The Giant's Causeway is located on the north coast in North Antrim. Irish lore says that the basaltic blocks in geometric shapes are the work of the giant Finn McCool. There are 40,000 basalt columns that lead to the sea and beneath it. Most are hexagonal, but some have four, five, seven or eight sides with the tallest extending 40 feet into the air.

The lowlands are mainly in the center of the country, which is cut by the Shannon River. It rises in the northwest and flows 230 miles to the Atlantic at Galway Bay. Numerous peat bogs covering a tenth of Ireland are scattered across the rolling hills of the central lowlands. The area is actively farmed for potatoes, vegetables, and other crops.

The coasts of Ireland are the location of its mountains. In the southwest are the Kerry Mountains. The Donegal Mountains are in the northwest. The Sperrin, Antrim, and Mourne Mountains are in the north. The Mountains of Mayo and the Mountains of Connemara are in the west. The highest elevation in Ireland is Carrautoonhill (3,414 feet, 1,041 meters) in the Connemara Mountains. The Wicklow Mountains in the east are the source of the Liffey River, which empties into the Irish Sea at Dublin.

The Boyne River is in the northeast; the Barrow, Nore, and Suir Rivers are in the southeast; and the Moy flows through the northwest. The rivers are fed by the mild wet ocean winds that bring rain, which is heaviest in the western mountains with flooding a regular problem in the lowlands. The North Atlantic Current, a branch of the Gulf Stream, warms the island, making snow rare along the coast although it does occur in the mountains.

There are no snakes in Ireland, driven out by St. Patrick according to Irish legends, and only three amphibians. Of the mammals on the island, only 31 are native. These include the red fox, Irish hare, red deer, and the hedgehog. Other mammals including rabbits were introduced at one time. There are, however, over 400 species of birds.

Irrigation

IRRIGATION IS THE artificial application of water to land for the purpose of supplying moisture essential for plant growth. Although irrigation is an old art, its importance has increased in recent times with the increased demand for food to meet the needs of a growing population. Today, irrigation accounts for 70 percent of all water used by humans. Although irrigation works are found almost everywhere, they are most important in arid and semiarid regions, where the quantity and timing of rainfall are not inadequate for crops. For instance, in those parts of Asia where rainfall is seasonal, and most precipitation occurs in three to four months of the year, irrigation is highly critical to agriculture.

The importance of irrigation is evident from the fact that, historically, the development of human civilizations has followed the development of irrigation. For instance, Egypt claims to have had the world's oldest dam, 355 feet long and 40 feet high, built some 5,000 years ago to store water for drinking and irrigation. In fact, basin irrigation introduced in the Nile valley around 3000 B.C.E. still plays an important part in Egyptian agriculture. Similarly, in the valley of the Euphrates and the Tigris (the two rivers which pass through Turkey, Syria, and Iraq, and which defined what was once called Mesopotamia), there are remains of the largest irrigation canals built around 2200 B.C. Historical references to the practice of irrigation from wells, tanks, and canals are also found in countries such as China, India, Iraq, the former U.S.S.R., Mexico, and Peru.

The importance of irrigation has grown further since the 19th century, particularly with the application of modern engineering technology. The 19th century saw the world's irrigated area increase from 8 million hectares to about 40 million hectares, of which the single largest share was that of India (17 million hectares). Considerable irrigation development also took place in the western United States and Italy in the latter half of the 19th century. Irrigation development continued in the 20th century, particularly after World War II, when the use of irrigation technology, along with other inputs, led to the so-called Green Revolution in many parts of Asia. But since the late 1970s, irrigation expansion has slowed markedly due to a number of reasons such as low commodity prices, high energy costs, and economic conditions that discourage agricultural production.

Currently, the Asian continent accounts for nearly 70 percent of the irrigated area in the world, and the Americas for 15 percent. The three countries with the largest areas under irrigation are India, China, and United States, in that order.

According to estimates by the Food and Agriculture Organization, the share of irrigation in world crop production is expected to increase in the next decades, although the rate of increase will slow down. Irrigated land will expand by 45 million hectares to reach a total of about 242 million hectares by 2030, at a projected annual growth rate of 0.6 percent compared with the 1.9 percent observed in the period from 1963–99. The expansion of irrigation is projected to be strongest in south Asia, East Asia, and Near East/North Africa. Rising economic and environmental costs, along with declining public investments in irrigation, means that a significant increase in the rate of addition of irrigated areas is unlikely in the future; therefore, irrigation's contribution to food production will have to come from improving existing systems rather than from expanding them to new lands.

METHODS AND CLASSIFICATION

Irrigation systems can be classified in a number of ways. The most common mode of classification is by the characteristics of the water and power source. The water source can be surface (canals and tanks) or groundwater (wells). In some parts of the world, such as South Asia, most of the recent expansion in irrigated area has been through private investments in wells to exploit groundwater. Wells in turn can be open wells (where water is pumped up by manual or animal labor or motors) and shallow and deep tubewells (which are almost exclusively operated by diesel engines and electric motors). Further, water can be conveyed by gravity flow or lifted via pumps, depending on whether the irrigated area is located downhill or uphill of the source of water.

Other criteria for classifying irrigation systems include capital labor ratio, scale, institutional arrangements (whether water is directly appropriated by the user, acquired via contract, or allocated by a community or a bureaucracy), and degree of farmer control over availability and timing of irrigation.

The method of water application also varies. Irrigation water can be applied to crops by flooding it on the field surface, by means of furrows, applying it beneath the soil surface, spraying under pressure (sprinklers) or applying it in drops (drip irrigation). Of these, drip and sprinkler irrigation are water-saving techniques, but drip irrigation involves high initial investment and sprinkler irrigation involves high level of power. Ultimately, the choice of method is dictated by a number of factors such as the available water supply, type of soil, topography of the land, and the crop to be irrigated. Irrigation can be intensive or extensive. Intensive irrigation is usually used when the motive for irrigation is increasing production per unit area, and extensive irrigation is used when the motive is to protect crops from droughts by expanding the cultivated area.

MULTIDIMENSIONAL

Irrigation is a subject that has a number of dimensions. The science and engineering dimension includes the construction and maintenance of structures and channels for the conveyance of water, as well as the adequate application of water to maintain plant growth. The economic dimension of irrigation arises from the fact that water is a primary input in agriculture, as well as one that increases the benefits from other inputs and makes possible the use of high-yielding varieties of seeds and fertilizers. Another important economic aspect of irrigation is its profitability. The unit cost of irrigation development varies with countries and types of irrigated infrastructures, ranging typically from $1,000 to $10,000 per hectare, with extreme cases reaching $25,000 per hectare. The lowest investment costs are in Asia, which has the bulk of irrigation and where scale economies are possible. The most expensive irrigation is found in sub-Saharan Africa, where irrigation schemes are usually smaller and development of land and water resources is costly.

The social aspect of irrigation stems from the fact that it often necessitates collective action, for which it may draw upon existing institutions and organizations, as well as cultural practices. For example, the Indonesian *subak* is an irrigation institution where there is a strong interrelationship between water and religion. Each *subak* or irrigation group has two temples—one dedicated to the goddess of fertility, the other to the god of water—and there is a complex, albeit synchronized, relationship between rituals in the temple and agricultural activity. Irrigation projects that do not take into account preexisting local social structures, or social and cultural practices, can result in conflict.

There is also a political aspect to irrigation. This is because irrigation is not just an economic resource, but also a source of power and patronage at the local, regional, and national levels. In fact, the relationship between irrigation and general political authority has been the subject of considerable discussion among social scientists. The most well-known theory in this regard is Wittfogel's (1957) theory of Oriental Despotism, which hypothesized that agriculture in arid regions required the building and operation of large-scale irrigation works, the control and management of which gave rise to a highly centralized and elite bureaucracy; this in turn provided the base for the emergence of despotic, "agro-bureaucratic" states in ancient China, India, Egypt, and Mesopotamia. In other words, hydraulic societies have an inherent tendency to become centralized, despotic states. Wittfogel's thesis has been critiqued on a number of grounds, such as the presence of local autonomy in irrigation management in many countries and the lack of systematic correlation between the existence of irrigation and the nature of the overall political authority.

CAUTIONS AND CAVEATS

There is no doubt that irrigation is important not only in food production, but in the multiplier effect of creating employment opportunities and bringing about development via linkages with other economic activities. Further, irrigation can also help to bring about social change because of its linkage with social and political power. But in spite of its importance, irrigation has also resulted in a number of problems. For instance, lack of adequate drainage and lack of knowledge of the appropriate relationship between soil, crop, and irrigation, have given rise to serious problems of waterlogging, salinity, and alkalinity in many irrigated projects in India, Pakistan, China, the United States, and Central Asia. This has resulted in once-fertile land becoming unfit for agriculture. Similarly, overpumping of groundwater in many regions is beginning to make continued irrigation too costly—as well as resulting in drying up of aquifers—thereby forcing land out of agriculture. For instance, about one-fifth of U.S. irrigation is achieved by pumping groundwater at rates that exceed the water's ability to recharge, which means that aquifers like the Ogalla in the Midwest are being rapidly depleted.

Apart from environmental problems, there are also problems of underutilization of existing systems (due to inefficiencies such as leaky pipes and unlined canals) and low rates of cost recovery, as well as social problems (for instance, as a result of displacement due to big dams). There are also pressures on irrigation water due to growing demands for water from other sectors, the most important among these being industry and increasing urban populations. Shifting water from farms to cities is already being done in a number of places such as the western United States, China, Mexico, and India. Water-scarce countries often satisfy the growing needs of cities and industry by diverting water from irrigation, then importing grain to make up for lack of production. This practice has now come to be called trade in "virtual water"; the water used to produce an agricultural commodity.

The multifaceted nature of irrigation means that a wide variety of factors, such as geography, agrarian structure, population pressure, cultural factors, the role of the state, and the vision of development, determine the direction and pace of irrigation development. This, in turn, has led to considerable differences in the way irrigation development has taken place. For instance, in many parts of the world (such as in South Asia), the state has played an important role in undertaking irrigation development. In others (like Australia, Canada, and the United States), governments have encouraged irrigation development by private individuals or groups.

There have been a number of changes in the nature of irrigation development since the 20th century, and particularly in the last two decades. First, irrigation has been extended even to areas of sufficient and abundant water supply. Second, there has been considerable interest in the science of irrigation techniques and works, resulting in changes in the way irrigation is conceived. For instance, the concept of single-purpose irrigation projects first gave way to multipurpose projects (which include water supply, hydroelectric power and flood control), then to river basin planning and to the integrated development of a river basin. Third, there has been greater emphasis on the necessity of learning from traditional water management systems. Fourth, there is a trend toward privatization and user participation in irrigation systems.

Israel

FOLLOWING DECADES OF tumultuous political and cartographic struggle, Israel was created as a Jewish state after World War II, setting the stage for decades of bitter divisions between Jews and Muslims in the Middle East. An Israeli victory in a number of separate conflicts and Israel's close ties to the West have exacerbated the ongoing religious and territorial tensions with her Muslim neighbors and with indigenous Palestinians. Bordering on the Mediterranean and Dead Seas, Israel has a coastline of 169 miles (273 kilometers). The terrain is diverse, ranging from the Negev Desert in the south to low coastal plains and central mountains to the Jordan Rift Valley. Israel has a temperate climate, and the southern and eastern desert areas are hot and dry. The country experiences periodic droughts and sandstorms in the spring and summer.

With a per capita income of $22,200, Israel is the 44th richest country in the world. However, 21 percent of the population live below the poverty line. There is a good deal of economic inequity, with the richest 10 percent controlling 28 percent of the country's wealth. Natural resources include timber, potash, copper ore, natural gas, phosphate rock, magnesium bromide, clays, and sand. Even though less than 3 percent of the workforce is engaged in agriculture, forestry, and fishing, the only regular food imports are grains. Israel exports fruits and vegetables to surrounding areas, and diamonds and high-technology equipment are exported around the world. Tourism is also essential to the Israeli economy. The United Nations Development Program (UNDP) Human Development Reports rank Israel 23rd in the world in overall quality-of-life issues.

The Israeli government's commitment to environmentalism began with the creation of the Environmental Protection Service in 1973. In 1988, the Ministry of the Environment was established to implement laws and monitor compliance. The lack of fresh water resources severely taxes Israel's environment. Consequently, the government has developed wastewater treatment facilities that allow 65 percent of generated water to be reused for agricultural purposes. Less than 10 percent of the population live in rural areas, and heavy industrialization and urbanization have led to substantial levels of air pollution. There are 230 cars for every 1,000 people in Israel. Between 1980 and 2002, carbon dioxide emissions per capita metric tons rose from 5.6 to 11.0. Israel produces 0.3 percent of the world's CO_2 emissions.

Israel is home to 2,600 plant species, seven amphibian species, almost 100 reptile species, over 500 bird species, and around 100 mammal species. Of 116 endemic mammal species, 14 are endangered. Likewise, 12 of 116 bird species are threatened. Approximately 6.1 percent of the land area of Israel is forested, and 15.8 percent of the area is protected. These areas include 142 nature reserves and 44 national parks. However, Israeli environmentalists insist that the government has not taken all necessary steps to protect the land, citing the practice of encouraging farmers to sell agricultural land for development by paying them 30 percent of profits.

Other environmental issues involve desertification, groundwater pollution from domestic and industrial waste, and the irresponsible use of chemical fertilizers and pesticides. A study by scientists at Yale University in 2006 ranked Israel 45th of 132 countries on environmental performance, well above the relevant geographic group but well below the relevant income group. The lowest rankings were received in the categories of air and water quality, biodiversity, and natural resource protection. The environment perhaps has suffered most greatly in the Israeli-occupied Palestinian territories where instability and continued transitions of authority and violence have left forests, grazing lands, and water in relatively poor condition.

Extensive ecological damage has also occurred in the Dead Sea, which Israel shares with Jordan. The lowest point in the world, the Dead Sea is in danger of disappearing altogether. The practice of harvesting the minerals that balanced the sea's ecology has led to a drastic decline in the water table, and levels of brine have drastically increased. Massive sinkholes have appeared that engulf land and forests. A number of environmentalists have expressed opposition to proposed plans to build pipelines to transfer water from the Red Sea, which is ecologically different, to the diminishing Dead Sea.

Israel's commitment to the global environment has been demonstrated through participation in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Ozone Layer Protection, Ship Pollution, and Wetlands. The Marine Life Conservation agreement has been signed but not ratified.

Great Fire of Rome

The Great Fire of Rome raged for five days in Imperial Rome, destroying about two-thirds of the city, and resulting in it being rebuilt by the Emperor Nero in a grand style. The fire broke out on July 19, 64 C.E., and started in shops selling heating oils near the Circus Maximus, where the chariot races were held. It was a densely populated part of the city, with wooden houses easily catching alight and spreading quickly. The fire raged for nine days, but is only mentioned by three historians. Tacitus, who was nine years old at the time of the fire, wrote that the Emperor Nero watched the fire from the Maecenas Tower; and Suetonius and Pliny the Elder also mention the fire. Other Roman historians who were there at the time make no references, causing some later commentators to doubt the seriousness of it. However, archaeological evidence of the fire in blackened remains found during "digs" in Rome have shown its effects.

The Emperor Nero was said to have "fiddled while Rome burned" but this comes from a reference to him playing the lyre—the fiddle had not yet been invented. Nero provided shelter for many people in his palaces, and when Rome was to be rebuilt, the emperor laid down regulations about the spaces between houses, encouraged building in brick, and wanted wider roads.

Some blamed Nero for the fire, and he seems to have quickly passed the blame onto Christians, large numbers of whom were crucified or thrown to the lions in arenas—the Colosseum had not yet been built. Nero also used the fire as an opportunity to enlarge his palace, building the Domus Aurea ("Golden House"), which had an entrance so large it could accommodate a 120-foot-tall statue of himself.

1913 poster showing Nero playing the lyre while Rome burns.

Italy

ITALY, A STATE of Europe in the south of the continent, has a land area of 116,305 square miles (301,230 square kilometers, including the large islands of Sardinia and Sicily) and an estimated population of 58 million people in 2006. The country can be divided into three main physiographic units. The north, dominated by the Alpine mountain arch; the center, whose main feature is the Po river plain; and the mountainous south, with the Apennines mountains stretching to Calabria. Coastal lowlands are also frequent, especially in the Adriatic sea. In Sardinia and Sicily, high and rugged mountains and volcanoes (in Sicily) alternate with lower elevations and coastal plains. The climate is Mediterranean except for the Alps and the Po river plain, where continental conditions (cold winters and warm summers) prevail.

The most pressing environmental issues faced by Italians concern air and water quality; soil erosion and desertification linked to agricultural abandonment (especially in the south and in the islands); and a wide array of natural hazards (floods, droughts, landslides, earthquakes and volcanic eruptions). Air pollution shows some improving trends, such as the decrease in sulfur dioxide emissions (largely as a result of the reduction in coal burning and the increase in the use of the cleaner natural gas), but a serious deterioration in cities due to traffic. Italy has one of the highest per capita rates of car ownership in the world. Atmospheric pollution remains especially acute in cities where thermal inversions are frequent, and the concentrations of some pollutants in Rome, Milan, and other capitals often exceed the standards of the European Union (EU). Also, air pollution constitutes a serious threat for the rich historical heritage of Italian cities. However, several policy initiatives launched in the 1990s in order to curb pollution have attained some success, such as "car free" Sundays or rotating the use of cars with alternate plates on given days. Moreover, Rome was the first European city to establish a fee for cars willing to access the center.

Water pollution continues to be an important environmental problem, because of agricultural and industrial discharges, especially into the Adriatic. The so-called "yellow" and "red" tides (algae concentrations in highly eutrophied waters) of this sea are less

Mount Vesuvius

The eruption of Mount Vesuvius on the afternoon of August 24, 79 C.E.—coincidentally on the day after Vulcanalia, the festival of the Roman god of fire—engulfed the city of Pompeii. There had been a previous eruption on February 5, 62 C.E., and some of the damage was still being repaired when the second and larger eruption took place.

Although the eruption is described well in two letters by Pliny the Younger—his uncle, Pliny the Elder was commander of the nearby Roman fleet, and died in the eruption—it is best known because of the discovery of the buried city of Pompeii in the 18th century. In 1709 there were some finds at Herculaneum, and in 1748 work started at Pompeii. By the 1990s, two-thirds of the city had been excavated, and relics have been shown in exhibitions around the world. Although these two eruptions are the best-known, Mount Vesuvius has erupted many times. Indeed, it was the rich volcanic soil of Vesuvius that encouraged large settlements such as Pompeii. Formed from a collision between the African and Eurasian tectonic plates, Vesuvius has erupted in 472, when ash was reported to have fallen at Constantinople; and in 512, with Theodoric the Great, King of the Goths, exempting the area from taxation.

There were further eruptions in 787, 968, 991, 999, 1007, and 1036. The eruption in December 1631 resulted in the death of 3,000 people. Mount Vesuvius has continued to erupt at intervals since then, with 18 eruptions between 1660 and 1872. It erupted in 1906, when 100 people were killed; in 1929; and in March 1944, the most recent. In that eruption, some nearby villages were destroyed and the U.S. Army lost a number of aircraft. Since then there have been a few landslides and the occasional appearance of small clouds of ash dust.

common than in the past, and important efforts have been made to reduce marine pollution, for example in the Venice area. During the 1990s, Italian river basin authorities have been plagued by a crisis of underinvestment and mismanagement.

Agricultural land in Italy covers around 27.1 million acres (11 million hectares), or one-third of the total land area of the country, but it is declining fast; more than 20 percent disappeared between 1970 and 2000. Urbanization, on the contrary, is progressing, especially in the coastal areas. In 1996, it was estimated that only about 30 percent of the more than 4,960 miles (8,000 kilometers) of coast were free from development. In 2003, 11.2 percent of Italy was subject to some environmental protection. The country has created a network of 468 natural parks, including 46 Ramsar Sites and 5 biosphere reserves, notably the Ticino Valley in the Alps and the Tuscan islands. In 2004 Italy was the fourth-largest user of energy in Europe. The country disregarded nuclear energy in the 1970s and depends heavily on oil and natural gas. Only 2 percent of the energy generated comes from renewable resources (excluding hydropower).

Between 1991 and 2001, the country experienced some 12,000 flood and landside episodes affecting about 300,000 people and causing damages above 2 billion euros. Between 1980 and 2002, Italy sustained 17 percent of all flooding episodes in Europe but 38 percent of fatalities, including the 147 people killed in the floods and mudslides of Sarno (in the South) in 1998.

Ivory

IVORY IS THE hard, mellow-colored dentine substance of elephant and walrus tusks (the upper incisors). The teeth of the hippopotamus and the sperm whale resemble tusk ivory and also carry commercial value. Elephant ivory, however, is the most sought-after type, deriving from the African or Indian elephant. Wooly mammoth and mastodon ivory is also popular, the remains of which are found in Canada, America, and Siberia. Connoisseurs note a difference in the quality of "live" and "dead" ivory, the former from recently deceased animals and the latter having lain in the ground for thousands of years. Live ivory is more resilient and resists cracking and is therefore preferred. The high value placed on live ivory, however, is driving the African elephant into extinction. For millennia, people have worked ivory because it is easier to carve than bone, serving therefore as a medium for detailed sculptures and, when cut, emitting an oily substance that is amenable to a high polish. Ivory is also simple to bleach or paint. In addition to its use in the creation of jewelry and sculptures, ivory has also been cut into plates and used for book covers and inlay.

Upper Paleolithic peoples (40,000–12,000 B.C.E.) were the first to carve the tusks of mammoth and mastodon into beads and religious amulets. With access to elephant and hippopotamus ivory from Nubia, the Egyptians used ivory for a wide range of items. It was with the Classical-era Mediterranean (500 B.C.E.–500 C.E.), however, that massive amounts of ivory flooded the consumer market. An increasing demand in ivory corresponded especially with the beginning of the Roman Empire, when it was used to create, for example, musical instruments, statues, furniture, floor coverings, chariots, and birdcages. The Emperor Caius Caligula built a stable of ivory for his horse, and the philosopher Seneca owned 500 tables with ivory legs. By the late 1st century, supplies of African ivory had diminished, but the Indian market maintained steady supplies to Rome. Indian elephant tusks are significantly smaller, more easily breakable, and have a less beautiful natural color than those of African elephants, whose tusks can reach up to 3.5 meters in length with a cross-section of eight inches. The east coast of sub-Saharan Africa, therefore, was the major supplier of the best ivory during the Late

Antique and Medieval periods. Byzantine Christians in particular employed ivory in religious sculptures. In northern Europe and Russia, however, the elites began to make use of a new supply ivory from walrus tusks; albeit inferior, it was accessible.

However great, the impact of the ancient and medieval demand on ivory-producing animals was negligible compared to the devastation wrought in modern times. Ivory was used increasingly for such mundane objects as piano keys and billiard balls. A dramatic decline in African elephant populations coincided especially with the expansion of East Asian markets, notably Japan. From 1979 to 1989, the African elephant population fell from 1.3 million to 750,000. A worldwide ban on the ivory trade in 1989 had mixed results. Illegal poaching continued in all African countries. While the creation of wildlife reserves helped, an estimated 80 percent of African elephants lived in unprotected areas. As elephant populations slowly returned, several African countries urged for a partial lifting of the ivory ban, and dispensation was granted to South Africa and Zimbabwe, to allow the legal hunting of African elephant ivory.

Ivory is easier to carve than bone, serving as a medium for detailed sculptures with a high polish.

Ivory Coast

HIGHLY PRIZED FOR its abundance of natural resources during colonial times, the Cote d'Ivoire, or the Ivory Coast, has continued to be closely tied to France since winning independence in 1960. Controversy developed in the country after a military coup in 1999 established a government elected through rigged results. After this government was overturned by popular protest, fighting continued between government and rebel forces. A ceasefire in 2003 has been enforced by the continued presence of French and West African peacekeeping forces. The Cote d'Ivoire is among the world's major exporters of coffee, cocoa beans, and palm oil, and oil production is expected to reach over 200,000 barrels per day by 2010. Other natural resources include natural gas, diamonds, manganese, iron ore, cobalt, bauxite, copper, gold, nickel, tantalum, silica sand, clay, and hydropower.

Some 68 percent of the workforce is engaged in an agricultural sector that generates less than a third of the gross domestic product. Economic potential has been adversely affected by the political situation and weather conditions. The Cote d'Ivoire has a per capita income of only $1,500, ranking 196th among world incomes. Around 37 percent of the population lives in poverty, and income is unevenly divided. The most affluent 10 percent of the population holds 28.8 percent of the country's wealth. The United Nations Development Program (UNDP) Human Development Reports rank Cote d'Ivoire 163 of 232 countries on overall quality of life issues.

Bordering on the Gulf of Guinea in the North Atlantic Ocean, the Cote d'Ivoire has a 515 kilometer coastline and 4,460 square kilometers of inland water resources. The Cote d'Ivoire shares land borders with Burkina Faso, Ghana, Guinea, Liberia, and Mali. The terrain of the country is generally flat with undulating plains except in the mountains of the northwest. Elevations range from sea level to 1,752 meters at Mont Nimba. Along the coast, the Cote d'Ivoire experiences a tropical climate. However, in the north, the climate is semiarid. The Cote d'Ivoire has three distinct seasons. The period between November and March is warm and dry. Temperatures continue to rise until the end of May. The hot rainy season that begins in June lasts until October, frequently producing torrential flooding. The coast, which is subject to heavy surf, has no natural harbors.

The population of 17,655,000 is beset by both poverty and disease. Due to an HIV/AIDS prevalence rate of 7 percent, some 47,000 people have died and another 570,000 are living with the disease. While 84 percent of the population has sustained access to safe drinking water, only 23 percent of rural residents and 40 percent of all residents have access to improved sanitation. Ivoirians are also susceptible to a very high risk of food and waterborne diseases, as well as malaria and yellow fever. Such high incidences of disease have resulted in low life expectancy (48.82 years) and growth rates (2.03 percent) and high infant mortality (89.11 deaths) and death rates (14.84 deaths per 1,000 population). Ivoirian women give birth to an average of 4.5 children. Literacy rates of 43.6 for females and 57.9 for males make it difficult for the government to educate Ivoirians about disease prevention.

At one time, the rain forest of the Cote d'Ivoire was the largest in West Africa. Today, however, the forest has become overexploited; between 1960 and 1987, forest cover was reduced from 37 million to 8 million acres. Some 71 percent of land area is currently forested, but deforestation is occurring at a rate of 3.1 annually. Most of the population lives along the coast, particularly in the area around Abidjan, which is the commercial and administrative capital of the Cote d'Ivoire. In urban areas, agricultural runoff, the dumping of raw sewage, and industrial effluents have produced severe water pollution. The government has, however, improved air quality by reducing the rate of carbon dioxide emissions per capita metric tons from 0.7 percent in 1980 to 0.4 percent in 2002. The government has also protected 6 percent of land area. Nevertheless, the biodiversity of the entire rain forest is threatened by the expanding population. Of 230 endemic mammal species, 19 are endangered, as are 12 of 252 bird species. In 2006, scientists at Yale University ranked Cote d'Ivoire 86 of 132 countries on environmental performance, slightly above the comparable income and geographic groups. The overall score was greatly reduced by the poor showing in the category of environmental health.

Between the mid-1960s and 2002, the government of the Cote d'Ivoire began passing a body of legislation designed to deal with mounting environmental problems, assigning responsibility for implementing and enforcing laws to the Minister of Environment. New laws dealt with protecting fauna and with revising existing forestry, mining, petrol, environment, rural land management, and water codes. The government also established a national park system and set aside nature reserves. Implementation and enforcement of these laws, however, has been hampered by a lack of funding, personnel, and technology. The Cote d'Ivoire participates in the following international agreements on the environment: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, and Wetlands.

Jamaica

THE BRITISH SEIZED the Spanish Caribbean island of Santiago in 1655, establishing a slave plantation colony that would not achieve independence until 1962. Despite the optimism associated with Jamaica as a fee-market experiment built on export crops and tourism in its early years, economic downturn in the late 20th century left the country in poor condition, exacerbated by high levels of international debt, leading to further political and social instability. Bordered entirely by the Caribbean, Jamaica has 634 miles (1,022 kilometers) of coastline. The climate is temperate in the interior but tropical elsewhere. The terrain is mountainous with a narrow, discontinuous plain. While hurricanes may occur at any time on the island, they are most likely from July to November. Recovering from hurricanes such as Ivan, which hit Jamaica in September 2004, is difficult both financially and environmentally.

Jamaica's limited natural resources include bauxite, gypsum, and limestone. Around 16 percent of the land area is arable, and 20.1 percent of the workforce is engaged in the agricultural sector. Most Jamaicans are involved in the service sector (61.3 percent). Slightly over half the population live in urban areas. The largest contributors to the Jamaican economy are tourism, remittances from Jamaicans who work abroad, and the bauxite/alumina industry. Unemployment is persistently high (currently 11.5 percent), and the population of 2,732,000 people live on a per capita income of $4,300.

Almost one-fifth of all Jamaicans live below the national poverty line. Some 93 percent of the population has access to safe water, but 20 percent do not have access to improved sanitation. Because land is scarce, squatter settlements have sprung up, leading to vast overcrowding and enormous sanitation problems. Government funding for environmental programs and health programs is hampered by high external debts. The United Nations Development Program (UNDP) Human Development Reports rank Jamaica 98th of 232 countries on general quality-of-life issues.

Less than a quarter of Jamaica's land is forested as a result of a high level of deforestation. In the industrial area of Kingston, air pollution is a major threat. Marine pollution is also extensive. Industrial waste, untreated sewage, and oil spills have been dumped into the Caribbean, and the coral reefs have been damaged.

Poor agricultural practices have led to serious soil erosion. Development, agriculture, mining, and tourism all contributed to the pollution of ground and surface water. A 2006 study by scientists at Yale

University ranked Jamaica 43rd of 132 countries on environmental performance, well above the income group average and slightly above the geographic group average. Jamaica's lowest scores were in the categories of air quality and sustainable energy. The island did particularly well in the field of biodiversity and habitat, in large part because 84.6 percent of Jamaica's land is protected. However, there are problems. Of 25 endemic mammal species, five are endangered. Likewise 12 of 75 endemic bird species are threatened.

The Ministry of Land and Environment, the National Environment and Planning Agency, and the National Resource Conservation Authority are responsible for implementing environmental policy and identifying particular areas of environmental concern. Current government projects include the Biodiversity Strategy and Action Plan, the National Forestry Management and Conservation Plan, the Master Plan for Sustainable Tourism, the Water Sector Strategy and Action Plan, the National Strategic Plan on HIV/AIDS, the Inner City Renewal Program Phase 2, and the Agro-Industrial Development–Neutraceutical Project. Jamaica has also reactivated the Sustainable Development Council, and regional groups are actively involved in environmental issues in Jamaica.

Jamaica has expressed concern for the global environment by signing the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Marine Life Conservation, Ozone Layer Protection, Ship Pollution, and Wetlands.

Japan

WITH A population of approximately 127,417,000, Japan is one of the most remarkable success stories in the post–World War II era. Shifting the focus from war-making to economic progress allowed Japan to become the second major industrial power in the world, outranked only by the United States. Unfortunately, along with industrialization and economic growth, Japan has also become a major environmental polluter. To offset this, the country has also become a leader in antipollution technology. In a 2006 study conducted by Yale University, Japan ranked 14th in environmental performance.

The quality of life in Japan is high, and the United Nations Development Program (UNDP) Human Development Reports ranks the country 11th in overall quality of life. All Japanese have access to clean water and proper sanitation, and the amount of malnourishment in the country is negligible.

With only 4.6 percent of its population in agriculture, Japan is a major importer of food products. Despite the fact that they are small in number, Japanese farmers use more pesticides per acre than any other nation in the world. Local governments were assigned the responsibility for monitoring industrial and agricultural pollution until the mid-20th century, when major environmental fiascos called for greater national oversight. However, local governments retained the right to pass supplementary environmental legislation, which is often more rigid than national laws.

Japan is an island chain located between the North Pacific Ocean and the Sea of Japan. The topography is generally rugged and mountainous, and the climate varies from tropical to cool temperate. Japan is also a land of volcanoes, with some 1,500 seismic occurrences each year, along with typhoons and tsunamis that cause major flooding and environmental damage. Japan has suffered both politically and economically from a dearth of natural resources, possessing only fish and a few mineral deposits. Environmentally, Japan's major problems are air pollution from power plants that have caused acid rain and the acidification of lakes and reservoirs that have lowered the quality of drinking water and posed a hazard to marine life. In addition to threatening its own environment, Japan has been called an "eco-outlaw" because it creates major environmental problems in others nations, particularly through the depletion of tropical timber. Japanese industrialists have also set up businesses in countries such as Indonesia, Venezuela, and Brazil, where environmental laws are less strict. As a result, these countries have increased levels of pollution.

Almost 80 percent of the Japanese people live in urban areas. Consequently, Japan is responsible for 5.2 percent of the world's carbon dioxide emissions, which are believed to be the major reason for global warming. In order to cut down on these emissions, the Japanese government has begun using low-emission vehicles for official use and has enacted the NO_x (nitrogen oxides) law of 2001 that tightened pollution standards for diesel vehicles. Other attempts to control pollution include stricter standards for the use of pesticides and tighter control over the emission of nitrate nitrogen, fluorine, boron, and ammonia into water sources.

Japan's long history of organized environmental support began in the late 19th century, when locals discovered that the Ashio Copper Mine, 100 kilometers north of Tokyo, was releasing large clouds of sulfuric acid into the air and polluting the water of the Watarase River used by rice farmers. In addition to health problems, the pollution was destroying nearby forests. The Ashio Riot of 1907 lasted three days, culminating with miners setting fire to the mining complex. Martial law was subsequently declared to restore order. Environmental protests were revived in the 1960s due to high-profile lawsuits involving the cadmium poisoning of residents of Toyama, the mercury poisoning of the inhabitants of Minamata and Niigata, and high incidences of asthma caused by exposure to sulfur dioxide in Yokkaichi.

Other illnesses during this period were traced to high emissions of sulfur dioxide and to industrial and agricultural pollution of water sources due to the lack of adequate treatment facilities. Between 1960 and 1965, the concentration of sulfur dioxide in Japan rose from .015 ppm to .060 ppm, resulting in high incidences of asthma and other respiratory diseases. Between 1960 and 1980, concentrations of nitrogen oxide rose from .005 ppm to .03 ppm. In the Inland Sea, scientists discovered red tides, caused by chemicals in the water that stimulated the growth of algae and destroyed marine life. The incidence of red tides increased from 60 in 1968 to 300 in 1977.

Japan is the second major industrial power in the world, outranked only by the United States.

During the 1970s, some 3,000 Japanese environmentalists groups were formed, and the government responded by passing new environmental laws and establishing stronger enforcement mechanisms. The Japan Environment Corporation, which funded business costs of installing environmental control equipment, was also established. In 1968, Japan passed the Basic Law for Environmental Pollution Control and forced industries to compensate the victims of industrial pollution, even in the absence of overwhelming evidence to link particular pollutants to local health problems. The law has since been revised, with stricter regulations and enforcement. In 1971, Japan created the Environment Agency to monitor environmental compliance and provide aid to victims of environmental pollution.

GOOD ON ITS PLEDGE

When the major industrial nations attending the 1972 United Nations Conference on Human Environment in Stockholm, Sweden, pledged to reduce sulfur dioxide emissions, Japan was the only nation to follow through. However, economic problems in the 1980s and early 1990s led to decreased attention to the environment, despite the fact that physicians and scientists had identified nitrogen oxide in the air as a major cause of respiratory illnesses. Interest in environmentalism was rejuvenated in 1995 and 1997, when Japan experienced nuclear reactor accidents, and a major oil spill in the Sea of Japan in 1997 further aroused public interest. However, 90 percent of Japan's 4,500 environmental groups are locally based, and they have little power at the national level. Japan Tropical Action Network has been the most effective Japanese environmentalist group, successfully promoting a decrease in the amounts of tropical timber imported into the country.

The processes of industrialization and afforestation, and converting open land into forest to supply timber demands, have left Japan with almost no wilderness and with major problems in sustaining the wildlife population. Of Japan's 144,687 square miles (374,744 square kilometers) of land, only 6.8 percent is under national protection. Critics claim that formerly protected land has been given over to recreational areas. Japan is home to 188 species of mammals, and 37 of these species are threatened with extinction. At least 210 species of birds reside in Japan, and approximately 34 of those species are currently threatened. Japan has also been harshly criticized by environmentalists around the world for its continued support of the whaling industry.

Since the 1997 Kyoto Protocol, the Japanese government has remained committed to curbing environmental pollution and is attempting to achieve its goal of reducing greenhouse gases 6 percent by 2012. This is being accomplished in part through the Official Development Assistance (ODA) program that ties development loans to other countries to the purchase of carbon credits, as is permissible under the Kyoto Protocol. The government also requires such countries to purchase Japanese products and services. In 2001, the Japanese created a Ministry of Environment to replace the Environmental Agency. The new ministry was given the responsibility to establish new regulations for air, water, and soil conservation and to protect wildlife and national parks. Recycling has become a major goal of Japan's new environmental policies, as is regulation of chemicals, radioactivity, wastewater treatment, and conservation of all natural resources.

Japan participates in the following international agreements designed to promote improved guardianship of the environment: Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Seals, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling.

Jet Stream

THE JET STREAM is a relatively narrow band of fast, west-to-east flowing air found above the polar front at an altitude of around 6–7 miles (9–12 kilometers) above the surface. The jet stream is produced by the strong pressure gradient that arises from the contrast between the cold air north of the polar front and the warmer air to the south. Winds in the jet stream average about 75 miles per hour (125 kilometers/hour) in winter, when the temperature contrast across the polar front is greatest, and are slower in summer when the temperature contrast is reduced. Wind speeds are variable, however, especially in winter, when segments of the jet stream will often have wind speeds topping 125 miles per hour (200 kilometers/hour). The location of the polar front, and the jet stream above it, also varies seasonally, retreating northwards into Canada in summer and shifting southwards as far as northern Mexico during the winter.

Upper level winds, including the jet stream, tend to flow in sinuous patterns called Rossby Waves, in which the prevailing west-to-east flow meanders north/south in large arcs known as troughs (curves to the south) and ridges (northward bends). These wave patterns gradually change over a period of days, typically with the ridges and troughs slowly migrating to the east and gradually increasing and decreasing in curvature. Jet stream winds flow through the Rossby Waves like water flowing down a curving river, while the shape of the Rossby Waves continuously varies.

The earliest experience of the jet stream came during World War II, as high-altitude U.S. aircraft such as the B-29 bomber encountered extremely fast headwinds as they attempted to fly westward across the Pacific. Today, aviators rely on accurate knowledge of the jet stream position in planning routes in order to avoid the delays, excessive fuel consumption, and turbulence that result from attempting to overcome these strong headwinds. Although the jet stream would assist an eastward bound flight, the associated turbulence can still be hazardous to aircraft and passengers.

The position of the jet stream also has a significant affect on surface weather. Cold air is found north of the polar front, while warmer air is to the south. Troughs in the jet stream guide cold air southward, while ridges bring unusually warm air to the north. More dramatically, the speed and path of the jet stream helps to determine where storm systems such as midlatitude cyclones are able to form. When a deep trough forms in the jet stream, there is a tendency for upper-level air to diverge or spread out on the downstream (east) side of the trough. This upper-level divergence causes air to be drawn up from the surface, which produces a cyclone (a region of low pressure with winds spinning in a counterclockwise direction). As the cyclone spins, cold air is pushed south, producing a cold front, while warmer air is pushed northward, producing a warm front. The entire system is blown generally eastward in the direction of the upper-level flow. Midlatitude cyclones tend to form in the winter when upper-level flow is strongest, and often are associated severe weather, including thunderstorms, heavy precipitation, and tornadoes.

Johnson, Lyndon Administration

THE PRESIDENTIAL ADMINISTRATION of Lyndon B. Johnson (1963–69) is most remembered for the sweeping domestic reforms under its Great Society Program and the continual struggle presented by the war in Vietnam. The Great Society initiative was announced by Johnson in a speech given at the University of Michigan in Ann Arbor on May 22, 1964, in which he set out his plan to establish a series of working groups to hold conferences "on the cities, on natural beauty, on the quality of education, and on other emerging challenges." Soon after, task forces were established to study virtually every aspect of the American society and to come up with domestic policy to address problem areas. Among these was the Task Force on Pollution of the Environment.

In the years preceding Johnson's Great Society, environmental programs concentrated primarily on the conservation of natural resources and less on proactive measures to remedy environmental degradation. The environmental programs proposed and created under the Great Society umbrella were precedent setting in their scope. During the Johnson Administration, the environmental programs enacted included the Aircraft Noise Abatement Act (1968), a series of acts and amendments addressing air and water quality, The Endangered Species Preservation Act (1966), The Land and Water Conservation Fund Act (1965), the National Historic Preservation Act (1966), the National Trail System Act (1968), the Solid Waste Disposal Act (1965), the Wild and Scenic Rivers Act (1968), and the Wilderness Act (1964).

Amendments to the Clean Air Act of 1963 included the Motor Vehicle Air Pollution Control Act (1965), which established standards for automobile emissions. The legislation also set up research efforts to determine resulting health damages. In 1966, an amendment to the act expanded local air pollution control initiatives, and the 1967 amendment established Air Quality Control Regions throughout the country to monitor and report emission levels. In addition, the 1967 amendment established one national standard for emissions.

The Solid Waste Disposal Act of 1965 was established, and the Public Health Service was charged with creating and enforcing regulations for the collection, transportation, recycling, and disposal of solid wastes. Prior to this legislation, most solid wastes ended up in unregulated landfills. Subsequent to the new regulations landfills were required to have a liner and an integral collection system to prohibit contaminated water from entering groundwater systems. The Land and Water Conservation Fund Act of 1965 established a fund for federal and state acquisition of land and water bodies for recreational and conservation purposes.

The degree and quality of the environmental legislation created under the Johnson administration was superb and far reaching. For the first time in U.S. history, a collective societal view existed toward environmental protection. This view carried forward to the Richard Nixon administration when the expansive National Environmental Policy Act of 1969 was prepared and signed into law on January 1, 1970.

Joint and Several Liability

JOINT AND SEVERAL liability is a U.S. legal provision where all parties to a prosecution can be held individually liable for up to the full amount sought by a plaintiff, irrespective of the amount of responsibility the individual defendant may be for the overall cost. For example, a negligent ship's maintenance crew could be held severally responsible for the full cost of an oil spill occurring when the ship suffers a mishap. The very high costs of many forms of environmental degradation greatly exceed the ability of most defendants to pay. Consequently, there has been a tendency for plaintiffs and their legal representation in such cases to "search for deep pockets"—that is, attempt to prosecute those individuals and organizations considered best able to pay for damage allegedly caused, no matter how tenuous their connection to the incidents. This has led to pressure upon individual states to amend their laws, largely because of the pressure that has been brought to bear on medical care providers as well as medical insurance systems.

This process of reform has led to legal changes in 37 U.S. states in the process known as tort reform. This was a central policy of the second Bush candidature in 2004 and received more prominence due to Democratic candidate John Kerry's choice of running mate, John Edwards, since Edwards was a trial lawyer and was characterized, somewhat unfairly, as an "ambulance chaser." The power of the corporate lobby under the Bush administration has led to a tide of tort reform legislation. Many people claim that joint and several liability—an important part of the checks and balances of an advanced democratic state—represents the only meaningful method of holding corporations to account for damages, and that abolishing or compromising it represents a serious impairment of the rights of individual people. Corporate malfeasance, environmental degradation, lack of appropriate health and safety conditions in workplaces, and other questionable practices represent a potent body of evidence to support this viewpoint. Joint and several liability is of particular importance in the area of maintaining effective protection of the environment because of the multifactorial nature of environmental degradation.

Joint Forest Management

THE FOOD AND Agriculture Organization of the United Nations (FAO) defines *Joint Forest Management* as "a forest management strategy under which the government (represented by the Forest Department) and the village community enter into an agreement to jointly protect and manage forestlands adjoining villages and to share responsibilities and benefits."

Taking from the principle of the "Inhabited Forest," Joint Forest Management (JFM) aims to promote a fair way to define and organize the relationships between four elements: the state, forests, forest exploiters, and the local population. Instead of conceiving the local communities as nonexperts or ignorant indigenous who can not exploit forest or take advantage of the woods or would spoil the resources, Joint Forest Management calls for local people's participation with the forest exploiters, keeping in mind that most of the productive forestland (known as "Public Forests," or "Crown land" in Canada) is owned by the state: that is, the whole population. In that sense, Joint Forest Management is conceived as a way to fight poverty or to avoid conflicts with aboriginal groups, wherever forest resources are exploited in a specific region.

In many aspects, Joint Forest Management as a concept emerges from the principles of various, earlier perspectives such as "local community involvement in conservation," social forestry, ecomanagement, and sustainable development. For instance, an early report made for the United States Agency for International Development in Nepal in 1978 already called for "*Community Involvement in Conservation*." Furthermore, sociologist Nandini Sundar even argues that the idea of Joint Forest Management already existed in the 1930's (without using that specific expression), but the strategy did not flourish because it did not have the support of advocacy groups and NGOs.

In many ways, the advent of Joint Forest Management is like a possible answer to the wish of Jack Westoby (1912–88), who was Senior Director of the Department of Forestry at the FAO, when he called for "a truly social forestry," made first for humans. In his posthumus book *Introduction to World Forestry: People and Their Trees*, Westoby argued that

"Forestry is not about trees, it is about people. And it is about trees only insofar as trees can serve the needs of people."

Although many initiatives were experienced in the 1980's, Joint Forest Management officially began in India in 1990, when the Government of India issued its new policy guidelines for the involvement of village communities and voluntary agencies in the regeneration of degraded forest lands. Currently, Joint Forest Management is applied in a few countries, like Nepal, Australia, Canada, India (in the province of Karnataka), and in some African countries.

Since Joint Forest Management is an evolving policy in various contexts, critics and concerns have been raised, for instance by communities who were counting on more stable profits. Sharachchandra Lele, from the Centre for Interdisciplinary Studies in Environment & Development (CISED) in Bangalore has expressed some worries.

That emerging concept has various labels that are much similar. In Canada (and mostly in Québec), Joint Forest Management is refered to as "Aménagement conjoint des forêts." In France, NGOs use a rather different expression: "Gestion forestière conjointe." In India, people sometimes say "Joint Forest Planning and Management," "Participatory Forestry," or "Participatory Forest Management." A group of Canadian scholars have published an online annotated bibliography on Joint Forest Management, which remains the most comprehensive source on that matter.

Jordan

MANAGING TO MAINTAIN an independent stance in the face of enormous international pressure, the Hashemite Kingdom of Jordan under King Hussein (1953–99) evolved in the late 20th century as a parliamentary democracy that promoted liberalization of its economy. After succeeding to the throne upon his father's death, King Abdallah II instituted political reforms aimed at fighting poverty and ending political corruption. With a per capita income of $4,800, Jordan is ranked 139th of 232 countries in world incomes. Official estimates place the poverty rate at 15 percent, but it is likely that the actual rate is at least twice the official count, partly because of the high unemployment rate. There is considerable economic inequity in Jordan, with the richest 10 percent of the population holding nearly 30 percent of all wealth. The United Nations Development Program UNDP Human Development Reports rank Jordan 90th in the world in overall quality-of-life issues.

With only 26 miles (42 kilometers) of coastline along the Gulf of Agaba, Jordan's other significant waterways are the Dead Sea, which is shared with Israel, and the Jordan River, located along the Israeli and Syrian borders. Both Jordan and Israel bear responsibility for the ecological damage done to the

Dead Sea, where the water level has diminished to such an extent that it is in danger of disappearing altogether. Proposals for preventing further damage have led to intense controversy, and some environmentalists fear for the ecological balance of the Dead Sea. Around 90 percent of Jordan's land area is arid desert, but the western section of the country experiences a distinct rainy season from November to April. The Great Rift Valley divides the East and West Banks of the Jordan River. As a result of the arid climate, Jordan experiences frequent droughts and periodic earthquakes.

With an average of only 42,268 gallons (160 cubic meters) of water per individual available for consumption each year, Jordan is among the top ten countries in the world suffering from the lack of a fresh natural water supply. Consequently, the government began developing policies to address this issue in the first quarter of the 20th century. Solutions include the use of water-saving devices and the practice of recycling wastewater for agricultural use. Less than 3 percent of Jordan is arable, and the Jordan River provides the only major source of water for agriculture and industry. The government has purposefully curtailed agriculture because of its intensive drain on scarce water supplies. In 2000, the Ministry of Water and Irrigation in conjunction with the American Academy for Educational Development launched the Water Efficiency and Public Information for Action program designed to promote the installation of water-saving devices in homes and businesses and teach Jordanians of all ages and social classes how to conserve water.

Deforestation in Jordan has reduced forested areas to only 1 percent of total land area. Less than 4 percent of the land is nationally protected. Jordan was once home to some 347,000 species of birds. Currently, of 117 endemic bird species, eight are threatened. Of 71 endemic mammal species, 10 are endangered. For instance, the oryx, a large desert antelope, totally disappeared in Jordan in response to hunting and disease. An international effort to restore the oryx to Jordan has been successful, although the animal's survival remains somewhat precarious. Several species of apes are also endangered in Jordan due to their being killed for bush meat and to loss of habitat.

Agricultural mismanagement in Jordan has led to overgrazing, soil erosion, and desertification. In 2006, scientists at Yale University ranked Jordan 64th of 132 countries in environmental performance, roughly in line with the relevant income and

The Roman City of Jerash

Although the deserted city of Petra is the best-known tourist site in Jordan, Jerash in the north of the country is the best-preserved Roman provincial city in the Middle East.

Curiously, the city of Jerash was not along any important trade routes, but the area was very good for growing corn. It had been inhabited since Neolithic times but it became an important center during the period of Alexander the Great (died 323 B.C.E.). In 64 C.E., the Roman general Pompey conquered the region and Gerasa, as it was then known, became an administrative center for the Romans. By this time iron ore was mined near the city and in the 1st century C.E., the whole city was drawn up again on Roman lines with a colonnaded main street cut across by two side streets. The Temple of Artemis was in the center of the town and there were also two theaters. The Emperor Trajan centered more of the Roman regional administration in the city, and his successor the Emperor Hadrian visited it in 129 C.E. with a Triumphal Arch erected to mark the visit. Much of it still survives at the entrance to the old city. In the 3rd century Gerasa became a colony but then went into slow decline.

By the middle of the 5th century, Christianity was emerging as the major religion, and churches were built, with a few more added under the Emperor Justinian (reigned 527–565 C.E.), including the Church of St. John the Baptist near the remains of the Temple of Artemis. The town was captured by the Sassainian Persians in 614, and by Muslim Arabs in 636. It experienced an earthquake in 747 and massively shrunk in size. During the 12th century it became a Crusader garrison town but remained little known until 1878 when Circassians from Russia started work on the archaeological remains.

geographic groups. The lowest ratings were assigned in the categories of air quality, water resources, and the production of natural resources. Between 1980 and 2002, Jordan's carbon dioxide emissions rose from 2.1 per capita metric tons to 3.2. The country produces 0.1 percent of the world's share of carbon dioxide emissions. While only 7 percent of Jordan's population of 5,760,000 lack access to improved sanitation, the number of people with access to safe drinking water fell from 98 percent in 1990 to 91 percent in 2002. Jordan's natural resources are limited to phosphates, potash, and shale oil.

In 1980, the Jordanian government established the Department of Environment within the Ministry of Municipal, Rural and Environmental Affairs, assigning the department the task of coordinating the implementation and enforcement of Jordan's environmental laws and regulations. In 1986, Jordan adopted the National Environment Action Plan. Over the next five years, the government committed itself to pursuing sustainable development by passing the Law of Environmental Protection, which enhanced the government's ability to monitor compliance with environmental laws through the General Corporation for Environmental Protection. Jordan participates in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, and Wetlands.

Justice

JUSTICE, LIKE SO many political, legal, and theological terms, has always challenged some of the best minds in the world. It is a key concept that plays a major role in the thinking of ethicists, human rights, natural law, and procedural law. And it is an elusive concept that is very difficult to define precisely. Fundamentally, it is the moral principle that a person should receive the type of treatment that he or she deserves.

Most people can easily recognize numerous actions that can be considered unjust. Injustice evokes anger at unfair treatment of either themselves or of another. However, even here, unfair treatment will evoke different responses depending upon what a person feels to be unfair.

Injustice is seen as a departure from a naturally occurring moral order. In Western civilization, concepts of natural justice or divine justice have been the grounds or inspiration for developing numerous moral concepts. Similar notions of a cosmic moral law expressive of justice are to be found around the world. In all cases they involve ideas of fair treatment. To some are due rewards and to some are due punishments, but in all cases fairly delivered.

As a theory of moral deserts, justice is the foundation of ethical judgments. In short, it is a system of rewards and punishments that are designed to fit the actions of those receiving justice. This should apply to the ethical theory that is the foundation of legal and social systems. It often does not.

In the case of justice and the environment, there are a range of views over what is and what is not justice. And these lie at the heart of what a state should establish in its governing of the relations between people.

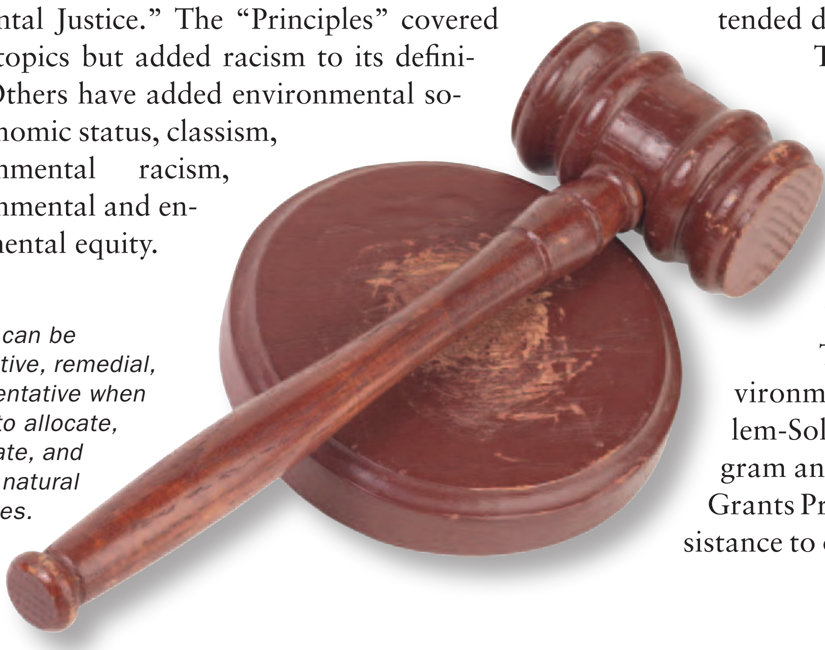
In relations between people, there have always been resource disputes over land, forests, water, minerals, or other aspects of nature or over the right to access. Historically, nature has been conceived as a commodity. However, the advent of the environmental movement has added a new element to the idea of justice, namely environmental justice. The concern is over the right use of nature.

ENVIRONMENTAL JUSTICE

Historically, for many in Western civilization, the creation mandate in the Book of Genesis (Gen.1:28) has been a passage that called for dominion over the earth and it creatures. However, the passage has also been interpreted as a obligation to exercise stewardship as a responsible ethic. This type of ethic has been brought to the public forum by environmental activists who are seeking to establish relationships between modern industrial society and the remnants of unspoiled nature, or demands for the restoration of spoiled nature.

Justice can be distributive when some authority acts to allocate available resources. Justice can also be remedial when it acts to remedy wrongs by restoring what was lost. Justice can also be preventative when it acts as a form of equity to prevent irreparable harms from taking place.

There are a range of definitions for environmental justice that go beyond the mere impact of environmental conditions such as the impact of pollution. In 1991 the People of Color Environmental Leadership Summit adopted "Principles of Environmental Justice." The "Principles" covered many topics but added racism to its definition. Others have added environmental socioeconomic status, classism, environmental racism, environmental and environmental equity.



Justice can be distributive, remedial, or preventative when it acts to allocate, remediate, and protect natural resources.

The National Governors Association uses a definition that focuses on protecting minority and low-income communities from having to bear a disproportionate share of pollution. A different definition has been adopted by the Board of Trustees of Environmental Defense, which operates a "Scorecard." The type of justice sought by environmentalists is preventative and remedial. It has been institutionalized in current American law as the fair treatment and meaningful involvement of all people irrespective of race, color, national origin or other qualification in the development of environmental policies, laws, and regulations.

ENVIRONMENTAL PROTECTION AGENCY

The Environmental Protection Agency (EPA) has set this as its policy goal so that the environment may be protected, health hazards may be prevented, and equal access to both natural resources and to the decision-making process about the environment. In order to implement its policy, the EPA created the Office of Environmental Justice in 1992. Its goal was to integrated environmental justice into EPA's policies, programs, and activities. On September 30, 1993 the EPA established the National Environmental Justice Advisory Council (NEJAC). The council was created as a forum for academics, the community, environmental groups, industry, and indigenous peoples, and also for the state, local, and tribal governments, who are all stakeholders in the environment. NEJAC exists to find solutions to environmental justice problems through extended dialog about specific topics.

The business of NEJAC is conducted under the leadership of a Designated Federal Officer (DFO). It is bound by the requirements of the Federal Advisory Committee Act (FACA) of 1972. The findings of subcommittees of the NEJAC make recommendations.

The EPA also supervised the Environmental Justice Collaborative Problem-Solving Cooperative Agreement Program and the Environmental Justice Small Grants Program. Both provides financial assistance to organizations to achieve a number of objectives including identifying local environmental or public health issues, and for developing solutions that will empower the community through education, training, and outreach.

On February 11, 1994, President Bill Clinton issued Executive Order 12898 on Environmental Justice. This executive order made each federal agency responsible for making environmental justice a part of its mission. This was to be accomplished by identifying and addressing ways in which health and environmental effects of the respective federal agencies impacted people, especially minority and low-income populations in the United States and its territories: the District of Columbia, the Commonwealth of Puerto Rico, and the Commonwealth of the Marian islands.

It also applied to Native American Programs operated by the Department of the Interior in consultation with tribal leaders. The whole cost was to be borne by the federal government. Each agency was ordered to form working groups that would formulate strategies for implementing environmental justice into it regulations and practices. Among the specifics of the executive order were directions for collecting data and for identifying consumption patterns of fish and wildlife. The federal agencies are responsible for publicizing the risks posed by the currently polluted environment of eating fish, fowl, and wildlife.

Ultimately, proponents of environmental justice believe that the environment is where people live, work, and play, and seek to overcome the institutionalize forces that they believe work against a clean environment. The variations in definitions, goals, practices, and contradictory theories of environmental justice reflect the many local conditions and groups of people from which the movement arose.

Kalahari Desert

THE KALAHARI DESERT is an arid region of sand and dry lakebeds in southern Africa extending into parts of Botswana, South Africa, and Namibia. The region is an interior plateau covering an area of approximately 100,000 square miles and lies between the Orange and Zambezi Rivers. The name Kalahari derives from the Tswana word *keir*, which means "the great thirst." Rainfall in the region averages eight inches annually, identifying it as a true desert. However, annual rainfall is extremely variable and ranges from a high of 15 inches to a low of three inches.

The Boteti River flows northward into a marshland at the northern edge of the desert, and carries excess water in years of high precipitation into Lake Xau. During the late 20th century and early 21st century, this volume of water significantly diminished. During periods of low precipitation, animals in the Kalahari are are forced to wander in search of water. A number of smaller, temporary streams and rivers will carry water, depending on the amount of precipitation. Vegetation in the Kalahari Desert is typical for an arid region and includes acacia woodland, savanna grasslands, and some palm trees. Animal life is abundant: springbok, giraffe, hartebeest, hyena, and warthog predominate.

The Kalahari is relatively sparsely populated. The main culture groups include the San people, Tswana, Herero, and Kgalagadi. In 2002 the Botswana government moved into permanent encampments all the San, who have lived in the region an estimated 30,000 years by traditionally hunting, gathering, herding, and raising crops. The governmental effort to settle the Bushmen was justified by a concern for environmental conservation, specifically to save diminishing water supplies. Experts on the region suggest that the government will increase the number of encampments in the future in order to more easily expand diamond-mining activity and formal ranching by majority populations.

There is considerable mineral wealth in the Kalahari. Coal, nickel, copper, and uranium deposits add to the economic inventory of the region. In addition, The Kalahari is home to diamond mines and one of the worlds largest is located at Orapa in the northeastern area of the region. There are a number of important game reserves within the Kalahari Desert. The Central Kalahari Game Reserve ranks as the second largest in the world. Also notable are the Khutse Game Reserve and the Kgalagadi Transfrontier Park.

The Gods Must Be Crazy

In 1980 the film *The Gods Must Be Crazy* was released. Directed by Jamie Uys and set in Botswana and South Africa, it was about the bushmen of the Kalahari presenting them as the "noble savages" leading a simple and utopian life style, which changed dramatically when a pilot in a passing aircraft drops an empty glass Coca-Cola bottle.

The bushmen recover the bottle, and soon start using it for a variety of purposes. The film pursues the concept of the discovery of something new, which everyone has survived for centuries without having, becoming so vital to the existence of many people in the tribe that they cannot do without it. The bottle is used in agriculture, craft work, and cooking. However, with only one bottle to share around all the members of the tribe, it soon leads to arguments over its use, hatred, and eventually even violence. For this reason, the bushmen decide that the bottle should be taken away and thrown off the edge of the world, with one of the bushmen, Xi, being delegated the task. The film is about his journey.

Although a comedy and a contrast between the new "civilized" world and life in primitive societies, *The Gods Must Be Crazy* reinforces problematic stereotypes about the society in which the bushmen lived. Drawing on ideas typical of colonial writing and so frequently invoked in the writings of Laurens Van der Post, romantic representations of hunter-gatherer societies like these produce a skewed vision of the "noble savage," where one modern invention leads to the upsetting of an otherwise perfectly adjusted society.

There has been a sequel, *The Gods Must Be Crazy II,* which was filmed in 1985 and released four years later. There have also been three unauthorized Chinese sequels that were intended to be pure comedies, and have only a vague connection with the authentic *The Gods Must Be Crazy* films.

