharat Sanchar Nigam Limited), the local telephone service provider in the area of concern, was identified as the resource for connectivity.

The **needs assessment** was done through a personal field visit to the affected areas in the second half of January 2005. This consisted of a survey of the affected areas where we analyzed the location-specific health needs and available health services provisions directly by the government or camps run by other NGOs. Our emphasis was to look for and thereon fill the gaps, if any. (Figure 2)

Figure 2. Map of areas affected by the Tsunami. Chennai was our main centre



Simultaneously, meetings were held with local NGOs to assess their willingness as well as capabilities to do the tasks required. Availability of connectivity was to be at a level which could ensure video conferencing (VC).

Box 3. IDSP program

The IDSP program is a World Bank funded project where the local health care workers collect door to door data pertaining to disease incidence and health status and then upload to a central server via a satellite link from the district centre. Nagapattinam district, after the tsunami, was the very first place to launch this program.

The needs assessment survey showed that as far as healthcare was concerned, the first and second phases of the disaster were well managed by the government and supporting NGOs in the areas visited (parts of Pondicherry and Nagapattinam district of Tamilnadu). Epidemiology and disease surveillance had already been activated in the entire district. This was part of an Integrated Disease Surveillance Program (IDSP) run by National Institute of Communicable Diseases (NICD), a central government organization.

However, a need for mental health support was found due to a high incidence of a sense of loss and bewilderment among the survivors who continued to be gripped with fear and a sense of shock. They were anxious, depressed, displaced from their homes, and had lost their family members and loved ones. Most were too frightened to rejoin their regular occupation of fishing. Alcoholism was rampant as well as mass panic reactions; we experienced one ourselves where we found the entire populace, vehicles, and even animals running away form the coast at a time of a particular high tide (see Box 4).

The people were ignorant about the tsunami: What was it? Will it strike again? How will we be prepared? How will we cope with its after effects?

The occurrence of this problem was articulated by WHO (The Hindu, 2005). Steps taken by the government for upgrading of mental health of the victims were found to be inadequate as well as wrongly directed. There was a mismatch between needs and services with an inadequate number of mental health specialists. A high incidence of stress and fatigue among relief workers with no community participation was also found.

As per the WHO reports, following disasters, 80–90% of the population have a lowered mental health status, a situation which would improve in most. However, 4–5% would be serious cases requiring specialist help. PTSD (post-traumatic stress disorder) and other serious mental problems manifest a few weeks after the disaster and the effects can last for up to 1–2 years in some cases.

The problem was in identifying the exact victims who would require specialized medical help. This meant a virtual door-to-door search on a repeated basis. Telemedicine was thought to be the right solution to these problems since it would allow the specialist to train the health workers, who being in the community could organize such searches better and on a continual basis to identify this 4–5%. This would ensure access to specialists' services for the real victims and would also ensure quality. Since health workers might themselves be affected, one could not rely on them alone without external specialist help.

The Healing Touch was conceptualized after the above assessment. Possible solutions were analyzed and specifics of the telemedicine network planned. Various possible additional partners and stakeholders were identified and an advocacy and orientation plan rolled out. This included concept

Box 4. Panic reaction in Vellangani

The village of Vellangani is a religious tourist spot with an ancient church on the sea coast. This church was flooded during the tsunami. During our visit there, we were at a villagers' residence around a kilometer from the coast. At around 5:00 p.m., we heard a loud noise outside and suddenly we were confronted by the entire population of the village, people, vehicles, and even animals running further inland yelling "*Thaneer Thaneer*" (Tamil for "water, water"). The most vivid image was of two teenage girls panting and running with eyes popping out.

The reason was later found to be a high tide.

We were told that such panic reactions had become a regular phenomena. Although the panic lasted only a few minutes, it was this single moment that made us decide to provide mental health support to the affected population.

marketing and social mobilization of additional NGOs and those who could contribute specialized mental health support.

Once the partnering NGOs were identified and found agreeable, Memoriam of Understandings (MOUs) between the various stakeholders, between OXFAM and local NGO, as well as between various NGOs themselves, were drafted and presented for formal signature.

During preliminary discussions, SATHI had planned for and thereby placed an initial order for complete telemedicine systems, with peripherals like scanners and the like. On reassessment, mental health support was found to be the sole healthcare requirement with all other healthcare needs of the tsunami victims already being well provisioned for by the government and other agencies. Disease surveillance was well in progress through IDSP. Thereby, the planned epidemiology module was found unnecessary. With funding becoming a problem, orders for the entire set of add-on peripherals like an ECG machine and scanner and other equipment were also shelved. A limited scope meant a more focused approach with a decreased need for orientation and capacity building. Thus, finally VC and basic data collection through an EMR (electronic medical record) module were selected as the components to be used.

The following were provided at each location:

1. Pentium II PC with Windows 2000 as OS and standard hardware prevalent at that time:
    - 256 MB RAM
    - 40 GB hard disk
    - External modem
    - Printer
2. Video-conferencing equipment was provided by the systems vendor which consisted of:
    - Add on VC card to the above PC
    - PC based VC camera
    - Multimedia speakers
    - PC microphone
    - Telephone type handset
3. EMR software was provided as part of the system. The entire system was a stand-alone self sufficient plug and play type, the vendor also sent its own engineer to train the community workers for usage.
4. USB (universal serial bus) and other relevant ports were provided for connectivity through external devices, modem, and ethernet card.
5. Regular power was a problem so a UPS (Uninterrrupted Power Supply) was provided. Option of a generator was left to the local NGO managing the system.

Connectivity add-ons were to be provided as per local availability. Possibilities were:

- **Satellite,** which could provide mobile connectivity and could reach all possible areas. Free satellite connectivity daily for one hour was promised for a month or so along with the relevant hardware (INMARSAT) through the equipment vendor who happened to have a relevant tie up with European Space Agency for the same. However, it did not happen as trials by them regarding VC had not been very successful with the INMARSAT equipment in a separate project in Sri Lanka. The only local provider of satellite connectivity was ISRO. After disappointment with INMARSATs, we petitioned ISRO, but could not get the requisite linkages. The quoted cost of satellite connectivity (Rs 60/approximately US $1.33 per minute as per 2005 currency rates) was a limiting factor. Connectivity costs were to be managed by the local NGO.
- **ISDN** (integrated switching data network) was found to be the low cost option wherein the average per minute cost was one local phone call (less than one U.S. cent per minute for every 64 Kbps connectivity). 128 Kbps was felt to be adequate for video

conferencing. ISDN connectivity, although promised by the local telephone company at all possible locations, was found to have limitations and could not be used wherever we desired. There were some limitations: The regional telephone exchange had to be electronic and capable of providing ISDN services, and the final location should require less than 2.5 Kms of wiring from the regional exchange. At some places, the exchange itself had been flooded. Therefore, provision of any land line service was expected to take time.

Table 1. Implementation details of various locations for the Healing Touch Project

Location	*Reasons*	*Outcome and Remarks*
Tharangammbadi	Largest rehabilitation colony in affected area with over 1000 families Local Taluk hospital in midst of rehabilitation colony Support from local NGO available (PEDA) Willing staff and doctors in the hospital	The first peripheral location where the equipment was installed. Local staff and doctors both from the Taluk (community) hospital as well as PEDA were trained. Later connectivity by ISDN was not found possible as the local exchange was too old. Attempts for reaching though satellite were also unsuccessful for reasons cited above. Finally the equipment was shifted out.
SCARF Chennai (Expert service provider)	Reputed mental health facility Voluntary organization already working in providing support to the Tsunami victims Willing and ample support from the director (Dr. R. Thara) and staff IT aware and knowledgeable staff No language problems	Equipment and staff were trained within a day of installation. This was in late February 2005. ISDN connectivity was provided on demand. SCARF sent its doctors and staff for its initial orientation and training to all peripheral locations. They have been a major contributor to the success of the program.
Dharmakulam	Support from local NGO (ISED) Part of affected area Connectivity possible	It was initially planned to install in the local government health facility (Thiruvengadu) but that was too far from the affected area. Thereafter a room was taken on rent near the affected area in Dharamkulam village near Poompuhar a noted tourism centre of Tamilnadu. ISDN connectivity took a long time and finally was made available only in May 2005. This centre has been successfully working since then. The mental needs are over after 79 teleconsultation sessions and 249 patients seen over 6 months. Two possible suicides have reportedly been prevented.
Kariakal	Support from local NGO (PEDA) Good connectivity options	Equipment promised for Tharangambaddi was eventually shifted here with management by the same local NGO. However, the decision to shift was taken late, as there had been hope of getting satellite connectivity through INMARSATs or ISRO in the previous location. Equipment and connectivity became available only by February 2006. This centre has been successfully working since then (see enclosed case report).
Seradure Village	Deeply affected area Supporting staff and orientation provided in the government health centre	Could not find a suitable local NGO to manage the project.
Kalpakkam, Akaripettai and many others	Affected area Exchange has ISDN capability	Late decision and funding limited though local NGOs were identified for some of these locations.
Sundaram Medical Foundation (SMF) (Expert Service Provider)	Super specialty medical facility in Chennai Works in close alliance with SCARF No language problems	Decision to limit the project as a pilot Consultations for nonmental health needs could be done by the doctors traveling to the SCARF centre nearby in the absence of their own telemedicine unit.
Various places in Nagapattinam	These were possible partners of the project for the expansion which did not take place.	Planned for mobile connectivity wherein a van hired or owned by the NGO would travel to the location at a fixed time and provide consultancy. Lack of satellite linkages shelved this approach.

- **Dial-up networking,** though possible at all places, was found to provide inadequate bandwidth as video conferencing was an essential component.
- **Mobile** connectivity was again found to provide inadequate bandwidth.
- **Broadband** Internet through ADSL (asynchronous digital subscriber link) was not yet prevalent in the affected areas, except in Chennai.
- **WiMax** similarly has still not become prevalent widely.

Finally, ISDN was decided to be the connectivity option of choice as it was the cheapest, could support video conferencing, and was available albeit at select locations. An application was placed with BSNL, the company providing telephone and ISDN services locally. Though connectivity on demand had been promised in view of the scale and emergent nature of the problem, actual delivery was delayed by a few months.

SATHI ascribed the delay to a poor initial understanding of the above requirements. In one place, considered ideal for provision of telemedicine services (Tharangammbadi), the equipment could not be utilized and had to be shifted elsewhere as ISDN connectivity was not possible. Associated training of personnel and preparation of the site got wasted (see Table 1).

The network provided counseling (through video conferencing for the victim) in the presence of the health worker. Individual and group sessions were possible. No traveling was required by the victims. The local volunteers were responsible for identifying the possible members of the community who required support after a short training course by a personal visit of the expert team to the field. A time and date for the counseling sessions was set and the volunteers held responsible for providing continuous learning and supervision on the job as well as on the spot.

A teleconference based training module was developed by SATHI. This was used for the orientation of the community health workers and experts. Hard copies were also made available for review. These were based on WHO recommendations with some separate guidelines for relief workers themselves affected directly or indirectly by the disaster.

Experts from SCARF, on their own, had arranged to travel to the affected areas before the start of the project to familiarize themselves with the persons whom they would be meeting through VC. The local volunteers were trained to identify mental health problems in the community and how to bring the more affected to the telecentre for direct teleconsultations with the experts. Initial sessions were managed in the presence of our representative or the engineer installing the systems. Later, on the job and continuous training using an innovative interactive and participatory training methodology supported through audiovisuals was made possible through VC.

Since SATHI is based in New Delhi, far from the affected area, the experts traveled to the affected area for planning and implementation spending over 40 days for the project planning and implementation. Many activities and online discussions took place later through VC from its office with the project partners at the peripheral as well as expert locations.

*Box 5. Health systems in Indi*a

In India the health system is structured according to the Bhore Committee report (1948) wherein the basic health services are provisioned at the primary, or community, level through PHCs (primary health centres) and their subcentres who refer, if required, to the secondary level (district and Taluk hospitals) and thereafter for specialty services to the tertiary level (medical colleges and tertiary care hospitals in select locations).

Since SATHI could only offer occasional and limited help after the initial orientation and installation, it can be said that the project has been conceptualized and managed by the community itself. Being operable at the village level, it integrated well with the present health system in India (see Box 5) both vertically (i.e., across the primary, secondary, and tertiary care providers) as well as horizontally (i.e., among the networked units). It turned out to be an empowering exercise for the community and an exemplary partnership between the government, NGOs, as well as community and development support agencies.

Telemedicine enabled the affected people and community to reach out and to articulate their needs. The affected persons participated in interactive sessions with experts and enabled healthcare service provider to be need specific. It strengthened the healthcare delivery system and increased the efficiency of service provider by allowing wider coverage.

The Project Cycle

The tsunami disaster occurred on December 26, 2004. The project was conceptualized in January 2005. All initial processes, identification of stakeholders, operators, locations, and so forth were ready by mid-February 6–7 units were planned in the periphery and one in the centre. SCARF (Schizophrenia Research Foundation), a psychiatric care centre in Chennai, was identified as the expert or central unit, which would provide mental health support.

This selection was based on the aspects of willingness to do voluntary work, familiarity with the local (Tamil) language, as well as proximity to the affected areas. SATHI tried to ensure that in case of need, actual transfer for the more serious cases and continued care through the same facility would be possible.

Units in the periphery were to be located in various places depending on:

- The percentage of the population affected by the tsunami.
- Motivation level and capability of the local NGOs. In this, their motivation and initiative was assessed along with the ability to run the system. They had to have access to or in possession of a room at least 10 feet by 10 feet with relevant furniture for housing the telemedicine facility. Access to government channels if using government facilities IT skilled personnel capable of running and troubleshooting the equipment were required. Adequate financial capability with a willingness to pay the day to day running costs of the staff and connectivity was essential.
- Proximity of the proposed location to the exchange (to allow ISDN connectivity).

The units were to be located in the Primary Health Centre or a government hospital in the tsunami affected area and run by the health workers with supervision and support by local NGOs. Funding support for the machines as well as for maintenance and connectivity for the first 6 months was assured by the funding organization. Alternatively, as stated above, if the NGO had enough funds and their own doctors, they were invited to run it fully themselves.

A review of the decided locations and there eventual outcome is hereby listed in Table 1.

Thus, in summary, the project could not start until middle of May 2005 due to the reasons outlined above and summarized below:

- **Funding** was slow. It was never fully released.
- **New type of technology**, so there were doubts about the project. Some senior functionaries in the funding organization were not in favor. SATHI being a recently registered organization, its capabilities were felt to be suspect by some. Delays meant that continues retraining of volunteers was

required. With delayed funding which was cut short, the expansion plan was delayed and had to be shelved ultimately. By the time it was actually released (October 2005), many earmarked places had already lost interest and some of the need for mental health support had decreased.

- **Connectivity** took too long. In Chennai connectivity was provided in a day in early February 2005. In the periphery, the regional office was around 100 Kms from the coast. Though orders were placed for ISDN lines in February, the lines were not made available until May. Reasons for nonrelease of the connectivity (see above) were understood only following a personal visit from a SATHI representative to the regional office during mid-April 2005 in what was its fourth visit. Thereafter, the location plans were changed but it still took a month more for starting the sessions.

Currently, there are three systems, two in the periphery and one in the centre (SCARF). At all these places, connectivity has been established and the system are up and running. Initially, there used to be thrice weekly sessions wherein patients—those felt to be most affected—were asked to come to the local telemedicine centre by the specially trained community health workers. These patients were seen online by doctors from SCARF and counseling was done; medicines prescribed by the doctors online were provided to the patients by the attending volunteers; a separate stock of medicines used was kept locally as no chemists were available in the periphery.

The patients in Dharmakulam and surrounding areas requiring mental health support have been largely treated. Volunteers from here are now asking for online treatment for other specialties like general medicine, cardiology, and so on.

An evaluation has been done independently by OXFAM. This was by Mr. Saharaj Louis and submitted in May 2006. The summary of his findings have been listed in Box 6.

Current Status and Outcomes

A model telemedicine network has been developed. The design of this model is specific to the needs and integrates the service providers with field level facilitators.

The capacity of the field level NGOs has been built in terms of the operation of the telemedicine network and skills to conduct counseling sessions at the community level.

A unified approach to respond to the disaster situation with application of the communication technology and network of health and other professionals has been developed. This would enable reducing the response time to future disasters. Professionals as well as a service providers' network will be available in future.

The project has contributed to defining the modalities for disaster response.

A parallel attempt of using IT to improve disaster preparedness has been recommended. This includes making available IT facilities in many areas so that trained persons are readily available as well as a national database of the population,

Towards a better childhood

There were many children who were traumatized due to the aftermath of the tsunami, as they were either sole survivors or those who have escaped the clutches of death in a fraction of second due to their presence of mind. Arul, aged 14 years who belongs to the fishermen village of Karaikalmedu, is one such lucky victim. He has two younger sisters. Arul's mother was helpless even though she knew that her son showed abnormal symptoms and reported the same to her neighbors. Barefoot counselors who visited the village did provide some counseling help to the family and tried to verbally motivate Arul. However Arul's condition had been the same for the past 1 year with more irritating symptoms and conditions unmanageable.

His mother was not able to even take him to the district hospital, as he was not cooperative and used to disappear from the neighborhood when insisted. PEDAs initial community training that was imparted with the help of SCARF, Chennai to the Self-Help Group Leaders was the stepping-stone in bringing back the lost childhood for Arul. Maivizhi, the SHG leader who attended the training on identifying people with psychological symptoms noticed the child and confirmed the same with the community health worker from PEDA during her field visit. She was very instrumental in bringing the child to the telemedicine centre by motivating her parents. Arul's family did have the opportunity to speak to the psychiatrist about his condition and his treatment plan was put in place.

The community health worker and the SHG group leader today are regular in following his improvement. Today Arul is back to normalcy after 4 months of treatment, he was also the first among the few who were referred to the telemedicine centre. He has shown remarkable improvement in his mental health condition that has been very beneficial for the PEDA staff to reach out to more number of people. Maivizhi has become an ardent supporter of the system and the technology. She advocates to many who chat with her about such symptoms and provides voluntary service and referrals to the telemedicine centre on a weekly basis as she puts it right by saying "I have seen the progress of Arul and many others back to normal like us and that is the reason why I am very much involved in raising awareness about the issue of mental illness as it is one area which our community believed to be as witchcraft."

A happy and reformed Arul posing with his sister.

NGOs, healthcare facilities, and so forth, which can quickly set up a response team.

FUTURE CHALLENGES

Funding has been a problem for most healthcare IT projects as the outcomes of previous ventures had been disappointing.

Excessive promotional efforts by vendors used to result in far higher allocation for the technology itself rather than its implementation. Technology however, contributes only 20% to the success of any new technology project; 75% depends on proper implementation (i.e., change management) and 5% on luck (Karthikeyan, personal communication, 2006).

The role of IT in managing healthcare has been recognized but implementation has been a problem. A proper response requires a cultural change and availability of software and hardware at all and especially the disaster prone ones who are running the systems as part of daily routine. Once they are trained, getting such systems to work in emergencies will not require the massive orientation and marketing exercise that SATHI had to do.

Chapter 4.6

Planning and Control and the Use of Information Technology in Mental Healthcare Organizations

I.J. Baars
Maastricht University, The Netherlands

G.G. Van Merode
Board of Maastricht University Medical Center & Maastricht University, The Netherlands

INTRODUCTION

Demand for mental healthcare increases. Simultaneously, the need for more patient oriented processes increases and the market develops towards more competition among providers and organizations. As a result of these developments, mental healthcare organizations are becoming more aware of efficiency and effectiveness. Often, they choose to transform to more process oriented organizations, which require changes in planning and control systems and information technology (IT). However, little is known about the required planning and control systems and IT for mental healthcare.

We argue that IT for planning and control of mental healthcare organization needs to be adaptive and support short term planning. IT has to be adaptive to be able to support first and second order control which is needed for planning and control of mental healthcare processes. Short term planning or reactivity is needed to deal with stochasticity and variability as present in mental healthcare. These subjects are further described in the background.

This article reports the results of two studies on the use of standard care processes and IT for planning and control of mental healthcare processes. The results give insight in the needed functionalities of IT and planning and control of mental healthcare processes. The first study is a case study in a center for multidisciplinary (mental) youth care. This center implemented care programs and an automated planning tool. We studied the success of this implementation and particularly the fit between the care programs and the planning tool. In the second study we studied the characteristics

of ambulant mental healthcare processes and the actual and preferable use of planning and control models and IT.

BACKGROUND

Mental healthcare is often multidisciplinary and includes several professionals, disciplines, and departments within one or more organizations which all need to be planned and controlled. Consequently, the object of control is mainly professionals and patients, but also resources like rooms. We define planning as the determination of what should be done and control as the process that assures that the planned results are obtained (Van Merode, Groothuis, & Hasman, 2004).

According to Hofstede (1981), the way non-profit organizations, such as mental healthcare organizations, can be planned and controlled depends on the type of processes. The type of process can be determined by answering the following questions: is the output measurable? Are the objectives unambiguous? Are the effects of management interventions known? And, can the activities be repeated? The type of processes determines the control model and instruments (e.g., protocols, case management and budgeting) that can be applied.

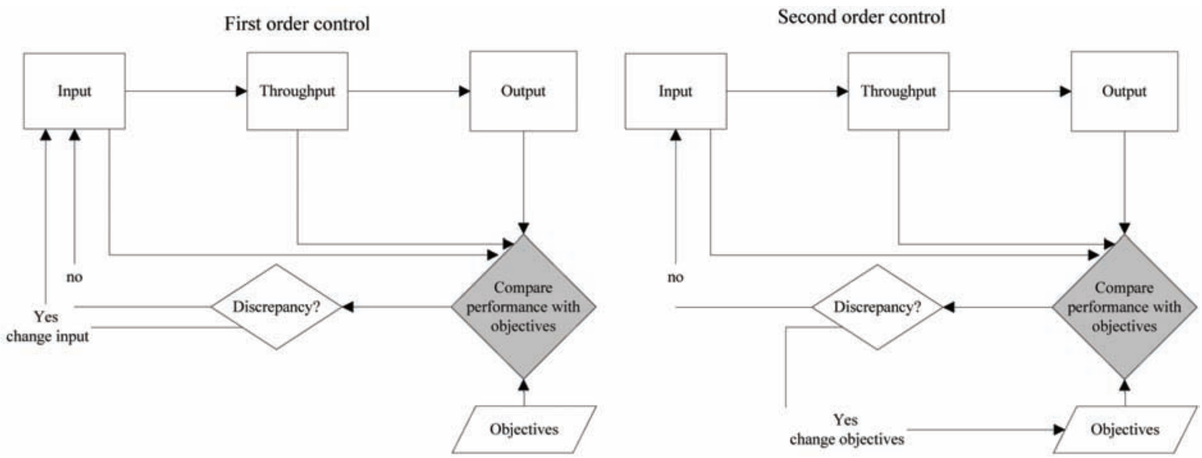
Hofstede (1981) defines six different control models, as shown in Table 1. The more standardized, well-defined, and structured the processes are, the more routine control can be used.

A mental healthcare organization consists of various processes. These processes are possibly different and thus need different control models. To select a control model that best suits a situation, processes have to be analyzed. Especially the distinction between routine and less routine processes is important here.

Routine processes can use standards and can be controlled by routine control or, when the activities cannot be repeated, by expert control. For routine control, and marginally for expert control and trial-and-error control, models that compare automatically what actually happens with the standards about what should happen apply. These models use feedback for control. The feedback from relevant indicators provides information that can be compared with targets. A number of care processes can be coordinated to a large extend by planning and control integrated in one system and by providing feedback from control to planning (Hofstede, 1981; Van Merode, Groothuis et al., 2004; Van Roth & Van Dierdonck, 1995). Moreover, for intuitive and judgmental and political control only vague models exist (Hofstede, 1981).

An example of control by feedback in mental healthcare is a protocol for the process of the treatment of depression. This protocol describes that the target of the indicator “number of sessions” is

Figure 1. First and second order control



15. If a patient receives 17 instead of the targeted 15 sessions, this is evaluated. Several actions can be undertaken to meet the target of 15. One such an action is adapting the input of the process so that the 15 sessions are not exceeded. This is first order control (Figure 1).

A problem with first order control can be that the aim becomes to keep the activity on target at any cost. To overcome this problem, a second order feedback loop that can periodically adjust the targets of the first order feedback loop is necessary (Figure 1). A second order feedback loop provides information (e.g., by new insights or outcome of evaluations) that enables decisions on the appropriateness of the target. By means of a second order feedback loop, the interventions of the first order loop can be overruled. With that, the targets of the process can be adapted so that the outcome better fits the targets. In our example of 15 sessions where the output did not meet the target of 15 sessions, the target of the standard can be changed to, for example, 17 sessions. An advantage of second order feedback is that it can cover more complex organizational control situations. Furthermore, variability and stochasticity can be accounted for with a second order feedback loop.

Information Technology for Planning and Control

Planning and control by feedback on performances can be supported by IT. IT provides the backbone for collecting, compiling, and utilizing information on patients, activities, methods, costs, and results (Porter & Olmsted Teisberg, 2006). Because of the multidisciplinary care and the involvement of several professionals, disciplines, and departments that need to be planned and controlled, a central automated system for planning and control might be needed. In industry Enterprise Resources Planning systems are often used for this purpose. Enterprise Resource Planning (ERP) systems attempt to integrate all corporate information in one central database, and information can be retrieved from many different organizational positions and in principle they allow any organizational object to be made visible (Dechow & Mouritsen, 2005).

Likewise, for healthcare, ERP systems can integrate many functions such as patient scheduling, human resource management, workload forecasting, and management of workflow (Jenkins & Christenson, 2001). However, when implementing ERP systems in an organization, several implementation and structural problems can occur, for example, ERP may not fit the structure of the organization.

Implementation and structural problems may occur in healthcare because ERP systems require fixed, deterministic processes and ignore alternative processes (Van Merode, Groothuis et al., 2004). But in healthcare, stochasticity (e.g., patients not showing up) and variability (e.g., demands for care differ between several individual patients) exist. Because of the existence of stochasticity and variability, a more reactive decision making technology or short term planning systems as, for example, Advanced Resource Planning (ARP), better suit the less deterministic processes (Vandaele & De Boeck, 2003; Van Merode, Groothuis et al., 2004). Another possibility for planning and control in mental healthcare is to physically separate deterministic processes suitable for ERP from nondeterministic processes requiring a more reactive decision making, or short term planning, technology.

PLANNING AND CONTROL AND THE USE OF IT IN MENTAL HEALTHCARE ORGANIZATIONS

To study the possibilities of planning and control and the use in mental healthcare organizations, we performed two case studies. Here we present the results of these two case studies.

Case 1: Planning Tool and Care Programs

In the multidisciplinary youth (mental) healthcare center, processes were standardized by care programs. The aim of the care programs was to plan processes more efficient and effective, and also to improve the patient-oriented way of working. A care program is defined as a framework with which organizations, professionals, and patients should comply and it is used to get a patient-oriented organization of a well described target group. It integrates the activities between different disciplines, professionals, and departments and indicates the way the care should be given, by which professional, in which setting, and with what frequency (Berg, Schellekens et al., 2005).

Care programs consist of several standardized modules. The planning of a care program, that is, which modules will be performed, is done based on the demand of the patient. Further, for planning and control of the activities of a module, each module contains a Bill of Resources (BOR), which is described in the protocol of the module.

A BOR is derived from a Bill of Materials that is used by ERP systems. However, mental healthcare includes more than materials such as professionals and patients. Therefore, the use of a BOR is more appropriate for healthcare organizations (Van Roth & Van Dierdonck, 1995). In the center, a BOR defined the location, type of activity, professional, and patient.

Because of the multidisciplinary care, the coordination of the care programs was complex. Automated support might reduce this complexity. Therefore, IT, that is, the planning tool, was used for planning and control of activities of patients and professionals. The planning tool was a software application, intended to support working with care programs. The features of the care programs, such as the involvement of several professionals and departments and the standardization of modules, require certain functionalities of the planning tool. The planning tool contained the following functionalities: a BOR to plan activities, an event handler to react to ad hoc changes by revising timetables and re-arranging activities, an electronic organizer, and a control function for process control by first order feedback and second order feedback.

To test the functionalities in relation to the care programs, the planning tool was tested in a pilot. The evaluation of the pilot was done with a document analysis, interviews with all those involved, and analysis of e-mails to and from the planning tool helpdesk.

The results of the evaluation show that the fit between the standardized care programs and the planning tool was insufficient. The main cause was the noncompliance of the professionals with the standard modules because they feared inflexibility in performing their activities due to the standardization and first order control. However, the professionals did have some flexibility in planning. They could use the event handler to react to ad hoc situations and they had the possibility to deviate from the standards to react to variability which is second order control. But the results show that the flexibility possibilities were not known and not used by the professionals.

As the results illustrate, the characteristics of care processes and the functionalities of IT must fit to function. In this case, the IT demands a certain amount of standardization while in daily practice the professionals require flexibility in performing their activities. Therefore standardization and flexibility have to be balanced. Because the professionals did not comply with the standard modules of the care programs, and did not know of, or use, the possible flexibility, we do not know for sure that the care programs and the IT did not fit. It seems also due to implementation problems of the IT and care programs that professionals did not comply and did not have knowledge about the possibilities of second order control.

Professionals do need some planning freedom to be able to react to the present variability and stochasticity. A planning and control system, including the IT, need to support this in an efficient way. In the second case study, we studied the actual use and the possibilities of a planning and control model which is based on performance measurement and second order feedback.

Case 2: Optimizing Planning and Control in Ambulant Mental Healthcare Centers

Due to increasing competition in mental healthcare, planning and control based on performances is needed. Therefore routine control is necessary and processes have to fulfill the characteristics as described by Hofstede (1981). But as shown in the evaluation of the planning tool, also flexibility in planning is needed.

The case study of four ambulant mental healthcare centers presents information about characteristics of their processes and the planning and control models as used. These results are used for recommendations that can guide mental healthcare organizations in their planning and control and the use of IT. These are presented in the conclusion.

In this case study, we first described the present processes by using process mapping techniques. Next, we assessed these processes on the uncertainty of demand, supply, and the service process itself, complexity of coordination, and staff inflexibility. These three factors determine the efficiency and adaptation possibilities of a process (Van Merode, Molema, & Goldschmidt, 2004). These factors incorporate the conditions of Hofstede's (1981) model.

The results of this study showed that most of the processes were not planned and controlled in a consistence way. Three of the four ambulant mental healthcare centers hardly used performance indicators to monitor the processes. The uncertainty and complexity were high and instruments, like protocols or IT, to decrease the unnecessary uncertainty and complexity were hardly used. One center did use care programs. However, the opportunities for planning and control of these care programs were not used to their full extent. Besides, a planning and control system based on feedback did not exist. This center had the most extended IT software. Nevertheless, this software was not used to monitor the results of the processes with performance indicators. Therefore, planning and control based on feedback was not performed. IT use for planning and control was very minimal in all four centers.

FUTURE TRENDS

In mental healthcare organizations, we mainly see two developments. The first is that many mental healthcare organizations continue in their old ways in organizing their care, that is, that no standards or IT are used. However, a second development is that, because of growing attention for more efficiency in mental healthcare, more and more mental healthcare organizations standardize their processes by, for example, the introduction of care programs.

Standardization can be very fruitful in decreasing unnecessary uncertainty in care processes. However, mental healthcare organizations often do not change their organization structure simultaneously with the introduction of care programs. Additionally, IT with planning and control functionalities is underused. The use of IT for integrated planning and control will probably increase. But, what we observe in somatic healthcare is that (standard) ERP packages are implemented while they do not suit the situation. These ERP systems are often implemented without a change in organization structure. By the lack of the fit between the organization, processes, and ERP systems, this can result in many problems. New, adaptive, software is there but is not successful.

As we claimed in the introduction, first and second order control should be supported by IT. Therefore IT has to be adaptive and support short term planning or reactive decision making. However, mental healthcare organizations are not yet interested in this kind of technology. In the future, mental healthcare organizations consider IT more to profit from care programming and, as a result, work more efficient and effective.

CONCLUSION

Mental healthcare organizations are on their way to more efficiency in their processes; yet IT is still underused for planning and control.

As shown in the first case study, processes and IT must fit. In this center, the organization thought that planning and control was possible with routine control supported with information technology. The care programs met the conditions for first order control and second order control. However, in the pilot it did not work out as intended.

In the second study, we observe that almost no use is made of possibilities of standardization and feedback for control purposes. Moreover, IT is hardly used for planning and control purposes. As a result, the ambulant mental healthcare centers miss the possibility to direct the outcome of processes to a certain target, and efficiency is not optimal. As a result, the centers miss the opportunities to be competing on the (regulated) market.

The results emphasize the need to carefully consider process characteristics before introducing a planning and control system. Careful consideration is needed to avoid type I and type II errors. Type I errors occur when opportunities for routine planning and control (with standardization and IT) are not used by management. However, some processes are not deterministic and cannot be controlled with routine models. When they are controlled with routine models anyway, type II errors occur. To avoid either type I or type II errors, a fit between standardization and flexibility has to been found. Hofstede (1981) states that type I errors often occur in not-for-profit organizations because the concern for cost and effectiveness is often missing. However, mental healthcare is subject of social and political developments resulting in the need to be more aware of efficiency and effectiveness. Therefore we assume that type II errors may occur in future more often.

The results also show the necessity of balancing between process standardization and the flexibility of the working practice. Routine models can be applied for processes in mental healthcare in certain circumstances. Nevertheless, routine models need to use second order control because not all activities can be planned in advance due to variability and stochasticity. This balance between standardization and flexibility has to be considered carefully before fully implementing care programs and a central planning and control system integrated in IT. To be able to balance between flexibility and efficiency by means of care programs, the organization structure also has to be changed and IT has to be adaptive.

We recommend the following to develop more efficient processes in mental healthcare organizations. First, performance indicators should be developed to be able to compete in the (regulated) market. Simultaneously, time horizons should be distinguished in which planning and control on several different levels (e.g., establishing different care programs by board 3 years, planning of professional 6 weeks) can be defined. Next, processes need to be distinguished on uncertainty and complexity of the process. The difference in characteristics of a process (more or less routine) decides on the possibility of standardizing processes. After that, the processes that satisfy the possibilities for routine control need to be standardized and a BOR should be described. For the actual control on performances, a system based on first order control and second order control must be developed and adaptive IT that supports short term planning or is reactive is needed to support the planning and control.

The use of these recommendations helps in finding a balance between standardization, use of IT, and flexibility. In addition, IT interacts with the social system and the working practice and, therefore, it is necessary to tailor both. However, it is a process of trial and error and therefore requires adaptive IT.

KEY TERMS AND DEFINITIONS

Adaptive Information Technology: Information Technology that can be adapted to changing circumstances in finding a balance between processes and IT.

Care Program: A care program is a framework where organizations, professionals, and patients should comply with and is used for patient-centered organization of a well described target group. It integrates the activities between different disciplines, professionals, and departments (Berg, Schellekens et al., 2005).

Control: The process that assures that the planned results are obtained.

Enterprise Resource Planning System: Enterprise Resource Planning systems attempt to integrate all corporate information in one central database, and information can be retrieved from many different organizational positions and in principle they allow any organizational object to be made visible (Dechow & Mouritsen, 2005).

Feedback: Information about the output is fed back to the input.

Planning: Determination of what should be done.

Reactive Decision Making: Decision making based on reacting to unexpected situations due to variability and stochasticity.

Short Term Planning: Planning on short terms with data about monthly, daily, and hourly demand and meaning full statistical distributions to be able to deal with stochasticity and variability.

Chapter 4.7

The Use of Information and Communication Technologies for Health Service Delivery in Namibia:

Perceptions, Technology Choices, and Policy Implications for Sub-Saharan Africa

Meke I. Shivute
Polytechnic of Namibia, Namibia

Blessing M. Maumbe
Eastern Kentucky University, USA

ABSTRACT

Information and communication technologies (ICT) have transformed health service delivery (HSD) in developing countries although the benefits are not yet fully understood. This chapter examines the use of ICT for HSD in the Namibian context. To obtain insights into the extent and degree of the current ICT uses, the chapter begins by mapping a HSD landscape for Namibia. The reported ICT use patterns are based on a primary survey of 134 patients and key informant interviews held with 27 health service providers (HSPs) in Khomas and Oshana regions of Namibia. The results from the survey indicate that Namibian patients use diverse range of ICT to access health services including the traditional television and radio, and the more modern mobile phones and computers to a limited extent. HSPs reported the growing use of ICT in various functional areas such as admissions, clinical support, family planning, maternity, and emergency services. The chapter identifies key challenges and policy implications to enhance the uptake of ICT-based health services in Namibia. The relatively high penetration rates of traditional ICT such as televisions and radios coupled with a growing use of mobile phones presents new alternative opportunities for expanding HSD to Namibian patients in remote settings. The chapter will benefit HSP and patients

DOI: 10.4018/978-1-60566-820-8.ch012

as they decide on affordable technology choices; and policy makers as they design interventions to stimulate the use of ICT in HSD in Namibia. The results provide key insights for other Sub-Saharan African countries contemplating ICT integration in health services.

INTRODUCTION

Information and communication technologies (ICT) have transformed the way health services are delivered in today's global society Sargeant (2005:305). For any society, however, it is important to understand how ICT are being deployed to support the delivery of health services to patients. In the case of Namibia, health service providers (HSP) in both the private and public health sectors must have the capability to use ICT as this will subsequently influence how they deliver services to their patients in the future. On the other hand, patients too, need to use relevant ICT to support and improve their access to health services. This chapter, therefore, examines the landscape for health service delivery (HSD) in Namibia. The Namibia Health Service Delivery Landscape (NHSDL) provides key insights and a better understanding of the current utilization and the future potential for ICT applications in health service delivery (HSD). The proposed NHSDL provides a comparative assessment of the emerging ICT use patterns in both rural and urban areas in Namibia. Patient's views and perceptions about ICT applications in HSD are described. Furthermore, the chapter highlights some considerations for improving access to ICT by both rural and urban-based patients in Namibia.

Namibia's health sector is distinctive and different from other sub-Saharan countries. What makes Namibia's HSD unique is the critical role that missionaries have consistently played in health care provision. Health services in Namibia are supplied by the government, missions and private providers (Namibia, Ministry of Health and Social Services, 2004b:5). The HSD system comprises two main components: a *public* and *private* health services sector (El Obeid Mendlsohn, Lajars, Forster and Brule, 2001:1). The government of Republic of Namibia (GRN) through the Ministry of Health and Social Services (MOHSS) supplies public health services, while the private health services are offered by private practitioners, hospitals and clinics. Mission health services are subsidized by the MOHSS and include hospitals, health centers and clinics. Mission health facilities are considered key part of the public health services.

In view of the fact that the healthcare sector is one of the fastest growing industries in the service sector, stakeholders in healthcare will be forced to make some adjustments to reposition themselves for the future. Those health service providers (HSP) that fail to introduce the necessary changes arising from increased use of ICT will either become obsolete or less competitive in the long-run. As a developing country, Namibia is confronted with the global competitive issues and this serves as a further motivation for this study. A competitive health service sector will play a major role in the GRN effort to meet the challenges of the Millennium Development Goals (MDGs).

Namibia is among the leading countries in Sub-Saharan Africa that have made significant strides in using ICT to transform government service delivery. Hesselmark & Miller (2002:40) indicates that Namibia's infrastructure has tremendously improved in the twelve years after independence, the number of telephone lines has doubled, the mobile network covers most of the population, the Internet can be accessed throughout the country, and 600 leased lines are in operation. Hesselmark & Miller (2002:40) further adds that ICT competence is widespread and that several large companies in the modern sector operate sophisticated enterprise software.

According to the MOHSS, Namibia has implemented a computerized health information system (HIS) that is currently being used in the public sector (Namibia, MOHSS, 2004a:26).