Karst Topography

KARST TOPOGRAPHY RESULTS from the dissolution of subsurface carbonate rock (calcite and dolomite) through the percolation of slightly acidic moisture in the form of carbonic acid, which is formed from rainwater picking up carbon dioxide in both the atmosphere and the soil. Once within the carbonate rock layers, the acidic liquid begins to dissolve the rock, leading to landscapes with numerous cave features. A common outcome is also the development of sinkholes, where the dissolved subsurface rock layer can no longer support soil and rock above it and collapses. Karst landscapes can develop from fluvial formations (surface water) and underground drainage. The term *Karst* is rooted in the German place name, Kras, designating a region in Slovenia extending into Italy, where the first research on Karst topography was conducted.

Sinkholes can appear suddenly and with no warning, resulting in the loss of farm machinery, buildings, and cattle. In 1981, a sinkhole in Winter Park, Florida, opened up to a diameter of nearly 1,000 feet, swallowing several cars, a home, and half of a swimming pool. It is estimated that more than 25 percent of the world's population lives in an area of Karst landscape or relies on areas of this composition for its water supply. Because Karst regions are particularly susceptible to water pollution, sources of drinking water can be at risk. The flooding of caves in the Bowling Green, Kentucky, area in the mid–1980s caused industrial waste to enter wells in the region.

The conterminous United States, with 20 percent of its land surface on Karst topography and nearly 40 percent of groundwater deriving from Karst underground sources, is particularly vulnerable to water pollution. The presence of landfills, cattle gazing areas, and septic tanks on Karst landscapes provide additional hazards to water supplies when disruptions occur. Agriculture within Karst regions can also be problematic. Normally fertile soils can become leached of nutrients when rapid drainage occurs, preceding periods of drought. Millions of dollars are spent in the United States alone to repair fields and roads disrupted by Karst dissolutions and resulting sinkhole formation.

Karst regions are found throughout the world. A considerable number of Karst landscapes are found in Asia (China, Laos, Malaysia, Thailand, and Vietnam), a number of countries in Europe, the island of Madagascar, and throughout North America and Central America. Kentucky and Florida lead all states in the number of Karst regions. Karst topography can also become a tourist attraction. The famous Carlsbad Caverns in New Mexico is a case in point. Thousands of tourists visit the expansive caverns annually to view its dramatic stalactite and stalagmite formations.

Kazakhstan

DOMINATED BY RUSSIA during much of its history, the Republic of Kazakhstan has struggled to develop a national identity after the exodus of large numbers of Russian immigrants following independence in 1991. Today, Kazakhs make up 53.4 percent of the ethnic mix in Kazakhstan, while remaining Russians and Ukrainians constitute one-third of the population. The Kazakh economy has traditionally been dependent on oil, gas, and mining. In 2001, the Caspian Consortium pipeline stretching from Tengiz, Kazakhstan, to the Black Sea, provided a means of substantially increasing Kazakh oil exports. The government is currently negotiating with China to build an additional pipeline.

The government is now attempting to diversify the economy, in which one-fifth the workforce is involved in agriculture. Extensive natural resources include iron ore, manganese, chrome ore, nickel, cobalt, copper, molybdenum, lead, zinc, bauxite, gold, and uranium. With a per capita income of $8,800, Kazakhstan ranks 81st of 232 nations in world incomes. Some 19 percent of the people live below the national poverty line. The United Nations Development Program (UNDP) Human Development Reports rank Kazakhstan 80th in the world in overall quality-of-life issues.

Kazakhstan borders two sections of the Aral Sea (663 miles) and the Caspian Sea (1,174 miles). With a total area of 1,049,150 square miles, the country supports a population of 15,186,000. The continental climate in some areas leads to cold winters and hot summers. Elsewhere, the climate is arid and semiarid. Kazakhstan extends from the Volga to the Altai Mountains, with the plains in western Siberia giving way to oases and desert in Central Asia. Elevations vary from 433 to 22,949 feet. Southern Kazakhstan is subject to earthquakes, and mudslides are common in the Almaty area.

Kazakhstan's main river, the Syr Darya, was diverted from its course during the Soviet era to irrigate the desert. This river, along with the Amu Darya in Uzbekistan, flows toward the Aral Sea bordering the country in the south, leaving this historically vast freshwater body with almost no inflow. As a result, the Aral Sea is drying up, and is now half its original size, leaving large deposits of chemical pesticides and natural salts that turn into noxious dust storms when they are picked up by the wind. Coupled with chemical and biological warfare waste deposits, the area represents an ecological disaster on an enormous scale. Conversely, the sea level at the Caspian Sea on Kazakhstan's western border, which is also heavily polluted, is steadily rising.

As in many former Soviet republics, Kazakhstan was left with a legacy of toxic chemical sites created by the defense industry. Radiation residue from test ranges places all life forms at great health risk. Fourteen percent of Kazakhs lack access to safe drinking water, and 28 percent lack access to improved sanitation. In urban areas, where 55.9 percent of the population reside, industrial pollution is widespread. The country produces 0.5 percent of the world's carbon dioxide emissions. Kazakhstan's two main rivers, which were diverted from their course toward the Aral Sea, are also drying up. Conversely, the sea level at the Caspian Sea, which is also heavily polluted, is steadily rising.

Agricultural mismanagement, including overuse of poisonous chemicals, has polluted the soil; and poor infrastructure and improper irrigation have produced salination. In 2006, a study by scientists at Yale University ranked Kazakhstan 70th out of 132 countries in environmental performance, slightly above the relevant geographic group and below the relevant income group. The lowest score was received in the category of biodiversity and habitat. With 4.5 percent of the country forested, only 2.7 percent of Kazakhstan's land area is protected. Sixteen of 178 endemic mammal species are endangered, and 15 of 379 endemic bird species are likewise threatened.

A large grassroots environmental movement has surfaced in Kazakhstan. The largest group is the Nevada-Semipalatinsk, which gathered more than two million signatures within a week in 1989 to force a ban on nuclear testing. Operating under the National Environmental Action Plan for Sustainable Development, the Ministry of Natural Resources and Environmental Protection has the responsibility for policy planning and implementation of environmental laws and legislation in Kazakhstan.

The U.S. Environmental Protection Agency and international agencies such as the World Bank and the International Monetary Fund are also heavily involved with cleanup activities in Kazakhstan. The government has signed the following international agreements: Air Pollution, Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Ozone Layer Protection, and Ship Pollution. The Kyoto Protocol has been signed but not ratified.

Kennedy, John F. Administration

JOHN F. KENNEDY (1917–63), a Democrat, was the 35th president of the United States. Elected in 1960 and assassinated three years later, Kennedy was succeeded by his vice president, Lyndon B. Johnson. Kennedy was a glamorous and charismatic figure from a large and influential family in Boston, Massachusetts.

Kennedy narrowly won the 1960 presidential race, having defeated the Republican candidate, Richard M. Nixon. Kennedy's 1,000-day presidency was dominated by the threat of the Cold War and Communism. Kennedy was determined to advance the American national interest by combating Communism around the world. This led to an escalation of support for the government of South Vietnam and, ultimately, to the full-scale American war in Vietnam.

Kennedy presided during a period when environmental policy and issues were largely state and local level regulatory affairs and pollution controls were managed primarily through nuisance law. As a result, his administration has no direct environmental legacy in policy innovation. Nevertheless, the Gemini and Apollo programs, designed to put a man on the moon in less than a decade, radically reconfigured not only the relationship of science and engineering in the government but resulted in some of the most important transformations of human relationships with the planet.

The development of the National Aeronautics and Space Administration (NASA), an interdisciplinary science and engineering effort, linked military flight engineering and experimentation. This innovative conglomeration of expertise, funded heavily from federal sources, not only propelled attention to the moon, but also resulted in countless ancillary benefits of innovation in environmental management, materials engineering, and computing. The legacy of the Apollo program in directing science and engineering research and inspiring young people to pursue education in physical and environmental sciences fundamentally changed America.

Less instrumentally, the Gemini and Apollo programs resulted in startling images of the earth as seen from space, images that would help to transform the imagination of people around the world towards seeing the planet not as a boundless and differentiated place, but as a unified and fragile one. This image and others that followed over the next decades are fundamental to the global imaginations of contemporary environmentalism, and are essential even to the founding of "Earth Day," with its ubiquitous picture of the globe.

Kenya

THE REPUBLIC OF Kenya is a relatively young geopolitical entity, having gained independence from British rule in 1963. Yet, the area that comprises present-day Kenya and its East African neighbors has been called the cradle of humankind, due to fossil evidence that suggests the region has been a hub of hominine activity for over 4 million years. While Kenya's landscapes are renown for their wildlife, nature reserves, and national parks, continuous human and prehuman presence means they are entirely anthropogenic.

Kenya is bordered by the Indian Ocean and Somalia to the east, Ethiopia to the north, Sudan to the northwest, Uganda and Lake Victoria to the west, and Tanzania to the south. The country is bisected by the equator. With an area of approximately 225,000 square miles (about twice the size of Arizona), Kenya has great geographic diversity. It includes wide, sandy beaches and coral reefs along the coastal belt; the Eastern African plateau with its semiarid plains; the Rift Valley, its series of lakes, and its surrounding fertile uplands; northern deserts; and Mt. Kenya's snow-capped peaks at 5,199 meters above sea level, making it Africa's second tallest mountain, the tallest being neighboring Tanzania's Mt. Kilimanjaro.

The few millennia prior to colonization saw population increases and subsistence practice shifts due to in-migrations of Cushitic, Nilotic, and Bantu speakers. Although Arab traders had settled the East African coast a millennium beforehand and established a string of thriving Swahili city–states, the Berlin Conference (1884–85) marked the beginning of colonial demarcation of African land, through which Britain claimed an area including today's Kenya. The Imperial British East Africa Company (IBEAC) received a royal charter in 1888 to "prepare" the colony and promote its commercial interests, and to some degree it did. However, the IBEAC went bankrupt by 1895, after which the British government assumed direct control over Kenya.

By the mid–1890s, the British had relocated, recruited, and imported enough people to begin work on the Kenya–Uganda railway. With its railhead in Nairobi, the railway stretched from coastal Mombasa to Lake Victoria by 1901, thus further opening the interior of Kenya to British and Asian settlers, farmers, and traders. British colonists restricted access to land and animals, relocated Africans (Maasai and Gikuyu) into reserves, and established means by which they could act upon the Dual Mandate: the notion that the colonial enterprise was not only meant to benefit resource-challenged, industrial and expansionist Britain, but also to enable the "development" of Africans. A British crown colony by 1920, Kenya Colony attracted increasing numbers of white settlers, whose social and economic investments in Kenya severely disrupted the ideals of indirect rule established by the British crown. Settlers and colonial administrators relied on the labor of colonized peoples to build the infrastructure for transporting cash crops and other raw materials to Europe. Colonial rule imposed systems of taxation, compulsory labor, cash-based markets, and limited, skills-based education on Africans.

Kenya's expansive game reserves were meant to serve colonists and elites from abroad. The game reserves of the late 1890s and early 1900s were eventually replaced by national parks and reserves (1946 onward), as well as a conservationism that led to a thriving tourist industry and a post-colonial ban on sport hunting in the 1970s.

Kenya's independence from British colonialism in 1963 followed a period of bloody conflict called the Mau Mau, or the Emergency, which lasted from 1952–60. The Gikuyu-dominated Land and Freedom Army (LFA) rose against the British colonial government to fight for fair representation and access to the lands from which they had been alienated.

Post-independence Kenya has been described as simultaneously stable and corrupt. Jomo Kenyatta, president from 1963–78 and known as Baba wa nchi (Father of the State), established a patrimonial, patronage system of government. Kenyatta and his successors, including current president Mwai Kibaki, have embraced pro-capitalist, modernization theory and its attendant emphases on large-scale, export-oriented agriculture and industrialization.

Although only an estimated 8 percent of Kenya's land is arable, nearly three-fourths of Kenya's labor force engages in agriculture. Chief cash crop exports include cut flowers, tea, coffee, and horticultural products. Much of the expanding industrial sector of Nairobi take advantage of Kenya's export processing zone and the country's status as

Kenya is renown for its wildlife, nature reserves, and national parks; its landscape has great geographic diversity.

the regional center for trade and finance. Tourism and ecotourism remains among the most significant foreign revenue earners in Kenya.

Today's Kenya has a population of nearly 35 million, half of whom are listed as living at or below the international poverty line; the median age is 18 years. Unemployment estimates range between 25–40 percent in Nairobi.

Although Kenya is renown for its biodiversity, it is also beset by multiple environmental issues that have coevolved with the rapidly growing population—which has more than doubled since independence—as well as through the diffusion of people, technologies, ideologies, and introduced species. Current environmental problems include deforestation; soil erosion; desertification; water pollution from urban, suburban, and industrial wastes; diminished water quality from increased use of pesticides, herbicides, and fertilizers; water hyacinth infestation in Lake Victoria; wildlife poaching; recurring drought; and flooding in some regions during rainy seasons. Other significant large-scale concerns include malaria and HIV/AIDS.

The 2004 Nobel Peace Prize was awarded to Kenya's *Mama Miti*—mother of the trees—Wangari Maathai. Maathai has been a prominent figure in Kenya for decades because of her commitment to environmental issues, democracy, and human rights. The first Kenyan woman to earn a Ph.D., she founded the world-renowned Greenbelt Movement in 1977, served as a leader of Kenyan Debt Relief Network and its partnership with Jubilee 2000, and has received numerous international awards for her work. In 1989, Maathai received international attention for her historic opposition to then-President Moi's attempt to erect a skyscraper in Nairobi's Uhuru Park. Maathai charged Moi's government with grabbing public land and intensifying Kenya's debt crisis when Kenyan citizens faced starvation, land insecurity, and diminished access to health care and education. Maathai's arguments convinced foreign investors to pull out of the project. Elected in December 2002 as a member of parliament (MP), Maathai now serves as Kenya's Assistant Minister for the Environment, Natural Resources and Wildlife. Maathai's receipt of the Nobel Prize is significant for the link it makes between environmental issues and peaceful governance.

Keystone Species

THE TERM *KEYSTONE* was introduced to the fields of ecology and conservation biology in 1969 by Robert T. Paine, a professor of zoology at the University of Washington. A keystone denotes one stone at the top center of an arch or vault that provides critical structural support. Due to the keystone's strategic location, if removed, the entire arch will collapse to the ground. This in essence explains the role of keystone plant and animal species—they are the central critical piece holding other associated species together.

Similarly, in the natural world there are *keystone resources* (natural resources like food, water, mineral deposits, shelter, mineral deposits, among others) on which a variety of species depend. When a keystone resource is threatened, lost or become unavailable, it needs to be supplemented by artificial means such as the setting up of wildlife feeding stations, artificial waterholes, salt licks, and the creation of wildlife refuges to arrest the loss of important wildlife habitat.

Keystone species have become an important concept in conservation biology because of the disproportionate influence they have in relation to their abundance in the environment. In a biological community, they can hold power over other species by determining which species propagate and which do not. This has led to the prioritization of keystone species for conservation.

Ironically, the keystone function of a plant or animal is usually recognized when the species is removed or lost from an ecosystem. As a result of Robert Paine's groundbreaking research on the ecology of the sea otter and the biodiversity of marine communities in the Pacific Northwest, we know that sea otters play a keystone role by consuming and regulating sea urchins. Sea urchins feed on forests of giant kelp and bull kelp, and an explosion in sea urchin populations can destroy kelp forests. This helps maintain marine biodiversity, allowing California sea lions, harbor seals, sea otters, and many other species to feed and shelter in the kelp.

Top carnivores are some of the most visible keystone species. Wolves are threatened around the world for different reasons; they can seriously affect rural milk and dairy economies by destroying livestock, and in parts of Asia, wolves are hunted in the belief that they are child-lifters. In areas from where the endangered gray wolf was exterminated, populations of deer have increased, resulting in overgrazed habitats that cannot support other herbivores and insects.

Examples of other keystone species include pollinators and seed dispersers in tropical forests such as bats essential to the reproduction of many trees; species called *ecosystem engineers* (e.g., beavers) because the new wetland habitats they create are used by other species; elephants, which help maintain grasslands by browsing on and removing trees and bushes that would otherwise shade out grasses; and disease-causing organisms that multiply and regulate excessive animal populations.

Animals are not the only keystone species. Fig trees comprise a small proportion of all trees in a forest but produce a copious and continuous supply of fruits critical to many birds and small animals, especially during a drought. Adding new information to the knowledge base on keystone species is an ongoing activity that helps continuously improve wildlife and forest management. For example, fig trees and keystone resources, like den trees and fallen trees that shelter many animals and provide unique humid environments for plant regeneration, are now often retained during forest logging operations.

Kilimanjaro, Mount

MOUNT KILIMANJARO IS a mountain in the African country of Tanzania near the border with Kenya. Kilimanjaro is actually a massif, a mountainous complex with a number of peaks, the highest being Uhuru Peak at 5,895 meters, the highest point of land on the continent of Africa. The massif is considered a strato-volcano containing magma 400 meters below the surface. No eruptions have taken place in the modern era.

Mount Kilimanjaro came into prominence in 2000 when researchers reported that its glaciers and ice fields were fast disappearing. The most prominent explanation for this phenomenon was global warming, which has also been blamed for the loss of comparable ice accumulations on a number of other mountain ranges in the equatorial regions. Studies in the early 2000s by researchers from Ohio State University indicated that the Kilimanjaro ice field began forming over 11,000 years ago and that three extensive droughts occurred before the drought during the 21st century. However, none of these resulted in the complete loss of ice cover. Other factors also contribute to loss of ice cover. Forest cover on Kilimanjaro’s slopes has been severely reduced for agricultural expansion and from forest fires caused from the smoking out of bees from their hives for honey collection. Forest reduction brings about a loss of moisture entering the atmosphere, lower precipitation levels, increased short wave radiation, and hastened glacial evaporation.

The demise of the Kilimanjaro ice sheet is damaging the Tanzanian economy in a number of ways. Tanzania is already one of the poorest counties in the world; 90 percent of its population lives below the established poverty level of $2 per day. The country relies heavily on income from agriculture, which employs more than three-quarters of the workforce. Loss of the ice fields will greatly reduce the amount of runoff for downslope settlements during the dry seasons. Loss of the ice cover also results in the diminishment of hydroelectric generating potential and a curtailment in the supply of water for irrigation. If hydroelectric generation declines, the shortfall in power production will most likely be made up with an increase in the burning of fossil fuels, an increase in greenhouse gasses, and more global warming. Tanzania and other African countries were already under severe development pressure before the demise of the Kilimanjaro ice sheets. Studies have been initiated by the United Nations to find ways in which science, technology, and innovation can be brought to bear on the socioeconomic difficulties in African countries.

Klamath Basin

THE KLAMATH BASIN is a watery wildlife refuge area shared by California and Oregon, and drains the Kalmath River. It is located in Klamath, Lake, and Jackson Counties in Oregon and areas of DelNorte, Humbolt, Modoc, Sisiyou, and Trinity Counties in California.

The watershed of the Klamath Basin includes in Oregon the Sprague River, Williamson River, Sycan River, Link River, and Lost River, which is shared by both California and Oregon. It also includes Agency Lake and Upper Klamath Lake in Oregon. In California it includes the Shasta River, Scott River, Salmon River and Trinity River. California also holds Tule Lake, Lower Klamath Lake, and Butte Creek.

Much of the Klamath Basis is protected by the federal government. The Klamath Basin National Wildlife Refuges Complex is run by the U.S. Fish and Wildlife Service (USFWS). The refuge was started in 1908 as the first waterfowl refuge in America. Eventually, six wildlife refuges were established for both local and the millions of migrating birds on the Pacific Flyway that come every year. The six wildlife refuges were eventually united under the USFWS.

The ecology of the Klamath Basin Refuges varies widely over its area. It includes freshwater marshes, rock cliffs, grassy meadows, coniferous forests, juniper grasslands, hills, and other features. It supports many fish, bird, and predator species.

In a conflicting move, the U.S. Bureau of Reclamation began the Klamath Reclamation Project in 1905. The goal was to drain areas of the Klamath Basin so that agricultural fields could be created. In other areas of the upper Klamath Basin, dams were created to provide water to farmers. Thousands of acres of sage land were converted into cropland. The success of the Bureau left only 25 percent of the historic wetlands in the Basin by the end of the 20th century.

The Klamath is a study in Western water politics. Conflict has existed for decades over fishing and the water needed to preserve the health of the fish, as well as the health of the wildlife of the area versus the demand for water farming makes.

Knowledge

FEW ASPECTS OF human adaptation are as instrumental, and at the same time as difficult to define, as indigenous knowledge. The concept is knowledge with a technical and/or environmental component, which has been labeled by the overlapping terms *traditional environmental knowledge, indigenous technical knowledge, ethnoecology, folk science,* and *local knowledge*. These terms all refer to locally constituted understandings, innovative capacities, and environmental practices utilized by indigenous groups. These terms recognize a category of knowledge apart from that generated and disseminated by professional researchers, policy makers, marketers, or development personnel. It generally excludes the use of information delivered from formal institutions of knowledge. Day-to-day interaction of people with their environment shapes problem-solving strategies for indigenous populations and guides practices as varied as agriculture, resource management, health care, and environmental conservation.

The concern for indigenous knowledge arose largely as a reaction to the ignorance, misunderstanding, and dismismissal of indigenous practices. One reason was simple ignorance: explorers, missionaries, colonial officials, and even development experts consistently misunderstood the logic of indigenous practices and hence dismissed them. A classic recurrent example is swidden (slash and burn) cultivation, widely believed to an indigenous practice ignorant of its environmental effects (deforestation). While swidden cultivation can sometimes lead to deforestation, it is now known that it was practiced productively for millennia in many places, guided by indigenous knowledge of fallow land management.

Interaction with the environment shapes strategies for indigenous populations in areas such as as agriculture.

Corporations selling inputs such as hybrid seeds, pesticide and fertilizer, and development projects benefit from the image of hapless producers lacking knowledge. It is also convenient for commercial ventures and even local governments to neglect indigenous claims to the genetic resources they manage for commercial gain or funding.

SOCIAL SCIENCE RESEARCH

Early studies of indigenous knowledge were conducted primarily by anthropologists and other social scientists, and were aimed at documenting and understanding the nature, structure, and value of non-Western knowledge systems. It revealed an often surprising depth of knowledge and cohesiveness of the resource management strategies and world-views of indigenous groups. In the 1960s and 1970s, key works in cultural ecology lauded the knowledge underlying indigenous production systems; they also showed how ecological knowledge became culturally institutionalized. For instance, Kofyar cultivators in Nigeria knew how to maintain high levels of fertility on annually cropped infields, while their institutions of household formation and festive work parties “knew” how to mobilize labor to exquisitely match the demands of local ecology. By the 1980s, indigenous knowledge emerged as a major topic in its own right, and since then, there has been an outpouring of research on indigenous knowledge.

Several salient themes have emerged from this work. One is that there is a vital social component to indigenous knowledge. Within many indigenous populations, knowledge is widely shared among members of the group, and a tendency for relatively high agreement on, for instance, ethnobotanical knowledge. Indigenous knowledge is also closely linked to social institutions. The household tends to assume center stage in intensive smallholder cultivation systems, in large part because it is well suited to the knowledge-intensive techniques required by this form of cultivation. Indigenous knowledge may even be embedded in cultural institutions that individuals themselves do not fully understand. For instance, in Alpine Switzerland, researchers documented a complex mountain-wide system for managing irrigation schedules that no individual irrigator could describe.

Indigenous knowledge tends to be more holistic and experiential than the professionalized knowledge to which it is often contrasted. However, some criticize this view on the grounds that it constructs a false dichotomy between Western/scientific and indigenous epistemologies. Such a dichotomy holds Western science as the standard of comparison, while ignoring that all systems of knowledge are culture-bound. Furthermore, attempts to define the boundary of knowledge systems typically fail because knowledge and its reproduction are dynamic and cannot be fixed. There is also considerable diversity among indigenous knowledge systems, and just as many similarities as differences between indigenous and Western/scientific epistemologies.

It has become increasingly clear that indigenous knowledge systems tend to be hybrid, incorporating elements of Western/scientific knowledge. This hybridity is not, in general, a recent phenomenon. Some of the most insightful work on indigenous knowledge in recent years has provided historical analyses of how indigenous production systems have selected, altered, and adopted elements from Western scientific knowledge. Examples are work on Kenyan intensive terrace-farmers and Indonesian rubber cultivators.

POLITICS OF INDIGENOUS KNOWLEDGE

Several factors have led to a surge of interest back towards treating indigenous knowledge as a distinct, and even ownable, entity, and encompass and intersect theories of rural development, bioprospecting, and changes in intellectual property regimes.

Bioprospecting

The move to capitalize on indigenous knowledge contributed to a rise in "bioprospecting" ventures, in which scientists from industrialized countries collected and analyzed plants from tropical areas in search of medically valuable compounds. Bioprospecting endeavors frequently culled the potential value of indigenous knowledge of local plants and animals by working directly with indigenous farmers and herbal healers. Indigenous groups were rarely provided financial compensation for their contribution to these ventures. In response to this development, The United Nations Convention on Biological Diversity (1992) promoted equitable sharing of the economic and commercial benefits associated with the use of indigenous knowledge and genetic resources.

These developments coincided with an international movement towards strengthening intellectual property rights, at the center of which was the 1995 emergence of the World Trade Organization with its stipulation that all member nations provide patent (or comparable) protection for plant varieties. This nexus of rural development, bioprospecting, and intellectual property rights engendered a forceful international response that labeled this enterprise as "biopiracy" and intellectual property theft. This left indigenous knowledge at the center of a complex and hotly contested battle of globalization, with a range of disparate but important effects.

One effect was a trend by writers and nongovernmental organizations (NGOs) to reify and romanticize indigenous knowledge. Environmental campaigns have widely touted indigenous peoples as living in pristine harmony with their land. Such idealized depictions obscures the complex realities of people–environment interactions and belies the critical role indigenous knowledge plays in the survival of many minority groups. Romanticized images also undermine the economic and political interests indigenous groups may have in the use and regeneration of their knowledge.

Theories of rural development have changed considerably over time. From the 1960s until the 1990s, development initiatives were primarily oriented towards technology transfer and "top-down" approaches. Characteristically, these approaches saw practices based on indigenous knowledge as an impediment to development, or at best, "festive and folkloric dimension of cultural performance for tourist development." For instance, Green Revolution development programs undermined the temple-based rice fallowing system in Bali. However, the early 1990s saw the advent of the International Cooperative Biodiversity Group (ICBG), a grants program supported by the U.S. National Institutes of Health, National Science Foundation, and Agency for International Development. One of the program's goals was to foster development that capitalized on indigenous knowledge, especially of biodiversity.

DESKILLING AND DEMISE

Indigenous knowledge may be threatened, and in some cases severely disrupted. Environmental destruction and the cultural pressures of modern nation-states threaten the lifestyles and knowledge systems of indigenous peoples. The introduction of poorly understood technologies to indigenous cultivation systems may also prove destructive.

For example, researchers examining the effects of the spread of hybrid maize in the United States have suggested that this development led to "deskilling" of farmers, or an interruption of knowledge regeneration processes. Recent ethnographic studies among Telugu farmers in Andhra Pradesh, India, shows that agricultural deskilling is quite different from the natural replacement of one body of indigenous knowledge by another. Farmers need to be constantly acquiring and revising their knowledge to inform their decision making, and several key factors can disrupt this process. In the Andhra Pradesh case, the disruption occurred in cotton cultivation, and the culprits were reliance on hybrid seeds (which normally have to be repurchased each year) coupled with an anarchic cotton seed market. As farmers found themselves planting seeds of questionable identity and unpredictable performance, they found it increasingly difficult to acquire the requisite knowledge. Eventually, farmers turned to more or less indiscriminate mimicry of each other's cultivation practices, regardless of their efficacy.

Researchers probing the relationships between environmental and cultural change among indigenous groups advocate allowing indigenous peoples to preserve and regenerate knowledge *in situ* in their local environments, rather than documenting knowledge *ex situ* in computerized databases. Reflecting the considerable diversity of indigenous groups and cultural practices worldwide, indigenous peoples range widely in their views regarding how best to regenerate their knowledge systems, and moreover, how the ownership rights of knowledge and the genetic resources it manages should be determined.

Documenting Knowlege

There has been a surge in efforts to document and preserve indigenous knowledge. Discovery of the usefulness of indigenous knowledge, and the recognition that indigenous cultures are rapidly disappearing, have prompted governments, NGOs, commercial researchers, and indigenous groups to lead campaigns to document indigenous knowledge, particularly ecological knowledge, in computerized databases. These organizations offer competing views on their purpose and method of documentation, including codifying and documenting knowledge for general use, preserving it for future generations of indigenes, or to stake claim to patent rights on genetic resources for indigenous groups.

One critique is that this form of data preservation effectively divorces indigenous knowledge from the very context in which it has been useful for indigenous groups. The codification of knowledge into databases also suggests the existence of a definable body of knowledge that is timeless and unchanging. Other controversies have arisen from attempts by local groups to exert political and economic control over indigenous knowledge in the face of bioprospecting projects.

Korea, North

JAPAN ANNEXED THE independent kingdom of Korea in 1910, continuing to occupy the country until the end of World War II when the country was split into North and South Korea. Although allied with the Soviet Union, the communist dictator of the Democratic People's Republic of Korea (North Korea) managed to resist total domination by either the Soviets or the Chinese. At the same time, South Korea maintained a close alliance with Western powers. Despite enormous international pressure, North Korea has refused to suspend a suspected nuclear weapons program. Significant economic resources in North Korea go toward maintaining the one-million-strong army and the development of weapons, which leads the population of 22,912,000 to depend heavily on international aid for survival.

With a per capita income of $1,800, the country is the 46th poorest country in the world. Although 36 percent of the workforce in the centrally planned economy is engaged in agriculture, a series of natural disasters and systemic problems have led to major food shortages since the 1990s. With a growth rate of only 1 percent, North Korea is experiencing severe economic hardship. South Korea has provided fertilizer assistance, and international agencies have provided food. However, at least 36 percent of the population is undernourished, and one-fifth of all children under the age of five are underweight. Because information on many social indicators is not released, the United Nations Development Program does not rank North Korea's standard of living.

ENVIRONMENTAL CONDITIONS

Located in the northern half of the Korean Peninsula and bordering on the Korea Bay and the Sea of Japan, North Korea has a coastline of 1,547 miles. The climate is temperate, and rainfall usually occurs only in the summer. In the late spring, droughts may be followed by severe flooding. Occasional typhoons are possible in the early fall. The terrain is generally comprised of hills and mountains interspersed with deep, narrow valleys, but wide plains fill the landscape along the coast.

Specific information on environmental problems in North Korea is sketchy because of the closed society. In August 2003, the North Korean government published its first State of the Environment report, written by the National Coordinating Council for the Environment, which was made up of 20 government and academic agencies who worked with UN officials to assess North Korea's environment. The report revealed that the major environmental problems include water pollution, deforestation, and soil erosion and land degradation.

With almost three-fourths of land area covered by forests, deforestation has accelerated in response to commercial logging, fuelwood, agricultural clearing, and insects and fires in times of drought. Only 2.6 percent of the land is protected by the government, and biological diversity has diminished with at least 13 endemic mammal species and 19 endemic bird species in danger of extinction. Over 60 percent of the people live in urban areas. Consequently, waste

North Korea's Pyongyang

The city of Pyongyang, located on the Taedong River, was founded, according to tradition, in 1122 B.C.E. on the site of the legendary capital of the founder of Korea, Tangun, who reigned in 2333 B.C.E. In 108 B.C.E. There was a Chinese trading center at Pyongyang, which was subsequently fortified and was the capital of the Koguryo kingdom from 427 until 668 C.E., when it was captured by the Chinese. It was then the secondary capital of the Koryo dynasty who ruled from 918 until 1392, Kaesong being their seat of government.

In 1392 the new Yi dynasty moved the capital of the country to Seoul, with Pyongyang going through a short period of decline. In July 1592 the city was sacked by the Japanese, and retaken by the Chinese in the following year. In 1627 the Manchus captured the city, which they left in ruins. With the opening up of Korea from the 1880s, Christian missionaries established as many as 100 churches in the city. However during the Sino-Japanese War of 1894–95, the city was again sacked, and then devastated by plague. It was rebuilt as an industrial center by the Japanese, who renamed it Heijo. In 1945 it became the capital of communist North Korea.

During the Korean War, the city was heavily bombed with most of it destroyed. It was fought over in 1950 when United Nations forces captured it, but it was retaken by the Chinese communists in the following year. After 1953 it was rebuilt on a grandiose scale. Massive monuments, vast sports and cultural complexes, and large statuary dominate the skyline. A few parts of the original city walls survive, but many of these have been moved to new locations.

During the 1970s, Pyongyang, the capital of North Korea, remodeled itself as a "Garden City." Officially it has more greenbelt than any other capital city in the world. it is also a major textile and food-processing center for the rest of the country with a thriving silk industry, and many factories. It has a population of 2,811,500.

management and energy consumption are of major concern. Untreated water and sewage is discharged directly into rivers. Soil deterioration has been a direct response to natural disasters, deforestation, and the use of chemicals in industry and agriculture. Although the entire population technically has access to safe drinking water, there is a shortage of potable water. Forty-one percent of the population does not have access to improved sanitation, and food and waterborne diseases are common.

North Korea's commitment to global environment is limited to ratification of the following agreements: Antarctic Treaty, Biodiversity, Climate Change, Environmental Modification, Ozone Layer Protection, and Ship Pollution. The government has signed the Law of the Sea agreement, but it has not been ratified.

Independent Scholar

Korea, South

AT THE END of World War II, the Allied victors released Korea from Japanese occupation. With Soviet troops in the northern half of the peninsula, and U.S. troops occupying the south, the onset of the Cold War resulted in the division of the country into two separate states, North Korea and South Korea. After an invasion by the north, thwarted with U.S. and United Nation (UN) forces, the armistice of 1953 established the Republic of Korea (South Korea) with a northern border along the 38th parallel. Through close government and business cooperation and strategic planning, over the last several decades, South Korea has transformed itself from one of the poorest economies in the world to a trillion-dollar economy. With a per capita income of $20,400, South Korea is now the 51st richest country in the world. The UN Development Program (UNDP) Human Development Reports rank South Korea 28th in the world in overall quality-of-life issues.

South Korea is located in the southern half of the Korean Peninsula. Bordering on the Sea of Japan and the Yellow Sea, the country has a coastline of 1,496 miles. The climate is temperate. Rain tends to be heavier in winter months. The terrain is mostly hilly and mountainous except in the west and south, which is composed of wide coastal plains. South Korea is subject to occasional typhoons with accompanying winds and floods, and there is low-level seismic activity in the southwest.

A period of environmental degradation accompanied South Korea's rapid economic growth, and over 80 percent of the population of 48,423,000 live in urban areas. With 205 cars per 1,000 people, South Korea produces 1.9 percent of the world's share of carbon dioxide emissions. The discharge of untreated or improperly treated sewage and industrial effluents into water resources have resulted in extensive water pollution, which has adversely affected rice farming. Skin diseases have surfaced in a number of areas in response to contact with polluted water. Drift net fishing is likewise creating hazards. Eight percent of the population lack access to safe drinking water.

More than 60 percent of the land in South Korea is forested, but acid rain has damaged many areas. The government has protected 6.9 percent of the land area. Of 49 mammal species endemic to South Korea, 13 are endangered. Of 138 endemic bird species, 25 are likewise threatened with extinction. In 2006, scientists at Yale University ranked South Korea 42nd of 132 nations on environmental performance, below the relevant income group but well above the relevant geographic group. The lowest rankings were received in the categories of air quality, the production of natural resources, and biodiversity and habitat.

The Minister of Environment is responsible for oversight and implementation of a body of environmental laws and regulations that were passed from the late 1960s through the 1990s. The Asian financial crises of 1997 and 1998 created a setback in South Korean environmentalism, forcing the government to postpone its Long-Term Development Plan and di-

Siberian Tiger in the DMZ

The Amur, or Siberian tiger, has a particularly important symbolic role in Korean history and was revered by many people as being sacred. An Amur tiger called Hodori was chosen to represent the 1988 Summer Olympic Games held in Seoul, South Korea.

Although the tigers did roam in the forests, and were always rare, it was during the Japanese occupation of Korea from 1910–45 that hunting of the tiger is thought to have driven them to extinction in Korea, although a few exist in some parts of China. North Korea claims that there are tigers in the areas around Mount Paekdu, the official birthplace of North Korean leader Kim Jong Il, and also around Wagalbong Mountain and Chuae Mountain. None exist in the wild in South Korea, although there have been claims that a few might have survived in the demilitarized zone (DMZ) which divides the two Koreas.

The South Korean naturalist Lim Sun Nam has devoted his life to trying to prove the existence of tigers in the DMZ. He resigned from his job, sold his house and along with his family and older brother, spent many years in Siberia learning how to track tigers and spot the signs of their presence. In his unprecedented work in the DMZ he has found footprints and fur, as well as eyewitness testimony, but detractors argue that the footprints could be from wild dogs, and the eyewitness accounts are vague or exaggerated. Nevertheless, Lim Sun Nam, nicknamed the "Tigerman," spends all his time in the DMZ on his so-far elusive quest.

vert funds intended for the environment to economic recovery. However, existing environmental laws and regulations combined with strict enforcement have led to a decrease in emissions of sulfur dioxide and other air pollutants. Unfortunately, high levels of carbon dioxide emissions have somewhat offset this gain. As a result, government incentives have been instituted to deal with this problem. It has been predicted that over the coming decades, increasing levels of coal consumption used to generate electricity will substantially increase air pollution in South Korea.

Efforts to address environmental problems have led South Korea to build more than 50 nuclear power plants, thereby reducing reliance on traditional methods of energy. The National Vision for Environmental Policies in the 21st Century was established and charged with planning environmental policy that will promote environmental responsibility while maintaining economic growth. Industries such as the Dusan industrial plant, which released 30 tons of phenol-contaminated wastewater into the Nakdong River during a chemical leak in 1991, are now strictly controlled.

South Korea's commitment to the global environment is expressed through participation in the following international agreements: Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling.

Kropotkin, Peter (1842– 1921)

PETER KROPOTKIN [PYOTR Alekseievich], anarchist and geographer, was born in Moscow into a princely family. He was educated at the Corps of Pages (1857–62), an elite military school in St. Petersburg, and served as an officer in the Far East where he undertook important work in exploration, glaciation, and orography with the support of the Imperial Geographical Society, whose gold medal he was awarded. He resigned his army commission in 1867 to study mathematics at St. Petersburg University (1867–68) and then continued his geographical work on the Far East, extending his glacial studies to Finland and Sweden. He had already repudiated his title of prince, and on a visit to western Europe in 1872 he turned to anarchism, returning to Russia to join the revolutionary Tchaikovsky circle in St Petersburg. He was arrested in 1874 and held without trial, but escaped in 1876 and went into exile in the West. In 1878 he married Sofiya Grigoryevna Ananyeva-Rabinovich.

Under Kropotkin's influence, the international anarchist movement developed an ideology known as *anarchist communism*. Kropotkin was imprisoned in France in 1883, but was granted amnesty in 1886 and came to England where he stayed until 1917. He continued the work as a scientific journalist that he had begun on an earlier visit to England (1876–77) with the support of the geographer John Scott Keltie. He also continued to develop his social and political thought, which was influenced by geographical ideas of the interdependence of nature and society. His stress on the cooperation and mutuality evident in nature and in human history made his arguments attractive to many contemporaries, though some later commentators deprecated his lack of emphasis on class antagonism. Conversely, such commentators approved his argument that the final stages of his historical schema would come through popular revolution. He was influenced by his friend and fellow geographer and anarchist Elisée Reclus, to whose *Nouvelle Géographie Universelle* (1875–94) he contributed. Some of Kropotkin's numerous articles were collected in books, of which *The Conquest of Bread* (1892) and *Mutual Aid: A Factor of Evolution* (1902) were the most influential. His books and articles were published in many European languages and commanded a wide audience. He contributed scientific articles to the *Geographical Journal* and *Encyclopaedia Britannica,* the 11th edition of which also contained his important article on anarchism (1910).

Kropotkin returned to Russia in 1917, the year of the revolution for whose success he had long worked. He settled in Moscow but moved to Dmitrov, where he died on February 8, 1921. His funeral in Moscow on February 13 brought together fellow anarchists in demonstration of their support of ideas for which the prevailing Bolshevik regime had no sympathy. Kropotkin was remembered in geographical circles for his work on glaciology, desiccation, and orography, where his discoveries and hypotheses, even where wrong, stimulated important subsequent research. His wider impact, however, was due to his work on anarchism which, under his influence, became an attractive ideology, though one that went unrealized after developments in his homeland took a very different ideological turn.

Kudzu

KUDZU IS A woody or semiwoody, perennial, deciduous, and leguminous vine. Kudzu grows in a wide range of conditions and soil types, and thrives in areas with abundant sunlight and rainfall, and warm summers and mild winters. Kudzu vines can reach 100 feet in length, and will grow up and over trees, buildings, hillsides, and across flat ground. Kudzu's relatively high rates of energy expended in photosynthesis, ability to fix nitrogen, and tendency to root rapidly contributes to its rapid spread. Once established, kudzu can grow up to 12 inches per day in peak conditions, with tap roots averaging 4–8 inches in diameter and up to 6 feet in length. Such a large root mass may weight up to 400 pounds and can store water, enabling the plant to survive occasional droughts.

The genus *Pueraria* includes 17 species spanning its native range from China and portions of India to Korea, Japan, Malaysia, and Indonesia. The vine has been integrated into medicines, cuisines, textile production, livestock fodder, and more for over two millennia. From China, kudzu and its uses easily spread to Asian neighbors long ago. The vine is not considered a pest in that region because its growth is limited by climatic conditions, certain insects, and its multiple uses for humans.

Kudzu's uses inspired many introductions into different climes around the world. It has reputedly taken hold without negative consequence in parts of South America, Switzerland, and Australia's eastern territories, but its growth rate in the United States beats all. There, kudzu shifted from an exotic species introduced for environmental benefit to being re-characterized as an invasive species and a biopollutant.

Kudzu seems an inherent part of the U.S. South, but it is a relatively recent import to the continent. Kudzu made its debut in the United States in 1876 at the Philadelphia Centennial Exposition, where Japanese participants had planted it to shade and decorate their pavilion. With a followup appearance at the New Orleans Exposition of 1883, kudzu became an aesthetic must. A booming mail-order business for kudzu hastened this process, as the vine was touted to grow where nothing else would.

From 1910 until the mid–1930s, kudzu was largely promoted for the production of livestock fodder, starch, cloth, and paper. By the 1930s, the Soil Conservation Service implemented numerous schemes through which the rapidly growing, nitrogen-fixing kudzu would rejuvenate depleted agricultural lands as well as reverse the effects of erosion along highways, byways, railways, and dam projects. Although some farmers had become leery of its aggressive growth, kudzu was declared "the miracle vine," and 20,000 card-carrying members were recruited to the Kudzu Club of America by the mid-1940s. Amidst the parades, rallies, and even Kudzu Queens, kudzu grew across 500,000 southeastern acres.

INTRODUCED SPECIES GONE WRONG

A mere decade later, attitudes shifted dramatically as kudzu notably overgrew its intended boundaries. In 1953, concerns about kudzu overtaking native trees and shrubs, as well as built structures, led the U.S. Department of Agriculture to remove it from the list of permissible cover crops. By 1970, kudzu became a weed, and by 1997, the U.S. Congress declared it a Federal Noxious Weed.

Today, kudzu covers approximately 7.5 million acres in the United States, most extensively in Alabama, Georgia, and Mississippi, with an estimated growth rate of 120,000 acres per year. There is a high degree of genetic diversity in current kudzu populations. Kudzu's emissions of isoprene (a photochemically reactive hydrocarbon), its ability to fix atmospheric nitrogen, and its tendency to overwhelm forest trees may substantially impact not only biodiversity, but also forest nitrogen cycles, watershed nitrogen saturation and freshwater eutrophication, and air quality. Kudzu exhibits markedly increased growth rates in response to high levels of carbon dioxide, which could in turn further increase kudzu's competitive dominance in an era of global warming.

Efforts to eliminate or reduce kudzu are difficult and expensive. Herbicides can be applied repeatedly for up to 10 years to kill an established population of kudzu, but the larger ecosystem consequences of such applications must also be considered. Experiments in natural and introduced biocontrols are ongoing, although critics note previous examples of the cane toad in Australia and that kudzu itself is an introduced species gone wrong.

Kudzu was brought to the U.S. as a "miracle vine," but now overtakes trees at a rate of 120,000 acres per year.

Larger-scale efforts to harvest the protein-rich, fibrous kudzu powder from its roots are ongoing, as are attempts to convert kudzu into biofuel. Naturopaths continue to investigate the myriad uses of kudzu in Asia and to adopt those healing techniques in the United States.

Kuwait

LOCATED IN THE strategically important oil region of the Persian Gulf, Kuwait achieved its independence in 1961. In August 1990, Iraqi forces invaded Kuwait, but were forced to withdraw after the United States and the United Nations (UN) launched a retaliatory strike in February 1991. While retreating, the Iraqi military intentionally set fire to 60 oil wells and dumped 4 million barrels of oil directly into the Persian Gulf. The Kuwaiti government was subsequently forced to spend $5 billion to renovate its oil infrastructure, and the environmental impact will continue for decades.

Kuwait's natural resources include petroleum, fish, shrimp, and natural gas. Accounting for close to half of the Gross Domestic Product, 95 percent of export revenues, and 80 percent of overall government revenue, the petroleum industry is Kuwait's most valuable resource, representing 10 percent of world reserves. Kuwait has a per capita income of $22,100, making it the 43rd richest nation in the world. However, approximately 80 percent of the workforce of 1.67 million are non-Kuwaitis, whose income is a small fraction of that of native Kuwaitis. The UN Development Program (UNDP) Human Development Reports rank Kuwait 44th of 232 nations on overall quality-of-life issues.

Along the Persian Gulf, Kuwait's coastline runs for roughly 310 miles. The terrain is generally flat with desert plains that undulate slightly. Kuwait's dry desert climate produces intensely hot summers and short, cool winters. From October to April, sudden damaging cloudbursts and heavy rain are frequent, and sand and dust storms are most likely to take place between March and August.

ENVIRONMENTAL CHANGES

Because of limited access to freshwater resources, the Kuwaiti government has installed sophisticated desalination facilities. Three-fourths of all potable water used in Kuwait is either imported or distilled. Less that 1 percent of the land is arable. Because the government limits agricultural development, most of the food supply is imported. Other environmental problems include air and water pollution and desertification. With 96.2 percent of the population residing in urban areas, Kuwait's carbon dioxide emissions rose from 19.7 per capita metric tons in 1980 to 24.6 in 2002. Kuwait produces 0.2 percent of the world's supply of carbon dioxide emissions. The government has converted to unleaded fuel and implemented modern technologies designed to reduce emissions of sulfur and toxic gases. Forested land in Kuwait amounts to only 0.3 percent of the total land area, and these forests are generally part of the plantation system where exotic tree species are grown. Only 1.5 percent of Kuwaiti land has been brought under national protection. Of 21 endemic mammal species, one species is threatened. Seven of 35 endemic bird species are endangered.

Kuwait passed its first environmental legislation in 1964 to check the spread of oil pollution in navigable waters. In 1986, the government began monitoring the quality of air and sea water. Over the next four years, the National Ecological Network was established to promote biodiversity. The Kuwaiti government has expressed commitment to the global environment by participating in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Law of the Sea, and Ozone Layer Protection. The agreement on Marine Dumping has been signed but not ratified.

Kyoto Protocol

THE KYOTO PROTOCOL was signed in December of 1997 and entered into force as international law in February of 2005. More than 160 countries are parties to the treaty, which is the cornerstone of the global climate change regime. Its main purpose is to impose binding commitments on industrialized nations to reduce their emissions of greenhouse gases, the major cause of global warming, within a specified time frame. The treaty also requires all signatory governments to submit national reports on their efforts to reduce emissions, thereby promoting transparency and compliance.

UNITED NATIONS AND CLIMATE CHANGE

The global climate change regime, centered around the United Nations (UN), represents one of the most ambitious projects in the history of international environmental law. In 1988, responding to concerns from scientists and environmental groups, the World Meteorological Organization and the UN Environmental Program (UNEP) established the Intergovernmental Panel on Climate Change (IPCC), a multinational group of scientists and other experts, to survey existing studies on global warming and to present their findings to governments. In 1990, the IPCC reported that global warming did pose a threat and was likely the result of human activities.

Thus, in the context of the 1992 UN Conference on Environment and Development (commonly known as the Earth Summit) in Rio de Janeiro, UN member states negotiated the Framework Convention on Climate Change (FCCC), the first international treaty to address the issue. The FCCC sets the objective of stabilizing greenhouse gas concentrations in the atmosphere and requires industrialized countries to inventory their emissions. The FCCC promotes the "precautionary principle," the idea that lack of full scientific certainty should not be used as an excuse for inaction. It also recognizes the notion of "common but differentiated responsibility"; while all countries have a responsibility to tackle climate change, the industrialized nations, given their historical responsibility and greater means, should bear a greater share of the burden than their developing country counterparts.

However, the FCCC was vague and imposed no binding commitments on states. In 1995, parties to the FCCC embarked on negotiations to create an additional agreement with specific limits on greenhouse gas emissions. Years of intense negotiations resulted in a new treaty, adopted in Kyoto, Japan, on December 11, 1997. The Kyoto Protocol sets targets for 39 industrialized countries to reduce their greenhouse gas emissions by 2012, with an average reduction of just over 5 percent below the established baseline levels of 1990. Many of the details on how to implement the protocol were left to future negotiations, which were completed in 2001 with the signing of the Marrakech Accords.

In order for the protocol to enter into force—to become binding international law—two criteria were established. First, at least 55 states would have to ratify. Ratification is the domestic legal process by which countries formally accept their treaty commitments. Second, these ratifications would have to constitute at least 55 percent of industrial nations' total emissions of greenhouse gasses. While the first threshold was crossed early on, several large emitters, including the United States (36 percent of industrial emissions), Japan (8.5 percent), Russia (17 percent), and Canada (3.3 percent) faced substantial domestic political obstacles to ratification. In March of 2001, U.S. President George W. Bush pronounced the treaty "fatally flawed," and withdrew his government from the Kyoto process. With strong European Union (EU) leadership and Russia's ratification in late 2004, enough emissions were covered to achieve the second threshold for entry into force, which went into effect shortly thereafter.

FEATURES OF THE PROTOCOL

The Kyoto Protocol outlines several different policy options in order to meet emissions reduction targets. Governments may employ a variety of "policies and measures" in the form of industrial, agricultural, and transportation regulation and incentives, as well as investment into improved energy efficiency and alternatives to fossil fuels, to reduce emissions of greenhouse gases. The protocol also allows governments to enhance carbon "sinks," which are natural mechanisms that draw carbon dioxide out of the atmosphere. Most sinks are in the form of forests, although land use techniques can also store carbon in the ground.

In addition to these domestic measures, the treaty also provides for three international policy options, commonly referred to as the "Kyoto mechanisms." First, the Clean Development Mechanism (CDM) allows industrialized countries (with binding emissions targets) to sponsor projects that reduce emission in developing countries (without binding targets). The former can earn credits toward their own targets through such practices, while the latter benefit from investment and infusions of cleaner technology.

Second, similar to the CDM, Joint Implementation allows industrialized countries to earn emission reduction credits by paying for projects in other industrialized countries. Third, government may meet their targets by engaging in "emissions trading." Those governments that exceed their required targets accrue credits, which can then be sold to governments that have not met their targets. This "carbon market" allows governments additional options of buying their way into compliance.

The principle behind these international mechanisms is that net emissions reductions are equally helpful wherever they occur since the atmosphere is a global commons. Without geographical constraints, investments into emissions reductions will flow to where they can be applied in the most cost-effective manner, providing both flexibility and efficiency.

Two additional features of the treaty are notable: the employment of successive five-year "commitment periods" and substantial reporting requirements. The first commitment period is from 2008 to 2012; the targets established in the protocol must be met by the end of that time. New targets will be negotiated for each subsequent five-year commitment period, and countries that are not bound by targets can assume commitments for future periods. To monitor compliance, all parties must submit national reports on implementation at regular intervals, and industrialized countries must provide additional information on greenhouse gas emissions and removals, including any activities under the international mechanisms.

Kyrgyzstan

THE KYRGYZ REPUBLIC attained its independence in 1991 after over a century of Russian/Soviet domination. Still in the process of defining itself as a nation, Kyrgyzstan is attempting to expand democracy and political freedoms while reining in government corruption, easing ethnic tensions, and combating terrorism. Some 55 percent of the population is involved in cotton, tobacco, wool, and livestock agriculture. Kyrgyzstan also exports gold, mercury, uranium, natural gas, and electricity. Kyrgyzstan remains poor with a per capita income of $1,800, and is ranked 186th in world incomes. Eighteen percent of Kyrgyzstanis are unemployed, and 40 percent of the people live below the national poverty line. The United Nations Development Program (UNDP) Human Development Reports rank Kyrgyzstan 109th of 232 countries in overall quality of life.

The landlocked, central-Asian nation has 2,780 square miles of inland water. The climate ranges from dry continental to polar in the higher elevations of the Tien Shan Mountain Range. The subtropical climate of the Fergana Valley in the southwest gives way to a temperate climate in the northern foothill zone. The land area alternates between the peaks of the Tien Shan, and its valleys and basins.

Kyrgyzstan has abundant hydropower and significant deposits of gold and rare earth minerals, but coal deposits and oil and natural gas reserves are suitable only for local exploitation. Less than 10 percent of the land area is arable, but Kyrgyzstan has the largest natural-growth walnut forest in the entire world.

Kyrgyzstan has signed a water-sharing agreement with four other Central Asian republics that limits domestic use to one-fourth of the water supply, most of which goes for irrigation. Consequently, almost a fourth of the population of 5,146,000 lack access to safe drinking water. A weak infrastructure and lack of funding has forced the government to rely on obsolete water purification systems; waterborne diseases are easily contracted from contaminated streams and wells. In mining areas, water supplies may be contaminated with heavy metal such as mercury, antimony, and uranium and with oils and sanitary wastes. Agricultural and livestock waste contaminates water in other areas. The Aral Sea has also been heavily contaminated with municipal, agricultural, and industrial waste.

Kyrgyzstan's status as a largely agricultural nation makes it environmentally vulnerable. Poor irrigation practices and management have led to salinity and depletion of the soil. Some 40 percent of the population have no access to improved sanitation. A chronic land shortage has been made worse by flooding agricultural lands for hydroelectric projects, several of which are located in seismically active areas.

Another major environmental concern is the Soviet legacy of uranium dump sites. About 230 mining facilities in Kyrgyzstan produce over 600 million cubic meters of toxic waste each year. Approximately 15 percent of land in Kyrgyzstan is protected. Of 83 endemic mammal species, seven are endangered, as are four of 168 endemic bird species. In 2006, scientists at Yale University ranked Kyrgyzstan 80th of 132 countries in environmental performance, slightly below the relevant geographic group but well above the relevant income group. The lowest scores were received in the areas of sustainable energy and air quality.

International agencies such as the World Bank, the Asian Development Bank, and nongovernmental agencies are providing funding and technical knowledge to Kyrgyzstan, and work with the State Committee of Environmental Protection and the Hydrometeorological Administration to implement and monitor environmental policy. In 1991, the government passed new legislation to update Soviet-era environmental regulations. Kyrgyzstan participates in the following international agreements: Air Pollution, Biodiversity, Climate Change, Desertification, Hazardous Wastes, Kyoto Protocol, and Ozone Layer Protection.

Lab Animals

INVERTEBRATE and vertebrate animals are vivisected for a wide range of laboratory research, testing, and teaching purposes. Vertebrates, however, serve as the primary experimental lab subjects for toxicity testing, as well as for pure and applied research by universities, corporate pharmaceutical testing labs, governmental health agencies, and the military. The number of vertebrates used annually as laboratory animals is estimated at approximately 100 million. Mice and rats are the most frequently used lab animals, but any animal may be bred, captured from the wild, or procured from pounds and specialized dealers for use in experimentation. While most lab animals are purposely bred, previously many wild animals were used in laboratories and this resulted in the depopulation of some species. For instance, population estimates for Indian rhesus macaques neared 10 million monkeys in the 1930s but, after a vivisection trade erupted for the animal due to its use in producing a polio vaccine and other experiments, their number was reduced to fewer than 200,000 by the late 1970s and India was forced to enact conservationist protections.

Vivisection of nonhuman animals has a long history dating back to early Greek manuscripts from the 5th century B.C.E. The Roman physician Galen first conducted experiments on dogs, monkeys, and pigs during the 2nd century C.E., utilizing vivisection to test biomedical hypotheses and study biological anatomical structures. Experimental surgery on animals in the context of modern science dates back to the work of Vesalius in the 17th century, but it was not until the 19th century that modern lab experimentation on animals became truly systematic and widespread through the work of scientists such as Claude Bernard, Louis Pasteur, and Robert Koch. Bernard, who is regarded as the founder of modern experimental medicine, held that laboratory experimentation on animals was essential for biomedical advances and he disparaged clinically based studies made by practicing physicians. By the late 1800s, scientists such as Pasteur and Koch made highly popularized advances in immunology and microbiology based on their own lab animal studies.

Anesthetics for animal experimentations were unknown until well into the 1800s and are not always used on animals even today. As a result, vivisected animals have often suffered greatly from experiments and therefore there has always been controversy surrounding the practice. During the 19th century, a strong anti-vivisection movement arose alongside animal research and its legacy

Animal Tests

The most common toxicity test is the LD 50, in which lab animals are administered an increasing amount of a substance until it proves fatal to 50 percent of them. This test remains widely instituted despite the fact that it has proven to be only relatively effective at determining human toxicity over the last few decades. Another common test, the Draize test, in which substances are dripped into lab animals' eyes to determine their capacity for irritation to humans has also been at the center of vigorous debate for its methods and clinical effectiveness.

An estimated 100 million vertebrates are used as laboratory animals every year.

currently lives on in animal welfare and rights organizations, humane societies, and more radical animal liberation groups. Largely because of their political action, laws governing the code and conduct of animal research now exist, but activists continue to argue that they are frequently not enforced and need to be broadened.

Alternatives to animal tests such as in vitro testing of cell and tissue cultures, epidemiology, and computer modeling exist; but many researchers insist that while they are useful, lab animal studies are also required to effectively monitor the thousands of drugs and tens of thousands of synthetic chemicals now on the market.

Researchers are promoting new forms of animal experimentation such as genetic modification of animals and xenotransplantation as necessary for achieving a new age of scientific breakthroughs. Many fear that these experiments unethically threaten society and the environment and should be regulated as a precaution. Yet, some genetic experiments on animals could result in improved animal and environmental welfare. For instance, Australian scientists have attempted to produce genetically modified sheep that would be resistant to flies and parasites. If successful, the inhumane act of mulesing sheep—surgically removing strips of skin from near the tail—and the heavy use of pesticides by the sheep industry would become unnecessary in the future. Therefore, while alternatives to laboratory animal science exist and should be increasingly utilized, some forms of lab animal experimentation could lead to environmental and societal improvements.

Lakes

LAKES ARE BODIES of water surrounded by land. They cover about one percent of the surface of the earth and contain about 0.02 percent of the water of the earth. Lakes are relatively new from a geological point of view. They are very transitory because they are continually being formed or destroyed. Some are destroyed because they are dried up by declines in their water source(s), or by silting, or by earthquakes, or by other geologic actions. Humans have also played a major role in the destruction of lakes. Excessive drawing down of the water levels of lakes by humans can easily destroy their unique ecosystems. For example, Lake Huleh on the Jordan River above the Sea of Galilee (Lake Tiberius) has been drained nearly dry in the last 50 years to supply human consumption.

Lakes vary widely in their biological, chemical, and physical features. Each lake has its own origin, occurrence, size, shape, sedimentation attributes, circulation patterns, water chemistry, water depth, and life forms. The water chemistry of lakes varies widely. In Croatia, the Plitvice Lakes have unique limestone water chemistries. The dissolution of the limestone rock has created mildly acidic water. The lakes are in the karst region where there are few other surface sources of water. In contrast, many other lakes have high acid concentrations or in other cases have a basic pH number. Some lakes are shallow; others such as Lake Superior and Lake Baikal in Siberia are thousands of feet deep. Some cover only small areas and others are vast seas.

The sedimentation patterns (lacustrine deposits) in lakes are very important to geologists. Lacustrine deposits in lakes that have not been subjected to the actions of glaciers are stable because they remain at the bottom of the lake forming undisturbed layers of sediment. The sediment characteristics of modern lakes are used to interpret the sedimentary records of ancient lakes. From these sediments in ancient lakes, conclusions can be inferred about the earth's climate and life forms in earlier geologic times.

Limnologists have classified lakes into 76 types. The major categories are tectonic, glacial, volcanic, dissolution, landslide-influenced, fluvial-influenced, wind-formed, coastal, and meteorite impacts.

TECTONIC LAKES

Great movements of the earth's crust have formed tectonic lakes. Lake Tanganyika, Lake Malawi, and Lake Victoria are African rift valley lakes. They are located in the Great Rift Valley, which also includes the Dead Sea and the Sea of Galilee (Lake Tiberius). Other tectonic lakes are Lake Baikal in Russia, which is in the Baikal Rift Zone of the Siberian Platform. In the United States, Lake Tahoe and Pyramid Lake in Nevada are in the Basin and Range Province of the west. There are other smaller lakes in the region that are also the result of great

Lakes cover about one percent of the earth's surface and contain about 0.02 percent of the water of the earth.

shifts in the earth's crust including Lake Bonneville and the Great Salt Lake. Some tectonic lakes are shallow. Reelfoot Lake in northwestern Tennessee was one of several lakes created by the New Madrid Earthquake (1811–12). Centered near New Madrid, Missouri, the quake is believed to have been of a magnitude of 8.0 on the Richter scale.

GLACIAL LAKES

When the glaciers retreated after the last ice age, they created numerous periglacial lakes. These were lakes formed by the ice sheet or glacier, and the ice created obstructions that blocked the flow of water. Many lakes in Scandinavia are glacial. The Great Lakes—Lakes Ontario, Erie, Huron, Michigan, and Superior—are glacial lakes. In addition, many lakes in Canada, including the Great Slave Lake and the Great Bear Lake, are glacial lakes. In North America, the retreat of the glaciers left depressions in the ground that have since filled with water. These potholes or kettle lakes are very important ecologically for the breeding of ducks, geese, and other waterfowl. In Europe, glacial lakes formed by glacial sediment creating natural dams include Lakes Geneva, Lucerne, Zurich, Constance, and many others in Austria and Slovenia. In New York, the Finger Lakes were formed from glacial action. Subglacial lakes are in liquid form even though they are covered with ice. Lake Vostok in Antarctica is the world's largest. The ice acts as a thermal insulator so that energy is retained in the water. In other subglacial lakes, pressure from the mass of the ice sheet keeps the water liquid. In some cases, geothermal heating causes the water under the ice to melt or to remain liquid.