Given new and emerging changes taking place in ICT provision, MOHSS is revising the current HIS with the view to modernize it and make it more efficient. The newly established Ministry of Information and Communication Technology has assumed the responsibility for (i) the overall national ICT policy development functions and (ii) establishment of a legal framework for the ICT industry (Namibia, 2008). The use of telephones, faxes, emails and Internet in the health sector is becoming widespread. However, there is need to assess the extent and degree to which the modern ICT are used to support HSD in Namibia's public and private health sector. Given the foregoing, the specific objectives of this chapter are to:

i. Describe Namibia's health service delivery landscape (NHSDL).
ii. Examine existing ICT uses in Namibia's health sector and identify major constraints in health service delivery (HSD).
iii. Discuss ICT policies and their implications for health service provision.
iv. Recommend measures to enhance the uptake of ICT in HSD in Namibia.

The rest of the chapter is organized as follows: the next section provides a review of the literature and that is followed by a brief description of the research methods in section 3. Section 4 presents the results of the patient survey and health service provider key informant interviews and that is followed in section 5 by a brief discussion of the policy implications and future directions. Section 6 concludes our chapter with suggestions for future studies.

LITERATURE REVIEW

The Use of ICT in Health Service Delivery (HSD) in Developing Countries

ICT has the potential to radically change the way health services are delivered to patients and improve the quality of these services by providing easy access to health care information in developing countries especially in Sub-Saharan Africa. The benefits of ICT as a technique to improve the quality of health services is widely acknowledged worldwide and health institutions are striving to identify ways to deliver their services efficiently and effectively (Hjelm, 2005; Chandrasekhar, 2001). The benefits of telemedicine (i.e. ICT applications in HSD) have been summarized as improved access to information, provision of new healthcare services, improved access to existing service, increase in care delivery, improved professional knowledge, better quality control of screening programs, and reduction in health care costs (Hjelm, 2005). The effective use of ICT can help overcome geographic isolation for the populations that live in remote rural areas, as it facilitates access, dissemination, utilization and exchange of information on combating debilitating diseases such as malaria, tuberculosis and HIV/AIDS (Yamuah, 2005:1). A study in a remote north-west district of Russia reported that a Mobile Telemedicine Unit with endoscopy, electrocardiography and digital photography capability was used for emergency and screening purposes (Uldal, et al, 2004). Mobile ICT is important in reaching patients in remote rural locations without access to primary care facilities. In Cameroon, mobile phones helped medical residents from University Cameroon deployed in remote villages reduce their isolation and maintain contact with mentors during their rural training (Scott.et. al., 2005).

Chandrasekhar (2001:851) explains that ICT has the potential to be used as a mechanism to increase the transparency and efficiency of governance, which in turn would improve the availability and delivery of health services. The author argues that the potential of ICT in the health sector can be that of acting as mediatory role between the HSP and beneficiary (i.e. patients). In the mediatory role, ICT is used as a medium to deliver health services to patients or can be used as tool to organize information more efficiently and effectively. Yamuah (2001:2) identifies similar benefits, which include the use of ICT to facilitate communication between different levels of delivery units (e.g. district hospitals, health centers, clinics and referral hospitals). At the referral level there is added value through effective resource management and planning, efficiency in processing transactions, and access to more reliable information. Health professionals would have the advantage of effectively and efficiently sharing the information with other health professionals (Yamuah, 2001:2). ICT such as email, telephone or mobile technologies facilitate communication between two or more health professionals by sharing information on various diseases that may afflict the patients.

In developing countries, innovative uses of ICT involve the dissemination by medical experts of disease surveillance, disease treatment, and disease control interventions which saves the patient both time and monetary costs in the form of transportation charges. Such advances in telemedicine allows for the exchange of health information and delivery of health care across distances by using telecommunications (Rao, 2001:223). With the growth of telemedicine, patients can have their regular consultations with medical specialists across a distance and they do not have to travel long distances for such health services. Zolfo & Lynene (2008), explain how telemedicine is being used in remote areas to assist physicians in clinical support and mentoring. A study conducted in Tanzania to investigate the use of ICT tools such PDA's to assist members of parliament in decision making confirmed that indeed MPs do need to use PDAs to support them in decision making processes, data management and enhance information accessibility (Kirondoma *et, a.,,* 2008*).* Such modern ICT provide opportunities to support health service provision or health researches especially in rural or remote areas without basic infrastructure. Telemedicine offers a wide range of benefits which include accessibility to health services, efficient and professional healthcare delivery, quality control of screening programs and reduced health-care costs (Hjelm et.al, 2005). Bynum, Cranford, Irwin and Banken (2006:39), observed that telemedicine can improve the quality of the diagnosis and management of patients in remote areas. Richards, King, Reid, Selvaraj, McNicol, Brebner and Godden (Richards's *et.al*, 2005), are of the view that the use of ICT in health has the potential to improve access to educational opportunities for professionals and access to care in remote areas.

The use of ICT may not deliver the expected health benefits automatically. Before ICT applications in health can become a real success numerous challenges that currently serve as obstacles to their effective utilization need to be resolved (Anderson, Vimarlund & Timpka, and 2002:159). These barriers that limit access to ICT have been defined as internal (first order) and external (second) barriers (Ertmer, Addison, Molly and Woods, 1999:54). Studies by Ertmer.*et al*. (1999:54) and Lim & Khine (2006:99) characterize *internal barriers* as those barriers that are extrinsic to the ICT user and this includes lack of access ICT, insufficient time to plan instruction, and inadequate technical and administrative support. All of the above can inhibit ICT access in health institutions. On the other hand, *external barriers* are those barriers that are intrinsic to the ICT user, and are more concerned with the unwillingness to change, or user's attitude and preferences about ICT use. These barriers are referred as "fear factors" (Yamuah, 2005:2; Ertmer *et al*.1999: 54).

Health stakeholders can be unwilling to use certain ICT due to certain beliefs or they can be resistant to change due to unfamiliar ICT (e.g.

telephones, computers). Resistance to change can therefore hinder ICT use in health institutions for example if a HSP is used to record patient data in manual files, they might be resistant to using a computer for the first time if they have not been given proper training or administration support.

Hjelm (2005), identified four major constraints to ICT-based HSD and these include (i) breakdown in the relationship between health professional and patient, (ii) break-down in relationships between (and among) health professionals, (iii) potential threat of quality deterioration of health information and (iv) organizational and bureaucratic constraints. According to Yamuah (2005:2), the challenges that hinder ICT use in developing countries are (i) lack of electronic means to capture data, (ii) low literacy rates among health providers, (iii) infrastructure constraints such as low distribution of reliable telecommunications and grid power in community health units, (iv) lack of technical support and (v) high establishment costs for ICT projects given limited budget for health services. Sargean (2005:304), identified challenges for ICT use in health services as technological, educational, and social environment. These challenges hinder the widespread use of ICT by patients and staff members in health institutions. Furthermore, Huggins and Izushi (2002:114) added that the delivery of ICT learning in rural communities often has to start with quite a low level of ICT awareness and knowledge among target groups, the target groups being different stakeholders in the health sector. Overall, the barriers in using ICT to enhance HSD relate to the attitude and preference of users, access to certain ICT, and loss of social capital among some professional health workers. Hence, practical solutions to overcome these ICT challenges and enhance effective access to ICT and use are required.

Developing countries are lagging behind in new developments in ICT applications for health service delivery to patients. Despite the aforementioned challenges, telemedicine which is one of the fastest growing areas of ICT applications in the health sector offers numerous opportunities for expanding both urban and rural patient outreach (Baldwin *et.al,* 2002). Telemedicine which started back in the 1920s has been evolving ever since, and its use in developing countries is rising (Richards's *et.al*, 2005). Not only does the use of ICT in developing countries offer tremendous opportunities to enhance HSD, but it also offers new opportunities for poverty alleviation by improving life expectancy.

In Namibia, initiatives have been implemented in the education sector to encourage ICT use. The ICT policy for education is cited as one of the most successful endeavors by the GRN's in its continued effort to spread the use of ICT among its population. 21st century (Tech/na. 2007). The effectiveness, relevance, and potential to address national educational goals aligned to the MDGs goals could be duplicated by MOHSS in its vision to deploy ICT broadly in HSD in Namibia. In other countries such as Egypt, the Ministries of Health have established e-Health programs for purposes of rendering better health services to their society. The Ministry of Communication and Information Technology in Egypt has initiated the incorporation of ICT in health services. The services range from clinical consultation and administration to the provision of medical education to isolated areas. This initiative is made possible by different projects that are underway in Egypt. These include the telemedicine project, the health record system, the emergency medical service call center ambulance project, and the information system and national network for citizen health treatments by the Government (Egypt, 2005). Other African countries can follow the example of Egypt in introducing initiatives to improve ICT use for health services in the context of their countries.

METHODOLOGY

The chapter describes ICT use in the health service delivery in Namibia. The study describes how HSP and patients use ICT to deliver and access health services respectively. The chapter presents HSP and patient views about ICT uses in health service delivery (HSD) and discusses ICT-related health service delivery policy issues. The results are based on a primary survey of 21 health service providers (HSP) and 134 patients in the private and public health sector in Namibia conducted in 2005. The questionnaires covered three main sections; 1) existing ICT and how it is used to deliver health services to patients 2) the constraints in delivering health services, and 3) patient and HSP perceptions about ICT uses for health service delivery in Namibia, particularly in the Khomas and Oshana regions. The sample size was 144 patients and 21 health service providers. The data for the study was collected from the Khomas and Oshana region.

Khomas is representative of a typical urban area in Namibia while Oshana region is situated in the northern part of the country which is primarily a rural setting. The two regions were chosen in order to identify infrastructural and socio-economic deference's in ICT usage that could be attributed to geographic disparities. Khomas region is situated in the central part of Namibia and it is 37,007 square km², and this is where the capital city Windhoek, is situated. The region consists of various health facilities of which, one is a national referral hospital, one intermediate hospital, two health centers, seven clinics, three private hospitals, private clinics and thirty-three outreach points. The region has the highest population which stands at 264,616 compared to other regions in the country, and the population per hospital is 121,278 (Namibia, 2006). Access to ICT in the Khomas region might be higher than Oshana, as the community tends to have better access to resources especially infrastructure endowment. Oshana region is the smallest region (5,290 km²) with a population of 167,797, hence it is densely populated (Namibia, 2004a:1). The Oshana region is the second largest population concentration in Namibia after Windhoek, but it lacks basic infrastructure and most of the services and facilities normally found in urban areas of this size (Anon, 2007a).

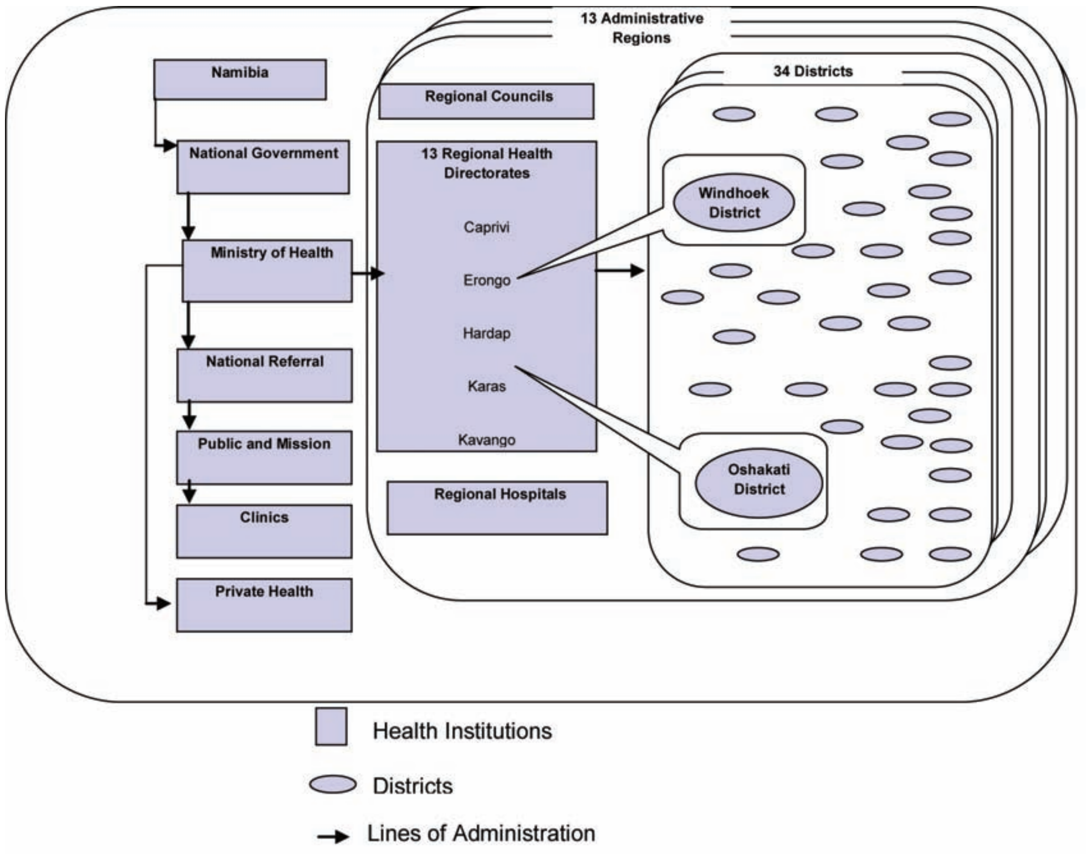
Secondary data sources that were utilized included publications such as journals, white papers and health policies some of which were still under construction. Government policies were examined to determine the enabling environment for ICT applications in HSD. In cases where the necessary documents were not easily accessible, GRN officials from the Policy and Planning Directorate were interviewed to provide additional insights on the potential of ICT deployment in Namibia's health sector.

The study is limited to the use of ICT in the health service delivery and it excludes use in other areas of the health sector such as pharmacies. The study explored ICT use by HSPs in the health facilities such as mission, private and public hospitals. The data collection was limited to the Oshana and Khomas regions, where a sample of stakeholders from each region was interviewed on ICT use in their health facilities and did not cover all the regions of Namibia.

The Namibian Health Services Delivery Landscape

The Oshana health directorate is divided into fifteen health facilities, one Intermediate Hospital (regional), four health centers and twelve clinics. The district also has twenty-eight outreach points. The intermediate hospital is the ultimate referral point in the Oshana region and it is responsible for providing essential back up services and support for clinics and health centers in the region. Health centers are smaller than intermediate hospitals and they are found in two types, namely, day care health centers and rural health centers (i.e., the latter is common to Oshana region). The population per hospital in the Khomas region is 169,147 (Namibia, 2006). The idea of a landscape development was first researched by Korpela et,al. 2004a. In their study, they explained that a

Figure 1. The health service delivery landscape in Namibia, 2007. Source: Survey data, 2006



health landscape is used to depict health service provision to patients in different health sectors and that the landscapes would differ from one country to the next. The 'generic' health service delivery landscape for the Namibia was the first step taken in developing a health landscape model for other regions and a 'generic' model for the whole country. A number of documents were specifically reviewed during the landscape development and these include national health accounts and other government publications. The Namibian generic landscape is depicted in Figure 1 and it illustrates the various stakeholders in the health sector and how they provide ICT related services to patients. The landscape further depicts inter-relations among key stakeholders.

The Ministry of Health and Social Services (MOHSS) is responsible for providing health and social services to the citizens of the country. There are 13 regional directorates, namely; Caprivi, Erongo, Hardap, Karas, Kavango, Khomas, Kunene, Ohangwena, Omaheke, Omusati, Oshikoto, and Otjozondjupa. These directorates are under the management of the MOHSS and within these directorates are 34 districts. The Khomas region has one directorate namely Windhoek. There is one national referral hospital country wide and it is located in the Windhoek district. The national referral hospital is under the management of the MOHSS which is at the national level. It is important to note that the description of NHSDL excludes other stakeholders in healthcare such as, pharmacies and medical aid companies because the study's purpose will primarily focus on use of ICT in the health service delivery for hospitals and health facilities (mission, public and private) in the

Khomas and Oshana region. The entire NHSDL should encompass ICT utilization by both formal and informal health service institutions including traditional care providers.

RESULTS AND DISCUSSIONS

The ability to access affordable health services plays an important role in the effective delivery of health service especially to the poor communities. The use of ICT depends entirely on whether HSP or patients have access to affordable ICT. In addition to the cost factor, effective use of ICT also depends on positive perceptions about deploying these modern technologies to deliver and access health services. The data on patients' ICT use patterns and perceptions is shown in tables 1 and 2 for the Khomas and the Oshana regions respectively.

ICT awareness in the Khomas region (Table 1) is relatively high as patients indicated they have access to most of the technologies. Most (99%) patients showed that they have used a radio and television before, even though for some patients they do not own these ICT at home. In case of television, some patients who did not own a television set at home indicated that they

had access either in their neighborhood, or when they visit health facilities where they watch video cassettes on health education. Awareness of ICT also proves to be strong in mobile phone use, as 92 percent of patients that took part in the survey indicated that they own a mobile phone. Those that did not own them explained that they had at least one person in their household who owned a mobile phone. The high penetration of mobile phone use provides new avenues for the delivery of mobile health services.

There were various perceptions displayed by patients on ICT use. Some patients expressed the view that they cannot operate some of the ICT (e.g. computer, Internet). Most of the patients that expressed the view that they did not know how to use a computer or Internet either felt that the technology was too advanced (i.e. functional illiteracy) or either they had no access to working computer at all. ICT literacy implies the ability for users to operate diverse ICT tools. The surveyed patients indicated a high ICT literacy rate in terms of their capability to operate the radio (100%), mobile phone, and a landline telephone (99%). The ability to use different ICT was also high for PC (74%) and average for Internet (50%).

Large proportions of patients indicated that they use mostly radio (83%) and television (74%) for health related services e.g. listening to health programs or watching health education programs on TV. Telephone (56%) trailed by mobile phone (44%) were the common ICT used for health-related purposes. The traditional ICT such as radio (76%) and TV (69%) are mainly used as mediums for educational purposes. Radio ranked high (i.e. 100%) as the ICT that all the patients in Khomas region could operate, and which could easily be adapted for health education purposes. This is consistent with the results of Kenny's study where he reported that radio was highly used (71%) by rural people in Nepal as their source of information (Kenny, 2002:150). The Internet is slowly being used for health-related services as only (21%) of patients use it for this purpose. The study did not ask respondents on whether or not they used email to obtain for health services.

On the other hand in the Oshana region (see Table 2), a lot of patients indicated relatively low access to ICT such as computers (31%) and the Internet (19%). The main reasons provided for not having access to these ICT were (i) lack of knowledge and (ii) absence of necessary infrastructure to enable access to specific ICT. Despite the low access to ICT, all the patients surveyed stated that they use radio (100%) for entertainment and for listening to health services and that (98%) owned radios in their household. Mobile phones (95%) are also highly used in the Oshana region. Patients in the Oshana region demonstrated a relatively high functional literacy, as most of them could operate radio (100%), telephone (99%) and mobile phone (97%). A summary of ICT use patterns and perceptions in Oshana are shown in Table 2. In the Oshana region, radio (92%) and television (79%), were the two leading ICT that are mostly used for health-related purposes while telephone (45%) and mobile phone (39%) came third and fourth respectively as being used for health-related services. ICT such as mobile phone (55%), radio (95%), television (63%), are currently being used for educational purposes in the study zone of Namibia. In the case of television, HSP mentioned that they provide health education to patients by playing videos with films that inform patients about dangers of spreading diseases such as HIV and AIDS etc and how to combat the disease outbreak.

During the survey, patients were questioned on their willingness to improve their ICT skills. Patients displayed a strong interest in learning how to improving their ICT skills which shows a positive perception towards ICT. On the other hand HSP had different opinions on how existing ICT in their institutions has helped them to enhance the services provided to patients. It is remarkable to note that there was complete consensus among HSP on the view that ICT helps them to access new health information. It was observed that use of computers helps to improve efficiency and effectiveness of health management information. This mostly applied to departments such as admissions, where patient data needed to be captured and stored accurately.

Ninety-one percent of HSP viewed ICT as helping them to interact with other HSP and other health institutions and higher levels of authority. Eighty-one percent of HSP strongly agreed that ICT does provide ways to improve health services even though there are costs involved in the introduction, maintenance and utilization of ICT. More training of staff on ICT use is required to achieve more effectiveness. Ninety-five percent of HSP strongly agreed that the GRN needs to play a more prominent role in the provision of ICT for HSD, as they felt that the public sector is lagging behind in ICT use as compared to the private sector. HSP felt that the public sector should learn from the private sector how ICT is used in the process of service provision to the patients. Results of specific uses of different ICT in HSD are presented in table 3 and discussed in the following section.

The results indicate that ICT are deployed across different functional areas in health service provision in Namibia. The functional areas where ICI is currently deployed are admissions, consultation and clinical support, maternity, family planning, and emergency purposes. Overall,

Table 4. ICT use constraints in the Khomas and the Oshana regions, 2007

Constraints	Description
Budgetary constraints	Finances are not enough to buy all the necessary ICT to assist in the process of service provision to patients.
Lack of basic infrastructure to support health service delivery	Some health facilities especially those in the rural areas lacked basic infrastructure such as electricity and this was a constraint in using ICT such as personal computers.
Lack of basic technological skills	Some HSP providers do not have skills in operation ICT related tools such as Personal Computers

Source: Survey data, 2007

telephone was the most commonly used ICT across all the various health departments. It is interesting to note that HSPs mentioned that TV was a common form of communication channel for health education as this corresponds with the patient's responses that they use TV as their main source of health information. Mobile phones usage was reported in admission and for emergency services especially when the cheaper landlines are not functioning. Pagers were commonly used in clinical support and emergency services. The personal computers and Internet were used in administrative support in admissions and clinical support respectively. The electronic patient record was used in clinical support to keep track of medications (ARVs) for HIV and AIDs patients. These results demonstrate the extent to which ICT have been deployed in different functional areas in Namibia. Despite making some tangible progress in ICT deployment for HSD, Namibia still confronted with some major challenges which are described in Table 4 above. These challenges were grouped into three main areas, (i) budgetary constraints, (ii) poor ICT infrastructure, and (iii) lack of basic ICT skills among health workers and patients. Budgetary constraints imply the shortage of sufficient public and private) funds required to acquire the necessary modern ICT in order to upgrade HSD systems in Namibia. Related to the problem of funding, is the weak back-borne infrastructure for ICT service delivery. The shortage of electricity hinders the effective utilization of ICT especially in remote rural areas. Without electricity, or alternative energy sources such as solar panels, the use of

computers and Internet will remain limited in geographically remote locations of the country. Even if the country were to allocate adequate funds for the purchase of needed ICT equipment and machinery, and rural electricity generation were to be expanded further, shortage of a critical mass of well trained ICT cadres will remain a major handicap for ICT use for HSD in Namibia. With new ICT constantly coming on stream annually, the development of human capital skills required to support and manage ICT-based health service delivery is central to its effective utilization and sustainability of such services. Although Namibia faces a number of constraints in delivering health services to patients, the foregoing results show a relatively high level of ICT use in both Khomas and Oshana region. This confirms that ICT use in Namibia has been growing and there is scope for further expansion and progress (Schware, 2003:3).

POLICY IMPLICATIONS AND FUTURE DIRECTIONS

In order to sustain the initial progress in ICT use in Namibia, the development of sound effective ICT policies is pivotal. The development of ICT policies plays a vital role in terms of providing timely interventions to stimulate ICT deployment and uptake. Namibia's health sector provides ample opportunities to create a huge market for ICT-based health services that will benefit both HSP and patients alike. According to Galloway and Mochrie (2005:41) policies interventions are needed to support rural ICT development and promote economic sustainability. Such policies should be developed with clear objectives and specific goals in mind, regarding expected achievements of the health institutions. Policies help determine the rate and direction of ICT uses for health purposes and benefits of policy development spills over artificial borders that exists between jurisdictions (Scott, 2004). In addition, key lessons can be drawn from policies, administrative and institutional arrangements, and ideas that work in a given setting. According to the United Nations (2007) public policies are often best designed and implemented in close dialogue with various stakeholders. The UN report specifically mentioned examples of South Korea and India that close cooperation between public and private sectors was crucial to the success of their ICT Industry. Further, in those countries, private industry associations participated in ICT-related policy formulation. Sub-Saharan countries should draw some key lessons from the development of ICT related policies on HSD that have been successfully implemented elsewhere (UN, 2007).

In the East Africa, there is ICT policy coordination at the regional level. The approach aims to increase levels of regional cooperation and development. The ICT policy framework in East Africa is designed to foster sustainable development in various areas and this includes the health sector (UN, 2003:2). McFarlane, Murphy and Clerkin (2006:245) discussed a number of health information policies in Ireland as they relate to telemedicine services. They concluded that using ICT in telemedicine is a challenge that need to be tackled by taking cognizance of the complexities involved, and actively fostering levers to implementation and sustainability through policy, practice and research initiatives. With reference to Asia, Quibria, Ahmed,Tschang and Reyes-Macasaquit (2003:819) state that policies to promote ICT involve investment in education, infrastructure, creation of favorable institutions, fostering new institutional innovations and international cooperation.

Governments and health institutions in Sub-Saharan Africa should have clear policies and specific strategies on how certain ICT should be implemented (Schware, 2003:3). Maumbe and Owei (2007:1) argue that ICT policy in Africa is lagging behind other regions. In order to achieve long term success in e-government policy development and implementation, institutions should examine the socio-economic context, key constraints and formulate appropriate policies that address those challenges. However, governments cannot merely set up their own policies but they must adhere to the international standards. Namibia (2002:33) has adopted the position that government policies, standards, and procedures must be internationally benchmarked for best practices. Furthermore, policies and standards should also facilitate interoperability within an international, voluntary and consensus-based environment for standards setting. The international standards bodies such as International Telecommunication Union guide Namibian policies and standards formulations. According to (Maumbe and Owei, 2007:1) the area of ICT policy development has received less attention in Sub-Saharan Africa, and South Africa is not an exception despite making great strides in e-government development. A study conducted by Joseph and Andrew (2006), recommends that policies must be developed in such a way that they support and stimulate ICT use by rural people. Furthermore, policies should be crafted in such a way that it improves ICT access at low cost especially through public service. E-health policy response of countries has been classified as “none”, “reactive” or “proactive” (Scott, 2004). While none is self-explanatory, reactive suggests policies that are crafted in response to some major internal shock or external pressure. Proactive, which what African countries should strive for, deals with policy development in advance of immediate need and guided by a context specific development strategy that is unique to given country and its socio-economic circumstances or resource endowments.

At the time of our study, Namibia's MOHSS did not have an ICT policy for HSD to patients as it was still in a development stage. But there is a national ICT policy that the MOHSS adheres to. According to the interview with the Directorate of Policy and Planning, the MOHSS adheres to policies established by the public service committees. With the recent establishment of a Ministry of Information and Communication Technology, Namibia is in a much better position to design a sustainable ICT policy for HSD. In addition, successful ICT policy initiatives in education and lessons drawn from other African countries could provide further insights into critical issues for consideration when crafting such a policy.

As already alluded, Namibia's Ministry of ICT is still in its infancy stage (Namibia, 2008). The new Ministry of ICT aims to establish future mechanisms for the collection of relevant information from operators and to conduct comprehensive research to identify relevant context specific issues, trends and other matters that may affect the sector. Further, the Ministry plans to establish a formal process for the periodic reviews of ICT policy documents with a comprehensive feedback mechanism from key stakeholders. Therefore, our chapter contribution to the book on e-government is expected to benefit the Namibian government and several other African governments involved in the design and implementation of sustainable ICT policies in the twenty first century.

CONCLUSION

This chapter examined the use of ICT in HSD in the Namibian context. The chapter described the NHSDL which shows the key health service facilities in the country and the existing and potential arteries for ICT utilizations. The results from the primary survey conducted with patients and also interviews held with HSP in Khomas and Oshana regions highlight the existing patterns of ICT use among patients and the health service departments or functional areas that have deployed ICT. The chapter outlines some of the major constraints in delivering ICT-based health services in Namibia namely, funding shortages, poor infrastructure and low ICT literacy. The high penetration rates for traditional ICT such as televisions and radios coupled with a growing use of mobile phones presents alternative relatively under-explored opportunities for HSD to patients. The increased use of mobile phones and mobile computer lat tops could help overcome geographic and infrastructural challenges associated with ICT use for HSD in Namibia.

The chapter highlights the need for the Government of the Republic of Namibia (GRN) to actively pursue the opportunities presented by ICT such as personal computers and mobile phones to complement traditional ICT-based HSD channels such as radios and televisions. The Namibia Ministry of Information and Communication Technology working in collaboration with the Ministry of Health and Social Services should develop "pro-active" ICT policies that will create an enabling environment for ICT use, and stimulate its uptake by both patients and HSPs. The results indicate a strong momentum for ICT use in HSD that can be further developed, strengthened and natured with the backing of a sound and effective policy development process. Without targeted policy development for ICT use in HSD, the current momentum will fizzle out, and one of the best opportunities to transform HSD in Sub-Saharan Africa (and thereby alleviate poverty) will be sadly missed.

The results in this chapter can be used to provide insights into similar efforts to incorporate ICT in HSD in other African countries. Future studies should examine ICT use in private or public health care focusing on specific patient groups (children, elderly, physically disabled members of society etc), functional areas (e.g. admissions, emergency services, maternity, clinical support, family planning etc), and the treatment of highly contagious disease outbreaks (e.g. HIV and AIDS, SARs, avian flu, swine-flu (HIN1), etc.). An alternative study could assess the willingness to use ICT such as mobile phones, personal digital assistants, and mobile lap-tops, as these are the likely future channels for HSD. Such a study should provide a comprehensive analysis of both the tangible benefits and the negative externalities associated with the use of such applications for HSD in both the short-term and the long-term.

Chapter 4.8

Factors Affecting the Adoption of ICT for Health Service Delivery in Namibia:

The Role of Functional Literacy and Policy Implications

ABSTRACT

The article examines ICT use in health service provision in Namibia. The patterns of ICT use for health services by patients, public and private health service providers are not yet fully understood. This study describes ICT applications in health service delivery to patients in the Khomas and Oshana regions of Namibia. The study interviewed 134 patients and 21 health service providers. Factor analysis on ICT use identified three main factor groupings namely, 'high technology', 'mobile technology' and 'traditional technology'. Multinomial regression results showed the major factors affecting multiple ICT awareness in the two regions as functional literacy, diverse sources of health information services, age and educational level of the patients. Logistic regression results on individual ICT use identified functional literacy, personal privacy, cost of ICT, age, education, and positive perceptions about ICT applications in improving health services as statistically significant factors influencing adoption by both rural and urban patients in Namibia.

INTRODUCTION

The use of Information and Communication Technologies (ICT) in the provision of health services is growing rapidly throughout Sub-Saharan Africa and the developing world. As ICT are deployed in health service delivery (HSD), there is a need to understand how individuals are using the new devices to access health services. Namibia is one of the few African countries that have demonstrated leadership in ICT utilization (SIDA, 2002; Hesselmark & Miller, 2002:36), and HSD seems to provide growing opportunities for the application of these modern technologies.

For the effective use of ICT for health services to occur, both patients and health service providers (HSP) must be willing and able to use the new devices in health service provision. In addition, the use of ICT for HSD must be socially inclusive; that means both rural and urban-based patients must be exposed to the new ways of health service provision. Moreover, social inclusivity requires that both young and old, rich and poor, able-bodied and physically challenged, and individuals of various backgrounds must have equal access opportunities.

However, the emerging patterns of ICT use for health services by Namibian patients are not fully understood. Similarly, the use of ICT by public and private health service providers remains unknown, yet this may influence how they deliver services to their patients in the future. Given the gap that exists between the understanding of (i) the patterns of ICT use by patients and (ii) the degree or the extent to which ICT are being used for HSD by HSPs in Namibia. It is of paramount importance that knowledge is amplified of how this growing phenomenon is unfolding. Therefore, successful utilization of ICT for HSD requires that digital divide constraints, patient technology demand patterns, service provider access and utilization, and public policy among others are seriously addressed.

Failure to understand the key factors affecting ICT use for health services by patients may lead to gaps in enabling policies, ineffective policy formulation, or a total absence of policy. In turn, this may lead to a general lack of ICT awareness or it might affect the effective use of ICT in HSD in general. Without doubt, HSPs in both private and public health sector play a central role in the provision of ICT-based health services. In order to improve our understanding of the circumstances surrounding ICT use for health services, this particular article seeks to examine; (i) the factors affecting the use of both individual and multiple ICT by Namibian patients (ii) Highlight key constraints that inhibit patient's access to ICT for health services, and (iii) Recommend policy considerations for improving the uptake of ICT for HSD in Namibia. In order to address the above stated issues, this study analyzes the type of ICT being used in HSD to patients in the Khomas and Oshana regions of Namibia, an urban and rural setting respectively.

The rest of the article is structured as follows: In the next section, background information on transformations in HSD in Namibia is presented. Then secondly, the significance and limitations of the study will be described. Thirdly, institutional policies in support of ICT for HSD in Namibia will be examined focusing on government ICT policy and its implications for HSD and this is followed by a presentation on the theoretical framework of the study. Fourthly, the next Section presents the methodology used to collect and analyze data. And finally, the results and discussion of the findings will be presented and this will lead into the concluding remarks and recommendations for future research.

BACKGROUND: TRANSFORMATIONS IN HEALTH SERVICE DELIVERY (HSD) IN NAMIBIA

As in most developing countries, Namibia is at the threshold of expanding its ICT use in HSD to promote sustainable development and the knowledge society (Schware, 2003; Crede□ & Masell, 1998). In today's information society, health professionals need to maximize the potential benefits offered by ICT as a means to improve public access to health care and information (Wallace: 1997:88).

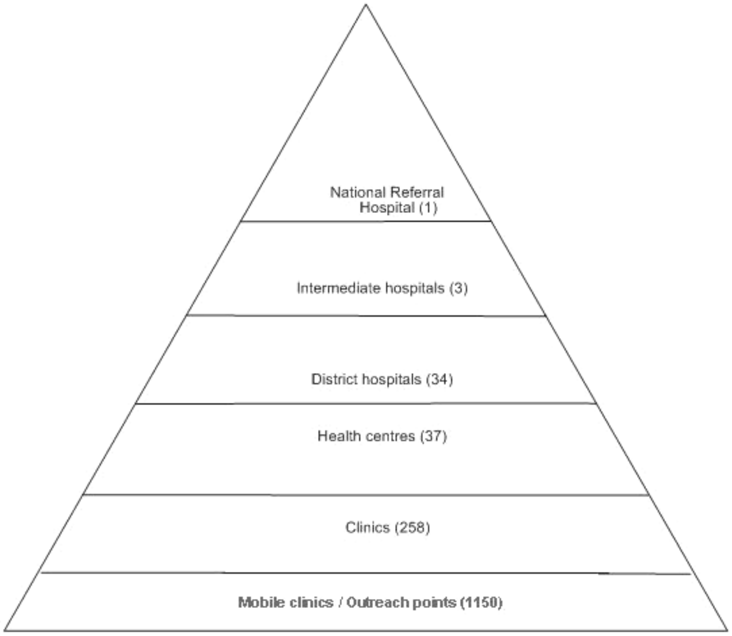
The Government of the Republic of Namibia (GRN) has developed a general ICT policy which was an outcome of several consultative workshops. This policy was aimed at shaping the use of ICT in the country, starting with the education sector. The policy provided the basis for the telecommunications policy and regulatory framework of 1999 (Namibia, 2002:19). In addition, there have been policy reforms in terms of ICT implementation in Namibia (Hesselmark & Miller, 2002:5). According to the Namibian National Information and Communication Infrastructure (2006), the country has been active in ICT policy formulation and in developing the necessary infrastructure for the information society. The country's telecommunications and Internet infrastructure is very advanced by African standards, (United Nations Economic Commission for Africa, 2006). It is important to observe that although a general ICT policy has been developed and implemented, there is still no official policy on ICT use for HSD.

A GRN's national development plan entitled "Namibia Vision 2030" aims to "improve the quality of life of the people of Namibia to the level of their counterparts in the developed world by 2030" (Namibia, 2004c: 7). The 2030 vision pertaining to ICT status in Namibia aims to advance ICT to achieve social and economic transformations in the country. As the cost of ICT continue to fall while the capabilities increase, ICT are bound to be applied throughout all the development sectors of the economy for the benefit of society (Namibia, 2004c: 79). One of the weaknesses of the "Namibia vision 2030" is that it does not describe the current state of ICT for HSD in Namibia, but it simply focuses on what is aimed to be achieved by the year 2030.

The Ministry of Health and Social Services (MOHSS) has adopted a decentralization policy to improve health service provision and management by devolving authority to the thirteen regional directorates of the MOHSS (Namibia, 2003:31). The thirteen regional directorates manage service delivery in all health districts. The provision of health services in Namibia is divided proportionally between the government (i.e., provides 70-80%), missions (i.e., provide 15-20%) and the private sector which provides 5 percent of the health services. Delanyo (2001:2) explains that the non-governmental HSPs in Namibia are mainly in the form of various religious missions, which are subsidized by the government and include hospitals, health centers and clinics, mainly in the rural areas of the northern part of the country. For example, the missions (i.e., Lutheran, Anglican, and Roman Catholic) are non-profit providers, and they are 100 percent subsidized by the MOHSS (Namibia, MOHSS, 2004b:5). The organization of health services in Namibia is depicted in Figure 1.

Given this background on health services provision, what is important to note is the fact that the state of health services is poised for a major improvement with the introduction of ICT in the Namibian health sector. ICT are used to support HSD to all the thirteen regions and thirty four districts. The main aims of using ICT tools such as personal computers is to analyze, document, and distribute the planning, implementation and evaluation of health information, and also to assist with resource allocation and direct changes in policies and strategies. Furthermore, the use of ICT aims to improve the delivery of quality health services and improve the effectiveness of strategies, monitor performance over time and

Figure 1. Organization of health service delivery in Namibia



Source: Namibia, 2003:7.

identify health facilities that need support and supervision (Haoses-Gorases, 2005).

According to Baldwin, Clarke, Eldabi and Jones (2002:312), ICT plays an increasingly crucial role in delivering healthcare nowadays. In Namibia, ICT applications to support HSD are growing, partly because the MOHSS has completely decentralized and computerized the health information system (HIS) to the regional and district level (Namibia, 2004a:26). The foregoing shows that ICT are being used to some extent to support HSD, even though there is need for improvement on the efficiency and effectiveness of the processes at the operational levels.

This study describes and analyzes factors that influence the adoption of ICT for HSD in Namibia with specific reference to the role of functional literacy and policy implications.

MOTIVATION, SIGNIFICANCE AND CONTRIBUTION OF STUDY

Given the growing importance of ICT use for socio-economic development in Africa, it is crucial to study the use of ICT in improving HSD in Namibia. It is crucial so that health services are diffused to communities in remote locations and those faced with health emergencies that require immediate diagnosis and intervention. There are signs of growing ICT related developments in the area of HSD in Namibia. HSD encompasses the provision of information for health care, prevention and treatment. By examining the literature and conducting a survey with both the patients and HSPs, recommendations can be made to policy makers on how to effectively deploy ICT in delivering health services in Namibia. The results of this study can be used to provide lessons for other African countries and draw some insights for policy and further research work.

LIMITATIONS OF THE STUDY

The limitations of this research are threefold; (i) it covers only two regions of Namibia, (ii) targets a specific age group of patients (i.e. those who were 15 years and older at the time of the study), and (iii) the fact that these results are drawn from a cross-sectional survey that are specific to the time of the study. We recognize the fact that ICT uptake is constantly evolving and the value of longitudinal studies should not be underestimated. It is also important to emphasize that this study does not address the use of ICT for the treatment, prevention or caring of patients with a specific disease ailment. Such more specialized studies will help provide valuable contribution to ICT applications in HSD.

LITERATURE REVIEW

Potential Impacts: ICT has the potential to radically change the way health services are delivered to patients and improve the quality of health services by providing easy access to health information. The potential use of ICT as a means to improve the quality of health services is widely acknowledged worldwide, and health institutions are striving to identify ways to deliver their services more efficiently and effectively. ICT can be utilized to minimize geographic isolation for the population in rural areas, and they can facilitate access, dissemination, utilization and exchange of information on combating debilitating diseases such as malaria, tuberculosis and HIV/AIDS (Yamuah, 2005:1). Chandrasekhar (2001:851) adds that ICT has the potential to be used as a mechanism to increase the transparency and efficiency of governance, which in turn would improve the availability and delivery of health services. ICT encourages easy dissemination of disease treatment and disease control and it also helps to reduce costs on patient transfers (Yamuah, 2001:2). Telemedicine is a good example of this, as it simply allows exchange of health information and delivery of health care across distances by using telecommunications (Rao, 2001:223).

Benefits: Numerous benefits in ICT use for health services abound. For instance, ICT use can facilitate the delivery of information in a reliable manner and enhance communication in the health sector. Technologies like the Internet and e-mail have the ability to send information in a fast, efficient and cheap fashion, which can provide remarkable improvements in access to information and care in the health sector (Pradhan, 2003:157). Historically, traditional technologies such as telephones have improved delivery of health services to patients, especially those in remote areas, and they continue to play a major role in this process. Mcwhirter (2003:341) suggested a wide range of ICT options and amongst them a bedside television that has been used as a source of health information for patients in hospitals in England. Radio has also been widely used as a means of communication especially in rural areas to better communicate health information to communities in remote areas. Kenny (2002: 141) reviewed the potential efficacy of radio and telephones and concluded that such ICT are powerful and sustainable tools that meet diverse information needs of the poor and that traditional technologies are less expensive than high technology such as Internet. In Uganda, FM radio transmission and modern graphics transmitted via the TV stations are one-way communication channels that are being utilized to deliver health service information to patients (Kasusse, 2005:148). Similarly, mobile computing or technology which includes laptops, palmtop computers, Personal Digital Assistants (PDAs) etc., are examples of portable ICT that are increasingly being used for health services (Hameed 2003:100) and are making health procedures more accurate and efficient thereby reducing the risk of human error (Chao, Jen, Hung, Li & Chi, 2006:1;Chau and Turner 2006: 307). PDAs have proven useful in African countries such Uganda (Satellife Inc, Uganda Chartered Healthnet and Makerere University in 2003).

Challenges: While there are many benefits offered by using ICT in the health sector, there are a number of challenges which need to be tackled before the benefits are realized. Yamuah (2005:2) states that developing countries are facing a lot of challenges that hinder ICT use. The challenges in the health sector may be summarised as outdated modes of data collection, lack of electronic means to capture data, dependency on manual processes in hospitals for administrative, diagnosis and referral services in Africa and other developing countries, and low literacy rates among health providers that in turn affect ICT utilization, since literacy is critical for ICT use. The literacy problem is actually spreading from computers to new ICT, such as PDAs, 3G mobile phones, etc. Infrastructure constraints such as low distribution of reliable telecommunications and grid power in community health units, and lack of technical support have been identified as a hindrance in ICT use and the high establishment costs for ICT projects given limited budget for health services. The barriers in using ICT to enhance health services relate both to the specific use and access to certain ICT.

Computer use in HSD: Over the past decades, the use of computers in HSD has increased. Computers are being used particularly in large public hospitals and also in different applications such as Health Information Systems (HIS), computer-based psychological testing applications and individual patient monitoring in the intensive care units (Egan & Liu, 1995:357). Rao (2001:222) states that computers have become indispensable to the healthcare industry. The Internet has been widely used in health care industry and it has brought remarkable changes in the way services are delivered. It has been used especially in developed countries to supply health related information, such as diseases symptoms, research in the medical fields, etc. The Internet plays a vital role in the health sector and it has improved the process of delivering services to patients. According to Seror (2001:2), the Internet provides rapid access to medical information and expert consultation, and this will help in the process of delivering services in developing countries. Tele-health is one of the key ICT uses which include health services, education and research supported by the Internet, and it affects the way health services are provided (Seror, 2001:2).

INSTITUTIONAL POLICIES IN SUPPORT OF ICT FOR HEALTH SERVICE DELIVERY

Policies play a vital role in the use of ICT in any sector. According to Galloway and Mochrie (2005:41) policies have been developed for a number of ICT related issues. Galloway and Mochrie (2005:41) stated that policies may best intervene to support rural ICT development for economic sustainability or advantage. Policies should be developed with clear objectives and specific goals in mind, regarding expected achievements of the health institutions. In East Africa, ICT policies are being coordinated at the regional level with the aim to increase socio-economic development. The ICT policy framework in Eastern Africa is designed to foster sustainable development in various areas including the health sector (UN, 2003:2). In Asia, Quibria, Ahmed, Tschang and Reyes-Macasaquit (2003:819) state that policies to promote ICT involve key investments in education, infrastructure, creation of favorable institutions, fostering new institutional innovations and international cooperation. Schware (2003:3) argues that governments and health institutions should have policies and strategies on ICT implementation. Maumbe and Owei (2007:1) are of the opinion that in order to achieve long term success in e-service delivery and e-government policy development, it is critical to examine the socio-economic context and identify key constraints that inhibit the formulation and implementation of appropriate policies.

However, governments cannot merely set up their own policies but they must adhere to the international standards. Namibia (2002:33) has adopted a position that local government policy standards and related processes should be internationally benchmarked and must also facilitate interoperability within an international, voluntary and consensus-based environment for standards setting. The international standards bodies such as International Telecommunication Union guide Namibian policies and standard formulations. According to Maumbe and Owei (2007:1), the area of e-government and ICT policy development and implementation has received less attention in Africa, and South Africa is not an exception despite making great strides in e-government development.

At the time of the study, the Namibian MOHSS did not have an ICT policy developed specifically for the delivery of health services to patients. But there is a national ICT policy that the MOHSS adheres to. According to the interview with the directorate of policy and planning in the MOHSS the ministry adheres to policies set up by the public service management committees. However, it was established that the policy for HSD was in draft form at the time of the study and was still to be implemented. Even though, there is no ICT policy specifically for HSD in Namibia, there have been initiatives in other sectors such e-education. The ICT policy for education has been implemented with the aim of articulating the relevance, responsibility, and effectiveness of integrating ICT in education with a view to meeting the challenges of the 21st century (Tech/na, 2007:1). In this regard, Namibia is deemed to benefit from a similar focused ICT policy for HSD.

THEORETICAL FRAMEWORK FOR TECHNOLOGY ADOPTION IN HEALTH SERVICE DELIVERY

The use of ICT such as PDAs, PC, mobile devices etc. in the health sector has grown and both patients and health service providers need to be aware of these changes. According to Schaper & Pervan (2004), applications such as electronic patient records, telemedicine, clinical information systems will become common place in the health industry. However, the key question should be if such applications are implemented, will the stakeholders adopt or use the applications or ICT provided to them? Understanding the adoption factors and diffusion of ICT is paramount.

Damanpour (1991) study on adoption of health innovations reports that managerial attitudes towards change have positive influence on innovation adoption. Ma and Liu (2004) used the Technology Acceptance Model (TAM) to explain the usage of information technology. Johnson (2005) argues that TAM explains perceived ease of use and perceived usefulness predicts attitude toward use of technology. Further, the author adds that "attitude toward use predicts the behavioral intention to use". Davis (1989), defined perceived usefulness as the extent to which a person believes that using technology would enhance job performance and perceived ease of use refers to the extent to which a person believes that using the technology would be free of mental effort. According to Gagnon et, al, (2005) successful implementation of telehealth will ultimately depend on both human factors and organizational (and managerial or operational) factors.

A number of studies have used TAM as a basis for discovering the effect of external variables on the internal beliefs, attitudes, and intentions of users. A study by Lu, yu , Yiu and Yao (2003) developed a TAM for wireless Internet via mobile devices. Their study focuses on explanatory factors for use of wireless Internet and mobile devices. Lu, yu , Yiu and Yao (2006), conducted a comparison study whereby they compared various theories on technology adoption.

In contrast, the Theory of Planned Behavior (TPB) is believed to provide more specific information that can better guide development (Mathieson, 1991). TPB speculates that individual behavior is determined by behavioral intentions where behavioral intentions are a function of an individual's attitude toward the behavior, the subjective norms surrounding the performance of the behavior, and the individual's perception of the ease with which the behavior can be performed (behavioral control) (Ajzen,1991). The TPB theory was later extended and integrated with TAM by Taylor and Todd (1995). The integrated model further incorporated additional factors that were not present in TAM.

The Unified Theory of Acceptance and use of Technology (UTAUT) explains end user intentions to apply an information system (IS) and subsequent usage behavior. According to Venkatesh et. al.,(2003), the theory consists of four key constructs namely, performance expectancy, effort expectancy, social influence, and facilitating conditions that are direct determinants of usage intention and behavior (dependent factors). Independent factors such gender, age, experience, and voluntariness of use are hypothesized to mediate the impact of the four key constructs on usage intention and behavior (Venkatesh et. al., 2003).

Not much research has been done to understand factors affecting multiple technology adoption in health service provision to patients. This particular study uses a different approach based on (i) the multiple nature of the ICT being adopted for health services. Secondly, the study setting is unique in that it compares the circumstances affecting ICT use for HSD among both rural and urban patients in a developing country context. The selection of variables affecting adoption draws upon common categories of independent variables that were used in previous studies namely, attitudinal, demographic, facilitative, managerial/operational, geographical, and performance related variables. A selection of previous studies and models used on technology adoption are summarized in Table 1.

Since this study focuses on the adoption of several ICT for HSD, it will employ multinomial and logistic regressions to determine significant factors that influence the aggregate use of these modern technologies and to draw policy implications. Those two models help us to understand factors affecting multiple as well as individual ICT adoption respectively. The empirical model uses key factors such as functional literacy, sources of health information services and demographic variables (e.g. age, gender, and level of education) to explain ICT use for HSD to patients. Table 2 summarizes the different categories of independent variables used in the empirical models. Based on the fore-going information; the next section will therefore describe the methodology used to collect and analyze data from respondents.

METHODOLOGY

The study examined ICT use in HSD in Namibia's rural and urban areas. The main focus of our study was on how patients and HSP use ICT in HSD. The study also examined patient views, constraints they face in using ICT to access health services, as well as government ICT policy and its implications for HSD.

Location of the Study

The study was conducted in the Khomas and Oshana regions of Namibia. The rationale for choosing these regions is that Khomas is representative of a typical urban area while Oshana region is situated in the northern part of the country which is primarily a rural setting. By conducting the survey in two different geographical areas, the researchers sought to make comparisons of any geographical and socio-economic differences and or similarities in ICT use for HSD.

Table 1. Selected technology adoption studies

Author	Model description	Data Collection (Sample Size)	Factors	Remarks
Davis (1989)	Technology acceptance model (TAM)	Cluster analysis used to determine the structure of the substrata.	-Near-term usefulness -Long-term usefulness -Ease of use -Behavioral intention to use	Developed the TAM to validate perceived usefulness & ease of technology use.
Lu, et.al., (2003)	Technology Acceptance Model (TAM) for wireless Internet via mobile devices	Empirical study used to examine the entire TAM for wireless Internet model.	Behavioral intention -Usage behavior -Performance expectation -Effort expectancy -Social influence -Facilitating conditions-age, gender, experience, willingness to use.	TAM for wireless Internet proposes a framework for understanding, explaining and predicting factors that influence individual acceptance of wireless Internet and mobile devices.
Chau and Hu (2001)	Comparison of TAM, Theory of Planned Behavior (TPB) and decomposed TPB models.	An empirical survey was used to get responses on telemedicine technology acceptance from more than 400 physicians in public tertiary hospitals in Hong Kong.	-Behavioral intention, attitude -Subjective norms -Perceived behavioral control -Perceived usefulness -Perceived ease of use compatibility	The model was limited to explaining technology acceptance by individual physicians.
(Venkatesh et. al., 2003).	Unified theory of acceptance and use of technology (AUT).	Longitudinal field studies conducted among individuals being introduced to a new technology in four different organizations.	-Individual differences, -Technology complexity, -Facilitating conditions -Social influences - Wireless trust environment - Near-term usefulness -Long-term usefulness -Nature of use-voluntary versus mandatory -Ease of use	The Unified Theory of Acceptance and Use of Technology (AUT) explains 70 percent of the variance in intention to use technology.
Gagnon et. al., (2005)	Contingency Analyses	Telephone interviews to 32 hospitals participating in Extended Telehealth Network of Quebec.	Identification of organizational factors affecting telehealth adoption.	Adoption affected by larger geographical, economic, and socio-political environment.

PEPTRNW	Perception on training	[1]= positive perception on training [0]= otherwise

Source: Survey data, 2006

Khomas region is located in the central part of Namibia and it is 37,007 square km², and this is where the capital city Windhoek, is situated. The region consists of various health facilities that include a national referral hospital, an intermediate hospital, two health centers, seven clinics, three private hospitals, private clinics and thirty-three outreach points. The region has the highest population which stands at 264,616 compared to other regions in the country, and the population per hospital is 121,278 (Namibia, 2006). Access to ICT in the Khomas region is expected to be higher than Oshana, as the community tends to have better access to infrastructural resources. However, access to infrastructure cannot be taken to imply actual use, because it is possible that the community might have access to various ICT but may not necessarily utilize them. Nonetheless, Khomas region tends to have better health facilities as it is more developed than the Oshana region.

On the other hand, Oshana region is the smallest region (5,290 km²) with a population of 167,797, hence it is densely populated (Namibia, 2004a:1). The Oshana region forms the second largest population concentration in Namibia after Windhoek, but it lacks basic infrastructure and most of the services and facilities normally found in urban areas (Anon, 2007). The Oshana health directorate is divided into fifteen health facilities, one Intermediate Hospital (regional), four health centers and twelve clinics. The district also has twenty-eight outreach points. The Intermediate hospital is the ultimate referral point in the Oshana region and it is responsible for providing essential back up services and support for clinics and health centers in the region. Health centers are smaller than Intermediate hospitals and they are found in two types, namely, day care health centers and rural health centers (Namibia, 1998:16). The latter is common to Oshana region. The population per hospital in the Khomas region is 169,147 (Namibia, 2006).

DATA COLLECTION

Primary Data

Two separate surveys on patients and HSPs were conducted. The surveys were carried out in private and public health facilities in the Khomas and Oshana regions to explore ICT use by both patients and HSPs. The surveys were conducted during the period from July 2006 to August 2006. Given the privacy and confidentiality associated with health studies, permission to conduct the research study was first obtained from the Permanent Secretary of the MOHSS before data could be collected. Respondents were given the opportunity to not participate on the survey and were informed that their answers will be kept anonymous and their personal information will not be disclosed publicly. In addition, prior to the implementation of the actual survey, the structured questionnaires were pre-tested to improve the logical flow and rephrase vague questions that both patients and HSPs had some difficulty understanding. In that regard, pre-testing the questionnaires helped to evaluate the clarity of the instructions on the questionnaires and exclude sensitive health questions.

A total of 21 HSP were interviewed to determine factors that influence their use of ICT in delivering health services and specifically how ICT was being used to serve patients. The questionnaire for patients sought to establish kinds of ICT used when seeking health services, and obtain their views on ICT related services rendered by HSPs. The researcher made sure that all the patients who participated in the study were screened based on (i) if they had visited a health facility in the past three months and, (ii) if they were at least 15 years of age. Data was collected from a total of 134 patients in both the Khomas and Oshana regions. Table 3 shows the number of responses from questionnaires in different health facilities.

Table 3. Number of questionnaires administered in the Khomas and Oshana health facilities

Type of health facility	Number of questionnaires administered with patients	Number of Health service providers interviewed
Khomas region	72	10
Oshana region	62	11
Total	134	21

Source: Survey data, 2006

Secondary Data

Firstly, secondary data was sought *from various government publications such as white papers and public health policy documents. The research examined Namibia's ICT policy development and specifically its implications for the health sector. Secondly,* GRN officials from the P*olicy and Planning Directorate in the MOHSS were interviewed to further investigate* policies that engender ICT use in HSD. Secondary data obtained from the review of public policy documents and personal communications with government officials from the Policy and Planning Directorate provided useful insights on Namibia's readiness for ICT use in HSD.

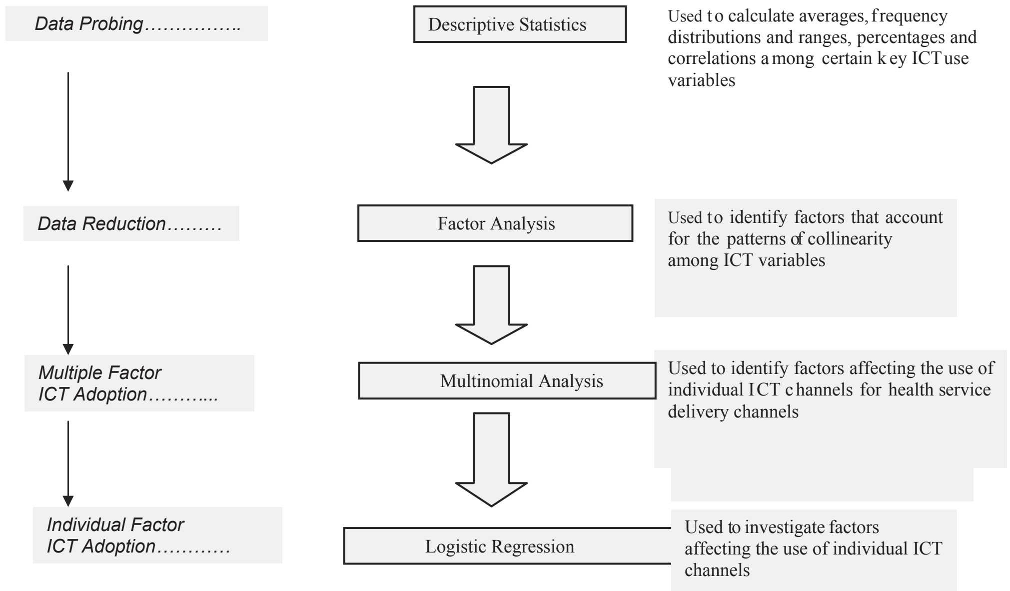
Sampling Procedure

The first step involved the identification of the target population to be studied. The target population in terms of a geographical area studied was the HSPs and patients in health institutions in the Khomas and Oshana regions. The sampling procedure was therefore designed to produce a representative sample of patients from various public and private health facilities in the two regions. The selection procedure of the population sample was based on two sampling methods, namely multi-stage stratified sampling and purposive random sampling. Multi-stage stratified sampling sought to capture different regional health facilities and purposive random sampling sought to include only those patients who met a specific qualifying criteria as already highlighted above.

TECHNIQUES OF ANALYSIS

The analysis was conducted in a series involving four steps. The steps that were used in the analysis are (i) descriptive statistics, (ii) factor analysis, (iii) multi-nominal regression and (iv) binary logistic regression. A summary of the steps or techniques used for data analysis are depicted in Figure 2.

Figure 2. Summary of steps in data analysis procedure



Used to calculate averages, frequency distributions and ranges, percentages and correlations among certain key ICT use variables

Used to identify factors that account for the patterns of collinearity among ICT variables

Used to identify factors affecting the use of individual ICT channels for health service delivery channels

Used to investigate factors affecting the use of individual ICT channels

Source: Survey data, 2006

Descriptive Analysis

This was used to calculate averages, frequency distributions, ranges, percentages and correlations among certain key ICT use variables as well as between ICT use and patient demographics.

Factor Analysis

Factor analysis was conducted *on eight ICT based HSD channels used in the study areas namely, PC, email, Internet, fax, mobile, radio, telephone and television. The aim was to find out if they could load on a common component in the component matrix. Kaiser- Meyer-Olkin and Bartlett's test was conducted to test if the variables were suitable for factor analysis. Bartlett's test was found to be statistically significant for the combined data set*

Multinomial Analysis

Multinomial regression was used to identify factors affecting the use of multiple ICT channels for HSD. The ICT awareness variable was developed using results obtained from the factor analysis which generated three categories which were labeled, 'high technology', 'mobile technology' and 'traditional technology'. A chi-square test was conducted to identify important variables affecting ICT awareness.

Results from the chi-square test were then used to identify variables that were used in the multinomial model. Since there were multiple responses for ICT use, multinomial regression analysis was carried out to determine factors influencing the use of multiple ICT in HSD in Khomas and Oshana region. The dependent variable (ICTAWARE) was determined based on the patient's usage and ownership of ICT.

Logistic Regression Analysis

The data was analyzed further using a logistic regression model to investigate factors affecting the use of individual ICT channels. *Logistic regression analysis was conducted on pre-selected "high technology" and "mobile technology" channels to determine the specific factors driving individual ICT use. Booysen (2006: 46) explains that logistic regression analyzes the relationship between one dependent variable and a number of independent variables. The selected ICT based channels used as dependent variables in the two separate Logistic regression models were (i) PC and (ii) mobile phones respectively.*

RESULTS AND DISCUSSION

The analysis of the results from the Khomas and Oshana regions was carried out to identify patterns of ICT use for health services in the two regions.

Descriptive statistics were conducted on data obtained from patients. Initially, the data sets from the urban and rural health institutions were analyzed separately to describe the ICT use patterns by region. Exploratory factor analysis was conducted to identify factors that explain patterns of collinearity among the eight ICT-based communication channels. Results of factor analysis identified three main factor groupings namely, '*high technology*', '*mobile technology'* and '*traditional technology'*. These factors were then used in the multinomial regression analysis to investigate factors affecting awareness of multiple ICT use by the patients. *Logistic regressions were used to reinforce the results from the multinomial regression analysis by identifying specific factors that influence individual ICT use by patients.*

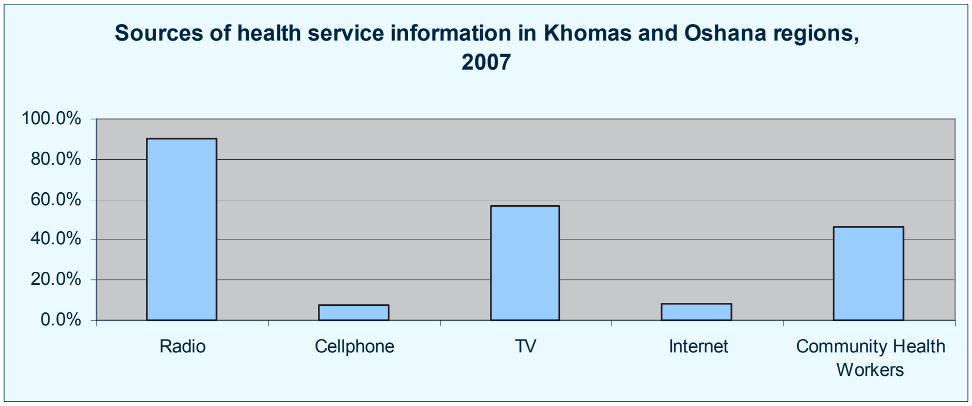
Results of Patient Demographics

Patient's demographic characteristics by region are presented in Table 4. Out of a total of 134 respondents from both Khomas and Oshana regions, 71 percent of the respondents were female. The largest group of patients (47%) was in the 21 to 30 years age group from both regions. The majority of patients (89%) were black and (60%) have at least completed secondary education and 15% had finished college. The majority (61%) of the patients surveyed reported a household income of less than N$5000.

Figure 3. Distribution of information sources used by patients in the Khomas and Oshana regions



Source: Survey data, 2006

Comparison of the Khomas and Oshana Regions

The study compared the patterns of ICT use in the two regions. These comparisons covered mainly ICT health information sources, ICT-based communication channels, and their use in HSD.

Figure 3 shows the distribution of sources of information used by patients in the two regions. The two main ICT channels that were being used by patients as their sources of health information are radio and television (TV). Patients in the Khomas region tend to have more access to TV which was expected due to the fact that Khomas is in an urban area. Similarly, Internet use as a source of health information is higher in the Khomas (13%) than in the Oshana region (8.2%).

However, community health services rendered by health workers are higher in the Oshana (55%) than Khomas region (39%). The majority of patients indicated that they depend on multiple sources of health information. In addition, patients from both regions indicated that they also obtain their health information from other sources such as, newspaper, pamphlets from health facilities, health education offered by nurses at health facilities, local or national campaigns and also through telephone enquiries to a health facility.

From the foregoing results, it is evident that ICT use is comparatively higher in the Khomas than in the Oshana region. Khomas being an urban region where most relatively high income people live this could be partly the reasons why access to, and use of ICT is higher than in the Oshana region. Combined data analysis results (i.e. Figure 3) clearly show that radio (90%) was the leading source for health information followed by national TV (58%), community health workers (48%), Internet (13%) and mobile phone (12%). It is interesting to note that mobile phone usage for HSD is still evolving despite more than 90 percent penetration rate recorded during the survey demonstrating a high mobile phone usage in general.

Factor Analysis Results on ICT Use for Health Service Delivery

The study revealed that eight ICT-based channels were used for HSD by patients in Khomas and Oshana regions of Namibia. These ICT-based channels are namely, (i) personal computer, (ii) e-mail, (iii) Internet, (iv) mobile phone, (v) television, (vi) telephone, (vii) fax and (viii) radio. Exploratory factor analysis was conducted to identify common factor loadings that explain collinearity

among the eight ICT variables. A correlation matrix was computed to test variables and confirm whether factor analysis was appropriate for the data. Bartlett's and Kaiser-Meyer-Olkin (KMO) tests were conducted to test for factorability of the data. The Bartlett's test result for sphericity was 276.720 and it was statistically significant at 1 percent level. The result of Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy for this data was 0.677. Both tests indicated appropriateness of using factor analysis in this study.

It is considered that all factors that achieved eigenvalues greater than 0.5 were significant and conversely, those that were less than one were excluded. The number of components and the respective eigenvalues are shown in Table 5.

Principal component analysis (PCA) was the method used for factor analysis. This method aims to minimize the large number of variables to a small set of uncorrelated variables (Hair, Anderson, Tatham & Black: 1995). The PCA produced 8 components of which three were retained, and they had eigenvalues greater than or equal to one. The factor loading cut off point was 0.5. Table 6 shows the structure matrix and the loadings of the specific technologies on different components. The technologies that were grouped under component one are; personal computer, e-mail, Internet and fax. This group comprised of relatively modern technologies and was thus labeled '*high technology'*.

Table 6 shows that the technologies that loaded on component 2 were mobile phone and radio. One of the major characteristics for these technologies is the mobility aspect; and as a result this group was labeled '*mobile technology'*. Telephone and television loaded on component 3, and these technologies comprised traditional media channels and were therefore labeled '*traditional technology'*. According to Hopkinson and Pujari (1999: 282), factor loadings indicate the correlation between the variables and the factors such that variables with large loadings on the factors are grouped together. In this study, a factor loading of the value 0.50 and above is considered good and significant.

The study also examined ICT related constraints in delivering health services to patients. To uncover the constraints, an analysis of the factors that influence ICT use was conducted. However, since the study examined multiple ICT use in HSD, understanding factors affecting such use required a determination of awareness levels of the different technologies.

As already highlighted, the ICT awareness variable was determined using the results of the factor analysis. The awareness variable was based on the use of the three technology groups identified above. For instance, level one referred to the use of *'traditional technology'*, level two *'mobile technology'* and level three *'high technology'* in that particular order. Therefore, the index for ICT awareness comprised four different levels namely; high technology, mobile technology, traditional technology, and no awareness. However, the results show that respondents fell into the first two categories. No respondent showed complete lack of ICT awareness on "traditional" technologies as stated above.

All the variables except one have communality values above the cut off value of 0.5. This suggests that all the variables were adequately represented by the 3 components identified. A multinomial model regression was conducted to investigate factors affecting awareness of multiple ICT channel use for HSD.

Multinomial Logistic Regression Results

The independent variables that were included in the model are, demographics (e.g. age, gender, education etc), sources of health service information, functional literacy, attitude towards privacy and confidentiality, ICT use in HSD, and perception variables on ICT training appreciation and ICT infrastructure. Multinomial logistic regression predicts categorical outcomes with a potential of more than two categories (Statistical Package for the Social Sciences, 2007).

The model fit results of the multinomial regression are presented in Table 7. The model was found to be statistically significant at 1 percent level of significance. Salkind (2004:144) defines statistical significance as the degree of risk one is willing to take that one will reject a null hypothesis when it is actually true. He further explains that significance level is the "risk that is associated with not being 100 percent confident that what one has observed in an experiment is due to the treatment or what was being tested" (Salkind, 2004:144).

The results of chi-squared goodness of fit are reported in Table 8. The Pearson chi-square and a deviance (likelihood ratio) chi-square indicated a 1.000 significance level and this shows a good prediction of the ICT awareness (ICTAWARE) variable. The result (1.000) is not significant; therefore the model fits the data adequately. Lee, Kwon and Schumann (2005:429) explain that values that are greater than 0.05 in deviance statistics indicate a good fit with the data, and this makes the model acceptable. Garson (1998: 1) also

states that the chi-square statistic test is desired to have an outcome of non-significance, as this indicates that the model has adequate fit for the data. The chi-square goodness of fit intends to find out how well a set of data "fits" an existing set (the observed data set), (Salkind, 2004: 266). Discrepancies between the model and data are also measured in the goodness of fit test. Li, Tan and Xie (2003:299) refers to the goodness of fit as the degree to which the structural equation model fits the sample data. The results of the Cox and Snell and McFadden R-square were 0.603 and 0.880 respectively, and this indicates that the model is highly robust.

Table 9 present the significant variables from the multinomial regression results. The results show that there are three key variables that were statistically significant at 1 percent level, and these are functional literacy (LITCOUNT), age, and sources of health information services (INFOSCOUNT). This finding suggests that functional literacy, access to diverse information sources for health services and age particularly influence multiple uses of ICT channels. Education (EDUC) and a positive perception on health services (PEPSERV) were statistically significant at 5 percent level. Perceptions on health services entail views from patients on whether or not they perceived private and or public ICT services positively or negatively. These results clearly show that patient's ability to effectively utilize the ICT channel (i.e. functional literacy); access to diverse sources of health services information, better educational attainment and age are the most important factors that influenced multiple ICT channel use in HSD in Namibia, particularly in Khomas and Oshana regions. Logistic regression was conducted to further confirm key factors that affect the adoption of individual ICT channels. The results are presented in the next section.

Results of Binary Logistic Regression on Individual ICT Channel Use

According to Agresti (2002: 175), the logistic regression model compares the observed counts and fitted values by using either likelihood ratio (G^2) or Pearson X^2 statistic. The logistic regression analysis was conducted to ascertain factors that influence individual ICT channel use for health services. In order to identify key factors affecting individual ICT channel adoption, a likelihood ratio chi-square X^2 test of independence was initially conducted to establish associations between the eight ICT based communication channels and the independent variables.

A backward-wald selection method was used to identify the most significant variables influencing ICT adoption leading to the selection of a final model. In this method, variables specified for the model are entered into the model together and they are removed from the model based on their significance of Wald statistic. The pre-selected ICT channels were personal computer and mobile phone. The aim was to select at least one ICT from the "high technology" and "mobile technology" groups and identify major factors affecting its use by Namibian patients.

PC Adoption Results

Table 10 presents the logistic regression results for PC which represents the "high technology" ICT group. Results for PC show seven significant variables namely, functional literacy, age, education, perception on importance of personal privacy in health information, perception that ICT improves health services and perception on infrastructure support. Functional literacy was highly statistically significant at 1 percent level and has a positive effect on the likelihood of PC use. Functional literacy represents the ability for one to operate various ICT communication channels. Results showed that unitary increase in functional literacy (LITCOUNT) increases the odds of using PC by 26 times. This variable had the greatest effect on PC adoption in both Oshana and Khomas regions of Namibia. This result is consistent with the findings of the Multinomial

Table 11. Binary logistic regression results for mobile phone

	Mobile phone			
Variable	B	S.E	Sig.	Exp (B)

Ns = Not significant

regression model. Perception on the importance of privacy of health information for patients (IMPORTP) was statistically significant at 5 percent level and it had a positive (19.386) effect on the likelihood of PC use. This implies that an increase in positive perception on the importance of privacy of health information increases the likelihood of PC use by 19 times. This means that patients that had a positive perception on the importance of privacy of their health information were more likely to adopt PC as they are confident that it secures their private health information. Age was also statistically significant at 5 percent level, but had a marginal positive effect on PC adoption. Education (EDUC), perception on ICT infrastructure and perception that ICT improves health services (ICTIMPR) had a positive effect on the likelihood of PC use at 10 percent level of statistical significance.

Mobile Technology Adoption Results

Logistic regression results on mobile phone are shown in Table 11. Functional literacy (LITCOUNT) and privacy (INFCOUNT), meaning the number of ICT channels with personal contact details that the patient is willing to share were statistically significant at the 1 percent level of significance. It is important to note that functional literacy was highly significant in both the PC and mobile phone logistic regression results. This implies that functional literacy measured by the patient's ability to operate the modern ICT is critical for their adoption.

Furthermore, a unitary change in functional literacy increases the odds of using mobile phone by 15 times. The result of privacy (INFCOUNT) indicate that a unit increase in the number of ICT related contact details that a patient is willing to share increases the likelihood of mobile phone use by up to 13 times.

A positive perception on infrastructure and the cost of ICT were statistically significant at 5 percent level. A unit increase on the perceptions on infrastructure increases the likelihood of mobile phone usage by approximately 25 times. In addition, a positive perception on the cost of purchasing a mobile phone had a positive effect on the likelihood of mobile phone usage, although the magnitude was marginal. Furthermore, the willingness to share personal contact details specifically with HSP was statistically significant at 10 percent level. This means that individuals who are predisposed to sharing their ICT contact details with HSP are more likely to use mobile phone, although the effect is marginal in this case as well.

Policy Implications of Findings

In finding answers to the research questions posed, literature was reviewed to get a better understanding of the status of ICT in Namibia and other developing countries. From the literature it has been established that:

1. There was no ICT policy specifically for HSD in Namibia at the time of study, but it was only in draft form. However, a general national lCT policy for the Republic of Namibia and a general Information Technology for the public service are in existence and these were further used to comprehend current ICT policies.
2. The ICT policy for education has been implemented with the aim of articulating the relevance, responsibility, and effectiveness of integrating ICT in education with a view to meeting the challenges of the 21st century (Tech/na, 2007:1). A similar policy is needed in the health sector to promote the adoption of ICT for HSD. Key considerations should be given to enhance the use of ICT in the HSD in Namibia. These will be presented in the next section.

CONCLUSION

This study investigated the use of ICT for HSD in Namibia. The results showed that there was widespread ICT use for health services by Namibian patients. The study identified eight different ICT-based channels that were being used in one way or the other for health services. These were television, radio, telephone, mobile phones, personal computers, Internet, email and fax.

Television and radio stood out as the leading sources of ICT-channels for HSD, although there was clear evidence of widespread use of mobile phones and also personal computers to an extent. Results for multinomial regression and binary logistic regressions showed that the key factors affecting ICT use for HSD were functional literacy, sources of health services information, age, level of education, and a positive predisposition towards ICT use for health services among others. From a public policy standpoint, the study suggests the need for the Government of the Republic of Namibia to actively pursue the opportunities presented by ICT such as personal computer and mobile phones to complement traditional ICT-based HSD channels such as radio and television.

It is also recommended that a comprehensive ICT-based HSD policy be drafted to guide strategies and procedures for HSD in the Namibian health sector. Results of the study demonstrate the presence of a relatively high potential to use ICT to transform HSD in Namibia.

Furthermore, the results of this study can be used to provide insights into ICT use in HSD in other African countries. Future studies should probe ICT use in private or public health care focusing on a specific patient group or functional area, e.g. HIV and AIDS, maternity, emergency services etc. Alternatively, a similar study could assess the willingness to use modern technologies such as mobile phones, as there are likely future platforms for HSD; and some risks and benefits associated with such applications.

Chapter 4.9

Decentralisation and Health Systems Performance in Developing Countries:

Impact of "Decision Space" on Primary Health Care Delivery in Nigeria

Adebusoye A. Anifalaje
London School of Economics and Political Science, UK

ABSTRACT

This article attempts to elucidate the intricacies of primary health care delivery in Nigeria. Among myriad complexities, the central proposition made herein is that the absence of an effective regulatory and enforcement framework in developing countries results in a prominent informal decision space. The findings show that the prominence of an informal decision space compromises the objectives of an information-based public health system. The article concludes that decentralisation in developing countries must have a coordinated top-down and bottom-up development component for it to be effective in improving the performance of primary health systems. One of the implications of the study is that researching decentralised healthcare delivery requires analytical models which are able to illuminate the complexities of local accountability in developing countries. The study also reveals the need to further research the dynamics of democratic decentralisation in developing countries as this goes beyond administrative structures but involve socio-cultural institutions.

INTRODUCTION

Health systems simply defined, are the foundational (i.e. institutional, political, legal, economic, technical and socio-cultural) arrangements through which health services are delivered to the population (Berman and Bossert 2000). There is a complex chain of interdependent factors which influence the performance of health systems. In developing countries where there are high mortality and morbidity rates, a multiplicity of stakeholders (i.e. rich nations, international donors, non-governmental organisations (NGOs), bilateral and multilateral agencies) employ different strategies to try and improve specific aspects of the health system (Okuonzi and Macrae 1995). These diverse and often uncoordinated interventions usually have a fragmentary effect on these systems (Buse and Watt 1996). In essence, the imperatives of international health policies and donor-aid practices have a tendency to weaken the capacity of national governments to independently formulate and implement policies which address the health needs of the population (Smith *et al*. 2008).

This article highlights the implications of decentralisation on the performance of health systems in Nigeria. By conceptualising decentralisation as a strategy for delivering health services through a primary health care system, the study is able to focus on the micro-level processes of the health system. The performance of a health system can therefore be investigated through the effectiveness of primary health care delivery. To study this phenomenon, decision space is adopted as an analytical tool (Bossert 1998). This framework conceptualises the multi-level dynamics of primary health decisions made by local government agents. Decision space illuminates the choices of local government actors and how these impact health system performance. It also frames the role of information in monitoring and evaluating the performance of health systems. There are three main reasons for adopting a local perspective of the decision space approach: firstly, primary health care services are the building blocks of general public health systems therefore we would expect a strong association between local and general public health systems performance; secondly, information systems are implemented with a view to aid planning and decision making at the local level. Consequently this focus provides an opportunity to go back one step to evaluate the intricacies of information practices (in a general sense) without reference to a particular health information systems project; lastly, local agents make health decisions out of a quagmire of often conflicting motivations and opposing evidence: this study will provide some insight into the possible factors that actually influence choices made regarding primary care delivery.

With decentralised health sectors, central governments through the Ministry of Health have a complex task of designing the framework through which local government agents can provide adequate health services (WHO 2000). Their challenges include developing the socio-economic, political, legal, administrative and institutional arrangements that will support the efficiency and effectiveness of primary care systems. The formal (and informal) authority afforded local government agents by the central government, combined with the discretions they exercise (both within and outside formal authority) make up their "decision space". The relationship between central and local government actors contributes formally and informally to the decisions made at the local level with consequences for the performance of primary health care systems.

The Decision space framework conceives the relational dynamics between the local and the central government through a principal-agent theory (Griffith 1966 and Rhodes 1986 in Bossert 1998) the central (or State) government as the principal and local governments as agents. It analyses the capacity of the principal to influence decisions made by local government agents in order to align them to the principal's objectives e.g. better performing health system. This being the case, the primary role of the Federal Ministry of Health for instance, would be to make adjustments to local agents' decision space in a way that would align their interests with national public health objectives. The central government can accomplish this by adopting a scheme of rewards and sanctions.

The framework tries to balance this top-down bias by suggesting the mutual influences of central and local government agents. The influence of local government agents is framed in terms of having direct and primary access to contextual knowledge and information which is required by central government agents. Information plays a crucial role in the study and analysis of health systems performance. Within the decision-space framework, local agents use information to evaluate the technical effectiveness of current primary care units and formulate appropriate operational intervention strategies. On the other hand, central government agents also employ this information to build a general public health picture as well as monitor the performance of local agents from a managerial perspective. However, the main thrust of the framework is geared towards the role of central government in aligning the interests of local government actors.