VOLCANIC LAKES

Volcanic holes left by volcanic explosions or by collapse of a volcano provide collection points for volcanic lakes. Crater Lake in Crater Lake National Park, Oregon, was formed in a volcanic pipe or caldera created when the 12,000 ft. (3,660 m.) high Mount Mazama collapsed 7,700 years ago following a large eruption. Caldera or volcanic lakes are found around the world. Many volcanic lakes are very beautiful such as the Caldera de Taburiente on the island of La Palma in the Canary Islands.

DISSOLUTION LAKES

The erosion of bedrock forms dissolution lakes. Usually the rock is limestone. As it dissolves a cave is formed, and if the cave's roof eventually collapses, a sinkhole is created. Many lakes in Florida were formed as sinkholes. Silver Springs is one of the best known. Lake Skadar is a dissolution lake located at the southern end of the Dinaric Alps on the border of Yugoslavia and Albania.

OTHER LAKES

Eudorheic lakes are terminal or closed lakes with insignificant amounts of water flowing in or out. The primary method for water to leave is by evaporation. These lakes are usually located in desert areas. Lake Eyre in central Australia and the Aral Sea are examples. The Hueco Tanks in western Texas are natural rock basins containing trapped rainwater. The water leaves by evaporation or is removed by travelers. Meromictic lakes have a water chemistry that is unique. The various layers of water in the lake remain stationary and unmoved so that they do not mix. As a result, the bottom of the lake has not dissolved oxygen. It is often saline as well. These kinds of lakes will have bacteria that feed on sulfur compounds. Earthquakes can disturb the equilibrium in the layers of water and cause a limnic eruption. When this happens, the water in the lake overturns. There may be sudden triggering of carbon dioxide. In 1984, Lake Monoun in Cameroon overturned and caused the death of 37 people. In 1986, nearby Lake Nyos overturned killing 1,800 people.

Coastal lakes include those formed by water trapped behind sand dunes, such as the Okefenokee Swamp in Georgia. In northern Poland on the Baltic Coast, Lakes Lebsko, Gardno, Dolgie Wielkie, and Dolgie Male are coastal lakes formed by the isolation of part of a bay on the Baltic.

Meteorites, asteroids, and comets striking the earth are also a source of lake formation. Mistastin Lake in Newfoundland and Labrador, Canada, are thought to be impact crater lakes as is Lake Lappajarvi in central Finland.

Wind forms lakes, especially in hot or cold desert regions. Some lakes on the north slope of Alaska may be forming in this way. In hot desert areas playa lakes are standing bodies of water left after rare periods of rainfall. These lakes are soon dried by evaporation and leave precipitated salts on their shores to resemble a beach. The meandering of rivers can form lakes. Many ox bow–shaped lakes that are the remnants of the old riverbed parallel the lower Mississippi River.

By 2006 the Land and Water Conservation Act had resulted in the funding of some 40,000 projects.

Land and Water Conservation Act (1965)

THE LAND AND WATER Conservation Act of 1965, which was subsequently amended, was U.S. legislation designed to regulate access to and acquisition of land for the use of American citizens and the betterment of their health. During the late 1950s and early 1960s, there was concern that leaving the provision of public spaces and recreation opportunities to the private sector would lead to inadequate facilities and the enclosure of too much land for private use.

As the cold war intensified, the U.S. government also wanted to keep sufficient numbers of young Americans fit enough to fight in the army if required. As a consequence, a number of government agencies were empowered during the early years of the Kennedy administration so that national and state-level plans to implement enhanced land access were put into practice. Agencies and plans were supported by the creation of a Land and Water Conservation Fund that would use federal funds to purchase and maintain land areas for public use that were likely otherwise to have been used for housing or industrial development. Priority was given to areas with very high levels of population density, and the principle was adopted that land set-aside for public recreational use must be done so in perpetuity, unless it should be replaced by land of equivalent utility.

The act received bipartisan support and was signed on September 3, 1964. Funds were provided initially by such measures as charges for using national recreation areas, a tax on motorboat fuel, and the proceeds of sales of existing publicly held real estate properties. However, there was continual pressure on the fund to gather sufficient levels of money, not least because of the rising price of land where it became apparent that the government was willing to purchase it. Additional sources of funding were authorized and from 1971–89, an annual levy of $300 million was also provided. The vision of the act was modified to include more recreational land use within urban and residential areas, as well as within driving distance. This was important in helping poor people to partake of recreational areas despite lacking resources for transportation. Such use of shared public space also had a measurable beneficial impact upon urban living.

One of the most innovative components of the law was its Section 2, which established that the fund would be funded by federal revenues, especially including a proportion of receipts from oil and gas leasing on the Outer Continental Shelf. This lucrative source of capital, property of the people of the United States, has been utilized successfully to maintain the fund for decades, though not always to the degree intended by the original act.

By 2006 approximately $7.2 billion had been disbursed on some 40,000 projects in just about every part of the United States and overseas territories. The funds were provided equally from state and federal treasuries. State-level agencies have become increasingly innovative and imaginative in planning and managing outdoor resources in the interests of their residents.

After 1994 Congress also permitted the disbursement of funds from this program to reduce crime. The act has stimulated improvements in public management generally, and is an important symbol of the importance of the public sector providing common goods for all people that would be unavailable in a purely market-based system or with an insufficiently powerful government sector. The administration of George W. Bush proposed to end the scheme.

Land Cover

LAND COVER REFERS to the actual covering of the surface of the earth at any of its points. This includes plant life such as grasses, trees and forest cover, the sand of the desert, or the concrete and asphalt of developed areas. It is defined by the Food and Agriculture Organization (FAO) of the United Nations as "the observed (bio)physical cover on the earth's surface." It should be distinguished from *land use*, which explains what commercial or agricultural purpose to which a part of the earth's surface is being put, but the two may coincide in many cases.

It is estimated that of approximately 13,400 million hectares of dry land in the world, 3,325 million are suitable for cultivation and a further 156 million are used for urban infrastructure. Meanwhile, 774 million hectares are still under forest. These numbers are dwarfed in terms of raw size by water cover, which is approximately 70 percent of the total global land cover.

Many systems exist to classify different types of land cover, with two principal areas of difference being hierarchical versus nonhierarchical systems and a priori versus a posteriori systems. Hierarchical systems allow for subdivisions within broader categories while nonhierarchical systems tend to treat each separate type of land cover as a unique phenomenon. A priori systems posit a finite number of possible land cover types and then maps the ground to determine the extent to which each of these occurs, if necessary fitting observations into an existing scheme; a posteriori schemes, on the other hand, conduct mapping activities first and then seek to identify separable types of land cover, irrespective of whether they were anticipated or not.

Determining which scheme is most useful in any particular situation depends on balancing the need for inclusiveness with avoiding unnecessary complexity. The enormous expansion of computing power and computer memory available to scientists means that new and more sophisticated land cover mapping schemes are consistently being introduced.

Land cover is determined by mapping and, in the modern world, sophisticated satellite-based mapping systems that can be used for transmitting scanned data into computers directly through digital means. Since the time taken to complete full mapping activities can be extensive, completely up-to-date figures can be difficult to obtain, especially considering the rapidity with which land cover can change.

Many aspects of the classification of land cover are controversial in that they impact zoning regulations and the ability to develop land commercially. The extent to which commercial development is permitted to vary land cover is generally regulated by state-level controls but there may be some unregulated and unpoliced changes as well.

The form of existing land cover and the degree to which it is permissible to change this has considerable importance for opportunities to obtain commercial gain from the land. Hence, zoning controls and supervision are highly contested issues in most countries.

Land Degradation

GEOGRAPHERS Douglas Johnson and Laurence Lewis define land degradation as a significant decrease in either the biological productivity or the usefulness of a region for humankind. This definition initially appears quite straightforward, but since land degradation has both biophysical and social components, characterizing land degradation soon becomes much more complicated. The biophysical components are wide-ranging, including: soil erosion, soil fertility, vegetation diversity and coverage, and hydrological functions. The social components draw attention to the notion that "usefulness" has multiple definitions. *Land degradation* is a perceptual term that has different meanings to different people at various times and places.

Conventional definitions of land degradation classify land as degraded only when the decreased productivity is the result of human activities rather than natural events. Natural catastrophes—such as earthquakes or floods—often result in the decreased productivity of a region, and fall outside the conventional definition of land degradation unless they are exacerbated by human activities.

Additionally there is the growing awareness that the term *land degradation* has become part of a dominant environmental and resource governance discourse that often points to the most marginal peoples as the drivers of land degradation rather than seeking to understand the external political and economic factors that influence the land use practices of marginalized people. These multiple layers of complexity associated with land degradation make it a difficult concept to assess and measure. It is even more complex to design appropriate policies that reach even the most marginal farmers and that can mitigate the degradation.

Biophysically, a decline in the productivity of land cannot be determined by any single ecological measure. Therefore, when trying to address land degradation, land managers usually use soil, water, and vegetation as the primary indicators of overall land productivity.

Soil degradation includes erosion from wind and water and a decline in soil fertility. There are many elements to consider in assessing soil fertility, including a loss of organic matter; degradation of soil properties (such as structure, aeration, and water-holding properties); changes in key soil nutrients; and the build up of toxic substances such as pesticides, salts, and heavy metals.

The most frequently cited causes of land degradation as the result of human activity include: overcultivation of agricultural lands, overgrazing of pastures, desertification, deforestation, water logging—or salinization—of irrigated land, and pollution or industrial causes.

Associated with the biophysical definition of degradation is the assumption that land degradation is an undesirable and avoidable process that can be mitigated with appropriate land management techniques.

THE AMERICAN DUST BOWL

The creation of the Dust Bowl in the 1930s in the American Great Plains is a dramatic example of land degradation resulting from inadequate land management practices. The semiarid areas of the Great Plains are known to experience cyclic droughts. Normally, if the sod cover is undisturbed, vegetation protects the soils from wind and water erosion. This relatively undisturbed prairie ecosystem was radically impacted when thousands of farmers were lured to the southern Great Plains by the promise of rich and plentiful soil.

Using farming techniques that had been successful in the northeastern United States, farmers plowed millions of acres of grassland. By breaking up the sod cover for agriculture, they exposed the underlying soil to severe desiccation during the droughts in the 1930s. As a result great windstorms swept up the dusty soil, blowing it as far as Washington, D.C., and out over the Atlantic Ocean. While the average soil erosion rates in the region are estimated to be around a few centimeters per thousand years, during the 1930s wind erosion removed up to one meter of soil in certain areas.

Given examples like the American Dust Bowl, where local farming practices were completely at odds with the environmental conditions, it is not surprising that land degradation is often perceived as the result of ignorant farmers implementing inappropriate management practices on fragile landscapes.

PLACING THE BLAME

The belief that land degradation is the result of land management decisions by irrational, wasteful, or lazy farmers living in marginal ecosystems gained a great deal of momentum in the 20th century. Growing concerns over the perceived crisis surrounding population growth and environmental change resulted in a burgeoning neo-Malthusian conviction that people in the developing world were destroying ecosystems out of ignorance, selfishness, and out-of-control population growth. The general thrust of this argument is that growing population pressure will result in exhausting the soil as people strive to produce more food, causing yields to decline and leading to hunger or starvation.

A globalized discourse emerged that placed the blame for land degradation on smallholders throughout the developing world. Despite a scarcity of scientific evidence to support these conclusions, economists and technocrats introduced environmental policies based on this orthodoxy, taking for granted certain stereotyped narratives about irrational and wasteful smallholders. For instance, shifting cultivators throughout the developing world are often labeled as "voracious forest eaters" since they cut a section of forest for their rice gardens, and then after a few years leave the field to fallow, moving on to clear a new section of forest. Ideally after 10–15 years they can return to the original plot of land, beginning the process anew.

Policies implemented throughout the developing world have made shifting cultivation illegal and placed the blame for environmental degradation on these socially, politically, and economically marginalized peoples. Yet when a similar-sized plot of land is cleared for timber, oil palm or soy bean plantations—all much more intensive land use practices—similar concerns over land degradation are rarely expressed. In this case, the factors driving the assessment of land use strategies are not the ecological outcomes, but rather economic concerns. Following this logic the profits realized from large-scale land use justify environmental degradation while subsistence farming does not, making it easy to shift the criticism away from economically profitable (and ecologically unsustainable) land use practices onto the backs of the smallholders.

To an agriculturalist, the conversion of the forest to agricultural land would not be considered degradation.

NEW DEFINITIONS

In the 1980s, several social scientists began to challenge the conventional wisdom that blamed smallholders for land degradation. Human geographers Piers Blaikie and Harold Brookfield developed a more inclusive definition of land degradation than the one provided earlier by Johnson and Lewis. Their definition of land degradation considers both natural and human effects on a landscape in order to develop an equation that captures "net gradation." To Blaikie and Brookfield, net degradation equals (natural degrading processes plus human interferences) minus (natural reproduction plus restorative management practices).

This definition places more emphasis on the viewpoint of the land manager whose management practices include both natural and human influences on the landscape. This type of land manager makes appropriate management decisions based in a holistic approach, integrating the multiple social, economic, and ecological factors.

Blaikie and Brookfield were at the forefront of a significant wave of scholars who sought to break apart the neo-Malthusian discourse regarding marginalized farmers and land degradation by emphasizing the ways in which their land use decisions are influenced by prevailing social, political, and economic conditions often outside of their control. In later works, Blaikie develops a strategy of inquiry urging researchers to follow "chains of explanation" in order to identify the range of variables that influence land degradation. According to Blaikie, studies of land degradation should begin with the landholder examining the "place-based" factors that influence land use. From there the researcher should seek to combine an understanding of these "place-based" factors that influence land use with "nonplace-based" factors that originate in the political and economic relations between land users and in regional landscape. Some of these factors include access to key resources such as land, labor, and capital, as well as technological and informational resources.

Other scholars, such as James Fairhead and Melissa Leach, have also broken down the myths that point to the supposedly ignorant natives as the perpetrators of land degradation. In their seminal book, *Misreading the African Landscape,* they challenge the contention long held by colonial and postcolonial scientists that the African savanna-rangeland is a region where extensive climax forest has been reduced to savanna as a result of human mismanagement.

Fairhead and Leach demonstrate that current islands of forest were in fact created by human settlement in a once vast savanna. Their analysis reverses the traditional understanding of the direction of environmental change in the African savanna and challenges long-held orthodoxies about the role of local farmers in the processes of land degradation. Fairhead and Leach show that colonial science, and years of subsequent forest and agricultural policies, were based on assumptions that could not be supported by existing evidence.

During this same period in environmental studies scholarship, many environmental historians, geographers, and anthropologists have drawn attention to the fact that all understanding of landscape is constructed through social systems of meaning and dominant categories of knowledge. They raised important questions such as: Who controls the language and normative assumptions of how a landscape should look? Who determines which landscape should be preserved and which ones are degraded?

Human geographer Paul Robbins describes walking through an orderly German forest engineered by some of the first commercial foresters. The even-aged, single-species plantings enhanced harvesting and improved the forest from the utilitarian perspective of the greatest (economic) benefit for the greatest number. But to Robbins, this forest also represents a degraded landscape where commercial interests have arrested natural processes and created a sterile environment in pursuit of the maximum economic potential. To many, this landscape could never be considered degraded given its huge potential for economic "usefulness." To others, this landscape is the height of misguided state schemes aimed at systematically ordering the environment.

This discrepancy draws attention to the perceptual issues surrounding "usefulness." What is considered useful to one person may not be useful to another. To an agriculturalist, the conversion of the forest to agricultural land would not be considered land degradation. Yet to a hunter, who relies on finding game in the forest, croplands might represent significant degradation of the landscape. Therefore, it is worthwhile to consider that economic value is not the only measure of land's usefulness. Furthermore, even under the rubric of economics, productivity can be measured in a variety of ways.

While full-time, large-scale farmers with exclusive control over their land might measure usefulness based on an economic cost-benefit analysis, for subsistence farmers it is seldom a field-based cost-benefit analysis that influences their understanding of usefulness. Instead subsistence farmers need to balance risk associated with market-orientated crop production with the security of sufficient food production.

Land-management decisions that have the potential for high financial gain in the markets may be considered too risky given past experiences with boom and bust market economies. Instead of taking such a risk, a subsistence farmer may choose to stay with a more reliable food crop with little market value, defying rational-actor–based theories. Factors such as: insecure land tenure, inefficient access to markets, limited or no access to capital for land improvements, and an inability to hire a labor force influence the range of alternative calculations of the "usefulness" of land.

POLICY IMPLICATIONS

The policy implications of this line of thinking are tremendously powerful. In his book, *The Political Economy of Soil Erosion in Developing Counties*, Blaikie poses the question, "What level of soil erosion need occur before appropriate legislation is implemented and appropriate agricultural and pastoral technologies are induced?" Using the Green Revolution as an example, Blaikie argues that since farmers in developing countries have a limited ability to access the inputs needed for agricultural intensification, the diffusion of the Green Revolution technology was ultimately based on meeting the interests of large multinational companies.

To Blaikie, the political and economic centers have been blind to the signals from ecologically marginal areas and the farmers who depend on them, and as a result appropriate innovations for these areas are rarely a priority. But since agricultural policies and science are generally believed to be apolitical and an uncontested reality, the blame for land degradation is repeatedly placed on smallholders who refuse (or are unable) to adopt modern technologies that conform with the existing policies.

Improvements are being made in scientific techniques to accurately assess the biophysical characteristics of land degradation. The broader view, however, which includes the multiple dimensions of degradation based on the interactions between people, cultures, political-economic institutions, and a range of biophysical factors, is rarely adopted in the policy-making arena.

Social scientists agree that generic technological solutions to land degradation based on ecological conditions will rarely be successful. Continued research at a range of scales that can synthesize biophysical characteristics with historical transformations and existing social, political, and economic institutions is necessary for successful policies aimed at alleviating land degradation.

Land Ethic

THE EMERGENCE OF the specific ethical relationship to the earth known as the land ethic is attributed to Aldo Leopold, a forester and natural resource manager who lived and worked in the first half of the 20th century. The land ethic moves beyond economic valuation of natural resources to incorporate intrinsic values such as "love, respect, and admiration for land."

Prior to Leopold's construction of his land ethic, American conservation ethics had undergone two major iterations. J. Baird Callicott, a prominent environmental ethicist, describes the two preceding philosophies as, first, a Romantic-Transcendental Preservation Ethic, put forth by Ralph Waldo Emerson and Henry David Thoreau and expanded upon by John Muir in the early 1900s, and second, a Progressive-Utilitarian Resource Conservation Ethic, largely attributed to Gifford Pinchot and the U.S. Forest Service's philosophy of a "best" or "highest" use of the natural resources possessed by humanity. Leopold's Evolutionary-Ecological Land Ethic, Callicott states, was the third important ethical construction for describing man's relationship with nature.

Leopold was trained as a forester in the tradition of Pinchot and initially adhered to Pinchot's resource conservation ethic, but later in his career he diverged from this anthropocentric focus to develop his own ethic. His book, *A Sand County Almanac and Sketches Here and There,* published in 1949, outlines his developing philosophy in an essay called "The Land Ethic." Leopold states, "There is as yet no ethic dealing with man's relation to land and to the animals and plants which grow upon it." This unification of land with animals and plants indicates Leopold's burgeoning biocentrism: a focus on a respect for life itself. As Leopold put it: "the land ethic simply enlarges the boundaries of the community to include soils, waters, plants, animals, or collectively: the land."

Leopold's land ethic philosophy, proposed in the first half of the 20th century, was far ahead of his time and was not acknowledged for its applications to the field of environmental ethics and ecological thought until the 1970s and 1980s, when environmental ethics emerged as a discipline and the science of ecology shifted from viewing ecological systems as "climax equilibriums" to a more flexible model of dynamic stability.

A simplistic reading of the land ethic may place Leopold in an earlier ecological tradition that believed in ecological equilibriums and therefore proposed a respect for the land based on the astounding climactic balance ecosystems achieved. However, upon closer reading, it becomes apparent that Leopold was in fact rejecting the "balance of nature" paradigm for a "tangle of chains so complex as to seem disorderly, yet the stability of the system proves it to be a highly organized structure."

THE LAND ETHIC AND CONSERVATION

Leopold's land ethic, while contributing to conservation philosophy, does overlook many considerations relevant to the practice of modern conservation. The environmental ethicist Holmes Rolston III cites a few of these omissions in an essay on the land ethic, mentioning movements such as environmental justice, population growth in third world countries, the rights of indigenous peoples, and other human-environment concerns brought to light in current conservation and development debates.

The land ethic can be applied to many of the problems faced by modern-day conservation, which has been criticized for overly subscribing to a romantic construction of man's relationship to land. The modern conservation practice of trying to preserve "wilderness" by constructing unnatural barriers between human populations and the natural systems that support them ultimately results in conservation failure in many parts of the world. The land ethic includes people as citizens of a biological community.

Leopold fully acknowledges and supports the necessity of human alteration of ecological systems. His approach is both anthropocentric and biocentric; his ethic proposes an approach to land management that treats land use decisions and ecological alterations as actions that must be informed by ecological knowledge and a consideration for the long-term needs of both humans and the land upon which they depend.

Conservation has undergone many critiques for its treatment of marginalized peoples in the past few years. Proponents of the land ethic in the conservation movement argue that the land ethic empowers local populations. As Amy O'Neal writes, the land ethic "demonstrates a respect for biodiversity and the experience and knowledge of local peoples." Employing the land ethic could help the conservation movement become more sustainable in the long run. Globalization of the land ethic via conservation organizations and land managers around the world may be the next step in the expansion of Leopold's original philosophy.

Landfills

A LANDFILL IS any low area to be filled in for road building or for storing waste. More commonly, a landfill is a waste disposal site designed and constructed to accommodate municipal solid waste and hazardous waste while protecting against environmental and public health hazards.

One of the earliest forms of waste management was reported in 5th century B.C.E. in Greece where individuals were responsible for collecting garbage and transporting it to a dump site. Standard waste practices for centuries included land and water dumping of ashes, rubbish, and garbage, and household organic waste was often consumed by hogs. Such practices drew increased criticism in the late 19th and early 20th centuries, generating a new class of waste engineers and sanitarians that looked to a variety of alternatives to dispose of municipal solid wastes.

Efficient trash management in controlled landfills did not arise until the 1930s. The Fresno Municipal Sanitary Landfill, located three miles southwest of the City of Fresno, California, and which opened in 1937, is considered to have been the first modern, sanitary landfill. New techniques of trenching, compacting, and the daily covering of trash with soil were used on the Fresno site.

Daily coverings of soil layers reduce environmental and health problems, such as at this landfill in the UK.

Cities with populations of more than 100,000 adopted some form of organized refuse collection and disposal in the United States during the 1930s. Still, even into the 1970s, open and uncontrolled dumps were used to dispose of solid wastes, which increasingly consisted of discarded packaging materials associated with disposable household and industrial items. Often wastes of all types were burned on site. Open dumping caused a variety of environmental impacts, mainly through noxious odors, noise, birds, and smoke, and occasionally uncontrolled combustion occurred.

Most landfills today are regulated by environmental agencies to protect public health during waste disposal activities. Landfills are carefully designed and built into the ground to isolate trash from the surrounding environment. The purpose is to avoid any water-related connection between the waste and the surrounding environment, particularly groundwater. Landfills generally require at least one containment liner, generally made of compacted clay or a synthetic flexible membrane, to avoid leachate seepages into the surrounding soils and groundwater. Daily coverings of soil layers reduce environmental and health problems. Capping systems also avoid precipitation into the landfill and gas emissions into the atmosphere. A landfill siting plan and on-site environmental monitoring systems provide additional safeguards.

Continued problems with landfills include groundwater contamination from leakages, high operative and transport costs, and greenhouse gas emissions. Recent years have seen a shift from smaller to much bigger landfill sites, or mega-fills, some of which have disposal capacity equivalent to 1,000 football fields. Not only has urban waste amplified, its composition has changed from dense and almost completely organic to bulky and increasingly nonbiodegradable.

Changes in lifestyle patterns play a major role in waste generation, which is significantly higher in more affluent regions. Today's trash or garbage consists of everyday items such as product packaging, grass clippings, furniture, clothing, bottles, food scraps, newspapers, appliances, paint, and batteries. Besides household waste, landfills can also receive nonhazardous sludge, industrial solid waste, and construction and demolition debris. Even computers are being dumped in landfills.

On the positive side, the number of landfills in the United States has decreased from 8,000 in 1988 to about 1,767 in 2002. Increased knowledge of the biological, chemical, and physical processes in landfills has also led to improved technologies and more efficient waste utilization. For instance, over 25 megatons of carbon dioxide equivalent are being generated annually from Canadian landfills, which is equivalent to approximately 5.5 million cars on the road. By 2001, 41 landfills in Canada captured this harmful emission, resulting in an annual reduction of over seven megatons per year of carbon dioxide emissions. Such practices also generate green power, offsetting the need to consume fossil fuels to provide an equivalent amount of energy.

Disposal of solid wastes is still by far the most common method in use today to contain generated waste. Still, alternative solutions that focus on the 3Rs (reduce, reuse, recycle) are currently promoting waste diversion from landfills. For example, recycling diverted over 72 million tons of material away from landfills and incinerators in 2003, up from 34 million tons in 1990—doubling in just 10 years. Cities and municipalities all over the world are aiming for high waste diversion rates from landfills.

The focus of traditional landfill activities is also shifting. A landfill can no longer be seen as a "dry tomb" where strict liner systems ensure that emissions will occur for decades or centuries. The idea of not leaving behind a landfill body to subsequent generations has led to technologies that stabilize waste in a shorter period of time while concentrating on landfill gas collection and utilization. Separation of waste at the source (consumer) and separate collection activities have made it possible to treat the organic portion of generated waste for soil fertilizer and to generate biogas, which then can be turned into electrical and thermal energy. Where landfill space is extremely limited—for example, in Sweden, Norway, and Germany—thermal treatment of waste is key.

Humans will likely always produce waste, but only time will tell whether landfills will be needed in the future. Waste is increasingly becoming a viable source of energy.

Landrace

A LANDRACE IS a race of plants or animals that are ideally suited for the environment in which they are grown, or sometimes work. They are ecologically distinct populations with obvious genetic diversity. Landrace animals or plants usually grow well and need little, if any, assistance from people. Landraces are usually older stocks that have not been exposed to modern breeding methods. They are an important part of traditional agrodiversity, sometimes called "folk varieties" or "heirloom" seeds. Local farmers have produced landraces for centuries.

Landrace breeds of sheep have flourished in a number of localities for generations. The Pomeranian coarsewool is also known as the Rauhwolliges Pommersches Landschaf, or as the Pommernschaf. Fishermen favor its wool in winter. It has been bred in small flocks along the Baltic Sea in Pomerania and Mecklenburg since the 19th century, and its preservation is due to the poverty of the small farmers who were unable to switch to the more lucrative fine wool breeds of sheep.

Dogs that are landrace breeds occur in many different localities. Some were developed for hunting, others for herding, guarding, or just to show. The salukis of the Middle East are a landrace breed developed purely for desert hunting in wide open spaces. In contrast, Scottish border collies often show a number of variations, but are still recognizable, especially when they work a flock of sheep.

Beginning in 1895 Danish landrace hogs were developed from the native Danish hog and the large white hog imported from England. The crossing of the two kinds of hogs has enabled Denmark to become a great bacon exporting country with England as a major market. In 1934, the U.S. Department of Agriculture received a shipment of the Danish landrace and began to crossbreed them at various agricultural experiment stations. The Danish landrace contributed to the development of the American landrace. However, other strains of hog, including small strains of Poland China, and larger strains of Swedish landrace and Norwegian landrace played a role in increasing the breed's gene pool. There are a number of swine landrace associations (Poland China Record Association, American Berkshire Association, Gute Sheep Society of Sweden, and the American Landrace Association).

In many places, such as the Andes Mountains, local farmers have developed landrace seeds. Using traditional techniques they select, store, and propagate their specialty seeds. Other areas such as Nepal are rich in landrace diversity.

Land Reclamation

LAND RECLAMATION IS both the creation of solid land from swamps and other watery areas and the restoring of polluted land to either a natural or usable state. The practice of land reclamation has been a human activity from early in human history.

The creation of new solid land from watery areas has usually been accomplished by filling in swamps or wetlands. Many famous cities are the products of at least some land reclamation. For example parts of New York City, Rio de Janeiro, Singapore, Hong Kong, Macau, the Chicago shoreline, and the Back Bay area of Boston are all larger in area than they would be if some areas of marsh or wetlands had not been filled to produce solid land for building.

FARMLAND

Often areas that have been reclaimed have first been drained or filled to create farmland. Areas of Florida, some of the Dismal Swamp in Virginia, and some of the wetlands in Louisiana have been drained or filled in order to make them suitable for farming.

Louisiana and eastern Arkansas are major rice growing areas in what were originally swampy areas. The broad flat lands in the rice growing areas are amenable to the use of machinery, which has substantially lowered the cost of rice production making it profitable to sell in the international market.

These rice production areas replace the older rice growing area in South Carolina, which was worked by hand by slaves until emancipation took effect in 1865. The area was eliminated as a rice growing area because the labor cost to work the area was too high. Some areas have been allowed to revert to their natural wetlands state.

The draining of swampy areas for conversion to farmland also destroys areas of wildlife habitat. Often the affected wildlife can relocate to areas near the farmed or inhabited areas. In some cases wildlife adapts to the human presence without significant harm.

Sometimes the destruction of wildlife habitats is the specific purpose of the land reclamation; areas are drained to eliminate health hazards, such as in the exercise of mosquito control. Without this destruction of the wet mosquito breeding grounds, many human populations would be destroyed by malaria, yellow fever, West Nile fever, or other diseases transmitted by mosquitoes.

THE MARSH ARABS

Historically land reclamation has been accomplished in river deltas. The famous deltas of the Nile and the Rhine are places where reclamation has turned marshes and swamps into working farms. For example, the Marsh Arabs, who live in the swampy delta area of the Tigris and Euphrates Rivers in the Tigris-Euphrates alluvial salt marsh, which is surrounded by desert, use the area for producing crops. Sometimes they create islands upon which to build their houses and livestock sheds. Unlike some other delta regions, they have not sought to completely drain their swamp because it has provided them protection from enemies. Invasion of an enormous swamp by people who are accustomed to desert warfare is a technical challenge that historically most potential enemies have avoided. In another example, the Seminole Native Americans in Florida have utilized their swampy regions in ways similar to the Marsh Arabs. They have reclaimed small areas, but otherwise have generally used their wetlands as a natural defense barrier and as a source of livelihood.

ARTIFICIAL ISLANDS

In some areas of the world, land reclamation has taken the form of the creation of artificial islands. Artificial island creation was practiced by the Aztecs before the arrival of the Spanish Conquistadors. In modern times, artificial islands have been created in areas where the scarcity of land makes it necessary to create them for use as airports and other building projects. For example, Kansai International Airport in Osaka, Japan, and the Hong Kong International Airport are built upon artificial islands.

The high-rise Burj al-Arab—known for being shaped like a billowing sail—stands on an artificial island reclaimed from the sea just off of the coast of Dubai in the United Arab Emirates. One of the most amazing modern artificial island creations is also currently under development in Dubai. The Palms is a virtual archipelago of residential islands that have been created by pumping sand into containers that are then fixed as islands. Together the islands form the shape of a palm tree.

Even more ambitious are the nearby World Islands off of Dubai; this collection of artificial islands will be shaped like the continents of the world. When finished, the 300 small, private islands will feature private homes, offices, and other dwellings that will cover an area 5.4 miles by 3.6 miles in length. A seawall will surround the oval island group.

THE NETHERLANDS

In the Netherlands more than a quarter of the country is below sea level and over 60 percent of the Dutch people live in flood prone areas. Historically, the country has been plagued by flooding rivers or incursions by the sea. In an ongoing struggle against the sea, the Dutch have created the Zuyder Zee and Delta Projects. The Zuyder Zee Project began in 1930 with the enclosure of a vast area by the Afsluitdijk (closure-dike). Eventually the area changed from an inland sea into a freshwater lake.

By the 1950s, these areas were drained and the land reclaimed for farming, housing, and other uses. The Delta Project was instituted after great sea storms broke open the dykes in 1953, causing great flooding. Through this project, some of the area has been preserved as a shellfish habitat by the building of gates that control the entry of seawater into the southwestern Netherlands.

RESTRICTIONS

Because the work of land reclamation from wetlands has been so persistent in recent centuries, many countries have restricted the practice. The destruction of wildlife habitat and of the breeding marshlands along coasts has threatened wildlife as well as the survival of many parts of the oceanic food chain. A growing number of countries are adopting environmental protection laws to prevent more land reclamation by wetland recovery.

LAND RESTORATION

Land reclamation is more than the recovery of wetlands. It can also be the restoration of land damaged by environmental degradation. Environmental degradation is caused in a number of ways such as mining, chemical dumping, urban development, logging, flooding, housing development, and other human activities. The goal of this form of land reclamation is to restore the area to a pristine natural state.

One of the culprits of environmental degradation, mining, removes great quantities of material by tunneling or stripping surface layers. Mine overburden may erode into streams and cause flooding. The pollution caused by water seeping into old mine tunnels or pits, which then leaches out chemicals that can pollute streams, rivers, and lakes, killing fish and damaging human health, is even more significant.

Coal mining is the leading cause of land disturbance in the United States and restoration of lands disturbed by mining is ongoing in old coal mining regions and in places where the tailings of arsenic, gold, or other mines have left streams and watersheds exposed to poisonous chemicals. These pollution sources are eliminated by filling in old mines or mine pits, the installation of chemical treatment systems, or the restoration of the land surface. The U.S. Federal Strip Mine Law now requires topsoil removed for mining be reapplied after the mining is finished. However, even this form of land reclamation may require fertilizer treatments in order to create a new layer of protective vegetation.

Another significant cause of environmental degradation, chemical dumping, has created areas that are virtually uninhabitable. In previous decades, chemical dumping was unregulated and the filled-in land was thought to be safe. However, in recent decades tragic consequences have come from the failure to properly reclaim land used for waste chemical disposal.

Reclamation of urban areas is a new activity, but one that has been growing in need. When municipalities need to remove old buildings, the issue of where to take the rubble arises. This is particularly the case in areas where the aftermaths of hurricanes or floods have created an enormous volume of building waste, which has to be placed somewhere and the area from which it came has to be cleaned of materials that could be hazardous to health.

The intentional destruction of abandoned building or factories has the advantage that the unwanted materials are removed and deposited in a location that will be supervised. By using evolving engineering techniques, the land is cleared of debris and rendered usable for natural or human activity much more quickly.

Landscape Architecture

LANDSCAPE ARCHITECTURE IS an academic discipline and a profession whose aim is the analysis, planning, design, and management of built or nonbuilt environments in order to conserve, restore, change, or create sites according to specific human or ecological needs. Its main task is to relate the multiple elements comprising a landscape, such as topography, fauna, flora, buildings, and inhabitants with all the aesthetic and social values and uses associated with it in order to undertake specific action on sites. Landscape architecture is not a branch of architecture since it focuses not only on the design of single elements but also on the integration of diverse elements in a landscape.

Traditional landscape architecture projects include the design of gardens, parks, and grounds.

During the 20th century the discipline extended to streets and transportation infrastructures, such as highways and train stations, and to larger facilities, such as monuments, hospitals, malls, and residential housing. Now landscape architects are also increasingly designing sites meant to be natural, such as wetlands, rivers, or woods.

Design concerns about the arrangement of gardens, courtyards, and even streets existed in several ancient civilizations such as Greece, Rome, and China. However, it was not until the 17th century that designing sites became a separate, specialized activity. French royal gardener André Le Nôtre, who designed the parks at the castles Versailles and Vaux-le-Vicomte in France, is sometimes considered to be the precursor of landscape architecture. He was the first gardener of his kind to acquire an international reputation through his personal style.

The title of landscape architect was used for the first time in 1858 for Frederick Law Olmsted, one of the designers of Central Park in New York City. A few decades later in 1899 the American Society of Landscape Architects became the first national association created in this field. Throughout the 20th century the title was used more frequently as landscape architecture became an established profession requiring specific training and degrees.

Because landscape architecture deals not only with the design of buildings but also takes ecological functionalities into account, it is sometimes considered to be at the border between art and science. On the one hand its concern with aesthetics and well being, as well as the importance of individual creativity during the design process, makes landscape architecture a normative field. On the other hand, its concern with organizing complete sites, including biological organisms such as plants, trees, and soils, compels landscape architects to have a strong scientific background. Even when there are aesthetic considerations behind the planting of trees or the inclusion of biotopes in landscape architecture projects, proper living conditions must be maintained to retain these aesthetic values.

Landscape architects are divided when it comes to defining whether their approaches should rely on normative or scientific consideration. Different tendencies came to light in the second half of the 20th century. Increasing urbanization and the ecological consequences of industrial activity have pushed landscape architects to pay more attention to the environment. They have had to try to limit the impact of buildings or conserve portions of the environment in built areas and there has been a growing incorporation of ecological knowledge in landscape architecture projects.

Landscape architects are increasingly designing sites meant to be natural, such as wetlands, rivers, or woods.

Simultaneously the multiplication of environmental projects near or in urbanized areas has led environmental agencies to pay more attention to social needs and sustainability when carrying out ecosystem conservation or restoration projects. Project promoters increasingly rely on landscape architects because of their capacity to link heterogeneous elements in a landscape design and integrate the values of local residents, users, and visitors.

Landscape Ecology

THE SCIENCE OF landscape ecology is a comparatively young knowledge discipline that is concerned with the variation in types of landscape or land cover and the implications that this variation has on human settlement, land use, and planning. Landscape ecology and the tools it provides may be used as a means of envisioning and conducting spatial planning through such parameters as heterogeneity, fragmentation, and connectivity. Heterogeneity refers to the degree to which different types of land cover exist within a particular area. Fragmentation refers to the degree to which individual areas of heterogeneous land are or become insufficiently large to maintain the biodiversity that might otherwise obtain. Connectivity refers to the extent to which heterogeneous or fragmented pieces of land with similar land cover may be linked to each other at different scales.

Landscape ecology techniques are used in urban and spatial planning to help integrate people into the landscape with a view to minimizing energy use and hence promoting resource efficiency. In doing this, techniques from a wide range of other disciplines are employed and integrated, including zoology, botany, geology, and sociology, among others. The use of Geographic Information Systems (GIS) has become a very important tool for landscape ecologists and much of the practical work of the discipline is focused on accurate data collection, management, and analysis.

Landscape ecologists frequently concentrate on the borders between different areas of land. These borders may be termed *ecotones* as they mark the distinction between different types of land cover or other environmental difference. The ecotone might be obvious and distinct in nature or else gradual and "fuzzy"—as in hard to discern where one area of land begins or ends. In some cases, ecotones arise naturally, for example through a sudden change in altitude or a water barrier; in other cases, the ecotone might have been man-made, as in the case of a stretch of farmland or the presence of a herd of livestock.

Different ecotones may support different forms of flora and fauna, although some may be held in common. An ecotone that occupies a significant portion of land might support biodiversity that is not supported in the neighboring areas of land. Ecotones are important in providing possibly diverse sources of food and make good habitats, especially for species that are nomadic and can follow the ecotone as it moves in response to environmental or climatic change. This phenomenon has been used to explain the rise and fall of empires created by the nomads of the Asian steppes by identifying the motivation for the nomads to expand away from their traditional lands.

Studying the formation and movement of ecotones and related phenomena requires extensive, long-term analysis of the earth's surface and this in turn requires cooperation from many states in providing access to data on land use and cover within their jurisdiction. This can be problematic when secretive or security-conscious states are unwilling to yield such data. Global coverage of the earth's surface by satellites can partly resolve this problem but will not necessarily promote scientific cooperation and understanding.

One large-scale landscape ecology mapping project that has already been completed is the Multi-Resolution Land Characteristics Consortium (MRLC). Begun in 1992, this project mapped the landscape ecology of 48 U.S. states. The Environmental Protection Agency (EPA) of the U.S. Government conducted the project in partnership with the U.S. Geological Survey (USGS), the National Oceanic and Atmospheric Administration (NOAA) and the National Atmospheric and Space Administration (NASA). The effort required to complete the task was considerable and it has yet to be extended around the world at a sufficient level of detail.

Techniques within landscape ecology include the mapping of gradient change, multivariate analysis of resource usage within patches of land and the identification of fragmentation of land use and connectivity between different patches of land. Many complex statistical techniques are being employed in this field of research. Additionally, it has become increasingly evident that spatial patterns are dynamic rather than static and, hence, it is necessary to integrate temporal change into spatial change patterns. Unfortunately, accurate measurements have only started to be taken in recent years and so it will only be possible to develop a comprehensive database of land use and change from a point after which rapid climatic change has already begun. Consequently, understanding past patterns of use will only be possible through the use of recreation and simulation.

The principles and techniques of landscape ecology have been facilitated by the introduction of modern technologies such as aerial and satellite-enhanced mapping techniques. In addition the enormous increase in the scope and capacity of computational power has made large-scale analysis possible. Even so, these innovations are only starting to be integrated into the discipline. Research is still being aimed in part at determining what can be done and how it should be managed. Concepts such as metapopulations, source-sink models, and percolation are being explored in this sense with a view to understanding how they can be used to help plan the use of space efficiently.

As global climate change has an increasingly negative impact upon the use of the land, with growing populations making more intensive use of fresh water resources, it will become more important to understand in what ways—if at all—it will be possible to improve land use planning. Of course, it may be found that improvements in planning will be insufficient to cater for the increased demand for land and its resources.

Landscape ecology can help in forestry management and in the management of many forms of land cover. Previously most environmental management programs tended to be fairly small-scale in nature and generally focused on specific sites or issues. Landscape ecology has helped to demonstrate the interconnections between land use in patches of land that may be widely spread. Indeed, it has become increasingly clear that the environment of the whole world (and the atmosphere beyond it) is part of a single and to some extent self-regulating system in which change at any one point may bring about change in other points. Solving environmental problems can only be meaningfully undertaken with an understanding of the holistic nature of the global environment. This means that environmental issues can only rarely if at all be tackled without a cross-border perspective and international cooperation. The need for internationalized responses to environmental issues is becoming increasingly evident.

Land Tenure

LAND TENURE (or rural property rights) is generally regarded as a system of rights and obligations about land and property within a society or community. Land tenure can be viewed as a "bundle" of rights, where rights can be added, removed, or divided.

FORMAL VERSUS INFORMAL TENURE

There are several broad types of land tenure prevalent in most countries. Private property is a popular form, particularly in developed Western countries. In a private property system a piece of land belongs to a person or corporation, and this person or group has the right to sell it, lend it, use it as collateral, or split it up. Rights in the bundle are usually prescribed, as in zoning for a particular purpose (commercial, residential, agriculture, and so on), and are often specifically delineated, such as surface, mineral, water, or timber rights. With private property there exists a documented title, and a paper trail documenting the steps taken to obtain title.

Socialist tenure in various forms has been common in the past, most typified by the approach pursued by the former Soviet Union and its then-satellite states. With socialist tenure approaches, collective agricultural programs held that property rights and land use decisions are not made by individuals, but by either a group made up of the land resource users, or a state-appointed committee.

Socialist tenure can take a number of forms, but generally an individual household is assigned a portion of a farm or piece of land, but such an allocation might or might not be their first choice about where to farm. Individuals may have shares in the production (farm yield) or in the revenue from sales of the produce. Or, individuals may work as wage laborers on a collectively owned farm. This form of tenure also included villagization programs in Africa and elsewhere, where people were brought together from a more dispersed farming arrangement into a nucleated settlement and given land to farm. The logic here was usually that populations were more easily taxed, educated, provided with health care, and controlled, but in addition, villagization freed up vacated land.

Another form of land tenure currently favored by a number of developing countries is state ownership, whereby the national government declares all land to be property of the state. Usually this arrangement allows large areas to be declared "vacant and ownerless" national property to be subsequently distributed according to the state's priorities. In this approach there can be considerable confusion over exactly what rights are possessed by individuals, communities, and the state. Land nationalization can be a problem when a country changes from other tenure systems to state ownership. The logic behind such nationalizations can include the state's attempts to throw off an exploitative system, thus preventing what is thought to be a form of "re-colonization" via land purchases by large numbers of foreigners, or preventing the creation of a large landless class. A number of African states currently pursue this approach.

Customary tenure systems are informal, unwritten systems. Also called indigenous or traditional tenure by some, customary rights of access to land can be backed by "law-in-action." In other words, what establishes itself are the ad hoc arrangements that develop to meet the variety of situations in which people find themselves. Such informal behaviors outline the undocumented rules of land and resource use that are actually in operation.

There exists a pervasive disconnection in land tenure systems in many areas of the world. This occurs where both customary forms of tenure exist alongside formal tenure systems (such as private property, socialist, or state-owned approaches) with little ability for the two to connect as a system. The result includes land disputes, evictions, and tenure insecurity. The problems include the fact that customary systems are already in place, and have often developed over long periods of time. Formal systems, on the other hand, are imposed as peoples, areas, and countries are incorporated into a global system and feel pressure to have a land tenure system that can accommodate foreign investment; or, as they become decolonized, newly independent governments want to have a national land tenure system that they view as more fair than what occurred during the colonial era.

Formal systems are also imposed as governments express the desire for power over land allocation decisions and as governments want to regularize land tenure from many different informal systems belonging to indigenous groups within a country. The imposition of formal tenure systems onto customary systems can be problematic, because they must be enforced by the state, which means state intervention in the activities of communities, tribes, and religious groups, with potentially negative repercussions.

TENURE SECURITY

A primary component of all land tenure systems is tenure security. Tenure security is usually defined by how secure one's claim to access and use of land resources is. How secure one feels then influences decision making regarding agriculture, investments, resource management, and property transactions and is thought to be important to agricultural productivity and rational use of environmental resources. This is because the more secure the landholder, the more he or she will invest, and become invested in, the long-term viability and productivity of land resources. As a result more care will be given to how land resources are treated. Insecure land tenure, on the other hand, often results in environmental degradation, because affected populations feel there is little incentive to care for land resources they could be easily evicted from.

Much social science research and development work has been focused on the nature of tenure security and how it functions. However, tenure security can be difficult to understand, measure, and provide for in a consistent and predictable way. This is because tenure security is not very tangible, and many variables, processes, and contexts are bound up in it.

Tenure security embodies the idea that a claim to land resources is secure because it is to a significant degree defendable against virtually all other potential claimants. Thus tenure security necessarily resides within (and depends on) some notion of community (or "others"), and one's position within the community; as well as an ability to access and utilize what others in the community regard as legitimate and workable institutions (rule sets) used in defending claims.

While a community can be a local farmer village in a developing country, such a village can exist within a wider commercial or national community. This is important because a local community can be unable to defend its claim against "others" in a national community—with impacts on tenure security and resource use strategies. Ultimately this becomes a problem for indigenous land rights and environmental degradation.

Land Trusts

A LAND TRUST is a legal agreement by which one party holds ownership of a piece of land on behalf of another party. The laws by which such agreements are regulated vary across different countries and change over time. Land trusts may be divided between broadly public sector and broadly private sector agreements. The latter are most commonly used as a means of maintaining the integrity of a patch of family-owned land or as a way of minimizing tax requirements. The former are more typically organized by a state agency as a means of protecting environmentally important areas and of influencing the commercial and residential development of areas previously used for agriculture or not brought under human use.

Land trusts in a recognizable form have a long history and examples date back to at least the time of Henry VIII of England, when land ownership formed the basis of taxation and military *corvée*. However, a claim might be made that the land set aside for former soldiers and colonists in, for example, the Roman and Chinese empires also represented forms of land trusts in that the state could revoke ownership if certain responsibilities were

The Land Trust Movement

When governments step too far toward commercial interests and fail in their duty to protect the environment, people at the community or state level may intervene to make the necessary adjustments, volunteering extensive amounts of personal time and money if necessary.

In recent years the number of privately held land trusts aimed at protecting the environment has greatly increased in the United States, having been stimulated by the slashing of federal funding for this function during the Ronald Reagan administration. The creation of the U.S. Land and Water Conservation Fund (LWCF) in 1964 enabled the provision of some $11 billion for the federal purchase of lands to maintain and conserve environments. However, LWCF funding was slashed in the early 1980s and the burden was picked up at personal and state levels through the mushrooming of smaller-scale conservation projects and the emergence of the concept of "smart planning," which married the innovation of private sector solutions in well-defined and controlled geographic areas. Between 1998 and 2002, voters in the United States approved the use of $25 billion for creating land trust sites, realizing the failure of the federal government to meet this need and the depredations of many private sector developers whose goals are antithetical to the need for sustainable, livable, and aesthetically pleasing urban development. Inevitably, there has been a reverse side to this coin as some private sector corporations have used similar tactics to disguise ownership of land and buy numerous small pieces in order to obtain control of tracts of desirable land at comparatively low costs.

not discharged appropriately. Many states awarded land to newly created aristocratic elites or religious orders on similar bases.

In the modern world, international organizations such as the United Nations have been able to designate certain areas as places of outstanding historical interest and hold them on behalf of local people to prevent unwanted or unplanned development. Most developed countries have schemes that aim to protect wildlife or water resources or else to maintain a "green belt" around urbanized areas to provide recreational and aesthetic opportunities for residents.

In countries where such schemes are not operational or not well policed, nongovernmental organizations (NGOs) may aim to purchase or otherwise acquire land for similar purposes. Since there is often a conflict between the intentions of developers and conservers, the use of land trusts can be contested, controversial, and even subject to coercion of various kinds.

There is considerable scope for increasing the use of land trusts internationally, especially in those countries where inadequately maintained and supported legislation prevents the poor from registering and obtaining leverage from those assets that they do have. Incentives to improve land would be much greater for many such people if they could have confidence that they would be able to reap the long-term benefits for themselves and their families. However, providing common land for people is always subject to the free-rider problem that created the original economics conundrum called the Tragedy of the Commons. Consequently, strict regulation and maintenance of use is required to guard against such an occurrence.

Land Use

LAND USE REFERS to the way, if any, in which land is used. In many cases, the use to which land is put is directly related to the type of land cover or the "observed (bio)physical cover on the earth's surface." More than two-thirds of the world is covered by seawater and is therefore unsuitable for much use by humans other than fishing or extraction of underwater resources. Of the remainder, land use varies from agriculture, urban infrastructure and residential use, commercial development, and fallow ground.

In most developed or developing countries, governments enforce a set of zoning regulations to ensure a balance between agricultural, commercial, and industrial development of the land. Various legal agreements such as land trusts and covenants regulate these agreements. However, the degree to which these are policed around the world varies significantly.

One of the principal problems faced by the world's poor is the difficulty they have registering their assets and leveraging them to borrow for future investment. The lack of clearly defined and policed regulations determining the ways in which land may be used has a direct influence on the ability of the poor (or anybody else) to take advantage of their assets. This reveals the importance of a coherent, transparent, and accountable government in promoting an environment in which people can obtain better economic and social opportunities.

Land use has been radically transformed over time due to the spread of humanity. The understanding of how to conduct intensive agricultural or industrial use has resulted in the homogenization of land use. For example, the colonization of Southeast Asia led to the large-scale change of land use from forest or jungle to rubber plantations or rice paddy field maintenance.

The ability of people to transform land use so that it produces some kind of surplus encourages urbanization and drives further alterations in land use to sustain growing populations. However, not all peoples follow the same pattern. Nomads and herders prefer to reserve land use for animal maintenance. In these cases, there has been conflict throughout history between nomadic and sedentary peoples. Previously the superior martial abilities of the migratory peoples dominated. but this is no longer the case.

Modern approaches to land use planning have tended to feature concepts relating to sustainability. Top-down approaches to land use have focused largely on the commercial benefits that can be obtained, irrespective of the impact upon local people. Community-based initiatives in many countries have challenged this, stressing the importance of traditional knowledge in maintaining and conserving the land and its fertility without inputs such as unnatural insecticides or fertilizers.

Land Use and Cover Change

THE TERM *land use* refers to the purpose to which land is put—for example, agriculture, industry, urban, or untouched. Land cover refers to the observable physical or biophysical cover of the earth's surface such as forest, sea, or desert. Clearly, there are direct relationships between many aspects of the land cover and the use to which land is put.

In general terms, the type of land cover that exists influences the type of land use that is possible: the presence of forested areas limits agriculture, while rivers and waterways promote fishing and irrigation. Since the interaction between land use and land cover does not always appear to be convenient for human settlement, the land cover can be changed to what appears to be a more profitable form of land use. This has happened extensively over the past thousand years: the virgin forests of Southeast Asia have become irrigated rice fields and rubber plantations; the Great Plains region of the United States has become in many parts intensively farmed. These changes in land cover have had many impacts on climate change, along with other effects on the environment. While these changes have been occurring over an extensive period of time and are in some cases caused by naturally occurring phenomena, such as volcanoes and earthquakes, it is undeniably true that changes intensified in the 20th century and are set to do so even more in the future.

Land use and cover change (LUCC) may be complex and the underlying causes may be difficult to identify. Causes may also be quite obvious: for example, the intensification of agriculture in many parts of western China has involved the unsustainable use of water resources. This has led to the desertification of much of the land. This desertification has impoverished the local people pursuing agricultural activities, made traditional herding very difficult, and caused sandstorms in which cities such as the capital, Beijing, can be subject to intense bombardment by particles whipped up by winds in the desertified areas. In Thailand the intensive logging of teak forests and other valuable woods has all but removed the once dominant land cover and left the land increasingly subject to flooding and mud slippage. This phenomenon is also evident in Malaysia, the Philippines, and Indonesia.

The large-scale deforestation of the Amazon River region has led to significant reductions in the ability of the earth's land cover to sequester carbon from the atmosphere and has contributed to global warming. Other impacts include the loss of habitable land and attendant land conflict, and increases in poverty and negative health outcomes. These effects tend to cause land cover change to accelerate, as the remaining resources of the land are acquired as rapidly as possible before disappearing completely.

When the land is subject to additional pressure resulting from population increases or from the desire for commercial exploitation, then the land use change can be further intensified. Peasants—the poor land-users—will use whatever forms or combinations of land use that will minimize risk and provide a regular income in the foreseeable future. This tends to mean that, freed from external influences, the poor find methods of land use that are generally sustainable. However, when external influences are brought into play, perhaps because of central government advice for a more productive set of practices or through large-scale extraction of resources, then the local wisdom is generally discarded and the land use change becomes unsustainable.

The use of dams has also caused considerable changes in land use both through the act of their creation and in downstream regions. The world's largest dam, the Three Gorges Dam in China, has involved the creation of a reservoir stretching more than 600 kilometers upstream and has seen the relocation of more than 1.25 million people. Hundreds of villages and even small cities have been dismantled and rebuilt or just abandoned and the traditional lifestyles of all those affected have been changed, often radically.

Downstream effects have included changes in the migratory patterns of fish and, hence, ability to catch those fish, as well as the restricting of water flows which, together with industrial extraction of water from rivers has meant that many large waterways now frequently fail to reach the sea. Clearly, this has considerable impact on the ability of people to pursue long-standing agricultural activities in the downstream regions. Rapidly growing urban areas are also forced to maintain public health services in the absence of accustomed water resources. A lack of interest in the welfare of the displaced is also evident in the projected dam building projects on the Salween River in Burma and to various extents in projects around the world.

DATA COLLECTING PROJECTS

In recent years, international cooperative scientific efforts have sought to establish data collecting projects to document LUCC and to study the implications of changes around the world. For example, a Land Use and Cover Change Project was a Programme Element of the International Geosphere-Biosphere Programme (IGBP) and the International Human Dimensions Programme on Global Environmental Change (IHDP), based in Belgium. Its primary objective was "to obtain a better understanding of global land use and land cover driving forces; to investigate and document temporal and geographical dynamics of land use and land cover; to define the links between sustainability and various land uses and to understand the interrelationship between LUCC, biogeochemistry and climate." This resulted in a series of investigative projects aimed at integrating comparative case studies, diagnostic and empirical observations, and analyses at different geographical levels. Projects like these have gathered baseline information about the nature of LUCC around the world. However, much remains to be done before it is possible to accurately predict implications of future changes.

GOVERNMENT RESPONSES

Responses to LUCC at the governmental level have taken place at both national and international levels. At the national level, governments have considered zoning systems and schemes to encourage sustainable land use, although these have not always been well-planned or executed. At the international level, some agreements have been made to deal with specific phenomena such as acid rain or with respect to damming of rivers but, in general, these have proved to be very difficult to establish in practice.

Land Use Planning and Policy

THE EARTH'S LANDSCAPE performs a multitude of functions, from providing the natural resources for human activities to recycling carbon dioxide to produce oxygen. It is the home of city-dwellers and desert nomads, along with aquatic, terrestrial, and avian species. Activities performed on the landscape range from nonrenewable extractive industries to landscape modifications by natural events such as volcanic eruptions. No matter what the activity, function, or purpose, the human population manages the landscape according to their environmental, cultural, and political philosophy.

LAND OWNERSHIP AND COMMUNITY

Land is owned either by the private or government sector. Attached to land ownership are basic responsibilities and rights to the use and maintenance of the property. The private landowner, however, is part of a local government that provides goods and services to the property. The jurisdictional control is the power of the local government to manage and regulate private activities that impact on the general public's "health, safety, and welfare." Land use planning provides a balance between preserving the rights of the individual property owner and meeting the needs of the community. The community can represent the local population or the nation.

Currently in the United States, there are no national land use policies even though different federal agencies manage large tracts of land. Overall, federal land encompasses approximately 1.29 million square miles (3.34 million square kilometers) or 34 percent of the total land area of the United States (3.79 million square miles). Each federal agency adheres to management policies that have

There are no national land use policies in the United States even though federal agencies manage large tracts of land. Federal land encompasses approximately 1.29 million square miles or 34 percent of the total land area of the country.

been established by law. In addition, national laws have specific standards for establishing air and water quality, solid waste disposal, noise pollution, and transportation that directly or indirectly regulate land use activities. Thus, federal agencies manage lands and federal laws regulate land activities, but individual states have the responsibility of land use policy through their police powers.

States' police power provides the ability to establish laws and ordinances to maintain civil order and provide for the public health, safety, and general welfare of their citizens. Through enabling legislation, the states have established the procedures and methods for land planning and regulation. They have also laid the foundations for local level planning by identifying specific statewide goals or allowing the individual local entities to construct their own land use goals. In addition, the state may impose specific health and environmental standards and guidelines that the local government must follow. Thus, the local government possesses the ability to manage land use within the powers and methods provided by the state government.

Several states have identified specific areas or types of land as "critical" and have imposed specific land management techniques to ensure their protection. These areas may be vulnerable to human impacts, and need to be preserved, enhanced, or protected. The area or land type may possess valuable natural resources or have historic, cultural, or scenic value. Land types—e.g., prime agricultural land, forested areas, or wildlife habitats—can be granted special protection to preserve their production capabilities or their contribution to the ecosystem.

States may use financial or investment entitlements to support or locate specific land use. Forty states provide preferential property tax treatment to farmland as a means to sustain this activity. States regularly invest in new or expanded infrastructure, facilities, or services to promote development. The placement of a new state prison, centers of higher learning, or hospitals encourage development to support new employment opportunities, complementary services, and economic diversity.

State-enabling legislation generally provides the local government with the authority to regulate the density, type, location, and height of buildings and structures. The local authority can divide their jurisdiction into districts and regulate and restrict building construction, use, alteration, and repairs. In addition, local land use plans are employed to: lessen congestion, create safe environments, reduce overcrowding, provide adequate light and air, and facilitate adequate infrastructure. All of this is done by local government to provide for public health, safety, and general welfare.

PRINCIPLES

Land use policy is based on the interactions between the environment, society, and the political/economic structure. The framework upon which land use planning is built depends on the sustainability of a system that recognizes the importance of meeting the complex needs of human society while maintaining the integrity of natural systems that support all life.

Land use planning goals and decisions are best determined at the local level with community knowledge of the environment, economy, and society. There are five basic principles that should be integral to land use decisions. These principles are: (1) create a land use system that is sustainable for future generations, (2) analyze local impacts in a regional context, (3) provide for social equity, (4) produce an economic system that produces community well-being, and (5) preserve cultural/historical and environmentally-sensitive areas.

There are four dimensions to the land that need to be considered in land use planning: (1) land as a functional space, the overall parcel dimensions and location, the environmental characteristics, the building(s) and structural/infrastructure dimensions and capacities, and use characteristics; (2) land as an activity center, the interactions that take place on the site, human interactions or ecosystem dynamics; (3) land as a commodity, the value of the land for economic exchange or value to society; and, (4) land as an image or aesthetic resource, its psychological value to the community. The land use is the expression of the particular dimension the citizens want to emphasize.

LAND CLASSIFICATION

The land classification system used to describe the characteristics of the land depends on the purpose of the classification. Land use refers to the activities taking place on that parcel of land, but a parcel of land can have multiple uses. For instance, land in the national forest can be used for: hiking, camping, bird watching, as protection of our nation's woodlands, a source for timber harvesting, protection of our watersheds, an area for mining, and as a scenic landscape. Thus, the purpose for the classification system will depend on: (1) the legislative responsibilities of the government entity; (2) the type of impact assessment (environmental, social, economic, transportation, or technological); and (3) the interaction between land use elements (residential and commercial, urban and environmental).

PLANNING PROCESS

In developing a land use plan, identification of community values is an essential first step. These values assist in the articulation of the idea of "sense of place," what is important to the local community. The next step in the process is to produce the overall land use goals and objectives. In order to obtain the goals and objectives, the third step is to identify different policy strategies and evaluate their feasibility. The fourth step is to select and implement the policies that will attain the community's goals. The final step is the establishment of a system to monitor and evaluate the policies to ensure they produce the desired outcome. Decisionmakers integrate citizen input into the process so that it is assured to be a community-based land use plan.