The main observation made in this study is that the decentralisation of health systems in developing countries operates predominantly through an informal decision space. This article therefore shows the consequences of this phenomenon on primary health care delivery. It further argues that this political dimension to analysing health systems performance is fundamental to understanding the challenges of health information system initiatives in developing countries. For these reasons it is important to conceptually explore and empirically investigate the impact of decision space on the delivery of primary health care. Consequently, the overall objective of this research project is to gain a better understanding of the implications of a decentralised health sector on the performance of the health system. To delimit the research focus and scope three questions are framed:

1. How does the decision space of local government actors impact primary health care?
2. In practice, what are the factors that shape, influence and determine the decision space?
3. To what extent does information drive health care decisions?

The empirical fieldwork for these questions was conducted in Nigeria. While agency-centred studies analyse the dynamics of the situated local contexts, they do not provide adequate tools to investigate the influence of the structures within which the agents exist and operate (some IS literature have tried to address this see Alvarez 2003). For instance, instead of studying the implementation or use of a specific information system, this study locates the problem domain within the socio-political dimension of health care delivery in Nigeria, providing a more robust platform for understanding the challenges of health information systems projects. This is because decision space approach serves as a multi-level contextual platform which incorporates the mutual influences of the macro and micro-level environment.

The main contribution of this article therefore is to illuminate the socio-political arrangements which affect the delivery of primary health care in Nigeria. Although focussing on the characteristics of local government agents, this study is able to reveal how the capacity of the State and Central governments impact on local agents' effectiveness in delivery primary health care. The study extends these findings to analyse the role information plays in local health systems and extrapolate to discuss the potential implications for the implementation and use of health information systems.

The rest of the article is presented in two broad sections. The first section is conceptual in nature including the literature review, conceptual framework and methodology. The second section details the empirical content of the study including the analysis and discussion and the research conclusions. A brief outline of implications for future research is also provided.

LITERATURE REVIEW

Health Care Delivery Strategies in Developing Countries

This section will provide the historical context of health delivery strategies in developing countries. Focussing on the challenges and complexities of primary health care, the literature shows the influences of global economic and political ideologies on national and local health care delivery policies.

Primary Health Care System

In the late 1970s, the international health community—comprising of World Health Organisation (WHO) member countries— turned its attention to the failing health systems of many developing countries. The central concern at the time was that majority of the population in poor countries lacked access to basic health care services and therefore suffered high rates of mortality and morbidity (Magnussen *et al.* 2004). An effort to address these failing systems was articulated in the WHO Alma Ata declaration (WHO 1978). The declaration conceived of health as a basic human right and sought to initiate programmes that will build sustainable health systems, with indiscriminate access for all, in developing countries. It proposed the primary health care (PHC) system as the principal means of achieving equitable health service delivery within and between countries (Starfield *et al.* 2005). By focussing on the community-level, health services are more accessible and interventions are likely to be more responsive to local needs as there is increased opportunity for effective local participation (Tarimo and Fowkes 1989). The argument is that there is increased accountability and improved health care service when policies and intervention strategies are formulated with the "users" in a way that aligns with their particular needs (Cornwall *et al.* 2000). With this system, greater emphasis is placed on health promotion and preventative strategies (Atkinson *et al.* 2005) rather than technologically sophisticated and curative bio-medical interventions (Bossert 1979). Cueto (2004) also suggested that PHC was introduced based on the implicit assumption that diseases in developing countries were contingent on socio-economic arrangements and therefore interventions required political will. As a result, the most important task was to mobilise the support of the international community to support the bottom-up approach of improving the performance of health systems. Under this arrangement therefore, the performance of health systems is dependent on the effectiveness and coordination of community-based health units.

By the mid 1980s, the vision of global health suffered several significant setbacks. Firstly, the objective to raise the minimum level of health in all poor countries of the world, was deemed too idealistic (Magnussen *et al.* 2004). Secondly, the proposed PHC system received little support because of the deeply institutionalised tertiary model and a reluctance of "experts and politicians in developed countries to accept the principle that communities should plan and implement their own healthcare services" (Hall and Taylor 2003: 17). Furthermore, with the decline of communism in the former Soviet Union, marketisation was gaining more ground as the appropriate economic ideology for modern society. Economic support for health projects was conditional on recipient countries adopting liberalisation policies. Hall and Taylor (2003) discuss the "failure" of PHC in light of these changes.

As an alternative approach, selective primary health care (SPHC) was adopted (Cueto 2004). In contrast to PHC, SPHC assumes that diseases in developing countries are a natural phenomenon which can be curtailed through economically-viable and technical interventions (Cueto 2004). This approach attempts to tackle major diseases especially those responsible for childhood mortality (Cueto 2004). The "success" of SPHC was attributed to three main factors: 1) its bias towards a market rationality; 2) specific goal of child health and 3) appeal to "rational" and technical interventions (Cueto 2004). While PHC is oriented towards improving general population health, SPHC is a vertical programme addressing specific diseases. The performance of SPHC is judged according to specific project objectives such as immunization coverage, disease control or eradication etc.

Decentralisation

Still driven by a techno-economic rationality, the 1990s was accentuated by a sustained interest in health sector reform. According to the Harvard School of Public Health, health reform is defined as:

sustained, purposeful and fundamental change" – "sustained" in the sense that it is not a "one shot" temporary effort that will not have enduring impacts; "purposeful" in the sense of emerging from a rational, planned and evidence-based process; and "fundamental" in the sense of addressing significant, strategic dimensions of health systems (Berman 1995).

With experiences of the 1980s showing that general health systems had been significantly weakened (Chatora and Tumusime 2004), organisational change, innovative sourcing of funds, increased market rationality, and customer-focussed health services were strategies (e.g. *The World Development Report 1993: Investing in Health*) (World Bank 1993) advocated as a means to achieving sustainable health reforms (Blaauw *et al.* 2003). Nonetheless, decentralisation emerges as a distinctive feature of these reforms albeit employed in shades and degrees (Jeppsson and Okuonzi 2000). Jeppsson & Okuonzi (2000) note for instance that Ugandan health decentralisation model shows power devolved to district levels as part of a wider political decentralisation agenda. On the other hand, they acknowledge that only the health service structure is decentralised in Zambia. Maintaining that useful lessons can be learnt from both approaches, they note that neither approach has been able to produce better health service delivery or improve poverty conditions.

There are often mistaken inferences made about decentralisation of public health service (which is a feature of primary health care) as a form of rolling back the state (Collins and Green 1994). So, based on this rationale, donor agencies fund specific health projects usually without much collaboration with national governments or consideration for the defined health priorities of recipient countries (Loewenson 1993, Okuonzi and Macrae 1995). The perception that developing countries lack requisite capacity e.g. in terms of adequate analytical skills for health policy formulation, is represented as a major obstacle to the effective collaboration necessary for health reform (Filmer *et al.* 1998, Jamison and Mosley 1991). The resultant coordination failure amongst diverse stakeholders (Buse and Watt 1996) precipitated a call for donors to invest in building aid recipients' capacity to develop appropriate health systems (Lee 1998). Besides, the sustainability of health systems in developing countries demand that governments take active responsibility in deciding the direction of public health intervention strategies. Initiatives like Sector-Wide Approaches (SWAp) were responses to the urgent call for the coordination of donor-funded projects and better collaboration with national governments (Peters and Chao 1998). The logic behind these programmes is that projects are based around commonalities of goals and strengthening of national capacity to fulfil its development objectives in terms of effective institutional arrangements and economic policies. There is an expectation that the outworking of a coordinated approach will also stimulate local participation, increase active engagement and provide stability necessary for long-term planning (Chilundo & Aanestad, 2003). However, effective collaboration between donors and recipient countries is made more difficult because it is contingent on trust and confidence in the capacity of recipient countries to manage their health systems. The perception that developing countries lack requisite capacity e.g. in terms of adequate analytical skills for health policy formulation constitutes a significant setback for SWAp (Filmer *et al.* 1998, Jamison and Mosley 1991). Tarimo and Fowkes (1989) identify four main challenges of compartmentalized approach to health reform in developing countries: 1) short-term mindedness in goal setting; 2) insufficient financial aid; 3) lack of appreciation of differences in local contexts; 4) implementation of vertical programmes as a matter of convenience as opposed to needs.

Economic Growth Approach

By the turn of the 21st century, it is widely stated that the problems of poverty and disease are neither technological nor a consequence of knowledge deficiency. However, from the mandate of the Millennium Development Goals, the challenge is perceived in terms of mustering enough political will and finance for a vision of global health. From an economic standpoint, the World Health Organisation (WHO) commission on *Macroeconomics and Health: Investing in health for economic development* report argues that investment in health is of paramount importance (WHO 2001). The main concern is to break the poverty cycle—which reinforces poor health—by boosting economic growth through significant "public investment" (Sachs *et al.* 2004: 122). Economic growth in turn has the capacity to increase productivity and consequently lower poverty (Sachs *et al.* 2004). The foundation of this strategy built on globalisation and depends to a very large extent on the provision of foreign aid. Although the effect of globalisation—in addition to effective institutional arrangements and adequate infrastructures—has been largely beneficial to health conditions, this link is drawn from an economic growth, trickle-down effect. As a result, there are required domestic conditions that must be present in order to reap the benefits. Therefore, foreign aid in itself is unlikely to produce the desired result if there are no frameworks established to guarantee that the finance will be used effectively towards development. However, for most developing countries, deregulation and liberalisation policies have not yielded growth or better health conditions (Cornia 2001).

While there is some agreement with the central proposition of the WHO r*eport on Macroeconomics and Health* that disease is a major player in engendering poverty and therefore investment in health is a key proponent in achieving economic development, there is a major contention regarding its approach. The main criticism of the report is the "reform for finance" approach which betrays a disposition towards the familiar structural adjustment programme (Waitzkin 2003). In this sense, it is argued that developing countries will be worse off while developed countries are able to exploit the opportunities created by these policies (Garrett 2007). The weakness of the WHO report can be linked to paying lip service to health as an end in its own right while actively pursuing an economic growth agenda (Waitzkin 2003).

In contrast to macro-level, top-down growth strategies, others argue that health crises in the developing countries have necessitated a change of strategy in delivering public health services by increasing community involvement and participation (Cornwall *et al.* 2000). The argument is that the bottom-up approach to development is related closely to the "health for all" policy while "new public management" health models detract from this goal (Gwatkin 2000). The realisation that there is increased accountability and improved health care system when policies and intervention strategies are formulated with the "users" (Cornwall 2000), constitutes a new wave of efforts that have started building which gives attention to the health of the poor as well as health inequalities (Gwatkin 2000).

There are observable evidence to suggest that much has to be understood about the complexity of this field because "[d]espite the emphasis placed during the last two decades on public delivery of comprehensive and equitable primary care to developing country populations, coverage remains far from universal and the quality often poor" (Mills *et al.* 2004). It is therefore still contended that PHC is "the only way to reach the poor and the vulnerable groups" (Masaiganah 2004).

Paradoxical Insight

While the decentralisation of the health sector is often implemented through a top-down process, its goal is to develop a bottom-up approach to improving health system performance (Atkinson 1995). As a consequence, health systems research has paid little attention to the socio-political arrangements of decentralisation at the local level (Atkinson et al. 2000, Smith 1997). There are two analytical insights which can be gained by examining this paradox from the local perspective. First, we can empirically investigate how this paradox impacts the extent to which local governments can effectively exercise authority in matters of health service delivery (Adeyemo 2005). Secondly, we can also critically analyse whether the real objective of the top-down process is to actually facilitate increased local decision making.

However, we are not just interested in the extent to which health systems are driven by the transfer of decision-making authority to the local level, but also the factors that affect the nature (or quality) of these decisions. There is a body of literature which attempts to tackle this issue and is based around themes such as rational health planning, evidence-based public health, information-centred health policy etc. The literature advocates a strong modernisation ethos through these concepts, providing equal impetus for technology-based health systems as necessary instruments for collecting, storing, analysing and disseminating health information (some examples of the debates: Dobrow *et al.* 2004, McMichael *et al.* 2005, Murray and Frenk 2001, Niessen *et al.* 2000).

Information and Health Systems in Developing Countries

There is a resonant consensus that effective health planning and interventions depend on accurate data (Green 1999). It is also accepted that relevant and reliable information forms the bedrock of any effective public health system (Stansfield 2005). The effective control or prevention of disease from an epidemiological perspective for instance, is dependent on accurate information regarding its prevalence and geographical distribution. The underperformance of health systems in developing countries have been attributed to the paucity of health information and lack of an information culture. As a result, there is underlying demand for a systematic process of collecting, storing, analysing and disseminating health data and it is to this end that arguments are made in favour of health information systems (HIS) (AbouZahr and Boerma 2005). Despite the relatively strong rationale for these systems, their implementation in developing countries has been shrouded in partial or complete "failure" (Heeks 2006, Littlejohns *et al.* 2003). To illuminate the challenges of information practices in developing countries, we can assess three dimensions of health information systems diffusion for improving health systems performance: 1) dataset consensus; 2) HIS integration; 3) HIS sustainability.

Dataset Consensus

It is argued that although the problem with health information systems in developing countries is the absence of complete and quality data, planning ahead on how data will be used and by whom, and under what circumstances and constraints have implications for future accessibility of data from health systems (McGrail and Black 2005). Accordingly, one of the key features of an information system at the primary health care level is an *essential data set, which may be defined as a set of the most important data elements, selected from all primary health care vertical programmes, that should be reported by health service providers on a routine basis, with the aim of being able to generate indicators that monitor the provision of health services in an integrated manner* (Shaw 2005: 632)

From the above definition, the striking advantage presented by establishing an essential data set is the relevance of the data for local level use. It is also clear that establishing an essential (or minimum) data set for health information would most likely be fraught with a lot of challenges. Some of the difficult questions to resolve would include how to determine the "most important data elements", according to what criteria, and primarily serving what (or whose) purpose (Bowker and Star 1999). We can infer from the fragmented nature of the health system in developing countries that achieving any consensus would be even more difficult because of the multiple stakeholders and interests represented. The alternative is for health workers to collect numerous data for different overlapping projects without regard to the duplication of efforts and wastage of already scarce resource. This alternative is increasingly unacceptable and ways are being sought to address the issue. Without belittling the complexity of this process Shaw (2005) provides a framework for developing this essential data set using the experience of an HIS project in South Africa as an illustration. There are roughly two sides to the framework.

Firstly, data collection is stratified according to information needs along a hierarchical structure. This process is organised such that each level (e.g. national, state and local government) collects data relevant to their needs but only returns relevant data to the upper levels. Secondly, this progresses as a bottom-up approach but a minimum national dataset is negotiated and directed from a top-down process (Shaw, 2005).

Integrating HIS

As previously mentioned, a major obstacle for primary health care is the proliferation of uncoordinated vertical programmes. This has a direct spill over effect on information systems projects. In developing countries, health information systems are largely designed as silos of compartmentalised systems (Braa 2000). Employing the concepts of "historicity and heterogeneity," Aanestad *et al.* (2005) provide an extensive analysis of the challenges inherent in integrating health information systems in developing countries. The problem of historicity relates to the influence of institutionalised systems (e.g. legacy systems), established approaches and dominant values which contend with the introduction of novel health information systems (for theoretical discussion, see Ciborra 2002 , Ciborra and Associates 2000 on standards and information infrastructures). Heterogeneity on the other hand, reflects the impact of multiple donor agencies funding stand-alone vertical systems without consideration for the interdependencies that exist across health programmes (Chilundo and Aanestad 2004). Consequently, the integration of HIS goes beyond establishing standards like "minimum data sets" (Shaw 2005) or integrating different technological artefacts but by necessity includes the alignment of divergent actor orientations, goals and rationalities (Smith *et al.* 2008). Given the scale of the challenge, "coping" with some level of HIS fragmentation is arguably inevitable (Aanestad et al 2005).

HIS Sustainability

Embedded in the general idea of sustainability are the notions of self-sustenance and sufficiency but HIS sustainability focuses more on the capacity of "user organisations to identify and manage risks that threaten the long-term viability of the HIS, following the withdrawal of external support" (Kimaro and Nhampossa 2005: 276). Kimaro and Nhampossa (2005: 276-277) further propose factors that militate against the sustainability of HIS: "inadequate infrastructure and human resource capacity; inappropriate policies and strategies to manage the sustainability problem and fragmented donor policy." To mitigate these factors, they propose that HIS must become a part of the operational day-to-day fabric of the "institutions" using them i.e. they must become "institutionalised". Their central arguments are summed up as follows: 1) sustainable HIS, in addition to being institutionalised, must be designed and developed in a way that is easily adaptable to changing user needs and requirements; 2) the implementation of a new HIS embodies values that would demand the "cultivation and institutionalisation of a new kind of culture"; 3) "donors influence the processes of institutionalisation, and thus the sustainability of systems significantly."

An important perspective to HIS sustainability is the idea of scalability. This concept argues that health information systems must be dynamic and flexibly designed. Otherwise, rigidity to a specific level of the health care will limit its impact on general health systems, greatly diminish its acceptability and face oppositions to its institutionalisation. Therefore HIS must be have the capacity to be either scaled up (to national) or down (to local) according to the health information hierarchy of needs (for more discussion, see: Bergqvist *et al.* 2006, Braa *et al.* 2004, Mengiste and Nielsen 2006, Sahay and Walsham 2006)

A Case of Alignment

The HIS literature illuminate the rationale underpinning an information-based health system. The challenges to achieving consensus on data, integrating and sustaining HIS implementation initiatives can be understood from a different dimension by exploring the entrenchment of health systems in the political intrigue highlighted in the literature on health care delivery strategies in developing countries. The literature first shows a muddle of top-down versus bottom-up approach to health systems development. Therefore HIS implementation strategies although seeking to develop locally relevant systems, must navigate the politically-charged terrain of macro-level initiatives which have direct influence on the information gathered at the local level, how it is analysed, interpreted, used and disseminated. In the same breadth that the historicity of information systems resemble an infrastructure which has a direct influence on the introduction of new technologies, so does the history of primary health care delivery in developing countries impact innovative systems which may attempt to change the course of history. This is in the sense that central and local government agents in developing countries have developed motivations and capacities over the years. These represent their distinctive characteristics. Therefore any initiative to improve primary health care delivery through better information systems or any other tool will require an alignment of sorts which first and foremost appreciates the current and historical reality and culture and in collaborative dialogue allow a more effective system to evolve. There is an expectation that the outworking of these integrations will also stimulate local participation, increase active engagement and provide stability necessary for long-term planning *(Chilundo and Aanestad 2003).*

The motivation of this research project is therefore driven by the question: "How can we understand the characteristics of the local context in order to appreciate the challenges of primary care delivery in developing countries?" This is discussed in the next section.

Research Question

This article proposes that HIS analyses although contextual, can be better illuminated through the framework of political dynamics intrinsic to health systems performance. Similarly, Smith *et al.* (2008) also argue that HIS implementation solely founded on "managerialist grounds would tend to be subverted by the reality of long-standing political structures" (Smith, *et al.* 2008). The political dimensions of primary care delivery are thus essential in the domain of health systems performance. Therefore the question of this study is, "*What are the implications of a decentralised health sector on the performance of the health system?*" As a broad question, it is delimited and made more concrete by asking three distinct but interrelated sub-questions:

1. How does the decision space of local government actors impact primary health care?

This question attempts to deploy the decision space approach in understanding the implications of decentralisation on primary health care delivery. By critically adopting this approach, the study conceptually investigates the factors underpinning health systems performance at the primary care level. The question is important in framing how the decentralised health sector operates and the perceived influence of the principal on the decision space of local agents. Theoretically, this approach states that the principal (e.g. Central or State government) is able to align the activities of the agent (e.g. local government officials) to its objective through a scheme of rewards and sanctions. On the other hand, it also observes that agents wield considerable influence because they produce contextual information required by the principal. This question therefore illuminates how this tension impacts the primary health care system.

2. In practice, what are the factors that shape, influence and determine the decision space?

This is a more contextual question aimed at finding out the diverse instruments, belief systems and ideologies that actually influence decisions at the local level. From an empirical angle, this question will assess and query the primacy of a formal decision space in the context of developing countries where there is significantly reduced capacity of the principal to either reward good performance or punish aberrant activities. This question will therefore attempt to draw out the prominence of an informal decision space.

3. To what extent does information drive health care decisions?

This question problematises the linear conceptualisation linking information, health delivery strategy and outcome. The question is critical because the resultant informal decision space has far-reaching implications for the institutional, political and socio-cultural arrangements which influence decision making and health systems performance. The question therefore provides a more insightful study into the diverse role of information in primary health care delivery and health systems performance.

ANALYTICAL FRAMEWORK

While the conceptual framework is implicit in the research questions it is important to highlight its key features and how it will be used in this study.

Theoretical Context

Bossert (1998) developed the concept of decision space as part of a comprehensive framework to analyse the decentralisation of health systems in developing countries. In developing this analytical framework, it is noted that decentralisation is an instrumental means to achieving "equity, efficiency, quality and financial soundness" (this article refers to these goals generally as the objectives of better performing health systems) (Bossert 1998). The rationale underpinning such analytical tool was based on the claim that there was no adequate means of analysing three constitutive aspects of decentralisation:

(1) the amount of choice that is transferred from central institutions to institutions at the periphery of health systems, (2) what choices local officials make with their increased discretion and (3) what effect these choices have on the performance of the health system (Bossert 1998: 1513).

Bossert suggests that the principal-agent approach is possibly the most illuminating framework with which to analyse decentralisation. At the heart of the principal-agent approach is the conceptualisation of the relationship between the centre and the local. He maintains that there are policy implications for how the centre can influence decisions made at the local level in such a way that will increase the likelihood of better performing health systems.

Conceptual Tool

According to the principal-agent approach, decentralisation is understood from the perspective of the principal who uses various strategies to align the activities of the agent in achieving the principal's objectives. These include rewards, punishments and the monitoring of compliance through information returns. According to Bossert, the weakness of this approach is that it does not provide a way of identifying the "range of choice allowed by decentralisation" (pg. 1517). The decision space approach is essentially a modification of the principal-agent approach such that it incorporates this spectrum of choice devolved from the centre to the local levels.

There are three broadly defining aspects of the decision space approach: 1) *mapping the boundaries of the space;* 2) *conceptualising the consequence of decision space on local choice;* 3) *analysing the performance implications of the space.*

For the purposes of the questions posed in this study, the decision space approach will be adapted as an analytical framework in the following ways:

Mapping the decision space boundary: contents of national policy documents regarding the role and responsibilities of local governments in primary health care delivery will be discussed at a general level in descriptive terms. Emphasis will be placed on empirically investigating the actual (i.e. informal) decision space boundaries of local officials in Nigeria and the relational dynamics between central (analytically including State government) and local government agencies. The nature of this informal decision space will also be analysed to draw implications on the level of contestation that exist between the two levels of government. Data will be collected to illuminate these dynamics and subsequent analysis would be guided by three propositions of the framework. 1) the decision space is created by legislative act; 2) informal decision space exists when there is ineffective enforcement of legislation; 3) decision space may be contested by local officials.

Decision space and local choice: the issue of choice and decision space will be investigated along the lines of the following singular proposition: the impact that the decision space (formal and informal but concentrating more on the latter) has on the kinds of choices made by local officials.

*Decision Space and performance implications: t*he study will look at the implications of the following three propositions of this framework (from the local actors' perspective) on primary care health systems performance in Nigeria: 1) incentives and sanctions used by the principal to align interests according to the characteristics of the agent; 2) health information as a monitoring tool: this proposition will analyse the response and perception of local agents to information as a performance management tool; 3) health information as a reflection of health systems performance: this proposition will investigate the opinions of local agents to information as a vital public health resource with implications for health systems performance.

METHODOLOGY

The methodology adopted by this study is by nature reflexive and located within the tradition of interpretive qualitative research (Walsham 1995, 2006). This approach has two basic characteristics – interpretation and reflection. Interpretation implies that the multiple perceptions provided by participants involved in the field situation are taken to represent 'reality' and that these perceptions are then interpreted by the researcher according to the adopted theories about the domain of study (Geertz 1973). The reflexivity mentioned here is in the spirit of what Scott (2000) defined as "lived methodology". Reflexivity is viewed as an essential part of the research process by stimulating critical reflection on taken-for-granted theories, accounts and interpretations (Walsham 1995, 2006). According to this approach, the empirical material is not bound to fit the framework of theoretical ideas, rather it allows research findings to inform and reshape analytical conceptions. At the same time, this approach allows a certain degree of flexibility in accommodating creative and innovative interpretations of decentralisation in the developing country context without prejudging their relevance to current understanding of health systems performance. While the research will involve studying the policy, institutional, structural and social context within which decentralisation is implemented, the focal unit of analysis will be the primary health care unit.

Research Method

Myers (1997), with specific reference to IS research, critically analyses the use of four possible qualitative research methods e.g. grounded theory, ethnography, action research and case study research. This next section justifies the appropriateness of a case study method for this research project.

Case Study Research

Case study as a research method is used to empirically investigate "a contemporary phenomenon within its real life context, especially when the boundaries between phenomenon and context are not clearly evident" (Yin 2003: 13). This article argues that according to Yin's (2003) criteria and definition, this research topic is best investigated using a case study method. Although in building the context of this study it is necessary to include historical and "processual" analysis (Pettigrew 1997), the principal focus of the investigation will concentrate on contemporary challenges of primary health care provision in Nigeria. From another perspective, case studies can also be employed for building new analytical frameworks (Eisenhardt 1989) for understanding the complexity of primary health care delivery.

This research employs a single-case design which gathers different perspectives within the Nigerian public health system but all these perspectives serve as a representative type of primary health care delivery (for example Shaw *et al.* 2007). These different perspectives are from different levels of the primary health care system. For instance, health information systems national consultant, State public health director, Community physician, Local family physician, general practitioner and Facility health care worker. These perspectives also have a wide geographic span ranging from East, West, North, South and Middle-belt.

The circumstance under which it would be suitable to conduct a single case study is when the case is either "critical," "unique," "typical," "revelatory" or "longitudinal," (Yin 2003:41-42). Accordingly, the choice of a single-case design is justifiable from the viewpoint of the case being representative i.e. "typical". The next section introduces a more concrete discussion of data collection methods including the unit of analysis and how these methodological considerations were translated in the fieldwork research.

Data Collection Methods

Interviews are arguably the most significant means of gathering qualitative data and semi-structured interviews the most widely used in information systems research (Myers and Newman 2007). Accordingly, the primary data collection method for this project was made up of five semi-structured telephone interviews of Nigerian primary care practitioners. This included: former state Director of Public Health, Permanent Secretary and current Head of Department of Community Medicine and Primary Care; Senior Registrar Family Medicine; and three primary care doctors. Information was also gleaned from personal communication with an health information system consultant in Nigeria.. Copious amounts of notes were taken during each interview after which they were word processed immediately. The main criteria for choosing interviewees were the depth of experience in their respective level of primary health care in Nigeria, the breadth of knowledge including levels of health care delivery and geographical location, understanding of the political dimension of delivering primary health care.

The substantive questions asked were related to the complexities of primary health care delivery in Nigeria. These questions were classified along the three sub-questions of the research project. The particular focus was on the experiences of local practitioners and their perspective regarding the influence of local and central government agents on the delivery of primary health care. Anecdotal or illustrative responses were encouraged especially where they provide a rich description of the situation.

To ensure reliability of data, evidence is triangulated from the different data sources to evaluate the congruence of opinions. Where there is a divergence of ideas, this is followed up by seeking clarity from the respondent after presenting the contrary view. In addition feedback was given to all interviewees to give them a chance to clarify the interpretations given by the researcher. Most of the interviewees were conducted over a couple of days which also gave room for reflection by both the respondent and the researcher.

The data is expected to serve as evidence in three main ways. First, the analysis and discussion should serve as a tool in persuading the audience of a more complex dynamic at work in delivering primary health care at the local level. Secondly, the evidence should be contextually rich enough to show that primary care delivery is not only technically challenging both also politically intricate.

Data Analysis and Discussion

In order to produce data that are more reflective of reality, data analysis will be conducted through the identified propositions of the conceptual framework and the researcher's informed intuition (Valsiner 2000). Under each proposition, themes from different data sources are highlighted, detailing the most recurring or significantly pronounced themes for the narrative analysis.

Understanding Decentralisation and Health Systems Performance in Nigeria

This section presents the findings from the field in an analytical way by adopting the framework propositions to discuss the evidence from the field. The analysis captures the main areas of input from all interviewees and represents the chain of recurring themes. Where this is not the case, a clear indication of the data source and the counter views are provided (interestingly, this only occurs in the discussion relating to the perceived quality and role of information in primary health care). An attempt is made to analyse these variations using the analytical framework and the researcher's understanding of the field.

Mapping the Decision Boundary

Decision Space: An Act of Legislation

Under the Nigerian *concurrent legislative list*, the constitution allows the provision of a decentralised health care system within the three tiers of government i.e. Federal, State and Local. General and specialist hospitals are principally assigned to the State and Federal government respectively and primary health care is provided by the local government. Having said this, the State and Federal government still provide technical assistance to the local government for instance on polio immunisation and rollback Malaria programme.

Primary health care is the first level of health care delivery service. It is community based therefore patients are only referred to general hospitals or specialist tertiary hospitals if this transfer is deemed necessary at the primary care level. There are three main delivery strategies: 1) health promotion including health education; 2) prevention of diseases (particularly communicable diseased) and immunisation programmes; and 3) provision of facilities for early diagnosis of diseases.

To deliver these functions, the primary care system comprises of health centres, clinics and posts. The health posts are the most remote, providing the most basic form of health care service. It typically operates as an outpatient facility. Health clinics mainly consist of maternity centres and dispensaries. They provide the treatment of minor diseases like malaria and diarrhoea. In the primary health system, health centres are the closest representation of hospitals. They provide extensive preventive health services including health promotion (e.g. environmental sanitation and education on personal hygiene). They also provide the diagnosis and treatment of diseases.

It is therefore constitutionally recognised that local government agents have the principal authority and responsibility for fulfilling these functions under the primary health care system. However, by legislation, the operations of the local government primary health care are directly supervised by the State Ministry of Health (SMOH) who is then accountable to the Federal Ministry of Health (FMOH). The local government reports to SMOH and these report annually and quarterly to the FMOH. One of the direct consequences of a weak accountability structure is presence of a considerably large informal decision space.

Informal Decision Space

In practice, there is no enforceable accountability structure at the local level. The oversight of the FMOH is across a wide distance therefore logistics are difficult for the FMOH which is based in the Capital, Abuja. There is also the issue of misplaced empathy and priority regarding the development of the health system in Nigeria. The FMOH gives an inordinate amount of attention to building hospitals and to curative medical approaches, even though this is not in concert with the national health policy. In effect, local government officials are not only autonomous but a significant proportion of their activities are carried out through an informal decision space.

In terms of proximity, the State has a better chance of being more effective in supervising PHC delivery because all medical officers from the local government meet monthly at the State level. Notwithstanding, the local health system is rife with general political apathy and instability. In theory, constituents can make complaints to the State regarding local government agents who do not deliver according to their terms of office. The State then calls the Local Government Chairman to account. If they can't defend their position then sanctions may be considered. This is however highly unlikely. The SMOH does not have the capacity to either sanction or reward local government officials. The practical option is usually to appeal to their better judgement and sense of duty when they come together at the monthly meetings. In addition, downward accountability to local constituents does not really exist because of an endemic problem with the democratic process: voting is perceived as dangerous and so most people stay away instead of risking their lives. Therefore, local constituents have limited electoral power to call their public representatives to order because of the immature state of the democratic system.

The activities of local government agents are typified by self interest and excessive corruption. Even though there is a concerted effort by the federal government to curtail behaviours of corruption, the commissions set up to enforce this (i.e. National Anti-Corruption Commission and Economic and Financial Crimes Commission), are themselves perceived to be susceptible to corruption and are therefore ineffective. The ineffective enforcement of the formal decision space mapped out by legislation therefore produces a thriving informal decision space at the local level. Nigeria's primary health care system is perceived to be run by local officials who are not bound either by Federal or State health policy imperatives or legislation. There is therefore a different kind of contestation regarding the decision space afforded these local agents.

Decision Space Contested

Instead of local agents seeking a wider decision space, public health practitioners are seeking to extricate the functional delivery of PHC from the influence of politicians. Among other things, they argue that the bureaucratic bottleneck affects the effectiveness of the service provided. Some examples are that, requisitions are intolerably delayed before being fulfilled and immunisation exercises undertaken are not paid for in time. There is therefore a contention that health care delivery should not be run by government but possibly by health boards. This autonomy will include budget facilities and financial independence for public health practitioners.

Public health practitioners ascribe to the view that primary health care is a vital public health service with particular outreach to the poor. Their contention is not regarding the State provision of this service as a public good but its operational involvement. Therefore they protest that a lot more should be done to encourage initiatives such as the National Health Insurance Scheme because they are run by Health Maintenance Organisations and are therefore more accountable and scrutinised. In this case, Government should cater for the poor through a social security system but the primary health care service would still be provided by a third party.

As a summary, we observe that legislation allows the decentralisation of the health sector in Nigeria. However, the lack of an effective enforcement structure leads to a situation where the informal decision space is more prominent than the formal. Consequently, the exception becomes the rule and conceptually speaking, anomaly reigns. There is also a sense that the lack of enforcement is not primarily due to capability but the informal decision space thrives because the FMOH is not really interested in primary health but tertiary health care. Therefore, primary health care is invariably inefficient and the general health system essentially underperforming.

Decision Space and Local Choice

Local Choice Within an Informal Space

The choices made by local government officials have primarily been not to pay adequate attention to primary health care issues. Most of these officers are there for their own selfish reasons because the remuneration for holding this post has recently become more attractive and therefore people vie for these offices without an interest of the community at heart. This attitude affects the local delivery of health services adversely. Local government choices are based on politics and not need. Even those who would like to make a positive difference are constrained because as politicians the feel obliged to payback their election campaign sponsors who strongly influence the political agenda.

For instance, some of these choices translate into charging for immunisation which is meant to be provided free of charge. Another illustration is that the General Hospital which the State government says should be provided free health services at the point of delivery have become an operational farce. The only service which ends up being free is the initial consultation. The required drugs are invariably out of stock. This is because only a proportion of the allocation makes it to the hospital in the first place, the consignment that makes it most conveniently find its way to the nearest pharmacy where more money will be paid for it. When patients come for drugs, they are directed to the nearest pharmacy.

Some of the more substantive factors that influence local choice include the background of the local government chairman. Where this is a health background, there seems to be a better appreciation of PHC otherwise it is treated as least priority. Highly educated local government agents also contribute to the level of attention PHC receives. Other factors also depend on the agenda of influential personalities who may want to boast about their local government area and therefore lobby politicians for rapid health care development programmes in their area. The effect of these diverse influences can be seen where for instance there is a local government area with a population of five thousand being served by three health care centres while another population of seventy thousand does not have any health care centres.

Decision Space and Performance

In Nigeria, a large proportion of the community is rural (it is estimated that about three quarters of the population live in rural areas). This has serious implication for the health profile of the country. For instance, in spite of how sophisticated health service delivery is in the urban areas, this improvement only represents a significantly small proportion of the total population. Similarly, the lack of vital public infrastructures for health delivery in rural areas combined with the high level of poverty in these areas has resulted in the poor health status of the country as a whole. The primary health care service has a major role in determining the overall performance of the health system. However, PHCs in Nigeria are not efficient and there are significant difference between the extensive policy formulations at the centre and action at the local level. Even thought there are extensive policy directives on providing primary health care it is usually either ignored or not followed.

Incentives and Sanctions

To compound this issue, financial and non-financial incentives or sanctions are not applicable in the Nigerian context. In addition to the absence of an effective enforcement structure, the local government has an independent budget allocation and therefore the FMOH is not responsible for salaries of local PHC officials. The regime of incentives and sanctions are therefore too weak to bring about any substantial change in the local government's primary health care performance.

Nonetheless, the evaluation of health care delivery is conducted through the monitoring of health information.

Health Information as a Monitoring Tool

The local government sends required health information to the SMOH. These are received by career officers who normally should collate, analyse and verify the results but this is rarely done (if at all). Apart from the fact that there are very limited visits from the SMOH to verify data returns, when do visits do happen local governments are notified in advance, defeating the purpose of the exercise.

As an illustration, in one of the supposedly largest State hospitals serving a local government area, there have only been 3 visitations by the State Monitoring Teams and 1 visit by the federal government in the last 6 years. In fact, the purpose of the FG visit was to evaluate the feasibility of the hospital being a centre for AIDS treatment as supposed to monitoring the performance returns of the hospital.

In order to save face and not be found wanting, potentially damaging health data is often manipulated before being reported to the upper levels. For example there has been a programme of polio eradication every two months for the last one year where all children under five are supposed to be immunised however, polio is still widespread but the federal government does not report this. It is often said that anyone who knows anything about the health care system in Nigeria will not trust the health records.

Health Information as Health Systems Performance

The problems with reliable health records are much more nuanced as a component strategy of general public health. Information management is very crucial to primary health care in terms of health planning, disease monitoring and surveillance etc. There is a view from the Director of Public Health that primary health care in Nigeria has a good information management system. The argument is that prior to any intervention programme in a locality, a situational analysis is conducted to identity the main health problems and need. Therefore subsequent action is based on concrete and well studied information. From an operational management level, the State Primary Health Doctor's perception is also that health workers in the rural areas take data recording seriously. In addition, they are said to be meticulous in reporting the information they collect to the extent that some go out of their way to ensure accuracy. However, it is noted that there is another extreme set of workers who are unscrupulous regarding information collection. For example, an independent examiner on the programme for Polio eradication noted the "super-efficiency" with which certain health workers had administered the vaccinations and had logged all the information. On further investigated she realised that the vaccines had been disposed of and the time was spent meticulously cooking the log books.

Some other public health doctors (e.g. in the local government and private sector) however feel that many health workers don't appreciate data collection probably due to their level of education but still collect the data because it is mandatory. They admit that some errors in the data may suggest that health workers may not be as meticulous as community health physicians. Nonetheless, there is a view that it is highly unlikely that health workers would intentionally fabricate data especially since the data reported have to tally with other stakeholder data and reports (e.g. drug consignments).

There are two categories of data collation: the first is on disease surveillance and notification, the second is on monitoring and evaluation. A designated local primary care officer collects weekly disease surveillance data from primary health centres including some private establishments. These data focus on specific epidemic prone diseases like cholera. These data are sent to the SMOH epidemiologist who analyses the figures to see if an epidemic prevalence threshold has been broken. A monitoring and evaluation officer collects data from peripheral facilities monthly. These facilities ideally fill in the National Health Information Management System form everyday. Data collected include drugs dispensed, family planning, deliveries, treatments etc. Health data for the month are verified by the community health physician before being reported to the SMOH.

Generally, the reality of practice is that data reliability is not a priority in the primary health care system. As such there are no field surveys—conducted at either the local or state level—to verify the data reported. Data reliability is a major problem in Nigeria to the extent that there are even problems with the national census.

Assuming that records collected at the primary care level is mostly reliably. The data is rarely analysed and when analysed seldom lead to concrete action plans which will improve performance of the primary health care. There is therefore a substantial gap between information, policy and action. For example, when polio was reported at a local government area there was only one follow-up when there should have been a few.

Closely related to this is the fact that there is no feedback structure for local health practitioners to review the data submitted in light of a set performance target. There is a notion that the absence of feedback is partly due to the lack of appreciation of the effect it can have on performance at the ground level. Apart from the lack of appreciation, it is also suggested that local agents shy away from the additional cost of getting extra resources to fulfil this role.

There is evidence however to suggest that when the occasional feedback is given, it proves highly effective. For example, a feedback workshop on immunisation, which showed the performance level of a particular local government, motivated workers to try and bridge the gap between target and performance. This reaction is usually more accentuated when there is a comparison with other local government areas or states.