POLICY OPTIONS

Land use policies generally align to one of six approaches. The most often cited approach relates to regulation—most notably zoning—but this also includes subdivision ordinances and different types of codes (buildings, architecture, landscaping, etc.). Incentives are another set of policy approaches to provide options for land owners and developers. The incentive policies do not punish or restrict land uses but give beneficial options based on set action criteria. The third approach is land acquisition, the purchase or entitlement of land (conservation easements) by the local authority and placing the land in a specific use, e.g., recreation, land conservation, or preservation. Another policy approach is to use the placement of capital infrastructure to direct land use into specific areas or dimensions. Thus, the local community and not market pressure dictate the position of roads and utilities. Fifth, financial policies can serve two purposes—a method of collecting needed revenues to acquire land or build infrastructure or as a means to make development fiscally responsible for its impacts. Finally, the least utilized policy is educating the community about the benefits and impacts of land use decisions to this generation and future generations.

Laos

THE LAO PEOPLE'S Democratic Republic (PDR), or Laos, is a nation of 6.4 million people and nearly 237,000 sq. km. situated in the heart of mainland Southeast Asia. It is bordered by China and Vietnam to its north and east, respectively; Myanmar and Thailand to the west; and Cambodia to the south. The climate is dominated by tropical monsoons, with a fairly well-defined rainy season from May through November alternating with a dry season from December through April. Laos is, by many

The Plain of Jars

On the plains of Xieng Khuang Province in north-central Laos, large numbers of enormous stone jars litter the landscape. Rival archaeologists dispute both their age and their purpose. The general views are that they were either used for wine fermentation, for rice storage, or for sarcophagi—or possibly for all three purposes. A few surviving stone lids have been used to advance all of these theories. Human remains have been found in jars, and rice has been found in others. Many local people associate legends with them, including one that tells of an ancient king who used the jars to brew large amounts of rice wine to reward his supporters after a great battle.

Madeleine Colani, a French archaeologist, worked on the jars for three years during the 1930s and found a nearby cave which held some bones. She also found artifacts in one of the jars and wrote about them extensively. However, during the Vietnam War, there was massive damage to the area and the cave was destroyed. Colani felt that the jars lay along a caravan route to northern India and that the area was also an important burial ground over a long period of time. Her work dated the jars at around 1,500 to 2,000 years old.

Although many archaeologists have wanted to work on the site, and tourists visit it regularly, it is a hazardous pursuit. Large numbers of unexploded bombs blight the land—the result of the Secret War in Laos, during which the United States embarked on one of the largest bombing campaigns ever. The area is gradually being cleared of ordnance but many places remain dangerous and visitors are are forced to keep to certain well-marked paths.

socioeconomic measures (such as life expectancy, infant mortality, and literacy) one of the least-developed countries in the world.

Ethnically diverse and largely dependent on agriculture and natural resources for their livelihoods, the people of Laos practice rice paddy cultivation in the low-lying plains (only four percent of the land area of the country is arable) near the capital city of Vientiane, while those living in the mountainous regions of the north and east rely on a variety of livelihood practices, including upland rice cultivation, fishing, collection of nontimber forest products, and hunting of wild game.

The most pressing environmental issues facing the Lao government and people revolve around efforts to stimulate economic development through the exploitation of the country's two primary natural resources: forests and hydropower. Nearly half of Laos's entire Gross National Product is generated through the sale of these two resources. Deforestation and the exploitation of resources more generally has accelerated since the government's adoption of economic reforms in the late 1980s stressing foreign investment and market-oriented policies.

While forest cover remains at an estimated 55 percent in Laos, illegal logging continues to present a major challenge to the government. Although Laos has been ruled by the socialist Lao People's Revolutionary Party for the past 30 years, the governors of its 16 provinces and individual military commanders retain a good deal of independence from the central state. This has contributed to the unregulated sale of timber at the provincial and regional level to firms from Thailand, South Korea, Japan, and other Asian countries.

The Lao state has long planned to convert the energy of its numerous streams and rivers into electricity through the construction of large hydroelectric dams on the main stem of the Mekong River and its numerous tributaries. Major hydroelectric dams include the 1,150-megawatt Nam Ngum project on the Ngum River near the capital city Vientiane and the 210-megawatt Nam Theun-Hinboun project on the Theun River in the province of Khammouane. The government is constructing the massive Nam Theun 2 project on the Theun River in Borikhamsai province with funding provided by the World Bank, the Asian Development Bank, and other sources of international finance. The Nam Theun 2 dam has engendered considerable controversy, with several transnational and regional NGOs arguing that the project's social and ecological disruptions, including displacement of local communities and loss of valuable fisheries, are considerable and not fully accounted for in dam planning.

The conservation of biodiversity is another major issue in Laos. The territory of Laos comprises several ecological zones of high biodiversity, especially in terms of large mammals and other large fauna. Endangered species found within Lao territory include the Asian elephant, Eld's deer, western black-crested gibbon, Siamese crocodile, and tiger. While the Lao government, with the assistance of international conservation groups such as the World Conservation Union, has designated over 14 percent of its land area as National Biodiversity Conservation Areas (NBCAs), illegal logging and other environmentally damaging activities remain rampant in these sites.

Another critical environmental issue concerns ongoing soil erosion and loss of arable land, particularly in the highland areas where a form of shifting cultivation continues to be practiced by a variety of the region's ethnic groups such as the Yao and Hmong minorities. A relic of the war between Vietnam and the United States in the 1960s and 1970s, unexploded ordnance in the form of land mines, artillery and mortar shells, rockets, and grenades continue to present a tremendous danger to rural families, particularly in those provinces bordering Vietnam.

Latitude

LATITUDE IS THE measure of the geographical distance from a point on the earth's surface to the reference parallel or equator, symbolized by phi. Latitude and longitude are the two angular distances—using either degrees, minutes, and seconds, or decimal degrees—in the geographic coordinate system to precisely communicate the position of a certain location, and their measurement is fundamental for mapping representation and navigation.

Latitude is an angle formed by the plane that crosses a certain location on the earth's surface, the center of the earth, and the equatorial plane. Latitude values range from 0 degrees and 90 degrees to the north of the equator, expressed as a positive angle, and from 0 degrees and 90 degrees in the Southern Hemisphere, expressed as a negative angle—or respectively accompanied by the letters N or S.

The lines that connect the points with the same latitude are called parallels or lines of latitude. There is a constant distance between any two parallels and they cross meridians at right angles. Parallels are constant true east-west lines that decrease in their length toward the poles, represented as straight lines in the Mercator projection. The equator is the longest parallel, which makes it the natural reference or origin parallel and separates the Northern Hemisphere from the Southern Hemisphere. The poles are points, not lines, of latitude 0 degrees. The length of a degree of latitude along any meridian varies little, from 110.567 meters in the equator to 111.699 meters in the poles.

There are four other latitudes of specific interest, which are due to the obliquity or the angle between the equatorial plane and the ecliptic of the earth. The Tropic of Cancer (23 degrees 27'N) is the northernmost latitude where the sun is vertical at noon on summer solstice in the Northern Hemisphere. The Tropic of Capricorn (23 degrees 27'S) is the southernmost latitude where the sun is vertical at noon on summer solstice in the Southern Hemisphere. Both parallels comprise the tropical latitudes.

The Arctic Circle (66 degrees 33'N) is the southernmost latitude in the Northern Hemisphere and the Antarctic Circle the northernmost in the Southern Hemisphere where the sun does not set in summer and does not rise in winter. Polar latitudes are comprised within each circle. Mid-latitudes extend between the tropics and the polar circles.

The determination of latitude was achieved very early using a fairly accurate method, based on celestial navigation. This method involved measuring the angle of the sun above the horizon at noon during the day, or the position of any other astronomical object using common instruments such as the astrolabe, sextant or octant. Celestial navigation during the night consists of measuring the angle of the pole star in the Northern Hemisphere and the Southern Cross in the opposite. Latitude is the result of operating 90 degrees minus the measured altitude angle plus the sun's declination for the date.

Latvia

LATVIA IS LOCATED on the eastern shore of the Baltic Sea, bordering Estonia, Lithuania, Russia, and Belarus. Latvia's government became a parliamentary democracy after it gained independence from the Soviet Union in 1991. Latvia has since reduced its trade dependency on Russia, and the majority of Latvia's trading is currently with member countries of the European Union (EU). Latvia joined the EU in May 2004. Since 1993 Latvia's Gross Domestic Product (GDP) per capita has grown each year at an average rate of 5.7 percent per year.

The state of the environment in Latvia has been in transition since independence. There was significant industrial decline after the fall of the Soviet Union, as much of Latvia's economy shifted to the service sector. A result was that pollution levels declined substantially. Latvia recently underwent major land reform. Almost all land in Latvia was owned by the state during the Soviet era and was restituted to its former, pre-Soviet owners after independence. Along with land restitution, Soviet-style cooperative agriculture dissolved, and smaller farms were established throughout the country. To obtain EU membership, Latvia complied with EU directives regarding nature protection and biodiversity. This process has helped lead to the current 542 protected areas, totaling 2.14 million acres (866,800 hectares), or 13.4 percent of Latvia's land territory at the end of 2002.

Latvia's largest export is wood products. Forests cover approximately 44.5 percent of the Latvian land territory, and the total forested area in Latvia has increased continuously since 1935 (except for a small decrease between 1983 and 1988). Latvia's current environmental priorities are the improvement of drinking water quality, sewage systems, household and hazardous waste management, and the reduction of air pollution.

Latvia's current population is 2.3 million. Latvia's total fertility rate (TFR) is one of the lowest in world, with 1.29 births per woman in 2003. The TFR declined from its recent high in 1987 at 2.21 to a low in 1998 at 1.11, and is now on the rise. Latvia's total population, rural population, and urban population have all declined each year since Latvia's independence. Between 1951 and 1990 there was a substantial net in migration to Latvia, primarily from other parts of the Soviet Union. Since 1991 there has been a substantial net out-migration from Latvia, most of which occurred in the few years after independence.

Ethnic Latvians constitute 59 percent of Latvia's population. Thirty-five percent are ethnic Russians, Ukrainians, and Belarusians, most of whom migrated to Latvia from other parts of the Soviet Union during the Soviet era or are descendents of those who migrated. Many of these migrants and their descendents were not granted Latvian citizenship after independence, primarily due to a difficult Latvian language exam required for citizenship: 20.8 percent of current Latvian residents do not have citizenship of any country. This situation has caused some tensions within the country between ethnic groups.

Lawns

LAWNS, AS THEY are commonly understood in the United States today, are expanses of closely mown perennial grass. They are often found around suburban houses, sports fields, parks, and public sites. In order to maintain their uniform evergreen appearance, lawns generally require regular intensive management, including fertilizers, pesticides, and irrigation. Until mid-century, lawns in the north primarily included Kentucky bluegrass, and lawns in the south primarily included bermudagrass. Since the 1970s and 80s breeders have hybridized and cloned grasses to produce varieties suited for high-traffic areas, shade, and disease-resistance, and differing conditions of soil and climate. Current varieties include types of bahia, bentgrass, zoysia, fescues, and perennial ryegrass.

The modern American lawn has its roots in late 18th century Europe. There the Romantic Movement led some aristocrats to convert their formal geometric gardens to a naturalistic style including swaths of lawn. Mimicking flowery meadows grazed low by sheep and cows, these Romantic lawns required servant labor to keep them shorn. In the early 19th century a few wealthy Americans began imitating this style. By the 1880s, the middle classes followed suit by creating smaller lawns on their new suburban house-lots. Magazines promoted the lawn as an aesthetic and social ideal that allowed leisure activities such as croquet, lawn tennis, lawn bowling, and archery. The growing sports of golf and baseball also played a role in the evolution of lawns. By 1912, in response to pressure from the United States Golf Association, the U.S. Department of Agriculture began research into turfgrass breeding. The growing desire for lawns also encouraged private research in grass seed, mowers, sprinklers, chemical fertilizers, and pesticides. First patented in England in 1830, the lawnmower became widely available to wealthier households in the United States during the 1870s.

DEMOCRATIC LAWNS

After World War II lawns truly became democratized. Increasing home ownership and rapid suburbanization created a vast market for the lawn care industry. The prosperity of the postwar years provided many households with the time and money needed for a weed-free, evergreen lawn. New chemicals were also key to the modern lawn. Nerve agents invented for use as weapons during World War II were converted to home use in the 1940s and 50s as insecticides such as DDT, malathion, and parathion. Following Rachel Carson's book *Silent Spring* (1962), the public became concerned about persistent chemicals in the environment. Soon writings on organic lawn care appeared, beginning a wave of interest in reducing the environmental impacts of lawns.

In 2005, researchers completed the first comprehensive estimate of the land area occupied by lawns in the United States. Their conservative estimate of 128,000 kilometers^2 (31.6 million acres) makes lawns the largest irrigated crop in the United States by area. Because of the magnitude of this land use, lawn management practices have profound impacts. Problems include water use, air pollution, petroleum and chemical use, and decreased biodiversity.

If all lawns in the United States were kept watered and green all year, irrigation would use approximately 200 gallons of fresh water per person per day year round. Water use for landscaping, primarily lawns, absorbs 50–70 percent of home water use in the United States. Facing water shortages, especially in the arid West, governments at various levels have begun encouraging "xeriscaping," that is, replacing lawns with native plants that require little to no irrigation.

Americans use up to 800 million gallons of gasoline per year to mow their lawns. Of this, approximately 17 million gallons are spilled while filling up lawn equipment—more than the *Exxon Valdez* disaster. Inefficient motors long made mowers extremely polluting. Running a 3.5 horsepower mower for one hour produces as many volatile organic compounds (VOCs) as driving a new car 340 miles. Because they are often operated on sunny days, mowers' exhaust exacerbates smog and ground level ozone. Since 1997, the U.S. Environmental Protection Agency has established emissions standards and regulates new gas mowers. Electric, solar, and hand-push mowers reduce or eliminate both petroleum use and emissions.

Americans spread 80 million pounds of chemical fertilizers and pesticides on their lawns annually that can run off into fresh water. Excess nitrogen causes eutrophication in surface water. Run-off can be reduced through careful attention to slope, soil moisture, riparian buffers, and other factors. This amount of knowledge may not, however, be practical for home applications. Leaving grass clippings to decompose on the lawn can reduce the need for nitrogen inputs by one-half.

Many herbicides, fungicides, and insecticides commonly applied to both home and "professional" lawns are known or suspected to cause cancer, birth defects, and kidney or nerve damage; though this information is not required to be printed on packaging. Children are especially susceptible as their nervous systems and organs are still developing and they tend to have greater contact with treated lawns through play. To reduce the use of lawn chemicals, insects can be controlled through Integrated Pest Management, while many weeds can be pulled or killed with boiling water or vinegar and lemon.

As extensive monocrops, lawns accommodate minimal biodiversity. Environmental advocates have suggested that lawn size be reduced to a minimum and replaced with native plantings that provide food and habitat for a wide variety of wild crea-

Lawns cover an estimated 128,000 square kilometers (31.6 million acres) of the United States.

tures. This message has gained ground even on golf courses, some of which now incorporate naturalized wetlands and prairies in their "rough" areas.

Lawns do provide a few environmental benefits, especially in urban areas. They can capture environmental carbon, filter some air pollutants, produce oxygen, and reduce urban heat island effect. Two key factors, overall, in reducing lawns' harmful impacts are reducing their area and changing the lawn aesthetic. If lawns were allowed to go dormant (brown) during hot, dry weeks—and to include a mix of broadleaf plants in with turfgrass—the need for water, herbicides, and fertilizers would drop. Researchers have created alternative grass mixes that include clovers, yarrow, and other broadleaf plants in a lower-impact lawn. This aesthetic echoes the origins of lawns as mown meadows.

Law of the Sea

THE LAW OF the sea defines the rights and responsibilities of states in the ocean. Every society has a law of the sea, as certain norms emerge regarding the relationship between water and land. The modern law of the sea, however, owes much of its legacy to Early Modern Europe, when states began to designate coastal waters—typically defined as three nautical miles from the coast—as their territory (one nautical mile equals 1.15 statute miles or 1.852 kilometers). During this period, the norm also emerged that the high seas—the ocean beyond territorial waters—could not be controlled by any state.

A more recent stimulus for the modern law of the sea occurred in 1945, when the United States asserted a right to manage "fisheries conservation zones" adjacent to its territorial waters and a right

According to the United Nations, a country's Territorial Sea extends 12 nautical miles out from its coastline.

to the mineral resources of its continental shelf. Although the United States was not claiming these adjacent waters as national territory, the proclamations encouraged other countries to pass legislation that came much closer to incorporating adjacent waters and seabed into the territory of the state. This could potentially endanger the "freedom of the seas" norm that had prevailed beyond the three nautical mile limit and that was crucial for global maritime commerce and military activities.

In response, the United Nations (UN) convened Conferences on the Law of the Sea in 1958, 1960, and 1973, eventually leading to the UN Convention on the Law of the Sea, which was signed in 1982 and went into effect in 1994. The Convention divides the ocean into zones: From the coastline out to 12 nautical miles is a country's Territorial Sea. A state can largely control what occurs there, although it must allow passage to other states' "innocent" vessels. An exception to this rule is made for international straits that are fewer than 24 nautical miles wide. High Seas freedoms prevail in these straits. In other words, even if a coastal state thinks that a foreign ship's intention is not "innocent" it must let the ship pass through the strait.

From 12 to 200 nautical miles from the coast is a country's Exclusive Economic Zone (EEZ). The waters and seabed of the EEZ are not state territory; High Seas freedoms of navigation prevail there. However, a coastal state has exclusive rights to manage and extract living and nonliving resources from its EEZ. Beyond 200 nautical miles, coastal states have no special authority. High Seas freedoms of navigation prevail and resources are designated "the common heritage of mankind."

The Convention on the Law of the Sea does not mandate specific environmental conservation measures. Rather, it establishes the level of authority that states have in various zones of the sea, thereby establishing a framework onto which unilateral legislation and multilateral treaties and conventions can be implemented.

Lead

LEAD IS A soft, heavy, and toxic metal. It is easy to extract and smelt, and is well-suited for many uses. The combination of lead's toxicity with its usefulness has proved to be a particularly hazardous pairing: lead is an extremely toxic and also ubiquitous environmental contaminant.

Lead has been employed throughout history in a variety of ways: in plumbing, paint, gasoline, lead-acid batteries, ceramic glazes, jewelry, glass, wine, firearm projectiles, lead solder, and radiation shielding. Lead has been used by humans for at least 7,000 years. The most memorable appearance of lead historically was in water pipes and wine in the Roman Empire.

Lead is toxic in the body because it is able to mimic other biologically-important metals (such as iron, calcium, and zinc) and thereby interfere with biological processes. The adverse health effects of lead are numerous. They include (but are not limited to): reduced IQ, developmental delays in children, other neurological problems, hearing impairment, hypertension, lethargy, hyperactivity, infertility, anemia, gout, colic, brain damage, seizure, coma, and death. The adverse effects of lead have been recognized for thousands of years. The Romans themselves attributed the prevalence of gout and dementia to lead toxicity. It is likely that Beethoven suffered from lead poisoning.

Acute lead poisoning encompasses a certain set of symptoms, occurring at particularly high levels of exposure (usually blood lead levels above 20 μg/deciliters). It is now widely agreed, however, that exposure to lead at any level is toxic. Lead exposure is especially dangerous to young children because they absorb more lead from their environment and are at a critical stage of their neurobehavioral development. It was not until after 1950 that it was widely accepted that the neurological effects of lead poisoning persist and that lead exposure is dangerous even at low levels.

Lead has a long and illustrious history. While Roman aristocrats acknowledged risks such as madness and death from significant lead exposure, they falsely believed that moderate exposure would not be harmful. Many historians argue that chronic lead poisoning was a major factor in the decline of the Roman Empire. From the Middle Ages through the Industrial Revolution, lead was employed widely in alchemy, printing, weapons, and other industry. By the 20th century, the United States was the leading producer and consumer of refined lead. The per capita usage in the United States in 1980 was approximately 10 times that in Ancient Rome.

Currently, the primary environmental sources of lead exposure are leaded gasoline and lead-based paint. Industry presents an additional source of lead exposure, but such exposure is largely confined to those who live near or work in lead-producing industries such as lead smelters, battery plants, or fuel-burning industrial facilities.

Tetraethyl lead was first added to gasoline in the 1920s to improve engine performance and reduce engine knock. Early in the use of lead, General Motors refinery workers fell sick and died. Despite the warnings of public health advocates (including Harvard professor Alice Hamilton) and journalists (who dubbed leaded gas "loony gas"), lead was approved for use in gasoline. In the following decades, the lead content of gasoline rose, as did the use of gasoline in automobiles. By the 1950s there was an average of 2.4 grams of lead per gallon of gasoline. Lead from gasoline is absorbed into the body directly by breathing in gasoline exhaust and indirectly from contact with lead deposits in soil.

In the early 1970s the newly formed U.S. Environmental Protection Agency (EPA) officially recognized lead as a substantial public health hazard and named gasoline "the most ubiquitous source of lead found in the air, dust, and dirt in urban areas." In 1974, under the authorization of the Clean Air Act, the EPA mandated a timetable for the reduction of lead in gasoline, requiring petroleum companies to meet specified targets of maximum grams of lead per gallon of gasoline. The average lead content of the gasoline produced by each refinery was to be reduced from 2.0 grams per total gallon to a maximum of 0.5 grams per total gallon by 1979. This time table was delayed somewhat, and further reductions implemented. By 1990, gasoline lead had dropped to a mere one percent of its 1975 levels.

Most countries in western Europe followed the United States, using a variety of financial incentives to remove lead from gasoline in the 1980s and 1990s. Worldwide, however, many countries still use leaded gasoline; as of 2005, 67 countries had not yet banned or phased out lead from gasoline. These countries are generally poorer and located in central Europe, eastern Europe, Africa, Southeast Asia, and the Middle East.

Lead in paint is the second major source of environmental lead exposure. Lead was originally added to paint as a pigment and to speed drying and increase durability. Many countries banned lead in residential uses early in the 1920s, but the United

States did not do so until 1978. In the United States, the lead content of paint declined relatively smoothly from 1920 on, with breaks in 1950 when lead-based paint was banned for interior use and in 1978 when it was banned for all residential uses. Lead paint is still used by the military and industry.

Lead in paint is not as readily absorbed as lead from gasoline. Currently, the primary danger stems from older housing with deteriorating paint: the main exposure pathway is via normal hand-to-mouth contact with lead dust. Children also may eat paint chips (because lead makes paint taste sweet). Exposure to lead in paint dust and paint chips represents a significant source of current environmental lead exposure for children. The U.S. government has a variety of programs aimed at increasing parental awareness of the hazards of lead exposure. Many states have residential lead paint regulations that mandate removal or abatement of lead paint in housing occupied by young children.

There is also emerging evidence that lead used in water mains throughout the world presents an additional hazard. Research suggests that water may leach lead from these pipes (either in mains or in residential pipes), providing a steady stream of low-level and largely undetected exposure to lead.

The U.S. experience—a drastic decline in blood lead levels since the 1970s—is widely viewed as a strong success of public health policy. The decrease was brought about by the work of advocacy groups, government agencies, and scientists such as the pioneer Herbert Needleman. This success, however, was not easily achieved: these groups and individuals overcame significant resistance from the paint and petroleum industries. While much has been achieved, hazards remain both in the United States and around the world.

The current public health focus in the United States is on the hazards posed by existing lead paint and the higher likely impact on children of lower socioeconomic status. In addition, many of the psychological effects of childhood lead exposure can persist into adulthood, potentially producing higher rates of adverse social behavior on a societal scale decades after the actual exposure. By affecting societal phenomena, such as learning disabilities and violent crime, lead may in fact have a larger impact on society than has been generally acknowledged.

Worldwide, lead contamination persists, and public health agencies and governments are taking important steps to reduce environmental lead exposure. The removal of lead from gasoline continues, particularly in central and eastern Europe and Southeast Asia. The challenge often encountered is the persistence of deposition from historical usage and the presence of lead in paint. The policy problem, particularly for poorer countries, is that the initial costs of removal may seem high relative to the less tangible and possibly distant health benefits. While the benefit–cost ratios are uniformly high (usually greater than 10), lead contamination presents a challenge for policy implementation.

League of Conservation Voters

THE LEAGUE OF Conservation Voters (LCV) is an American organization with an independent political voice that lobbies on behalf of the environment. The LCV is the political voice of the national environmental movement and the only organization devoted full-time to shaping a pro-environment Congress and White House. The LCV was created in 1970 as a result of the second wave of U.S. environmentalism that emerged out of the first Earth Day on April 22, 1970. The organization focuses its efforts on influencing politics as they relate to the environment in the United States. Marion Edey, then a U.S. congressional staff aide, and David Ross

Brower, the executive director of the Sierra Club from 1952–69, and then founder of the Friends of the Earth in 1969, created the LCV. Edey sought to create an organization that could act as the electoral wing of the environmental movement in the United States. Together, Edey, Brower, and a directorate made up mainly of members of Brower's Friends of the Earth organized the LCV.

The LCV's mission is to advocate for sound environmental policies and to elect pro-environmental candidates who will adopt and implement such policies. The LCV campaigns to defeat antienvironment candidates, and supports those leaders who stand up for a clean, healthy future for America. To assist voters in selecting pro-environmental candidates, the LCV publishes the National Environmental Scorecard, which gives ratings to all congressional members in terms of their voting records on key environmental and public health issues. These issues include energy, biodiversity, public health, environmental funding, and other priority votes (such as free trade and population policy).

The LCV also produces the Presidential Report Card, and with these publications the league holds Congress and the administration accountable for their actions on the environment while preventing antienvironment candidates from masking their records with pro-environment rhetoric. The LCV's National Environmental Scorecard and the Presidential Report Card are the authoritative record of how members of Congress and the administration handle the most important environmental issues.

In addition to tracking voting records and endorsing or opposing candidates, the group contributes to and participates in political and electoral campaigns. The LCV campaigns have been successful, defeating 23 out of 37 antienvironmental candidates targeted by their "Dirty Dozen" campaigns since 1996. The LCV has helped hundreds of environmental leaders to victory, both on Capitol Hill and at the ballot box. Also, since 1996 over 80 percent of LCV endorsed candidates have won their respective elections. Through regional offices, the LCV builds coalitions, promotes grassroots power, and trains environmental leaders. The League Family of Organizations includes the LCV Action Fund, the LCV Accountability Project, and the LCV Education Fund.

Leakey, Louis and Mary

FOR LOUIS AND Mary Leakey, the question of humanity's nature is precisely related to human origins. Humanity has a scientific definition, a definition that is directly connected to humanity's evolution and its manipulation of the environment. According to Louis Leakey, "during the slow course of physical evolution it would be impossible to say positively 'this is where the pre-human creature ceased to be sub-human and became a man' unless we have an agreed definition of what we mean by man." For this reason Louis Leakey defined man simply as a "creature belonging to the primate stock which had reached a stage where it actually made tools, as distinct from merely using suitable natural objects as tools."

There are two astonishing things about this definition. First, it describes humanity as a primate, an animal. Second, it describes humanity as a product of its distinct relationship with the environment: the making of tools. Through their tireless excavations in the Olduvai Gorge in Kenya, Mary and Louis Leakey provided striking proof of humanity's origins as a tool-making primate; an animal connected to nature through millions of years of evolution, but also separated from the environment through conscious manipulation and manufacture of simple stone tools: the first "artificial" products.

Louis Leakey was born to missionaries in British East Africa—now known as Kenya—in 1903. He was fascinated by fossils from a young age. After attending Cambridge he set out to prove Darwin's idea that humans first emerged from Africa, not

Asia, as it was then assumed. From 1926 he excavated at the Olduvai Gorge, a chasm that was once a lakebed and a perfect environment for finding ancient hominid settlements and bones.

After decades of excavation without any definitive human fossil finds, Louis Leakey married Mary Nicol in 1936. As a team Mary and Louis discovered several man-made tools and the prehuman jawbone of a creature called *Proconsul*. In 1959 Mary Leakey made an amazing discovery of *Zinjanthropus*—or *Australopithecus boisei*—which made the Leakeys world famous. The Leakeys speculated the fossil to be at least 600,000 years old; recent carbon-14 dating has pushed back the date of the fossil to an astonishing 1.75 million years.

In 1978 Mary made another astonishing discovery of three-and-a-half-million-year-old footprints of two hominid adults and a child in Tanzania. These were probably the same species as the famous Lucy skeleton discovered by Donald Johanson. The Leakeys made further groundbreaking discoveries in Africa of *Homo habilis*, "handy man" and *Homo erectus*, "upright man" that have profoundly shaped current understanding of human origins. Their son Richard and even their granddaughter have continued the family tradition in paleoanthropology. Louis Leakey died in 1972. Mary died in 1996 at the age of 83.

Leakey, Richard (1944–)

THE IDEA THAT humans gradually evolved from a fragile habitat of apelike creatures in Africa to bipedal, technological masters of the world has become an important—if not always accepted—part of defining modern society and culture. Although Darwin spoke of the descent of man, Richard Leakey—the son of the famous paleoanthropologists Louis and Mary Leakey—popularized the idea of human origins through his groundbreaking discoveries, his bestselling books, and his masterful melding of popular writing with scientific rigor.

While being raised in Africa by the world-famous Leakeys as they searched for hominid bones in the Olduvai Gorge in Kenya, Richard developed a keen interest in East Africa's diverse wildlife. His interest in wildlife and his passion for environmental preservation did not stop as he delved into paleoanthropology. His book *People of the Lake*, written with Roger Lewin in 1978, became a sensation as its conclusions about human nature impacted the arguments of several social movements in America.

The accessibility of Richard Leakey and Roger Lewin's work enhanced the understanding of evolution in the popular mind and opened the door for further studies of evolution in schools. He made other famous discoveries in 1984–85: the Turkana Boy, a nearly complete *Homo erectus* skeleton, and WT17000, the first nearly complete skull of the *Australopithecus aethiopicus*. These and other discoveries were outlined in his more recent book, also written with Roger Lewin: *Origins Reconsidered: In Search of What Makes Us Human*.

From 1989–94 Richard led the Kenyan Wildlife Service and successfully combated the poaching of rhinos and elephants. His keen understanding of environmental issues and the fragile balance between humanity and its environment lead him further into environmental politics. He was elected in 1997 to a seat in the Kenyan Parliament and was a leader in the opposition party Safina.

Maeve, Richard's wife, continues to research in paleoanthropology and recently described two new species of human. Louise, the granddaughter of Louis and Mary, is also engaged in paleoanthropology and has recently made her own discoveries. Over three generations the Leakeys have pointed a spotlight on human origins, compelling us to consider the fragile balance between our natural origins in the environment and our own humanity. They have become the most famous family in paleoanthropology, if not modern science.

University of St. Andrews

Lebanon

FOR MUCH OF the last quarter of the 20th century, the Lebanese Republic was involved in a debilitating civil war that drained the country of much-needed resources and destroyed the existing infrastructure. In 1991, the Ta'if Accord paved the way for reconciling divisions between the diverse religious populations and the government, leading to the institution of political and economic reforms. Both Israel and Syria established a military presence in Lebanon to assist in maintaining the tenuous peace. Israel's forces withdrew in 2000; and, bowing to pressure, Syria withdrew its remaining forces in 2004. However, in 2006 renewed hostilities and an Israeli invasion throughout the southern part of the country meant a revival of violence with serious implications for environmental conditions throughout the country.

With a per capita income of $5,100, Lebanon ranks 130th of 232 nations in world income. Roughly one million of the workforce of 2.6 million is non-Lebanese. Poverty is pervasive, and unemployment is high at 18 percent. The entire population of Lebanon has access to safe drinking water, and only 2 percent lack access to improved sanitation. The United Nations Development Programme Human Development Reports rank Lebanon 81st in the world on overall quality-of-life issues.

Bordering on the Mediterranean Sea, Lebanon has a coastline of 140 miles (225 kilometers). The Mediterranean climate produces mild to cool, wet winters and hot, dry summers. Heavy snows are frequent during winter months in the mountains. Much of Lebanon is composed of a narrow coastal plain, with the Bekaa Valley marking the division between the Lebanon and Anti-Lebanon Mountains. Sandstorms are common.

Natural resources include limestone, iron ore, salt, and arable land (16.62 percent). Lebanon has a surplus of water unlike most of her neighbors who suffer from severe shortages of freshwater. This is partially due to the presence of the Nahr el Litani, which is the only major river in the Near East that is contained in a single country.

ENVIRONMENTAL ISSUES

Environmentally, Lebanon is experiencing extensive deforestation, soil erosion, and desertification. In a 2006 study, scientists at Yale University ranked Lebanon 36th of 132 countries on environmental performance, well above the relevant income and geographic groups. Lebanon received the lowest rankings in the categories of biodiversity and habitat and air quality.

Roughly 88 percent of the population of Lebanon is urbanized, and pollution is particularly severe in Beirut from carbon dioxide emissions and the burning of industrial wastes. Between 1980 and 2002, carbon dioxide emissions in per capita metric tons climbed from 2.3 to 4.7, with the country producing 0.1 percent of the world's total. Raw sewage and oil spills have contaminated the coastal waters. Desertification in Lebanon is a by-product of poverty and climate, and responsible development is seen as the key to checking further ecological damage.

GOVERNMENT RESPONSE

The long years of civil war led to environmental issues being placed on the back burner in Lebanon, but in the last decade or so, the government has begun to deal with the problems of waste management and pollution. The Ministry of Environment heads up six departments that together have been charged with promoting sustainable development and protection of natural resources. The government has launched education programs at all levels to teach the people about protecting their environment. Spurred partly by the active participation of nongovernmental organizations (NGOs), funding for environmental research has increased significantly. Although only 3.5 percent of Lebanon's land area is forested, 0.5 percent of the land has been brought under national protection with the establishment of seven natural reserves. Of 57 endemic mammal species, five are threatened with extinction, and seven of 116 endemic bird species are endangered.

Lebanon participates in the following international agreements: Biodiversity, Climate Change, Desertification, Hazardous Wastes, Law of the Sea, Ozone Layer Protection, Ship Pollution, and Wetlands. The Lebanese government has signed but not ratified agreements on Environmental Modification and Marine Life Conservation.

It is too soon to determine the environmental implications of the renewed violence in Lebanon, but early indications suggest much of it will be serious and potentially irreparable. Following Israeli air strikes in July 2006, for example, the Jiyeh power plant near Beirut leaked some 15,000 tons of oil into the Mediterranean Sea, with critical implications for marine life. Forest fires, soil erosion, burning oil, and toxic waste are all ongoing parts of the conflict, while overall instability further contributes to an environmental crisis in the region.

Legume

LEGUMES ARE PODS or fruits of the *Fabales* order of plants. They include beans, peas, peanuts, alfalfa, soybeans, and vetch. Legumes are important because of their use in human and animal feed and because of the various products they yield, including fibers, edible oils, and plastics. Consequently, industries based on legumes are significant in terms not just of providing nutrition, but also of creating inputs into other economic activities. The current value of legumes is estimated at around two billion dollars annually, with many more used as local food sources and not included in official statistics. Since legumes are of particular importance in improving land quality, the use of legumes is likely to intensify in the future as population growth, climate change, environmental degradation, and desertification de-

Legumes yield many important products, including fibers, edible oils, and plastics.

crease the amount of exploitable and productive land per capita.

Legumes are of importance for their ability to fix atmospheric nitrogen and for the symbiotic relationship they can maintain with rhizobia, which means they are particularly useful in crop rotation schemes to prevent nitrogen depletion in the soil. This also enables legume growers to reduce the amount of artificial fertilizer used to grow plants. The high nitrogen content is also associated with the high level of protein within legumes. Some manufacturers produce rhizobia for use as seed inoculants on a commercial basis.

The rhizobia-legume symbiotic system can fix as much as 300 pounds per acre in the right circumstances. This process means that legume-rhizobia combinations can be of great assistance in promoting sustainable agriculture in areas that previously have not been very fertile. Several thousands of tons of cereal and legume seeds were dispatched to Eritrea, for example, to try to improve the fertility of the land in the wake of the drought of 2002. The necessity of inoculating the legumes is recognized by the Food and Agricultural Organization of the United Nations.

However, the use of genetically modified (GM) rhizobia is more controversial and it is clear that in many countries significant proportions of the population are opposed to any form of GM food. Any use of GM seeds that would contaminate non-GM food, and must be labeled as such, would be resented and rejected by significant numbers of consumers. There is also the risk that GM legumes would have unanticipated impacts on the soil and on surrounding flora and fauna.

Leopold, Aldo (1887–1948)

ECOLOGIST, EDUCATOR, AND pioneering wildlife manager, Aldo Leopold is best known as the author of *A Sand County Almanac* (1949), a work that explored humanity's proper role in what he referred to as "the land community." Part natural history, part philosophical exploration, and part radical environmental manifesto, Leopold's *Sand County Almanac* begins as a series of natural history essays detailing his rehabilitation of a worn-out farm in Wisconsin, and ends as a philosophical treatise that calls for nothing short of a complete realignment of the ethical relationship between humanity and nature.

Leopold was born on January 11, 1887 in Burlington, Iowa. His boyhood was divided between the study of history and literature inside the classroom, and ornithology and woods-lore outside the classroom. Hunting and camping trips across the Midwest provided Leopold with a passion for conservation as he tramped the region's rapidly diminishing prairies and river bottoms, seeing first-hand the damaging effects of habitat destruction on wildlife populations. After earning a master's degree in forestry from Yale in 1909, Leopold entered the U.S. Forest Service. His first job took him to New Mexico, where he would be instrumental in establishing the Gila National Wilderness, the nation's first official wilderness area.

In 1924 Leopold settled in Madison, Wisconsin, where he continued to work for the cause of conservation. His early work *Game Management* (1933), established him as the nation's preeminent authority on wildlife conservation. As a result, in 1933 Leopold was offered a position at the University of Wisconsin, in the nation's first graduate program in wildlife management.

In 1935, Leopold purchased an abandoned farm in Sauk County on the banks of the Wisconsin River. The tract of abused land quickly became a laboratory where Leopold could experiment with methods of reestablishing ecological health to a damaged landscape, and where he could endeavor to understand humanity's proper role in the natural world.

Leopold's experiences rehabilitating the land found their way into a series of essays that would become *A Sand County Almanac*. The book's key contribution to American environmental thought is its deft introduction of ecological concepts into the discussion of humanity's place in nature. Whereas earlier nature writers, such as Henry Thoreau and John Muir, had intuited an interconnected relationship to the nonhuman world, Leopold was able to use the emergent scientific discipline of ecology as the basis of his philosophical argument that each human should regard himself or herself as a "plain member and citizen" of a "land community," rather than a "conqueror" of nature.

Leopold's text is part of a tradition of American nature writing stretching back to Thoreau's *Walden* (1854), a tradition that blends an isolated narrator's first-person account of the workings of nature with broad social commentary. In both works, a simplified, more nature-centered existence becomes the vehicle for a critique of an increasingly technological, and increasingly misguided, American society.

In the book's final section, titled "The Upshot," Leopold addresses the ethical and philosophical changes that he saw as necessary to reverse the environmental losses of 20th century America. In the most influential of the final essays, "The Land Ethic," Leopold called for a radical rejection of land use decisions based on economics, suggesting instead that ethical consideration be granted to all members of "the land-community."

Rather than evaluating interactions with nature solely in terms of human benefit, Leopold called for a redefinition of proper conduct based on what is beneficial to the entire ecosystem: "A thing is right," he stated, "when it tends to preserve the integrity, stability, and beauty of the entire biotic community."

Leopold died while fighting a brush fire on a neighbor's property in 1948, a year before *A Sand County Almanac* was published. While early readers may have missed the philosophical significance of his ideas, later environmentalists of the 1960s and 70s took note of Leopold's push toward a more biocentric view of the universe, making his work a core text of the era's environmental movement.

Lesotho

FORMERLY KNOWN AS Basutoland, the Kingdom of Lesotho attained independence from Britain in 1996. After the return of King Moshoeshoe from exile and his subsequent reinstatement in 1995, constitutional government replaced two decades of military rule. South Africa and Botswana, however, were compelled to intervene when civil protests were followed by a military mutiny. Lesotho has been relatively peaceful since 2002.

Lesotho's natural resources include water, agricultural and grazing land, diamonds, sand, clay, and building stone. Some 86 percent of the population is engaged in subsistence agriculture. Although 35 percent of the adult male population works in South Africa, Lesotho has a 45 percent unemployment rate.

Some economic gains have been made in the past decades. A hydropower facility completed in 1998 allows Lesotho to sell water to South Africa, and a small manufacturing base and growing apparel-assembly sector have surfaced. Lesotho has been approved for an International Monetary Fund Interim Poverty Reduction and Growth Facility.

With a per capita income of $3,000, Lesotho is still a relatively poor country and is ranked 159th in world incomes. Around 49 percent of Basotho live below the poverty line, and great income disparities exist. The richest 10 percent of the population holds 43.3 percent of the wealth, while the poorest 10 percent shares 0.9 percent. More than three-fourths of the population of Lesotho has access to safe drinking water, but only 47 percent have access to improved sanitation. The United Nations Development Programme's Human Development Reports rank Lesotho 149 of 232 countries on overall quality of life issues.

As an enclave of South Africa, Lesotho is surrounded on all sides by its larger neighbor. The terrain of Lesotho is mostly mountainous with highlands, plateaus, and hills. The most distinct geographic features of the country are the Maluti Mountains, part of the Drakensberg Range, which extend from the north to the south. Over 80 percent of Lesotho is above sea level, with elevations ranging from 1,400 meters at the junction of the Orange and Makhaleng Rivers to 4,482 meters at Thabana Ntlenyana in the east. The temperate climate produces cool to cold, dry winters and hot, wet summers. Lesotho suffers from periodic droughts.

ENVIRONMENTAL ISSUES

One of Lesotho's major environmental issues is related to health. With an adult prevalence rate of 28.9 percent, Lesotho has one of the highest HIV/AIDS rates in the world. Out of a population of 2,022,331 people, 29,000 Basotho have died and another 320,000 are living with the disease. The prevalence of AIDS affects many other aspects of health in Lesotho, resulting in a negative population growth rate of negative 0.47 percent and a life expectancy of only 34.4 years. HIV/AIDS is also responsible for the high death rate (28.71 deaths per 1,000 population) and is partially responsible for the high infant mortality rate of 87.24 deaths per 1,000 live births.

Because of overgrazing and soil that has been exhausted and eroded, the Basotho have begun settling in marginal areas. Desertification is expanding, and the country faces increasing problems with air and water pollution. Current methods of dealing with solid and toxic waste management are inadequate.

The Highlands Water Project was designed to use Lesotho's abundance of water to generate needed government revenue, transferring water from the Sengue/Orange River to South Africa while generating hydropower for Lesotho. Critics claim that the project has resulted in overexploitation of Lesotho's resources and deprived many people of their livelihoods. Some people believe that the water should stay in Lesotho to be used during droughts. Only 0.5 percent of the land area of Lesotho is forested, and the government has protected only 0.2 percent of all lands. Lesotho is not rich in biodiversity. Of 33 endemic mammal species, three are endangered, as are seven of 123 bird species.

The National Environment Secretariat of the Prime Minister's Office has been charged with implementing and enforcing environmental laws in Lesotho. The Environment Protection Agency is also involved in this process. In 1989, the government instituted the National Environmental Plan as a framework for enacting laws on Biodiversity, Climate Change, and Desertification Control, with the overriding goal of promoting sustainable development. Specific goals focused on checking soil erosion and land degradation; dealing with water shortages caused by periodic droughts; meeting the needs of an increasing urban population while eradicating poverty in rural areas; preventing further pollution of land and water; devising improved methods of handling solid and toxic waste; promoting biodiversity; protecting and promoting human health; and educating the public about environmental issues. Lesotho has also instituted a universal HIV/AIDS testing plan.

Lesotho participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Hazardous Wastes, Marine Life Conservation, and Ozone Layer Protection. The Law of the Sea agreement has been signed but was never ratified.

Levees

SINCE ANCIENT TIMES, in countries where rising water levels present major residential problems and threats to agriculture, governments have built levees and canals to keep settlements and fields from flooding and to control the directions in which water flows. Archaeologists have discovered the remains of levees in China, India, Egypt, and Mesopotamia. In addition to providing flood protection and controlling water flow, the levee is also used in agricultural production and in regulating water and ice flow.

Some experts believe that today's levees are actually less efficient than those of the past and fault modern engineers for ignoring historical knowledge in constructing levees. From an engineering standpoint, the most important factors in constructing levees are the stability of the foundation on which they stand and the capacity of levees to withstand flooding. Most levees used in North America were originally erected around the turn of the 20th century on the Mississippi River in the United States and on the St. Lawrence River in Canada. Debates since then have focused on whether structural solutions (i.e., the construction of engineered control walls and river manipulations) should be favored over other options, including the restoration of wetlands, natural river paths, and the removal of human inhabitants from floodplains.

New Orleans

New Orleans lies 20 feet (six meters) below sea level, and the city is bordered by the Mississippi River and Lake Pontchartrain, both of which feed into the Gulf of Mexico. Its levees have been receiving attention in recent years as a result of the continuing devastation of the Gulf Coast that began in the 1930s. The worst fears of residents and environmentalists were realized in 2005 when, in the aftermath of Hurricane Katrina, two levees (of the total 350 miles [563 kilometers] of earthen works and cement seawalls) broke. These levees had been built to withstand Category 3 storms but not Category 4 storms like Katrina. Over the next 72 hours, some 37 billion gallons (140 billion liters) of water flooded over 80 percent of the historic city. The 23 pumping stations that dated to the early 1900s were not equipped to handle the deluge and shut down as stations flooded.

As water inundated the city, thousands of residents were stranded without food, running water, medicine, and other necessities. Human loss was estimated at 1,599 lives, with causes of death ranging from dehydration to lack of medical care to drowning to fire to suicide. Tens of thousands of people were displaced to cities around the country. Property damage was an estimated $75 billion, and Congress was forced to appropriate $100 billion for Katrina relief after refusing to appropriate funds to renovate the levees before Katrina hit.

In the months following Katrina, some experts contended that the levees were poorly constructed by the Corps of Engineers. In the spring of 2006, a new scandal erupted when a videotape provided proof that officials at all levels, including the White House, were aware that the scenario that developed in New Orleans was virtually a certainty. Because most of the stranded residents were black and poor, race and class were a significant factor in assessing risk, constructing and maintaining flood controls, and investing in infrastructure against environmental hazards.

Lewis and Clark Expedition

THE LEWIS AND CLARK Expedition (1804–1806) was the first U.S. overland expedition from the east coast to the west coast of the continent. It was led by Captain Meriwether Lewis and Second Lieutenant William Clark. After the Louisiana Purchase expanded U.S. territory in 1803, President Thomas Jefferson, inspired by French ideas for a similar scientific expedition through their territory, accelerated plans for what became the Lewis and Clark Expedition.

Initially there were 33 in the expedition. Captain Lewis, Jefferson's private secretary, was the leader. Captain Clark shared command, although he was technically second-in-command. Sergeant Charles Floyd was the quartermaster; his death early in the trip was the only fatality suffered by the team. There were three other sergeants, one corporal, and the rest were private soldiers, except for York, Clark's black manservant. There was also an interpreter, George Drouillard.

On May 14, 1804, the expedition left Camp Dubois near present-day Hartford, Illinois, and met up with Lewis and others at Saint Charles, Missouri. They then journeyed to La Charrette, the last white settlement on the Missouri River, before heading westward into territory that was then largely or totally unknown to them.

The first Native American tribe encountered by the expedition were the Yankton Sioux, followed by the Teton (or Lakota) Sioux. The first tribe was given five medals, which was a great disappointment, and the second wanted a boat, nearly precipitating a fight. However, the expedition managed to continue on and during the winter built Fort Mandan, near present-day Washburn, North Dakota, where they sheltered for the winter. It was there that they were joined by a French Canadian, Toussaint Charbonneau, along with his Indian wife, Sacagawea. They would become interpreters for the expedition.

In April 1805, Lewis and Clark decided to send back a return party from Fort Mandan. It included a detailed report on what had been discovered up to that point, botanical specimens, and also a prairie dog, which was delivered live to Jefferson in a box.

The rest of the expedition then followed the River Missouri westward. The exact boundaries of the Louisiana Purchase were unknown, and the U.S. government was keen to claim what would later be the states of Washington and Oregon. It was to this area that the expedition headed, finally reaching the Pacific Ocean, an event that Clark recorded in his journal on November 18, 1805.

The expedition spent the winter near the coast building Fort Clatsop. On March 23, 1806, the exhausted group decided to return home. In July, the party split, with Lewis and nine men heading for the Falls of the Missouri, on the same route as the outward journey. Clark followed a southern route along the Yellowstone River.

The two parties reunited on August 12 and returned to St. Louis on September 23, 1806. By that time many people thought the whole party had been killed. Their expedition helped subsequent U.S. claims to the Oregon territories, although there was some anger expressed by the Spanish. The expedition has a unique place in U.S. history as the first successful attempt by people living in the east to cross the entire continent after independence.

Liberia

THE REPUBLIC OF Liberia was originally founded and settled by black American settlers and freed slaves in the mid-19th century, with a structure of government mirroring to a great degree that of the United States. In the late 20th century, the country suffered through a series of civil wars, with a peace agreement signed in 2003. Despite the fact that the United Nations (UN) maintains a presence in Liberia, the situation remains volatile. Because the war and political strife drained so many resources, the country is still in the early stages of rebuilding its infrastructure and finding its path to economic recovery. Tens of thousands of Liberians were killed during the conflict, and at least 238,500 Liberians remain in other countries, unwilling to return to their homeland.

Liberia's rich natural resources include iron ore, timber, diamonds, gold, and hydropower, and the country exports both timber and rubber. Less than four percent of the land is arable. However, 70 percent of the workforce is engaged in subsistence agriculture. Eighty-five percent of Liberians are unemployed. At least 80 percent of Liberians live in poverty, and 46 percent are undernourished. With a per capita income of only $900, Liberia is one of the 20 poorest countries in the world. The UN Development Programme's Human Development Reports do not rank Liberia on standard of living issues due to insufficient data.

Bordering on the North Atlantic Ocean, Liberia has a 579 kilometer coastline and 15,050 square kilometers of inland water resources. Liberia shares land borders with Guinea, the Cote d'Ivoire, and Sierra Leone. The terrain of Liberia is generally flat with rolling coastal plains that give way to plateaus and low mountains in the northeast. Lagoons, mangrove swamps, and river-deposited sandbars characterize the coastline. Elevations vary from sea level to 1,380 meters at Mount Wuteve.

The tropical climate is hot and humid. Winter days are hot, but nights are cool to cold. Summers in Liberia are wet and cloudy with frequent heavy showers. From December to March, Liberia experiences the harmattan, hot dusty winds that blow in from the Sahara Desert, creating environmental damage.

Liberia's population of 3,042,004 experiences many of the health problems that beset other poor African nations, including a high HIV/AIDS prevalence rate (currently 5.9 percent). The HIV/AIDS epidemic has killed 7,200 people, and at least 100,000 more have contracted the disease. Around 62 percent of the population has access to safe drinking water, but only 26 percent (7 percent in rural areas) have access to improved sanitation. Consequently, Liberians also have a very high risk of contracting food and waterborne diseases that include bacterial and protozoal diarrhea, hepatitis A, and typhoid fever, in addition to schistosomiasis—caused by contact with contaminated water—and Lassa fever, caused by contact with infected aerosolized dust and soil. In some locations, Liberians are also at high risk for contracting malaria and yellow fever.

These environmental hazards negatively affect Liberians by producing lower than normal life expectancy (39.65 years) and growth rates (4.91 percent), high infant mortality (155.76 deaths per 1,000 live births) and death rates (23.1 per 1,000 population). Liberian women give birth to an average of 6.8 children each. The low literacy rate (41.6 percent) for females makes it difficult to dispense birth control and other health and environmental information.

The long years of war negatively affected environmental infrastructures, either destroying or damaging the energy, water, sanitation, waste management, and housing sectors. Liberia's other environmental problems are generally centered in the rain forest and along the coast. In order to finance the war, Liberia's forests were stripped of some of their most valuable timber, resulting in soil erosion and a loss of biodiversity. Along the coast, waters were heavily polluted from oil residues and the dumping of raw sewage.

In 2006 a study of scientists at Yale University ranked Liberia 109 of 132 countries on environmental performance, roughly in line with the relevant income and geographic groups. Low scores were assigned in the categories of environmental health and biodiversity and habitat. Just over 36 percent of Liberia is forested, but the rain forest is depleting at a rate of 2.0 percent per year. Only 1.7 percent of land area has been protected. Of 193 mammal species found in the rain forest, 17 are endangered, as are 11 of 146 bird species. Bush meat is being consumed by Liberians and exported to neighboring countries.

In 2002 Liberia enacted the National Environment Policy, the Environment Protection Act, and the Environment Protection and Management Law. By the end of the following year, the Environment Protection Agency Act was operational and charged with implementing and enforcing the existing body of environmental legislation and working with other government agencies and the public to plan and implement new policies and programs. The Forestry Development Authority—established in 1976—and the Division of Wildlife and National Parks—created by the 1988 Wildlife and National Parks Act—work closely with the Environmental Protection Agency on environmental issues. In 2003 the Liberian government created a Protected Forest Area Network designed to prevent further destruction of land and ecosystems.

Liberia participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, and Tropical Timber 94. Agreements on Environmental Modification, Law of the Sea, and Marine Life Conservation have been signed but not ratified.

Libya

THE NORTH AFRICAN nation formally known as the Great Socialist People's Libyan Arab Jamahiriya has been dominated by Colonel Muammar al-Qadhafi since 1969 in a unique combination of socialism, Islam, and Qadhafism. Under Qadhafi, the Libyan government became a haven for suspected terrorists, and Libyan oil money was used in repeated attempts to affect politics and access to resources in other countries, as was unsuccessfully attempted in Chad in 1973. In the wake of United Nations sanctions that followed the bombing of Pam Am Flight 103 over Lockerbie, Scotland, in 1992, overt support for terrorism decreased and Qadhafi moved toward normalizing relations with the West, including paying compensation for past terrorist activities.

Libya's only natural resource other than the petroleum and natural gas that dominate the economy is gypsum. Just over one percent of land area is arable, and only 17 percent of the population is engaged in agriculture. Libya imports around three-fourths of its food supply. The oil sector accounts for approximately 95 percent of export earnings and around 25 percent of the Gross Domestic Product. With a per capita income of $8,400, Libya is ranked 95th in world incomes, considerably higher than most African countries. Unemployment is currently 30 percent, however, and oil earnings tend to be concentrated among the richest segment of society.

Bordering the Mediterranean Sea, Libya has a coastline of 1,770 kilometers. Land borders are shared with Algeria, Chad, Egypt, Niger, Sudan, and Tunisia. The terrain of Libya is generally barren with flat to undulating plains, plateaus, and depressions; and over 90 percent of all land area is either desert or semi-desert. Elevations range from 47 meters at Sabkhat Ghuzayyil to 2,267 meters at Bikku Bitti. While the climate is Mediterranean along the coast, the desert interior is extremely dry. In the spring and fall, Libya is often beset by *ghibli*, a hot, dry southern wind that is loaded with dust particles and lasts from one to four days. Dust and sandstorms are frequent throughout the year in the desert that covers much of the country. The frequent dust and sandstorms and the *ghibli* have combined to produce extensive desertification in Libya, and wind breaks have been built in an effort to halt this process.

Libya usually experiences between 200 and 600 millimeters of rainfall each year. Consequently, fresh water resources are limited. The Great Manmade River Project, the largest of its kind in the world, is currently being erected to transport water via aquifers from under the Sahara to cities along the coast. Critics of the project believe that it is only a stopgap because the fossil reserves that propel its operation will eventually be exhausted. Coastal areas have been polluted from the dumping of raw sewage and from agricultural runoff and industrial effluents. Libya also has an extensive problem with handling solid waste, generating some 0.6 million tons per year.

For the population of 5,900,754, which includes 166,510 nonnationals, there is an intermediate risk of contracting food and waterborne diseases such as bacterial diarrhea, hepatitis A, and typhoid fever. From April to October, Libyans in some areas face a significant risk of contracting vectorborne diseases. Only three percent of Libyans do not have access to improved sanitation, but 32 percent of rural residents and 28 percent of urban residents do not have sustained access to safe drinking water. The United Nations Development Programme's Human Development Reports rank Libya 58 among 232 nations in overall quality of life issues.

More than 86 percent of the population of Libya lives in urban areas where they work for industries that include petroleum, iron and steel, food processing, textiles, and cement. As a result of the extensive population concentration, carbon dioxide emissions rose from 8.9 per capita metric tons in 1980 to 9.1 by 2002. Libya produces 0.2 percent of the world's carbon dioxide emissions. Just over nine percent of Libya's land area is forested, and it is only in oases that date palms, olives, figs, oranges, and wild pistachio nut trees grow. The government has protected 0.1 percent of all land. Of 76 endemic mammal species, eight are endangered, as is one of the 76 endemic bird species.

Environmental protection is still in its early stages in Libya, and the Environmental Agency is working with regional and international groups to formulate environmental policy for Libya. Libya participates in the following international agreements on the environment: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Marine Dumping, and Ozone Layer Protection. The Law of the Sea agreement has been signed but was never ratified.

Lifeboat Ethics

LIFEBOAT ETHICS ARE a set of guidelines for avoiding a global overpopulation crisis outlined in an influential 1974 *Psychology Today* article of the same name by microbiologist Garrett Hardin. Hardin argues that rich nations act against their own long-term interests by subsidizing continued population growth in nations already in excess of their local carrying capacity through humanitarian aid. Drawing equally from Malthus's *Essay on the Principle of Population* (1798), the Club of Rome's *Limits to Growth* (1972), and earlier publications by Hardin, "Lifeboat Ethics" maintains a firmly Darwinist view that populations inevitably grow to the limits of their environment, inevitably increasing faster than parallel increases in food production and other necessary resources. The article links this perception of Malthusian scarcity to an earlier article by Hardin, "The Tragedy of the Commons" (1968), which argues that any resource not protected through direct ownership will be exploited relentlessly. In both "Lifeboat Ethics" and "Tragedy of the Commons" Hardin argues that the surest path to global sustainability is through implementing policies of enlightened self-interest.

To illustrate his point Hardin asks that readers imagine a drifting lifeboat filled near to capacity, surrounded by hundreds of people in the water demanding to be let aboard. One option is to allow everyone aboard until the boat swamps. To Hardin this result is clearly self-defeating and irresponsible—an obvious reference to current aid policies that will inevitably overrun the global capacity to provide for everyone, and in the end save no one.

Another option is to allow as many swimmers aboard as there is surplus capacity. Although this appears to be a compassionate response, Hardin argues that the need to choose who survives from the multitude in the water renders this a fundamentally amoral option. This solution also presents a heightened risk of the absorption of the small surplus of resources on the boat, and if we wish to guarantee survival this is also an unsatisfactory solution.

An ostensibly selfish response is therefore the only moral option in this context, and abandoning those in the water and using the surplus as survival insurance is the only real solution. This improves the chances of those with the best hope at survival while not sacrificing anyone not already at risk. Against accusations that this is actually a thinly veiled rationalization for scientific racism, Hardin responds that it is foolish to risk the well-being of the whole species for the sake of a subset of superficial physical differences and imagined diversity. The rational choice in Hardin's scenario is to demonstrate our fitness for survival by making realistic appraisals of our options. In the lack of an authoritative global leadership that can make these decisions of resource allocation, the only real authority is invested in those in possession of the resources, which happens to be the developed world.

In common with many of the debates about population written immediately following the publication of *The Limits to Growth*, the argument presented in "Lifeboat Ethics" assumes an imminent overpopulation crisis in the underdeveloped world, which has, as yet, failed to occur. The avoidance of a classic Malthusian disaster has done nothing to deter Hardin from his conviction that the threat of a global population collapse is growing rapidly, and that climate change, conflicts over water and oil, ozone depletion, and other hallmarks of a looming environmental crisis are clear indications that we are nearing the global carrying capacity. Indeed, according to Hardin, the lack of a Malthusian crisis has only increased the danger by intensifying resource demands and the sheer numbers of people at risk. The avoidance of crisis through advances in science, particularly the Green Revolution and contraception, and the steep decline in global fertility rates since the 1970s has led many to doubt that resource crises are inevitable and cannot be circumvented through innovation and adaptation.

Life Cycle Assessment

IS IT BEST to use cups made of paper, polymer foam, or ceramic? Which ones cause the least environmental damage? Paper, of course, comes from wood, and wood is a natural renewable resource. On the other hand, foam cups are made of polystyrene, which is obtained from crude oil, a nonrenewable resource. Does this mean a paper cup is more environmentally friendly than a foam cup? However, even though paper is from a renewable source, many harmful chemicals are emitted during its manufacture. Do the advantages of renewability outweigh the harm from emissions? Life Cycle Assessment (LCA) aims to answer questions such as these and can be useful for making technological choices.

LCA evaluates the environmental impact of a product throughout its life cycle starting from raw material extraction, going through product manufacture, use, recycle, and disposal. The life cycle of a paper cup would thus include cutting down the trees to obtain wood chips, transporting them to paper mills where they are converted to paper cups, transportation of cups to the market, sale of cups to consumers, and use by consumers. The cycle would end when the cups are reused, recycled, or discarded.

A typical LCA of a product consists of four steps: goal and scope definition, inventory analysis, impact assessment, and improvement analysis. The first step consists of specifying the purpose of the life cycle study and in simple cases means comparing the environmental burden of two products with similar uses. Scope definition implies identifying and specifying the important processes to be included in the life cycle of a product.

For the second step, inventory data are collected for each of the processes in the life cycle. Input data typically includes material and energy consumption data, while output data includes the emissions of various substances. There can be a variety of emissions during the entire life cycle, such as carbon dioxide, sulfur dioxide, methane, or benzene. These have different impacts on human health and ecosystem quality.

Impact assessment, the third step, aims at understanding the quantitative magnitude and significance of the potential environmental effects of all these emissions in different impact categories. For example, carbon dioxide and methane can cause global warming; sulfur dioxide and benzene can affect human health. This is the step in life cycle assessment where the results are used to draw conclusions and make recommendations for improving the environmental performance of a product.

Returning to the example of the paper, plastic, and ceramic mugs, it turns out that each of these three cups has a dark side. A ceramic mug is made from clay, which is relatively clean; it can also be used multiple times, which reduces waste. These properties make it attractive. But is it better than a paper or plastic cup?

Wood, the original source material of paper, is supposedly green, but during the transformation of wood to paper, steam is needed to heat the wood, machines are used to grind the wood fiber, and vacuum pumps and dryers are essential to remove the water from the pulp. All of these consume energy. Additionally, many inorganic chemicals—chlorine, sodium hydroxide, sodium chlorate, sulfuric acid, sulfur dioxide, and calcium hydroxide—are used during the pulping and bleaching phases. Also, although paper is biodegradable, it releases methane during its degradation, which contributes to global warming.