Empirical Findings and Framework Critique

Mapping the Decision Boundary

Nigeria has had a long-standing decentralised health system (Gupta *et al.* 2003). The framework helps to insightfully analyse the tensions that exist between the central and local agents in the delivery of primary health care. Furthermore, it gives clear indications regarding the objectives of a decentralised health system i.e. equity, efficiency, quality and financial soundness.

The decision space lens also helped illuminate the circumstances under which an informal decision space might be created e.g. lack of effective enforcement. In the context of the Nigerian health sector, this was clearly an issue which had unquestionable impact on the delivery of primary health care. The framework however, did not provide tools for understanding how to interpret a situation where the informal decision space is the norm rather than the anomaly and how to understand its potential impact on the performance of the health system (this would be discussed further in the conclusion).While there are definite decision boundaries for the delivery of primary health care at the local level, the peculiar nature of the informal decision space somewhat makes the discussion about the range of choice available to local agents irrelevant. The reality on the ground suggests that there are no effective structures to enforce formally defined choices at the local level. Choices made regarding primary health care are therefore practically autonomous. Consequently, the focus of this analytical framework on local agents contesting or negotiating for a wider decision space is not applicable. The contestation is however present in a more classic debate about the role of the State in providing public services (this theme would also be elaborated in the concluding sections).

Decision Space and Local Choice

While the original framework conceives the range of choices available to local agents in concrete terms (i.e. finance, human resource, facilities etc), this study adopts the notion of choice as an empirical object. That is, the effective and actual perception of choices applicable in the field. This is because, the PHC choices made at the local level in Nigeria are analysed through the perspective of an informal decision space. The analysis showed a prevalence of apathy towards health delivery and self-serving motivations. While it is evident that this has been detrimental to the primary care system in Nigeria, the framework highlighted that the particular characteristics of the local government in terms of motivations and capacity affects health systems performance. In the Nigerian context, there seemed to be an association between the local government agents' professional background (including level of education) and the delivery of primary health care. Suggesting that agent's with a medical background and high level of education are usually more motivated and capable of effectively delivering primary health care. The framework was therefore useful albeit through a slight modification of focus being more on the informal decision space.

Decision Space and Performance

The notion of control to achieve better health systems performance was not well developed in this framework. The analytical weight is predominantly skewed towards the principal i.e. central or state. The suggestions of an incentive or sanction strategy were not really useful in understanding health decentralisation and performance in the Nigerian context. This is partly because this section of the analytical tool is built on the assumptions of a formal decision space (which is by and large insignificant in practice). Nevertheless, the framework also indicates that the local agents also wield some influence over the principal because they generate and own contextual information needed by the principal. This provided a little more ammunition in understanding decision space and performance through the dimension of information. The study for instance was able to highlight how the local agents can manipulate data in order to cover up their poor performance. This analysis was also quite superficial because of the instrumental view of information portrayed in the framework.

In the concluding section, this article suggests how some concepts from the development and information systems literature might be able to provide a richer and more robust analytical approach to studying the link between local agent's decision space and performance.

To bring all the component parts of the study together, Table 1 attempts to provide a brief snapshot of the links between the primary questions of this research project and its findings. This is done by operationalizing the research questions through specific analytical propositions and justifying the findings through exemplary evidence from the field.

CONCLUSION

In developing countries the study of decentralisation and health systems performance incorporates the analysis of an intricate web of agencies and institutional structures. This research project approached the problem domain from the perspective of tensions generated between the local level being agents and upper government levels (e.g. State and Federal) being principals. In particular, it investigated how the devolution of decision-making authority to local government agents (i.e. decision space) impact on the primary health care system. The following conclusions of this study navigate the subtle conceptual and empirical nuances of this problem domain.

Weak State, Rogue Agent: Complementary Vices

The findings of the study suggest that where you have a weak principal, agents will operate predominantly through an informal decision space. The formal decision space therefore serves as a platform for breeding unaccountable local agents. However, in developing countries, it is not just the lack of an accountability structure (see Abouzahr *et al.* 2005) that necessarily leads to the poor delivery of primary health care and the failing health system. Rather, the motivation and capacity of local agents also have some influence in determining the quality of primary health care in a particular locality. In the absence of a competent State to enforce the boundaries of a formal decision space, self-seeking local government officials exploit the opportunity to indulge in unscrupulous activities with public finances at the expense of the local health system.

The access of poor people to health care facilities are not only curtailed but their right to influence issues regarding their health is also limited. For public health systems to be effective, people have to take an active part in shaping health care strategies (Macfarlane *et al.* 2000). This necessitates a rethinking for national health policy makers to institute a public health system that collaborates with local actors to reflect the diversity of local needs as indicated by the local communities (see Newell 1989).

Information is an Elusive Reality

Developing countries face a host of challenges at different stages and functions of the primary care information process (Godlee *et al.* 2004). At the technical level, although the process is fairly routinized, the reliability of the data collected rests on the competence and motivation of health workers. A lack of appreciation for data may be due to not understanding how this data actually fits into the bigger picture of health care delivery. However, without a visible feedback and data verification structure, this exercise would only be perceived as theoretical. As supported by this study, the managerial imperative which views information as a monitoring and control instrument (Berg 2001) has been widely criticised as narrowly conceived in the information systems field (Ciborra 2000, Kallinikos 2006) .

In conclusion, this study explores the significant contextual factors which have far-reaching implications for the implementation and use of health information systems for improving health care delivery in developing country context. As far as it is exploratory, the study has not been particularly concrete in investigating a grounded HIS project. The viewpoint of the researcher, which was substantiated through this study, is that most matters in developing countries (and especially in the domain of health care) do not warrant the centrality of technology because a rich understanding can often be obtained by studying the social and political foundations on which previous technological initiatives have been built.

ABSTRACT

Evaluating clinician satisfaction with an electronic medical record (EMR) system is an important dimension to overall acceptance and use, yet project managers often lack the time and resources to formally assess user satisfaction and solicit feedback. This article describes the methods used to assess clinician satisfaction with an EMR and identify opportunities for improving its use at a 300-physician academic practice setting. We administered an online survey to physicians and nurses; 244 (44%) responded. We compared physician and nurse mean ratings across 5 domains, and found physicians' satisfactions scores were statistically lower than nurses in several areas ($p<.001$). Participants identify EMR benefits and limitations, and offered specific recommendations for improving EMR use at this facility. Methods used in this study may be particularly useful to other organizations seeking a practical approach to evaluating EMR satisfaction and use.

INTRODUCTION

The degree of interest and momentum in furthering the widespread adoption and use of electronic medical record (EMR) (or electronic health record systems) is at an all time high in the United States. Healthcare providers, purchasers, payers and suppliers are all looking to the EMR as a tool to help promote quality, enhance patient safety, and reduce costs. Despite this energy, recent estimates indicate EMR adoption rates in ambulatory care remain in the 15-20% range (Hillestad et al., 2005). Cost, lack of uniform interoperability standards, limited evidence showing use improves patient outcomes and clinician acceptance are among the barriers to widespread EMR adoption (Bates, 2005). Those who have overcome these initial hurdles and made the transition from a paper-based medical record system to an EMR often lack the time, resources and expertise to evaluate the system's impact on the organization, including clinician use and satisfaction with the system (Anderson & Aydin, 2005; Wager, Lee, & Glaser, 2005).

Use and satisfaction are two key measures of the success of any information system (DeLone & McLean, 2003), including EMR system success (Anderson & Aydin, 2005). Various researchers have assessed physician use and satisfaction with the EMR (Sittig, Kuperman, & Fiskio, 1999; Gadd & Penrod, 2001; Penrod & Gadd, 2001; Likourezos et al., 2004; Joos, Chen, Jirjis, & Johnson, 2006) and some have found that user group perspectives can differ even within the same institution (Wager, Lee, White, Ward, & Ornstein, 2000; O'Connell, Cho, Shah, Brown, & Shiffman, 2004b; Hier, Rothschild, LeMaistre, & Keeler, 2005). Assessing user reaction to the human-computer interface is also an important dimension (Sittig, Kuperman, & Fiskio, 1999; Despont-Gros, Mueller, & Lovis, 2005) in evaluating EMR satisfaction. Likewise, the timing of the evaluation study is important. Conducting formative evaluation studies during enterprise EMR implementation can be particularly useful in identifying perceived problems and making adjustments to the implementation plan or reallocating resources as needed (Friedman & Wyatt, 1997; Burkle, Ammenwerth, Prokosch, & Dudeck, 2001; Anderson & Aydin, 2005; Brender, 2006).

Our study was designed to assess physician and nurse use and satisfaction with an enterprise-wide ambulatory care EMR. We incorporated into the evaluation a means of assessing physician and nurses' reactions to the human-computer interface and also solicited their input and suggestions on how to improve the system's usefulness to our organization. This article summarizes the methods used, findings, and relevance to other organizations in the throes of implementing and evaluating EMR acceptance.

BACKGROUND

The Medical University of South Carolina (MUSC) in Charleston, South Carolina has implemented an electronic medical record (EMR) system, known as Practice Partner Patient Record® in the majority of its ambulatory clinics over the past few years. Although EMR use is not new to MUSC (family medicine has used the system since the early 1990s and internal medicine since the mid-1990s), it was not until February 2004 that we secured funding to deploy the EMR throughout the ambulatory care enterprise. When the system is fully implemented, paper medical records will have been replaced, and both primary care and specialty providers will share a *single* electronic medical record for their patients. This message was conveyed from the top down, starting with senior leadership and the dean of our medical school.

The EMR product itself has many of the attributes of a typical EMR system, including electronic health data capture, results management, decision-support, and electronic communications. However, MUSC has not yet installed enterprise-wide direct order entry nor activated the preventive care reminder functions. Disease-specific progress note templates are available for facilitating program note entry; however, direct data entry is not a requirement for using the system, and transcribed notes can also be incorporated. The system also includes a prescription writer, which allows prescriptions to be entered and tracked in the patient record while automatically checking for interactions with other medications and documented allergies. Patients receive printed prescriptions at the time of the visit; the prescriptions are not yet sent electronically to the pharmacy.

We provided formal training sessions to physicians, nurses and administrative support; however, nurses and administrative staff received at least four hours of initial training, while most physicians only had 30-45 minutes of training. Nurses and administrative staff were trained in small groups in a classroom setting with computer workstations for each individual. Physicians were offered several options for training, including small group sessions, but the far majority opted for one-on-one training with a clinical analyst. Knowing that physicians' schedules were harried, we decided to provide more intensive training to nurses and administrative staff. We felt if nurses and administrative staff were comfortable with the system, they could assist physicians in their respective departments as needed.

The purpose of the study was to gain insight into user satisfaction and determine if there were differences in user group satisfaction, and solicit formal feedback on how to improve the system's use at our organization. We defined 'user' as any MUSC employee or student who had been issued an EMR login and password. This article describes the methods used to conduct the survey and the results from our attending physician and nurse user community.

METHODS

Survey Instrument

We conducted preliminary interviews with physicians and nurses regarding their views and experiences with the EMR, but were interested in soliciting input from all EMR users at MUSC. Given the size of the user group, we decided to adopt a survey approach. We adapted the *Questionnaire for User Interaction Satisfaction (QUIS)*, developed by researchers at the University of Maryland, for use in this study after reviewing the literature, consulting with medical informatics professionals and soliciting input from EMR physician leaders at MUSC. The QUIS has been tested as a valid and reliable instrument in settings similar to MUSC (Chin, Diehl, & Norman, 1988) and was used recently by researchers affiliated with Brigham and Women's Hospital to assess physician satisfaction with its internally developed outpatient EMR (Sittig, Kuperman, & Fiskio, 1999). The QUIS has also validated for online administration (Slaughter, Harper, and Norman, 1994). The instrument assesses user satisfaction in five major domains, with four to six questions in each: (1) overall user reactions, (2) screen design and layout, (3) terminology and system messages, (4) learning, and (5) system capabilities. Recognizing that participants might respond differently depending upon whether they were assessing how long it takes to open the application or navigate within it, we separated the item "system speed" survey component into two statements—system launch speed and navigation speed. We asked participants to rate each question on a scale from 0 (the lowest) to 9 (the highest) level of satisfaction.

We included several additional items in the survey: (a) demographic data (e.g., position, age, gender), (b) use of the EMR (whether provider dictated notes or directly entered them into EMR), and (c) three open-ended questions, in which participants were asked to identify the three greatest benefits or advantages and three greatest limitations or disadvantages to using the EMR and any recommendations they have for improving the use and effectiveness of the EMR within their clinic or at MUSC. The items and scale from the QUIS were kept intact. A draft survey was sent to a pilot group of physicians, nurses and administrative staff. Suggested changes were incorporated into the final version of the survey. Institutional Review Board approval was obtained prior to conducting the study.

User Population and Survey Administration

We sent an e-mail message from one of the authors (who happened to serve as chair of the Physician Information Council) to all attending physicians and nurses listed in the EMR user database. Our sampling frame included all individuals who had been issued an EMR username and password—for a total population of attending physicians (245) and nurse EMR users (304) of 549. In the e-mail message, participants were asked to click on an embedded hyperlink to complete the online questionnaire. We gave participants the option of printing and faxing the completed survey to us (48 surveys were returned by fax). Two reminder notices were sent—one week and two weeks following the initial mailing. All participants were assured confidentiality of their responses.

Data Analysis

Survey responses were downloaded from the survey provider to an electronic database and then imported into SPSS for analysis (Windows, 2005).

Responses to open-ended questions were grouped and assigned to categories by the primary author, experienced in qualitative research. These were then tabulated within each of the categories and discussed among the participating authors.

Table 1. Reliability of domains (Crohbach's Alpha)

Domain	Alpha
Overall user satisfaction	.911
Screen design and layout	.859
Terms and system information	.891
Learning	.876
System capabilities	.835
Overall	.961

RESULTS

Demographics of Participants and Their Use of EMR system

We received 244 completed surveys from attending physicians and nurses for an overall response rate of 44%. Forty-seven (47%) of physicians and 38% of nurses responded. 32% of participating physicians and 98% nurses are women; 85% are between the ages of 30-60, equally distributed within each decade of life. Nearly 37% of physicians and 19% of nurses reported having prior experience with other EMR systems, and 62% have used the EMR at MUSC for at least one year.

When physician participants were asked how often they dictate patient information that is eventually transcribed into the EMR, 39% reported frequently (defined as more than 50% of the time), 4% sometimes (25-50% of the time) and 58% reported rarely or never (defined as less than 25% of the time) (n=109). Almost 40% of participants reported having paper medical records pulled daily for patient visits, 14% sometimes, and 44% rarely or never (n=108). 70% reported that they access the EMR remotely on at least a weekly or daily basis.

Satisfaction with EMR

We assessed the internal consistency reliability of the five domains of the QUIS part of the survey (Table 1) and examined mean satisfaction scores for attending physicians and nurses for each item within the five domains. Overall Crohbach's alpha was 0.961.

Attending physician and nurse mean scores are shown in Table 2. Items were rated on a scale of 0 to 9, with 0 being the most negative, 9 the most

Table 2. Physician and nurse mean satisfaction scores by domain/item

Domain	Item (0-9 scale)	Physician	Nurse
Overall satisfaction	Terrible……………Wonderful	5.07	5.92*
	Difficult……………Easy	5.17	6.21*
	Frustrating……………Satisfying	4.33	5.09*
	Inadequate Power……………Adequate Power	4.45	5.02
	Dull……………Stimulating	4.65	5.39*
	Rigid……………Flexible	4.42	5.41*
	Overall satisfaction composite score	**4.67**	**5.50***
Screen Design and Layout	Characters on the screen: Hard to read……………Easy to read	6.67	7.16
	Highlighting on the screen simplifies task: Not at all……………Very much	5.49	6.54*
	Organization of information on screen: Confusing……………Very clear	5.45	6.17*
	Sequence of screens: Confusing……………Very clear	5.56	5.81
Terms and System Information	Use of terms throughout system: Inconsistent……………Consistent	6.09	6.58
	Computer terminology is related to the task you are doing: Never……………Always	5.89	6.31
	Position of messages on screen: Inconsistent……………Consistent	6.05	6.48
	Messages on screen which prompt user for input: Confusing……………Very clear	5.42	6.14*
	Computer keeps you informed about what it is doing: Never……………Always	4.90	5.42
	Error messages: Unhelpful……………Helpful	3.22	4.19
Learning	Learning to operate the system: Difficult……………Easy	5.23	5.98*
	Exploring new features by trial and error: Difficult……………Easy	4.73	5.76*
	Remembering names and use of commands: Difficult……………Easy	4.93	5.51
	Tasks can be performed in a straight forward manner: Never……………Always	5.06	5.74*
	Help messages on the screen: Confusing……………Clear	4.14	5.12*
	Supplemental reference materials: Confusing……………Clear	4.10	5.45*
System Capabilities	System speed (to open or launch program): Too Slow……………Fast Enough	2.65	2.85
	System speed (to navigate within EMR, e.g. open a note): Too slow……………Fast enough	4.41	4.13
	System reliability: Unreliable……………Reliable	4.72	5.01
	System tends to be: Noisy……………Quiet	7.23	7.87*
	Correcting your mistakes: Difficult……………Easy	5.12	4.96
	Experienced and inexperienced users' needs are taken into consideration: Never……………Always	4.68	5.31

**significant at the p>.05 level*

positive. Both groups gave low ratings to system launch speed and clarity of error messages. Items rated most positive by both groups included system noise, ease in reading characters, consistency of terms, and the clarity of messages appearing on-screen. We calculated overall satisfaction scores for physicians and nurses using the average of the six items in the overall user reaction domain as a proxy. Overall satisfactions scores were 4.67 and 5.50 (t-test, $p < .001$) for attending physicians and nurses, respectively. We compared attending physician ratings of the other 22 individual items with those of nurses and found that the physicians' mean ratings of the EMR were statistically significantly lower in nine of the 22 items ($p<.05$). Using one-way ANOVA, we found no difference in overall satisfaction between experience groups, less than 6 months, 6-12 months, 1-2 years, and more than 2 years.

We also ran a standard multivariate regression with overall satisfaction score as the dependent variable and the 22 remaining items as independent variables and found two items were significant predictors of overall satisfaction—(1) task can be performed in a straightforward manner ($p<.001$) and (2) clarity of help messages on screen ($p<.01$).

Perceived EMR Benefits, Limitations and Recommendations for Improved Use

Participants were asked three open-ended questions:

- What have you found to be the three greatest benefits or advantages to using the EMR?
- What have you found to be the three greatest limitations or disadvantages to using the EMR?
- What recommendations do you have for improving the use and effectiveness of the EMR within their clinic/area at MUSC?

Benefits/Advantages to the EMR System

Nearly 82% of physicians and 56% of nurses identified availability and accessibility of the patient's record as a major benefit or advantage to using the EMR. See Table 3. Included in this category were comments related to having access to other clinic notes and records and having remote access to the EMR. One physician commented, "*Everyone has access to the entirety of the record across all disciplines.*" Another noted, "*The EMR greatly facilitates communication among primary care providers and specialists by having all patient information in one place.*" Other frequently cited benefits included (a) quality of record/documentation (legibility, data consistency and accuracy, organization of record, coding/compliance); (b) comprehensiveness and completeness of patient record (e.g., medications, results from diagnostic tests); (c) impact on efficiency (e.g., speed, timeliness in completing notes);(d) continuity of care and standards of care (e.g., templates, continuous outpatient record); and (e) avoidance of perils inherent with paper records (e.g., no lost charts, no moving charts).

Limitations/Disadvantages to the EMR System

Limitations or disadvantages identified by at least ten participants are listed in Table 4. The two most-cited limitations or disadvantages of the EMR were speed and cumbersome user interface. Both physicians and nurses described the system as being too slow. Approximately 20 participants mentioned that the start time to open the application was particularly problematic. System downtime, including the moments when the "system crashes", "locks up or freezes" and requires user to "reboot" were described as frustrating by 14% of physicians and 22% of nurses. One physician commented that system crashes are frustrating: "*The program froze three times*

Table 3.Most frequently cited benefits/advantages to using MUSC's EMR system

EMR Benefit	**Physicians** n=114	**Nurses** n=130
Availability and access to patient record	81.6%	56.2%
Quality of record/documentation	36.0%	14.6%
Comprehensiveness and completeness of record	33.3%	25.4%
Positive impact on efficiency	13.2%	10.0%
Continuity of care and standards of care	13.2%	10.8%
Ease of use	12.3%	15.4%
Avoidance of perils of paper	9.6%	20.0%

Table 4. Most frequently cited limitations/disadvantages to using MUSC's EMR system

EMR Limitation	**Physicians** n=114	**Nurses** n=130
Cumbersome user interface	38.6%	24.6%
Speed/too slow	37.3%	32.3%
Having to access multiple clinical systems or poor integration with other systems	17.5%	4.6%
Problems with templates	11.4%	4.6%
Insufficient training and support staff	11.4%	3.8%
Downtime (including system crashes or system locking/freezing up)	14.0%	21.5%
Time-consuming to use	13.2%	14.6%

today while I was editing the same note, losing the edits each time. I spent 30 minutes trying to edit a single note without success." A nurse noted, "*When the system is down, you are put completely on hold*." Several participants also expressed frustration with the amount of typing required and the time-consuming nature of entering data into the system. Understanding error messages and correcting mistakes also emerged as points of frustration. Comments reflecting concerns including statements such as: "*too much trial and error", "if you don't already know how to do something, you'll never figure it out", and "some error messages don't tell you how to solve the problem."*

Suggestions for Improving EMR Use at MUSC

Participants gave numerous written suggestions for improving EMR use at MUSC—73% of the physicians and 49% of nurses wrote comments. Suggestions ran the gamut from *"provide more training", "fix bugs in system", "address speed and reliability of system", to "make it more user friendly."*

Several common themes emerged from the written suggestions. Some of these relate to how the EMR is structured and used at MUSC and others relate more directly to the Practice Partner application itself. General suggestions included (1) address the speed/performance issues, (2) expand training and support personnel/resources, (3) improve the user interface/templates and simplify data entry, and (4) integrate more fully with other MUSC applications (e.g., scheduling, lab, radiology).

DISCUSSION

Nearly 250 physician and nurse EMR users at MUSC participated in this study. Nurses are more satisfied overall with the EMR system than are attending physicians. The greater system acceptance by nurses may be due to the approach MUSC took in implementing the EMR enterprise-wide. Initial efforts were focused on nurses and administrative staff, because these individuals were expected to lead in the effort. We felt if nurses were comfortable with the system, they could assist physicians. The downside of this approach is it has been time-consuming and resource-intensive to roll out the EMR throughout all the ambulatory care areas. Consequently, some physician users have not been fully trained on all of the system capabilities—yet, they have been using the application for two or more years.

Additionally, 58% of participating physicians report that they rarely, if ever dictate. Earlier studies have shown that data entry can negatively impact physicians' perceptions of their time, particularly if physicians are not proficient typists or comfortable entering information in the examination room with the patient (Gadd & Penrod, 2001; Penrod & Gadd, 2001; O'Connell, Cho, Shah, Brown, & Shiffman, 2004a; Hier, Rothschild, LeMaistre, & Keeler, 2005; Scott, Rundall, Vogt, & Hsu, 2005; Linder et al., 2006).

Researchers at Partners HealthCare System conducted a time-motion study and found no differences in primary care physician time utilization before and after EMR implementation, yet the majority of their physicians still perceived that the EMR required more time than paper records to document patient information (Pizziferri et al., 2005). Nurses in an earlier study reported that the EMR enabled them to finish their work much faster than before implementation (Likourezos et al., 2004); although we did not ask this specific question, it may help explain why MUSC nurses generally viewed the system more positively than physicians.

Nurses also tended to value the "avoidance of the perils of paper" more often than the physicians did, yet they did not mention availability as a major benefit as often as physicians did. We categorize these measures of availability/accessibility and avoidance of periods with paper separately, yet they are related. Nurses are responsible for ensuring that the patient's record is available at the time of the visit, thus, they experience the "grief" when the record is not available. Physicians are not the ones searching for the paper record, so they may not describe the benefit in quite the same manner. On the other hand, physicians were more likely to mention the benefits associated with having access to clinic notes from other physicians and more likely to comment on the overall quality of the documentation. Having a more "complete" picture of the patient's care (e.g., other visit notes, ancillary test results) stood out as particularly important to physicians. The EMR benefits identified by MUSC physicians and nurses are consistent with earlier studies (Sittig, Kuperman, & Fiskio, 1999; Gadd & Penrod, 2001; Penrod & Gadd, 2001; Likourezos et al., 2004; Joos, Chen, Jirjis, & Johnson, 2006).

Physicians and nurses had similar concerns when asked about limitations of the system or opportunities for improving its use at MUSC. In fact, speed and performance-related concerns seemed to cast a cloud over the benefits. Physicians and nurses identified speed and the slowness of the system as a *major* concern—launching the system was particularly problematic. Yet, in our multivariate regression analysis, system speed did not show up as a significant predictor of overall satisfaction. Although this finding surprised us, an earlier study at Brigham and Women's also found that system "response time" was not correlated with overall user satisfaction (Sittig, Kuperman, & Fiskio, 1999). Factors associated with physicians' ability to effectively use the system were more likely to be predictors of EMR satisfaction than speed alone.

In addition to their concerns with speed and performance, nearly 40% of the physicians felt the user interface was cumbersome, took too many clicks, and made it difficult to make corrections or changes. A common complaint was the "s*ystem requires too many steps or clicks to perform a simple task.*" Other institutions using different EMR applications have found their clinicians share these same concerns (Sittig, Kuperman, & Fiskio, 1999; Wager, Lee, White, Ward, & Ornstein, 2000; Gadd & Penrod, 2001; Penrod & Gadd, 2001; Miller & Sim, 2004; Scott, Rundall, Vogt, & Hsu, 2005). Some of the difficulty or frustration at MUSC may stem from a lack of sufficient training. For example, we observed from the open-ended comments that participants are frustrated with aspects of the system they may not fully understand how to use (e.g., writing prescriptions, modifying templates). Other frustrations may stem from using an EMR whereby primary care providers and specialists share and record their notes in a *single* patient record. Historically, each set of providers had specialty-specific records that only those in the specific group could view and modify.

Interestingly, the results of this survey are remarkably similar to those reported by researchers at Brigham and Women's in their ambulatory care division, despite this group's use of an in-house-developed EMR system. Using the same QUIS instrument, researchers there discovered that attending physicians scored their EMR lowest in the areas of system speed (although they did not distinguish between launch speed and speed of navigating within the application), helpfulness of error messages, and flexibility of system (Sittig, Kuperman, & Fiskio, 1999). The pattern of responses are quite similar, although MUSC physician reactions were less positive in terms of screen design and layout ($p<.01$), terms and system information ($p<.01$) and learning ($p<.001$). Brigham and Women's may have a more advanced training environment, and because they developed the EMR in-house, they have more flexibility in customizing the screens and layout to accommodate their physicians' preferences. No differences were found among overall user reaction and system capabilities. The physicians participating in the study at Brigham and Women had two or more years EMR experience.

Our study evaluated responses from both relatively new and experienced users. One might assume that due to the learning curve in moving from a paper-based system to an EMR, more experienced EMR users would be more satisfied with the system than less experienced users as Gamm et al. suggest (Gamm, Barsukiewicz, Dansky, & Vasey). We did not find that to be the case in our study. EMR users with less than one year of experience were equally satisfied overall with the system as were those who had used the application for two or more years.

Participants in this study provided a host of important suggestions for improving the EMR's use at MUSC. Other institutions would do well to address these issues and concerns up front to avoid problems later.

Our study has two primary limitations. First, the study is limited to a single healthcare organization and one EMR product. Thus, the results may not be generalizable to other healthcare organizations or those who use a different EMR system. Second, response bias is a concern. We compared the demographics of our physician and nurse participant populations with the general physician and nurse EMR population at MUSC and found no differences, yet response rate remains a limitation.

The real value of this study to other healthcare organizations may not be the results per se found at MUSC, but rather the methods and process used. Using the QUIS instrument, we were able to identify the aspects of our EMR system that stood out as problematic to clinician users—launch speed, navigation speed, and the clarity and helpfulness of error messages. Equally, if not more importantly, we provided all clinicians with the opportunity to offer suggestions on how to improve the system, and since this survey, we have incorporated many of their suggestions into our environment. Our leadership team has taken a number of steps to address the most widespread concerns identified by this survey and validated through other avenues. We believe other institutions will find the methods used in this study helpful in assessing clinician satisfaction and in soliciting suggestions for improvement.

CONCLUSION

Results of this survey suggest that MUSC physicians and nurses recognize and value having access to a single electronic patient record that is shared across the ambulatory care enterprise. However, they view the current system as less than ideal. Speed, performance and the user interface (e.g., need to simplify data entry) are of concern. Likewise, additional training and resources are needed to more effectively support the system and its users. Our leadership team has taken a number of steps to address the most widespread concerns identified by this survey and validated elsewhere. Steps to enhance system speed/performance and reliability are being taken, and multi-modal programs of improved training and user support are being implemented. We expect to observe the results of these initiatives and report outcomes in due course.

Assessing user satisfaction with the EMR is important in providing leadership with additional insight into the issues and concerns. Conducting formal evaluation studies, however, are often not done because of lack of available expertise and resources. We believe that surveys such as this one can prove to be a useful resource not only to our healthcare organization's leadership team, but to those in other healthcare institutions interested in easily assessing EMR satisfaction across the enterprise.

Chapter 4.11

Reforming Public Healthcare in the Republic of Ireland with Information Systems:

A Comparative Study with the Private Sector

David Sammon
University College Cork, Ireland

Frederic Adam
University College Cork, Ireland

EXECUTIVE SUMMARY

The need for reforming public healthcare towards greater efficiency and measurable returns on investment has been felt by governments in many countries. In Ireland, this led to the PPARS project, which sought to implement SAP across all public healthcare sites. This project, however, was unsuccessful and led to a parliamentary inquiry. To understand why the PPARS project failed, we carried out an extensive case study of the project and compared our findings to the implementation of JD Edwards in a multinational in the private sector. Our study reveals that despite specific circumstances in the public sector that contributed to the failure of the ERP project, the primary causes of failure result from a lack of understanding of what ERP involves and a failure to prepare adequately, which can be found in any organisation, public or private. This leads to significant lessons for ERP implementations and IS projects involving substantial change

NTRODUCTION

The need to reform the delivery of healthcare services to suit the needs of modern societies has been felt around the world and such reforms have been attempted in many countries, for instance, the USA, the UK, Germany, Canada, France, India, Australia, and The Netherlands. Faced with growing dissatisfaction and concerns regarding healthcare provision in the Republic of Ireland (for example, lengthening waiting lists for many key healthcare services such as major surgery and cancer treatment, and the ever increasing cost of labour and administrative overhead) successive

Irish governments have jumped on the bandwagon of healthcare reforms, in a bid to control and justify the ever increasing operational costs and so-called transformational investments in the delivery of public healthcare services.

At the core of the Irish government's National Health Strategy (2001) was the centralisation of governance of public healthcare under the authority of the Health Service Executive (HSE) which was established in 2005. The key requirement of this centralised agency is to manage the Health Service as a single national entity and provide a monitoring and leadership role so as to increase transparency of the services delivered to the Irish public and make available information pertaining to the use of funding and the responsiveness of services to demands.

In order to develop this information capability in one functional area, the HSE has tried to promote greater integration by deploying a nationwide Enterprise Resource Planning (ERP) application to administer HR and payroll issues in a way that gives more visibility on the hiring and allocation of staff (one of the greatest cost centres in the healthcare sector) within the entire organisation. However, despite years of efforts between 1997 and 2005, the Personnel, Payroll and Related Systems (PPARS) project, established to manage the development and implementation of the ideal—"a fully integrated Human Resource Management system"—has failed to deliver concrete benefits, being suspended by the Irish Government in the late 2005, pending a still on-going Parliamentary investigation.

In this article, we investigate the reasons why the HSE has found it so difficult to implement an ERP application and, using a similar case study of an ERP implementation in the private sector, we attempt to rationally establish whether the causes of failure are specific to the healthcare sector or if they are shared with ERP projects in other environments. The article is structured as follows: a background to ERP is presented and the issue of ERP implementation is highlighted. Following on from this, after a presentation of the context of healthcare in the Republic of Ireland, we present the research protocol we used in the two case studies presented in this article. The article then presents a narrative of the HSE's ERP implementation and, drawing comparison with the case of Banta Global Turnkey (BGT), establishes what is different and what is similar in the public healthcare case and in the private organisation.

Understanding Enterprise Resource Planning (ERP) Systems

ERP systems are positioned as one of the most sought after means of organisational transformation and IT innovation since the mid 1990s and form the cornerstone of IS for an ever increasing percentage of organisations (El Amrani, Rowe, Geffroy-Maronnat, 2006; Holland & Light, 2001; Markus & Tanis, 2000; Sharif, Irani, & Love, 2005; Stefanou, 2000; Swanson & Ramiller, 2004). Such an observation has been made in both the trade press and academic literature, suggesting that ERP systems have sustained their attractiveness to managers, and when their rate of adoption and implementation is examined (over the last decade) it can be observed that these ERP systems were indeed the *de facto* solution to organisational integration problems.

The basic concept of an ERP system is comparatively simple and has evolved over the past 30 years, from the ideal of optimising operations and reducing costs, through to control and standardisation (Sammon & Adam, 2002; Watson & Schneider, 1999). ERP systems also promised to deliver on the informational requirements of an organisation, such was its scope. For example, according to Wood and Caldas (2001, p. 387), ERP was described as "a comprehensive information technology package built on the promise that all critical information should be totally integrated in one single information database." In fact, the origins of ERP can be traced back much further, to the Industrial Revolution and the initial attempts at optimising industrial activities with regard to materials and inventory management (O'Gorman, 2004). Indeed, the issues of materials and inventory control addressed by Material Requirements Planning (MRP) in the 1960s, which evolved into the (Manufacturing Resource Planning (MRP II) systems of the 1970s, are still at the core of present day ERP systems. However, an ERP system differs from MRP/MRPII systems, not only in terms of system requirements, but also in technical requirements. While "MRP II has traditionally focused on the planning and scheduling on internal resources, ERP strives to plan and schedule supplier resources as well, based on the dynamic customer demands and schedules" (Chen, 2001, p. 376). Therefore, ERP systems are positioned as the second phase in the general progression towards the integration of "enterprises" internal and external constituencies (Kalakota & Robinson, 2001). The continued evolution of ERP systems has brought about an increased depth and breadth of "best practice" software functionality, supporting a wider range of industrial sectors.[1] As a result, even in nonmanufacturing industries, ERP systems offer the potential for consolidation of internal operations and an integrated, enterprise-wide view of the organisation.

The Issue of ERP implementation

Notwithstanding the obvious interest motivated by the concept of ERP, the record of organisations having sought to reap the benefits from highly integrated enterprise-wide systems has been rather mixed (Stefanou, 2000). James and Wolf (2000) reported that 80% of the benefit that organisations achieved from their ERP system came from changes, such as inventory optimisation, the benefits of which could have achieved without making the IT investment. Furthermore, Jahnke (2002) reported that over 50% of organisations that attempted an ERP implementation were dissatisfied with the results. In addition, Jahnke (2002, p. 1) commented that "forty percent of the projects failed to achieve their business case within one year of going live, and those companies that did achieve benefits said that achievement took six months longer than expected." This insight proves extremely worrying for organisations investing in ERP packages and calls into question the expectations of organisational decision-makers as to the initial benefit of ERP vs. the actual value-for-money from the changes introduced from the initiation of such an IS/IT investment. However, according to James and Wolf (2000, p. 2), reporting on an instance of an ERP implementation, many of the benefits that we are able to achieve today could not have been predicted at the time that we started work on ERP. In fact, in hindsight it appears that much of the value of these large systems lay in the infrastructure foundation they created for future growth based on Information Technology.

Indeed, Ward and Peppard (2002, p. 432) highlight that "benefits from strategic IS/IT investments are uncertain and depend on future events, making priority setting even more difficult." In fact, Ward and Peppard (2002, p. 434) further comment that, "setting objective priorities on scant evidence is not very reliable."

Swanson and Ramiller (2004, p. 554) noted in their award winning MISQ research article titled "Innovating Mindfully with Information Technology," that by the mid-1990s, ERP was a topic that was being banded about in boardrooms. It wasn't just an information technology (IT) project, but a strategic business imperative… the ERP genie was out of the bottle—every company needed to have an ERP implementation.

Indeed, it can also be argued that reports of this nature has further provided ERP packages with longevity greater than previous IS fads and fashions. However, Swanson and Ramiller (2004, p. 554), borrowing Weick's concept of *mindfulness*, suggest that *adopting organisations entertain scant reasoning for their moves. Especially where the innovation achieves a high public profile, as with ERP, deliberative behaviour can be swamped by an acute urgency to join the stampeding herd, notwithstanding the high cost and apparent risk involved.*

Indeed, this *mindless* behaviour in pursuit of best practice is the rule, with the exception being a *mindful* organisation engaging in such an IT innovation.

To summarise, investing in an ERP package has been characterised as a *transformation investment* (Ross & Beath, 2002), which requires managers to understand the importance of changes to the business in order to achieve the expected benefits from the project (Murphy & Simon, 2002; Ross & Beath, 2002). Paradoxically, while investments in ERP packages are amongst the most significant an organisation will ever have to engage in, the realities of ERP implementation are not fully understood by managers (Olsen & Saetre, 2007) and the benefits expected at the outset of the project are not always a realistic feature of actual project outcomes (Chen, 2001; James & Wolf, 2000; Law & Ngai, 2007; Murphy & Simon, 2002; Shang & Seddon, 2002). All too often organisations fail to prepare appropriately for an ERP project implementation, which has been referred to as *mindlessness* by Swanson and Ramiller (2004), and as a result invest in what is essentially an IT initiative as opposed to a business change project (Murphy & Simon, 2002; Wood & Caldas, 2001; Ross & Beath, 2002). In light of these observations, it can be argued that assessing the level of benefit realisation is a somewhat subjective exercise where operational efficiency could be considered of strategic value to an organisation (long term), and therefore categorised as a strategic benefit (Murray, 2005). This subjective view is based on managerial interpretation of the impact of the implemented enterprise-wide ERP system on organisational activity, used as a means of providing retrospective explanations for the earlier rationales in selecting an ERP package. The fact that so few organisations actually do carry out postimplementation assessments may be an empirical illustration of this point.

Context of Healthcare in the Republic of Ireland

The Irish Department of Health was established in 1947, under the Ministers and Secretaries (Amendment) Act, 1946. Prior to 1947, the public Health Services were the responsibility of the Department of Local Government and Public Health, and continued to be administered by local authorities until 1970. The Health Act (1970) established eight Health Boards (Eastern, Midland, Mid-Western, North Eastern, North Western, South Eastern, Southern, Western) and increased the Department of Health's direct involvement in the execution of health policy. The passing of the Health (Eastern Regional Health Authority) Act (1999) effectively dissolved the Eastern Health Board and replaced it with the Eastern Regional Health Authority (ERHA) and three new Health Boards namely, South West Area Health Board, Northern Area Health Board, and East Coast Area Health Board. Currently, the Department of Health and Children (DOH&C) has overall responsibility for the development of health policy and for the planning of Health Services. The Health Boards established under the Health Act 1970 were the statutory bodies responsible for the provision of health and personal social services in their functional areas. However, in 2005 the Health Service Executive (HSE) was established and was the first ever body to manage the Health Service as a single national entity.[2]

While the structure of the Irish Health Services remained unchanged for over 30 years, a number of health reforms were planned. In 2001, the Irish government launched its National Health Strategy: Quality and Fairness, A Health System for You. The strategy set out key objectives for the health system for the following 7-10 years. These objectives were centred on four national goals:

1. Better Health for Everyone,
2. Fair Access,
3. Appropriate Care in the Appropriate Setting, and
4. High Performance.

In addition, the strategy identified the need for a whole range of system changes to occur in order for these goals to be achieved. These Frameworks for Change were:

1. Primary Care
2. Acute Hospital Services
3. Funding
4. Human Resources
5. Organisational Change
6. Information

Furthermore, in June of 2003, the Government announced the Health Service reform programme initiating an unprecedented change programme for the Irish health system. The programme emerged from the recommendations contained in two reports: the *Report of the Commission on Financial Management and Control Systems in the Health Service*—referred to as the Brennan Report (DOH&C, 2003)—and the *Audit of Structures and Functions in the Health System*—referred to as the Prospectus Report (DOH&C, 2003). Both of these reports highlighted the need for quality information systems and the need to identify the negative consequences of inadequate investment in such systems in the past. A central tenet of the reform proposals was the establishment of a National Shared Services Centre (NSSC), which was intended to coordinate data, typically HR and finance data, previously gathered and processed within the health agencies. The Prospectus Report highlighted the need for a single HR Function to coordinate and lead system-wide activities and for the establishment of shared services in IT. It also placed a high priority on a robust information gathering and analysis capability, and on the national management of resources to integrate service delivery.