A foam cup is made entirely from materials derived from crude oil, a nonrenewable resource. Impacts from extraction of crude oil and its subsequent refining are significant. Any accidental spill during drilling, production, or transportation of crude oil can pose an ecological disaster. In the manufacture of a foam cup, pentane, an organic compound that may cause smog, is employed as the blowing agent. Since polystyrene is relatively inert to decomposition, it will persist much longer than paper in a landfill.

The last example is that of a ceramic cup. Although it requires a lot of energy during its manufacture, a ceramic cup can be used many times, therefore it should probably be better than a paper or plastic cup. However, the cup needs to be cleaned after each use, and this requires a large amount of hot water and soap. Energy is necessary to get hot water. The soapy wastewater needs treatment. These requirements might offset the benefits obtained from reuse. A ceramic cup is not biodegradable either, and may stay in the landfill forever.

This simple example illustrates that significant use of materials and energy, and emission of pollution, can occur in any phase of the life cycle: In the resource extraction phase for a foam cup, in the manufacturing phase for a paper cup, in the use phase for a ceramic cup, and in the disposal phase for all three of them.

This suggests that LCA is crucial to evaluating and comparing the broader environmental burden of products that perform similar functions. In addition, it can help identify opportunities for improving the efficiency of existing processes.

Life Expectancy

LIFE EXPECTANCY IS a term employed to statistically describe the average length of time a person within a given human population, such as a particular country or time period, lives from birth until death. Like other tools for determining the nature of demography, the measuring of life expectancy rates is sensitive to various factors. As a consequence, it can be calculated in different ways. For example, life expectancy may be measured without utilizing the infant mortality rate—this form of calculating life expectancy is commonly employed within nations that suffer from high child mortality levels.

Average life spans are longer today than in the past, thanks to modern technology and scientific understanding of disease. Increased wealth and improvements in standards of living have also led to better diets, making humans healthier and less

In some African nations, such as Swaziland and Botswana, citizens live on average for less than 34 years; in wealthy societies like Hong Kong and Andorra, people commonly live more than 81 years.

susceptible to particular diseases than in prior times in many parts of the world.

The introduction of technologies has been important in augmenting average life expectancies. Sir Joseph Bazalgette first developed urban sewage systems on a citywide scale in London during the Victorian age (in the mid-1800s). In addition, medical advances have played an important role in lessening the presence and influence of disease. Progressive medical thinking has helped make once life-threatening illness curable. Also in Victorian London, medical practitioners like Dr. John Snow were pivotal in understanding the true nature of disease. Dr. Snow, with his studies on cholera, was able to scientifically prove that cholera was a waterborne illness. Consequently, not only was the nature of disease better understood, but public administrations were better prepared to deal with incidents of illness. Over time this allowed levels of disease to decline and life expectancies to rise.

A variety of factors can influence life expectancy levels. Dietary patterns, in particular poor nutrition, greatly influence the level of life expectation. In places where diets are nutritionally poor, possibly as a result of famine or natural disasters like floods and typhoons that can devastate local harvests, occurrences of disease increase and life expectancy levels fall.

Of similar significance is the character of a society's urban places that may have rapidly grown to unprecedented levels in terms of spatial size, demographic scale, and urban density after the onset of industrialization. Extraordinary pressure may be put on the local infrastructure, which can result in environmental degradation such as water pollution and higher rates of disease, deprivation, and death. Under such conditions, epidemics may push up the mortality rates among those most susceptible to disease, such as old people, children, and disadvantaged social groups, thereby lowering life expectancy rates within the urban locale and the nation as a whole.

Generally, as the world has developed economically, life expectancy has increased. However, when a nation initially industrializes and experiences rapid urbanization for the first time, the poorest in society, especially in urban settlements, experience difficulties on an unprecedented level. Furthermore, as the number of poor within a nation may be great, this can negatively influence the life expectancy rate within the country. Immediately following industrial progress the country may experience a decline in average life span, even while national levels of wealth increase. On the other hand, as time passes following the onset of industrialization, life expectancy levels increase dramatically, especially when compared over a time frame of 100 years or more.

In England, the world's first industrial and urban country, life expectancy rose from about 36 years on average in 1801 to 49 years by 1901. By 2001 the English life expectancy was about 78.5 years, although great regional variances were known to exist. In industrial cities like Manchester, men on average live for just 69 years and women for 76 years. In contrast, in affluent suburbs of West London like Kensington and Chelsea, men usually live to 80 and women to 85. In the United States, life expectancies also vary and it is common to observe differences between ethnic groups and genders.

Worldwide, the level of life expectancy varies. The varying prevalence of poverty is commonly acknowledged as a reason for why national life expectations differ from place to place. Present life expectancies vary between that of African nations such as Swaziland and Botswana, whose citizens on average live for less than 34 years, to wealthy societies like Hong Kong, Macao, Andorra, and San Marino, where people commonly live for more than 81 years.

As a result of such differences, global strategies have been composed by organizations such as the United Nations to improve life expectancies in many parts of the world and so lessen life expectancy discrepancies between continents. In particular, much focus has been placed on nations within Latin America, Africa, and parts of Asia, where poverty and treatable disease, like malaria, typhoid, and influenza, still have the greatest influence on quality of life, longevity, and mortality rates, especially for children and the poor. In forging policies to deal with such human inequalities, it is hoped social justice can be demographically manufactured, allowing people within less developed and poorer continents to extend their life spans.

Linnaeus, Carl (1707–78)

CARL LINNAEUS, NATURALIST and taxonomist, was born May 13, 1707, at Råsult, near Stenbrohult, Småland, Sweden. He was educated at Växjö school and the universities of Lund and Uppsala. In 1732 he travelled to Lappland to study its little known natural history and economy. Linnaeus left Sweden for the Netherlands in April 1735, graduating with an M.D. from the University of Harderwijk that year. He then moved to Leiden where he published his *Systema naturae* (1735), which classified the three kingdoms of nature (plants, animals, minerals) and outlined the sexual system for the classification of plants. He became physician and garden superintendent to George Clifford, a wealthy Englishman living in the Netherlands.

Linnaeus visited England in 1736, where he persuaded leading naturalists to adopt his systems for classifying plants and naming all living organisms. His systems were developed at a time when European travellers were bringing back unprecedented numbers of plants and animals from previously unknown lands. It was extremely important that his methods were adopted by naturalists from imperial countries such as Britain and the Netherlands, especially when those naturalists were, like Sir Joseph Banks, actively involved in voyages of discovery. Linnaeus's pupils also helped to spread his ideas, which came to be almost universally accepted.

Linnaeus's main contributions are the sexual system for the classification of plants, and the design of his classification scheme, which is hierarchical and uses binomial nomenclature. The sexual system, described in successive editions of *Systema naturae* and *Fundamenta botanica* (1736) and *Classes plantarum* (1738), uses the number and arrangements of the sexual organs of stamens (male) and pistils (female) to group plants into 24 classes. The classification produced some anomalies and later classifications generally follow John Ray's practice of using morphological evidence from all parts of the plant and all stages of plant development, later attempting to infer evolutionary relationships from this evidence.

What survives from Linnaeus's sexual classification is its hierarchical nature (species are grouped into genera, genera into orders, orders into classes, and classes into kingdoms) and his use of binomial nomenclature in which the two elements of genus and species name form short names, much more convenient for quick reference than the discursive and mutable labels suggested by his contemporaries. Linnaeus was not the first to use binomial forms, but his consistency, precision, and rigor promoted the general acceptance of the practice.

Returning to the Netherlands in 1736, Linnaeus published further important botanical works before returning to Sweden in 1738, largely in order to marry (in 1739) his Swedish fiancée. He turned to medicine to make a living, but continued his scientific work, being a founder member and first president of Kungliga Vetenskapsakademien (the Swedish Royal Academy of Sciences) in 1739.

In 1741 Linnaeus became professor of botany at Uppsala University, reviving the botanical garden there. He was an inspiring teacher, drawing pupils from all over the world. Similarly he was honored by scientific societies worldwide. Linnaeus undertook several journeys in Sweden at the behest of the government, searching for plants that might be economically useful.

In 1758 Linnaeus bought an estate at Hammarby, near Uppsala. He was ennobled, taking the name Carl von Linné in 1762. His health deteriorated and he died on January 10, 1778, in Uppsala and was buried at Uppsala Cathedral. When his son Carl died, his family sold most of Linnaeus's botanical collections to a British naturalist who brought them to what became the Linnean Society of London. Most of the rest of the collections remain in Uppsala. In 1905 Linnaeus's *Species plantarum* (1753) was accepted as the starting point for modern botanical nomenclature and the 10th edition (vol. 1) of Linnaeus's *Systema naturae* (1758) is the starting point for modern zoological nomenclature. About 12,000 internationally agreed-upon names have "L" appended to them to indicate that they originate in a description published by Linnaeus.

Lithuania

AFTER BEING PART of the Soviet bloc for 50 years, Lithuania declared its independence in 1990, becoming the first country to seek independence after the dissolution of the Soviet Union. Lithuania joined the European Union (EU) in 2004. With the Baltic Sea forming part of its western boundary, the country of 3,596,617 people has 61 miles (99 kilometers) of coastline. The climate of Lithuania is transitional, alternating between maritime and continental, with wet, moderate winters and summers. The terrain is made up of lowlands dotted with small lakes. Lithuania has almost no natural resources except for arable land and peat.

Lithuania has gradually severed economic ties with Russia as it forges ties with the West. The government is still in the process of privatization, having converted around 80 percent of all industries. With a per capita income of $13,700, Lithuania ranks 67th in income among the nations of the world. The high unemployment rate that accompanied Russia's economic crisis of 1998 has been halved, and inflation is under control at 2.6 percent. One-fifth of the Lithuanian workforce is involved in agriculture. The United Nations Development Programme Human Development Reports rank Lithuania 39th on general quality-of-life issues.

ENVIRONMENTAL ISSUES

Environmentally, Lithuania experiences extensive air pollution and contamination of soil and groundwater from petroleum products and chemicals derived from military bases and industries. The greatest potential threat comes from the Ignalina nuclear power plant, which operates two reactors that are remarkably similar to the one that precipitated the disaster at Chernobyl, Russia, in 1986. Other threats arise from fertilizer and chemical plants, oil refineries, power stations, and cement factories that pollute the air around them and deposit chemical effluents in the rivers and lakes. Air pollution is so severe in Lithuania that at times it covers one-third of the country. Around 67 percent of the population resides in urban areas, and there are 346 cars for every 1,000 people. As a result, Lithuania produces 0.1 percent of the world's total carbon dioxide emissions.

Water quality in Lithuania has traditionally suffered from a shortage of purification plants, and untreated water has been released directly into waterways. Beaches have been closed to the public because of heavy pollution, and acid rain has damaged forests, particularly in the area of Jonava, Mazeikiaia, and Elektrenai, where chemical, oil, and power generators are located.

Some 28 percent of Lithuania's land area is forested, and the government has protected 10.3 percent of the land with the creation of national parks and reservations aimed at protecting biodiversity. Five of 68 mammal species endemic to Lithuania are endangered, and four of 201 bird species are threatened. Plant life has also been seriously threatened as a result of poor agricultural practices.

Although some environmental laws were passed during the Soviet years, widespread apathy and an emphasis on economic production meant that little was done to correct the problems. In 1990 Lithuania established the Environmental Protection Department, which became the Ministry of Environmental Protection in 1994. Working with eight regional departments, the ministry is responsible for monitoring and implementing environmental legislation. The focus of environmental policy is on preventing new sources of pollution and on providing economic incentives to facilitate enforcement of existing laws and regulations. In 1992 Lithuania passed the Environmental Protection Act to provide an environmental framework and to supplement earlier legislation such as the Atmosphere Protection Act and the Water Code. While some environmental legislation has been enacted, other bills are still in abeyance.

Lithuania's commitment to the global environment is demonstrated by participation in the following international agreements: Air Pollution, Biodiversity, Climate Change, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Ozone Layer Protection, Ship Pollution, and Wetlands. The agreement on Air Pollution–Persistent Organic Pollutants has been signed but not ratified.

Litigation, Environmental

ENVIRONMENTAL LITIGATION—the filing of lawsuits to protect the environment or to prevent or remove pollution, or countersuits to defend against environmental legal actions—has grown enormously in the United States since the 1970s. The legal basis for these suits has been a complex, growing web of federal and state statutes, which have also created environmental regulatory agencies to develop policy rules and regulations for implementing environmental public policy.

Environmental regulatory agencies, in fulfilling their legislative mandates, have developed a vast number of environmental regulations that are now part of administrative law. Their administrative rules and regulations are quasi-legislative and are usually enforced by the environmental agencies, which also have quasi-judicial powers. The net effect is that polluters can be fined or imprisoned for violating bureaucratic rules as easily or more easily than for actions violating some general laws.

HISTORY

Everyone lives in some kind of environment, whether natural or man-made. Whatever affects the environment can affect the personal health, social practices, or economic health of a community. The governmental actors, and especially the courts, have recognized this for centuries with health ordinances controlling sanitation practices in many forms. What is new is the explosion in environmental litigation.

Prior to the 1970s most environmental suits were filed on the basis of the common law or on earlier judicial decisions in specific cases. If a party in a suit claimed that an injury had occurred, then tort law allowed them to have cause for action. Cases were based on negligence to stop environmentally destructive practices, nuisances, trespasses, or acts for which a party is strictly liable. Other actions sought recovery of damages as compensation for environmental injuries.

Tort-based environmental litigation was often difficult to initiate because it was often hard to prove who caused an environmental injury. In addition, courts tend to favor property rights and were reluctant to restrain business activities with injunctions to prevent future environmental degradation.

POST-1970 ERA

While these earlier remedies for environmental torts are still available, since the 1970s the federal and state governments have passed comprehensive sets of environmental laws. These laws were designed as wholesale remedies for environmental problems. They were eventually followed by amendments that focused on manageable parts of environmental pollution problems.

Today the federal environmental policy program includes broad policy statutes, conservation statutes, and public health statutes. The broadest federal statute is the National Environmental Policy Act, which mandates that the federal government assess the environmental impact of its projects before they are begun. The conservation policy statutes include the Endangered Species Act, the National Forest Management Act, and the Wilderness Act. The latter two acts mandate how the nation's forests are to be managed. Congress has adopted a wide array of laws to protect the public's health. These include the Clean Air Act, the Clean Water Act, the Resource Conservation and Recovery Act, the Comprehensive Environmental Response, Compensation, and Liability Act, and other laws.

These federal laws, along with a growing number of state laws, have been used by both the federal and state governments as the basis of environmental litigation. In addition because some of these allow standing, or standing has been sought by environmental groups, the volume of environmental suits has grown enormously since the 1970s. So large and serious has the judicial business of environmental litigation grown that there are now law firms that specialize in environmental litigation as champions of plaintiffs or as counselors for environmental defendants.

With the adoption of massive new environmental laws in the 1970s, the legislation and the courts increasingly allowed private citizens to acquire standing for bringing a suit. The courts showed a growing willingness to allow citizen suits, even on a class action basis, to be brought to enforce the National Environmental Policy Act. The courts, in the absence of legislative authority for judicial review and in the face of bureaucratic indifference to environmental practices by the federal government, decided cases that forced the practice of developing environmental impact statements. Many of the suits that forced both federal and state bureaucracies to change old behaviors were brought by citizens or environmental action groups.

The exercise of judicial review to examine the constitutionality of governmental actions has been the basis of numerous suits, especially from business or industry seeking relief from environmental litigation. On the other hand, many environmental groups have also challenged governmental activities as unconstitutional violations. The use of tort law and judicial review are the basis of most environmental suits.

The political climate in which environmental litigation emerged in the 1970s was one of suspicion and hostility toward government. The Vietnam War had angered many on the ideological left from which the environmental movement's activists were usually drawn. Many court battles were fought with very hostile feelings driving the litigation. This original litigious atmosphere often made negotiations or compromises difficult to achieve. The consequences were legal duels to settle disputes over environmental issues that generated serious legal costs and more acrimony.

THE 1980s AND 1990s

In the 1980s some environmental groups resorted to civil disobedience and, in some extreme cases, to ecological terrorism. However, in the main the use of the Endangered Species Act and other legislation brought numerous environmental issues into the courts where the tendency was to favor the environment. In some liberal courts, the green political views of environmental extremes were often favored.

In the legal world of environmental litigation, business and industry have found that even if they have complied as fully as possible with current environmental law—they have used the best practices and worked with both federal and state agencies—they have not done enough to satisfy some litigiously minded environmental groups. The reason some lawsuits arise is due more to environmental philosophy than to actual illegal activity. For example, the forest philosophy of Gifford Pinchot was to manage resources; however, John Muir wanted the nation's forests left as unspoiled wilderness. Very different environmental philosophies abound in the United States, where litigation is relatively easy compared with the rest of the world.

As a consequence of the litigious environmental atmosphere some law firms have organized on a national basis and have legal incident reaction teams to respond to the filing of an environmental suit almost immediately and almost anywhere no matter how remote. The goal of these environmental defense firms is to promptly protect the interests of companies and individuals from suits that may have the power to damage or destroy a business.

In response to environmental litigation many businesses have engaged in SLAPP (strategic lawsuits against political participation) countersuits. These are punitive suits that seek to punish citizens or groups for using the courts or even for using public forums to criticize business activity. SLAPP suits usually lose in court; however, they can have a chilling effect and can be expensive to defend against.

The Environmental Protection Agency has been the source of many suits. It has also reflected the philosophical policy differences of the ideological spectrum in its history as different administrations have controlled the agency. In the long run environmental litigation will continue to flourish because technological changes will continue to have significant environmental consequences, and because the American public is concerned about individual and environmental health in at least a general sense.

Because of the expense of litigation and because using court decisions often creates a zero-sum game, the use of mediation has attracted attention since the 1990s as a way of negotiating environmental policies that avoids enormous legal costs. Mediation also allows all the parties interested, including environmental groups, to have a place at the bargaining table. Environmental litigation is also growing in many countries as resource extraction or manufacturing without regard to the environmental consequences causes severe environmental damage. International agreements are increasing to deal with global environmental issues.

Livelihood

SINCE THE EARLY 1990s the notion of a "sustainable livelihood" has come to prominence as a way to analyze poverty and natural resource use in international development circles. The sustainable livelihoods approach has been particularly influential in the study of community-based natural resource management, but it originates in studies of the relations between development, poverty, and food security. In its simplest sense, a livelihood is a means of gaining a living, but the concept has broadened with the recognition of the full range of diverse activities and resources that make up a person's or household's ability to survive over time. Rather than conceive of people as "peasants," "farmers," "laborers," or some other fixed category, the sustainable livelihoods approach recognizes that households may employ multiple economic strategies simultaneously, sometimes in different locales.

A livelihoods approach recognizes a household's reliance on natural resources like thatching grass, fish, and game.

DEFINITIONS AND AN EXAMPLE

In an important article, Robert Chambers and Gordon Conway defined a livelihood as comprising the full range of "capabilities, assets...and activities required for making a living." Later authors refined the concept of assets, identifying five key forms of "capital": human capital, natural capital, financial capital, physical capital, and social capital. The sustainable livelihoods approach also draws attention to the context of vulnerability in which livelihoods exist, typically conceived in terms of *stresses* and *shocks*. The former term refers to long-term, predictable processes like population growth, seasonal variation, or declining availability of resources, while the latter refers to sudden and unpredictable events like drought, flood, death or illness of a family member, loss of a job, and so on. A livelihood may be considered sustainable when it can avoid, resist, and/or bounce back from such stresses and shocks, while maintaining its capabilities and assets, and without undermining its natural resource base.

An extended example can illustrate both the kind of complex livelihoods that the concept was designed to understand and the advantages of the livelihoods approach. Consider the household of Sipho Mazibuko (a pseudonym). Sipho is a retired labor migrant living in rural South Africa and drawing a state old-age pension. His eldest son, Jongisizwe, works on a mine outside Johannesburg where members of his community have worked for generations and sends money home to his family. Sipho and his wife, Nokhaya, have a large garden adjoining their household, and a field a few miles away. They plow their land by combining their oxen with those of Sipho's extended family. Sipho's younger son, Patrick, is responsible for herding their cattle, sheep, and goats. Jongisizwe's wife, Vuyo, also lives with the family, caring for her two young children. While Sipho and Patrick are responsible for plowing, Nokhaya and Vuyo do most of the everyday work in the garden. At certain times in the agricultural cycle, when extra labor is needed for harvesting or weeding, Nokhaya brews beer and invites people from the neighborhood for a work party. Occasionally she brews beer for sale locally. Vuyo and Nokhaya are responsible for fetching water and for cutting thatching grass to repair the roof of the family's houses. Sipho and Patrick cut wood from nearby forests for building and maintaining the family's houses and the fences of their garden and livestock enclosures. Patrick also fishes in a nearby river, and sometimes sells fish to white tourists who stay at a hotel in a nearby nature reserve. At certain times of year, Nokhaya also gathers wild fruit from the forests for domestic consumption.

To return to the definition of a livelihood, the different members of the household have capabilities: the knowledge and ability to farm, to care for livestock, to find a job in an urban area, to negotiate government bureaucracy and secure an old-age pension, to brew beer, to locate wild foods, and so on. Together, this diverse package of capabilities gives the household the ability to respond to changing economic and ecological conditions and to manage stresses and shocks. In doing so, they draw on different forms of capital: human capital (the labor of the different household members), natural capital (land, water, livestock, forests, fish, and more), financial capital (wages, pension payments, and the proceeds of selling beer and fish), physical capital (their houses and domestic structures and the infrastructure that enables travel to and from the workplace), and social capital (extended family and neighbors). As is evident, the household draws on a wide range of activities. The household's diversification gives it the ability to manage stresses: for example, it has a way to recruit labor during seasons of scarcity; it also has some insurance mechanisms in the event of shocks: for example, it could sell livestock to cover hospital bills in an illness.

CONTRAST WITH OTHER APPROACHES

The livelihoods approach can be contrasted to older, sector-specific conceptions of poverty and its alleviation. A production-focused approach might conceive of Sipho as a "farmer," and propose measures to improve the agricultural output of gardens and fields, but this would ignore the contribution of wages and pensions to the household. An employment-focused approach might focus on the fact that several household members of employable age are not working, but this risks ignoring the contribution of their labor to agriculture. In contrast, notes Colin Murray, a livelihoods approach "acknowledges the need to transcend discrete sectors—urban and rural, industrial and agricultural, formal and informal, etc." Moreover, rather than focus on what households lack, the approach focuses on identifying their existing strengths and their potential.

The approach is particularly useful for facilitating community-based natural resource management because it calls attention to the contribution of the local environment to livelihoods. In the example above, note that neither a focus on production nor on employment would take into account the household's reliance on natural resources like thatching grass, building wood, fish, and wild fruit. Conventional socioeconomic surveys often tend to omit the value of natural resources. In contrast, the sustainable livelihoods approach draws attention to the role of the environment in the household economy, illustrating how the sustainability of a livelihood may be connected to the sustainable use of natural resources.

The example above came from South Africa, but the analysis of sustainable livelihoods has been applied throughout the world, to topics as diverse as understanding the impact of irrigation on fisheries in Sri Lanka, involving the poor in urban services development in Ethiopia, and analyzing the relation of climate variability and household welfare in the Andes. The approach has been used both to formulate new development interventions and to analyze and refine existing programs.

INFLUENCE AND SHORTCOMINGS

The approach has spread widely in international development and conservation circles. The 1987 Report of the United Nations Commission on Environment and Development (also known as the Brundtland Report), the 1987 Greening of Aid Conference at the International Institute for Environment and Development, and the 1992 United Nations Conference on Environment and Development in Rio de Janeiro (the Earth Summit) set the stage for Chambers and Conway's influential paper by linking conservation to poverty alleviation. In the 1990s, the United Nations Development Programme, Oxfam, CARE, and the British Department for International Development (DFID) have all developed programs aimed at promoting sustainable livelihoods. Drawing on the experiences of these organizations and others, the UK-based Institute of Development Studies has developed an important Web site (www.livelihoods.org) documenting the approach, providing "guidance sheets" on research methods and planning techniques to operationalize it, and offering dozens of examples of its application in development and conservation programming.

Despite its influence and widespread use, several significant critiques have been made of the approach. First, while access to different forms of capital depends on political processes, the livelihoods approach may lead to a focus on individuals and households, rather than changing the political and economic macro-environments that create "vulnerability contexts." Second, the focus on the household may lead to potentially false assumptions that households act in a unified manner toward common goals and may ignore inequalities of gender and age within households. Third, as Murray points out, the notion of "sustainability" is also seen to beg important questions: "'Sustainable' for whom? By what criteria? In the short term or the long term?" Finally, the holism of the approach may make it effective as a tool for describing existing diverse livelihoods but may lead to undue complexity when it is used as a basis for defining policy priorities and formulating interventions.

Livestock

THE TERM *LIVESTOCK* refers to domesticated animals utilized for food, fibers, hides, fertilizer, and/or labor. The category of livestock includes such domesticated ungulates as bison, camels, cattle, donkeys, goats, horses, llamas, reindeer, sheep, swine/pigs, water buffaloes, and yaks, with cattle and sheep being the two most abundant types of livestock worldwide. Nonungulate livestock include first and foremost poultry, as well as rabbits, guinea pigs, and even honeybees, among other animals. Livestock are usually distinguished from wildlife and pets, although there occasionally is categorical overlap (e.g., farmed ostriches or herding dogs).

The domestication of plants and animals for food began some 11,000 years ago in southwest Asia and was a hallmark of the Neolithic, or New Stone Age. Some humans transitioned from hunting, gathering, and fishing sustenance strategies to more stationary ones based on the deliberate production of foods. Based on archaeological evidence from northern Mesopotamia, it appears that sheep and goats were among the first animal domesticates ancestral to today's livestock. Although dogs appear to have been domesticated by 16,000 years ago, they apparently served as hunting companions and not a food source. Aurochs, the now extinct ancestors of today's cattle, were likely independently domesticated in multiple sites through Asia and Europe. Domesticated pigs had become popular in parts of southwestern Asia and chickens in southeastern Asia perhaps by 8,000 years ago. The domestication of these latter species overlaps with increasing trends of humans becoming less nomadic and the expansion of agriculture. From that point onward, humans intentionally and unintentionally reconfigured their environments, as they constructed ways to raise their domesticated plants and animals, as well as protect them from pests and predators.

Although domestic animals and animal husbandry practices have varied greatly around the world, livestock have become crucial to agricultural life in general. Livestock convert low quality (by human standards) roughage into protein, fat, and other nutrients fit for human consumption and provide fertilizer for croplands. Ungulates supply additional labor power as pack animals, transport, and plowing aids, and their manure can also be dried and then burned for fuel. With increasing specialization in agriculture and the growth of pastoralism, people have endeavored to control the reproductive rates and birth timing of their livestock and to breed them selectively for certain qualities.

Specialized pastoralism in precolonial East Africa serves as an example of how livestock-keeping, under certain conditions, fits ideals of ecological sustainability. In this semiarid savanna region, pastoralists focused on cattle, sheep, and goats, while also keeping donkeys and sometimes camels. They practiced transhumance, moving herds and family between wet-season pasturelands near temporary water supplies and dry-season grazing lands based near permanent water sources. They managed the grasslands by moving livestock in such a way as to limit encroaching bush while not overgrazing and thus damaging grasslands, and would practice what have been called "cool burns" of dry, nonnutritious grasses to promote new grass growth, with a side livestock benefit of reducing tick populations.

It appears that such management techniques also generally benefited wildlife, as wild ungulates grazed the new grasses and were afforded some protection from predators by remaining close to human activity. Conflicts arose between humans and predators when the latter attacked livestock. Still, the livestock and wildlife populations remained relatively stable for more than a century prior to the onset of the colonial enterprise in the late 1800s.

Colonialism in East Africa, as elsewhere, introduced new concepts of land management and ownership. Efforts to commercialize pastoralist livestock production and to make pastoralists stationary led to a series of land laws that restricted pastoral movement to more marginal lands, introduced commercial livestock industries, and placed various pressures on pastoralists to increase livestock turnover rates and sell animals for slaughter. The essential components of pastoralism—land, livestock, and labor—were largely appropriated and reconfigured into quantifiable, commodified units, managed by experts, i.e., government authorities and eventually outside development agents. In a context of an ever-growing global population, rural farmers and pastoralists became increasingly tied to regional and world commodity markets, had reduced access to land and other necessary resources, and thus became ever more vulnerable to natural disasters.

Meanwhile, in North America, the development of mechanical refrigeration enabled the dramatic expansion of the meatpacking industry. By the late 19th century, the Chicago stockyards had become an iconic representation of American capitalism and economies of scale. In 1906, Upton Sinclair's *The Jungle* exposed the brutal working conditions within the slaughterhouses and meatpacking plants, and Congress enacted the Pure Food and Drug Act and the Federal Meat Inspection Act that same year. Labor organizations began to improve some aspects of meatpacking, securing better wages and somewhat reducing job hazards. In the 1960s, a major revolution in meatpacking occurred when IBP (Iowa Beef Packers) redesigned the slaughter and packing process to fragment tasks and deskill work, thus reducing wages while making it easier to replace laborers; sped up the chain of production; and relocated plants to rural areas, which were less expensive operation locales and also without organized labor. The IBP model dominated beef processing and was adopted in poultry and swine operations.

Approximately 600 million rural poor people base their livelihoods on livestock.

Changes have also occurred in the rearing of livestock, as many moments in the production of milk, meat, and eggs have been consolidated by large, even transnational agribusinesses. For example, swine and poultry may now be raised entirely indoors to control all aspects of their growth. Concentrated Animal Feeding Operations (CAFOs) confine beef cattle to small areas and large amounts of grain (hard for the animals to digest) to fatten them up prior to slaughter.

Artificial insemination, antibiotics, and hormones are commonly used in industrial livestock to control for breed quality and durability. Genetic engineering and modification of livestock has expanded beyond selective breeding to include cloning, transgenic processes through which certain qualities of animals might be enhanced, and animal bioreactors (genetically modified livestock that produce pharmaceuticals used to treat human diseases).

Critics note that there are many negative repercussions of such practices, including problems with the general health of the livestock, as well as threats to the health of people and other animals in the ecosystem; high concentrations of manure leading to water, ground, and air pollution; heavy reliance on fossil fuels for the production of feed, as well as the transport and processing of the animals.

According to the International Livestock Research Institute (ILRI), demand for livestock foods is expected to more than double over the next twenty years. ILRI argues that this Livestock Revolution will see so-called developing countries producing 60 percent of the world's meat and 52 percent of the world's milk by 2020, and that could provide several hundred million people with the opportunity to raise themselves out of absolute poverty.

Currently, some 600 million rural poor people base their livelihoods on livestock. Although livestock contributes up to 80 percent of agricultural GDP in developing countries, livestock production efficiency is only one-fourth that in developed regions like the United States. Small-scale farmers and pastoralists face a variety of problems, including unfavorable policies, inadequate access to markets, degraded natural resources and poor livestock feeds and forage, and in some settings, debilitating livestock diseases. Whether they can overcome these problems and not be consumed or outperformed by agribusinesses will impact not only their individual livelihoods, but also the very future of livestock production and ecology.

Lobbyists

LOBBYISTS ARE INDIVIDUALS and groups organized to influence legislation or administrative action on legal, political, economic, environmental, and other issues. Lobbyists are advocates in the public policy arena who present themselves as providers of reliable information, analysis, and assessment relevant to legislators and government for informed and balanced decision making.

LOBBYISTS THEN AND NOW

The term *lobbyist* was first used in the mid-17th century. Citizens gathered in a large lobby near the British House of Commons to express their views to members of Parliament. In the early 19th century, the term *lobby-agent* was used in the United

States, where it was applied to citizens seeking legislative favors in the New York Capitol lobby. By 1832 *lobby-agent* had been shortened to *lobbyist* and was widely used on Capitol Hill in Washington, D.C. The term *lobbying* is claimed to date from the presidency of Ulysses S. Grant, who used to drink brandy and smoke cigars while relaxing in the lobby of the Willard Hotel, where he was often approached by those seeking favors.

The process of lobbying allows for competition among diverse interest groups. The All American League of Lobbyists lists the principal elements of lobbying as: researching and analyzing legislation or regulatory proposals; monitoring and reporting on developments; attending congressional or regulatory hearings; working with coalitions interested in the same issues; and educating not only government officials but also employees and corporate officers as to the implications of various changes. Lobbying is part of any democratic society and may take many forms including organizing petitions, running public relations campaigns, writing letters to the editor, or making telephone calls to public officials.

In order to prevent political corruption, lobbying in Western countries is regulated by law. The right "to petition the government for a redress of grievances" is protected in the First Amendment to the U.S. Constitution. In the United States, where the Congress dominates the legislative function, professional lobbyists represent interest groups and associations. The Federal Regulation of Lobbying Act (1946) requires that lobbyists register and report financial contributions they receive and their expenditure and that groups whom they represent make similar reports. Lobbyists representing foreign interests are required to register with the Department of Justice.

Many lobbyists are former politicians, government officials, or senior public servants. In the United States, the number of Members of Congress who turn to lobbying as a profession after they leave the legislature has increased in recent years. Only three percent of those who left Congress in the 1970s became lobbyists in Washington, but the figure increased to 12 percent in the 1980s, and by the 1990s, it had risen to 22 percent. Analysis shows that at least 128 former members of Congress were working as lobbyists in 2005.

In 1995 a ban was imposed upon former Members and most staff, preventing them from lobbying their former colleagues for one year after they left the Hill. This ban does not, however, prohibit them from devising strategies and then sending others employed by their firms to do the direct lobbying.

While lobbyists in the United States target the U.S. Senate, the U.S. House of Representatives, and state legislatures, lobbyists in the European Union (EU) focus primarily on the institutions and organizations of the EU. The European Commission estimated in 1999 that approximately 3,000 special-interest groups of varying types are based in Brussels, with up to 10,000 employees working in the lobbying sector.

Groups involved in active lobbying differ in relation to origin, size, and performance. They can also be seen in terms of "inside" or "outside" lobbyists, depending on their target audience. "Inside" lobbyists aim to influence politicians and legislators inside the legislature, while "outside" or "grassroots" lobbyists focus on changing public opinion. More than 6,000 lobbyists are registered in Washington, D.C. They lobby on behalf of 40,000 clients, including doctors, senior citizens, foreign governments, and religious organizations, as well as environmental public interest organizations and industries affected by environmental issues.

ENVIRONMENTAL LOBBYING

Environmental organizations combine inside and grassroots actions. Since the establishment of the first lobbying groups, which were concerned with the pollution that arose from industrial development and urbanization in the late 19th century, direct-protest actions have been merged with the lobbying of policy makers and political representatives. The objective of environmental lobbying is to influence the government leaders and influential persons in the community and to change public opinion.

The environmental community in the United States can claim many victories as result of both lobbying and coalition building, such as the Clean Water Act (1990). There are 12 major environmental organizations lobbying on issues at the national level. Studies of environmental lobbying indicate the mainstream Sierra Club (700,000 members) prefers grassroots action, while the more radical Earth First! (15,000 members) prefers to use 1960s-style protest and street theater to avoid the strategy of lobbying Congress directly. The Environmental Defense Fund (150,000 members) and the Natural Resources Defense Council (125,000 members) prefer legal action and employing lawyers to lobby and litigate.

One of the most influential environmental organizations, Greenpeace—with a presence in 40 countries across Europe, the Americas, Asia, and the Pacific and 2.8 million supporters worldwide—has built its powerful organization by emphasizing direct action rather than lobbying. It and other transnational environmental organizations, such as the World Wildlife Fund or Friends of Earth, use research, lobbying, and diplomacy, as well as nonviolent protest, to raise the level and quality of public debate and influence governments to work harder for environmental well-being. Activists lobby government officials in diverse countries and try to influence state officials at international conferences and other forums to support environmental protection measures. Centralized coordination of international campaigns makes possible the exchange of information and expertise while simultaneously supporting lobbying at the global level.

Lobbyists, no doubt, have a significant impact on the legislative process, whether they come from industry, the environmental community, or science. But many say the way lobbying is done needs improvement. There is a call for campaign finance reform, stricter disclosure laws so the public knows where a campaign's money is coming from, and restrictions on former government officials and employees becoming lobbyists. Despite the imperfections, there seems to be a consensus that lobbyists have a legitimate role to play in environmental policy making in forums such as Capitol Hill or the European Parliament.

Locke, John (1632–1704)

JOHN LOCKE WAS a British empiricist and social/political philosopher whose ideas on property, self-determination, and liberty influenced American politicians such as Thomas Jefferson. Locke asserted that humans initially existed in a God-created state of nature governed by divinely established moral rules that transcend social and economic "best use" considerations.

Locke believed that all humans have the right to sustain themselves and to accumulate wealth as long as they do not harm themselves, one another, or another's property. All laborers, he declared, must be granted equal access to the resources necessary to sustain themselves while discouraging the overuse or waste of the limited land and resources provided by God.

The *Lockean proviso* asserted that the right of humans to maximize their freedom to use the planet's land and resources is limited both by the equal access right of all humans to the land and resources and by the moral obligation not to waste the land and resources provided by God. Individuals may use the land and resources as they deem appropriate as long as they do not waste those resources and do not restrict the right of other humans to control their own lives. This provision was not as restrictive at the close of the 17th century as it is in the 21st century because there were substantially fewer people seeking access to finite land and resources. Today, resources are much scarcer as growing human populations use more land and expend resources while producing waste that the planet must absorb.

Locke did not envision the production of waste from land and resource use. He regarded waste as produced goods that were not used or that spoiled. He asserted that individuals could accumulate as much property and use as many resources as long as they abided by the *Lockean proviso*. Locke believed that trade, barter, and the use of money to purchase goods or assets eliminated both the inequality of individual overuse, accumulation, and waste by recompensing those whose access to the property or resource was limited by the one accumulating or using the asset. He argued that there is no waste when one accumulates money rather than assets that spoil. Any spoilage or waste is the responsibility of the purchaser. Locke believed that these transactions and the accumulation of monetary wealth were justifiable as long as the land and resources available to all humans were sufficient for all to live without the abrogation of their rights.

Locke believed that the need to protect these accumulated assets, private property, and the rights of all humans involved in these transactions gave rise to social contracts among the participants and the creation of governments to enforce the provisions of the contracts. He also asserted that a government exists as long as the people who formed the government consent to its existence and that consent is contingent on the protection of the rights of the people, especially their private property rights. Locke realized that some humans will accumulate assets at the expense of other humans but implied that it is not the government's role to equalize these disparities because they result from the proper exchange of assets. He also implied that it was the role of government to moderate inequalities that develop from these disparities, although he does not outline specifics on how this ought to be done.

Locks and Dams

DAMS ARE IMPOUNDMENTS of rivers and streams. They block the free flow or water, or they may direct or retard the flow of water. Usually a dam impounds water behind it, creating a lake or reservoir. Dams have an outlet for the water that they impound. The spillway or weir is usually a trough or pipe or some outlet that allows the build up of water behind the dam to flow out at the rate that it is flowing in once the reservoir had been filled. The water may flow out continuously or be released intermittently.

Dams may be the results of acts of nature. Landslides or earthquakes that block the flow of streams or rivers have formed numerous lakes. Animals, especially beavers, also build dams on streams. Farmers or developers have often fought their impoundments; however, beaver engineering of dams increases the amount of water available for fish, birds, and other wildlife. Their dams also raise the local water table providing for a different ecology than if their dams were not there.

Human construction of dams began over 2,000 years ago in China when dams were built on tributaries of the Yangtze. The first dams were built from earth, timber, and stone. Modern dams may be simple earthen containment dams, or elaborate concrete and steel dams such as the Hoover Dam. Dams have been built for many purposes, including irrigation, water supply, hydroelectric power, recreation, habitat, flood control, or for containing industrial or mining effluent. Many dams are built to facilitate shipping. The level of water in a river or stream usually varies with seasonal rainfall. Dams deepen the water in a waterway and allow shipping to take place all year long, unless the water freezes in the winter.

In order to facilitate shipping or transportation on rivers or other waterways, dams have been built

In the United States, rivers like the Tennessee have numerous dams that can affect plant and animal life.

to maintain a more or less constant water level. At places where rapids exist as a natural barrier, boats and ships have been in ancient times off loaded and then loaded below the rapids. Or they have been hauled overland to the next navigable area of water. Some dams have locks built into them or beside them. The lock is a structure that facilitates shipping on the dammed waterway. It allows cargo or passenger boats to easily navigate over a natural water barrier.

Locks operate by shutting doors to a box that is then filled with water or emptied of water. If a vessel is going upstream, the lock receives it at a lower downstream level. The doors to the lock are closed and water is pumped into the lock to raise the vessel to the higher upstream level. The lock acts like an elevator to raise or lower vessels to the upstream or downstream level. Once the doors of the lock are opened the vessel can then go on its way.

Today many of the rivers and streams in the United States have been dammed. Rivers like the Tennessee have numerous dams with locks in them that permit barges to move vast quantities of goods. Dams can have positive benefits, including the regular flow of water provided by a system of dams that allows for irrigation, recreation, and shipping.

However, damming streams or rivers can have a mild to severe impact on some species of plants, fish, or other life forms. For example, the snail darter in the rivers of east Tennessee were threatened by damming because they need clean gravel beds with flowing water in order to flourish. Other negative impacts that dams can have are the spread of disease and the accumulation of silt. The great Aswan Dam in Egypt has facilitated the spread of "snail fever" (schistosomiasis or bilharzia) and other diseases. It has also caused a decline of fish in the Mediterranean because nutrients needed by fish are being held behind the dam.

Loess

LOESS (PRONOUNCED "LUSS") is soil comprised almost entirely of silt (soil particles 2–50 µm diameter), with some very fine sand and coarse clay, that has been deposited by wind, often during glacial periods. Most loess soils on the present global landscape are geologically recent, having been deposited during and after the most recent Ice Age (1.6 million to 10,000 years ago). As the climate gradually warmed and glaciers retreated, massive deposits of glacial till and outwash were left on the landscape and in river valleys. Windstorms plucked fine soil particles from these enormous, barren expanses of glacial debris and deposited them equator-ward, where they were layered as bluffs.

Usually several meters thick, extensive loess deposits are found in the central, midwestern, and northwestern United States, eastern and central Europe, Argentina, northwestern Africa, and central Asia. The extensive loess deposits in the central plains of the United States account in part for the high agricultural productivity in that region of the world. Some of the largest loess deposits are located in China, where they range from 30–100 meters thick and extend approximately 800,000 kilometers^2. (Unlike loess deposits that originate from glacial till and outwash, loess in China originated from erosion of silt from central Asian deserts to its west.)

Over time, loess deposits may take on a stepped appearance in the landscape, because mineralogically, silt particles are typically microscopic quartz grains that slide easily past one another. This mineral structure of silt also accounts for the soft, lubricious feel of loess when rubbed between the fingers. Loess soils are fertile and productive for agriculture, particularly when combined with sufficient clay and soil organic matter.

Loess soils are also highly vulnerable to erosion, however, because silt particles are much smaller than sand grains, and they are not as tightly bound to one another (or to organic matter) as clay particles. Because silt is not sticky and plastic like clay, loess cracks when it settles and dries. Thus, water entering cracks in settled loess quickly erodes silt particles and carries them away. As erosion widens the cracks, more surface area is exposed and erosion proceeds more rapidly in a positive feedback process termed *piping*.

Soil texture plays a central role in determining agricultural productivity, and texture is also critical to consider when making decisions about human infrastructure development. This was highlighted by a recent case study in the United States: In 1977, a large earth-fill dam on the Teton River in Idaho failed, killing 11 people and leaving 25,000 people homeless. The dam failed unexpectedly because it had been built on loess, which, unlike clay, cannot be compacted into a water-impermeable mass. Cracks formed in the silt underlying the dam, and piping of silt from these cracks compromised the integrity of the soil base. In a similar vein, much attention has been paid recently to ensuring that enough clay is incorporated into the replacement levees surrounding the U.S. city of New Orleans, where storm surges and flooding from Hurricane Katrina destroyed protective levees in August 2005, killing 1,000–1,500 people and leaving tens of thousands of people homeless.

Longitude

LONGITUDE IS THE measure of the geographical distance from a point on the earth's surface to the reference or prime meridian, the Greenwich meridian, symbolized by lambda. Latitude and longitude are the two angular distances—using either degrees, minutes, and seconds, or decimal degrees—in the geographic coordinate system that precisely communicate the position of a certain location, and their measurement is fundamental for mapping representation and navigation.

Longitude is an angle formed by the meridian plane that crosses a location on the earth's surface, the center of the earth, and the Greenwich meridian plane. Longitude values range from 0 degrees and 180 degrees to the east of Greenwich, expressed as a positive angle, and from 0 degrees and 180 degrees to the west of Greenwich, expressed as a negative angle—or respectively accompanied by the letters E or W.

The lines that connect the points with the same longitude are termed meridians. They converge at both poles, are true north-south lines, and cross parallels at right angles. The distance between any two meridians increases toward the equator and decreases toward the poles, except for opposite meridians, which form a great circle.

Since the earth makes one 360 degree revolution in approximately 24 hours, and one hour represents a displacement of 15 degrees of longitude, the earth has been divided into 24 time zones—plus other fractions—allowing for the same standard time in a time zone. The antipodal meridian of Greenwich forms the International Date Line in the middle of the Pacific Ocean.

The Greenwich Meridian, which separates the Eastern and Western Hemispheres, was agreed upon as the prime meridian in October 1884 at the International Meridian Conference held in the United States. This reference meridian is arbitrary but commonly accepted; historically multiple prime meridians were used for mapping.

Finding longitude accurately at sea was a problem for centuries, making navigation unsafe; many vessels were lost in shipwrecks and voyages impeded until a solution was found. The usual method used to calculate the vessel's position was dead reckoning, measuring the distance traveled in a fixed direction from a previous position. This repeatedly proved unsatisfactory since error was high. While some complex calculations had existed since the 17th century (including measurement of the moons of Jupiter), a reliable solution remained elusive.

Seeking a resolution to the problem, the British Parliament passed the Longitude Act in 1714, and a Board of Longitude was commissioned to examine and judge proposals submitted by the public for methods of calculating longitude at sea, with a prize attached as an incentive.

The problem was solved not through mathematics and celestial observation, but rather through the application of mechanical invention. Since longitude is a function of time, knowing both local time and time at a known position and simply calculating the difference allows a precise measurement of east/west position. With this in mind, John Harrison, a clockmaker, designed an ingeniously accurate chronometer that could keep time without a pendulum (and therefore at sea). Despite the elitist hesitation of the Board of Longitude—who would have preferred both an elegantly mathematical solution and a winner from a higher social class—Harrison was acknowledged the prize winner in 1773.

Long Term Ecological Research Network (LTER)

THE LONG TERM Ecological Research Network (LTER) was born as a result of a series of workshops sponsored by the National Science Foundation (NSF) to explore the nature of collaborative research within the environmental sciences. Researchers may apply for funding and network membership for a center where meaningful ecological research can take place.

The LTER's mission is to provide the scientific community, policy makers, and society with the knowledge necessary to conserve, protect, and manage the nation's ecosystems, their biodiversity, and the services they provide. It envisages a world in which exemplary science contributes to the advancement of the health, productivity, and welfare of the global environment that, in turn, advances the health, prosperity, welfare, and security of the United States.

The NSF funds the LTER. Consequently, sites accepted to the network are expected to conduct high-quality research, share research data, and participate in the networking activities of the LTER. Other funding comes from government bodies such as the

Department of the Interior, the National Aerospace and Space Administration, and the U.S. Geological Survey. The goals of the network are summarized in six terms: understanding, synthesis, outreach, education, information, and legacies. These activities center on conducting existing and new research, using that research to inform publications in a wide range of styles, and creating a repository of knowledge to assist the general public, fellow researchers, and policy makers in understanding the complexities of ecological research.

In 2006, the LTER consisted of 26 different sites in the United States, ranging from the study of salt marsh and oyster reefs of the Georgia Coastal Ecosystem LTER to the research into the Sonoran desert scrub at the Central Arizona-Phoenix LTER. The sites currently active represent the full range of the diversity of the ecosystems of the United States, and include monitoring of both urban and nonurban areas.

The International Long Term Research Network (ILTER) is an international network of scientists and researchers working in fields relating to ecological research. The network was established in 1993 at an international conference of researchers in Colorado who expressed the desire for greater communication among scientists working on common issues.

Scientists recognized the need to create international links to research issues that are clearly globally interconnected in nature. By May 2006, 32 national networks of scientists had joined the ILTER and another 11 were considering membership. Coverage of the territory of the world was best in the Americas, southern Africa, western Europe, and East Asia. Its activities focus on consolidating relevant data at the international level, improving global networking, and facilitating education and policy making on ecological issues around the world.

Lorenz, Konrad (1903–89)

KONRAD LORENZ WAS an Austrian zoologist who is best known for his founding of the science of ethology, which is the study of animal behavior and is also associated with the work of Nikolaas Tinbergen. Lorenz graduated in the field of medicine, following in his father's footsteps, and then began a career of academic study, interrupted by a period of service in the German army during World War II. He was captured on the Russian front and not repatriated until 1948. Subsequently he joined the Max Planck Institute and the brilliance of his work enabled him to rise to high office within that prestigious organization. His work combines careful observation with a lucid style, which makes it accessible to nonspecialist readers.

Lorenz viewed ethology as a means of understanding different forms of behavior that are common across many different species, rather than evident within any particular type of creature. His work focused on representative forms of animal behavior such as aggression, responses to captivity, and daily routines. His observations centered, in particular, on the concepts of instinctive behavior and imprinting. Although he was not the first to create these concepts, his research reinvigorated the ideas with substantial new data, including that of various birds.

He was able to show how different forms of instinct acting simultaneously become integrated into a single, mostly coherent form of behavior. His work has applications in the study of evolution, and this has provoked controversy among those who seek to deny it. However, by concentrating mostly on group selection approaches to evolution, Lorenz's work is considered to have been surpassed by more recent work and, more broadly, many of his research findings have been challenged by those who have followed in his wake. His later work moved on to the study of humanity and those forms of behavior that he had earlier identified among animals that could be used to explain the nature of human societies.

Lorenz won the Nobel Prize for Physiology or Medicine in 1973 with Nikolaas Tinbergen and Karl von Frisch. Some held his joining of the National Socialist Party in 1938 and the framing of some of his research according to Nazi ideology against him. He apologized for one such paper at his acceptance of the Nobel Prize. In 1984 he became involved in supporting the Austrian Green Party and opposition to a proposed power plant that would have led to the destruction of valuable forestland.

Los Angeles River

THE LOS ANGELES River is located in southern California. It is only 52 miles long but is very steep: It drops 795 feet in elevation from the headwaters in the San Fernando Valley to its end in Long Beach. The majority of its sourcewaters flow from the San Gabriel Mountains, which are east of the San Fernando Valley, and from the Santa Susanna Mountains to the north.

The Los Angeles River flows through the San Fernando Valley, the Glendale Narrows, and the city of Los Angeles, and empties into the Pacific Ocean. Major tributaries to the river in the San Fernando Valley are the Pacoima Wash, Tujunga Wash, Burbank Western Channel, and Verdugo Wash; the main tributaries to the river in Glendale Narrows are the Arroyo Seco, the Rio Hondo, and Compton Creek.

Most of the Los Angeles River is bedded by concrete. To prevent flooding and make room for construction, 47.9 miles of the river were channelized from 1914–70. The Glendale Narrows to Long Beach section of the river still has a natural bed, and is surrounded by forest, grassland, savannah, and shrubland, but flora and fauna still exist in the channelized section. Sixty species of native plants have been identified in the river, including fish, reptiles, amphibians, and some mammals.

Despite its concrete bed, the river continues to flood. The Los Angeles River has other problems as well. Due to the high urbanization of the Los Angeles area, much of the Los Angeles River watershed is covered with residential, commercial, and industrial areas, including major refineries and petroleum product storage facilities.

This situation increases the demand for water and also increases the contamination of most local water sources. Although the Los Angeles River boasts water that is cleaner than water in most urban rivers around the world, it is still polluted from residential, industrial, and other urban activities. Contamination is worse during rainy seasons and pollution is more concentrated in some areas than in others. Erosion problems and fires also affect this watershed. These problems in the Los Angeles basin have sparked efforts to decrease water contamination, protect the wildlife habitat, enhance recreational areas, manage storm water quality, and prevent flooding and fires.

The Los Angeles city government has developed several programs to aid in these efforts, such as the Los Angeles River Master Plan, adopted in 1996, which focuses on flood protection and sustainable development, and the Revitalization Master Plan, adopted in 2005, which seeks to restore the river and create a wildlife corridor from the mountains to the sea.

One important aspect of the Revitalization Master Plan is the participation of environmental groups, such as Friends of the Los Angeles River (FoLAR) and Unpave L.A., thus permitting public involvement and participation in the real processes of decision making.

Lotka-Volterra Curve

IN NATURE, MANY of the phenomena that capture our attention, such as the sight of a large predator in pursuit of prey, involve two or more interacting species. Alfred James Lotka (1880–1949) and Vito Volterra (1860–1940) independently developed a simple model to explain interactions between predators and prey, unlike the single species model. Born in the Ukrainian city of Lviv, then called Lemburg, Austria, Lotka was raised in France and arrived in the United States in 1902. He worked for U.S. government institutions—including the Bureau of Standards—followed by a position at Johns Hopkins University, before retiring as a statistician from the Metropolitan Life Insurance Company in New York in 1947. At that time, biologists were seeking ways to analyze the relationships of organisms with their surrounding environment. Lotka theorized that similar to the laws in physics, such as Newton's Laws of Motion, the idea of natural selection could be established in its own right as a physical law.

Volterra was born in Ancona, Italy, and was interested in mathematics from an early age. Earning a doctorate in physics in 1882, he went on to a distinguished academic career in mathematical physics and was elected to the Royal Society in 1910. Volterra worked on partial differential equations during the 1890s and after World War I became interested in mathematical biology, applying the theory of differential equations to prey-predator interactions. Instead of looking at prey-predator populations as snapshots in time, differential equations allow us to observe population change continuously over time.

The Lotka-Volterra model relies on a set of two assumptions, (a) as the number of prey increases the birth rate of the predator also increases and (b) as the number of predators increases the death rate of the prey also increases. The general model for two species is expressed in the form of the following differential equations:

$$\begin{cases} \dfrac{dx}{dt} = ax - bxy \\ \dfrac{dy}{dt} = -cy + dxy \end{cases}$$

The first equation describes the change in the prey population. The second equation describes the change in the predator population. In these equations, dx/dt and dy/dt are respectively the prey and predator populations at any time, a is the prey's natural growth rate when predators are absent, b is the prey's death rate or rate at which predators eliminate or consume prey, c is the natural death rate of the predator in the absence of prey, and *d* is the efficiency of the predator or the rate at which predator numbers increase in the presence of prey.

Early studies in the life sciences in North America provide a fitting backdrop to the subsequent interest in prey-predator relations that led to the Lotka-Volterra model. The work of fur traders employed by the Hudson Bay Company in Canada in the 18th century resulted in two centuries of fur-trade records. Analysis by wildlife biologists showed that the populations of the snowshoe hare *Lepus americanus* and its predator the Canada lynx *Lynx canadensis* rise and fall at regular 10-year intervals. The highs in hare numbers are closely followed by highs in lynx numbers. These cycles of rise and fall in prey-predator numbers are predicted by the Lotka-Volterra model (Figure 1).

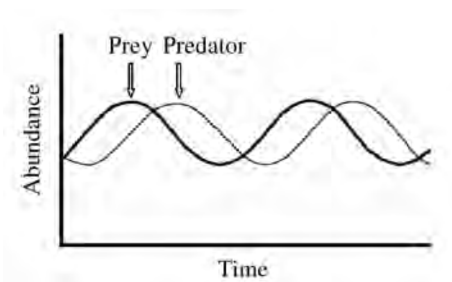

Figure 1 (Modified from Wilson and Bossert, 1971)

The Lotka-Volterra curve is important because it was the first model of biological populations based on sound mathematical principles. The fact that in the wild, numbers of some prey-predators go up and down in a predictable cyclic fashion—as in the case of the snowshoe hare and the lynx—is often seen as a validation of the Lotka-Volterra model. However, dramatic ups and downs in animal numbers puzzle those ecologists who believe that nature tends to prevent the occurrence of such imbalances. Useful as it is, biologists now recognize that the model is too simplistic and does not include environmental factors that may significantly influence animal populations. Depending on the number of external factors investigated, single-factor or multiple-factor studies are conducted; for example, a study on the effect of food limitation will be single-factor, while food and disease taken together is a multiple-factor effect. Tests of the Lotka-Volterra model have resulted in attempts to improve it by incorporating such environmental factors.

The existence of the Lotka-Volterra model has helped improve our understanding of prey-predator interactions and the importance of food supplies. Importantly, the model and ecological studies resulting from it helped explain that the dramatic declines in herbivorous prey numbers affect not only their principal predator, but also have cascading effects on other predators, as well as on the structure of surrounding plant communities. Studies of prey-predator populations have helped provide data necessary for habitat conservation plans to protect threatened species such as the Canada lynx.

Love Canal

FOLLOWING DISCLOSURE OF toxic dumping in a site that later became residential, the case of Love Canal demonstrated the hazards of buried and long-forgotten toxic chemicals, galvanized grassroots environmental action, and became the paradigmatic case for the control and management of brownfield sites. It also put working people and mothers at the center of environmental action, setting a precedent for environmental justice activity in the decades that followed.

The Love Canal is a neighborhood in the southeast district of Niagara Falls, New York, named for 19th century entrepreneur William T. Love. Love obtained the area approximately four miles upstream from the falls in 1892, hoping to harness water to generate power to the number of industries developing on the seven-mile stretch of the river to the mouth of Lake Ontario. He also intended for the canal to be a bypass route around the falls. After only a few years it was obvious Love's plan had failed, largely due to a nationwide economic depression and the invention of alternating electronic current. Love abandoned the project with only one mile dug, and the area remained a recreational spot into the early 20th century.

In 1920 the land was sold at a public auction and became a landfill and chemical dumping site. Hooker Chemical, a subsidiary of Occidental Petroleum Corporation, used the site from 1942 to 1953 and was the primary corporation responsible for the nearly 21,000 tons (42 million pounds) of toxic chemicals dumped on the site. The City of Niagara Falls and the U.S. Army both dumped assorted wastes there as well. As the landfill reached maximum capacity in 1953, Hooker filled it with dirt. At the same time, the postwar baby boom created a huge demand for housing in the area. The Niagara Falls Board of Education purchased the Love Canal land from Hooker Chemical for a dollar.

Hooker claims they included a brief warning about the chemical wastes buried on the property in the deed transfer, as well as a disclaimer absolving the company from liability. Single-family housing was quickly built on and near the land, and soon the 99th Street Elementary School was erected on the former landfill. Homeowners were not provided any information about the chemicals below their homes or their potential hazards.

Early on, between the 1950s and 1970s, residents of the area complained of odors and "substances" appearing in their yards. Families also complained of their children being burnt. City officials visited the neighborhood and the school and responded by covering the "substances" with dirt or clay. Complaints persisted, however, and the city hired Calspan Corporation to investigate. Calspan's report, completed in 1976, documented the presence of toxic chemical residue in the air and in sump pumps of residents. They also found 50-gallon drums buried just below the surface of the canal cap and high levels of polychlorinated biphenyls (PCBs) in the storm sewer system. The consultants recommended covering the canal cap with a clay cap, sealing home sump pumps, and installing a tile drainage system to control the movement of wastes. No action was taken.

The area continued to grow despite the complaints, with approximately 800 private, single-family homes, 240 low-income homes, and three schools there by 1978. The story broke that year, as a reporter for the *Niagara Gazette,* Michael Brown, wrote a series of articles about hazardous waste problems in the Niagara Falls area. He included the Love Canal dump site, prompting residents to renew complaints to city officials. By this time residents were complaining of more than just noxious smells and substances; many were also documenting mysterious health problems, including a high rate of birth defects and miscarriages. Also in 1978, the New York State Department of Health began to collect air and soil tests in residents' basements and to document the health concerns of 239 families in the area.

On April 25, 1978, Dr. Robert Whalen, New York State Commissioner of Health, proclaimed the area a public health hazard and ordered the Niagara County Health Department to remove exposed chemicals from the site and to install a protective fence around the area. The report prompted further action by residents. Lois Gibbs, mother of two small children, canvassed the area to petition for the closure of the 99th Street School, which her son attended. Residents and state and local health department officials met throughout the spring and summer of 1978. In the fall of 1978, State Commissioner of Health Whalen issued a medical emergency for the Love Canal area and ordered the immediate closure of the 99th Street School.

Immediate cleanup plans began, and it was recommended that pregnant women and children under the age of two move from the area. On August 7, 1978, President Jimmy Carter declared Love

Canal a federal emergency, providing funds for the permanent relocation of 239 families living in the first two rows of homes encircling the landfill. The remaining ten blocks of homes, including that of activist Lois Gibbs, were not included.

LULU

LULU MEANS "locally unwanted land use" or "locally undesirable land use." According to planner and urbanist Frank Popper, there are many different types of LULUs, including low-income housing projects, junkyards, and strip developments. This definition suggests that nearly any change in the character of a community's land use can be defined as a LULU. The term also ties to the idea of NIMBY (not in my backyard), a term used to describe community opposition to LULUs. Some LULUs, as Popper notes, are obvious. Almost no one wants to live next to a noisy, toxic, dangerous, or ugly facility. Other communities may oppose strip development because it increases traffic and can lead to discordant and unattractive development. However, the nature of a LULU depends heavily on the character of a community. An urban community may support the construction of a stadium because of the business opportunities it would create, while a suburban community may oppose the project because of the significant increase in traffic and other negative outcomes that such a facility would generate.

Popper notes that there are several ways to address community opposition to LULUs. One is to concentrate LULUs in one part of a city, reserving other land for residential or office uses, and another is to disperse LULUs. Ordinances that require bars, adult book stores, and strip clubs be no closer than a fixed distance from a similar business, or a church, school, or other public facility, are common in many cities and seek to avoid the creation of a "red light district." LULUs can be randomly built in a community, thereby avoiding favoring or disfavoring any community, and leaving siting decisions to market forces.

However, it is doubtful that communities with differences in political power will see LULUs sited in areas with the most political power. Popper argues that LULUs' negative effects can be mitigated, although often at a great expense that is borne by the landowner and the user of the services provided on that land (electricity, for example). Declaring anything a LULU means that the overall social benefit of a power plant may be, in the community where it is built, less important than the overall social benefit of the facility. This is one of the major shortcomings of simply compensating neighbors for the costs, or "negative externalities" created by a LULU. Such a compensation scheme may not properly account for the overall benefit to society from a LULU, and the expectation that sometimes people have to bear burdens for the broader community good.

Maathai, Wangari (1940–)

WANGARI MAATHAI was born in Nyeri, Kenya. She was trained in biological sciences and pursued doctoral studies in Germany and Nairobi, becoming the first Kenyan woman to receive a Ph.D. In 1977 she founded the Green Belt Movement. This initiative responded to the needs of local women for firewood, clean drinking water, balanced diets, shelter, and income, which they had been unable to meet due to continuous environmental degradation, replacement of household crops by commercial farming, and declining income due to distorted world market prices for Kenyan commodities. The program began with the planting of nine trees in Maathai's own backyard and resulted in a citizen education program that led to the planting of more than 30 million trees that survived all over Kenya, and the creation of similar initiatives in many other African countries after the establishment of the Pan African Green Belt Movement.

Maathai promoted a holistic approach with a vision of "healing Africa," and she encouraged Africans to rediscover the positive aspects of their culture to raise their sense of belonging, identity, and self-confidence, emphasizing the need for the conservation of biodiversity and cultural diversity. Understanding the causes of environmental degradation and their connection to governance, she continuously addressed the need for democracy, combining the protection of the environment with the protection of human rights, the need for good governance, and equality between women and men. She also mobilized citizens to challenge widespread abuses of power, corruption, and environmental mismanagement.

In the 1980s Maathai became the chairperson of the National Council of Women, and she also became one of the leaders of the pro-democracy movement. Her many initiatives exposed her to harassment. She was repeatedly sent to prison, but the government met with little success in its efforts to curb her. Maathai became internationally known and was elected to parliament in 2002, when the previous authoritarian Kenyan regime relinquished power. In 2003, in the broad coalition government that took over, Maathai was appointed deputy minister of environment, natural resources, and wildlife with 98 percent of the vote.

Maathai won many awards for her work. She received honorary doctoral degrees from Williams College in Massachusetts (1990), Hobart and William Smith Colleges (1994), the University of Norway (1997), and Yale University (2004), where she also taught as a visiting professor. Some of her other honors include the Right Livelihood Award (1984), the Woman of the World (1989), the Hunger Project's Africa Prize for Leadership (1991), and the Conservation Scientist Award (2004). Most notably, Maathai was the first African woman to receive the Nobel Peace Prize. By giving her this honor, the Norwegian Nobel Prize Committee challenged and broadened the world's common understanding of peace: that there can be no peace without equitable development; and that there can be no development without sustainable management of the environment in a democratic and peaceful space.

Macedonia

IN 1946 MACEDONIA became an autonomous republic within the Federation of Yugoslavia. Forty-five years later, independence was peacefully obtained, but problems with neighboring Greece followed when the Greek government insisted that the name *Macedonia* was Hellenic in nature. Briefly known as the Former Yugoslav Republic of Macedonia, the country's name was shortened over Greek objections. Economic relations between the two countries have resumed, but the relationship remains tenuous. Although Macedonia is landlocked, it shares Lake Ohrid with Albania and Lakes Prespa and Dyran with Greece. The Vardar River runs through much of Macedonia. Summers and autumns are warm and dry in Macedonia, followed by cold winters and heavy snow. The land is generally mountainous with deep basins and valleys, and the country is vulnerable to high seismic activity.

Due to its strategic location, Macedonia serves as a major transportation corridor from western and central Europe to the Aegean Sea and between southern and western Europe. Despite rich natural resources of low-grade iron ore, copper, lead, zinc, chromite, manganese, nickel, tungsten, gold, silver, asbestos, gypsum, timber, and arable land, the Macedonian economy remains weak. Economic woes have been influenced by outside factors, which include the breakup of Yugoslavia, the fragile relationship with Greece, and civil strife in Albania.

With a population of 2,045,262, Macedonia has a per capita income of $7,400. An accurate picture of the Macedonian economy is virtually impossible because of the large informal sector that employs around one-fifth of the population. Unemployment is estimated at 38 percent, and over 30 percent of Macedonians live below the poverty line. The United Nations Development Programme Human Development Reports rank Macedonia 59th in the world in overall quality-of-life issues.

ENVIRONMENTAL ISSUES

Macedonia's major environmental problems are air pollution from numerous metallurgical plants and a lack of waste management facilities. Nearly 60 percent of the people live in urban areas such as the capital city of Skipje. Like the capital, other areas experience severe problems from industrial pollution. Mining and energy plants in Bitola are responsible for the release of sulfur dioxide, carbon monoxide, nitrogen oxides, and dust. In Veles, metallurgical and chemical plants release gases and heavy metals into the air. Such companies are also responsible for the pollution of groundwater and waterways.

Approximately 36 percent of Macedonia's land is forested, and the government has protected 7.1 percent of the land area. National parks have been established in Mavrovo, Galicica, and Pelister. National reserves on Prespa Lake and Crna Reka Gorge are strictly protected. Macedonia's unique geography, which is derived from the three tectonic lakes and over 30 glacial lakes, merits special care. Consequently, specific sections of lakes and swamps are under natural protection to oversee the rich variety of flora, fauna, and fungi that flourish in these areas. Of 78 mammal species endemic to Macedonia, 11 are endangered; however, only three of the 199 species of birds are endangered.

Environmental compliance has been difficult in Macedonia because monitoring mechanisms have not been in place to enforce existing laws. In response to renewed commitment to environmentalism, parliament passed the Act on Environment and Nature. Under the Ministry of Environment, the Inspectorate for Environment and Nature Protection and Promotion has been given the authority to oversee compliance with the law in the areas of air and water pollution, protection of natural resources, soil degradation and pollution, hazardous noise, and radiation. Violators face a fine of 200,000 to 300,000 denars.

Macedonia's commitment to the global environment has resulted in participation in the following international agreements: Air Pollution, Biodiversity, Climate Change, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Ozone Layer Protection, and Wetlands.

Madagascar

IN 1896 THE island of Madagascar lost its status as an independent kingdom to French colonialism. Independence was reinstituted in 1960, launching almost two decades of one-party rule. In the mid-1990s, Madagascar rejected socialism and began a process of privatization and liberalization by following the guidelines of the World Bank and the International Monetary Fund. In 2001, during a hotly-contested presidential election, half the country threatened to secede. Stability was restored when the High Constitutional Court declared a winner in April 2002.

With just over five percent arable land, more than 80 percent of the work force is engaged in agriculture and fishing. In recent years, the economy has become more diversified, and revenue from apparel industry exports is increasing. Natural resources include: graphite, chromite, coal, bauxite, salt, quartz, tar sands, semiprecious stones, mica, fish, and hydropower. With a per capita income of \$900, Madagascar is the 18th poorest country in the world. Half of the population lives below the poverty line, and 37 percent of the people are severely undernourished. The United Nations Development Programme's Human Development Reports rank Madagascar 146 of 232 countries on overall quality of life issues.

With a total area of 587,040 square kilometers, Madagascar is the fourth largest island in the world. Surrounded by the Indian Ocean, the Republic of Madagascar has a coastline of 4,828 kilometers. A narrow coastal plain gives way to high plateau and mountains in the center of the island. Elevations range from sea level to 2,876 meters at Maromokotro in the northeast. Madagascar's climate is varied; it is tropical along the coast but changing to temperate in inland areas and to arid in the south. Madagascar is subject to periodic cyclones, drought, and locust infestations.

Poverty plays a major role in the lives of many Malagasy. Some 55 percent of the population lack sustained access to safe drinking water, and 67 percent lack access to improved sanitation. Consequently, Madagascar's population of 18,595,469 faces a high risk of contracting food and waterborne diseases that include bacterial and protozoal diarrhea,

The Aye-Aye of Madagascar

One of the rarest animals in the world is the aye-aye, which is the world's largest nocturnal primate. It dwells in forest canopies on the east coast of the Indian Ocean island of Madagascar. Although a primate, it somewhat resembles a rodent with long claws that it uses to pull grubs from trees after tapping at and then gnawing the wood. The animal has black or dark brown fur, with a bushy tail similar to some squirrels. Its face looks like a bat's, and it moves around its habitat like a lemur.

It is thought that the name *aye-aye* comes from a human cry of alarm upon seeing the animal. Many local people have long regarded the aye-aye as an evil creature and have killed them on sight. This is partly from superstition over its long middle finger. There are stories in folklore of an aye-aye coming into a village and pointing its finger at someone, who then later dies, or even of the animal stabbing people with this finger and puncturing their hearts.

Superstition, however, has also resulted in no one wanting to hunt the aye-aye for food. Nevertheless the massive destruction of the animal's habitat has resulted in a large decline in its population and it is endangered. There are many captive breeding programs. At the largest, the Duke Lemur Center at Duke University, there are 22 aye-ayes.

hepatitis A, and typhoid fever and schistosomiasis, a water contact disease. In some areas, Malagasy are at high risk of contracting vectorborne diseases such as malaria and plague. There is also growing concern about HIV/AIDS, which affects 140,000 Malagasy. Social indicators such as infant mortality (75.21 deaths per 1,000 live births), life expectancy (57.34 years), fertility rate (5.4 children per female), and literacy rate (68.9 percent) further reveal the effect that poverty has on the population.

Madagascar is experiencing soil erosion in response to overgrazing and to deforestation, which is occurring at a rate of 0.9 percent per year. Fires intentionally set to clear land for agriculture, particularly for use as rice fields, have done major damage to the environment. Ecologically valuable timber has been stripped from the rain forests and sold, sometimes earning as much as $2,000 a ton. Other trees are used in the production of charcoal. Desertification is also a growing problem, and surface water has been contaminated from the dumping of raw sewage and organic wastes.

The biodiversity of Madagascar's rain forest is unique, and some scientists have dubbed Madagascar the "eighth continent" because of its biology. Eighty percent of the species found in Madagascar are endemic, such as the giraffe-necked weevil and the 33 species of lemurs for which Madagascar is best known. For centuries, the medicine men of Madagascar have known that certain plants had medicinal properties. In 1958, for instance, natives pointed out to foreign researchers that the Madagascar rosy periwinkle could work miracles. It has since been used to develop drugs that fight Hodgkin's disease and childhood leukemia. Several species of flora and fauna that do not grow anywhere else in the world are now endangered.

Of 141 endemic mammal species, 50 are endangered, as are 26 of 172 endemic bird species. Some endangered animals are killed outright in response to local superstitions. The government has also played a role in endangering wildlife. In 1980 troops commandeered the Zinave National Park and set up a meat processing center. The introduction of aggressive alien species into Madagascar has further threatened the existence of endemic species.

A 2006 study by scientists at Yale University ranked Madagascar 116 of 132 countries on environmental performance, in line with comparable income and geographic groups. The lowest scores were received in the areas of environmental health and biodiversity and habitat. Around a fifth of Madagascar's land area is still forested, and the government has protected 4.3 of all land, including an extensive network of national parks and reserves.

In 1988 the government of Madagascar published its first National Environmental Plan, establishing a framework for environmental policy that is focused on sustainable development. The plan was divided into three stages, designed to take effect over a period of 15 years, establishing the priorities of management and protection of biodiversity in conjunction with sustainable development; improving living conditions and production of natural resources; expanding conservation and developing of national parks and reserves; promoting environmental training and education; and establishing research and monitoring mechanisms.

The third stage, launched in 2003, stressed the issues of conservation, sustainable economic growth, and an improved quality of life for the people of Madagascar. The minister of environment was charged with implementing and enforcing all laws derived from the three plans. The government also invested in efforts to discover reliable sources of alternative energy that include wind, solar, and waste-to-energy initiatives.

Madagascar participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, Marine Life Conservation, Ozone Layer Protection, and Wetlands.

SEE ALSO: Biodiversity; Endangered Species; Poverty; Rain Forests.

Mad Cow Disease

MAD COW DISEASE, or bovine spongiform encephalopathy (BSE), is a degenerative disease of the nervous system in cattle. It is always fatal. Cattle with BSE develop minute holes in their brains, have difficulty standing and walking, produce less milk, become irritable, and lose weight. The disease has an extended incubation period. Symptoms usually appear four to five years after infection, and death often occurs within weeks of symptom onset.

BSE belongs to a group of diseases called transmittable spongiform encephalopathies (TSEs). Other TSEs include scrapie in sheep, chronic wasting disease in deer and elk, and Creutzfeldt-Jakob Disease in humans. TSEs can spontaneously arise in individual animals or can occur due to genetic mutations. They are believed to occur when certain cellular proteins, called prions, become misshapen. The misshapen prions then alter the shape of other prions. These proteins clump in the cells and damage nervous tissue. They are difficult to destroy: Heat, UV light, radiation, and disinfectants that destroy infectious agents such as bacteria and viruses do not destroy prions.

BSE was first seen in Great Britain in 1985 and was recognized as a disease in 1996. There are two lines of thought regarding its origin in Britain. Some researchers think the disease was passed to cattle in feed containing the remains of sheep infected with scrapie. Other researchers question this, because the prions of scrapie differ from those of BSE, and suggest the disease arose spontaneously in a single animal.

Whatever the origins of the disease, feeding practices in the United Kingdom (UK) allowed BSE to become established. Meat and bone meal, made from the remnants of animals after butchering, were routinely used as protein supplements in cattle feed. When meat and bone meal from infected animals entered this food chain, the disease spread throughout the UK. Changes in the processing methods for meat and bone meal in the early 1980s, which lowered the heat compared to that used in previous methods, may have led to a higher incidence of the prions in cattle feed. Cattle are not infected with BSE through contact with an infected animal.

The number of confirmed cases of BSE in the UK reached 14,000 by 1990, and 181,376 by 2002. In addition to the UK, infected cattle have been discovered in European, North American, and Asian countries. In 2003 the first cases of BSE were reported in both Canada and the United States.

To contain the outbreak, British cattle thought to be infected were slaughtered, and feeds containing remains of sheep and cattle were banned in the UK. Other countries took similar measures. In addition, some nations banned the import of cattle or beef from countries where BSE is known to have occurred. BSE is decreasing. The disease killed a reported 878 cattle worldwide in 2004 and 474 in 2005.

Since the mad cow epidemic began, a new TSE has been discovered in humans: variant Creutzfeldt-Jakob Disease (vCJD). It was first reported in 1996. It appears that vCJD is caused by eating beef from BSE infected cattle. Most infected individuals are known to have consumed tainted beef in Britain. The prions are similar, as are the patterns of brain damage seen in victims of BSE and vCJD. Victims of vCJD are usually young. The incubation period for vCJD can be as long as ten years. Death occurs, on average, 12–14 months after symptoms appear. Symptoms include depression, difficulty walking, shakiness, a sensation of sticky skin, dementia, and eventually muteness, the inability to move, and death. A cure for vCJD has not been found.

As of 2006, the UK's National Creutzfeldt-Jakob Disease Surveillance Unit reported 158 confirmed and suspected vCJD deaths in the UK. An additional six living individuals are thought to be infected. Seven deaths have occurred in France, plus one death each in Canada, the United States, Ireland, and Italy. Other individuals may be incubating vCJD.

Maize

MAIZE (*ZEA MAYS*), also known as corn, is one of world's major cereal grains along with wheat and rice. It was domesticated as long ago as 12000 B.C.E. from a tropical grass in the Americas, where it became the foundation of agriculture for the Mayans, Incans, Aztecs, and other American indigenous groups. After European contact with the Americas, maize spread throughout the world, becoming extensively grown in former European colonies from Africa to Asia and in eastern Europe. Today the United States remains by far the top producer of corn, followed by China, Brazil, Mexico, and Argentina. Maize is still a staple in subsistence communities in Mesoamerica.

Maize is a tall grass-like plant that grows from six to twenty feet tall and produces two to six ears of corn per plant. From the top of the maize plant emerges a tassel-like inflorescence of male flowers. Along the stalk several ears emerge with the silk, the elongated stigma of a female flower. Maize is an allogamous (cross-pollinating) plant; each individual fruit on an ear of corn is formed when wind-blown pollen from the tassel lands on the silks. Maize is a C4 plant, meaning that its photosynthetic pathway is different from most crop plants, which are typically C3. This allows a corn plant to produce more dry matter per unit of water.

There are several hypotheses about the origins of maize domestication, which is often cited as one of the greatest achievements in human ingenuity. One theory suggests that indigenous populations domesticated maize from a wild, sexually compatible relative called teosinte. Another argues that it was a cross of teosinte with another wild relative of maize, either *Zea diploperennis* or *Zea luxurians*.

The development of hybrid corn at the beginning of the twentieth century was a watershed event for plant breeding. Employing the principles of the newly rediscovered Mendelian genetics, George Shull coined the term *heterosis* in 1914. Also known as hybrid vigor, heterosis happens when the cross of two inbred lines yields more than either of the individual parent lines. In 1917 Donald Jones discovered that a cross of two hybrids exhibited even more hybrid vigor.

While hybrid seed yielded significantly more, hybrid seed does not breed true, so farmers must return to the seed producer instead of saving seed, an age-old practice of farmers. As pointed out by Jack Kloppenburg, Jr., this hastened the process of seed commodification. Before the advent of hybrid seed, commercial enterprises in seed production were less profitable because once an initial sale was made, the farmer only had to save some seed from his crop to grow the next generation. But hybrid seed decoupled the grain from the seed and by the 1930s hybrid seed production was controlled by a handful of large seed companies including U.S. Secretary of Agriculture Henry Wallace's Pioneer Hi-bred. By 1965 95 percent of corn was grown with hybrid seed produced in the private sector. By this time public sector research in plant breeding was seen as redundant and unnecessary, and research was subordinated to private companies.

This had several unanticipated consequences. To effectively mechanize the harvest, maize ear should fall in approximately the same place on each stalk in a field. Plant breeders turned to making uniform plants that were suitable for mechanization. This led to a reduction in the genetic diversity of the plants being grown, making them susceptible to disease and pest outbreaks, often necessitating the application of pesticides. The significant quantities of agro-chemical fertilizers and pesticides applied to corn grown in the Midwest have been cited as part of the cause of a large dead zone off the Mississippi River Delta.

The massive increases in maize yields in the 20th century have turned the crop into the foundation of the industrial food system. Maize is used to produce citric acid, xanthum gum, lecithin, high fructose corn syrup, and many other foodstuffs that comprise the modern industrial food system. A significant portion of the corn grown in the United States is used as feed at the top of the cattle commodity chain. Another significant amount is used in ethanol production.

Maize domestication is often cited as one of the greatest achievements in human ingenuity.

Much of the maize grown today is grown through advances in genetic engineering, where it has been the subject of considerable controversy. The StarLink™ controversy happened when a genetically engineered variety of maize not approved for human consumption made its way into several brands of processed tortillas. Even though StarLink™ has not been grown since 2001, it is still found by inspectors of Japanese imports of corn. Corn engineered with the DNA segment that expresses endotoxins from the soil organism *Bacillus thuringiensis* (Bt) was at the center of the monarch butterfly controversy when it was asserted that milkweed dusted with Bt caused higher mortality rates when fed to monarch butterfly larvae.

Perhaps one of the most serious of the concerns about genetically engineered maize regards gene flow to wild relatives and landraces in Mexico, the center of crop-wild diversity. In 2001 a study by two Berkeley scientists found that transgenic traits were found in Mexican landraces grown by indigenous farmers despite a moratorium on genetically engineered maize in that country.

Malaria

MALARIA IS THE most serious vectorborne disease in the world. At the end of 2004, approximately 3.2 billion people lived in areas at risk of malaria transmission in 107 countries and territories. Between 350 and 500 million clinical episodes of malaria occur every year. It is a leading cause of death in many developing countries, where young children and pregnant women are most vulnerable. Of the one million deaths every year worldwide due to malaria, about 60 percent of the cases and more than 80 percent of the deaths are in Africa.

Malaria is caused by protozoan parasites of the genus *Plasmodium*. Four species of *Plasmodium*, namely, *P. falciparum, P. vivax, P. ovale,* and *P. malaria,* can produce the disease in its various forms. Among the four species, *P. falciparum* is the most widespread and dangerous. Malaria parasites are transmitted from one person to another by the bite of the female mosquito of the genus *Anopheles*. The parasite develops in the gut of the mosquito and is passed on in the saliva of an infected insect each time it takes a new blood meal. The blood in the victim's liver carries the parasites. After incubating for nine to 16 days, the parasites penetrate red blood cells, multiply, and then progressively break down the cells. This induces bouts of fever and anemia in the infected individual. Generally, antimalarial drugs can cure the symptoms of malaria such as fever, shivering, aching joints, and headache. However, in certain regions, the parasites have developed resistance to some drugs.

Malaria has been known since ancient times, but it was centuries before the true causes were understood. Although people were unaware of the origin of malaria and the mode of transmission, protective measures against the mosquito were used for many hundreds of years. Systematic control of malaria started after the discovery of the mosquito parasite in 1889.

Malaria occurs mostly in tropical and subtropical areas of the world. In Africa, especially south of the Sahara, an estimated 90 percent of the deaths occur due to malaria. Though malaria is a less prominent cause of death in the rural areas of some countries in South America and Southeast Asia, it causes substantial disease and incapacitation and remains a health threat for people who live in these countries.

Factors affecting the occurrence of Malaria can be broadly divided into three main categories: Environmental, biological, and behavioral. First, warm temperature and abundant rainfall provide conducive conditions for the *Anopheles* mosquitoes to breed and survive long enough to complete their transmission cycle. Second, the distribution and abundance of various species of *Anopheles* in the region at a given time will influence the intensity of malaria transmission. Also, if these mosquitoes become resistant to the insecticide(s) used locally for spraying, transmission will increase. Third, human behavior, often dictated by social and economic reasons, can influence the risk of malaria for individuals and communities. For example, poor rural populations often cannot afford the housing and bed nets that would protect them from exposure to mosquitoes. They sometimes also lack the knowledge to recognize malaria and to treat it promptly and correctly. The absence of adequate health services frequently results in recourse to self-administration of drugs and incomplete treatment. Human activities can also create breeding sites for larvae, such as standing water in irrigation ditches and bur-

Dr. Carlos Juan Finlay

The Cuban scientist Carlos Juan Finlay made great strides in research into mosquito-borne diseases. He was born at Puerto Principe, Cuba, and was of French and Scottish descent. After attending Jefferson Medical College in Philadelphia, Pennsylvania, Finlay graduated in 1855 and continued his studies in Havana, Cuba, and then Paris, France. Returning to Havana, he opened a medical practice.

The 1860s saw much interest in yellow fever and other tropical diseases. Finlay wrote a paper for the Cuban Academy of Sciences in 1865 in which he correlated weather conditions with the prevalence of yellow fever. He continued working, and in 1881 was able to theorize that the mosquito was the vector for the transmission of the disease. He was later able to identify the organism causing yellow fever as the genus *Aedes*. His work also led to discoveries regarding the spread of malaria, which were later confirmed by the Walter Reed Commission.

When work began on the construction of the Panama Canal in 1903, many workers started suffering from malaria and yellow fever, with up to 10 percent of the workforce dying each year. The pioneering work by Finlay managed to massively reduce the incidence of the disease.

Finlay was chief health officer of Cuba from 1902 until 1909. He is commemorated with a giant syringe-like obelisk in the Cuban city of Marianao, and also with a postage stamp, which was issued in 1981 on the 100th anniversary of the publication of his theory of biological vectors.

row pits. Agricultural work such as harvesting (also influenced by climate) may force increased nighttime exposure to mosquito bites. War, migrations (voluntary or forced), and tourism may also expose nonimmune individuals to an environment with high malaria transmission.

Malaria has socioeconomic consequences for both individuals and government. Costs to individuals including preventive measures and drugs and treatment expenses, and costs to governments including maintenance of health facilities and lost days of work, add substantially to economic burdens and impede economic growth. It has been estimated that annual economic growth of countries with intensive malaria was 1.3 percent lower than that of countries without malaria.

Malawi

FORMERLY THE BRITISH protectorate of Nyasaland, the Republic of Malawi won its independence in 1964, setting the stage for 30 years of one-party rule under President Hastings Kamuzu Banda. In 1994, Malawi held its first multiparty elections. The long colonial legacy in the region, which made Malawians the labor force for agricultural and mining economies in adjacent countries, has continued to prevent the country from making substantial economic progress, along with problems in governance and policy.

Malawi is one of the least developed countries in the world even though natural resources include limestone, hydropower, and deposits of uranium, coal, and bauxite. Barely 16 percent of the population is urbanized. More than 23 percent of land area is arable, and over 90 percent of the workforce are engaged in subsistence agriculture, generally in growing tobacco. Prolonged droughts such as the one that hit Malawi in 2005 and 2006 are capable of creating major food shortages.

With a per capita income of only $600, Malawi is the third poorest country in the entire world, outranked only by the newly formed East Timor and the politically turbulent Gaza Strip. Some 55 percent of Malawians live below the national poverty line, and a third of the population is seriously undernourished. Government revenues are heavily dependent on economic assistance from the World Bank and the International Monetary Fund. In 2000, Malawi was approved for the Heavily Indebted Poor Countries initiative.

Although landlocked, Malawi shares a 580 kilometer border along Lake Nyasa with neighboring Tanzania and Mozambique. Malawi also borders Zambia. Except for some rounded hills and mountains, the land area of Malawi is comprised of a narrow elongated plateau with rolling plains. Elevations range from 37 meters where the Shire River meets the international border with Mozambique to 3,002 meters at Sapitwa Mlanje. Malawi's subtropical climate has a distinct rainy season that lasts from November to May when the six-month dry season begins.

Environmental health issues are of major concern among Malawi's population of 13,013,926, in large part because of the HIV/AIDS epidemic. With a 14.2 percent adult prevalence rate, 84,000 people have died from HIV/AIDS since 2003. Another 900,000 are living with the disease. One-third of the population lacks sustained access to safe drinking water, and 54 percent lack access to improved sanitation. As a result, Malawians have a very high risk factor for contracting food and waterborne diseases such as bacterial and protozoal diarrhea, hepatitis A, typhoid fever, and the water contact disease schistosomiasis. In some areas, Malawians are also at very high risk for contracting vectorborne diseases such as malaria and plague.

Because of the high incidence of disease in Malawi, the country is experiencing lower than normal life expectancy (41.7 years) and growth rates (2.38 percent), and higher than normal infant mortality (94.37 deaths per 1,000 live births) and death rates (19.33 deaths per 1,000/population). Malawian women give birth to an average of six children each. The fact that less than half of all females over the age of 15 can read and write makes it difficult for the government to educate them about disease prevention. The United Nations Development Programme's Human Development Reports rank Malawi 165 of 232 countries on overall quality of life issues.

Other major environmental problems include deforestation, which is occurring at a rate of three percent annually, and land degradation. Water has been heavily polluted from the dumping of raw sewage, agricultural runoff, and industrial effluents. Water resources are being depleted, and increasing siltation of spawning grounds has created major obstacles for marine life. Because 60 to 70 percent of protein in the Malawian diet comes from fish, the 40 percent decrease in fish production has threatened food supplies and presented a health hazard.

The destruction of the forests is contributing to a significant loss of biodiversity, and habitats are increasingly being threatened. In 2006 scientists at Yale University ranked Malawi 91 of 132 countries on environmental performance, below the relevant geographic group and considerably below the relevant income group. The overall score was reduced because of the low score in environmental health.

The Constitution of 1995 acknowledges that the government has a responsibility for preventing degradation of the environment and for providing healthy living and working environments. In 1996 the government adopted the National Environmental Policy based on the National Environment Action Plan, focusing on bringing the public into partnership with the government to halt further environmental degradation. The National Council for the Environment was given the authority to mediate when necessary, and the Environmental Affairs Department was charged with coordination of all environmental policy. The government has focused a good deal of attention on reversing the damage to fisheries by protecting breeding grounds and placing restrictions on how fish are caught. With 27.2 percent of Malawi still forested, the government has also protected 11.2 percent of land area. Of 105 identified mammal species, eight are endangered, as are 11 of 210 bird species.

Malawi participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Marine Life Conservation, Ozone Layer Protection, Ship Pollution, and Wetlands. The Law of the Sea agreement has been signed but not ratified.

SEE ALSO: Biodiversity; Deforestation; Pollution, Water.

Malaysia

MALAYSIA CONSISTS OF two regions divided by the South China Sea: Peninsular Malaysia, and east Malaysia (on the island of Borneo). Its total land area is about 329,750 square kilometers. The total population is about 25 million, of which 20 million live in Peninsular Malaysia. The population growth rate is 1.78 percent, with a birth rate of 22.86 births per 1,000 people. The capital city (and largest city, with 1.5 million people) is Kuala Lumpur. The prime minister's office relocated to Putrjaya in 1999, but the parliament still meets in Kuala Lumpur.

In 1948 the British-ruled territories on Peninsular Malaysia formed the Federation of Malaysia, which gained independence from the United Kingdom within the Commonwealth on August 31, 1957. In 1963 the Federation was expanded with the admission of the British colonies of Singapore, Sabah, and Sarawak, and was renamed Malaysia. Singapore left Malaysia in 1965. Malaysia is a constitutional monarchy: the nominal head of state is the king of Malaysia, who is selected for five-year terms from among the nine sultans of the Malay states (four states, Melaka, Penang, Sabah, and Sarawak, have governors appointed by the government, and do not participate in the selection). Malaysia has a bicameral parliament consisting of an elected lower house and a nonelected upper house. In 2003, Premier Mahathir bin Mohamad retired after 22 years as the prime minister in favor of his deputy, Abdullah Ahmad Badawi.

The official language is Malay. The population is classified ethnically as: Malay 50.4 percent, Chinese 23.7 percent, non-Malay indigenous (mostly in east Malaysia) 11 percent, Indian (mostly Tamil) 7.1 percent, and other, 7.8 percent. The Malay are by constitution Muslims, and Islamic law is applied to Muslims in matters of family law. Muslims are 60.4 percent of the population, Buddhists 19.2 percent, Christians 9.1 percent, and Hindus 6.3 percent.

The Malaysian climate is tropical, and characterized by annual southwest monsoons from May to September and northeast monsoons from November to February. Peninsular Malaysia is cut by a mountain range that separates the narrow eastern coast from the fertile western plains. The highest peaks are Gunong Tahan (2,190 meters) and Gunong Korbu (2,183 meters). East Malaysia is composed of alluvial and swampy coastal plains, and the hinterland of areas of rolling rain forests interspersed with mountain ranges. The highest peak is Gunung Kinabalu, at 4,095 meters above sea level.

From the early 1970s to the late 1990s Malaysia transformed itself from a producer of raw materials to a manufacturer and exporter of industrial goods, especially computers and consumer electronics. Because of its reliance on exports, the Asian economic crisis of 1997 hit Malaysia hard.

In the early 2000s the economy recovered, and in 2004 Gross Domestic Product (GDP) grew by seven percent, and in 2005 by five percent. In 2005 agriculture accounted for 7.2 percent of total GDP, industry 33.3 percent, and services 59.5 percent; 14.5 percent of the labor force works in agriculture, 36 percent in industry, and 49.5 percent in the service sectors. Strong growth beginning in the 1980s resulted in labor scarcity, which attracted an estimated two million migrant workers from Indonesia (half of them illegal).

Malaysia's main natural resources are tin, petroleum, copper, iron ore, natural gas, bauxite, and timber. It is the world's largest exporter of natural rubber and palm oil. The emphasis on logging and on rubber and palm oil has caused the destruction of most of the natural forests. Although an estimated 59 percent of Malaysia is forested, only an approximate 11.6 percent is primary forest.

Maldives

THE MALDIVES CONSISTS of a chain of atolls stretching 860 kilometers southward from Sri Lanka into the Indian Ocean. While the Maldives encompasses a total of 1,192 atolls raging in size from 0.5 to 5.16 square kilometers, only 199 are inhabited. Over time, this number is falling as smaller, less-populated atolls are abandoned by choice or through government policies to centralize populations. Most atolls are highly vulnerable to sea level rise and coastal erosion. Approximately 80 percent of atolls rise less than one meter above mean sea level, with the highest point of the country being only three meters above sea level. This also makes the country highly vulnerable to tidal surges and tsunamis. Significant damage to tourist resorts and inhabited atolls, as well as the loss of approximately 100 lives, resulted from the December 26, 2004, tsunami.

The Maldives, with a current population of 300,000, has undergone a significant economic transformation over the past twenty years. Despite high economic growth rates the economy remains dependent on a limited economic and employment

Cemetery Clearing

The Maldives faces a serious shortage of land as the population continues to increase. This has resulted in the clearing of many of the cemeteries on the main island, Male'. Until the 1970s there were cemeteries throughout Male', mostly attached to mosques, as the Maldives is mainly Muslim. British traveler T.W. Hockly bemoans the sheer number of them in his 1935 account of the country. One that has survived adjoins the Hukuru Miski mosque and is the tomb of Abu Al Barakat, a North African credited with converting the inhabitants of the island to Islam. Many others have not been so lucky. Most were cleared between 1974 and 1978, with some of the mosques also being demolished. Old tombstones have been retained at a few mosques, such as the Henveru Bandara Miskit and the Dolidan Miskit. A monument to the Arab traveler and writer Ibn Battuta at Henveiru Avaru has been lost, although another on Kuredu Island, Fadiffolu, is still maintained.

While most of the cemeteries in Male' have been cleared, more survive on remote islands. On the Addu Atoll, one of the southernmost of the Maldives and the site of a secret World War II British naval base, sixty-eight men from India who died there between 1942 and 1944 are either still buried on the island or were cremated. The monument honoring them is regarded as the most isolated memorial maintained by the British War Graves Commission.

base, which is dominated by fishing and tourism. Economic growth has resulted in higher incomes but also increasing environmental impact from rising levels of production and consumption.

The country's rich marine biological diversity faces threats from coral and sand mining (for use in construction), destructive fishing, waste disposal (few islands treat sewage or can bury solid waste), and intensive use of reefs in tourism (diving and snorkeling). Many atolls face long droughts as water lenses are exhausted, polluted, or made undrinkable by salinity. Pollution and waste management is becoming a challenge in the face of limited space. To date they have only been managed through the development of "new" islands, which act as the primary rubbish sites for both hazardous and nonhazardous waste.

Pollution, especially sewage, and solid waste management pose a considerable problem for the capital, Male'. Male' has one of the highest population densities of anywhere in the world, with approximately 100,000 people living on 1.7 square kilometers. Male' faces considerable problems of future population growth and limited capacity to sustainably deal with demand.

The Maldives remains one of the most vulnerable countries in the world in terms of sea level rise and changes to ocean temperatures, as well as the impact of pollution resulting from changing lifestyles and consumption patterns, and population growth (2 percent per year) and concentration. Though it has achieved considerable success in terms of economic development, the fragility of the country's ecosystem means that it will remain highly vulnerable to both externally driven change and threats arising from its own development patterns and demographic growth.

Mali

THE REPUBLIC OF Mali is completely landlocked and lies in the center of the West African landmass. This nation of 1,240,000 square kilometers is the largest in terms of surface area in West Africa. Mali's 10.7 million people comprise 10 ethnic groups of which the Mande groups (Bambara, Malinke, and Soninka) are the most numerous (50 percent). The country is composed of three major climatic zones: a vast desert region in the north, a Sahelian band through the middle of the country, and a Sudanian zone in the south.

About 65 percent of Mali's land area is considered desert or semi-desert. Average rainfall in the desert region ranges from 0 to 350 millimeters, in the Sahel region from 350 to 600 millimeters, and in the Sudanean region from 600 to 1,200 millimeters. Southern Mali (Sudanean region) has two distinct seasons: A rainy season from June to October and a dry season from November to May. The dry season is divided into a cold season (November–February) and a hot season (March–May). Dust-laden harmattan winds from the North often sweep across the country during the dry season.

After several years of above average rainfall in the 1950s and 1960s, Mali experienced severe droughts in the 1968–72 and 1984–85 periods. These droughts led to concerns in the scientific and donor communities that Mali was experiencing a broad pattern of desertification largely caused by human activities. Subsequent research has demonstrated that declining vegetative cover was driven more by cyclical downturns in rainfall than local management practices.

The French ruled Mali from 1916 to 1960 as part of the French Sudan. The French were never very numerous in the country and practiced a highly-centralized and direct form of rule. Mali gained independence in 1960 as part of the Mali Federation with Senegal. Senegal left this federation after only a few months.

While French is the administrative language, Bamanan is the most widely spoken language (particularly in the south), followed by Fulani. Approximately 80 percent of the population understands Bamanan. Islam is the predominant religious practice (90 percent) and has been noticeably influenced by

Timbuktu's Crumbling Buildings

The fabled city of Timbuktu on the southern edge of the Sahara Desert has long been a byword for an exotic, inaccessible, and distant place. It was established by the nomadic Tuareg peoples in the 10th century and was a major city through several empires. In 1591 it was captured by Moroccans. The arrival of the Portuguese on the west coast of Africa changed the nature of trade and gradually eroding the land trade routes, which had operated for hundreds of years.

The account of the city by Leo Africanus, a Spanish Moor, awed many in Western Europe in 1494. An African-American sailor who went by the name of Robert Adams also wrote an account of his time in Timbuktu in 1816. Other visitors included Gordon Laing, a Scot, who was killed on his return journey; René Caillié, a Frenchman who reached the city in 1828; and a German, Heinrich Barth. All their stories emphasized the isolation of a city so remote from anywhere else.

Today Timbuktu is visited by increasing numbers of tourists, who fly in from Mali's capital, Bamako, or come overland via land rovers. The house where Laing stayed is one of the sights, although it is now in such a state of disrepair that visitors are not allowed inside. In the same street is the house Caillié stayed in during his time in the city. The current population is 15,000, down from an imperial high of 100,000. Camel caravans crossing the Sahara still stop in Timbuktu to offer salt and other goods.

now waning animist traditions. One legacy of French colonialism was a militaristic forest service that aggressively established tree plantations and repressed bush fires in the 1980s. This led to popular resentment and the near dissolution of the forestry service following a transition to democracy in the early 1990s.

Mali is ranked among the poorest countries in the world. This poverty, combined with concerns about environmental degradation, led many analysts to assert that Mali was trapped in a vicious downward cycle of poverty-induced environmental degradation. Subsequent research has questioned such causality. Mali's economy is largely natural resource–based with 80 percent of the labor force involved in agriculture.

Mali was sub-Saharan Africa's leading cotton exporter in 1998–99 at 560 million tons, with the crop accounting for half of the country's foreign exchange earning and nearly half of government revenues in recent years. Some analysts have raised concerns about the sustainability of cotton production in Mali. Such concerns receive limited governmental attention due to the importance of cotton exports to the national economy. Other major exports include cattle and gold.

Malnutrition

MOST FREQUENTLY, MALNUTRITION speaks to an inadequate diet. Two major types of malnutrition are protein-energy malnutrition and micronutrient malnutrition. Malnutrition is especially prevalent in developing countries, particularly in sub-Saharan Africa and southern Asia. In the developing world, one in three children under the age of five is malnourished. While young children are particularly susceptible, pregnant women are also at higher risk for the implications of malnourishment. Other than the forms of protein-energy malnourishment, the primary manifestations in developing nations include iron, iodine, vitamin A, and zinc deficiencies. Malnourishment is estimated to be directly responsible for 300,000 deaths annually and indirectly responsible for about half of all deaths among young children.

Protein-energy deficient malnutrition is of particular concern as it can lead to starvation. In 2000–02 it was estimated that worldwide 852 million people were undernourished, the majority of whom (95 percent) were in developing countries. In some parts of the developing world outside aid and efforts to encourage breast feeding have helped to decrease malnourishment; however, the numbers of undernourished worldwide remain relatively stable.

Protein-energy malnutrition often manifests at an early age, between six months and two years of age, and can affect a child's development. With an insufficient supply of protein, chronic infections such as diarrhea may occur and lead to further malnourishment. The problems of malnourishment and infection-induced diarrhea can result in a persistent cyclic pattern that can lead to further medical problems, and potentially to starvation and death.

Micronutrient malnutrition affects at least two billion people worldwide. Today, approximately 740 million people experience iodine deficiencies. Much of this occurs in underdeveloped nations where seafood or iodine-fortified salt is less available. Iodine-fortified salt has been the primary reason that much of the developed world no longer faces iodine deficiencies. About two billion people worldwide are zinc deficient, one billion experience iron deficiency—which is highly correlated with anemia—and approximately 250 million, primarily children and pregnant women in developing nations, are vitamin A deficient.

The underlying cause of malnourishment is poverty, but several factors play a role in the experience and likelihood of malnourishment. One factor found to be elemental in malnourishment in the developing world is the role of women. In many societies women play an active role in food collection, preparation, and administration, which is especially important in the care of young children. The higher women's educational attainment levels and status are relative to men, the less likely malnourishment will be found among children.

National food security, or the availability of an adequate food supply, is also a primary factor in the existence of undernourishment in a society. In countries with low levels of food security, such as the nations of sub-Saharan Africa and South Asia, improving the food supply is found to be as important as improving women's education and roles when seeking to alleviate malnourishment. In societies with relatively high levels of food security, however, such as many countries in East Asia, the Near East, North Africa, Latin America, and the Caribbean, the availability of food is less impactful than improving the role of women. Environmental factors, such as water sanitization, pollution, and agricultural capability, are also prime factors in the likelihood of malnourishment. The availability of potable water is especially important as water that is not sanitized can harbor pathogens that can lead to infection and illness, thus bolstering the impact of malnourishment.

Malthus, Thomas Robert (1766–1834)

THE POLITICAL ECONOMIST Thomas Robert Malthus was born on February 13, 1766, at Wotton, Surrey, England. He was known as Robert Malthus. Taught by radical thinkers, including his father, and at the famous dissenting academy at Warrington, near Liverpool, Malthus then entered Jesus College, Cambridge (1784–88), where he studied under the radical William Frend. Malthus graduated with a B.A. degree and as ninth wrangler (ninth-best mathematician in the university) in 1788. He earned his M.A. degree in 1791 and became a fellow of his college (1793–1804). After being ordained in the Church of England (deacon 1789, priest 1791), he held various curacies and livings and was a conscientious and pious priest. In 1804, Malthus married Harriet Eckersall (1776–1864); they had three children. In 1805 he was appointed professor at the East India Company's College at Haileybury, Hertfordshire, where he taught and lived for the rest of his life and was a well-liked teacher.

In 1798 Malthus anonymously published his *An Essay on the Principle of Population*. He argued that population can increase in a "geometric ratio" (1, 2, 4, 8, 16, and so on), but the food supply can increase at most only in an "arithmetic ratio" (1, 2, 3, 4, 5, and so on). Population is kept in balance with the food supply by "checks," which he characterized as "vice" or "misery," and which included war, famine, plague, delayed marriages, and prostitution. He also characterized the checks as either "positive" (those that increase the death rate) or "preventive" (those that reduce the birth rate).

A second edition of the *Essay* (1803) added much empirical evidence of the population checks at work in various countries and periods. He identified moral restraint (delayed marriage preceded by sexual abstinence) as the most desirable check on population and argued that its operation would tend to increase individual happiness. The edition was thus more optimistic than the first, which had stressed misery and vice. His main idea (that unchecked population tends to outrun the food supply) became known as "the principle of population" and became a central tenet of classical political economy. Although Malthus declared that he had deduced the idea from the works of other political economists, it became firmly attached to his name.

The *Essay*'s argument was highly controversial from the start and Malthus used editions of 1806, 1807, 1817, and 1826 to refute erroneous claims that he had argued in favor of war and immoral practices but also to reiterate his denial that the poor have a right to be supported. He argued that support for the poor funded by taxation tended to increase the price of food, undermine people's independence, and encourage imprudent marriages, thus creating rather than mitigating poverty. Malthus advocated the abolition of poor relief.

Malthus's critics included Karl Marx, who was particularly incensed at his attitude to the poor. His admirers included Charles Darwin, who acknowledged his influence in the development of his theory of natural selection, and J.M. Keynes, who admired his *Principles of Political Economy* (1820), which argued for the importance of distribution and effective demand as causes of economic growth. Malthus wrote on other aspects of political economy, notably on the classical theory of rent (1815). His work brought election to several learned societies and he helped to found new ones to promote the new sciences of political economy and statistics. Malthus died on December 29, 1834, at Bath.

After his death Malthus's name was associated with movements advocating mass contraception as a way of warding off rapidly increasing population, and zero population growth. In fact he rejected both of these approaches. He opposed contraception, partly on moral grounds and partly because he believed that its use would remove the desirable stimulus to work to provide for one's children. He thought population growth desirable, provided that it did not exceed the growth of the food supply.

Malthusianism

IT WAS, AS various writers have noted since, a "tract for the times"—a pamphlet published anonymously in 1798 by a young and unknown pastor, challenging the Enlightenment giants and taking a harsh stand on welfare policy in Britain. Its central point was that the prime driver of societal ill is population's tendency to outgrow food production. Its strengths, as its later adherents saw it, were unflinching honesty and scientific legwork; the result, as economist Alfred Marshall later put it, was "one of the most crushing answers that patient and hard-working science has ever given to the reckless assertions of its adversaries." By its second edition it was no longer anonymous: the name Thomas Robert Malthus was attached to the work, and this name has ever since been attached to its central point.

The pamphlet, *An Essay on the Principle of Population*, countered Godwin's and Condorcet's idealistic views on the perfectibility of social institutions, pointing instead to "fixed laws of our nature," specifically that "Population, when unchecked, increases in a geometrical ratio...subsistence increases only in an arithmetical ratio." These "fixed laws" comprised two claims, one agricultural and one demographic. For the demographic claim, Malthus did marshal some empirical support (including data from colonial America), but he mainly supported his case by appeal to the facts of human nature: Godwin may have predicted the triumph of mind over body, but Malthus countered that overpopulation resulting from "passion between the sexes" could only be checked by misery, vice, and death. The agricultural claim was seen more as a given, since he was writing when there was little inkling of how food production could be boosted except by putting more land under, or more men behind, the plow.

The centuries since Malthus's time have brought profound changes not only to human demography and food output, but to the scientific fields devoted to their study. These developments have been unkind to Malthus's basic postulates. On the population side, various effects of social institutions, government policies, education, and economic development have repeatedly overridden the constant effect of "passion"—baby booms and baby busts have come and gone, and total fertility rates have plummeted worldwide (including throughout most of the developing world since the 1960s).

On the agricultural front, it was soon after Malthus died that external-input agriculture began, first with the advent of global trade in nitrogen fertilizer, then by revolutions in mechanization, breeding, pesticides, and information technology. Malthus knew nothing of the common process of agricultural intensification, whereby output is increased by added labor and skill rather than acreage. Overall agricultural production has been outstripping population growth ever since 1798, and is expected to keep doing so for as far out as the Food and Agriculture Organization of the United Nations (FAO) makes predictions. The fact that famine continues to haunt humanity underscores the deep problem in malthusian causality. In recent years, a Nobel Prize has been awarded for an economic historian's work on the nondemographic underpinnings of famine, and overflowing grain stocks have been reported in the country with the world's largest population of undernourished.

Yet Malthus's "tract for the times" has proven to be one of the most timeless documents in Western intellectual history, contributing inspiration for—and adding shape to—a long and varied history of theories, schools of thought, movements, and policies. Much of this persistent power of malthusianism is due to its malleability, and the fact that its basic tenets and implications can be adjusted to changing agendas. (Some writers write instead of Neomalthusianism, but the distinction serves little purpose since Malthus himself tinkered with his basic arguments so much that he would have to be classified as a neomalthusian himself.)

Given the failures of malthusianism to fit the history of fertility and food production, or the dynamics of food shortage, why it has had such a long history of influence is an interesting question. The main answers are political and social, and anthropologist Eric Ross has provided a history of the political and social uses of malthusianism, beginning with its original use to explain and justify the burgeoning slums and short life spans of the Industrial Revolution workforce. In the mid-19th century, malthusianism was used as a justification of ruthless colonial policies. For instance, the Irish potato famine was held up as confirmation of malthusian doctrine, despite the fact that Ireland exported large amounts of meat to England throughout the crisis. Nineteenth century famines in the British colony of India, caused in large part by the forced replacement of food production by commodity production, were likewise attributed to Indian overpopulation—as was the need for high taxes on Indian colonial subjects.

In the first decades of the 20th century, malthusianism provided support for anti-immigrant societies and policies in the United States. Academic books stressed the dangers posed by the reproductive urges of "inferior races" such as Jews and Irish.

Malthusianism shaped cold war thinking in the United States, attributing the spread of Communism to high population densities. These fears were particularly focused on India, where peasant movements in the post-war years were taken as warnings that India might go the way of China. Through the PL-480 program, the United States transferred enormous amounts of grain to India well into the 1960s to check the spread of Communism (and to absorb U.S. grain surpluses). The Indian state therefore invested in industry and allowed the agricultural sector to stagnate, reinforcing the dependence on grain imports and perception of malthusian overpopulation. Therefore, the Green Revolution is often credited with averting a malthusian catastrophe.

Beginning in the mid-1990s, malthusianism helped fill the void in post–cold war thinking, with academic writers and journalists stressing environmental security as the new driver of third world conflict. This surge of malthusianism took local population/resource imbalance as the principal driver in what were presented as gathering crises. Robert Kaplan's lurid essay, "The Coming Anarchy," popularized this perspective in public and policy circles (although detailed case studies by geographers and anthropologists showed that such conflicts were consistently driven by other—nondemographic and nonlocal—factors).

Most recently, malthusianism has been used to great effect in the promotion of genetically modified crops. This began in the late 1990s, largely in response to European rejection of genetically modified foods. Biotechnology media began to raise alarms about population growth and impending food shortages in developing countries, FAO projections notwithstanding. This latest use of malthusianism furthers interests corporations (who stand to make or lose billions), states (who compete for niches in global trade), and universities (whose biology departments have moved rapidly into genetic modification).

Management, Environmental

ENVIRONMENTAL MANAGEMENT IS at once broader than resource management, yet emerged in part from it, as well as from new and emerging approaches in the 1960s and 1970s that drew on systems, ecosystems, and public interest and participation ideas. These ideas were themselves catalyzed by the social and environmental movements of the times. Key concerns of these movements included women's and civil rights issues on the social side, and endangered species and protected areas, pesticides, toxic wastes, and Great Lakes water quality issues on the environmental side. Numerous scientists, including Rachel Carson, Barry Commoner, Ray Dasmann, Rene Dubos, Paul and Anne Ehrlich, Aldo Leopold, Fairfield Osborn, E.F. Schumacher, Paul Sears, and Barbara Ward wrote at the time, or even earlier, about the need for more integrated, careful, and protective approaches to the state of the environment we live in. Such an approach would go beyond the older resource- and development-focused emphases of the earlier postwar period. The goals of environmental management are typically broader than those of resource management. They were initially defined in terms of air and water quality, reduced negative effects of development projects, improved human quality of life, and protecting endangered species. Environmental management goals now also include newer ideas such as biodiversity conservation, maintaining ecosystem services, enhancing human well-being and sustainable livelihoods, ecosystem health and integrity, or overall sustainability.

New environmental management goals take into account biodiversity conservation as well as human well-being.

Growing awareness of the interconnectedness of human systems and ecological systems, and the potential human health and economic effects of pollution, deforestation, wetland loss, or flooding provided a strong push for more comprehensive and systematic planning and regulatory approaches to reducing environmental effects of human activities. This knowledge had numerous roots but certainly included the spread of systems and ecosystem ideas that could be traced back to the 1930s and 1940s; more recent studies of eutrophication in the North American Great Lakes and elsewhere; the wide ranging results of the 1960s International Biological Program (IBP) and the 1970s Man and the Biosphere program (MAB) of UNESCO, as well as the extensive research and management experience in integrated watershed management and multiple use forestry in Canada and the United States in the preceding decades.

Rapid growth in urban and industrial development, intensification of agriculture, and recreation and travel in the postwar period led to particularly intense pressures on parks and other protected areas, forests, water resources, coasts, and agricultural land. Environmental management is a new, more integrated, comprehensive, and participatory approach to the complexity of managing and planning such deeply interconnected human-environment systems. In this context environmental management tries to apply multiple disciplines to environmental challenges, through inter- and trans-disciplinary approaches.

Environmental management has always had a strong base in natural and ecological sciences, as well as ever growing links to social science: initially in terms of participation, and social and economic effects of human activity, in recent years more and more in terms of considering issues of equity, power, and communication as considered in political ecology and ecological modernization theory. In this context, environmental philosophy, through movements such as deep ecology, ecofeminism and environmental justice, pushes environmental management to consider deeper issues of inter- and intra-generational equity, and the long-term merit, or sustainability, of anthropocentric versus ecocentric approaches. There is also a long-running discussion over whether we can, let alone should, manage ecosystems or environmental systems, or only human activities and interactions with them.

The first formal manifestations of modern environmental management are usually seen to be the establishment of national environmental protection legislation, environment agencies, environmental impact assessment requirements, and water management agreements and agencies. The United States established the federal Environmental Protection Agency (EPA) and National Environmental Policy Act (NEPA) in 1970, followed by Clean Air and Coastal Zone Management Acts in 1972. These strengthened numerous requirements, improved coordination, monitoring, and integration, and introduced Environmental Impact Assessment (EIA) requirements. There had been air and water pollution regulation and agencies for a couple of decades before that, and the Clean Air Act (1963) and Endangered Species Act (1966) also came earlier.

Many other countries followed suit with similar agencies, policies, and requirements in the ensuing decade. Canada, for example, created the federal Department of the Environment in 1971 and the Federal Environmental Assessment and Review Process in 1973. Subnational, provincial, and state governments also started taking similar steps during the 1970s. The Great Lakes Water Quality Agreement between Canada and the United States was signed in 1972, then substantially revised in 1978, and did much to promote integrated ecosystem approaches to environmental quality, and large-scale planning, monitoring, and restoration as components of environmental management.

All of these approaches have been further developed since the 1970s. Ecosystem approaches have helped foster ecosystem-based management, emphasizing integrated, transdisciplinary collaborative approaches to planning and management of multiply-defined spatial units such as watersheds, bioregions, or greater ecosystems. EIA has been very strongly developed, first to better include social and ecological, as well as environmental and economic, effects; then to be more participatory and equitable; and more recently to address cumulative effects and strategic assessments.

EIA is also increasingly developing links to land use planning and sustainability initiatives and will only become more important in environmental management in future. Environmental monitoring has been a component of environmental management, and especially EIA, since the start, although it is often more talked about than done. Its profile is rising, although government funding cuts in the 1990s certainly reduced activity. Monitoring is currently supported by strong national, multistakeholder networks in both Canada and the United States, and growing legislative requirements in a range of sectors.

ENVIRONMENTAL PLANNING

Environmental management has been extended to, or has influenced several related areas. Environmental planning focuses on environmental management and protection through land use planning at scales from the local or municipal to regional and larger. It builds on Ian McHarg's work in the 1960s to use mapping approaches and ecological, social, and economic information to identify the best configuration of natural and human land uses in a region to minimize negative environmental and human effects. Today environmental planning applies from urban core densification through urban fringe subdivisions to very large, resource-based wilderness regions.

ADAPTIVE MANAGEMENT

Adaptive environmental assessment and management (AEAM) was developed in the 1970s from the conjunction of ecosystem science, systems and complexity ideas, and simulation modeling as a way to address uncertainty and complexity in the management of large, complex environmental problems. Now known as adaptive management, it emphasizes viewing management as an experiment to foster ongoing learning about ecosystems and management, drawing on multidisciplinary, scientific knowledge. The goal is to recognize uncertainty in decision making and management, but to ensure uncertainty does not prevent necessary action and additional learning.

SUSTAINABLE DEVELOPMENT

Although sustainable development ideas go back to at least the United Nations (UN) Conference on the Human Environment in Stockholm in 1972, they did not become widely influential until the 1987 release of the report of the World Commission on Environment and Development, "Our Common Future." Since then sustainable development has become a key goal for a very wide range of environmental and economic management and planning activities. While there are challenges in defining just what the concept means in a very wide range of contexts, and without watering it down until it is meaningless; the notion has nonetheless been highly influential and likely successful at underscoring the multiple dimensions of sustainability and the change needed to achieve it. Arguably parts (but only parts), of the private sector have most thoroughly adopted and implemented the idea, through Environmental Management Systems (e.g., ISO 14001) and product certifications (e.g., from the Forest Stewardship Council) and broader movements such as the Natural Step, triple bottom line, and corporate responsibility.

RECENT CHALLENGES

While early approaches to environmental management were often strongly regulatory, and led by national or provincial/state government, the 1990s saw major shifts away from this. These have been a reflection of reduced government budgets, reduced priority on the environment, and, arguably, public pressure to reduce taxes and government spending. This trend has been widespread globally, and of course tied to neoconservative political and economic perspectives. In practice it has resulted in federal passing of responsibilities to provinces/states and passing of responsibilities from provinces/states to municipalities. It has also led to greatly reduced staff levels in many government environmental agencies and reduced enforcement and monitoring activities.

It has often been argued that lower tier governments have little of the expertise, personnel, or funds to properly fulfill their new responsibilities. Environmental and human health disasters in a number of places have lead to inquiries, such as Justice O'Connor's investigation into the Walkerton tragedy in Ontario, Canada, which have catalyzed some retreat from these policies. In addition, public opinion seems to have been increasingly returning to environmental issues in the early 21st century and there are signs of a reversal of declining government interest.

Allied issues resulted from efforts to weaken long-standing environmental regulations and policies, e.g., in the United States, in some cases through free trade agreements and in other cases through changes to air, water, protected areas, and endangered species protection. Simultaneously there has been growing interest in market- and incentive-based mechanisms for environmental protection. Such approaches include industry self-regulation, emissions trading, and carbon taxes. While some have certainly been successfully implemented, others remain controversial. A decreased federal presence and devolution of responsibilities can also lead to less standardization of environmental requirements. Different countries, or jurisdictions within a country, may compete to attract industry via lower environmental standards. This frequently has negative environmental and social consequences at both local and global scales.

More positively, since the 1970s a wide range of international environmental agreements have been negotiated (and there are a few, such as the Canada/U.S. Migratory Bird treaty of 1916 that are much older). Some agreements are binational, but many are multinational. These commit national governments that have signed and ratified the conventions to implement particular policies and actions via domestic legislation and action. A few of the more significant are the 1973 Convention on International Trade in Endangered Species (CITES), the International Convention for the Prevention of Pollution from Ships (MARPOL), the 1972 World Heritage Convention, the 1985 Vienna Ozone Convention and 1988 Montreal Protocol, and the 1992 UN Framework Convention on Climate Change and its 1997 Kyoto Protocol.

Environmental management is still developing, through EIA and land use planning in practice, through sustainability, well-being, and related concepts to guide it, and through numerous other initiatives. Interest in environmental stresses and ecosystem responses in the 1970s led to state of the environment reporting and ecosystem health approaches. Environmental and ecological economists have built on these ideas to propose national environmental accounting systems and new measures of progress that go beyond the old throughput or consumption-oriented measures like Gross National Product (GNP). Such initiatives, together with environmental monitoring, are critical for better tracking and evaluating environmental management progress and failures.

Further supporting monitoring, assessment, and evaluation are the benefits of information and observation technologies. Technology has long assisted in resource management and surveying, but now its reach is being extended. Remote sensing and geographical information systems are a great boon to data collection and organization. Communication technologies can facilitate multidisciplinary teams in environmental management and organizing around environmental (and other) issues. Still, technology is no substitute for first-hand field observation or consultation. Combining new technologies with new collaborative and community approaches to resource and environmental management may be key to truly achieving long-term sustainability.

SOCIAL DIMENSIONS

As with resources management, there has been increasing interest in social dimensions of environmental management since the 1980s, and before. This includes the role of participation and communities, and different, often disadvantaged, groups within society.

This implies attention to equity, and gender and discrimination, and the broader issues of power relationships within environmental management. It is also extending, as Western societies become ever more culturally diverse through immigration, to seeking to understand different cultural perspectives on environment. There are political and practical implications to different cultures' perspectives on, for example, environmental health, wildlife conservation, and protected areas. Such perspectives are often different from historical Canadian, American or European perspectives.

There are numerous other challenges for environmental management. One is developing conflict resolution approaches to foster better, more efficient, and more effective solutions to environmental assessment and land use planning conflicts than are often produced by legal or quasi-legal hearings or proceedings in these areas. Facility siting, and "Not In My Backyard" (NIMBY) responses remain a challenge. Better collaboration, communication, and conflict resolution may be part of the answer, along with efforts to reduce the need for new, undesirable facilities.

Great challenges revolve around continuing processes of environmental and landscape change due to land use and resource development and consumption. These may require deeper lifestyle changes than traditional environmental management is usually seen as encompassing. The particular challenges of climate change and water resources management, for example, underscore the need for international cooperation on many issues, and arguably for new mechanisms and institutions of global environmental governance.

Man and the Biosphere Program (UNESCO)

THE MAN AND the Biosphere Program (MAB) is a network of biosphere reserves that are nominated by national governments and designated by the United Nations Educational, Scientific, and Cultural Organization (UNESCO). It was established in 1971, with the first reserves coming into the World Network of Biosphere Reserves in 1976. The World Network of Biosphere Reserves is the only intergovernmental network whose objectives lie in meeting sustainable development, conservation, and scientific cooperation. The delay in official designation was due to the need for the MAB Coordinating Council to define the procedures of designating biosphere reserves, as well as deciding what the overall objectives and characteristics of the program were.

This scheme was initiated by UNESCO as a follow-up program to the International Biological Program. Unlike its predecessor, the Man and the Biosphere Program was intended to unite the biological information resulting from the International Biological Program and other complementary sources with social science and policy analyses. The purpose of this was to make the resulting knowledge of practical use to policy makers at various levels from municipal to international. In practice, it has taken time to incorporate social science into the framework.

Many nations nominated areas to be biosphere reserves from the outset, often choosing preexisting national parks or other types of protected areas. A significant number of reserves in some nations were recognized in that first round of nominations. For example, the United States received recognition for 27 of the 47 Man and the Biosphere Reserves. Today there are 507 Man and the Biosphere Reserves in 102 countries.

Fourteen program areas were originally designated in order to promote policy-orientated research, synthesis, and comparison. These included studying specific biomes and ecosystems, such as tropical forests, arid lands, and high latitudes. There were also cross-cutting themes such as perception of environmental quality and grazing lands. Most significant was the theme "Conservation for Natural Areas and the Genetic Materials Contained Therein," from which the term *biosphere reserve* itself originated.