The Brennan Report included in its terms of reference the need to enhance the capability of the Health Services regarding: Management Accounting, Costing, and Associated Information Systems. Furthermore, in a section of the report calling for greater investment in IT, the report argued that the on-going PPARS project (which, since its beginning in 1997 and up to that point had been confined to five Health Boards and Saint James Hospital) should be extended to "all major spending agencies." Of its seven IT recommendations, three explicitly focus on the centrality of the PPARS project in a reformed Health Service, while a further three include PPARS implicitly (albeit with a much revised scope). Therefore, these two reports devote key parts of their findings and recommendations to the positive role that PPARS has to play in the Irish Health Services of the future.

Therefore, in June of 2003, the government made key decisions relating to the reform of the Health Service. The key elements of the programme included:

1. A major rationalisation of existing Health Service agencies to reduce fragmentation. This includes the abolition of the existing health board/authority structures.
2. The reorganisation of the Department of Health and Children, to ensure improved policy development and oversight.
3. The establishment of a Health Services Executive which is the first ever body charged with managing the Health Service as a single national entity.
4. The modernisation of supporting processes (Service Planning, Management Reporting, etc.) so that the Health Service is in line with recognised international best practice.

Table 1. Principles of preparedness

Principles of Preparedness	Description
Priority Project	Management has to categorise the ERP project as one of the priority projects of the organisation and an ERP system should be looked upon as the acquisition of an asset, not as an expenditure.
Proactive Approach	An ERP implementation should be undertaken as a proactive measure in addressing organisational symptoms that suggest the pressing business need.
Organisational Goals	The implementation of an ERP system is based on a business engineering blue-print; therefore, organisations must chart their organisational goals and identify the key processes that affect the organisational success.
Communicate and Manage Expectations	The objectives in implementing ERP and the corresponding expectations should be clearly documented. The discipline of conducting work through documentation is a necessary prerequisite.
BPR	Carry out BPR in advance of ERP or alternatively implement an ERP package in its *vanilla* form. Facilitate the opportunity to incorporate best practices from industry into the organisations systems and procedures (a clear policy has to be made for implementation of the ERP in vanilla and its review could be made only after 6 months.
Implementation Methodology	Work on a proven methodology to reduce the actual implementation time and the associated direct and indirect costs and implementation delays with partners and certified consultants who are experts in the area. Overall, the morale of the organisation would be high if the implementation could be completed at quick speed, even if it may not be an optimal implementation.
Education on ERP	Organisational personnel should be apprised as to what ERP would be and what it would not be. An apprisal should cover ERP principles in generic terms and case studies to highlight attitudes and principles that have been successful and issues that have been problematic.
Best Business Personnel	Once it is decided to implement ERP, it is necessary, although difficult, to release the best and committed business personnel to the project on a full-time basis. In fact, those who cannot be spared are the ones who will be required on the project team. An advanced plan and commitment is essential at all levels to release the selected personnel.
Cross–Functional Team	The team should span the entire organisation and a representative from each critical business area to be impacted by the ERP implementation should be a member of the team.
Approach to Training	A training centre with adequate facilities must be planned, as a "make-shift" temporary one could be counter-productive.
Technical Infrastructure	Ensure the availability of adequate network infrastructure pre- and post-implementation. For example, it is absolutely necessary to have adequate network infrastructure, as close to real environment as is possible for training and testing purposes.
Mindset Change and Attitude to Learning	Top managers must be ready to allow a mindset change by accepting that a lot of learning has to be done at all levels, including at top management. This attitude would facilitate the exchange of ideas with people who have already experienced and successfully implemented this change.

As a result, this reform programme was aimed at ensuring that the health system was organised and managed in a way which helped it achieve the four national goals of the health strategy, and, therefore, set out a range of structural, organisational, financial management, and systems reforms.

Research Protocol and Research Methods

Yin (2003) proposed that case studies are most appropriate when the research objective involves studying contemporary events, without the need to control variables or subject behaviour. In fact, Benbasat, Goldstein, and Mead (1987, p. 370) commented that "the case research strategy is well-suited to capturing the knowledge of practitioners and developing theories from it." As a result, the research strategy adopted for this research study is guided by the framework proposed by Eisenhardt (1989). The objective of this research to (1) understand the reasons for the complete failure of the PPARS project and (2) to establish the extent to which these reasons are specific to the health sector or the public sector was operationalised under three research questions as follows:

Research Question 1: Understanding Preparedness and Awareness

For this research question, we defined preparedness as the actions taken by the organisation towards ensuring the smooth execution of the ERP project. Furthermore, we defined awareness as the level of understanding in the organisation, at the beginning of the project, of what an ERP implementation involves as shaped by knowledgeable internal human resources and the discourse of external experts.

A number of researchers (Chen, 2001; Gargeya & Brady, 2005; Kim, Lee, & Gosain, 2005; Markus, Axline, Petrie, & Tanis, 2000; Shehab, Sharp, Supramaniam, & Spedding, 2004; Siriginidi, 2000; Teltumbde, 2000) have commented on the importance of preparedness for embarking on an enterprise-wide ERP project. These researchers propose a number of factors that should be considered prior to implementing an ERP package. In rating organisations for these two criteria, we predefined *Principles of Preparedness*, which we extracted from a review of the existing literature (see Table 1).

Research Question 2: The Nature of Problems during Project Execution

The focus of this question was squarely on understanding and recording what actually went wrong, in the words of the participants, as the project unfolded. Given the reliance on the case study method, and the use of multiple perspectives in collecting data about our cases, we were able to obtain very accurate, confirmed facts about what happened during the projects. Although the process of uncovering the problems that occurred in our case studies was largely emergent, it appeared that standard categories of problems could be found that could be used in general and proved useful in helping us draw comparisons between the cases. The areas we used were: Planning, Fit to Organisation, Staffing, and Change Management.

Research Question 3: Benchmarking the HSE Case against a Private Sector Organisation

This question involved drawing a systematic comparison between the case of the HSE and the case of a private sector organisation having gone through a similar project, in a similar time frame and in a contemporary fashion. This required a replication of the protocol followed for the case of the HSE (under research questions 1 and 2 above) and trying to establish whether the events reported by informants and the problems encountered could lead us to specific conclusions with regard to the specificities of the HSE case vs. the similarity with the project in the private organisation. Whilst this is not an absolute method for comparing the health sector to other sectors, it allowed us to verify that, in fact, the stories told in both cases are much more similar then dissimilar, as the findings sections indicate.

We applied the first two research questions to the PPARS project, which was the *intrinsic* case

Table 2. Initial perceptions of cases selected for the research study

Characteristic	BGT	HSE
Sector	Private	Public
ERP Package	JDE World	SAP R/3
ERP Footprint	Core Operations (Supply Chain Manufacturing and Finance)	HR / Payroll
ERP System Type	Value Chain Operations	Support Operations
Project Type	IT	IT
Enterprise-Wide View	No	No
Project Initiation	1996	1997
Project Outcome	Near Failure	Failure (project suspended)
Point-of-Contact Comment	"I could tell you all the things not to do. We have not done well with our implementation"	"This project is not going well. It will face huge issues in use the way it is being rolled-out nationally"[3]

Table 3. Breakdown of interviews by case

Organisation	Interviewee	Duration of Study
HSE	National Assistant Director of the PPARS Project Agency Implementation Manager HSE Area Payroll Manager HSE Area Applications Manager HSE Area Change Manager HSE Area * Implementation Manager HSE Area * IT Project Manager HSE Area Business Analyst National Project Team *	2 years
BGT	Former Vice President of IS * Vice President of IS Software Development Director IS Project Manager Director of Finance Global Director of Supply Chain Management * Global Director of Supply Chain Management General Manager of BGT site Corporate Selection Team Member	1 ½ years

study we had elected to carry out (in the words of Stake, 2000). We also looked for a second organisation in the private sector for the purpose of comparison. In the context of this study, for an organisation to be considered suitable for selection, it had to have undertaken an enterprise-wide ERP project, and at the time of first contact with the organisation, be in the post-implementation phase for all or part of the project, depending on the implementation approach followed by the organisation. This somewhat *opportunistic* (Patton, 1990) approach to purposeful sampling led to the selection of Banta Global Turnkey (BGT) due to its similarities with the PPARS project in terms of duration, problems encountered and outcome (see Table 2).

The principal method of data collection we relied upon was the interview of key participants in both organisations. Table 3 presents a breakdown of the personnel interviewed within the two organisations and identifies their positions of responsibility within their respective organisations. Furthermore, the personnel interviewed were most of the remaining key decision-makers and most knowledgeable persons, in relation to the decisions made at the outset of the enterprise-

Table 4. Documentation reviewed within each case

Organisation	Documentation Reviewed
HSE	PPARS Project Web Site (www.ppars.ie) Hay Report (*Quality Assurance Review of PPARS,* 2002) Irish Medical Times Report (www.imt.ie) (various reports throughout 2005 and 2006) Annual Report (2005) Various HSE Web Sites (Web Sites of the HSE Areas) Various National Newspapers Television Programmes (Prime Time, RTE News Reports) Oireachtas Reports (www.oireachtas.ie) Masters Dissertation completed by the Implementation Manager at the Western Area HSE Comptroller and Auditor General Report on Value for Money Examination (Development of HRM system for the Health Service – PPARS) (2005)
BGT	Enterprise Ireland E-Business Report (BGT) Annual Report (2003-2005) BGT Web Site (www.bgt.com) Masters Dissertation completed by the VP for IS at Banta

wide ERP project.

To further allow for triangulation of the opinions expressed and facts reported to us by our informants, we also made extensive use of written and published documents whenever this was useful and possible. For each case, the documentation provided specific details to corroborate, and in some instances clarify, factual evidence collected through interviews. Table 4 presents a list of the documentation collected and examined for each organisation.

The PPARS and BGT Cases

This section presents a case narrative for the Irish Health Service PPARS and BGT ERP projects. These constructed case narratives afford the researcher an opportunity to understand the uniqueness of the approach that each organisation adopted in undertaking the enterprise-wide ERP project within their specific organisational context. This helps to explain that, although the two organisations pursued their project for a variety of different reasons, their experiences in arriving at the outcomes from the project initiative, based on their levels of awareness and preparedness, are somewhat similar.

The PPARS (Personnel, Payroll, and Related Systems) Narrative

In 1997, 6 years before the Health Service reform programme was formalised, five Health Boards (ERHA - Eastern Regional Health Authority, Midlands Health Board, Mid-Western Health Board, North-Eastern Health Board, North-Western Health Board), but not all of them nationally, along with Saint James Hospital were interested in a replacement HR/Payroll solution. At that time, HR systems were extremely primitive and largely paper-based throughout the Irish health sector and, in whatever electronic mode they existed, they would have been rather simplistic and certainly stand-alone. Payroll solutions would have been more sophisticated but would not have necessarily been able to provide the DOH&C with the whole array of information that was required. In fact, even the total number of personnel employed by the Health Service nationally, employee absenteeism rates, and cost efficiency of services by area, and so forth, were not available. Furthermore, existing systems were no longer appropriate to support the delivery of a world-class Health Service, where limited interfaces existed between Payroll, Personnel, and

Finance functions resulting in large volumes of paper transactions. As a result, the PPARS project was established when the five Health Agencies and Saint James Hospital secured funding in the mid-1990s. This heralded what is referred to as Phase 1 of the PPARS project.

The ERP software selection process undertaken by the Irish Health Services in 1996 as part of the PPARS project is somewhat of an unknown. While a procurement process was conducted, the transparency of this process has indeed been called into question. In fact, on suspension of the PPARS project in 2005, government investigations commenced into the procurement process followed, from which SAP was selected as the package to meet the requirements of the Irish Health Services. It is difficult to establish whether the decision to select SAP was made following a review of a number of shortlisted competing ERP packages. However, it has been suggested that alternatives to a single, integrated, standardised, national system of the nature of SAP were never fully considered at the outset of the project. In any case, the selection of the SAP package can be seen as an extreme choice for the original project goals, given the extreme complexity of this ERP application. The lack of information makes it difficult to reach definitive conclusions, but some informants speculated that the Health Services software selection process had been a politically motivated decision making process, which would make it characteristic of a *mindless* approach (Swanson & Ramiller, 2004).

Thus, in 1997, the five Health Boards and Saint James Hospital commenced PPARS Phase 1, with the implementation of a revised Organisational Structure (Organisation Management module) and Personnel Administration (gathering of core personnel data: Personnel Administration module). Furthermore, as part of Phase 1, the SAP Basic Pay module and a number of HR modules such as qualifications, and training/events management were also implemented. As a result of the Phase 1 deployment, some of the Health Boards involved also implemented interfaces to their existing payroll systems as they continued to use their existing payroll systems.

Following the Western Health Board "going live" with Phase 1 in July 2001, the DOH&C decided to do a "stock-take" of the PPARS project. They hired Hay Management Consultants to do a Quality Assurance Review of PPARS, including a brief fact finding review of the benefits that had been realised from Phase 1 and those expected from Phase 2, an identification of the key issues and concerns regarding the project to-date and expected in Phase 2, and general experiences to-date in PPARS (Phase 1) from the point of view of a National Health Service project across all participating Health Service entities. In January of 2002, the Consultants made a number of recommendations towards ensuring that the project delivered "value-for-money" in the national context. As a result, Phase 2 of the PPARS project kicked-off (2002), and the DOH&C sanctioned the additional funding to continue and complete the PPARS project accordingly. The deployment of the SAP functionality within the PPARS project remained on a phased basis (Phase 1 and Phase 2) for the original sites and became an amalgamation of Phase 1 and 2 for the remaining Health Boards joining the project in mid-stream (see Table 5). Deloitte Consulting was chosen as the implementation partner for Phase 2 of PPARS.

Phase 2 commenced with the development of an agreed blueprint for the relevant business processes in each Health Board. All of the Health Boards were included and, as a result, PPARS became a two-speed project, with six sites engaged in Phase 2 and the rest playing catch-up.

The PPARS SAP HR/Payroll ERP project was never completed on a national scale and the "post-implementation phase" was not reached by the time the project was terminated. The PPARS project is estimated to have cost the Irish state anything between €150 and €500 million, where original estimates of costs were set at €8.8 million. Furthermore, the project was due to have a

3 year implementation schedule, but 8 years later, it was still not fully implemented. Saint James Hospital was the first Irish Health Service entity to "go-live" in November of 2003. The North-Western Health Board went live in July of 2004; the Midlands Health Board went live in September of 2004; the Mid-Western Health Board went live in November of 2004; while the Western Health Board, North-Eastern Health Board, Eastern Regional Heath Authority, South-Eastern Health Board, and Southern Health Board, who were due to "go-live" in 2005, were never completed. The reasons behind the suspension of the project are highlighted in Research Question 2.

The BGT Narrative

The Banta Global Turnkey (BGT) Group is a $400 mllion division of Banta Corporation, founded in 1995 following the takeover of an Irish company called BG Turnkey Services. BGT serves as a global outsourcing partner to leading companies in the technology, pharmaceutical and medical device sectors and has established a network of global manufacturing and distribution facilities located in key markets of the Americas, Europe, the Middle East, and Asia, having 11 sites in total worldwide, and employing 2,200 staff. In 1995, at the time of the takeover, BG Turnkey had 5 European sites and 1 North American operation. Banta Corporation also had a few Turnkey sites (three in North America) conducting similar business to BG Turnkey. At that stage, Banta Corporation did not have JD Edwards, but a small ERP system called Acuman (provided by a Dublin-based software firm) was operational in BG Turnkey.

Initially, the nine Turnkey sites merged into one group and then, Banta Corporation, in the U.S., decided to leave the European operation function on its own. So while the European sites were still referred to as Turnkey, they essentially had a separate management group and had very little involvement with the North American Turnkey sites. As a result, there was effectively a two-group structure: a North American group and European Turnkey group. However, when they commenced the ERP package evaluation process in 1996, in an effort to select an ERP system for the Turnkey business, the two groups proceeded together. The joint project was led from the U.S. and a steering committee was formed, consisting predominately of managers from the U.S. and members of a small U.S.-based consultancy group. Following a series of site visits a full set of requirements for BGT were established and documented.

A large number of prospective ERP vendors were selected and a mix of business and IT personnel were involved in a "show-and-tell."[4] The business and IT personnel developed a series of scripts, which were provided to vendors so that they could demonstrate that the product did what BGT wanted it to do. This led to a short-list of vendors, namely: Oracle, SAP, and JD Edwards. SAP was never a real contender as it was perceived

Table 5. Outline and project phase detail

Phase	Focus of Phase
Phase 1	• Personnel Administration (PA) • Organisation Management (OM) • Personnel Development (PD) (qualifications) • Training and Events (T&E) • Absence Recording
Phase 2	• Time Management (TM) • Payroll (PY) • Compensation Management (CM) • Mass Pay Increases only • Enhancements to existing modules through further integration

as far too complex for BGT. Furthermore, Oracle, although short-listed, did not seem to be able to demonstrate the capability that BGT needed in support of the business. As a result of this attrition, the JD Edwards World ERP package was selected. Despite having spent a considerable portion of their budget (about half a million dollars) on the selection process, BGT decided not to go ahead with the implementation of the JD Edwards World package, because they simply could not cost justify the investment at that time. However, in 1997 the Year 2000 (Y2K) problem was becoming an issue for both groups. The European operation had a Y2K problem with their Acuman system, but the vendor had a ready made Y2K upgrade. However, the U.S. operation discovered that their systems were not Y2K compliant and decided to proceed with the implementation of JD Edwards.

In 1998, the U.S. sites rolled-out JD Edwards World and the European group upgraded their Acuman system. The scope of the ERP project was to cover the financial requirements and the Supply Chain Manufacturing requirements in the SCM part of the business across the entire US operation. Then, in May of 1999, BGT won a large contract with Compaq, and it was decided to reform a single Global Turnkey group worldwide and implement a global ERP system. Thus, on the back of winning that contract, it was decided to implement JD Edwards World in Europe by rolling it out in a number of the European sites (e.g., Cork in late 1999) and a number of "green-field" sites (e.g., Singapore in early 2000—specifically setup for the Compaq business).

Faced with a heightened level of frustration regarding their experiences and struggles with the JD Edwards World ERP package, mostly due to the reactive approach adopted to roll-out within the European operation, BGT took a decision in 2003 to finish out all of the European sites properly. An additional $5 million expenditure was allocated. As part of this, BGT decided to roll-out the ERP in Scotland in 2004. However, BGT won business in Scotland, at the start of 2004, and had to roll it out in 10 weeks, in a similar approach to the previous rollouts in the other European sites. Thus, BGT found themselves in a situation where the Scottish site was being finished up, Cork and Holland, respectively, had to be finished, and Limerick would be completed in 2005. In fact, even as of late 2005, not all of the sites in the BGT group had JD Edwards fully implemented as *the* ERP system, for example, the Cork site still had a combination of Acuman and JD Edwards World supporting their operations and in 2006 the Limerick site still did not have the JD Edwards World system in place.

The true accumulated cost of selecting, implementing, supporting and modifying JD Edwards over 10 year period covered by the project is unknown. The ERP project had not been completed on a global scale at the time of this research and, as a result, BGT had not reached a post-implementation phase with its ERP. In this 10 year period, BGT has also undertaken a number of other project initiatives. For example, in 2001, a number of Business Process Improvement (BPI) initiatives were undertaken in the areas of Finance and SCM within BGT. These BPI initiatives focused explicitly on the business and adding value through standardising internal business processes and tightening integration with customers and suppliers, in an effort to drive out costs by removing surplus activities across the entire BGT global organisation. Therefore, these initiatives have directly impacted on the JD Edwards system at the site level, where the focus and objective has been to address the need for a global organisational architecture and business process infrastructure, that is, to rectify the disastrous experiences of BGT due to the absence of a coherent approach to implementation from the outset of the JD Edwards World ERP project as evidenced by the analysis presented in the next section.

ANALYSIS AND DISCUSSION

Prima facie, it is interesting to note that despite the very different situations and organisational contexts of the two organisations studied, the narratives presented feature very striking similarities in terms of the extensive project timeframe nearing 10 years in total and the failure to complete the project in a strict sense, despite some results being achieved. The following sections analyse these similarities in greater detail.

Research Question 1: Analysing the Preparedness of the Organisations

The goal of research question 1 was to use the principles of preparedness which we had extracted from current literature on ERP to judge the extent to which the organisations we studied had the requisite level of awareness when they undertook their ERP project and whether they then took requisite actions in order to attain a level of understanding and direction that would serve them well toward successfully implementing their new applications. Table 6 shows how the HSE rates against the principles of preparedness. It indicates that the PPARS project began its life firmly understood as an IT project, with virtually no support from key business areas. This lack of high prioritisation was combined with a very weak understanding of just what an ERP project involved in terms of impact on the organisation and required change to business practices. Against this backdrop, the project lacked focus and specific business goals from the beginning and, even when there were simple objectives that could be pursued, such as the integration of payroll systems nationally, the pre-requisite steps of practice harmonisation and process standardisation were never even attempted. This sealed the fate of the project in that, 10 years later, newspapers reported satisfyingly that the HSE was still not able to tell how many staff they had and how much they were being paid.[5] Faced with this reality, the Irish government was pushed into a knee-jerk reaction and terminated the PPARS project.

In parallel, the organisation of the project was poor and never achieved the requisite level of professionalism and leadership. This was highlighted several times during the life time of the project (notably by consultants' reports) but was never addressed. A failure to allocate knowledgeable staff to the project, a chronic lack of training, and excessive turnover of participants all conspired to ensure that the key problems in the deployment of the ERP application were never adequately communicated to the national directorate of the project and therefore never tackled at the appropriate level.

By contrast, Table 7 shows how BGT rates against the principles of preparedness. The BGT case is characterised by the observation that although the enterprise-wide ERP project commenced in 1995, over a decade later the project had not reached completion. Fundamentally, this was due to the failure to articulate a global business need for the project and to poor management of the project throughout its life-cycle. The implementation of an enterprise-wide ERP system could not be cost-justified in BGT in 1996, due to the lack of a real strategic need for the project, and so it was undertaken as an IT project, in the context of Y2K compliance in the U.S. operation. This compliance objective was indeed met but key elements, such as an enterprise-wide organisational architecture, a global process infrastructure, and embracing a standardised BGT group-way of doing things, did not exist. As a result, no real long-term business value-added was realised from the project and the overall outcome of the project has been judged to be less than successful within BGT. In particular, there was a chronic failure to realise that the nature of the activity was changing and that the days of the one site one customer organisation were numbered.

Going forward, BGT needed to be able to serve all customers from many sites and this required an integrated ERP which could not be delivered out of the mosaic of ERP instances running in the different sites, especially in Europe. Thus, standardisation was neither pursued nor achieved until the project was relaunched in the shape of the BPIs. There were also latent causes of failures in terms of the management of the project, which lacked direction and never focused on acquiring the best resources for the project on a full-time basis from any of the key functional areas. Training was also largely ignored, which, coupled with the lack of serious support for the user population post go-live, led to much frustration and dissatisfaction with the application in-use.

Research question 1 leads us to conclude that some organisations (either public or private sector) are ill-prepared for ERP projects and that they compound their lack of awareness with poor project management which sets the scene for largely negative outcomes being reported for their ERP projects.

Both cases show the failure to provide clear directions for the project at the start by not stating objectives clearly, making the project a number one priority, and allocating the best staff in the key positions to the project team. They also show the failure to comprehend the difficulty of what is being undertaken and the lack of vision in terms of forecasting where problems will arise or even monitoring when and where they do arise. Specifically, in the HSE, the lack of leadership and political will to drive required changes in local practices and pre-empt the implementation of the ERP application with a specific programme of harmonisation of procedures and reduction of local idiosyncrasies led to the project unfolding without any realistic hope of achieving its primary aims, a fact which was known to many actors well before the project was terminated. Thus, it was hoped that, somehow, the technical solution (the piece of software) could solve all the problems of visibility in this complex organisation without having to go through the pains of reforming *the beast* through a comprehensive change management programme.

Research Question 2: Categorising the Problems Encountered

Research question 2 was about scanning the case data to report in a great detail, the consequences of the lack of preparedness in terms of what problems actually arose in the organisations we studied. As already discussed, we used standard categories for reporting problems in both cases, namely: Planning, Fit to Organisation, Staffing, and Change Management, which greatly facilitated the comparison between the two organisations. An interesting follow up from the presentation of the problems involved trying to understand whether the organisations had been able to identify that they were faced with these problems early enough so that they could find ways to cope with them. It is interesting to see that in both cases, the key problems, that is, the lack of a standard approach, was identified, but managers failed to address the problems that arose from this initial failure until later in the project lifecycle. In the case of the HSE, it was actually simply too late to rescue PPARS and turn public perception around.

Table 8 presents the problems faced by the HSE in their PPARS project. In the Health Service, the real drivers of the project are unknown, although its origins did address the replacement of various agency-specific HR/Payroll solutions. However, the vision and primary goal of the PPARS project was never clearly articulated, communicated, understood, and agreed nationally. Where the primary goal of PPARS may have been to transform HRM in the Health Service, it was simply perceived as the computerisation of employee records and the replacement of existing Payroll systems. Furthermore, at the outset, involvement in the PPARS project was not compulsory across the Health Service, while those entities involved were given total autonomy in how they approached the project. Therefore, no real strategic business need existed for the project and the Health Service failed to identify and prioritise the crucial business processes that needed to be represented on the ERP system.

Thus, it was a defining characteristic of the Health Service case that:

1. The vision and primary goal of the project (which was a business transformation project) was never clearly articulated, communicated, understood, and agreed nationally. Where the primary goal of PPARS may have been to transform HRM in the Health Service, it was simply seen as the computerisation of employee records and the replacement of existing payroll systems.
2. There was very little executive sponsorship and organisational buy-in to PPARS throughout the Health Service.
3. The allocation of key business personnel onto the project (best resources and full-time participation) was not a feature of the PPARS project on a national level. While some areas had representative groups on the project, some areas had little or no representation on the project.
4. No project governance existed for the lifetime of the PPARS project. The PPARS project was characterised by the fact that there were no clearly defined lines of authority, responsibility, and accountability.
5. Preparations around the governance of the project were lacking. In fact, in 2002 the Hay Management Group recommended that the issue of governance be addressed if the project was to continue. However, the commencement of Phase 2 of the project did not bring a re-examination of the approach to the project from that of Phase 1. Furthermore, a change in scope from Phase 1 to Phase 2 did not sufficiently highlight the needs that were being addressed over-and-above those of Phase 1, and it appeared as if Phase 2 of the project was not given adequate consideration and planning. As a result of this lack of preparation, considerable cost and time overruns characterised the PPARS project.

Table 9 presents the problems identified within BGT in relation to their ERP project. Traditionally, BGT would have rolled out the JD Edwards World ERP system very quickly across sites, on the back of winning business and in support of the customer service model requirements, but without an appreciation of the possibilities to standardise the internal business processes. As a result of this approach, BGT would then have to return to those same sites (post-implementation) to rectify the problems inherent in their initial approach. In fact, the former Vice President of IS commented that if it was not for the fact that BGT embraced other initiatives that were being undertaken (Finance and SCM BPI),

BGT would have to report an ERP disaster. However, as the BGT organisation has proceeded with implementations, they have got better and have become more familiar with the JD Edwards World package. BPI is the key to getting value out of our ERP.

The BPI initiatives focused on what existed within BGT in terms of the JD Edwards World infrastructure, introduced proper training for personnel, automated processes, standardised processes to provide a global process infrastructure, and coded data in a standardised way in order to facilitate global reporting. These BPI projects were not IT projects (unlike the initial JD Edwards project) and they were understood to be business projects that were IT-enabled. According to the former Vice President of IS "what we are doing in the BPI projects will give us more benefits that we will ever get out of upgrading or buying a new piece of IT to be honest."

A serious issue around the introduction of the JD Edwards World ERP system within BGT was the approach taken to project management. In fact, no formalised approach to managing the project existed or was adopted across the BGT sites. It was reported that as a result of the lessons learned in their approach to introducing the JD Edwards World system, BGT then adopted a more formal approach to undertaking and managing a project. In fact, this formal approach to managing a project, focusing on the importance of: documentation, project objective, project scope, project personnel, and project time-frame, was developed as a result of the lack of preparations in these areas at the outset of the initial JD Edwards World ERP project.

The observations presented here prove that the same organisation (BGT in this case) can become very successful with regard to the implementation of an enterprise-wide ERP solution if they have a greater level of understanding (awareness) as to the true nature of what is required in an enterprise-wide ERP project. As a result, the organisation can leverage this increased awareness to ensure that the required preparations are made to undertake the implementation. This is characteristic of the organisation appreciating the concept of being *mindful* (Swanson & Ramiller, 2004) with regard to their implementation approach and the desired outcomes to be achieved.

It was a defining characteristic of the BGT case that over the last decade the organisation has learned the hard way with regard to the undertaking of an enterprise-wide ERP project, and according to the former Global Director of SCM,

BGT still has not implemented those lessons. It was not until 2000 that BGT started to become global and think globally. So when you put that on a timeline vs. when we implemented ERP (selection commenced in 1996), it presents an interesting gap.

In fact, it was immaterial to BGT which enterprise-wide ERP product they selected and implemented, due to the fact that it was the approach to implementation and the organisational mindset that was the cause of their problems throughout. In the end, improving the JD Edwards World system through dedicating additional resources and management bandwidth was the best option available to BGT to add organisational value.

Overall, based on the analysis conducted in this case, it was a defining characteristic of the BGT experience that:

1. There was a need for an organisational architecture and a global process infrastructure which would have been supported by the ERP system. In fact, a series of BPI initiatives facilitated retrofitting the ERP system to the global business processes, once these processes were designed.
2. Efforts to promote education and training amongst the business personnel improved the businesses appreciation of the system in-use, in support of their functional areas.
3. Processes needed to be put in place to attract highly skilled resources in an effort to establish and maintain support structures for the ERP system in-use, therefore freeing up more valuable resources to undertake value-added activities as opposed to support roles.
4. The importance of allocating adequate numbers of skilled and knowledgeable resources full-time to a project and ensuring that the project is viewed as a “priority one” initiative are paramount to its success.
5. Ensuring that a well defined set of business requirements are communicated and understood by the business at the outset, where the business does not simply undertake a “wish-list” exercise, is another critical aspect.

Research Question 3: Comparing the Cases

Both BGT and the Health Services share a number of common characteristics in terms of their experiences with their enterprise-wide ERP project initiatives. Based on the analysis conducted, both organisations found themselves undertaking an

IT initiative from the outset, where the required level of business support was not a feature of the project. Therefore, the priority of the project was not at a high enough level within the business community. Furthermore, the project lacked a set of clear and consistent (universally understood) strategic business objectives and the criticality of adoption was not communicated from the top level.

Based on the analysis conducted within the two cases studied, evidence supports the fact that a lack of a real business objective at the outset of the project left BGT and the Health Services in a situation where the outcome of the project was less than successful in terms of delivering the required system functionality. Therefore, the existence of an actual strategic business need and the ability to prioritize critical business process areas, based on this need, is critical to ensuring that a project will produce the desired successful outcome in terms of business value and categorised functionality. In fact, an awareness of the importance of this strategic business need is required in order to guide managerial preparations in setting realistic goals and objectives for the enterprise-wide ERP project. Furthermore, the existence of this strategic business need will also ensure that top management commitment and support will be a feature of the enterprise-wide ERP project.

Both BGT and the Health Services implemented the ERP package on a site by site basis, embracing "as-is" site specific business process. This approach was as a direct result of their lack of preparation at the outset with regard to Business Process Re-Engineering (BPR), where very little attempt was made to analyse existing business processes in an effort to prioritise requirements and introduce process improvements wherever possible across the entire organisation. This prioritisation of requirements and business process improvement was something that the Health Services never achieved and BGT began to introduce through a number of separate Business Process Improvement (BPI) initiatives a number of years after the initiation of their ERP project. Evidence relating to this issue highlighted the fact that neither BGT nor the Health Services thought as one single organisational entity and as a result there was a lack of an enterprise-wide business process infrastructure in existence at the outset of the project.

It is a fact that this lack of an enterprise-wide process infrastructure makes it impossible to introduce a standardisation of processes throughout an organisation, as the organisational mindset of a *company way of doing things*, is not defined. As an example, the autonomy of the Health Boards within the Health Services and in some instances their exclusion from Phase 1 of the PPARS project further compounded the impact of implementing site specific "as-is" business processes. Therefore, when a national roll-out became a reality in Phase 2 of the PPARS project, the volume of localised idiosyncrasies represented on the ERP system increased. Indeed, it was such an issue that finally led to the suspension of the PPARS project in 2005.

Based on the analysis conducted within the cases studied, evidence supports the fact that there was a lack of a coherent implementation methodology, emphasising clear and consistent project scope focusing on critical aspects of the business, appropriate documentation of requirements to be addressed, and clearly defined lines of authority, responsibility, and accountability, from the outset of their projects. As a result, this left BGT and the Health Services in a situation where the outcome of the project was less than successful in terms of being delivered on time and within budget. In fact, an awareness of the importance of project management is required in order to guide managerial actions to deliver the project in a realistic time-frame and within the budget set for the enterprise-wide ERP project.

In both BGT and the Health Services, the active involvement of business personnel on the project was a cause of serious problem. It was a feature of both organisations that personnel were not seconded onto the project team full-time and as a result their commitment to the project was reduced as they were also performing their daily roles within the organisation. Furthermore, no real formal team structure was put in place and the roles and responsibilities of project team members were poorly defined, leading to a lack of ownership for the project by team members. As a result, this lack of ownership led to a less than successful project outcome. However, a failure to allocate sufficient business resources to the enterprise-wide ERP project, in both these cases, also compounded the impact of the problem of standardisation, in that the business personnel were not adequately skilled to perform their roles on the project team, in terms of understanding the business and driving change to introduce standardisations at a national level. Therefore, it is obvious that a lack of preparedness for such an issue as standardising to an enterprise-wide business process infrastructure from the outset, led to an extended project timeframe, with an associated escalation in costs, and a poor *fit* between the software and the business, in both BGT and the Health Services. Within BGT and the Health Services, the rationale for adopting their initial approach to the implementation of the ERP package hinged on the organisational structure and the mindset of those involved in the project at the time of initiation. Therefore, these organisations demonstrated a lack of appreciation of what an enterprise-wide view of the organisation entails, for example in terms of business process infrastructure, where very little attention was attributed to standardising processes to drive out efficiencies in the business. Therefore, the principles of preparedness for ERP implementations were not fully understood within these two cases.

CONCLUSION

Although the Irish public have been treated to a lot of horror stories associated with PPARS, for example, an HSE employee receiving a €1 million pay cheque in error in 2004; Saint James Hospital experiencing a weakened payroll process and a threat to basic functioning due to PPARS; threatened public protests about the operation of PPARS by HSE employees; certain stakeholders not "buying-in" to the system, and so forth, it has been argued by those interviewed throughout this research project that a lot of positive changes have been introduced into the Irish Health Service as a result of PPARS. In fact, the National Assistant Director of the PPARS Project commented in 2004 that *the DOH&C have also, in the past three years, adopted a single solution policy for Finance and Hospital Information Systems, so literally PPARS is a ground breaking project, where the financial solution (FISP) and the Hospital Information Systems will follow along on much the same sort of values, characteristics, and so forth, with the ability, ultimately, to consolidate all of that information into a business warehouse and take out particular performance measures.*

Based on this assessment, it is truly difficult to establish whether there was merit in the PPARS project. On balance, PPARS is a story of ERP implementation failure. Despite some benefits being achieved, the weight of compelling reasons *why* PPARS failed is overwhelming for an external observer, although it is clear from talking to the participants that few were aware, until recently, of the true extent of the problems. Ultimately, the project was badly managed, badly resourced, badly presented to organisational personnel, and badly supported by top management. However, as evidenced by the following concluding statements, many of these problems have their roots in the fundamental misconception about what the integration of a national HRM system would entail for the Irish Health Services.

As a result, it can be argued that organisations experience problematic similarities with regard to their enterprise-wide ERP project implementations. However, organisations address these mistakes made and lessons learned in a variety of different ways, relative to their specific case, which invariably impacts on resources (both human and budgetary), the scope and timeframe of the project, the actual outcome of the project, and the business value-added of the implemented system. To summarise, and based on the analysis conducted in this article, it is certain that a problem in the execution phase of an enterprise-wide ERP project is caused by a lack of focus on one or many of the *principles of preparedness* at the early stages of the project. Therefore, implementation problems in an ERP project, experienced at later stages, originated earlier in the project life-cycle. As a result, attentions have to be focused on the early identification and correction of problems. Based on the analysis conducted and presented in this article, the argument can be made that a *mindful* (Swanson & Ramiller, 2004) approach to an enterprise-wide ERP project can in fact lead to fewer implementation problems.

ENDNOTES

[1] SAP has more than 25 industries solutions tailored to the following industry groups: Consumer products and life sciences; Discrete manufacturing; Financial services; Process manufacturing; Public sector; Retail and wholesale distribution; Service industries. www.sap.com

[2] At present, the Health Services Executive (HSE) is structured into four administrative

areas, namely, HSE West (covers the former Mid-Western, Western and North-Western); HSE South (covers the former Southern and South-Eastern); HSE Dublin Mid-Leinster (covers the former Midland, South-Western and East Coast); HSE Dublin North-East (covers the former North-Eastern and Northern).

[3] as stated in the introduction, the project has been put on hold indefinitely since this interview was conducted

[4] "show-and-tell" was an initiative undertaken by BGT to demonstrate ERP systems capabilities to business personnel. It was an effort to bridge the gap between business and systems knowledge.

[5] This was due to the fact that local sites, faced with drastic shortage of certain resources, for example, special consultants in certain disciplines, did not want to reveal the special pay conditions they had granted to some of their staff.

Chapter 4.12

Aurora Health Care:
A Knowledge Management Strategy Case Study

Thomas Ginter
Aurora BayCare Medical Center, USA

Jane Root
Aurora Medical Group, USA

ABSTRACT

Aurora Health Care, Wisconsin's largest employer and healthcare provider faces intense competition, consolidation, and reform. Its choice is to view these challenges as opportunities instead of problems. A key component to realizing Aurora's opportunities is an aggressive knowledge management system. They understand that to maximize their potential, they must get the most out of their knowledge management. The purpose of this chapter is to present to you a case study of knowledge management applications in the healthcare industry through the many lenses of Aurora Health Care. First we will describe the background of this accomplished healthcare provider. We will then look at their business and knowledge management strategies. Next will be a review of the major components: core competencies, knowledge base, culture, implementation, and key success indicators.

DOI: 10.4018/978-1-60566-348-7.ch010

INTRODUCTION

Successful healthcare providers will employ robust knowledge management systems that promote positive clinical outcomes, align clinical business aims, and enable effective assistance to the surrounding communities. This chapter will describe Aurora Health Care's knowledge management strategy. We will explain Aurora's history with a SWOT analysis completed by the authors. Then we will show the organization's business and knowledge management strategies. This is followed by communicating Aurora Health Care's knowledge management strategy and its major components: core competencies, base, culture, implementation, and key success indicators.