Nations nominate areas to be designated as a Man and the Biosphere Reserve. This is done through MAB National Committees, whose designation, organization, and composition varies depending on the individual country. UNESCO reviews nominations and provides the designation as a biosphere reserve. It also facilitates the World Network of Biosphere Reserves. UNESCO provides expertise and occasionally funding to design and implement projects concerning biosphere reserves. In general, though, individual biosphere reserves within the program are expected to find principal funding from sources other than UNESCO, whether they be municipal, national, private, or from business.

The prestige of being designated as a Man and the Biosphere Reserve in developing areas is particularly significant in terms of tourism marketing. National and international tourists have been documented to travel to areas primarily on the basis of the designation. Other draws are often the perception of an ecotouristic experience. UNESCO's management of the system has, however, come under criticism for not revoking the designation in cases where human rights infringements are alleged. Such was the case for the Danube Delta Man and the Biosphere Reserve. This is a transnational biosphere reserve shared by the Ukraine and Romania. The Romanian government sold off the fishing rights to large sections of the Danube Delta to private owners, whose rights supersede those of local people. The claims of local people to traditional fishing grounds and seasonal habitations within the Danube Delta are under question, with the continuity of both extending into prehistory. The case has been protested by activists and academics.

In fact the Statutory Framework of the Man and the Biosphere Program does make provision for periodic review of sites every 10 years. Yet the reports are composed by the managing authority and forwarded to UNESCO, thus leaving open the possibility of a biased submission. One other shortcoming, or challenge, is sharing information between sites when each one evolves individually in terms of management and data collection. Yet, despite these challenges, the Man and the Biosphere Program is seen on the whole to be a very worthwhile and positive endeavor.

Manioc

MANIOC, OR CASSAVA yucca, is a tropical root vegetable originally from Brazil that was used for thousands of years by natives in Latin America. European explorers first came across it in the Amazon region in the mid-16th century. Many archaeologists agree that manioc was an important crop in the tropical forest of the Amazon region. Today, the starchy roots of cassava form the staple diet of over 500 million people in dozens of developing countries on four continents.

There are two main types of manioc. Bitter manioc, which can become a staple food after heating, drying, and leaching, is toxic in its natural form because it contains cyanide. Sweet manioc has a lower concentration of toxic elements. According to ethnobotanist Serena Heckler, because of its toxicity, women who succeed in manioc cultivation gain social prestige. Manioc's many uses include flour, bread, tapioca, a sauce called "tucupi," and countless dishes in various cultures and traditions. The history of manioc is linked with slavery, colonialism, and trans-Atlantic history; it was introduced in Africa from Brazil in the 19th century. In his book *Manioc in Africa*, William O. Jones explains that manioc was fundamental to the African agricultural economy, especially in the Congo.

According to the statistics division of the Food and Agriculture Organization of the United Nations (FAOSTAT), the most important producers of manioc are Nigeria, Brazil, Thailand, Indonesia, Congo, Ghana, India, Tanzania, and Mozambique. The productivity of manioc has changed dramatically in recent decades. While South America's volume has decreased in the last 30 years, India's production has risen sharply. In a new development in Brazil, researchers have succeeded in creating high-protein hybrids.

As a strategy to cut greenhouse gas emissions, countries like China are building fuel ethanol plants to produce biofuel for cars; using cassava to generate ethanol is less expensive than grains such as corn or wheat. The extensive production of manioc is sometimes seen as a solution for dire problems like famine, food shortages, and the need for renewable energies. However, the effort to develop disease-resistant varieties of cassava or cassava biofuel has generated controversy among experts debating the possible risks of the transgenic varieties of genetically-modified cassava.

Maps

MAPS ARE GRAPHIC representations of the natural world and of culture and society. General definitions of maps typically include references to "simplified depictions of space" or "flat representations of some part of the earth's surface" that include "graphic representation of features." Maps are, however, a much more complex phenomenon. Maps are among the most successful forms of visual communication invented by humankind and arguably a critical element of human cognition. Maps are a key way of recording and illustrating information. They enable people to visually comprehend how space is organized. The power of maps to shape opinions, communicate ideas, and influence decision making has ensured their central role in economic and political life for millennia. Maps find uses in a wide variety of areas such as: environmental management, humanitarian aid, urban and regional planning, logistics, travel, trade, business, and war.

In addition to providing basic information about the relative location of places, maps help people to identify complex spatial relationships and distributions. In this way, maps assist humans to imagine, conceptualize, and make decisions about their environment. Maps relate to many aspects of everyday life and can be a central tool in the decisions people make about their mobility. They can be casual aids to navigation, high technologies essential to the function of modern life, or priceless cultural artifacts that have changed the ways in which people see the world and interact within it. Originally, maps were made almost exclusively by skilled scientists and draftsmen known as cartographers, but recent innovations in information technology and publishing has ensured that maps can now be created and used by a much broader constituency of people.

Maps are incredibly diverse in their forms and purpose and have changed dramatically over time

Gerardus Mercator

One of the most famous mapmakers was Gerardus Mercator, a cartographer whose family had previously come from Germany and settled in Flanders, now a part of Belgium. He was originally known as Gerard de Cremer and went to the University of Louvain to study humanities and philosophy.

During this period Mercator started to have some doubts over Biblical stories about the creation of the universe. He grew interested in geography and made friends with Gemma Frisius, a leading theoretical mathematician, physician, and astronomer. Frisius arranged for him to work with a cartographer in Louvain, and in 1535–36 Mercator helped produce a terrestrial globe; in 1537 he also worked on a celestial globe.

As soon as Mercator had finished the second globe, his italic lettering and skill as an engraver encouraged him to try his hand at maps. His first piece of work was a map of Palestine, which he completed in late 1537, and in 1538 he followed this with a map of the world that he transposed onto a flat surface with a double heart-shaped projection. He later worked on other maps, but in 1544 he was arrested and charged with heresy. Mercator was released after seven months in jail and returned to making maps. In 1552 he moved to Duisburg in the Duchy of Cleve, where he helped establish a grammar school and drew up its curriculum. He also set up his own cartographic workshop and hired engravers. Mercator started producing a map of Europe, and then a number of maps of other parts of the continent.

It was during this period that he developed his technique of the "Mercator projection." This appeared for the first time on his map of the world, which was published in 1569. Mercator then produced more maps, and even an atlas. He died on December 2, 1594, at Duisburg.

and between societies. Throughout history, the production of maps was controlled by powerful elites, monarchies, or the state. Special mapping agencies, such as the British Ordinance Survey, were established to survey national territories. The development of new mapping technology was often closely associated with the military. For instance, satellite data, which first emerged from space surveillance technology developed during the cold war, is now commonly used in map production.

HISTORY

The work of mapmakers from the ancient to the modern world—among them Ptolemy, Mercator, Muhammad al-Idrisi, Zheng He, John Speed, and Mason and Dixon—has emerged as a major area of study for geographers and historians. While some of the oldest maps can been seen on Babylonian clay tablets dating from about 2400 B.C.E., it was the ancient Greeks who made the first clearest advances in cartography in terms of technique and geographical range. These advances were preserved and developed further in the Arab world during the so-called Dark Ages.

In the West, the production of maps grew quickly during the Enlightenment. New techniques in land surveying, navigation, geometry, projection, graphic design, and printing technology eventually facilitated cheaper and wider circulation of maps, atlases, and globes. Indeed, cartographic knowledge was one of the basic building blocks of societal progress during this period. Between the 14th and 17th centuries, mapmakers were heavily influenced by European voyages of discovery during an "age of reconnaissance."

Early European cartography involved mapping seas, coastlines, and new found lands. Maps from this time are cherished for their artistic qualities, and often depict fantastic images of beasts and sea creatures, as well as elaborate cartouches celebrating the cartographer's patron. As well as assisting navigation, early European maps supported both facts and myths about faraway places, new worlds that the majority of people would never witness first-hand. Increased demands for accuracy from navigators, however, ensured that maps became increasing reliable and realistic representations of the world. In terms of European expansion, maps also proved to be important tools in the exploitation of natural resources, the development of trade, and the governance of colonies. The growth of literacy, travel, and tourism during the 19th and 20th centuries also created new roles for maps and ensured their continuing relevance to modernizing societies.

MODERN MAPS

Over time, cartography became more scientific and standardized, while at the same time maps became more specialized and thematic. This trend continues in the present day where we see maps for almost everywhere in the world and specialized to assist almost every economic and social activity. There are currently many classifications of maps. For example, orthophoto maps identify land features using photographic images; physical maps identify the earth's landforms and bodies of water; political maps identify boundaries that divide one political entity from another; relief maps identify relief data using contour lines and shading to evidence the elevation; raised-relief maps are three-dimensional portrayals of physical features; road maps assist travelers in moving from one location to another; online road maps often calculate different routes and distances; and thematic maps—such as heritage or tourist maps—provide an artistic element and entertainment and are often commercial products. Other types exist, and some fall into more than one category.

In recent years, the production of maps has been revolutionized by the emergence and development of Geographical Information Science (GIS), which links hi-tech computer mapping with spatial analysis. GIS is used for managing, storing, retrieving, analyzing, and displaying spatially referenced data. Because GIS systems digitize data, it can be manipulated into easily accessible and aesthetic forms. Broad areas of application include mapping environmental data, land use, social phenomena, and economic activities or attributes. GIS can be used from the scale of satellite images of countries to the scale of small towns. Typical categories of plotted information include densities and clusters, rates, and single point distributions of both social and natural phenomena.

Maps continue to evolve as the nature and use of this information technology develops. Maps can be found in mobile navigation systems, e-commerce internet sites, and in the technology supporting advanced mobile phone services. Map production has become a significant area of business, as companies with investments ranging from real estate to telecommunications appreciate the value of an exact knowledge of the geography of their markets. Maps are increasingly also produced by community-based groups with interests in issues related to heritage, identity, and environment. These new uses illustrate the ongoing significance of maps in shaping both the human imagination and man's relationship to the environment.

Marine Pollution

MARINE POLLUTION IS caused by the introduction (whether directly or indirectly) of substances or energy into the marine environment, which cause harm to living marine resources. Sources of marine pollution include: (1) direct discharge of effluents and solid wastes into the seas and oceans; (2) land runoff into the coastal zone, mainly from rivers; and (3) atmospheric fallout of pollutants transferred by the air mass onto the sea's surface. Research has shown that two-thirds of the total input of contaminants into the marine environment is from land-based and atmospheric sources, constituting 44 percent and 33 percent, respectively.

Ecological impacts of marine pollution include disturbances in the function of water biotic communities and habitats and changes to hydrology and geomorphologic systems. Impacts can manifest as changes in the abundance, diversity, and fitness of individuals, populations, and communities of living marine resources. Solid wastes, heavy metals, and chlorinated hydrocarbons can damage the respiratory, reproductive, and digestive systems of marine organisms. Excess nitrogen and phosphorous inputs from agriculture can cause algal blooms that disturb the balance and structure of water ecosystems. Sewage outflows can cause oxygen deficiency that can trigger the mass mortality of water organisms.

PESTICIDES, HERBICIDES, AND FERTILIZERS

Pesticides and herbicides used in agriculture and urban gardens are designed to kill unwanted pests. The most common type of pesticides is insecticides. They can be highly toxic and frequently pollute the coastal and marine biota due to storm water runoff. Studies have shown that less than one percent of pesticides actually end up on their target species, leaving 99 percent to pollute and contaminate the environment.

Pesticides have many effects on the marine environment, including changes to reef communities and structure, increases in algae and sponges and damage to seagrass beds and other aquatic vegetation. Further, pesticides move through the food chain as they accumulate in the biota.

An example of the impacts that fertilizers can have on the environment comes from the Great Barrier Reef Marine Park Authority, which analyzed the impacts of growing sugarcane along the coast adjacent to the Great Barrier Reef. To grow sugarcane in Australia, large amounts of inorganic fertilizer, particularly nitrogen, is required due to the abundance of nitrogen-poor soils along Queensland's coast. Approximately 200 kilograms of fertilizer per hectare is applied to the cane to promote growth every year.

Only approximately 70 kilograms are taken up by the crop; the remaining 130 kilograms pollute the environment with a significant percentage reaching the marine waters of the Great Barrier Reef through stream flow runoff. During the flood events common to the monsoonal weather patterns of the Queensland coast, dissolved inorganic nitrogen (DIN) concentrations in flood plumes range between 10 to 100 times ambient concentrations, along with high levels of particulate nitrogen. The impact of this pollution has been significant to the Great Barrier Reef including a major decline in the abundance and diversity of corals and fishes.

SEWAGE

Sewage is a significant marine contaminant. For example, in New Jersey between 1986 and 1992, approximately 8 million tons of sewage sludge was discharged annually in water depths of 2,500 meters. Sewage outflow has significant effects, especially in developing nations. Risks to human health are great, with World Health Organization estimates showing that gastroenteritis and respiratory infections are caused every year by bathing in contaminated seawater. In 1993, the Pan American Health Organization indicated that only 10 percent of the sewage generated in Central American and Caribbean countries was properly treated. Infectious hepatitis A, a serious and debilitating disease of the liver, is a virus frequently transmitted by shellfish contaminated by sewage.

CHEMICAL CONTAMINATION

Chemical contamination derives from the dumping of chemical wastes into the marine environment. Substances include chlorinated hydrocarbons, heavy metals, nutrients, oil hydrocarbons, surface-active substances, and artificial radio-nuclides. Ongoing bioaccumulation and biomagnification of trace elements such as mercury and lead has been found in marine mammals such as the bowhead whale (*Balaena mysticetus*), beluga whale (D*elphinapterus leucas*), gray whale (*Eschrichtius robustus*), and seal. This has serious health implications for peoples such as the Inuit of Alaska and other Arctic areas, who rely upon marine resources as significant sources of protein.

Marine pollution affects human health; for example, hepatitis A can be transmitted by sewage-tainted shellfish.

TOURISM

Coastal and marine tourism is one of the largest and fastest-growing sectors of the global economy. Visitor numbers frequently exceed the carrying capacity of the environment—its water supplies, available space, and the ability of habitats to absorb visitor impacts and provide an enjoyable experience. Coastal erosion, pollution, habitat destruction, and social decay are common consequences. Tourist boats, curio collectors, reef walkers, snorkelers and scuba divers have damaged coral reefs in many tropical countries.

SHIPPING

Shipping, ship groundings, and collisions are a major source of marine pollution. Contaminants include hazardous and noxious substances, hydrocarbons, ballast water discharge that spreads marine pests, and antifouling paints. An estimated 10,000 marine species are being transported in ships' ballast water between bio-geographic regions at any given moment worldwide.

It is estimated that the global shipping industry discharges up to 5.5 million items of waste every day. The application of antifouling paints remains an ongoing problem. For example, in Korea, while the practice of applying antifouling paint containing organotin compounds to ship surfaces was halted beginning in 2003, and antifouling paint is supposed to be completely removed from surfaces by 2008, ships are still frequently dry-docked for repainting in shipyards. There, high pressure water and sand particles are used to remove impurities, such as attached marine organisms, salts and slime, and old paint from the ship's surface. In this process, major contamination occurs from the particles of antifouling paint that are often discharged directly into the marine environment.

MARINE DEBRIS

Millions of tons of plastic and glass enter the oceans each year. Major sources of plastic are from fishing equipment, packaging materials, convenience items, and raw plastics. Wildlife is at particular risk from plastic, with over 100,000 birds, whales, seals, and turtles killed by plastic rubbish each year. Birds get tangled in plastic can holders and turtles ingest plastic bags, perhaps mistaking them for jellyfish. Recent entanglement studies estimate that in Australia, 1,478 seals die from entanglement in fishing nets each year; the entanglement rates for Australian sea lions were 1.3 percent in 2002 and for the New Zealand fur seal 0.9 percent. This issue is compounded by the long "shelf time" most marine debris has before biodegrading fully; plastic bags take up to 1,000 years, glass bottles one million years, and plastic bottles may last indefinitely.

NOISE POLLUTION

In some areas, noise pollution at sea has doubled every decade for the past 60 years. Sources of ocean noise pollution include explosives, underwater construction activities, ship traffic, seismic survey activity, and oceanographic experimentation.

Noise proliferation is a significant threat to the survival of many marine mammals, and to other resources. Research shows that noise pollution is reducing marine faunas' ability to find food, locate mates, avoid predators, and communicate with each other. This is particularly so with marine mammals who use sonar as a guidance mechanism.

MANAGEMENT INITIATIVES

Given the significant effect of marine pollution, there are a number of tools and treaties that attempt to mitigate its impact. The United Nations and others have established over 200 initiatives to manage and mitigate pollution and degradation of the marine environment at the global and regional levels including: (1) the Global Program of Action for the Protection of the Marine Environment from Land-Based Activities (1995); (2) the Protocol Concerning Pollution from Land-Sources and Activities in the Caribbean; (3) the International Maritime Organizations Antifouling Treaty (2001); (4); the Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (1972); (5) the Convention for the Prevention of Marine Pollution by Dumping from Ships and Aircraft (1972); (6) the Convention for the Prevention of Marine Pollution from Land-based Sources (1974); and (7) the Convention for the Protection of the Marine Environment of the Northeast Atlantic (1992).

Marine Science

SIMPLY STATED, MARINE science is the science of the sea. It is a multidisciplinary field of scientific inquiry that encompasses the fields of biology, fisheries, ecology, chemistry, geology, physics, and oceanography as they pertain to the marine realm. Marine scientists focus on a variety of marine habitats distributed worldwide in tropical, temperate, and arctic regions, including: coral reefs, estuaries, and lagoons, as well as benthic, pelagic, intertidal, coastal, and deep sea environments.

The marine realm encompasses over 71 percent of the earth's surface. It is a primary driver of the hydrological cycle, plays a major role in the earth's weather and climate system, and provides critical habitat for millions of marine species. The oceans contribute to international commerce, transportation, and tourism. They contain large amounts of valuable minerals such as hydrocarbons and manganese nodules. They are a source of fish, shellfish, algae, and plant species that form the basis of the world's commercial, artisanal, and subsistence fisheries and aquaculture operations. Marine species have given rise to new genetic and pharmaceutical products. The oceans also comprise a realm of strategic military importance. Understanding these mechanisms, roles, and resources is an integral part of marine science. In addition to providing insights into the structure, functions, and human uses of the ocean realm, marine scientific endeavors have also contributed to our understandings of the origins of life, human biology, and evolutionary, developmental, and tectonic processes.

Until recently, a lack of appropriate technology constrained the ability of humans to conduct scientific investigations of the marine environment. The development of the bathysphere, and, more significantly, SCUBA gear (also known as Self Contained Underwater Breathing Apparatus), manned and unmanned submersibles, and remote sensing (acoustic, seismic, optical, and satellite) technologies have generated a number of new insights and substantially enlarged our knowledge base in the field of marine science.

Although premised on the idea of objectivity, science is a particularly human endeavor and no accounting of the field of marine science would be complete without reference to some of the many scientists who have worked in this field to expand the boundaries of knowledge. The following represents an all too brief and incomplete sampling of internationally important marine scientists. Among them is Sir Charles Wyville Thomson, a Scottish scientist who directed the first purely scientific exploration of the oceans aboard the HMS *Challenger* from 1872 to 1876. It took an additional 10 years to complete the 50 volumes summarizing the cruise's findings. As a result of this work, Thomson stimulated the beginning of a modern science of the oceans, identifying thousands of new species of organisms and confirming that there was indeed life in the deep ocean—debunking the azoic theory, which posited that it was absent. The Norwegian scientist and explorer Fridtjof Nansen enhanced human understanding of arctic marine environments, exploring the Arctic Ocean aboard the vessel *Fram* and by dogsled.

Henry Bryant Bigelow conducted seminal studies of the Gulf of Maine, and emphasized the importance of creating interdisciplinary understandings, combining the natural and physical sciences to gain insight into the complexity of the marine environment. He became the first director of the Woods Hole Oceanographic Institution, one of the preeminent marine science institutes in the world, serving from 1930 to 1940. Jacques-Yves Cousteau, although not necessarily one of the great marine scientists in the world, did much to popularize the findings of marine scientists, introducing the general public to the study of the oceans in his numerous collections of photographs, books, television shows, and movies, and to the sea itself through his invention of SCUBA gear and techniques for creating underwater photographs.

Many countries, notably industrialized countries with coastlines, have established schools and institutes for the study of marine science. Due to the very high economic costs of conducting marine scientific studies, there exists a disparity between developed and developing countries with respect to their scientific infrastructure and human resources. Such economic disparities focus attention on the need for international cooperation in marine scientific endeavors, which is further necessitated by the global nature of the marine environment itself,

The marine realm encompasses over 71 percent of the earth's surface, providing habitat for millions of species.

transcending spatial and temporal boundaries, as well as those imposed by nation-states.

Elisabeth Mann Borgese, an expert in marine policy and law who championed the legal idea that the oceans are "the common heritage of mankind," founded the International Ocean Institute with centers around the globe, and convened yearly Pacem in Maribus (literally, Peace in the Oceans) conferences, captured the essence of the field. She wrote, "The marine scientist is the prototype of a new interdisciplinary, international scholar, one who bridges the gap between theory and action. More often than not, the marine scientist is an explorer, a sailor, a diver, exposed to physical hardship and adventure, as well as a scholar, a theoretician, a philosopher of nature."

Marketable Permits

MARKETABLE PERMITS ARE instruments aimed at reducing pollution on an individual level. The permits represent a quota of pollutant that the permit-holding individual or organization is allowed legally to emit, and may also be bought or exchanged with other permit-holders for financial considerations. The laws of supply and demand apply to such exchanges, with a national or international regulatory scheme monitoring observance of permit limits and, when necessary, reducing the total number of permits in circulation to cut down on pollution. Many firms find this system a powerful incentive to make their operations cleaner and more efficient because they will not exceed their permitted levels of emissions, and because the unused permit or some portion of it becomes a commercially valuable asset.

This system combines two other approaches that have been tried but, in some circumstances, found wanting. The "command and control" system relies on strong governmental control of pollution and the imposition of penalties on perpetrators. This system can only be successful when state governments take pollution control issues seriously and have the capacity to monitor and police levels of pollution emitted. The U.S. George W. Bush administration has not taken pollution and its implications seriously, and has not signed the Kyoto Protocol aimed at pollution control.

The second approach is to rely on market-based transactions to limit pollution, but this is impractical because those suffering most from pollution are rarely those who cause it, and because market operations are prone to failure unless strongly regulated so that abuses are prevented. By issuing permits, governments can control the marketplace, but also permit some market transactions to take place. Consequently, attempts to create monopolies or in other ways rig the market should be spotted by regulators, although at the cost of additional expense in the system.

There have been complaints based on ethical grounds that it is inappropriate to give the ability and right to pollute to those who are the greatest offenders. However, this need not be problematic so long as the polluters are properly monitored. Even so, it is possible that those firms or states that have already taken steps to reduce their emissions will be disadvantaged if the assessment of total permissible levels is taken on current rather than historic measurements. Given the importance of the problem of pollution, this argument is trivial and it may even be that such states can obtain economic benefits by selling their technology to others struggling not to exceed their permitted targets.

Problems with the marketable permits scheme and similar arrangements include the difficulty in identifying accurately the total level of appropriate pollution, together with the issues surrounding transaction costs and uncertainty. Transaction costs are all those costs that are part of an economic transaction but are not central to it. Examples include insurance, verification costs, transportation, and legal fees. Since there is a measure of uncertainty attached to pollution and environmental issues, which are complex and often chaotic in nature, the transaction costs involved in trying to accurately price permit purchases can be high or can be ignored at the risk of making the purchase inefficient. Despite the problems inherent in the system, the marketable permits approach appears the most helpful one currently available to tackle pollution.

Markets

MARKETS ARE PHYSICAL or virtual spaces where people buy and sell commodities in exchange for money or for other commodities through barter. Markets can be local, national, or international in scale and exist within larger social and cultural contexts that affect the rules governing market transactions. Because markets can only deal with commodities, i.e., goods or services that are treated as somebody's property that can be sold, goods can only be made subject to market forces if they are first converted to a commodity form.

For example, humans can be made into a commodity if they are enslaved, but this form of commodification is now illegal. On the other hand, the Kyoto Protocol opens the possibility of internationally trading permits to emit carbon dioxide, treating carbon dioxide emissions as a tradable commodity. The rules determining which kinds of things are treated as commodities, and how they can be exchanged, as well as the market structures that emerge, all affect how people use natural resources, with profound environmental implications.

COMMODIFICATION TRENDS

The general thrust within the last two centuries has been to transform more and more things into commodity form, for example, by enclosing commonly owned resources as private property. Karl Polanyi referred to this process as the "Great Transformation," making the market the dominant social institution. This transformation is justified as promoting the more efficient allocation of scarce resources, using Adam Smith's "invisible hand" of the free market to ensure that each resource is used by the people capable of making the best use of it. However, Polanyi showed that a countermovement, led by unions and other oppositional forces, led to a partial reversal of the trend toward greater importance of markets in the course of the 1930s and 1940s (particularly in Britain, but elsewhere as well). Yet another "great transformation" occurred with the rise of neoliberalism in the latter part of the 20th century, as described by Blyth and Harvey. Hence, despite the general trend toward expansion, markets are constantly subject to opposing social forces.

FREE MARKET FORCES

According to most economic theorists, a market only yields favorable results if it is free. For a market to be free, there must be many buyers and many sellers of a commodity, ensuring that no buyer or seller can manipulate prices. If a market is dominated by only a few sellers, it is an oligopoly market; if it is dominated by only one seller, it is a monopoly. In both oligopoly and monopoly markets, sellers can raise prices in order to get extraordinary profits; in fact, many profitable companies in the world operate in oligopoly markets (e.g., pharmaceuticals, agrochemicals, petroleum, and hi-tech manufactures).

If only one or a few buyers dominate the market, they can depress prices, as typically occurs in markets for agricultural commodities, mineral resources, and mature (low-tech) manufactures such as textiles. These markets tend to be dominated by companies that act as middlemen between producers and consumers. If the producers of these commodities have no other viable economic alternatives, they are forced to cut corners in order to continue in business. In agriculture, this may include the neglect of long-term investments to maintain soil fertility; in mining, it may include the indiscriminate dumping of wastes (e.g., mine tailings); and in manufacturing, it may include excessive pollution. In all economic sectors, it includes depressed wages and disregard for workplace safety (e.g., exposure to toxic chemicals).

If entire countries depend on sales in buyers' markets, these strategies pervade their entire economy, and development must be financed from foreign sources (e.g., foreign aid and loans). This increases the danger of falling into severe debt and of dependency on institutions such as the World Bank and the International Monetary Fund.

The companies that dominate the markets use their political and economic clout in order to perpetuate their market dominance, making it very difficult for a free market to emerge. For example, barriers to entry of new firms may be raised by the strategic use of below-cost sales, or by patenting of minor innovations. Furthermore, the core industrialized nations have until recently been very successful in bargaining for the relatively unrestrained entry of their products into the rest of the world at World Trade Organization negotiations, while keeping their own markets relatively protected.

Environmental impacts of these trade inequities include the inability of many Third World producers to invest in more environmentally sustainable production methods because of low profit margins and the wasteful use of cheap imported commodities (ranging from natural resources to many manufactures) in the wealthy industrialized countries.

LABOR MARKETS

Labor markets also usually deviate far from the model of the free market (as emphasized by Karl Marx, and the political left in general). If workers do not own the means of production, do not have an independent source of livelihood (e.g., farming), and have little or no access to social welfare payments from the government, their only alternative to being employed is to starve.

They are then not free to withdraw from the labor market and must accept any wages employers may offer. Only a scarcity of labor can enable workers to negotiate a wage that exceeds bare subsistence levels; that is, if there are few workers with particular skills that are in high demand. The contradiction between labor and capital involves persistent efforts on the part of both workers and employers to try to shift the labor market in their own favor.

Capitalists frequently employ a "spatial fix" (in the words of David Harvey) to circumvent higher labor costs in one place by moving production to another place (e.g., from the northern to the southern United States or from high-wage to low-wage countries), a strategy also referred to as the "race to the bottom." It involves not only the search for lower wages, but also disregard for worker safety and other environmental concerns. Employers may also invest in more machinery in order to reduce labor costs; this strategy depends on sources of cheap energy in order to be able to run the machinery efficiently.

REGULATION

Many "market imperfections" that cause undesirable social or environmental outcomes can be addressed through government regulations and/or through pressures from civil society. While the need for regulation is often clear, the methods by which regulations may achieve desired objectives are often far more difficult to determine.

In addition to market regulation, some environmentalists seek to remedy the problems of existing markets by developing alternative forms of marketing. One example is fair trade, in which Latin American, African, or Asian producers of agricultural commodities and some crafts products are guaranteed a minimum price for their products, to enable them to make a sustainable living. Fair trade often includes provisions for environmentally sustainable production methods, such as organically grown coffee. Another example of alternative marketing is local currencies, which are intended to stimulate local exchange among individuals and small businesses, usually with environmental aims in mind as well. This illustrates that markets exist in many forms, capitalist as well as noncapitalist, and will continue to evolve with society.

Marsh, George (1801–82)

GEORGE PERKINS MARSH was a lawyer, politician, diplomat, businessman, and farmer who studied a wide variety of subjects. Among his writings in favor of conservationism, his foremost influential book was *Man and Nature* (1864), which remains in print to this day. He was born in Woodstock, Vermont, on March 15, 1801, and died in Vallombrosa, Italy, on July 23, 1882. In 1820, he graduated from Dartmouth College, New Hampshire.

Marsh started his political career in Vermont, and from 1843 to 1849 he served as a Whig representative in the U.S. Congress. President Zachary Taylor appointed him minister resident in Turkey in 1849, where he served until 1853. He went to Greece temporarily as special minister in 1852. Later, President Abraham Lincoln appointed Marsh envoy extraordinary and minister plenipotentiary to Italy in 1861, a position that he held until his death.

From 1838 to 1862 he wrote on English and Scandinavian languages, and his work *Lectures on the English Language* (1859) was influential and contributed to the development of the linguistic study of English. His *The Origin and History of the English Language* (1862) offered a more historical approach.

Marsh was a pioneer in conservation studies and the movement that changed the perception of the relationship between man and environment. On September 30, 1847, he delivered a speech on agricultural conditions in New England to the Agricultural Society of Rutland County, Vermont. It draws on his early life interest in natural history, his farming activity, and his concern for the effects of deforestation. The American conservation movement was in its infancy. Henry David Thoreau's *Walden* was published in 1854. In 1857 Marsh wrote "Report on the Artificial Propagation of Fish," addressed to the Legislature of Vermont, in which he highlights the role of forests, river productivity, population restoration, and fish breeding.

In 1864 Marsh published *Man and Nature or, Physical Geography as Modified by Human Action,* the seminal work he revised in 1874 and published with the title *The Earth as Modified by Human Action: Man and Nature*. He brought a fresh, modern perspective to understanding the human capacity to be an agent of environmental change, and identified various environmental problems—deforestation, erosion, and pollution. Marsh called for sustainable resource management and anticipated the paradigm of the environment as a system. Marsh supported the establishment of the Smithsonian Institution by serving on the organizing committee and making donations of species obtained in his travels. His property eventually became part of Vermont's Marsh-Billings-Rockefeller National Historical Park.

Martin vs. Waddell

MARTIN VS. WADDELL was a court case that helped to establish in the United States the lawful ownership of environmental resources, including living things. Martin held lands alongside the River Raritan in New Jersey and he claimed ownership of these lands back to a grant made by King Charles II during the second half of the 17th century. He brought a court case with a view to developing an oyster industry based on those that were present in the river, and he desired to have exclusive use of them and their economic exploitation.

The presiding judge, U.S. Supreme Court Justice Robert Taney, ruled that this claim was not valid because King Charles II's ability to make such a grant should have been curtailed by the Magna Carta. The Magna Carta—the Great Charter—was a treaty forced upon King John by rebellious barons, signed first in 1215, and reissued several times subsequently. The Magna Carta makes a few concessions to the barons and to the people of the land, but subsequently it was employed to increase rights of individuals that were not contained in the original. In the United States, the Magna Carta has been used to justify many innovations, not always contained within its remit. Justice Taney's decision rather followed this precedent.

The result has become a central part of environmental law in the United States by establishing a principle that no one can own wild animals or creatures. Originally applying only to the 13 states, its provisions were subsequently adopted by later signatories. A consequence is that wild animals and fish are considered to be held as part of the "public trust" by the greater public, through the arm of the state, and so individuals are empowered among other things to access them as they see fit, within the framework of other regulations. The alternative, in which private interests are believed to hold exclusive rights to wildlife on their land and in streams on their property, would have considerably restricted the ability of the state to regulate many forms of resource use. Subsequent court decisions and the Tenth Amendment of the constitution have strengthened these rights. The Tenth Amendment states that rights revert to the federal government when they are not explicitly controlled by the states. The federal government has the power to control interstate commerce and, consequently, acts as the protector of the interests of wildlife.

The provisions of the *Martin vs. Waddell* settlement have been challenged by what has been called the Wise Use movement, which instead favors the economic exploitation of nature by private interests, in a context in which the environment has become overprotected and is not working to efficient market means. However, many people identify followers of the Wise Use argument as people bent on recklessly endangering the environment as a whole.

Marx, Karl (1818–83)

A WESTERN EUROPEAN social theorist and political activist, Karl Marx wrote voluminously, and his works rank among the most recognized contributions to social analysis. Best known for *Das Kapital* (1867), and for coauthoring *The Communist Manifesto* (1848) with his long-time collaborator Friedrich Engels, Marx's examination of the contradictions and crises entailed in social relations under capitalism has played a critical role in most "radical" political economic theory and politics since his death.

There are many ways in which Marx, and the various Marxisms that have followed, speak to the relation between society and environment. It is only since the last decades of the 20th century that the relevance of Marx's work to environmental politics has been widely recognized. Prior to the 1980s, many argued that Marx largely ignored nature—or even that he thought it unimportant. His "labor theory of value," for example, is frequently and erroneously brandished as proof that he believed nature contributes nothing of value to human production. Recent scholarship, however, has corrected this misinterpretation in two important ways: by demonstrating the relevance of Marx's concepts for the study of socio-environmental dynamics, and by bringing attention to the ways in which Marx's work reflects on the role of nature in the production and reproduction of human society.

First, beginning in the early 1980s, an increasing number of social scientists interested in ecological problems turned to Marx-inspired analytical tools to understand the ways in which environmental change is a product of political economic struggle between humans. Seminal contributions to the study of these dynamics in developing countries like Nepal and Nigeria looked at the political economic, that is, productive and distributional implications for natural resources of political conflict between classes, nations, and ethnic groups.

Marxian concepts like the "social relations of production" (the totality of human institutions that animate a particular "mode of production" like capitalism or feudalism) and "primitive accumulation" (the means through which subsistence producers are dispossessed of ways of providing for themselves without wage work) are essential to these studies. Much of the power of political ecology as an approach to understanding the "society-environment dialectic" is drawn from these explicitly Marxian roots, an analysis only made stronger by political ecology's marriage of political economy and cultural anthropology, which highlights important dynamics—religious beliefs and practices, for example—obscured by an emphasis on economic structures.

Second, the standard and grossly incorrect caricature of Marx as a dogmatic economic determinist who believed that labor was the sole source of anything meaningful is eroding, albeit very slowly. The work of writers like James O'Connor and John Bellamy Foster shows Marx's thinking on production as not only far more complicated than often thought, but as speaking, often directly, to environmental concerns. As Marx himself wrote in 1875, "Labour is not the source of all wealth. Nature is just as much the source of use values (and it is surely of such that material wealth consists!) as labour, which itself is only the manifestation of a force of nature, human labour power." These analyses, and

Highgate Cemetery

With the old church cemeteries in and around London becoming full by the late 18th century, plans were drawn up for large cemeteries in the new suburbs surrounding London. One of these "magnificent seven" cemeteries is Highgate Cemetery, which opened in 1839. It holds large Gothic tombs, vast mausoleums, and modest burial plots, and it also became an impressive garden in which many Victorians would promenade.

The cemetery fell into disrepair during the mid-20th century, but was saved by the Friends of Highgate Cemetery, who organize tours that point out interesting gravestones, including those of the many famous people buried there. Much wildlife, especially birds, live in the cemetery, and there are even some foxes. In recent years there have been studies of the flora and fauna at Highgate and in some of the other London cemeteries, such as Kensal Green.

One of the most famous people buried at Highgate Cemetery is Karl Marx. His modest grave was visited by many Communists and others interested in history and was later replaced by a massive monument with a large bust of Marx and the slogan "Workers of the World Unite." In Len Deighton's novel *SS-GB,* about a hypothetical German occupation of Britain in World War II, there is an assassination attempt on Josef Goebbels as he lays a wreath on the grave to commemorate the Nazi-Soviet Pact of 1939. Many Eastern European and Chinese politicians have visited the grave, and a number of other Communists have been buried in plots close to Marx, including members of Afghan and Iraqi Communist parties.

the work of many political ecologists, show the possibilities of a "green Marxism."

Mass Media

MASS MEDIA IS typically defined as a form of technology (including radio, film, and television, but also encompassing newspapers, magazines, and book publishing, as well as advertising, marketing, and public relations) or institutional organization (Time-Warner, RCA, BBC, AOL, Al-Jazeera, and so on). Beyond these narrow definitions, mass media also encompasses shifting cultural forms shaping human perception and possibilities for social change. Mass media therefore simultaneously includes technical, institutional, and cultural dimensions. This broad conception is required to understand how media shape contemporary human/environment conditions, including representations of nature, popular perceptions of environmental issues, and public opinion on phenomena ranging from swimming with dolphins to global warming.

MODERN ENVIRONMENTALISM AND MASS MEDIA COVERAGE

Many of the founding events of modern environmentalism were irrevocably shaped by mass media. Rachel Carson's 1962 book *Silent Spring* is a common touchstone for histories of environmentalism, but its initial serialization in a popular magazine (*The New Yorker*) and use in a CBS television exposé of the pesticide industry is crucial to a proper appraisal of its influence. Though it is hardly the first example of popular nature writing influencing attitudes and opinions regarding environmental advocacy, *Silent Spring* signaled the significance of mass media as a site for advancing environmental social change. Less than a decade later, subsequent events were not merely affected by media coverage but often *designed* as "media events" aiming to refigure human perceptions of nature and provoke action against the ill effects of industrialism. For example, Earth Day celebrations are public protest events designed to produce an agenda-setting effect, whereby prominent media coverage moves issues onto the public and political agenda. Prominent North American news coverage of the first Earth Day in 1970 was followed by increased public support for environmental protection, improved opinion polling on such issues, broad national environmental protection policies, and new political priorities, all of which underscored the importance of mass media as a tool for environmental change, while ensuring future conflict with antienvironmental institutions on its public terrain.

Greenpeace was probably the first environmental organization to explicitly design publicity strategies on the basis of mass media theory. Whereas the 1970 Earth Day was announced with a full-page newspaper advertisement, Greenpeace created dramatic coverage through direct confrontation with powerful industries. Finding inspiration in 1960s media guru Marshall McLuhan, images of environmental confrontation were released as a series of "mind bombs," or visual imagery triggering emotional response and support for issues usually obfuscated in abstruse regulatory language. These provocative conflicts were staged less to stop whalers, loggers, or nuclear testing than to create compelling images for mass media dissemination. As Kevin Deluca's important 1999 study made evident, these moments of radical confrontation were not romantically quixotic or irrational attacks on an impervious industrial system, but effectively measured tactics for conducting "image politics" in an increasingly televised or screened world.

More radical groups such as Earth First! and Earth Liberation Front (ELF) adopted new media as organization tools, finding in internet technology a medium well suited to their highly decentralized and antihierarchical style. Their direct action politics generally take the form of "monkey wrenching," a practice characterized across a wide continuum of frames ranging from harmless prank to ecoterrorism. Monkey wrenching is small-scale, low budget, nonviolent industrial and economic sabotage, including such activities as putting sand in gas tanks, billboard graffiti, tree spiking, and sport utility vehicle vandalism. Similar to the early radicalism of Greenpeace, the goal is mainstream media attention and public perception of natural destruction, not a belief that damage to property will suffice to halt industrial-scale exploitation. Edward Abbey's 1975 novel, *The Monkey Wrench Gang,* provided inspiration for the practice and gave expression to desires for new forms of environmental resistance, which proponents often conceive as an individualist or anarchist form of civil disobedience.

Critics associate monkey wrenching with forms of political terrorism, a view Michael Crichton extrapolates into a generalized state of paranoid anxiety in his 2004 novel, *State of Fear,* where well-funded, globally coordinated ecoterrorists stage a media-friendly tsunami in support of climate change activism. What remains clear in this broad range of characterizations is that, as Tim Lukes notes, "the whole design of monkey wrenching perhaps can be traced back to symbolic battles over environmentalism's image in the media."

As Greenpeace adopted a more conventional organizational structure in the 1990s, it came to rely less on McLuhanist principles than social marketing and fundraising techniques to the extent that it, like the World Wildlife Fund (WWF), is among the most recognized logos globally and a forerunner of what Naomi Klein has called "lifestyle branding." Lifestyle branding is the idea that identity, values, and lifestyle are sold more readily than actual commodities and that successful brands stretch across any number of actual products or issues, as the Canadian WWF recent brand-stretching into climate change issues indicates.

The use of attention-getting techniques employed in advertising and public relations to advance consumer ideologies has raised concerns regarding the appropriate means by which environmental goals should be achieved. Given that scientists, politicians, and activists must accommodate to prevailing media conventions in order to be heard at all, or "play by the rules of the game," does environmental crisis at times require or justify hyperbole and exaggeration? At what point do well-intentioned calls to recognize the urgency of environmental problems lapse into unwarranted fear appeals? As environmental organizations rely increasingly on fund-raising and publicity tactics typical of marketing industries, revelation of the use of such mainstream commercial techniques easily helps depict environmental groups as manipulative or propagandistic.

Controversial examples include a number of documentary-style films attacking Greenpeace, including *Survival in the High North,* which claim the organization utilizes propaganda methods, falsifications, and unseemly fund-raising in their campaigns. Bjorn Lomborg, in *The Skeptical Environmentalist,* echoes this antienvironmental refrain in linking proenvironmental public opinion to poor journalism and manipulative media.

As environmentalists claim that mass media express systemic antienvironmental bias, whether through outright exclusion, trivialization of issues, or "green washing," where consumerism is celebrated as the solution not the problem, questions about the role of mass media in shaping public opinion and environmental activism remain strenuously contested. Answers to these questions fall into three broad categories: (1) mass society and mass culture; (2) media reinforcement, dependency, and cultivation theory; and (3) framing and problem formulation distortions.

MASS SOCIETY AND MASS CULTURE

Mass society theory hypothesizes significant and direct effects for mass media content on public opinion, behavior, and culture. Largely a product of the 1920s–30s, with its innovations in mass media technology, propaganda technique, and the birth of modern advertising and public relations agencies, this line of thinking expresses concerns over mass media as tools for engineering consent and conformity. Modernization is often characterized as social transformation in which traditions dissolve, political and commercial power is centralized, and mass production stamps out a conformist, consumer society. As traditional community ties dissolve, alienated individuals become susceptible to control through mass mediated opinion management techniques, an indication that the instrumental intelligence evident in our technological domination of nature also seeks disciplinary control of human beings, though less through direct coercion than a debased popular culture.

Genuine insights in this tradition of thinking tend to get lost in the exaggerations of ironic skeptics and romantics alike. However, the connection between domination of nature and of humans, the opening rift between urban and rural sensibilities, and the provocative suggestion that environmental problems are simply intractable given the basic framework and institutions of industrial society admirably refuses easy accommodation to the truisms of consumer culture. The presence of some 75,000 significant dams in the United States as markers of progress and models for the world remains a visible reminder of the role of mass communication in equating progress with industrial and engineering development.

MEDIA REINFORCEMENT, DEPENDENCY, AND CULTIVATION THEORY

Reinforcement and dependency theories suggest media influence is expressed indirectly through the broader social system in which mass media find their role and is contingent on the extent to which we depend on them, such as in times of natural disaster. Media are contributory, not causal, factors reinforcing existing conditions along with other mainstream social institutions, such as the home, school, and church. Post-1960s evaluations tend to view this reinforcement function critically, as ideological or hegemonic, particularly as the popularity of television demands more weight be accorded its socializing or cultural influence. Cultivation theories have emphasized this point in arguing mass media provide a systemic source of socialization through storytelling that is thoroughly industrialized and bent to consumerist ends, while excluding representations of nature or "symbolically annihilating" environmental concerns. The main claim is that a small but pervasive, steady, directional, measurable, and independent contribution for television's influence on culture is observable and socially significant, in much the way a few degrees centigrade shift in mean temperature can severely impact local ecosystems. James Shanahan and his collaborators have built on this tradition to suggest heavy television viewers have less environmental knowledge, concern, and willingness to pay for protections, while directly challenging skeptics such as Lomborg on their claims about mass media effect.

FRAMING AND PROBLEM FORMULATION DISTORTIONS

Most research in this tradition focuses on the attention and framing given to specific environmental issues. One popular conceptualization of this process is Anthony Downs's (1972) "issue attention cycle," which suggests public perception of environmental crisis "does not reflect changes in real conditions as much as it reflects the operation of a systematic cycle of heightening public interest and then increasing boredom with major issues." Downs hypothesized a five-stage cycle through which environmental concern would pass: pre-problem, alarmed discovery and enthusiasm, realization of cost of resolution, gradual decline of intense public interest, and a post-problem stage, where issues reemerge only spasmodically.

Today, such conceptualization appears flawed in failing to acknowledge the specificity of environmental issues and too blunt given the results of more sustained study of mass media and public policy fields. Agenda-setting theory has proven important in finding that as media cover and attribute importance to an issue, through formal features such as story placement and amount of coverage, they alter public and political/policy agendas. Such theories strive to explain why some issues receive attention and, more importantly, how problems are defined and how possibilities for their solution often narrow to suit preexisting social institutions. Though there is considerable empirical support for such research, particularly regarding measurement and relationships of media and public agenda, the effect varies with respect to specific issues, the sorts of media employed, and the type of coverage, particularly the way concerns are framed. For example, vivid imagery tends to undercut agenda-setting power in focusing attention on people or unique characteristics rather than on underlying problems.

CONTINUING PROBLEMS

Those seeking to understand the relationship between mass media, public opinion, and environmental issues face two broad problems: (1) the nature of contemporary environmental problems, and (2) significant innovations in communication media.

First, contemporary formulations of environmental problems have expanded considerably in terms of their spatial-temporal scale, their complexity, and the diffuseness of their consequences, all of which make their adequate representation more difficult. The familiar symbols of environmental destruction in the 1960s and 1970s, such as burning rivers, dead lakes, razed forests, and mushroom clouds were easily represented and regionally delimited, with relatively clear causes for public opinion and policy regulation to address. Environmental problems today span the globe, stretch across generations, and remain largely invisible to common modes of perception. How does one effectively represent parts per billion of arsenic in drinking water, a gigaton of atmospheric carbon, or a critical oceanic desalinization point?

The problem formulation/resolution processes of mass media are particularly ill suited to mediating such environmental issues. Entertainment, educational, and news media alike tend toward dramatic representation and spectacle at the expense of ordinary, everyday engagement. Documentary films and tourist promotion tend to situate nature *as* spectacle, for spectators, which implies a stark dualism between humans and their natural world while routinely obliterating alternative and participatory engagements with nature from consideration. Such media continue belief in progressive technical domination and control of nature for human enjoyment, setting the stage for those converse instances of dramatic spectacle: natural disaster and catastrophe. Portrayals of disaster in Hollywood film and broadcast news are increasingly shaped by imperatives to capture attention and entertain, resulting in a vastly simplified framing of environmental crisis to the point these representations say more about narrative and journalistic production conventions than anything else.

In Hollywood film, environmental issues are portrayed as personalized conflicts between good and evil. This produces a simplified image of the complex and ambiguous process of claims making and responsibility attribution, while problem resolution takes place through heroic individual action, neatly tying up loose ends. In news media, problem formulation is similarly simplified. With the growth of 24-hour news and cable, news is now ever-present, continually casting events of the day into facile problem formats suiting television conventions like dramatic visualization, brevity, topicality, narrative coherence, blame, and action over criteria of multifaceted environmental appraisal.

The consequences of such distortion are most evident in coverage of natural disasters, where human/nature dualisms and "man versus nature" frames disguise the interaction of sociopolitical structures and natural processes. Failure to properly formulate the role of social policies in shaping structures of human vulnerability to disasters such as flood, fire, earthquake, and hurricane greatly impedes proper disaster policy analysis and the role of media therein.

Eric Klinenberg's 2002 book-length study of a single heat wave brilliantly elucidates the consequences of mass media failures to properly formulate and frame environmental crises. Heat waves are among the most consistently dangerous and well-understood environmental phenomena, easily predictable and ameliorated, yet, unlike flooding, they are difficult to visualize, affecting the most vulnerable in society without the widespread property damage images generally accompanying representation of disaster. As Klinenberg concluded in his analysis of the 1995 Chicago heat wave, which killed over 700 people, "several of the most probing and insightful accounts were overshadowed by prominent and sensational photographs, dramatic but misleading headlines, and false political debates that obscured the social aspects of the disaster."

The second set of problems concerns new information and communication technologies (ICTs), which have irrevocably changed the nature of mass media. Just as television altered the workings of print news and advertising, so digital media and internet access has transformed the relationship between mass media and society, creating new possibilities for perception and political organization. Optimistic proponents celebrate the interactive nature and participatory possibilities of new media, in providing near-instantaneous access to information on a vast array of issues and events, such as Scorecard, a regionalized pollution information site (www.scorecard.org) or Green Media Toolshed, which provides software and support for media components of environmental campaigns (www.greenmediatoolshed.org).

Other observers suggest answers to the problem of representing contemporary environmental problems might be found in the broad array of new visualization techniques ICTs offer, such as remote sensing, geographical information systems (GIS), and climate change modeling. At present, however, these gains are restricted largely to expert research tools. Their use in contemporary mass mediation tends to produce "chart junk" (visually appealing, scientific looking, but meaningless or misleading representations of data) and "data smog" (vastly increased production and distribution of unwanted and misunderstood information claiming our attention) as two consequences of decreasing costs and increasing availability of these media technologies.

More sober critics note a continuing Western bias to the global reach of news and advertising, as the same commodity orientation of mass media now characterizes the digital ones and zeros of these deregulated and privatized communication tools. As advertising-funded Western consumer media systems increasingly challenge subscription or tax-based public ones, observers remain genuinely concerned whether the digital extension of global advertising will contribute negatively to the magnitude and intensity of current environmental problems.

Mauritania

AFTER WINNING independence from France in 1969, the Islamic Republic of Mauritania annexed what is now Western Sahara, but was forced to cede the territory in response to repeated guerilla raids. After a coup in 1984 unseated the existing government, steps were taken to broaden political power. Although a free election was held in 2001, a bloodless coup in 2005 transferred power to a military government that pledged to move Mauritania toward democracy and away from the autocracy that still exists.

With a per capita income of $2,000, Mauritania is ranked 182nd in world incomes. Half of the workforce is engaged in agriculture, although less than one percent of land area is arable. One-fifth of Mauritanians are unemployed.

Forty percent of the people in Mauritania live below the official poverty line, and there is considerable income disparity. The richest 10 percent of Mauritanians share 30.2 percent of the wealth, while the poorest 10 percent claim only 2.5 percent of resources. The United Nations Development Programme's Human Development Reports rank Mauritania 152 of 232 countries on overall quality of life issues.

In addition to iron ore, which comprises 40 percent of export income, other natural resources include gypsum, copper, phosphate, diamonds, gold, and oil. Fishing has traditionally made up an essential element of the economy, but overexploitation by visitors to the country is threatening this important resource. Oil production is estimated at 75,000 barrels a day. Mauritania is still struggling with heavy debts and qualified for the Heavily Indebted Poor Countries Initiative in 2000.

Bordering on the North Atlantic Ocean, Mauritania has a 754 kilometer coastline. Land borders are shared with Algeria, Mali, Senegal, and Western Sahara. With the exception of a few hills in the central part of the county, Mauritania is generally comprised of the barren, flat plains of the Sahara Desert and the desert climate is hot and dry.

Drought may occur with devastating results in Mauritania at any time of the year. From March to April, the sirocco winds—which are hot, dry, and laden with dust—blow over Mauritania, creating major environmental damage. Elevations range from five meters at Sebkhet Te-n-Dghamcha to 915 meters at Kediet Ijill.

Environmental health is a major issue in Mauritania just as it is in other poor countries of Africa. Only 63 percent of urban residents and 45 percent of rural residents have sustained access to safe drinking water. While 64 percent of urban residents have access to improved sanitation, only nine percent of rural residents have similar access.

The population of 3,177,388 people is at very high risk for contracting food and waterborne diseases that include bacterial and protozoal diarrhea, hepatitis A, typhoid fever, and the respiratory disease meningococcal meningitis. In some areas, the people also have a high risk of contracting malaria and Rift Valley fever. Women are particularly at risk from the fertility rate of six children each. The dissemination of birth control and other environmental health information is hampered by a literacy rate of 31.9 percent for females and 51.8 percent for males.

Deforestation, which occurs at a rate of 2.7 percent annually, is a result of the population's demand for fuel and construction materials and the traditional practice of clearing the land for agricultural use by slash-and-burn tactics. These methods have produced extensive soil erosion, and agricultural mismanagement has led to overgrazing.

When these processes are combined with frequent drought, increasing desertification is a foregone conclusion. The entire country is subject to locust infestation. Outside the area surrounding the Senegal River, fresh water resources are limited. For this reason, the population is concentrated around Nouakchott and Nouadhibou in southern Mauritania, resulting in a 61.7 percent rate of urbanization. Water pollution has been caused by dumping raw sewage into waterways, along with agricultural runoff and industrial effluents and oil spills. A project is in the works to build a dam on the Senegal River intended to deal with the shortage of water for human consumption and agricultural usage.

In 2006, scientists at Yale University ranked Mauritania second from the bottom of all countries scored on environmental performance, significantly below the relevant income and geographic groups. Particularly low scores were assigned in the categories of biodiversity and habitat, air quality, and environmental health. Between 1980 and 2002, levels of carbon dioxide emissions jumped from 0.4 to 1.1 per capita metric tons. The decrease in forested land is leading to major loss of biodiversity. Only 1.7 percent of all land area is protected by the government. Of 61 identified mammal species, 10 are endangered, as are two of 172 bird species.

In the late 1980s, the Mauritanian government began working toward developing a national program to deal with mounting environmental problems. Subsequently, the Ministry of Rural Development and Environment prepared the National Work Plan for the Environment, and policies were instituted to work toward achieving the goals of promoting sustainable development, achieving food self-sufficiency, rehabilitating problem areas, ensuring the rights of inhabitants to remain in their homes, checking rates of deforestation and desertification, and instituting water and power programs. The National Council for Environment and Development was also created to coordinate environmental issues. Mauritania participates in the following international agreements on the environment: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, Ozone Layer Protection, Ship Pollution, and Wetlands.

Mauritius

SINCE OBTAINING INDEPENDENCE from the British in 1968 after more than four centuries of colonial rule by a succession of counties, the island of Mauritius established itself as one of the most stable and prosperous countries in Africa. With a per capita income of $13,200, Mauritius is the 72nd richest nation in the world. The economy is diversified, and the industrial, financial, and tourist sectors are expanding. With more than 9,000 offshore entities, investments in the banking sector have passed the $1 billion mark. Even though arable land (49.02 percent) and fish are the island's only natural resources, only 14 percent of the workforce are engaged in these industries.

As the island has flourished economically, the standard of living has risen for most Mauritians. All of the people have sustained access to safe drinking water, and 99 percent have access to improved sanitation.

There has been some concern in recent years that the standard of living has decreased in the Creole community because of a slowed economy resulting from adverse weather conditions and a drop in sugar prices. Among the population of 1,240,827, this economic slowdown has also produced an unemployment rate of 10.5 percent and a poverty rate of 10 percent. The United Nations Development Programme's Human Development Reports rank Mauritius 65th in the world in overall quality of life issues.

Surrounded by the Indian Ocean, the Southern African nation of Mauritius has a coastline of 177 kilometers, encompassing the Agalega Islands, Cargados Carajos Shoals (Saint Brandon), and Rodrigues. The islands are comprised of a small coastal plain that gives way to discontinuous mountains around a central plateau. Elevations range from sea level to 828 meters at Mont Piton. The tropical climate of Mauritius is moderated by southeasterly trade winds. From May to November, winter temperatures are warm and dry, while the summer months from November to May are hot, wet, and humid. Cyclones occur every 15 years or so between November and April. The abundant reefs around the islands may present maritime hazards.

The waters surrounding the islands have become polluted, and coral reefs have begun to deteriorate. Around eight percent of the total land area is forested, and deforestation is occurring at a rate of 0.6 percent each year. Mauritius is not a land of great biodiversity, but three species of mammals are endangered. The nine species of endangered birds include the Mauritius kestrel, which was once identified as the rarest bird on the planet, and the still extremely rare echo parrot. The government has created a system of national and marine parks and protected other marine areas from further environmental damage. The Black River Gorges National Park is the largest nature reserve.

In 1989, the government of Mauritius created the Ministry of the Environment and the Department of Environment and charged them with implementing and enforcing environmental laws and regulations. Environmental policy was subsequently laid out in two National Environmental Action Plans that emphasized sustainable development by promoting the strengthening of existing institutions and improving management methods of land, marine, and coastal resources, water resources, and biodiversity. As industry has grown in Mauritius, there has been a greater demand for facilities to deal with expanded solid waste as well as basic sanitation and sewage. As a result, in 2000 the government instituted the National Solid Waste Management Strategy, and new regulations for handling hazardous waste were enacted the following year. A number of initiatives have been established to deal with the search for alternate energy sources and to minimize the impact of tourism on the environment.

Mauritius participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change-Kyoto Protocol, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Law of the Sea, Marine Life Conservation, Ozone Layer Protection, Ship Pollution, and Wetlands.

Maximum Sustained Yield

MAXIMUM SUSTAINED YIELD (MSY) is a central concept used in the management of renewable, biological resources, most prominently in forestry and wild fisheries. It is based on the deceptively simple notion that harvesting pressure should be limited or controlled such that aggregate harvests—

usually calculated on an annual basis—equal the rate of growth in the exploited population, and that in particular, harvest volume equilibrates with the maximum possible growth rate of the resource. This maximum in biological resources (again in theory) corresponds to the "culmination age," the point in the life cycle of individual members of the commercially exploited species when annual growth is maximized. Mathematically, this corresponds to the maximum marginal and average rates of growth calculated over the life span of the species. By harvesting all individuals in the target population at the point when their growth rate (not their actual size) is maximized, the aggregate harvest will correspond to the maximum sustainable yield over time.

Note, however, that this does not necessarily mean management for maximum economic profit. In fact, these are unlikely to coincide, and the MSY is a strictly biomass maximum, not an economic one. The notion also implies that management for the MSY should result in the "production" of regulated populations, be they trees or fish, such that no individuals exceed the age of culmination. In this respect, despite the apparently desirable connotation of "sustainable" here, management for the MSY based on idealized and simple mathematical equations between maximum growth and maximum harvest can result in dramatic and often unforeseen ecological effects.

FORESTRY

In forestry, this idea derives mainly from the German *Normalbaum*, literally "normal tree" or "normal forest," and more generally, from the development of scientific forestry in Europe during the 19th century (although with some antecedents in Asian forest management). A normal forest has been defined as "an ideally constituted forest with such volumes of trees of various ages so distributed and growing in such a way that they produce equal annual volumes of produce that can be removed continually without detrimental impacts to future production." The implementation of this idea in industrial forestry, wherein each tree is harvested at its culmination age, typically entails rationalizing forests by rotating harvesting pressure across a collection of discrete stands of commercially desirable trees, with each stand homogenous by age (if not species) and with different stands representing different age cohorts. As each stand reaches its culmination age, it is harvested. Subsequently, harvesting pressure moves to adjacent stands, while the harvested stand is allowed to grow back. The geography of implementing this principle requires not only shifting harvesting pressure from one stand to another, but also a total area often called a "working circle" can be derived from a given maximum harvest volume and known rates of growth per unit area.

Historically, adoption of MSY forestry arose in the context of increasingly science-based forest management, which was typically state-centered or coordinated and reflected and reinforced the conversion of "wild" (i.e., unmanaged by industry or science) forests into managed ones. Largely a 19th century development in Europe, the formalization of sustained yield policy in North American forestry is a product in certain respects of Progressive era championing of rationalized, state-led, and science-based resource management based on utilitarian principles, but oriented (à la Gifford Pinchot) to efficiency, order, legibility, and the production of "the greatest good for the greatest number" (again, in contrast with profit maximization).

The institutionalization of MSY forestry in the United States and Canada took place largely between 1937 and 1945. This timing followed important conceptual developments, including the work of E.J. Hanzlik who developed a formula for the "orderly" conversion of old-growth forests to normal forests based on the liquidation of accumulated, large volume and "overmature" stands, attended by harvesting rates that would, in the shorter term, exceed long-run sustainable levels. Initial adoption of the MSY as official forest policy on public lands in both the United States and Canada was precipitated not only by zealous Progressives such as Pinchot, but also by industry figures such as David T. Mason interested in conferring some predictability on harvest rates, and by more widely held social concerns with stabilizing and underwriting the future economic development of forest dependent communities with predictable, secure, and sustainable harvest volumes. This has largely failed because of the naïve equation of stable timber harvests with stable capitalist industrial employment and income.

FISHERIES

In fisheries, the adoption of MSY as orthodoxy is largely a post–World War II phenomenon. It followed the decline and collapse of numerous fisheries, and a concomitant shift from the perception of fisheries (particularly ocean fish stocks) as inexhaustible to recognition that the failure of many fisheries was tied to overharvesting, and regulation needed to rein in fishing effort.

Institutionalization of MSY in fisheries regulation was advanced by development of the Ricker model of stock and recruitment in the mid-1950s, which specified the culmination age given known species-specific dynamics of birth, growth, and mortality. However, unlike trees, fish move around and interact with other fish, including schooling with fish of the same species across multiple age and size cohorts. Moreover, some fish reproduce late in life, potentially after reaching their culmination age. Thus, successful MSY regulation in fisheries has had to target not only the amount of effort, but also the type of gear used (e.g., net mesh size) so as not to catch fish younger than their culmination age (with fish size used as a proxy), and in addition, models of MSY fisheries management have also had to account for the so-called recruitment problem, ensuring that harvesting pressure on reproductive age adults is controlled to allow sufficient recruitment of juveniles into the next generation.

Fishing regulations are maintained to avoid the catching of fish younger than their culmination age.