AURORA HEALTH CARE'S HISTORY

In 1984, Aurora Health Care, a not-for-profit Wisconsin integrated health care provider, was created

Table 1. SWOT Analysis of Aurora Health Care, prepared by Tom Ginter and Jane Root, May 2009.

Strengths	**Opportunities**
• Leadership • Financial Assets • Human Assets • Training • IT Infrastructure • Human Resources & Compensation • Centralized Decision Control	• Innovation • Access to Knowledge • Customer Service • Knowledge Reward System
Weaknesses	**Threats**
• Varied Business Unit Processes • System Interface • Knowledge Management Focus & Control • Best Practices	• Competition • Knowledge Loss • Poor Patient Outcomes

around one idea: there is a better way to provide health care. This concept has been a hallmark of the organization and central to its vision. Aurora Health Care believes there is a better way for:

- people to get the care they need in settings that are convenient and comfortable;
- families to receive the services and support they need to lead healthier lives;
- physicians to offer the latest technology and treatment options to their patients;
- talented people working in health care to fulfill their professional callings;
- employers to provide for the health care of their employees, more cost-effectively;
- building healthy communities.

Aurora simplifies the translation of this belief for its employees through a motto of their *#1 Priority*, “Our patients deserve the best care. When we achieve top performance in our clinical quality, patient satisfaction and caregiver engagement, patients receive a better care experience than they can get anywhere else,” (Aurora Health Care, 2009a).

Aurora Health Care serves a large geographic base with sites in more than 90 communities throughout eastern Wisconsin, including 13 hospitals, more than 100 clinics and over 130 community pharmacies. In excess of 3,400 physicians are affiliated with Aurora Health Care, including more than 700 who comprise Aurora Medical Group. The many strategic business units that form Aurora Health Care are dedicated to enhancing organizational knowledge. A portion of the Aurora Health Care mission statement is as follows: “We are committed to improving the quality of health care and health outcomes for people today, through the rapid and broad application of current knowledge,” (Aurora Health Care, 2009b).

AURORA KNOWLEDGE MANAGEMENT SWOT

An analysis of knowledge management strategy begins with a SWOT analysis to identify if Aurora Health Care is getting the most out of its knowledge management system. Table one represents a knowledge management SWOT analysis of Aurora Health Care.

Strength: Leadership

As identified in their mission statement, Aurora recognizes that organization knowledge is critical to improving the quality of healthcare and health outcomes. Leadership’s ability to manage know-how will help ensure effective performance. Examples of this begin at the top. Aurora has established several multidisciplinary councils to provide leadership and input on strategy, policy, clinical operations, and Care Management initiatives to Aurora Health Care senior leaders. In addition, the councils provide system-wide clinical leadership through collaboration with other senior leadership teams, along with identifying, sharing, and rapidly adopting best practices system-wide around quality, patient loyalty, employee engagement, and financial performance. These councils are the Physician Leadership Council, The Hospital Administrative Council, Aurora Nursing Leadership Council, and One Aurora Team.

To ensure future leaders have a base built upon best practices and value knowledge management, the organization established the Aurora Leadership Academy. This program aims to prepare Aurora's next generation of leaders from among current staff. During a 15-month period, the participants experience a series of leadership and skill-building opportunities. These activities are enhanced through a one-on-one relationship with an individually assigned mentor and through formal networking opportunities.

Strength: Financial Assets

Aurora's total net service revenue grew from $3.2 billion in 2007 to $3.5 billion in 2008. Revenue from inpatient services decreased 2.1% while revenue from outpatient hospital visits and visits to clinics rose 25.5%.

Strength: Human Assets

A good healthcare organization has a mix of highly mobile skilled, unskilled, and professional employees to perform care giving functions. Aurora Health Care is Wisconsin's largest employer. These employees have a strong corporate identity that operates in diverse business units. Leadership has defined a concept called "*Responsible Freedom*" for staff to maximize problem solving to enhance patient care and experience. Responsible freedom supports better ways to provide exceptional, patient centered experience. Each employee needs to know how to take independent action that benefits the customer and organization. Expectations for staff are to learn on a continual basis, be team players, respect diversity, and utilize cross-business unit, cross-cultural experience.

Strength: Training

Aurora Health Care as a whole is committed to continuous learning. The educational resources within the system are vast—and available to all employees. New hires are encouraged to create a "*Learning Plan*" with their immediate supervisor, which validates their scheduled class/educational event activities for the upcoming calendar year. All newly hired leadership positions (supervisor and higher) are required to attend the "Aurora Quest" program. This program is a series of sessions to expose new leaders in the organization to fundamentals as well as enhanced knowledge regarding leadership skills.

A learning culture has been established for staff to optimize best practice applications. The group responsible for this implementation is the Employee and Organizational Development (E&OD) department. The mission of E&OD is to be the collaborator with leaders and staff to identify and respond to training and development needs. This is accomplished by providing the following services:

- Leadership orientation and development programs
- Educational Assistance Program Administration
- In-service Recording Program Administration
- Title IV, U.S. Office of Education Student Financial Aid Program administration for Aurora schools
- Staff orientation and training programs with emphasis in the areas of:
    - Clinical patient care
    - Life Support Education

  - Office Professional Services
  - Service
  - Quality improvement
  - Diversity and cultural competence
- Internal consulting and executive coaching to leadership in the areas of:
  - Leadership and employee training
  - Service management
  - Workforce planning
  - Career development
  - Organization development, including:
    - Caregiver (Employee) Engagement
    - Team and partnership building and development
    - Change and conflict management

Strength: IT Infrastructure

Aurora seeks to lead in *the innovative use of IT in the health care market*. In support of this goal, Aurora Information Services works closely with the business groups to define and implement the Information Technology (IT) infrastructure component of Aurora's business strategy. In addition to the major IT projects, linked directly to the Aurora strategy, Information Services supports a large number of regional and departmental projects, and provides key infrastructure and operational support including: system operation and backup, the Aurora network, the help desk, user access and security, and desktop support. The Information Services website serves as a key source of information on many of these activities for both business and staff.

An overview of the electronic tools and technology used across Aurora:

- *Aurora iConnect:* the internal intranet that links all caregivers to information.
- *Employee Connection:* a link that allows individuals access to personalized information regarding compensation, benefits, emergency notification.
- *Learning Connection:* the link that monitors mandatory and elective education and training programs.
- *My Aurora:* the mechanism allowing electronic communication between patients and caregivers. This can be accessed both internally and externally.
- *Web Budgeting:* the electronic application that monitors budget trends and variances.
- *Web Management Reporting:* the electronic financial application with specific access parameters to information.
- *Brass Ring:* software application program that manages employment postings, applications and the applicant review process.
- *Cerner (Electronic Medical Record):* the patient medical record; includes numerous applications, security clearance levels and defined processes.
- *IREQ:* software application program that manages supply and services expense item purchases.
- *Authorization for expenditure (AFE):* software application program that manages capital item purchases.
- *Data Warehouse:* electronic application that collects different data sources through a repository.
- *Biorepository:* electronic application that processes the distribution of all biological products and related clinical information for clinical research and genetic knowledge enhancement.

Strength: Human Resources & Compensation

As with any successful business, Aurora relies on its mission, vision, and values to establish human resource and compensation philosophies. The philosophy supports hiring and retaining qualified and motivated employees to ensure appropriate patient care while managing human resources responsibly. Further elements involve accurate job descriptions, job analysis and evaluations, pay grades with established pay ranges, with individual incentive through performance measures based on merit. Individual workers receive pay incentive through a merit pay program conducted on an annual basis. Employees receive merit increases to their compensation when they meet or exceed job expectations. The annual performance through merit program will occur during scheduled performance evaluations that concentrate on employee general competency for organization, job specific standards, accomplishment on agreed upon goals, and skill competencies.

Strength: Centralized Decision Control

Aurora Health Care strives to mitigate varied business unit practices and ensure consistent best practices are uniformly used across the organization. Their motivation is to:

- Integrate care for patients.
- Standardize and support common practices that benefit patients.
- Constantly challenge one another to find better ways to achieve the highest quality and service for patients without competing with one another for patients and revenue.
- Work together to give people the care needed - when, where, and how patients want to access it.

Centralized decision control due to the enormity of Aurora's geographic span of services is sometimes hindered through centralized decision making. The time and energy to access decision authorities can mitigate how nimble decisions are made in local markets.

Weakness: Varied Business Unit Processes

With strategic business units spread over a large geographic base with sites in over 90 communities throughout eastern Wisconsin, including more than 28,000 employees and over 3,500 physicians, it is easy to appreciate the risk of varied business unit process. The organization works to mitigate mediocre know how by becoming *One Aurora*. This long-term strategy sets the vision to move from common practices partially applied to *Best Care Everywhere*. The vision and mission statements of the organization are well known to the general employee base. What is less known is the specific application for those statements to the everyday work environment. Application of best practices can at times be fragmented.

Weakness: System Interface

Within a large organization, it can be logistically challenging to make the necessary connections between departments and teams. It is essential to include representation from all appropriate entities that could impact any specific initiative. With a broad, comprehensive approach, there is less likely to be unintended consequences on effected departments. To maximize resources, it is important to align work and allow opportunity for various entities input to help support the strategies and initiatives.

Patients have provided feedback to Aurora Health Care that they want health care to be simple. Aurora has designed an integrated health delivery system work to make this possible. Offering a full range of care services, Aurora professionals include physicians, nurses, behavioral health therapists, pharmacists, social workers and other experts, working together to achieve the best outcomes for patients. The goal is to coordinate care across a broad spectrum of services and patient needs.

Weakness: Knowledge Management Focus & Control

The challenge of establishing knowledge management focus and control throughout a large healthcare provider in an industry that evolves daily is challenging. Knowledge management operations such as codification, knowledge oversight, selective encoding, and knowledge purging are typically problem prone.

Weakness: Best Practices

As with most complex organizations Aurora struggles with how to decide the benefit of exploiting known best practices or continuing the investment of further exploration and experimentation.

Opportunity: Innovation

Innovation is used to develop ideas, new opportunities and build the capacity to innovate within the Aurora organization. Aurora's strategic positioning as the premier innovator in the delivery of healthcare mandates that its staff have the capacity to innovate, develop new and better ways and recognize opportunities as they arise. Leadership understands that without new perspectives and a set of tools to help, idea generation can be difficult or even impossible. The innovation process uses a systematic approach that helps overturn beliefs that hinder, uses trends to identify emerging opportunities and evaluates and develops ideas into actionable opportunities.

Aurora Health Care has established innovation tools for idea generation by getting rid of old ideas and helping to get new ideas in play. The tools help employees remove barriers that hold them back when using traditional brainstorming techniques. A common approach and language for idea development help all understand what innovation is and how Aurora Health Care takes action based on a deep understanding of established strategy and goals. Decisions, once made, are implemented in a flawless manner. Aurora permits the use of creative tension and healthy debate to facilitate change. They know that the best ideas likely come from the organization's employees caring for customers every day. Innovation is ongoing and Aurora constantly measures and improves. To ensure a high level of performance, best practices are reviewed continuously. While patient needs change rapidly, the organization works to anticipate and change with them.

Opportunity: Access to Knowledge

Review of patient, financial and employee data is continuous. Leadership is expected to play an active role in this data review. The opportunity that exists involves the overwhelming amount of data required for collection, analysis, review, communication, and action.

Opportunity: Customer Service

Aurora Health Care has chosen and works toward a care model and philosophy that provides patient-centered care. This patient–centered concept comes in the form of individualized and personalized care developed from the patient's point of view and designed around what patients need to heal.

Opportunity: Knowledge Reward System

Front line staff has expressed the feeling of detachment from knowledge management reward measures. This connection is an opportunity for improvement.

Threat: Competition

Healthcare is very competitive, and the healthcare organization that does not value knowledge, risks loss of market share and efficient operations. Aurora Health Care has competition in each community it provides service.

Threat: Knowledge Loss

Failure to rapidly adapt "One Aurora" may lead to ineffectual encoding, fragmentation and ultimately mediocre know how. To mitigate this risk the organization works to effectively *on-board* new employees. This provides new staff with the necessary information, tools, and resources as they begin work with the organization. A good start for new employees is believed to make a big difference in how effective employees are on the job.

Threat: Poor Patient Outcomes

The healthcare industry is knowledge intense for several reasons. One reason is that the value associated with an individuals' health is of vital importance. It is therefore a tremendous expectation that those within the health industry do whatever necessary to positively contribute to maximizing healthcare delivery. In the focused review of the care management, the primary value is centered on patient outcomes. These patient-centered outcomes translate into the quality of care for the specific physician, entity and system. A subset of the patient condition outcome is patient loyalty. This *loyalty index* is another key component of the knowledge necessary for business success.

KNOWLEDGE MANAGEMENT STRATEGY

Next, the authors will describe in detail, the knowledge management strategy that is currently in place for Aurora Health Care. The strategy is focused on codification and internal development opportunities, along with an effective balance between exploitation and exploration (Russ et al., 2006).

Focus is Long Term

Aurora Health Care as a not-for-profit provider strives to maximize long-term societal benefits of activities and services. This requires a focus on disease prevention and treatment. They are Wisconsin's largest provider of charity care providing more than $25 million in community outreach and free preventive services. Their communities count on them and they feel the obligation to look ahead, preparing themselves, their programs and their facilities to meet the health care needs of tomorrow.

A Complex Knowledge Balancing Act

The identified challenges and responsibilities combine to make the delivery of health care services a complex and delicate balancing act. To address these challenges, the organization invests resources in developing knowledge through information systems that will put patient records at physicians' fingertips to help improve clinical outcomes. It means directing the energies of thousands of caregivers into finding and applying best practices to reduce the human and financial burden of illness. It also involves working with high schools and colleges to introduce and prepare young people for careers in health care. This action helps to alleviate personnel shortages that will cripple health delivery services in the decades ahead.

Addressing the challenges of today and tomorrow requires investing in clinical research and ensuring Aurora is on the forefront of applying new medical knowledge to the prevention and treatment of disease. Aurora Health Care also must enable the benefits from its economies of scale, and expanding services to provide people with the right care in the right place at the right time. It also calls for investing in the renovation and construction of facilities for tomorrow, even in the face of criticism that these investments contribute to today's health care cost burden.

Being a not-for-profit health care organization means Aurora Health Care must strive to balance what's in the long-term best interest of the people they serve, just as a doctor would for a patient.

Knowledge Codification

As stated, Aurora Health Care will only be satisfied when they give patients better access, better service, and better results than they can get anywhere else. They believe that working together, the people of Aurora will find a better way. This consistent approach reinforces and allows:

- Rapid adaptability
- Flexibility and efficient change
- Improved communications through common language

Aurora Health Care believes a consistent approach allows innovation, generates ideas to find better ways, overturns beliefs that hinder success, and uses trends to identify opportunities. Planning includes structured approaches and tools to design or establish processes. Data and IT tools are used to improve processes and reduce or eliminate waste. Control can also be used to detect and reduce or eliminate sporadic problems.

Internal Knowledge Development

Internal knowledge development is a key element toward the knowledge management strategy for Aurora Health Care. The organization has developed knowledge role definitions for leaders. They have created a structure for shared learning to drive improved results. This is accomplished by identifying subject champions; linking system teams to site teams to share results and lessons learned; establishing a team of experts as a problem solving resource; and developing and communicating feedback mechanisms on specific indicators.

They have also developed 60-day rapid action plans to improve outcomes, process, and efficiencies. Sites in the organization identify issues. A team is formed to review and provide feedback on the identified opportunities. Once the 60-day action plans are developed, the plans are made visible within the organization and system.

Balanced Knowledge Exploration/Exploitation

Aurora Health Care maintains a structured utilization/innovation scheme that applies focus on exploring new knowledge and exploiting knowledge that exists while codifying that knowledge. This knowledge is used to support new servicing of markets to achieve higher process and product effectiveness.

Next, the frameworks for connecting the business and KM strategies with the organization's core competencies and key success indicators (figure 1) will be described.

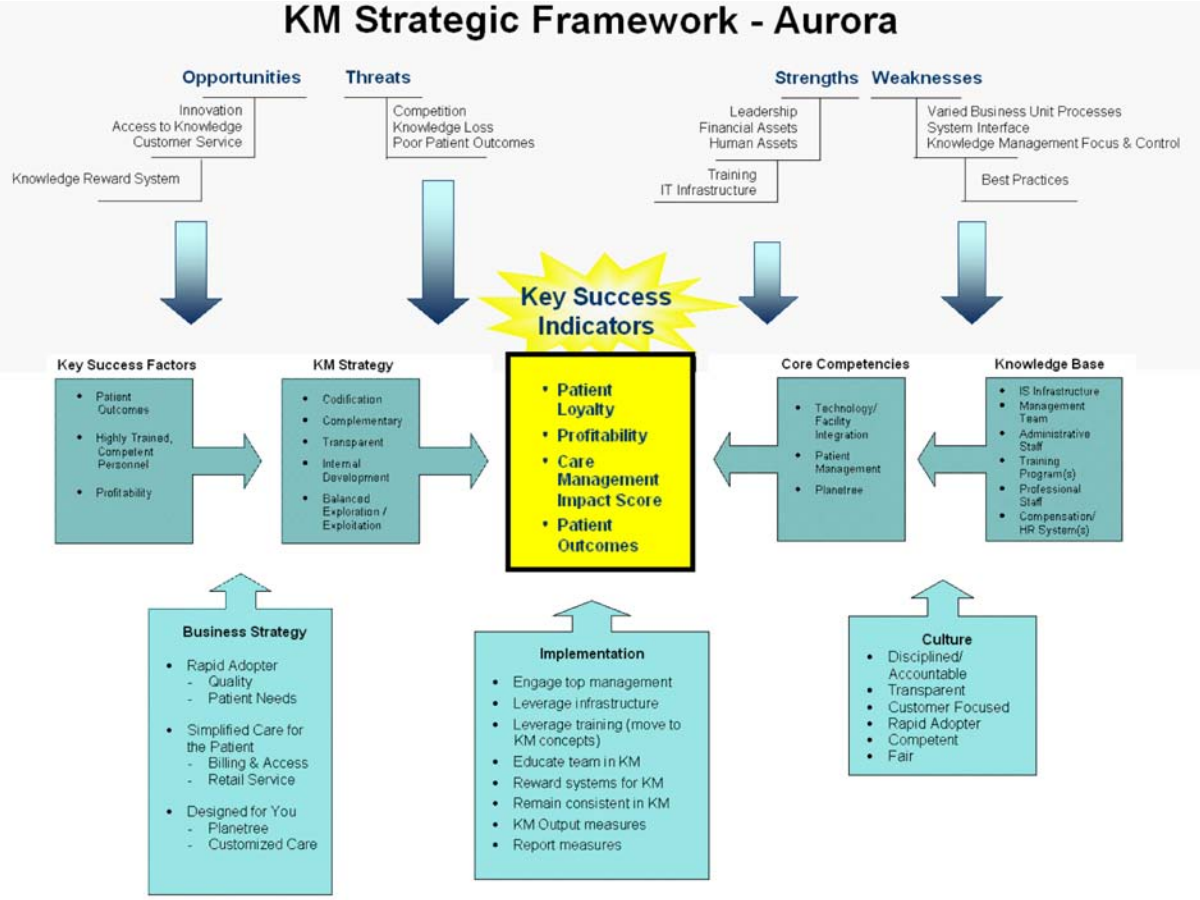
BUSINESS STRATEGY

The first building block described will be Aurora's business strategy.

Business Objectives Support Community Benefit

As a not-for-profit health care provider, Aurora has one overriding goal and that is to provide community benefit. They set a variety of business objectives to meet that goal. These objectives fall into two broad categories: finding better ways to work, and creating better value to offer patients, caregivers and communities. As they identify and achieve specific objectives in these areas, they succeed in generating the margin they need to fulfill the mission. At the same time, they keep moving closer to fulfilling the vision of providing people with better access, better service and better results than they can get anywhere else. They come full circle from mission to margin, and back again to

Figure 1. Aurora framework connection for business knowledge management (Source: by authors, prepared in May 2009, based on Russ et al., 2009).



the reason they exist, which is to improve the well being of the communities they serve.

Aurora Health Care's 2007 Strategic Plan defines their first key actions to successfully accomplish their strategy in the years to come:

- Advance Care Management
- Become One Aurora
- Develop a Patient Point of View
- Continue to Strengthen Aurora's Financial Performance

Three of these key actions have been mapped to their Long-term Strategy roadmap. Financial performance provides the foundation to achieve their Long-term Strategy. Strategic objectives come directly from Aurora Health Care's new Long-term Strategy:

- Simplified Care for the Patient
- Designed for the Customer
- Rapid Adopter

First Key Action: Advance Care Management – Integrate Care Management across care continuum and achieve their #1 Priority.

Measure top performance in quality – their #1 Priority – in the following ways:

- The Premier clinical performance measures, a database of the top performing hospitals in the country, provide Aurora Health Care with both quality and cost data for nine major diagnoses. Although a hospital-based measure, they will only be successful in achieving top quartile performance by utilizing the care continuum of their integrated delivery system and by everyone reducing costs.
- Aurora Health Care continues to track Care Management Impact Score. Similar to a school report card, each of their Care Management initiatives, their safety efforts, and their quality improvement efforts are scored as an "A", "B", "C", or "F" which, like a grade point average, earns points of 4, 3, 2, or 0.
- In addition to the #1 Priority measures, Aurora Health Care will provide a single accurate medication list to all Aurora care providers to improve patient safety and to simplify care for their patients.

Second Key Action: Become "One Aurora," with three areas of focus.

- Integrate clinical service lines across the system
- Simplify and design care for their patients
- Adopt clinical innovation into clinical practice

The first area of focus under becoming "One Aurora" is to integrate clinical service lines across the system. Currently Aurora Health Care's clinical service lines have been developed from a facility, market or regional perspective. At times, this has resulted in best practices being partially applied, fragmented care, confusion for patients, and differing prioritization or competition within the system.

The second area of focus under becoming "One Aurora" is to simplify and design care for patients. During the discovery phase of Aurora Health Care's Long-term Strategy work, they obtained hundreds of insights from their patients. Aurora Health Care heard how they could simplify and design their processes to better meet their patients' needs and selected the first five (5) system processes to improve in 2007:

- Patient billing
- Patient registration
- Managing resources responsibly (specific focus to be determined)
- Medicare length of stay
- Appropriately utilizing their diagnostic and inpatient resources

The third area of focus under becoming "One Aurora" is to adopt clinical innovation into clinical practice. Aurora Health Care will continue to integrate their clinical research to support the discovery and adoption of new knowledge within clinical service lines.

Third Key Action: Develop a Patient Point of View, with 3 areas of focus.

- Adopt and embrace Planetree
- Provide care to a defined patient group in a way that meets their needs
- Integrate retail into care delivery locations to better meet patients' needs

The first area of focus under developing a patient point of view is to adopt and embrace Planetree (a philosophy of patient-centered care in a healing environment). Aurora Health Care will measure success by:

- Increasing the percent of people who would recommend Aurora Health Care to family and friends (patient loyalty index).

- Increasing the percent of their patients who perceive that they received care in a coordinated, simple, and easy to use way.
- Increasing the system-wide employee engagement index by 5%.

The second area of focus under developing a "patient point of view" is to provide care to a defined patient group in a way that meets their needs. Health care typically groups patients based on their demographics (age – senior services, sex – women's health, etc.) or by their medical diagnosis (oncology, orthopedics, cardiac, etc.). An additive way of understanding their patients is by addressing their needs, behaviors, or preferences. Aurora Health Care is experimenting with new models of care delivery that include the focus on the needs of their patients, starting with offerings specifically asked for by very busy (time-starved) families. They will measure if these offerings make a difference in patients choosing Aurora for their needed services.

The third area of focus under "Develop a Patient Point of View" is to integrate retail into care delivery locations to better meet their patients' needs. How to integrate retail: Aurora Health Care's patients' experiences do not stop at their doors – they need to re-define and expand concepts of patient care beyond the hospital or physician visit. At times, patients and their families need to acquire retail products to support the care they provided. Consistent with their Long-term Strategy, they need to ensure the patient's experience in acquiring these products is as easy and convenient as possible.

Fourth Key Action: Continue to Strengthen Aurora's Financial Performance.

Aurora Health Care will improve profitability by increasing the operating margin by 0.1% in 2009 from base operations excluding start up facilities.

Next the core competencies will be described.

Core Competencies

Specific core competencies vary by position and job code. The general competencies for many caregivers include: understanding of clinical conditions, data collection, financial processes, medical records, use of information systems and communication skills. Intensity and level of expertise can be defined via the specific job standards associated with each defined role within the organization. As an example, a core competency within the Care Management is the ability to utilize the large amount of data they have exposure to and add value to it for the patients they serve.

The Planetree philosophy of care that is unique to Aurora Health Care (within business markets) can provide advantages as well. Planetree is a philosophy and model of personalizing, humanizing, and demystifying healthcare. This connection with a patient-centered focus allows capturing loyalty via the sharing of best practices through this international organization. All caregivers throughout the system, regardless of their actual direct patient contact, are accountable for knowledge and understanding regarding the Planetree philosophy.

Additionally, there is opportunity to capture a business lead on utilization of a *Just Culture* approach to patient safety. This approach focuses on investigation of the true cause of any error—individual, process, or system failure. Highlighting this as a cultural shift would be seen as a positive step. Even though many organizations can validate their processes for patient safety, this cultural focus sets the tone for significant system impact.

KNOWLEDGE BASE

In the complex environment of healthcare, a solid base to support administrative, declarative, pro-

Table 2. Aurora Health Care IT/IS knowledge management systems (Source: Developed by the authors in May 2009, based on Gottschalk, 2002)

Analytical Knowledge	-Lotus Sametime -Care Management AHC system database	-Institute for Healthcare Improvement website -Cancer, Trauma and Perinatal Registry databases	-Premier clinical performance website -Micromedex

cedural, and analytical knowledge is necessary. Aurora Health Care satisfies these base requirements through developing an intense information system infrastructure, and providing for a vision, understanding, and commitment to building a solid knowledge-base, as well as, with a firm development of knowledge roles and skills.

IS Infrastructure

A review of the information technology and systems utilized by the organization clearly indicates that Aurora Health Care relies heavily on both internal and external knowledge-based-systems. In the highly regulated environment of healthcare, the sharing of electronic information (data and meta-data) is a business necessity. The reimbursement system alone mandates compliance with electronic sharing of information. A positive impact of these requirements is that healthcare organizations can identify actions and opportunities for improved care and processes. When the opportunities promote action, there is value created for the patient and organization through knowledge management.

IT / IS Knowledge Based Systems

Knowledge Management Vision

The vision of Aurora Health Care is centered on the single idea: there is a better way to provide health care. The following segment of the vision describes their knowledge management philosophy:

"We are committed to improving the quality of health care and health outcomes for people today, through the rapid and broad application of current knowledge. We are also engaged in the education of health care professionals, and the ongoing quest for new knowledge through medical research, in order to contribute to the quality of health care in the future," (Aurora Health Care, 2009a).

Knowledge Management Understanding and Commitment

Within the employee base of the Aurora Health Care there is a strong understanding of the need for data and information review. There is continued assessment of the value this knowledge brings even when it is not commonly referred to or understood as Knowledge Management. Messages come from senior leadership for constant improvement and to maintain steady progress. This information is shared throughout every segment of the organization. The organization has identified knowledge champions that manage knowledge. These champions are the Chief Information Officer (CIO) and Vice President of Quality and Research. These two individuals lead the system teams that organize the work within many departments, specifically the technology and quality areas. Although very high-ranking employees, they are accessible and available to nearly every employee. From a clinician point of view they are well known. Another knowledge champion would be the Chief Financial Officer (CFO). This person is responsible for assisting all leadership with availability and understanding of financial data. The system also has established knowledge teams who collect and sort through data and processes involved in analyzing knowledge information for codification. There are local business unit teams for various initiatives that feed into larger regional or system teams.

Knowledge Roles and Skills

Development and implementation of new knowledge specific roles occur at the following levels:

The Individual

The development of new knowledge specific roles is truly based on individual motivation and interest. Every employee has the opportunity to identify areas in which they desire growth. This could be basic computer skills, to advanced analysis and interpretation of data. Based off of specific job duties and responsibilities, an employee is challenged to create their "Learning Plan" to improve their knowledge and skill set.

Team

Team development of new roles would be visible when a new initiative is identified. There would be opportunity to engage and lead the effort to establish protocols and processes regarding the identified initiative. There is significant support to have teams bring forward new ideas and share "best practices." There is recognition and support when an idea or process that has positive impact to the patient and/or organization is identified. These sharing opportunities can originate at the local and regional level, but are often taken to system teams.

Organizational

As information technology and quality initiatives continue to expand, so does the organization's need to respond to those challenges. The new perspective that comes with new leadership can quickly help the entire organization review old ways of thinking. This pause for review does not require sweeping change; it may only validate the right path.

Inter-Organizational

Within Aurora Health Care there is opportunity to network and engage in collaboration both inside and outside of the system. The system has both hospital and clinic based entities, which create opportunities for unique collaboration, learning and sharing. As a large health care organization, there is also the availability to work with outside systems for comparison and learning. This type of knowledge is limited due to the industry's reliance on regulatory agencies. Much of the data and information collected is subject to their review. This includes quality data and also financial data that impacts the business at all levels.

KNOWLEDGE MANAGEMENT CULTURE

Knowledge Philosophy

Within Aurora Health Care, there is significant effort to standardize and share best practices. Becoming "One Aurora" means that care will be integrated, with the goal of exceptional results for the patient. This is part of the long-term strategy that every employee receives training and education.

The philosophy of care is *patient-centered*. This means that all staff actions can be linked to the impact to the patient. Considerable time is focused on the specific quality outcomes employees are charged with obtaining. The focus on those outcomes and goals supports established behavioral expectations. The behaviors relate not only to individual expectations, but the expectations of departments, and strategic business units. The entities are established within various markets and regions as well as the overall system.

Knowledge Management Reward System

The reward system for achievement of knowledge management goals is seen at various levels. An example is the *Care Management Impact Score* which is a measure that combines both hospital and clinic based measures into one score. This score is part of the performance review of every employee within the Aurora Health Care system. The final score has an impact on the merit increase of an employee on an annual basis. This financial tie to initiatives places significant emphasis on achievement of the goals. Published accomplishments can be viewed on the Aurora internal website as well as in numerous mailings and publications.

Knowledge Networks

There is significant corporate support of informal networks. Staff at all levels is encouraged to connect and interact with peers in other regions and outside of the Aurora Health Care system. There are routine system based meetings, which promotes internal relationship building. It is a frequent event for staff to check with other internal and external parties for ideas on processes, solutions, or validation of an identified problem. These calls, emails and exchanges with colleagues are seen as value added.

KNOWLEDGE MANAGEMENT IMPLEMENTATION

The healthcare industry is knowledge intense for many reasons. Primarily, the public values individual health and the expectations for those within the healthcare industry are to positively contribute to healthcare delivery. This expectation requires effective implementation of knowledge.

Levers that Support Knowledge Management

Top Management Engagement

An expectation defined by Aurora Health Care leadership is that caregivers will continue to work together, taking responsibility for their actions, fulfilling their promises and helping one another to do their best work for their patients, because they believe in accountability, teamwork and respect. This value statement includes the following core beliefs:

- People are their greatest asset
- Aurora Health Care embraces their promise to their employees
- They are accountable to each other, to their patients, and to their communities
- They work with each other and with their patients and their families
- They welcome diversity of ideas and opinions
- They respect their patients' wishes. They effectively work with their patients and with each other within the context of cultural beliefs, behaviors and needs (cultural competence)

The organization has defined key expectations of its leadership team:

- Instill confidence, creativity and passion in others by
    - Building my own credibility, meaning: walking the walk, keeping promises, practicing the golden rule, treating staff fairly and equitably
    - Accentuating the positives in people's ability, and not dwelling on weaknesses
    - Praising employees for their efforts
    - Providing opportunities for growth - special projects, etc.
- Provide a vision with defined expectations and time frames
    - State clear expectations
    - Provide the "why" when outlining responsibilities
    - Challenge staff to go beyond their expected potential
    - Provide guidance in times of uncertainty
- Provide feedback regularly and hold employees accountable
    - Let staff know you are there and that you are interested in them
    - Seek to find times when staff are doing things right
    - Use informal coaching and just–in-time feedback
    - Give consistent, timely feedback
- Be fair and apply established practices consistently when addressing employee relation issues
    - Don't play favorites – apply rules and expectations to all staff
    - Don't assume guilt or fault during investigations – consider all sides until it's time to evaluate
    - Listen to all staff and all sides
- Treat others with dignity and respect by
    - Separating the behaviors from the individual – poor or inappropriate behavior does NOT give one license to treat the employee in a disrespectful or degrading manner. Disciplines and even "for cause" terminations should be delivered with dignity.
    - Remember the Aurora Promise to their employees. Aurora Health Care will provide them with the tools and resources to have them be successful in their jobs, to provide feedback and to be fair.

Highly Trained, Competent Personnel

As an organization, the employees, referred to as caregivers, are considered Aurora's greatest asset. To help define the commitment to the caregiver, a "*Promise*" was developed. It reads as follows:

"We promise to listen to and implement better ideas, recognize and reward contributions, offer competitive pay and benefits, and continue building a wide range of career opportunities.

We pledge to explain business issues and strategies, to anticipate and respond to change, and to provide needed technology and information. We will use resources wisely, operate cost-effectively, and maintain a sound financial base so we will be able to make investments in the future — improving health care for all of us. Together, we find new ways to deliver health care, from the simplest of preventive services to the most advanced, life-saving treatments. Every day each of us needs to use our knowledge, experience and creativity to find better ways of doing things. We improve current ways of providing care, combining science with common sense, and embrace best practices — setting new standards for quality care. Aurora's strength stems from the teamwork and collaboration among a talented and diverse group of professionals. That's why it's critical that Aurora continue to attract, keep and motivate talented people. Aurora provides the tools and resources we need to find better ways, and recognizes our successes. Working together, the people of Aurora can challenge conventional wisdom, solve problems through teamwork, develop innovative ideas, and implement best practices. Each caregiver is part of a leading-edge organization, doing important work for people and their families. We're passionate about caring, we're striving to provide better service, and every day…we find better ways," (Aurora Health Care, 2009a).

Human Resource Promise and Rewards

As an organization, everything Aurora does must be focused on providing the best patient care experience, which includes creating an engaging environment for their staff. The Aurora Pulse survey provides caregivers the opportunity to tell leadership how they are meeting this expectation. By asking caregivers to take the survey, leadership makes an implied contract that those results will be used to make Aurora a best place to work and to achieve great results for patients. They have committed to an annual survey and using the four-step *Making a Difference* process to provide:

- leaders with feedback and insight on how well caregivers think Aurora Health Care is doing in living the values, achieving the mission and vision, and following the strategy.
- caregivers with the opportunity to share their opinions regarding topics such as communication, recognition, and personal growth.
- caregivers with an opportunity to become engaged in discussions regarding survey results and development of action plans to improve and enhance current processes.

Caregivers have a chance to impact their day-to-day operations as they follow-through on the action plans and see the results of their activities.

Each Aurora Health Care caregiver has the opportunity to identify specific individual goals they can strive to accomplish per the corporate performance review process. Goal selection and accomplishment can be related to personal growth (learning) as it pertains to their specific role and job function. In addition, there are performance goals that are set via the department, region and system levels. There can be a monetary reward based on accomplishment.

From a recognition perspective, there is an established employee recognition program that allows acknowledgement of exemplary service or work. This program allows for the caregiver to be acknowledged in a setting of their peers, with specifics as to their accomplishment. In addition, there is a lapel pin called the Aurora Star that can be worn as a constant reminder.

Team recognition is often highlighted in the corporate messaging that occurs via the internal intranet system. The reward systems for achievement of care management goals are seen at various levels. The system *Care Management Impact Score* is a measure that combines both hospital and clinic based measures into one score. That score is part of the performance review of every employee within the Aurora Health Care system. The final system score has an impact on the merit increase on an annual basis. This financial tie to the initiatives places significant emphasis on achievement of the goals.

Other recognition for achievement is noted for individual physicians as well as regional and market teams. The published accomplishments can be viewed on the Aurora internal website as well as in numerous mailings and publications. Whenever possible, most leaders seek to publicly praise and recognize individuals for their contributions during meetings with peers.

A criticism of the reward system by front line staff is that they do not always feel they can have a significant direct impact on some of the measures. The clinical specifics involved in many of the initiatives are physician led. If the practitioner makes decisions that could change the overall goal achievement, front line staff feels disempowered. The leadership message that has helped to overcome this criticism is that every employee has the opportunity to contribute in some way to each and every goal.

Report Measures

Healthcare is ever changing. As most industries deal with technology changes, the research involved in disease management and cures is significant in meeting patient expectations to have the latest diagnostics and treatments available. This requires Aurora to maximize the ability to turn data and information into value-added knowledge.

A subset of the patient condition outcome is patient loyalty. The *Loyalty Index* is another key component of knowledge the organization requires for business success.

Another key benefit for the organization is financial stability. When Aurora Health Care manages the current patient population with a best practice approach, they have maximized that patient encounter and delivered the right care at the right time. This also translates to resources used wisely. Minimizing waste would be seen as a contribution toward future investments in strategies for continuous improvement.

Exploiting New Knowledge

Aurora Health Care is constantly being challenged to maintain the highest level of clinical care knowledge and standards. For the patient, this translates into high-end care within their local environment. To maximize this message, they rely on supporting technologies. To be considered "innovative" and "cutting edge" requires people, processes and equipment.

Leveraging Knowledge at All Levels

Nearly all teams within Aurora, feel that information can come from many sources and levels—the patient, the employee, the system and externally. The size of Aurora Health Care provides connectivity that is difficult to quantify. The organization has the opportunity to study a massive patient population base along with its employee group. They can look for value in small, intricate details, or large system processes.

Integrating Knowledge From Various Areas

The integration of knowledge for Care Management is founded in the structure. With the regional teams, there is clear flow of data/information and subsequent knowledge to the system and from the system. Aurora Health Care improved knowledge of company goals at all levels by linking each employee to the email system. This was a major success factor in improving the sharing of information. The corporate strategies, goals and initiatives are part of that knowledge. Although every employee does not have access to their own computer, they do have computer access close to their work environment. The cultural adjustment in this initiative involved clarifying the expectation that electronic communication was a standard, not an option.

Knowledge Used as Competitive Advantage

The organization's large patient base provides a tremendous amount of data and information. If used effectively, that information can provide significant advantages in looking at what a large number of patients want. Aurora Health Care was not the first healthcare entity to embrace LEAN principles to gain leverage over competition. Maximizing operational efficiency can be impressive for the patients—they see organization, communication and connectivity.

PROCESSES TO IMPLEMENT KNOWLEDGE MANAGEMENT

Key Points for Success

- Engage top management in knowledge management concepts and practices.
- Increase knowledge management awareness – begin small – utilize high priority project.
- Leverage existing infrastructure and identify hardware/software and information gaps.
- Leverage current training and consolidate to knowledge management concepts.
- Select Implementation team (provide education on knowledge management concepts).
- Create a CoP for small project.
- Adjust culture and knowledge management strategies through incentive and rewards.
- Utilize consistent approach.
- Allocate the resources and define the timeframe for the project.
- Have knowledge management outputs related to:
  - Quality – Performance
  - Financial improvement
  - Liability reduction
- Validate and report the results.
- Develop a pool of experts necessary for knowledge management applications at Aurora. Examples include the following:
  - Six Sigma: Six Sigma is a disciplined and rigorous analytical approach to quality improvement. It is typically used to decrease variation and eliminate defects for key business processes. Six Sigma is a proven methodology for improving the quality and financial performance of businesses.
  - Flawless Implementation: The Flawless Implementation model is used to help ensure that Aurora Health Care's opportunity to succeed is not by chance but rather by consistently and appropriately applying a disciplined management process. The Flawless Implementation model focuses on identifying and sharing lessons learned and best practices, ultimately improving quality in all that they do. The model has a well-defined cycle of four phases that include Plan, Brief, Implement and Debrief.
  - Tools for Innovation:
    - **Closely held beliefs:** All industries have closely held beliefs about, "how things are done here." The beliefs tool helps to view Aurora Health Care's

organization from the customers' perspectives in order to identify the deeply held beliefs and conventions that drive their behavior. By identifying the belief, they can "flip" it to see what other facets emerge and what opportunities exist with a fresh eye.

- **Trends and Convergences:** Trends can affect what will happen to a business today and in the future. When more than one trend converges with others, it can create even greater changes. The trends tool helps them to learn how to recognize and take advantage of trend convergences and generate opportunities with the new insights.
- **Idea Generation:** Combining multiple insights and discoveries generates ideas. By exploring the intersection of various insights, Aurora Health Care begins to see things with new eyes and new opportunities emerge. By clustering related ideas, larger domains of opportunities emerge.
- **Idea Elaboration:** Not all ideas are good ones. By taking an idea "through the wringer" it helps to more clearly define the idea and its scope and to assess the risks and benefits of the idea before implementing it. The idea elaboration tool guides an idea through the evaluation process to determine if it is worthwhile.
- **Statistical Process Control (SPC):** Once Innovation and/or Quality Planning and/or Quality Improvement work has been accomplished it is critical that the new process(s) are managed so that they are safe, stable, predictable and capable of meeting customer requirements. Statistical Process Control (SPC) is used to determine how a process is performing. Statistical Process Control, through the use of control charts, serves to reveal the "Voice of the Process," a term used to describe what the process is telling them. Time-ordered sequence data is used to objectively and statistically determine how a process is performing.
- **Baldrige Criteria** (Malcolm Baldrige National Quality Award): Baldrige is a business model used to evaluate an organization's approaches to addressing key business processes and their connection to results achieved. Consistent approaches provide for the alignment of resources to improve communication through a common language, productivity and effectiveness in achieving strategic goals. The criteria are intended to ensure that the strategies used are balanced among customers, objectives or goals.
- The Baldrige criteria are not prescriptive in what tools an organization uses or how they are deployed. In other words, it does not say that an organization needs to use Six Sigma or Plan Do Study Act. The selection of tools, techniques and systems usually depends on factors such as size, organizational

relationships, staff capabilities and responsibilities. What the criteria look for is systematic approaches used consistently throughout the organization that achieve the desired or expected results.

- **LEAN:** The purpose of LEAN is to identify and eliminate waste in order to facilitate process improvement and ensure that all activities create value to the customer. LEAN is a process used to create customer value – goods and services with higher quality and fewer errors or defects. This includes creating and/or improving value to customer, eliminating non-value added activities (waste), increasing efficiency and reducing cost, standardizing processes, reducing hand-offs, and improving quality and cycle time.
- **Plan Do Study Act** (PDSA) The PDSA process is a defined process for improvement. Through a series of steps each change is analyzed using data to assess outcomes in achievement of desired results.

KNOWLEDGE MANAGEMENT KEY SUCCESS INDICATORS

The Patient Loyalty Index

Today's health care consumer is much more savvy than ever in the history of health care delivery. They have certain expectations and it's our job to understand what those expectations are and work to exceed those expectations. The most important reason Aurora Health Care believes in increasing loyalty is that it's just the right thing to do. Aurora is in the business of caring for people. Each employee is considered a caregiver, as Aurora Health Care strives to personalize, humanize and demystify the patient's experience.

When Aurora can provide this patient-centered experience, it means they are providing the patient and their loved ones with what they need during their healing process. This results in loyal patients who trust their care. Patients use more of their services and they tell others about Aurora Health Care.

The benefits of patient loyalty are numerous and include:

- Increased revenue
- Positive word of mouth
- More donations to hospital
- Increased referral behavior
- Resistance to competition
- Increased use of other Aurora services

Aurora measures loyalty via review of key questions on their patient satisfaction survey. The Loyalty Index is the mean score of the *likelihood to recommend* Aurora Health Care to their family and friends on the Press Ganey surveys or *definitely yes* on the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. The mean score is closely monitored because research indicates that it is a good predictor of loyalty.

PROFITABILITY

As with most business entities, financial objectives are established. The big-picture focus within Aurora is to generate enough margin to accomplish its not-for-profit mission. The impact of effectively managing resources is a direct tie to its knowledge management. The immediate benefit of active knowledge management is the direct impact to each patient. The organization can see "results" when processes, protocols and guidelines are followed. This translates into a better quality of life for the patient as well as fiscal accountability for the organization. When resources are managed well, Aurora Health Care is able to focus funds on future opportunities such as disease prevention and research. Prudent financial management also allows capital fund availability to support high-cost IT and medical equipment technology needs.

Care Management Impact Score

As identified in early portions of this chapter, the commitment to quality care is evident throughout Aurora Health Care. A measurement of the outcomes related to quality initiatives is demonstrated via an assigned score. How that score is calculated is as follows:

Each of the twenty-seven (27) care management initiatives, safety efforts, and the quality improvement efforts are scored as an A, B, C, or F based on performance. If Aurora meets national targets, it is graded a B, if it is better than national targets, it is graded an A. If it is less than internal targets, it is graded a C or F. Like a grade point average, they earn 4 points for an A, 3 points for a B, 2 points for a C, and 0 points for an F. All points are summed and then divided by the number of initiatives to equal a care management impact (grade point average).

The care management impact score is like a grade point average for performance on clinical improvement and safety efforts. National targets/averages are set at a "B" level or a 3.0 grade point average. Their objective is to be at a 3.1 level or higher. The stretch objective is to be at a 3.4 level or higher.

Aurora believes that continuous support of a learning environment will support continued scores higher than the national targets.

PATIENT OUTCOMES

Care management is the philosophy of improving patient care through prevention, early detection and disease management. The purpose of care management is to keep patients healthy and out of the hospital. If hospitalization is required, patients can be assured that the care received will be safe and efficient. Successful implementation requires a focused, coordinated approach to delivering health care in the right place, at the right time, for the right price and with the best possible results.

Aurora's care management is unique. In its integrated health care system, patient care can be fully coordinated among many different providers, facilities, and services on an on-going basis. Aurora's care management provides staff with knowledge management tools and immediately accessible information they need to obtain the best results for patients by employing the best practices in medical care and treatment.

The Care Management approach to patient care is the foundation of how the Aurora system measures patient outcomes. The continuous monitoring of key indicators allows adjustment and reaction to achieve the best possible outcome. Comprehensive data is available at individual physician, site, and department levels. This allows for customized analysis, which promotes continuous learning.

Each Care Management initiative has specific goals. These goals are based on research-proven best practices from around the country. They regularly keep track of progress in achieving these goals. A number of national organizations focus on healthcare quality measures. They report Aurora Health Care results along with those of other participating hospitals and health care systems.

SUMMARY

Aurora Health Care's business strategy is based on objectives to support its benefit to the community. These objectives translate into key actions of advanced care management, aligning business practices across its organization, conducting business from a patient's point-of-view, and strengthening its financial performance. These key actions are mapped into a long-term strategy of simplified care for the patient, service designed by the customer, and rapid adoption of best practices.

The knowledge management strategy is structured to provide knowledge balance, codification, and internal development opportunities, along with effective exploitation and exploration. As a not-for-profit healthcare provider, Aurora Health Care strives to maximize long-term societal benefits of activities and services. This requires a long-term focus on disease prevention and treatment. A complex knowledge-balancing act of identified challenges and responsibilities is structured to ensure the best long-term interest of the people they serve. They believe that working together the people of Aurora will "find a better way." A consistent knowledge codification approach reinforces this belief and allows them to rapidly adopt innovation, be flexible with efficient change, and use common language to improve communication. Internal knowledge development is a key element toward knowledge management strategy at Aurora Health Care. The organization has developed knowledge roles and functions for leaders. They have a structure for shared learning to drive results. Aurora maintains a structured utilization/innovation scheme that applies focus on exploring new knowledge and exploits knowledge that exists while codifying that knowledge.

Core competencies are important to any knowledge management system. Aurora Health Care ensures core competencies that relate to operations, customer service, and safety. Specific core competencies vary by position and job code. Among the general competencies for many Aurora employees are: understanding clinical conditions, data collection, financial processes, medical records, use of information systems, and common communication skills. Aurora Health Care utilizes a philosophy of care that makes a connection with a patient-centered-focus. This supports capturing patient loyalty via the sharing of best practices in customer service. Aurora also uses a "just culture" method toward patient safety. This approach focuses on investigation of the true cause of any error made by an individual, process, or system.

In the complex environment of healthcare, a solid base system that supports administrative, declarative, procedural, and analytical knowledge is necessary. Aurora Health Care satisfies these base requirements through an intense information system infrastructure, knowledge, vision, understanding, and commitment, with a firm development of knowledge roles and skills. Aurora relies on both internal and external knowledge based systems. The sharing of electronic information (data and meta-data) is a must in healthcare. Knowledge management is identified in Aurora Health Care's Vision Statement. This vision is centered on the single idea: there is a better way to provide healthcare. The organization has instilled a strong understanding of the need for data and information review. Aurora's senior leadership requires constant improvement ensuring that the organization maintains steady progress. This message is shared throughout every segment of the organization. Knowledge roles and skills development, and implementation of new knowledge occurs at the individual, team, organization, and inter-organizational levels.

Knowledge management culture is an important ingredient to the strength of Aurora Health Care. Knowledge management philosophy, reward system, and networking, support the knowledge management culture. Aurora seeks exceptional results for its patients. All employees receive training on how to standardize and share best practices throughout the organization. Employees are incentivized toward knowledge management as a part of their annual merit increase. Knowledge management key success indicators are incorporated into each employee's annual performance review. This formal tie places significant emphasis on achievement. Staff at all levels are encouraged to connect and interact with peers inside and outside of Aurora.

The healthcare industry is knowledge intense for many reasons. Primarily, the public values individual health and the expectation for those within the healthcare industry is to positively contribute to healthcare delivery. This expectation requires the effective implementation of knowledge. Aurora Health Care knowledge management implementation begins with its levers that support knowledge. Top management has expectations for all staff regarding teamwork, responsibility of actions, fulfilling promises, and helping one another to do their best work for the patient. Human resource policies and practices support implementation through formal employee feedback and recognition of exemplary service and work. Aurora Health Care is constantly challenged to maintain the highest level of clinical care knowledge and standards. To meet this challenge, they rely on supportive technologies. Employees within Aurora feel that information can come from many sources and levels, such as the patient, employee, organization, and outside the organization. It is imperative to have the knowledge management systems that leverage this information into actual implementation. They use many tools to process and implement knowledge. Examples include Six Sigma, flawless implementation, tools for innovation, statistical process control, Baldrige Criteria, LEAN principles, and Plan-Study-Do-Act.

ACKNOWLEDGEMENTS

The authors wish to thank Philip Mattek for his work on the Aurora Framework Connection for Business KM Source (Figure 1), displayed on page 12.

Thank you to Patrick Falvey, Ph.D., Senior Vice President & Chief Integration Officer for Aurora Health Care for his support of this project.

The authors also wish to thank Kim M. Stencil for her assistance in editing the aforementioned information.

The authors wish also to thank Kelly Anklam for her assistance in editing this chapter.

Finally, a special thank you goes to the editor of this book for his thorough feedback and insightful comments.

As always, the authors take the responsibility for any mistakes.

Chapter 4.13

Organisational Factors and Technological Barriers as Determinants for the Intention to Use Wireless Handheld Technology in Healthcare Environment:

An Indian Case Study

Raj Gururajan
University of Southern Queensland, Australia

ABSTRACT

Traditional technology adoption models identified 'ease of use' and 'usefulness' as the dominating factors for technology adoption. However, recent studies in healthcare have established that these two factors are not always reliable on their own and other factors may influence technology adoption. To establish the identity of these factors, a mixed method approach was used and data were collected through interviews and a survey. The survey instrument was specifically developed for this study so that it is relevant to the Indian healthcare setting. Authors identified clinical management and technological barriers as the dominant factors influencing the wireless handheld technology adoption in the Indian healthcare environment. The results of this study showed that new technology models will benefit by considering the clinical influences of wireless handheld technology, in addition to known factors. The scope of this study is restricted to wireless handheld devices such as PDAs, smart telephones, and handheld PCs.

DOI: 10.4018/978-1-60566-030-1.ch007

INTRODUCTION

In the last few years, high expectations, technological developments, and effective and efficient services have been shown to be prerequisites for improvements in the healthcare domain (Rogoski, 2005). Latest trends in the healthcare sector include the design of more flexible and efficient service provider frameworks aimed at providing health services to all stakeholders. In order to implement such frameworks, wireless technology is increasingly being used in the healthcare sector (e.g. data management automation). A decrease in the cost of wireless devices and improved awareness of the benefits that ensue by using related wireless applications are two of the contributing factors towards the increased use of wireless technology in this sector (Gururajan, Quaddus, et al., 2005). Even though the future of this technology and its usability is promising, its adoption is still in its infancy, which is attributed to the complex and critical nature of the healthcare environment. In the current competitive and complex business environment, technology developments have played a critical role in delivering high quality of care (Reinecke, 2004). However, there is limited knowledge and empirical research on the effectiveness and adoption of wireless technology in general, and in the Indian healthcare system in particular.

Recent research has established that investment in emerging Information Technology (IT), including Information Systems (IS), can lead to productivity gains only if they are accepted and effectively used by respective stakeholders. Consequently, acceptance and utilization of IT/IS in the healthcare environment have been central themes in the information systems literature. Therefore, the fundamental focus of this research is to investigate and examine the influence of internal and external determinants on the usefulness of wireless technology. Further, this research also assesses how its acceptance contributes to the adoption of wireless technology. I believe that this research is the first of its kind attempted in the Indian healthcare domain and it employs empirical evidence to explore the impact of wireless technology and its usefulness in the Indian healthcare system. The Indian healthcare domain is at the forefront in adopting the latest medical technologies and applications, as evidenced by media reports and, as such, it constitutes an excellent context for validating existing adoption theories and extending them.

The main contribution of this research includes the identification of a set of drivers and barriers to using wireless technology in a given Indian healthcare setting. In addition to this, for the first time, a set of clinical factors influencing the adoption of wireless technology has been identified and validated using a second order regression model.

BACKGROUND

The concept of wireless technology in healthcare is discussed in many studies (Dyer, 2003; Hu et al., 2002; Sausser, 2003; Simpson, 2003; Wisnicki, 2002). For example, Wisnicki (2002) provides details of how broadband technology, an essential component of wireless technology, can be used in healthcare. While prior studies agree that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such applications (Gururajan et al., 2005; Gururajan et al., 2004). In general, the majority of the works reviewed are descriptive about the benefits of wireless handheld devices in healthcare in general, and medicine in particular. There is only a small number of studies that provide evidence-based information concerning these devices in healthcare (Fischer et al. 2003; Sax et al. 2005). Furthermore, five major studies in the area of healthcare (evaluated by (Spil & Schuring, 2006) testing the Technology Acceptance Model (TAM) produced findings which were inconsistent with the body of knowledge in non-healthcare settings. With ‘Perceived Ease of Use’ and ‘Perceived Usefulness’ as the major TAM attributes, these studies found that in the health environment, ‘Perceived Usefulness’ is an important attribute in technology adoption, while ‘Perceived Ease of Use’ was found to have no effect (Spil & Schuring, 2006). This is different to findings reported in non-health IS studies, where both attributes were found to be reliable technology adoption predictors. Therefore, further empirical investigation is required to explain the reasons why this variation exists in healthcare.

TAM in Healthcare Context

In healthcare literature, the discussion on wireless technology falls into three periods. For example, studies prior to and including 2000 discussed the status of wireless technology and the possible role the technology can play in healthcare. Studies between 2000 and 2003 discussed how wireless technology can be deployed in healthcare and the potential benefits the technology can bring to healthcare. It should be noted that these studies were only 'discussion' type studies. The majority of these studies did not provide any empirical evidence as to the use or acceptance of wireless technology in healthcare domains. Studies from 2004 to the current date have collected data to establish the usefulness of wireless technology in healthcare. These studies, to some extent, have focussed on the PDAs as these devices have been found to be useful in the nursing domain for clinical data management.

The studies between 2000 and 2003 discussed various capabilities of wireless technology in clinical domains. For example, how broadband technology can be used in healthcare was discussed by (Wisnicki, 2002); the ability to address the prevailing healthcare staff crisis by adopting intelligent solutions using agent and wireless technology that can identify the need and match the need with available resources in a timely and efficient manner was outlined by Davis (2002); better compliance with the rigorous regulatory framework was highlighted by Wisnicki (2002); reduction in medication errors and hence the benefits that can be realised was discussed by Turisco (2000); provision for greater flexibility and mobility of healthcare workers in performing their work was portrayed by Athey & Stern (2002); and effective management of the increasingly complex information challenges and improved access to information from anywhere at anytime was discussed by Stuart & Bawany (2001). Our review clearly identified that all these studies were only implying the potential of wireless technology and did not provide any empirical evidence.

While prior studies agreed that wireless applications have the potential to address the endemic problems of healthcare, very limited information can be found about the determinants of such wireless applications in order to establish the adoption of technology in a given healthcare context (Gururajan et al., 2005; Gururajan et al., 2004). During the period of 2004–2006, studies emerged in the area of technology acceptance, specifically focussing on the acceptance of wireless technology in healthcare domains. These studies were empirical in nature and were testing the available models of technology acceptance or a variation in order to ascertain whether previous models hold good for a new technology in a specific domain. These studies were reported in a book titled *E-Health Systems Diffusion and Use,* published by Idea Group Publishing in 2006 (Spil & Schuring, 2006). In addition, there is a need to explore whether further attributes exist which may influence the adoption of wireless applications in the healthcare environment.

In essence, the recent studies appear to suggest that the current models of technology acceptance or its derivatives are not suitable to predict the adoption factors of wireless technology in a healthcare environment. Strong support can also be derived from three specific studies that have tested TAM models in healthcare. The first study, conducted by Jayasuriya (1998), established that ease of use was not significant in a clinical domain. The second study by Chau & Hin (2002) echoed similar sentiments. The third study by Hu et al. (1999) also found similar findings. Further, recent studies conducted by Howard et a. (2006) also established that ease of use was not significant in determining factors of adoption in a clinical domain in regard to wireless technology. Further, Ivers & Gururajan (2006) also found that there are other factors beyond the TAM models influencing the acceptance of technology.

Interviews conducted by Gururajan and Moloney et al. (2005) with 30 Queensland nursing staff members revealed that clinical usefulness of wireless technology is far more significant than ease of use factor as established in TAM. Another focus group discussions between Gururajan and Quaddus et al. (2005) and Western Australian senior health managers by also indicated that aspects of clinical usefulness such as integration of clinical data may be a more significant factor than the ease of use factor. Howard et al. (2006) also identified clinical usefulness is far more influencing than the ease of use factor while determining factors of adoption of wireless technology in the Indian healthcare domain.

However, the recent findings that the ease of use factor is not strongly significant in the healthcare domain when determining wireless technology adoption warrants explanation—as this is different to many other reported studies in the generic IS domain where both attributes (ease of use and perceived usefulness) were reported to be reliable predictors.

This variation requires further empirical investigation in order to explain the reason behind this variation specific to healthcare. Therefore, there is a need to identify attributes that assist in the adoption of wireless applications in the healthcare environment. We argue that the initial validity of TAM was predominantly established by testing the model with students as surrogates in a generic software application domain. This environment is very different to the healthcare environment, where skills are at different levels. Further, the healthcare environment is complex, sensitive and time critical. These could be some of the reasons why TAM did not perform as expected in healthcare settings.

Therefore, there appears to be a basis to identify factors that contribute to the adoption of technologies in healthcare settings. Given that wireless technologies have started making inroads in healthcare, the overarching purpose of the research is to identify the factors that influence the adoption of wireless technology in the Indian healthcare system. The rationale of the purpose is justified by the fact that India is a leader in software technologies, especially medical applications. Further, India is emerging as a 'health tourism' nation, due to the advancement in medical technology and reduction in cost in offering high quality health services—as highlighted by various print media. However, our initial review of available literature indicated that this area is under-researched. Collectively, these aspects led to the following research question:

- What are the determinants for the adoption of wireless technology by physicians in the Indian healthcare system?

The first stage of this study is focused on answering the research question qualitatively and the second stage on answering the research question quantitatively. Details as to how the research question was answered are provided in the research methodology section below.

METHODOLOGY

The research question dictates the need for quantitative research methods, while the behavioural component of the same investigation dictates qualitative research methods. The rationale for this approach is based on the notion that behavioural components require a thorough understanding of how users apply wireless technology in a given setting in order to understand behavioural issues. To extract 'tacit' aspects, this is best accomplished by applying a qualitative approach. A quantitative instrument can then be developed to extract the quantitative aspects, such as the opinion scores.

Health professionals view the term 'wireless technology' in different ways, either as a product or a process. The combined domain of wireless technology and healthcare is relatively new in the Indian IS domain. While IS studies have discussed the impact of Information & Communication Technology (ICT) tools and associated behavioural intentions on healthcare users, limited information can be found as to how the combination of wireless technology and healthcare settings would influence users who are already conversant with novel and advanced medical technologies (Spil & Schuring, 2006). The workplace or organizational factors that influence such combinations are yet to be explored in detail. Such an exploration has close association with the choice of research method, as these methods pave the way for proper inquiry into the factors that determine technology acceptance in a given setting. On this basis, the suitability of one research method over another has to be carefully weighed. Consequently, this study identified an exploratory approach to be suitable for the initial investigation. This approach is particularly favourable in confirming the direction of the study, variables chosen for the study, and in helping refine the literature. The exploratory study can also possibly eliminate some variables, while providing opportunities for including emerging variables.

Qualitative Data Collection

As argued, for the first stage of this research the investigators used a qualitative approach to collect initial sets of themes for the adoption of wireless technology in the Indian healthcare system. For this purpose, 30 physicians operating in Indian healthcare were identified randomly. These physicians were aware of wireless technology, or were using some form of wireless technology in their workplace. They were derived from both public and private hospitals. I included certain administrative type physicians in order to identify aspects pertaining to the use of wireless technology in administration. Demographic details were not recorded to guarantee anonymity. These physicians were interviewed over a period of six months by an independent member (external to the team) who identified the attributes for the adoption of wireless technology by physicians in the Indian healthcare system. This approach was deliberate to address criticisms of 'bias' in the interview process. Further, due to linguistic issues, I required a person with proficiency in both the Indian language and English. The interview questions were derived from existing literature and our experience of conducting similar studies in Australia. The interviews were conducted over a 45-60 minute period and recorded using a digital recorder. Once they were recorded, the interviews were transcribed.

Quantitative Data Collection

This study developed a survey instrument from the interview data. The main reason for this digressed attitude was that previously tested instruments in the technology domain were not relevant to a healthcare setting and were found to be inadequate in answering the research question. The data from the interviews were used to develop specific ranges of questions to gather a more detailed view from the wider population. This survey instrument was pilot tested to capture the information reflecting the perceptions and practice of those adopting wireless technology in the Indian healthcare system. Particularly, it focussed on what internal and external environmental factors affect the adoption of wireless technology and the extent of this influence. The survey was then distributed to over 300 physicians randomly chosen from the telephone book, and a total of 200 responses were received. The survey responses were then entered into a spreadsheet file. A Visual Basic interface was written to generate numerical codes for various elements of the survey for data analysis using SPSS. The coded spreadsheet file was then copied onto a SPSS file format.

Table 1. The factors driving and inhibiting wireless technology adoption in healthcare

Drivers	**Barriers**
• Save-time • Improve-clinical-workflow • Efficiency-in-communication • Delivery-of-high-qual-info • Better-quality-of-service • Save-effort • Improve-clinical-performance • More-contact-time-with-patients • Improved-delivery-of-information • Reduce-overall-cost • Positive-impact-on-patient-safety • Reduce-inaccuracies • Improve-public-image • Reduce-medical-errors • Easy-access-to-data • Attract-more-practitioners • Reduce-workload	• Legal barriers • Administrative purpose • Communication with physicians • Patient education • Communication with colleagues • Obtain lab results • Note taking • Electronic medical records • Device usage barrier • Benefit evaluation barrier • Resource barrier • Electronic prescribing

DATA ANALYSIS

Qualitative data was analysed using the NVivo (version 7) application, which helped identify the initial themes from the interviews. Quantitative data were analysed using SPSS, which helped identify the factors and their correlation for the adoption of wireless technology in the Indian healthcare setting.

Qualitative Data Analysis

Prior to coding schemes on the qualitative data, reliability was assured through saturation of themes during interviews. Qualitative data was manually coded to extract themes that had an impact on wireless technology acceptance as stated by the physicians. In total, 63 themes were extracted from the interviews. The initial themes include awareness, cost factors, advantages and disadvantages, medical errors, information sharing, current state of technology, usefulness and role of wireless technology, and technology awareness. On the basis of the interviews and the literature review, the themes were classified into drivers and barriers as shown in the following table. Drivers were themes that exhibited positive tone, and barriers were themes with negative tone. The classification of drivers and barriers was subjective. I did not conduct in-depth discourse analysis on the data as this stage was expected to provide only the scope for the quantitative study. This purpose of developing the list of drivers and inhibitors was to provide a direction for the development of the survey instrument for the collection of quantitative data in order to capture the wider community views and to generalize the outcome of the research. This grouping is presented in Table 1.

It is to be noted that the content of the Table 1 is consistent with findings of previous studies conducted by Gururajan et al. (2004; 2005). This prompted conducting a quantitative study in order to establish causality among dependent and independent variables, as well as external validity and generalisability.

Quantitative Data Analyses

In order to ensure statistical reliability, suitable tests were run on the entire instrument, as well as selected group of variables. For example, the reliability test returned a Cronbach alpha value of 0.965 for the instrument, indicating high reliability (Zikmund, 1994). I ran this test because the instrument was generated from the interview data and, hence, it was necessary to establish statistical

Table 2. The factors driving and inhibiting wireless technology adoption in healthcare from data analysis of survey result

Drivers	Loading values	Barriers	Loading values
improve-clinical-workflow	.798	poor technology barrier	.605
tech-support	.764	time for training barrier	.572

attract-more-practitioners	.600		
Org-culture	.464		

reliability. In addition, reliability tests were also run for three factor groupings, namely, drivers, inhibitors of adoption, and other technology factors. The reliability tests returned values of 0.941, 0.447 and 0.536, respectively, indicating that the data were suitable for factor analysis testing.

I did not run any demographic analysis as the main aim of the research was to identify the determinants for the adoption of wireless technology. Therefore, it was decided that a correlation matrix would be suitable followed by a factor analysis. The correlation matrix was conducted on the questionnaire items and found to be acceptable. The matrix is not reported in this study because factor analysis provides the correlation implicitly.

As a second step, survey data were analysed for factor analysis using SPSS. I used the exploratory factor analysis techniques for this purpose. For the purpose of the study, a principal component analysis (PCA) was conducted using a Varimax rotation with a factor loading of 0.5. I ran the factor analysis with 2 factor components in order to verify the driver and barrier themes extracted from the interview qualitative data. It is evident from Table 2 that the two factor component matrix identified drivers and the barriers for the adoption of wireless technology in the Indian healthcare setting. This finding is consistent and aligned with the findings of the qualitative data collection stage (i.e. first stage) of this research.

Subsequent to the two component factor analysis, I ran another analysis on the driver factors

Table 3. The factors driving wireless technology adoption in healthcare from data analysis of survey result

	Organizational	Management	Clinical
save-effort	.716		
reduce-overall-cost	.708		
reduce-inaccuracies	.703		
save-time	.667		
easy-access-to-data	.659		
attract-more-practitioners		.769	
improve-public-image		.680	
tech-support		.680	
reduce-workload			.817
improve-clinical-performance			.797

alone to identify factor groups emerging from the data. This resulted in three major groups emerging within the drivers as indicated in Table 3.

I titled these three groups of factors as 'organisational', 'management' and 'clinical'. It should be noted that these titles are subjective and based on the questionnaire items. For example, saving effort, reducing cost, etc. are organisations issues and, hence, the title 'organisational'. Thus, the organisational components include wireless technology drivers that can generate specific benefits for organisations. The management components represent the benefits that healthcare managers can realise using wireless technology. The clinical components encompass clinical drivers of using wireless technology.

A similar factor model was generated for the inhibitors. The model resulted in Table 4:

Similar to the drivers, the inhibitors also resulted in three specific categories. The 'technology' category includes technology factors that inhibit wireless adoption in Indian healthcare. The 'resource' category encompasses resource barriers that are currently being encountered in

Table 4. The factors inhibiting wireless technology adoption in healthcare from data analysis of survey result

	Technology	Resource	Usage
poor technology barrier	.625		
time for training barrier	.582		
solutions barrier	.575		
benefit evaluation barrier	.528		
tech expertise barrier	.527		
system migration barrier	.511		
funding barrier		-.749	
resource barrier		-.690	
technical support barrier			.542
device usage barrier			.519

Table 5. The factors 'clinical usefulness' of wireless technology adoption in healthcare from data analysis of survey result

	General Communication	Clinical Communication	Records Management
Obtain lab results	.837

Generating exception list			.738
Note taking			.617
Disease state management			.563

the healthcare setting. Finally the 'usage' category is comprised of inhibiting factors, which are associated with usage issues.

In addition to the two factor groups, namely drivers and inhibitors, I also identified a third, and named this 'clinical usefulness'; its components are shown in Table 5.

This factor group yielded three components. The first component deals with the general communication aspects facilitated by wireless technology in healthcare settings. The second component refers to clinical communication using wireless technology. The third component is specific to records management. In summary, the data analyses yielded three specific categories of factors which can affect the adoption of wireless technologies in the healthcare setting. These comprise adoption drivers, inhibitors, and clinical usefulness.

The factor analysis provided me with initial answers to the research questions: the factors that determine the adoption of wireless technology.

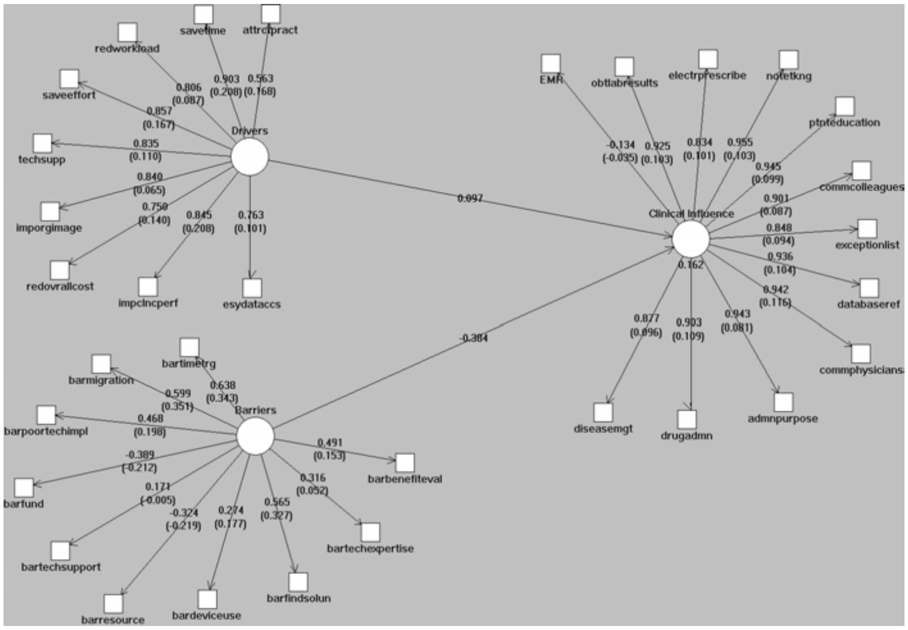
Hypotheses Formulation and Testing

Based on the evidence collected, the three sets of factors, namely, drivers, barriers and clinical usefulness, contribute to the adoption of wireless technology in healthcare. I hypothesise that the drivers positively impact clinical usefulness, whereas the barriers have a negative impact on it. While the drivers and barriers include factors beyond the technology aspects, their respective influences are restricted to the clinical domain as this is where the usefulness of wireless technology can be experienced. Therefore, the following two hypotheses were generated for testing:

H1: Drivers of wireless technology positively impact clinical usefulness.
H2. Barriers to wireless technology negatively impact clinical usefulness.

I digressed away from the traditional regression modeling because I felt that the data may be insufficient to run a traditional regression model. Further, the intention of the study is NOT to develop a cause and effect model, but to determine

Figure 1. PLS model of adoption of wireless technologies in Indian healthcare



the factors identified. Therefore, a Partial Least Square (PLS) model was developed in order to test the hypotheses. The rationale for using PLS includes: PLS is used for confirmatory factor analysis (CFA); the pattern of loadings of items on the latent constructs is explicit; PLS provides strong convergent and discriminant validity; p-value of t-value is significant (over 0.50 level) for constructs; and measurement items load highly on theoretically assigned factors and not highly on other factors.

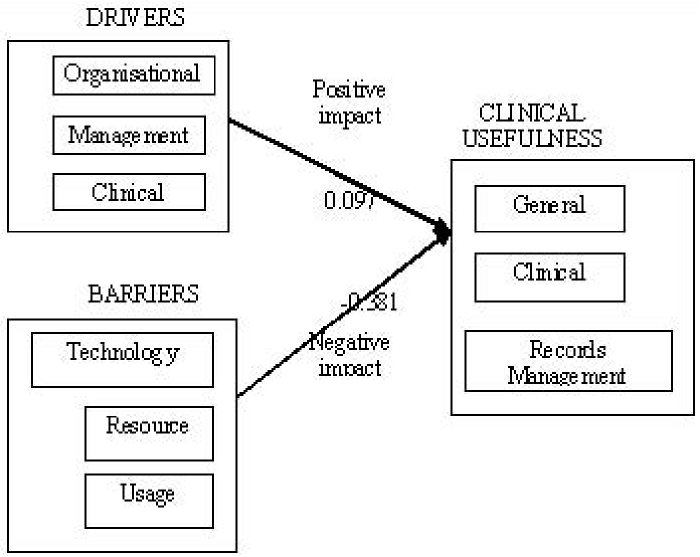
PLS MODEL DEVELOPMENT

In order to develop the PLS model, a PLS Graph prototype was used. Initially, the individual drivers, barriers and clinical usefulness were tested for CFA scores and these were found to be reliable. When the CFA was found to be satisfactory, a model was built with clinical infuences as dependent variable on drivers and barriers. The factors of these three constructs were linked using PLS Graph software and the model was run. The final outcome is shown in Figure 1 below.

Figure 1 shows that the factor loading (the number on the path: for example, for the construct Drivers, the 'esydataccs' has 0.763) and the factor weight (the number in the parantheses: for example, 0.101) for almost all factors are reliable. The drivers and clinical usefulness load very highly (over 0.8 for most of the items), indicating a high reliability. Further, all variables have a t-value of over 1.96 to indicate high convergent validity.

Upon construct validation, a simple PLS (consolidated) model was developed to test the hypotheses. The model consists of clinical usefulness as the dependent variable, and drivers and barriers as independent variables. The model was run with PLS Graph program and the screenshot shown in Figure 2 displays the values along the link from Drivers to Clinical Usefulness, and Bariers to Clinical Usefulness. As hypothesised, drivers exhibited a positive loading (0.097) and the barriers exhibited a negative loading (-0.384). The number below the circle Clinical Usefulness is the construct R^2, which is calculated and dis-

Figure 2. Result of model testing



played for each dependent variable. The lower the R^2, the minimum the error in the model. In the model the R2 values for the dependent variable 'Clinical Usefulness' is 0.167. This is not high and, hence, the error is minimal. This is shown in Figure 2.

IMPLICATIONS

Clearly, wireless technology can be used to facilitate access to clinical information and communications between clinicians, maximise clinician time, increase patient safety, and accomplish the strategic and business goals of health organisations. Taken together, these factors have a direct impact on clinical usefulness and its effectiveness. However, achieving clinical usefulness with wireless handheld devices can be a challenge and has several implications.

Firstly, the highest security standards must be achieved. This includes direct end-to-end data encryption, authentication, authorisation, maintenance of audit logs and session management (Chen et al. 2004). While high security standards are essential, their implementation is likely to affect usability. For example, the download and encryption of patient information from the server where it is stored into a wireless handheld device may not be prompt. Sax et al. (2005) argue that clinicians may experience increasingly longer time lags when they carry out increasingly more complex procedures. This is likely to adversely affect clinical usefulness and, hence, decrease user acceptance.

Closely associated with security is also the issue of patient confidentiality, which is of significant importance and concern. Although wireless handheld devices have locking security features and password protection functions which activate during periods of inactivity, the frequent use of these functions during the clinicians' busy daily schedules may have an impact on clinical usefulness. (see Figure 1 and Figure 2)

Secondly, the design of an effective human-computer interface, while challenging, constitutes a key factor for the acceptance of the technology and its routine use by healthcare workers (Chen et al. 2004). This is an important development consideration as the relevant information should be easy to navigate and read, and has to be presented in an organised fashion when required within the resource limitations (e.g. screen size and bandwidth) of a wireless handheld environment. Usability factors are not only likely to constitute an acceptance barrier, but can also be the cause of medical errors. Bates et al. (2001) argue, 'While it may be easy and common to blame operators for accidents [or errors], investigation often indicates that an operator "erred" because the system was poorly designed' (p. 301). Therefore, medical errors can also occur due to poor usability. Taken together, these factors would contribute to reduce medical errors. By implication, it is important to involve users in the design of the wireless applications, thereby maximising their clinical usefulness.

Thirdly, simply acquiring and implementing wireless technology alone would be insufficient to accomplish clinical usefulness and, subsequently, drive adoption and diffusion. Wireless technology should be integrated with process improvement and organisational change. Process improvement requires the optimisation of clinical processes and should be supported by technology, rather than driven by it (Smith 2004). Ultimately, this is likely to generate significant patient outcomes and financial improvements with health organisations.

Fourthly, as suggested by the empirical evidence collected in this study, cost constitutes an important factor which will affect the integration and, subsequently, the success of wireless handheld devices in the healthcare setting (Sax et al. 2003). Typically costs include the software, the server, upgrades of healthcare organisations' existing networks and legacy systems, the costs of the handheld units themselves, as well as maintenance and support. While existing research in this area argues that such technology has the potential to decrease charting time and medical errors and enhance patient care quality, there is no evidence that comparisons of costs before and after the implementation of wireless technology have been made. This suggests that further research is required, but also, most importantly, it shows that, indirectly, costs have the potential to affect clinical usefulness and threaten widespread adoption.

FUTURE RESEARCH

This research is an exploratory study to identify clinical influences of wireless technology applicable to the Indian healthcare system. While data were obtained on perceived opinions, actual measurement of usefulness of wireless technology in a clinical setting was not conducted. Currently, another project is being conducted that would enable measurement of clinical influences of using wireless technology in an objective manner. This new project will provide some insights into the efficiency gains of using wireless technology and the challenges people encounter in using this technology.

This study is confined to the Indian healthcare setting, which limits the generalisability of its findings. However, this study is also the first of its nature and, as a result, it has prepared the groundwork for further research which can confirm (or refute) whether the findings reported in this study are applicable to other settings. Data are collected using the same instruments in Australia, Taiwan and India. It is anticipated the data collection to be completed by in 2009.. This exercise, it is hoped, will enable to extend the notion to broader populations.

KEY TERMS AND DEFINITIONS

Health Informatics: In healthcare, information flow is critical. Thus, various aspects of information systems, such as the storage aspects in databases, quality of information captured and transmitted, usage of information sources also become critical. Thus, the management of information within health is considered as Health Informatics within the context of this article.

Technology Adoption: In order for a technology to be used, it should be adopted first. There are a number of adoption models available in the field of Information Systems. These models predominantly look at the behavior aspects leading to adoption. In this paper, technology adoption is discussed with healthcare professionals using a technology in clinical settings.

Wireless technology: Wireless technology is a technology that uses Infrared, Bluetooth and other radio frequency techniques to transmit data emerging from computers and other devices. In the scope of this chapter, the wireless technology is discussed as a system that consists of connectivity without wires for data transmission.