MSY REGULATION

Difficulties in fisheries management point more generally to some of the problems with MSY regulations. Neo-classical economists have been quick to point out that the MSY does not correspond to profit maximization of a fishery or in forestry except by chance, and thus is likely to dissipate rents. From this perspective, the emphasis is on privatization and market-led exploitation, a direction of reform that has garnered considerable momentum, particularly in fisheries, propelled not least by the ascendance of neoliberalism. This is despite the uncomfortable reality that, under the right conditions, economically "optimal" behavior for utility maximizing individual fishers may well be to drive fish to extinction.

There are other problems with MSY, too numerous to fully elaborate here. One is that the MSY approach to regulation tends to rely on idealized representations of abstract and single species population dynamics that can disguise how little is known about the basic biology of exploited species, including how they will actually respond to harvesting pressure. In forestry, unknown rates of soil depletion, responses to chemical fertilizers and herbicides, and to commercial thinning and pruning among forests whose history of regulated, commercial exploitation may still be only one or two generations (of trees) old all confound the ability to accurately predict future yields. As a result, "errors" have been introduced in MSY timber estimates based on persistently excessive optimism.

Similar problems have plagued fisheries science. In general, regulating wild fisheries for MSY or otherwise has proven extremely difficult largely because of commercial pressures to cheat, because of incomplete or uneven regulation of fishing territories (e.g., between domestic and international waters), because of the ecological effects of habitat destruction and by-catch, and because fisheries ecology has often been poorly understood. To some extent, these problems with MSY could be ameliorated with more precautionary models that emphasize unpredictable or nonlinear fluctuations in environmental conditions and population dynamics, and that set harvest limits below critical population thresholds.

But focus on single species in MSY regulation has also often failed to account for interactions of the commercially exploited species with their biotic and abiotic environment, not to mention with social behaviors and institutions. Simple population models and metrics, at least in their initial instantiations, tended to discursively erase other species and elements of ecosystems, helping to produce the abstraction, individuation, and ultimately alienation from ecological (and sometimes socio-ecological) context necessary for commodification. Yet this has proven problematic when other, ostensibly nondesirable elements of the ecosystems in question turned out to be important, even from a narrow instrumental standpoint, as well as from broader biodiversity conservation perspective.

It also becomes problematic when social sensibilities change. Increasing conflict over logging in old-growth forests of western North America, for instance, signifies the declining political legitimacy of MSY regulation, as the ecological impacts of forest simplification have become evident, and as these impacts have been politicized by changing sensibilities about forests. This points to the naïve or non-existent account of political economic context captured by simple MSY prescriptions for sustainable harvesting.

Responses to the shortcomings of the first generation of MSY regulation are myriad. They include not only the aforementioned emphasis on privatization and marketization, but also efforts to devolve governance and to involve resource user groups more directly in regulation, countering the generally top-down manner in which sustained yield has been implemented (and generally referred to under the rubric of community natural resource management). Alternatives also include efforts to regulate whole ecosystems in the form of ecosystem management, and to explore more adaptive forms of ecological management.

Measurement and Assessment

ALL DISCIPLINES USE some form of measurement for planning, performing, developing, and other purposes. They also seek to assign values or measures of quality and quantity to their objects of study, which can then be used as assessments of the subject. Much of modern measurement is performed as some form of descriptive statistics.

In the military, for example, the measurement may be the amount of ground captured, bridges wrecked, enemy units destroyed, or miles advanced into enemy territory. Similar goals are usually set in sports: a game is won by the team with the highest score, and this is usually achieved by the team with the longest possession time of the ball or puck, the most times at bat, or most ground advances toward a goal. In these and all other activities of life, measurement is an important task for determining what has been done and then assessing what needs to be done.

In the life sciences, measurements are most basically performed as a counting of the number of particular features of a representative member of a species; anomalies are also noted accordingly. For example, birds have two wings, fish have two primary fins, and dogs, cats, and horses have four legs. This form of measurement is very basic but is still done to describe a newly discovered species.

Other forms of measurement are those used to count the population of a species as well as its range. Some species such as dogs have large populations. Other species such as panda bears are confined to a small area and have small populations.

Counting the populations and the carrying capacity of an area is important to land and animal management. For example, an assessment of the size of a deer herd after a severe winter could be an important measure that could help forestry officials decide what extent of hunting should be allowed in the autumn. Or a survey of the size of the nesting habitat of migratory birds in the northern United States and in Canada (or in Europe and Siberia) could be an important study of the future prospects of the ability of species to survive, let alone flourish.

Many organizations working in the area of environmental protection or poverty reduction are seeking new instruments of measurement and assessment to use in setting goals. Key to the development of strategies for sustainable development that will help reduce poverty is the invention of measurement scales or tools that will aid decision making in public policy formulation.

In the case of those working with the poor in various areas of the world, the issue of defining poverty and the question of how to define levels of power is a subject of significant controversy. Because the resources available to people in the Philippines, for example, differ from the resources and needs of people in Brazil, Israel, or even in Japan, it is difficult to come to a single way of measuring the poverty of people in these countries.

In the Philippines, coconut palm trees grow readily. Any family with a small plot of land can easily grow coconuts trees, which provide food, fuel (the leaves and branches), and materials for other uses. However, in other countries, coconut trees may not grow easily, if at all. Therefore, to measure the impact and the absence of this resource and many other differences is difficult.

In Europe, the United States, and elsewhere, there have been debates for decades about the definition of poverty. However, there has been no universal agreement on the definition, nor has there been agreement about the approaches best used to define poverty. The struggle to define poverty in a scientific manner has been ongoing since the Industrial Revolution when impoverished workers inspired intellectuals to seek solutions to the problem of poverty.

Other ways in which measurements are made are of the factors of weather: temperature, wind, moisture, and clouds. These measurements provide data about the atmosphere, which become the weather of the day or hour. However, over a long period of time they become the climate and indicators used to assess whether the climate is warming or cooling.

Measurements in medicine are crucial to both individual patients and the physicians who treat them. For example, measurements of a patient's vital signs, blood sugar levels, cholesterol levels, white blood cell counts, and other factors are important measurements in determining the health of a particular body.

Some medical measurements and appropriate assessments are vital to the public at large. Public health officials keep watch on the number of cases of certain types of diseases. Significant increases may require major interventions to stop the advance of a disease. For example, a rapid rise in the number of E. coli cases may mean that restaurants or their suppliers of green onions, lettuce, carrots, or other vegetables may have to be shut down. Decisions in these kinds of cases may affect the financial success of individuals and companies, but they vitally affect the immediate health of people.

Statistical measurements of diseases are important to public health officials. The annual estimates of the number of influenza cases and the estimates of the likely mortality that will occur in population groups that are most vulnerable are a major health concern. It is because of measurements in the differences between serious and fatal reactions to taking vaccines compared with debilitation and fatality rates from the actual disease that decisions are usually made for urging large scale vaccinations. For example, if there is a sudden rise in the number of cases of tuberculosis or an outbreak of hemorrhagic fever, rapid responses can be made if the proper measurements are made in a timely manner.

Pharmaceutical companies aggressively develop new drugs by assessing the responses of drugs to viruses, bacteria, fungi, or parasites. However, they also engage in high throughput to assess chemicals in varied doses to various receptor sites in proteins, or in cells so that new leads for drug development can be identified.

Measurements of humans may be the most controversial of all measurements. From time to time the life sciences have provided material that has brought about political theory used to justify discrimination on the basis of race or to justify treating humans in an inhumane way. All people differ and those differences can often be easily recognized. However, establishing criteria for treating people unequally is often done by means of pseudo-measurements. In the case of natural differences, such as those of youth or age, different patterns of treatment are usually justified because of ancient tradition rather than by sound ethical reasoning.

All measurements of infants will show that they lack a number of capacities and that this justifies treating them differently from adults. For example, pharmaceutical companies spend great sums of money developing medicines and other drugs. These drugs have to be carefully tested and the results of the test assessed before they can be safely prescribed. It is a fact of biology that infants and children cannot absorb or utilize the same quantities of medicine as adults, and different doses must be prescribed.

Perhaps the most common forms of measurement and assessment are found in educational institutions. Teachers use many instruments to measure learning. However, test results also need to be weighed against other factors. Mere memorization will carry students to a certain point, but more important than mastery of the facts of a body of knowledge are the insights that come from applying information to a set of problems or to a set of facts. When this is accomplished, analysis can provide deeper types of information.

The use of biological ideas as a measure for assessing worth has a long history. Almost immediately after the publication of Charles Darwin's *Origin of the Species* in 1859, Herbert Spencer wrote *Social Statics,* from which developed the sociopolitical philosophy of Social Darwinism. The claim of Spencer, of his follower William Graham Sumner, and others was that humans compete for the resources of life. The unsuccessful and the unfit die off. The successful, it turned out, were the rich and the unfit were the poor. Using this measure of success, public policy advocates in the later 1800s argued against helping the poor. A similar politico-philosophic argument had been made in England in the early 1800s following the publication of Thomas Malthus's *An Essay on the Principle of Population*. Supporters of Malthus argued that because population increased geometrically and food supplies increased arithmetically, it was illogical to aid the poor with poverty programs. The Utilitarian doctrines of Jeremy Bentham, James Mill, and John Stuart Mill were developed and applied in opposition. The measure of sound policy, said Bentham, was its ability to deliver the greatest amount of good to the greatest number of people.

One of the most controversial forms of measurement is that found in intelligence studies. IQ tests measure the intelligence quotient of a person.

A person's IQ is their mental age divided by their chronological age. A child of eight with a mental age of 12 years will have an IQ of 1.5. If this were applied to a scale in which the statistical norm for the general population was 100, this child would have an IQ of 150. If this figure were more than two standard deviations away from the norm, the child would rank in the category of genius.

Intelligence tests, such as those developed by Alfred Binet at Stanford University and others, have been used to measure people and then to categorize them for jobs or other institutional situations. In the case of those falling at the bottom of the scale, they have sometimes been assigned to mental institutions as being mentally unfit for independent living in society.

Critics have, in many cases, claimed that IQ testing used as a criterion for admission to colleges or universities is unjust and discriminatory. One frequent argument is that these types of tests are culturally loaded. For example, immigrant children may be very bright, but their language skills are weak in the language in which the measurement and assessment is being made.

It may also be that children from underprivileged homes perform less well because they are undernourished or simply unexposed to the wider world. Another issue is the meaning of intelligence that IQ tests are supposed to measure. The term *intelligence* has never been precisely defined, which means that there is an open question as to what exactly an IQ test is measuring.

Economic measurements usually appear easily stated in terms of money. However, in many countries wealth is not measured in terms of cash or money; other resources may be used. While it is easy to appear to be using a scientific definition in terms of resources such as goats, sheep, services, or other values that are not readily stated in cash terms, these apparently operational measures of wealth may create false assessments. It is easy to raise a great number of rabbits; however, if a market for rabbits is significantly lacking, then this will not provide an equivalent mechanism for assessing value as cash does. Efforts at using scientific definitions to permit measurements that can be correlated between income and standards of living changes have proved to be difficult.

Meat

MEAT IS THE edible, fleshy parts of animals used as food. It is an important component of the human diet because it is rich in protein, iron, selenium, and zinc, as well as being a good source of vitamins, notably vitamins B_1 to B_5. It constitutes a major link between society and environment because environmental resources are necessary to produce it and society is partially sustained by it.

Throughout prehistory and history, meat acquisition, consumption, and trade have contributed to the development of society and been responsible for environmental change as hunting/gathering has given way to organized animal husbandry. In general meat is classified as red, white, or game. Red meat derives from sheep, cattle, and pig while white meat derives from poultry, and game is the flesh of wild animals or birds. Meat production and consumption are also controversial issues not only because of the fundamental issue of eating animal flesh but also because of the treatment and butchery of animals in agricultural systems. The production, processing, and selling of meat and meat products are sources of employment and wealth generation worldwide.

A BRIEF HISTORY OF MEAT

There are several thresholds that can be recognized in the context of meat eating in prehistory. First, there is the onset of meat consumption by the ancestors of modern humans about 2.5 million years ago. This practice is characteristic of the early hominids, specifically *Homo erectus,* and is one feature that distinguishes the hominids from their australopithecine, apelike ancestors. The evidence for meat eating derives from cut marks on animal bones and the patterns of wear on the teeth of hominid skeletons found in archaeological sites. Some archaeologists subscribe to the hypothesis that meat acquisition and sharing contributed to social, linguistic, and brain development. The earliest meat acquisition was probably through opportunistic scavenging.

Second, hunting developed about 2 million years ago as an active food procurement strategy that required cooperation, planning, and group activity. This is linked with the control of fire and tool making. Third, further control was exerted by modern humans (*Homo sapiens*) beginning around 12,000 years ago with the first animal domestications and the initiation of the first agricultural systems. The main center of origin was the Near East, where goats, cattle, sheep, and pigs, the mainstays of modern pastoral agricultural systems, were domesticated. Other animals, for example, chicken, turkey, goose, duck, ox (yak), and rabbit, were domesticated subsequently. The dog was the first animal to be domesticated, possibly around 20,000 years ago, mostly for assistance with hunting and guarding but dog is eaten by some societies in the Far East.

Most modern meat consumption involves these animals but other animals are also consumed, notably those referred to as game, such as deer and game birds, for example, quail and pheasant. Moreover, bush meat, comprising any type of hunted or trapped wild animal, is consumed in many countries, especially those of low income or where famine and/or war render food scarce.

Once domesticated, livestock were introduced into Europe, Africa, and Asia and in some cases, notably cattle, additional domestication may have occurred independently in Africa and Asia. Animal herding, along with the spread of crops, resulted in deforestation as woodlands were converted to agricultural land. It has thus been a major agent of environmental change during the last 10,000 years. The impact of livestock rearing has also been significant in the Americas and Oceania, notably in Australia and New Zealand. This impact has been more recent than in the rest of the world because it was not until the discovery and annexation of these lands by Europe that cattle, sheep, and other livestock spread to these continents. This began in the Americas following the voyages of Columbus, which began in 1492, but later in Oceania following annexation by the British of Australia in the 1770s and New Zealand in 1840. All of these regions are major livestock producers today.

Most livestock species are herbivores; this means that they obtain energy for survival and reproduction from plant material, which in turn derives energy from the sun through photosynthesis. Consequently livestock are described as primary consumers, insofar as they consume the plants that are the primary producers, and as secondary producers because they are second in the food chain. Human consumers are secondary consumers. In terms of energy transfers within the system, the sun is the ultimate source of energy, but only organisms that can photosynthesize can harvest the light energy. Thus plants as forage are vital to livestock production and ultimately to human sustenance, which requires an intake of protein. This can be obtained directly from plants but occurs in a concentrated form in meat.

Over the centuries, livestock have been bred for specific characteristics including food value. Meat production can be classified into three types. First, intensive animal rearing as it occurs in Europe and North America involves the use of animal health products such as vaccines and antibiotics, and possibly pasture produced using artificial fertilizers, along with "finishing," that is, indoor fattening prior to processing in a slaughterhouse. Second is small-scale animal rearing, in which animals such as poultry and pigs are raised for the needs of an individual household or farm to provide protein for the family and are fed from farm and household waste.

Third is the rearing of animals on much of the earth's surface that is unsuitable for growing crops but that can produce animal protein due to the capacity of ruminants to convert low-quality forage into protein as milk or meat. Such areas include the continental interiors of Asia, Africa, Australia, and the Americas. In Eurasia and Africa, millions of

World livestock production in 2002 amounted to 242 million metric tons of meat—five times that of 1950.

people are supported by this extensive type of pastoral system in lands where plant productivity, and, hence, animal productivity, is constrained by environmental characteristics, especially annual temperature and rainfall regimes and soil type. Here, grasslands and shrublands support herds of grazing animals at low density; the animals are managed by nomadic peoples whose animal herds represent their wealth. Examples include the Saami people of northern Scandinavia (Lapland) and the Nenet people of northern Eurasia, who herd reindeer; these animals graze lichen-rich pastures in far northern continental regions in summer and retreat to the boreal forest zone in winter. In contrast, the Fulani people of West Africa and their neighbors, the Tuareg, follow the rains in semiarid and savanna regions to seek green pastures for their herds of cattle, sheep, goats, and camels.

Over time, many socioeconomic factors have influenced the quality and quantity of meat consumed. These include proximity to production, wealth, costs of other foods, transport availability, religious constraints, and health considerations. Technological factors are also important, notably the development of large-scale meat processing; the establishment of rapid transport systems via land, sea, and eventually air; as well as the development of refrigeration, which altered meat production and consumption patterns at all scales from the international to the domestic. Large-scale meat processing requiring industrial-scale slaughterhouses developed in response to the rapid urbanization that accompanied the Industrial Revolution, which began in the 1750s.

The emergence of large concentrations of people in Europe and North America in particular provided a ready market for all types of animal products as well as fresh meat. Cities like Chicago came to preeminence for their meat packing capability. Consequently, livestock was transported to cities and towns and then slaughtered, in contrast to the former practice of on-farm processing. Initially, the animals were themselves herded from the pastures to the slaughterhouses, but this changed as rail and, later, road transport systems were developed.

The invention of refrigeration in the first half of the 18th century made enormous differences to meat transport, its market price, and availability. Moreover, it encouraged meat production in countries distant from the main markets, especially in South America, Australia, and New Zealand, where large-scale ranching of cattle and sheep in semiarid regions began to produce meat for the voracious European market to which it was transported via refrigerated ships. Exports of meat continue to be significant earners of foreign currencies for these countries, though the markets now include the rapidly developing nations of Southeast Asia. Additional technologies that have influenced meat consumption include canning, vacuum sealing, the advent of supermarket ready meals containing meat, fast-food outlets, and pet-food production.

PATTERNS OF MEAT CONSUMPTION

Table 1 gives global livestock data for 2004, though, of course, not all animal parts are consumed as meat. In some countries, such as India, which has the second highest number of cattle at 185 million, the animals are kept mainly for their milk; similarly sheep are kept for wool production as well as meat. Many countries export meat and meat products, which constitute an important source of revenue as is the case for Brazil which, at 192 million head, has the highest numbers of cattle in the world, and

Argentina, which has almost 51 million. The United States has almost 95 million head, but most of the meat produced is consumed at home.

	Number of Animals
Cattle	1,339,295,570
Goats	782,947,553
Sheep	1,058,600,770
Pigs	947,801,201
Chickens	16,351,860,000

Table 1. World livestock data for 2004 (FAO, 2005).

The Food and Agriculture Organization (FAO) also collects information on meat consumption. In 2002 almost 40 kilograms (or 88 pounds; 1 kilogram equals 2.2 pounds) of meat were consumed on average per person worldwide. However, there are marked differences between world regions, which mainly reflect patterns of income. Meat consumption in the richest nations of North America is almost 10 times higher than that in the poorest nations of sub-Saharan Africa. Moreover, meat production and consumption worldwide has been gradually increasing. In 2002 livestock production amounted to 242 million metric tons of meat; this was five times the production in 1950 and double that of 1977. The growth has occurred mainly in newly industrializing countries such as China and India.

ENVIRONMENTAL COST OF MEAT

In terms of the environment, there are concerns about this trend. First, grains, which could be consumed directly by humans in a more energy-efficient food chain, are being diverted into animal feed. Second, additional land is required to sustain meat production either through the increased production of grain or the creation of pasture. Such an increase in agricultural land occurs at the expense of remaining natural ecosystems resulting in the loss of forests and savannas and their store of carbon.

Mediterranean Sea

THE MEDITERRANEAN SEA is a sea of the temperate zone located between Europe to the north and west, Africa to the south, and Asia to the east. It represents approximately 0.8 percent of the total marine waters of the earth but contains 7 percent of global marine flora and fauna.

The region surrounding the sea and the numerous islands also contain one of the richest natural and cultural heritages of the earth, now threatened by phenomena such as pollution by agricultural and industrial discharges as well as that derived from oil tankers (25 percent of world traffic); urbanization linked to mass tourism; loss of natural and agricultural land; and possibly also sea level rise linked to climate change. The Mediterranean also presents one of the main socioeconomic fractures of the globe, with income differences of 1 to 5 between the northern and richer shore versus the southern and poorer shore. Hence the legal and, above all, illegal tide of immigrants from the south to the north.

The physical environment of the Mediterranean reflects the great complexity of an extremely dynamic natural setting. With over 28,520 miles (46,000 kilometers) of coasts, the sea is surrounded by high mountains, hills, and coastal plains and fragmented into several smaller water bodies separated by large land masses (peninsulas such as Iberia, Italy, and Greece and large islands such as Corsica,

Malta Burials

In Malta, with much of the island covered in rock, burials have always been a problem because of the difficulties in digging graves. In ancient times, people were buried in graves carved with great difficulty from the rock. The Romans forbade the burial of corpses in towns and cremation was used until 60 C.E., when Christianity reached Malta, and burials became preferred. This led to the construction of catacombs. The most famous surviving catacombs in Malta is the Hypogeum of Hal Saflieni, located in Burials Street, Paola. It was rediscovered in 1902 when workmen were building a water storage system, and is now a popular tourist site.

Gradually it became more popular to bury the dead inside churches and this continued up until a ban was placed on this in 1703 by the church, largely over worries about diseases and the disposal of bodies during epidemics. With the deaths caused by the plague of 1675–76, many bodies had to be buried in special graveyards in the countryside—prior to that the only cemeteries were for Turkish slaves and other Muslims whose bodies were not interred in Christian churches.

Another outbreak of the plague in 1813, a smallpox epidemic in 1830, and many deaths from cholera in 1837, 1865, and 1887 saw an enlargement of cemeteries throughout the island with many such as Ta Braixa becoming very large. A few burials in churches continued in country areas, especially when other members of the family were already interred in the church. By the mid-19th century civil authorities grew worried about the proximity of graves to the underground storage areas at Floriana, and even more new cemeteries were opened.

Sardinia, and Sicily). Climatically the most relevant characteristic is the presence of a distinctive summer drought, which historically has conditioned agricultural production, making irrigation necessary. Together with thermal conditions, however, it has also prompted the consolidation of mass tourism (228 million tourists in 2003 or more than 30 percent of the world total).

The combination of an active physiography (earthquakes, landslides, and volcanic eruptions) and climate (dominated by the hydrological extremes of floods and droughts)—plus a long history of human settlement—has produced one of the highest biodiversity rates of the planet. The Mediterranean is the home of 10 percent of the world's higher plants and ranks second only to tropical rain forests in the diversity of its many other plant and animal species.

In 2003 the 22 countries bordering the Mediterranean had an estimated population of 427 million (about 7 percent of the world total). Because of agricultural and tourist demand, water, which traditionally has been a limited resource in this region, has become critical, especially in the southern and eastern parts. Access to water and adequate wastewater systems represents perhaps the most important environmental challenge of the region. Most of the water is used for irrigation, and in many countries, available resources are unable to compensate for a growing demand. Thus it is estimated that about 108 million people in Mediterranean countries live with less than 264,172 gallons (1,000 cubic meters) per year available, and that about 45 million do with less than 132,086 gallons (500 cubic meters) per year (this figure is considered the "extreme scarcity" threshold). By 2025, the number of people with less than this threshold amount per year will rise to 63 million.

Alternative plans to correct growing water scarcities have tended to focus on the supply side through the building of dams and long-distance water transfers. Because of economic, social, and environmental reasons, however, these alternatives are being abandoned for demand management, and above all for new sources such as desalinized water.

In Spain in 2004, the socialist government commissioned the construction of some 18 desalinization plants with an estimated capacity of 35 billion cubic feet (1,000 cubic hectometers) per year. In some islands (such as Majorca and Malta) desalinization is already a regular source of water supply, and some oil-rich North African countries (Algeria and Libya) are also stimulating the development of this resource.

Land management, and particularly agricultural land management, is also a source of important environmental problems, although these assume different forms depending on the area. In the north, the rural population decreased 74 percent between 1960 and 2000. Abandonment has been particularly acute in the mountainous hinterlands where soil erosion, forest fires, and desertification are becoming serious environmental threats. In the south, despite migration, rural population still increased during the same period. However, intensive agriculture in some cases leads to soil salinization (affecting some 3.7 million acres [1.5 million hectares] in Turkey alone).

Urbanization and the related infrastructures are also destroying prime agricultural land. About 65 percent of the Mediterranean population lived in cities in 2002, but the patterns of settlement are again very different depending on the shore. In the north, the traditionally "compact" urbanization is changing to urban sprawl based on single-family houses (many of them with gardens and swimming pools) and the proliferation of the private car. Besides the loss of agricultural land and increase in energy consumption and emissions, an important effect of urbanization in the north is the production of waste (up to a ton per person per year in Monaco). In the south, cities are growing much faster, but 30 to 60 percent of their dwellers live in informal settlements. In 2025, 75 percent of the population will live in cities, especially those of the south.

In 1975, the Mediterranean countries and the European Community (EC) signed the Mediterranean Action Plan in Barcelona under the auspices of the United Nations Environment Programme (UNEP). The main objectives of this plan (later to be known as "The Blue Plan") were to protect the sea from pollution and to ensure development consistent with environmental protection. In the Monaco meeting of 2001, it was agreed to prepare a Mediterranean Strategy of Sustainable Development, which was presented in June 2005 in Athens and officially ratified by all member states in Slovenia in November 2005. Peace, political and social stability, and economic prosperity are seen as key factors in achieving sustainability, especially after the Balkan wars of the 1990s and continuing conflicts on the eastern shores.

Megalopolis

THE TERM *MEGALOPOLIS* combines *mega* (Greek for "big") and *polis* (Greek for "city") and has been used both to connote any very large city or city region and as a place name for particular large cities. The emergence in 19th- and 20th-century capitalist economies of cities that were both large and very rapidly growing led to a considerable literature on the opportunities and particularly the dangers that those cities presented. The coining of new terms to describe these cities reflected the feeling that they were unprecedented in scale, character, and significance.

EARLIEST USES OF THE TERM

The 1828 edition of Webster's *American Dictionary of the English Language* records the earliest known use of megalopolis, which it defined in terms of size and importance as "a chief city; a metropolis." This use is atypically neutral, but confirms that the term has always had most currency in North America. In *The Interpreter Geddes* (1927), the geographer and visionary Patrick Geddes (1854–1932) used megalopolis in a stage model of city growth and decay that was characteristic of his use in the social sciences of the concept of evolution. Geddes's "Polis" (city) grew successively into "Metro-polis" (the capital), "Megalo-polis" (the city overgrown), "Parasito-polis" (the degenerate city), "Pathalo-polis" (the diseased city), and finally "Necro-polis" (the city of the dead).

Geddes's pupil Lewis Mumford (1895–1990) extended the model. In *The Culture of Cities* (1938), he identifies six stages of evolution from "eopolis" (village) to "polis" (association of villages) to "metropolis" (capital city emerges) to "megalopolis" ("the beginning of the decline") to "tyrannopolis" (the overexpansion of the urban system based on economic exploitation), and finally to "nekropolis" (war and famine, city abandoned).

Mumford's use of the term and his gloomy prophesies continued in *The City in History* (1961) and in the double volume *The Myth of the Machine I: Technics and Human Development* (1967) and *The Myth of the Machine II: The Pentagon of Power* (1970), the latter of which uses images of New York's World Trade Center twin towers as exemplars of the "purposeless giantism" and "technological exhibitionism" of megalopolitan culture.

In 1961 the urban geographer Jean Gottmann (1915–94) published *Megalopolis,* which used the term "as a geographical place name for the unique cluster of metropolitan areas of the Northeastern seaboard of the United States." Gottmann's use of *megalopolis* consciously echoed its history as a place name in antiquity (Megalopolis was a city in the Peloponnese, Greece, founded in 371–368 B.C.E.) and, probably unconsciously, challenged the work of Geddes, who in *Cities in Evolution* (1915) had coined the term *conurbation* for the more or less continuous urban development characteristic of the same region, which he found to be "depressing life…[with] disease and folly…vice and apathy…indolence and crime." Gottmann describes Megalopolis neutrally as "an extraordinarily interesting laboratory *in vivo,*" but he admired it for the material and cultural opportunities it offered its inhabitants.

CONCEIT OR CONCEPT?

Whether "megalopolis" is an empty conceit or an unjustifiably neglected concept rests on whether the term has explanatory force. When Geddes and Mumford used the term, they were arguing by analogy from biology: organisms develop and decay, so too will cities because they are "organic." To Geddes's argument by analogy from nature, Mumford added an argument by extrapolation: because cities had fallen in the past, so would they in the future.

None of this identified a causal mechanism for cities' evident growth and posited decline, though the rhetoric, sharpened by use of neologisms such as *megalopolis*, was undoubtedly powerful in winning converts to the idea that uncontrolled capitalist city growth must be replaced with a rationally planned humane alternative. Mumford did attempt a causal explanation for his stage model, which included "megalopolis": in a mixture of classical economics and Marxist reading, he analyzed the economies and technologies that underlay the development of cities, suggesting that overconcentration in cities involved huge diseconomies and at the stage of "tyrannopolis" involved strategies of exploitation pursued over a wide geographical area to ward off the relentless fall in the rate of profit.

Despite having taken great pains over his choice of the word, Gottmann never explicitly claimed any explanatory power for it, and he was criticized in geographical circles from an early date for his refusal to define clearly what he meant by it. Gottmann's term was rooted in the rhetoric of classical erudition, internationalism, and scientific value freedom, but rhetoric could not compensate for the ambiguity of the term.

Gottmann defines Megalopolis as a place, a particular city region, and conceived of his study as a description of a unique region in classic French style, and an end in itself, although he stated that because the region was skillfully chosen it might also aid the study and the planning of similar regions. However, urban geographer Peter Hall asserts that in fact Gottmann had in mind not a physical definition, but a functional definition of urbanization and urban growth. Gottmann's ambiguity meant that megalopolis was not widely taken up by geographers as an analytical tool, but became simply a label bestowed by various authors on various very large city regions, a bestowal, however, which gave Gottmann great satisfaction.

The term megalopolis *has always had the most currency among North Americans.*

NEW INTERPRETATIONS

Contributors to a 2003 volume celebrating Gottmann's work, *Ekistics*, try to get beyond labeling by articulating what Gottmann apparently intended by "Megalopolis." They suggest "megalopolis" is a particular regional structure epitomizing Gottmann's general "geographical theory" of the relationships of man with space: geographical structures reflect the operation of both centralizing and circulatory trends, and analysis of those trends and the geographical entities they produce suggest a method for geography. They suggest that Gottmann was not simply a prophet of a new urban form, but rather that he clearly linked his case for the emergence of an American Megalopolis and possible ones elsewhere to a particular model of historical-geographical change. This model is based on the tension between pressures toward openness and closedness in territorial systems such as modern states.

They suggest that neither the possibility for linking the "megalopolis" to recent ideas about global city regions nor the fundamental insight about the political geographical underpinnings of urbanization has received much attention, and that instead megalopolis has misleadingly been associated simply with descriptions of urban sprawl and taken up in a literature that fallaciously considers city systems as separable from the particular economic systems of which they are a part. This is a valid criticism of urban studies, but the criticism is not new: neither is a new understanding or use of the term *megalopolis* necessary or sufficient for its solution.

Robert E. Lang and Dawn Dhavale also argue in favor of the term *megalopolis* to connote a functional, trans-metropolitan urban region. They suggest it is of value both in aiding description of a new geography, in which regional economies clearly extend beyond metropolitan areas, and as a basis for regional planning in an increasingly globalized economy. Perhaps most pertinently they argue that the U.S. Census Bureau is actively considering using "megalopolis" as a category in its work. Such an adoption would ensure the longevity of the term, but if, as seems likely, it would be based on size alone, it would probably ensure that the term remained a physical, not a functional term. (Interestingly *Ekistics* also uses the term as a simple measurement of settlement size.) Its adoption would, however, ensure that the term would increasingly be used following Gottmann's example, rather than Geddes's and Mumford's. The term continues to be used in pejorative, neutral, and approbatory ways outside the scholarly literature.

Mekong River

THE MEKONG RIVER is a major transboundary river with origins 5,000 meters above sea level in the Tibetan Plateau. The river's course runs through Yunnan Province, China (where it is known as the Lancang Jiang) and five Southeast Asian nations—Myanmar, the Lao People's Democratic Republic (Laos), Thailand, Cambodia, and Vietnam. The Mekong forms part of the borders of Cambodia, Laos, and Thailand. It drains an area of 795,000 square kilometers. Its annual discharge of 475 square kilometers and length of 4,180 kilometers makes the Mekong the longest and largest (by volume) river in mainland Southeast Asia, and the 12th longest and 10th largest in the world.

The population of the Mekong basin is estimated at 60 million, 50 million of whom reside in the Lower Mekong, the part of the river that flows through Southeast Asia. Approximately 25 percent of this Lower Mekong population lives in the Mekong Delta region, the most densely populated and agriculturally productive part of the basin. More than 70 ethnic groups live in the Lower Mekong basin. Human settlement in the basin dates back 6,000 years, and the Angkor civilization flourished on its banks (9th–15th centuries).

The Mekong is a vital livelihood resource for the people living on the banks of its tributaries and main stem, notably for irrigating some of the world's most productive rice fields, as well as the thriving fish catches. Mekong river ecosystems are some of the most diverse in the world. An estimated 400 fish species live in the Mekong and its tributaries, including the giant catfish (*Pangasianodon gigas*) and Irrawady dolphin.

Another unique environmental feature is the Tonle Sap, a lake in Cambodia that naturally regulates the extremities of seasonal flooding and low water levels in the main river. There is concern that dam construction on the river will impair the Tonle Sap's future ability to act as a "bladder" for the Mekong.

The Mekong has long held the imagination of institutions and administrations that have sought to exploit its potential. For the French seeking to expand colonial possessions in the late 19th century, the Mekong was purported to hold the key route to China. Although an 1866 expedition to chart this route failed to accomplish this, it succeeded in producing a number of mapping and qualitative surveys that were instrumental in guiding future French expansion in the region. Today, the river remains navigable only in sections.

Contemporary aspirations turned away from the river's navigability to the harnessing of its hydropower potential. In 1957, the Mekong Committee was formed with the aim of coordinating intercountry cooperation on flood control, irrigation, and hydropower. The first dams built were the Nam Pong and Nam Pung (1965–66) in Thailand's northeast, and the Nam Ngum (1971) in Laos. Other than these, activities of the committee came to a halt as the Indochinese (Vietnam) war escalated, and later, as Cambodia came under the control of the Khmer Rouge.

Cooperation was revived in 1995 with Cambodia's renewed participation in the newly reformed Mekong River Commission (MRC), which heralded a new era of regional cooperation, a move "from battlefield to marketplace." The commission revived scientific studies of the Mekong River, aiming at the sustainable development of the river's resources, although its true influence remains questionable, largely because two riparian countries—Burma and China—are not MRC members.

Although the Lower Mekong countries have agreed to avoid hydropower projects on the main stem, China has completed two main stem dams and has plans for more, with possible downstream impacts on the Lower Mekong. Dam-building on the Lower Mekong tributaries, however, gained momentum in the 21st century. The environmental and social costs of such projects have so far been secondary to the push for economic development in countries like Laos, where hydropower for export contributes a quarter of the annual Gross Domestic Product.

Mendes, Chico (1944–88)

FRANCISCO "CHICO" MENDES was a Brazilian rubber tapper, union organizer, and environmental activist who became an international symbol of the struggle to preserve livelihoods and the environment in the world's rapidly diminishing rain forests. Chico Mendes was born in Brazil's western Amazonian state of Acre to a rubber tapping family. He began working in the forest at a young age, combining small-scale subsistence farming with the harvest of rubber and Brazil nuts.

As the surrounding forests became increasingly threatened by deforestation by ranchers expanding their pasture holdings, often illegally, Chico Mendes became involved in local labor union and land rights issues. Elected secretary of his local rural workers union in 1975, Chico Mendes began organizing resistance to deforestation through a series of stand-offs (*empates*) in which local rubber tappers blocked ranch employees from clearing disputed forest areas.

In 1985 Mendes presided over the First National Rubber Tappers Conference in Brasília, resulting in the creation of the National Council of Rubber Tappers (Conselho Nacional dos Seringueiros). The formation of this entity propelled the rubber tappers' struggle to preserve their working and natural environment onto the national and international stage. The rubber tappers produced a declaration at the 1985 meeting entitled "Unity Among Forest Peoples" which consolidated the demands of indigenous and other local communities for the creation of extractive reserves that would combine forest protection with community economic survival. A key element of the declaration was the linkage between preservation of the natural environment and the protection of human rights, as evidenced in the opening statement of the declaration: "We demand a development policy for Amazonia that meets the interests of rubber tappers and respects our rights. We do not accept an Amazon development policy that favors large enterprises which exploit and massacre rural workers and destroy nature."

Chico Mendes also worked to publicize how international development projects including roads, ranching, mining, and other large infrastructure activities were linked to landscape conversion and deforestation within the Brazilian rain forest. In 1987, after traveling to Washington, D.C., Mendes worked with international environmental organizations to successfully pressure the Inter-American Development Bank to withdraw funding for a controversial road project that would have bisected his region.

Subsequently, legislation was passed in 1988 by the Brazilian federal government that would lead to the first extractive reserve in Brazil, officially demarcated in 1990 on land expropriated from ranchers in the municipality of Xapuri, Chico Mendes's organizing base and home. Named in his honor, the reserve today covers almost 2,500,000 acres and provides a forest-based livelihood for more than 6,000 families. By 2000, Brazil had created 12 extractive reserves on more than 8,000,000 acres. Economic activities on the reserves include rubber tapping, fishing, and the harvest of Brazil nuts, palm and other essential oils, and other forest products. Over 22,000 families live and work on the reserves.

For Brazilian and international audiences, the Chico Mendes story humanized the struggle to preserve the world's rain forests. Global discourse around forest preservation came to mean more than protecting biodiversity and addressing the problem of global warming by reducing deforestation, and to include discussion of the rights and roles of local peoples in combining conservation with social and economic development. Issues of social justice and political and economic empowerment became increasingly incorporated into international environmentalist discourse about ecological protection.

The story of Chico Mendes and the rubber tappers in Acre also highlights the evolving alliances between international nongovernmental and environmental organizations and grassroots groups around the world. Through such alliances local groups such as the rubber tappers of Acre learned the art and politics of international negotiation and the power of fostering a global discourse of solidarity that could bolster their local struggles. International environmental organizations learned the importance of valuing local knowledge about forest preservation and to recognize and protect the right of local peoples to sustainably utilize their local environments.

Local ranchers who felt threatened by the increasing political success of the rubber tappers' movement orchestrated the assassination of Chico Mendes in his home in Xapuri, Acre, Brazil on December 22, 1988. Darli Alves da Silva and Darci Alves Pereira were convicted of the crime in 1990 and sentenced to 19 years in prison. He was survived by his wife and two young children.

Merchant, Carolyn

DR. CAROLYN MERCHANT is a leading U.S. expert in the fields of environmental history, ecological feminism, and the history of science. Dr. Merchant is Chancellor's Professor of Environmental History, Philosophy, and Ethics in the Department of Environmental Science, Policy, and Management at the University of California, Berkeley where she has served as faculty since 1979. Merchant was born in Rochester New York and received a B.S. in Chemistry from Vassar College at a time when few women studied the subject. For graduate work she transferred her focus to the history of science, earning a Ph.D. at the University of Wisconsin at Madison. Dr. Merchant also holds an honorary doctorate from Umeå University in Sweden.

In addition to numerous articles on the history of science, women and environment, and philosophy, Merchant is the author of half a dozen books. Merchant's writings have expanded understanding of symbols of nature, the interaction between productive and reproductive forces in history, and the importance of ecological change in understanding social and economic history. Her seminal first book, *The Death of Nature: Women, Ecology and the Scientific Revolution* (1980), brought women and nature front and center in the history of science and established her as a pioneer in the field of environmental history. In *The Death of Nature* Merchant details major changes in the perception of the earth, science, and of the role of women in society as a result of the scientific revolution. This book was a founding text for the field of ecological feminism. Her *Major Problems in Environmental History* is widely viewed as the most extensive textbook in the field. In 1998 the American Society for Environmental History held a symposium on *The Death of Nature,* during which it was called one of the most influential books in environmental history, philosophy, and feminism.

As a founding member and past president of the American Society for Environmental History, she has been instrumental in bringing issues of race, class, and gender into the forefront of historical analysis of human interaction with nature. Carolyn Merchant's more recent work has centered around an earth ethic, advocating bringing nature to the table as an actor in environmental decisionmaking. She currently teaches courses in American History, Philosophy, and Ethics at the University of California at Berkeley.

Mercury

MERCURY, OR QUICKSILVER, is a dense, silvery chemical element named after the Roman god of commerce and trading. It has fascinated humans for centuries, in part because it is something of an oddity—it is the only metal that remains a liquid at body temperature. Its abbreviation in the periodic table, Hg, is derived from its Greek name, *hydrargyrum,* which means "water silver." In German, mercury is called *Quecksilber,* while in French it is known as *mercure,* from which the English word is derived.

Mercury is most commonly found in a reddish ore called cinnabar. When the ore is heated, the mercury liquefies and oozes out of the crevices of the cinnabar. The world's largest deposit of cinnabar was located in southwestern Spain in a mine named the Almaden, which is Arabic for "the mine." Another large deposit, the Idria in Slovenia, has been mined for the last 2,000 years. There are other smaller deposits of cinnabar in China and Latin America. The New Almaden and New Idria Mines in California are the largest deposits of cinnabar in the United States, though it has also been mined in Oregon, Nevada, and Texas. Mercury mining has decreased, due in part to depleting sources of cinnabar, but also to an increased awareness of its toxicity. Today, most of the world's mercury comes from mines in China, Kyrgyzstan, Spain, and Tajikistan.

For centuries humans used mercury for a variety of cosmetic, medicinal, and technological purposes. The Chinese used mercury as early as 2000 B.C.E. and evidence suggests the Egyptians used it about 500 years later. Native Americans in California decorated their bodies with red cinnabar pigment, but because it often burned their skin, they claimed the mines from which it came contained evil spirits. During the Middle Ages, alchemists thought quicksilver had the ability to turn objects into gold, while medical doctors believed mercury could cure humans of a variety of maladies. The ancient Greeks used mercury in ointments, while England's Dr. Thomas Dover (1660–1743) was known as the Quicksilver Doctor because he commonly prescribed mercury to patients suffering from everything from "apoplexy to worms." By the 19th century, doctors commonly mixed calomel and "blue mass pills" using mercury to treat diverse maladies from syphilis to tuberculosis and gastrointestinal disorders.

Today, medicines containing mercury are typically considered poisonous; however, mercury can still be found in some over-the-counter medications such as antiseptics, eye drops, and nose spray. In recent years, legislative efforts in both the United States and the European Union (EU) have tried to reduce the amount of mercury in such medications, though mercury amalgams are commonly used in modern dentistry.

Mercury was once an indispensable element in gold and silver mining operations. In 1557 the Patio process was devised to separate silver from ore. Later a more involved stamping and amalgamation process was invented to separate gold and silver from quartz. When gold was discovered in California in 1848, the demand for mercury greatly increased.

Scientists experimented with mercury and by 1643 Evangelista Torricelli invented the barometer; Gabriel Fahrenheit invented the thermometer in 1714. Edward Charles Howard found a military use for mercury in 1799. Howard dissolved mercury in nitric acid and alcohol, forming a crystallized substance called mercury fulminate. When he struck the crystals, it caused a small explosion. Mercury fulminate was used as a primer to detonate gunpowder in cartridges and shells. At the outset of the American Civil War, mercury fulminate was an essential ingredient in warfare.

Mercuric nitrate was used in the 18th and 19th centuries to make felt hats. The "carroting process" released toxic vapors into the air. As craftsmen inhaled the fumes, they exhibited symptoms such as shaking, irritability, insomnia, and in some cases, dementia and hallucinations. The term "mad as a hatter" refers to craftsman suffering from mercury poisoning. As a result, mercuric nitrate was banned in the hat industry by the U.S. Public Health Service in 1941.

After the Industrial Revolution, mercury commonly entered the environment as a pollutant from a number of sources, including coal-fired power plants and industrial waste, and through the improper disposal of products containing mercury, such as car batteries and thermometers. Perhaps the most infamous incident occurred in Minamata Bay, Japan. When fishermen and families around the bay began to exhibit troubling symptoms, scientists found that the fish and shellfish of the bay contained inordinate levels of mercury. Researchers traced the high levels of mercury back to a local fertilizer company that had been dumping hazardous waste into the bay for more than 30 years. Over 3,000 people suffered from a particularly virulent form of mercury poisoning that locals referred to as Minamata Disease. As a serious health risk, therefore, mercury levels in tap water are limited by U.S. law. Even so, the element persists throughout the country, sometimes at dangerous levels. Between 1998 and 2003, 18.5 million people in the United States drank tap water contaminated with mercury and in 37 communities water was contaminated at levels above health-based thresholds.

Methane

METHANE (CH_4) IS a colorless and odorless gas that is produced naturally and as a result of industrial processes. It is present in natural gas and in firedamp, which is associated with coal mining, as well as in marsh gas, which is a product of the anaerobic decomposition of animal or plant matter. Decomposition under water is the most common form of anaerobic decomposition. Methane is produced when bituminous coal is burnt in the production of other substances.

Its main use is as a fuel. Its burning with oxygen produces carbon dioxide and water in a highly exothermic process. Methane may be harnessed as an alternative source of power to oil. Animal guts, such as from cows, also produce methane. Commercial methane gas does have a strong odor as a result of sulfur additives introduced to allow detection of potentially dangerous gas leaks. The total amount of methane in the atmosphere is increasing because of intensive agricultural processes and this is contributing to global warming.

The digestive processes of animals, notably farm animals, contribute up to 14 percent of the global total of methane. Several state governments for which agricultural production is a significant industry have attempted to tax such emissions. However, powerful farming interests have managed to thwart these efforts.

Agricultural scientists have achieved more success with chemical solutions to the problem, achieving reductions in emissions of up to 70 percent, although these results have not yet been tested on a large scale. For countries such as Australia and Canada, such a reduction in greenhouse gas emissions would make a significant contribution to the Kyoto Treaty or other international commitments to total emissions reductions.

Methane is considered a greenhouse gas because its absorbs terrestrial infrared energy that would otherwise escape into space. The current level of methane in the atmosphere is at its highest recorded modern level. Ice core analysis indicates not only a rapid increase in the amount of methane since 1750, but also acceleration in its increase since the 1980s. Methane has now reached an average of 1,745 parts per billion of the earth's atmosphere. Earth's early atmosphere had a much higher amount of methane, resulting from volcanic activity; however, such conditions are not conducive to human life.

In addition to animal digestion, landfill sites represent another major contributor to methane emissions. In the United States, the Environmental Protection Agency (EPA) has organized a number of projects aimed at harnessing the value of methane from landfills and sites of natural production and converting it into an economically viable resource. Many hundreds of such sites have been identified as suitable for this kind of development. Production of energy from this methane has significant social and economic benefits.

The most common source of methane, nevertheless, remains the presence of natural gas in deposits associated with oil and hydrocarbons in the ground. The presence of such gas remains of considerable geopolitical importance owing to its role as a stable source of energy production.

The gas fields available to Russia, for example, have enabled it to further several international political goals. The withholding of gas at low cost to Georgia precipitated political change in that country, while negotiations with European Union leaders for continued supplies of the gas enabled the Russian leadership to achieve a higher profile and more respected position. The world's largest known gas field is located between Iran and Qatar at the South Pars field.

Methyl Tertiary Butyl Ether (MTBE)

METHYL TERTIARY BUTYL ETHER (MTBE) is a volatile, oxygen-containing hydrocarbon primarily used worldwide as an oxygenated fuel additive. Oxygenates are added to motor vehicle fuels to make them burn more cleanly, thereby reducing toxic tailpipe pollution, particularly carbon monoxide and volatile organic ozone precursors. Oxygenates are favored not only for their role in reducing combustion engine vehicle emissions, but also as octane boosters and volume extenders. The primary oxygenates are alcohols and ethers, including: fuel ethanol, MTBE, ethyl tertiary butyl ether (ETBE), and tertiary amyl methyl ether (TAME).

Following the U.S. Environmental Protection Agency's (EPA's) approval of MTBE as a fuel additive in 1981, it became the oil refiner's oxygenate of choice because its blending attributes include a high octane rating and gasoline miscibility, and it dilutes undesirable gasoline components such as benzene, a known human carcinogen, and sulfur. In 1988 the EPA extended the blending limit of MTBE in gasoline to 15 percent by volume (from 11 percent in 1981).

Worldwide MTBE usage grew in the early 1980s in response to octane demand resulting initially from the phaseout of lead from gasoline, and later from rising demand for premium gasoline. In the United States, the Federal Reformulated Gasoline (RFG) Program, established in the Clean Air Act Amendments of 1990 and implemented in 1995, required the use of RFG in cities with high levels of ground level ozone.

About 30 percent of gasoline sold in the United States is RFG, and it is currently used in 17 states and the District of Columbia. The RFG program stimulated a threefold increase in MTBE production from 83,000 barrels a day in 1990 to 269,000 barrels a day by 1997.

Worldwide, the United States is easily the largest consumer of MTBE at 12 million tons per year (Mtpy); followed by Europe and the former Soviet Union at 4 Mtpy; Asia Pacific at 3 Mtpy; South America at 1 Mtpy; and Africa and the Middle East at under 0.5 Mtpy.

Although MTBE has provided important health benefits in terms of reduced hazardous air pollutants, the increasing detection of MTBE in ground waters and reservoirs due to leaking underground storage tanks and pipelines, spills, and recreational water craft is cause for concern. MTBE is highly soluble in water and does not biodegrade easily. There is no human data on the health effects of drinking MTBE, although data have been collected to provide the risk assessment process with pharmacokinetic information relevant to the most common human exposures—through air and drinking water.

Studies with rats and mice suggest that drinking MTBE may cause gastrointestinal irritation, liver and kidney damage, and nervous system effects. There is no evidence that MTBE causes cancer in humans.

Two studies with rats found that breathing high levels of MTBE for long periods may cause kidney and liver cancer. The U.S. Department of Health and Human Services, the International Agency for Research on Cancer, and the EPA have not yet classified MTBE as to its carcinogenicity.

Because of the widespread presence of MTBE in water supplies, the EPA formed the Blue Ribbon Panel on Oxygenates in Gasoline. In 1999 the Panel recommended the following: (1) Reduce the use of MTBE substantially, (2) have Congress clarify federal and state authority to regulate and/or eliminate the use of gasoline additives that threaten drinking water supplies, and (3) eliminate the current Clean Air Act requirement of 2 percent oxygen, by weight, in RFG.

Several U.S. states have enacted bans on using MTBE in gasoline, including California, New York, Illinois, and Ohio; many others have limited the content of MTBE in gasoline to less than 1.0 percent by volume. Ethanol is projected as the likely oxygenate alternative, although its higher volatility makes it more difficult for refiners to meet emissions standards. However, the same volume of ethanol contains almost twice as much oxygen as MTBE, so only about half as much is needed to meet the RFG requirements.

Mexico

MEXICO IS A nation-state made up of 31 states and one federal district lying in the Western Hemisphere, south of the United States, north of Belize and Guatemala, and surrounded by the Gulf of Mexico and the Caribbean Sea on the east and the Pacific Ocean on the west. As of 2005, Mexico had a population of 107,000,000 and experienced a 1.16 percent growth rate.

Climatic, geological, and locational characteristics provide Mexico with a variety of biomes ranging from alpine paramo vegetation, highland pine forests, inter-montane grasslands, northern deserts and southern tropical wet and dry forests. This habitat diversity reflects the high levels of biological diversity in terms of both flora and fauna. A number of endemic and endangered species have focused worldwide conservation on Mexico in recent years.

EARLY AND PRECOLONIAL HISTORY

Although subject to debate, it appears that human beings arrived at what is today's area of Mexico approximately 20,000 years B.C.E. via the Bering Land Bridge in Alaska. While early inhabitants undoubtedly survived by hunting and gathering, it is now thought that agriculture began in Mexico around 10,000 years B.C.E., paralleling the development of agriculture in the Eastern Hemisphere.

One of the earliest crops cultivated was maize (*Zea mays* sp.), now the world's third most important grain. Other notable crops domesticated in Mexico include tomato (*Solanum lycopersicum* L.), chili peppers (*Capsicum annuum* L.), cacao

(*Theobroma cacao,* possibly domesticated in South America), vanilla (*Vanilla planifolia*), and tobacco (*Nicotiana spp*., L.). Other than the dog (*Canis lupus familiaris* L.) and turkey (*Meleagris ocellata*), very little evidence exists for domesticated animal species in Mexico.

Some have suggested that the brocket deer (*Mazama pandora*) was at least partially domesticated, but this species is no longer kept domestically. During this period, archaeological evidence indicates that house gardens began to be kept and some would indicate that these are the sites of earliest domestication.

Great civilizations arose in Mexico starting approximately 4000 years B.C.E., with early societies arising in the Izama, Olmec, and Teotihuacan cultures. These and the societies that followed—Maya, Mexica, and others—engaged in extensive and intensive agriculture. Religious practices reflected this tie to climatic and agriculture livelihoods with many deities associated with precipitation, seasons, and other production factors. Also, pre-Hispanic Mexican civilizations developed complex mathematical and calendrical understanding that allowed them to time cultivation and harvest activities based on seasonal variations.

Long thought to be an exceptionalist society—one that did not engage in intensive water management—studies in the 1970s and 1980s demonstrated that Mexican pre-Hispanic civilizations managed water intensively. Indeed, these early civilizations altered land cover dramatically with agricultural landscapes overtaking forests, grasslands, and other natural vegetation.

When present, soft metals, especially gold, and semiprecious gems were mined for decorative arts. While some groups changed production habits and the location of production throughout history due to socioeconomic and ecological factors, others maintained their close relationship with the land until the arrival of European colonizers in the late 15th and early 16th centuries.

COLONIAL AND POSTCOLONIAL TIMES

The arrival of Europeans represented a radical reorganizing of relationships between society and the environment in the Western Hemisphere in general

Smallpox in Mexico

In May 1520, Panfilo de Narvaez, a Spanish conquistador, left Cuba for Mexico. He planned to form an alliance with Montezuma, the Aztec king, and seize power from Hernando Cortez, who had arrived at the Aztec capital of Tenochtitlan (Mexico City) six months earlier. Panfilo de Narvaez brought with him a number of African slaves, one of whom was extremely ill when the force landed in Mexico.

It seems likely that this slave, along with others who may have been showing symptoms, was suffering from smallpox. The disease was transmitted to the Tlascalans, a tribe living around what is now Vera Cruz, and then it spread to Tenochtitlan. This seems to have taken place while Cortez was busy defeating the forces of Panfilo de Narvaez.

Cortez himself had already reached Tenochtitlan in November 1519, and was holding Montezuma, but had to leave when news came that Panfilo de Narvaez had arrived. He defeated the forces of his rival only to hear of a general uprising in Tenochtitlan. He rushed back to the capital, but was forced to evacuate his men. Allying himself with nearby tribes, he returned in April 1521 and lay siege to the city, but when he did take it, his men were surprised to learn of the number of Aztecs who had died of disease.

It is estimated that nearly half the population of Tenochtitlan had died in the smallpox epidemic, with large numbers of others dying throughout the region. In 1531 a second epidemic, also probably smallpox, hit Mexico. Again, it was introduced from Spanish ships.

Known as the "small leprosy," it resulted in a smaller number of casualties than the first wave. There was another outbreak in 1545, which led to the deaths of 150,000 in Tlascala near the coast, and 100,000 in Cholula. Two more outbreaks followed in 1564 and 1576. In all, it is estimated that 18.5 million out of an entire population of 25 million were lost to smallpox.

and Mexico specifically. Old World diseases decimated native populations in Mexico—some estimate place the loss as high as 95 percent in the first 150 years after contact. Disease coupled with new power relationships altered land use and land cover through disintensification, new crop introduction, and new production priorities. Mining, especially for silver and gold, increased, as did the production of animal and other commodity crops.

Lands thought to be little used were exploited, although recent efforts by geographers and others have concluded that Europeans frequently did not recognize Mexican land-use patterns and that depopulation due to disease decreased land use. Lands were expropriated from native owners and users by colonizers during the colonial period, a pattern that continued after the removal of the Spanish in 1821. Creole and wealthy mestizos assumed the roles of the previous colonial rulers of Mexico and similar land use and mineral exploitation patterns remained.

During the era of the Porfiriato—the rule of Porfirio Diaz—from 1876 until 1911, resource exploitation, including the harvesting of timber and other forest products continued. Much of that exploitation and purchase flowed to the United States and the United Kingdom, resulting in little reinvestment in Mexican infrastructure. While the majority of Mexico's population faced impoverishment in the countryside during this period, working as peons on large plantations, cities, most notably Mexico City, began to grow with the introduction of foreign-based industry.

The second Mexican Revolution began in 1910 and resulted in a transition to a socialist constitution intent on righting the wrongs of the colonial and early postcolonial period, especially in terms of land distribution and resource exploitation. Mineral resources—copper, petroleum, and others—were nationalized and the Mexican government distributed plantation and hacienda lands to landless farmers using communal forms of land tenure, most notably the *ejido*. Lazaro Cardenas was the father of the mineral nationalization and *ejido* reform programs. He hoped to engender a system of land tenure and land use based on small family farms that would produce commodities for Mexico's growing cities and enrich the countryside as well.

SOCIETY AND ENVIRONMENT TODAY

Riding the wave of the petroleum boom, Mexico's economy grew progressively through the 1970s. As industrialization intensified and Mexico was able to subsidize foodstuffs, the country experienced rapid urbanization. In the early 1980s the strength of the petroleum economy, coupled with other factors, led to a decade-long economic crisis in Mexico.

As part of national economic restructuring imposed by international lending and credit agencies, Mexico began to disinvest in subsidies for agriculture, forcing many poor farmers to abandon farming for urban centers or abroad. A series of constitutional reforms, including the potential dismantling of the *ejido* system, culminated in the signing of the North American Free Trade Agreement (NAFTA) with the United States and Canada. Decried by some as the death knell of Mexico's independence and economy, NAFTA intensified preexisting relationships, although it enabled freer trade in agricultural foodstuffs. To protect Mexican farmers, new subsidies were distributed with total phase-outs planned for 2009.

Accompanying the rural impacts of NAFTA, foreign industrialization in Mexico has sped up because of the country's proximity to the United States, the high skill levels of the workforce, and the federal government encouragement of industrialization. In industrial areas, environmental regulations are poorly enforced and numerous chronic and extreme environmental hazards threaten residents in Mexico.

The 1980s and 1990s also witnessed a sustained drive to protect Mexico's environment. Unilateral and multilateral agreements encouraged the establishment of national parks, biosphere reserves, and new environmental legislation. These programs represent an improvement from efforts earlier in the century to populate the countryside and utilize it for national economic interests.

FUTURE TRENDS

Despite encouraging signs of increased environmental protection and awareness, Mexico's future society-environment relationships remain murky. Overexploited fisheries, decreasing watersheds, and tired soils portend slow or fast acting environmental problems. At the same time, Mexico's balance of trade has improved, pointing to possibly wealthier economic and environmental horizons. Population growth rates continue to slow but cities, especially Mexico City, are already pushed to the ecological breaking point.

Microbes

MICROBES ARE A large, diverse group of organisms that exist as single cells or as colonies (clusters of cells of the same species) that are able to grow, generate energy, and reproduce independently of other cells. Microbes may be eukaryotic or prokaryotic. The eukaryotic microbes include algae, fungi, slime molds, and protozoa, and the prokaryotic microbes are the bacteria, archaebacteria, and cyanobacteria. (Because viruses cannot metabolize and reproduce without hijacking the metabolic processes of a host cell, viruses are not true cells. Thus, debate exists about whether viruses are living organisms and thus technically "microbes.")

Microbes colonize virtually all terrestrial and aquatic habitats on Earth, from polar glaciers to deep-ocean hydrothermal vents. Microbes contain the greatest species diversity of any group of organisms on Earth. Bacteria have particularly high species diversity, and their tremendous metabolic flexibility allows them to inhabit the extremely unfavorable environments of deep sea hydrothermal vents, polar ice, and deep buried sediments.

The first organisms to evolve on Earth, microbes have played a key role in altering the gaseous makeup of the Earth's atmosphere, and in the evolution of higher life forms. For example, early in the history of life, enormous colonies of aquatic cyanobacteria grew as pincushion-shaped organisms termed *stromatolites*. Over hundreds of millions of years, oxygen emitted by *stromatolites* as a by-product of their prolific photosynthesis progressively oxygenated the atmosphere. Scientists believe that the cyanobacteria-mediated oxygenation of the atmosphere facilitated the evolution of new organisms that rely upon oxygen. Soil fungi may have also facilitated the evolution of higher life forms. Root imprints of the earliest land plants fossilized in sedimentary rock show evidence of fungal symbionts present in root cortical cells. This suggests that the movement of plants onto land was aided by a mutualism with mycorrhizal fungi, specialized fungal microbes that today colonize the roots of most terrestrial vascular plants to aid in nutrient uptake.

People most commonly associate microbes ("germs") with human illness, and indeed microbes act as pathogens or parasites on a great number of humans and other animals. The effects of microbial colonization of animal tissue, however, may be positive, negative, or neutral. Hair follicles are inhabited by an array of bacteria, yeasts, and filamentous fungi. Various pathogenic bacteria cause diseases such as *Stapholococcus* and *Streptococcus* infections, diphtheria, Legionnaires' disease, tuberculosis, and sexually-transmitted diseases. The bacterium *Yersinia pestis*, transmitted to humans through bites from fleas that have fed on infected rodents, caused the bubonic plague, which killed 25 million people around the world over five years during the Middle Ages. Protozoan diseases such as leishmaniasis, African sleeping sickness, malaria, and amoebic dysentery cause serious illness and death to millions of people worldwide each year. The same bacteria that can cause illness when present in the mammalian stomach, however, are essential for nutrient transformation and uptake in the large intestine.

Ecological communities are also strongly affected by microbes. Pathogenic organisms, especially fungi, can have such broad-ranging effects that the composition of entire ecosystems can be changed indefinitely. For example, an Asian fungal pathogen *Cryphonectria parasitica* caused a widespread chestnut blight that virtually eliminated the stately American chestnut tree (*Castenea dentata*) from eastern deciduous forests in the mid-1900s. Other microbial plant pathogens cause significant plant and crop damage every year, and scientists are continually studying ways to mitigate damage to desirable plant species.

By no means are all microbes pathogenic. Microbes also have enormous positive impacts on agriculture, ecology, human welfare, and global economics. The discovery of the antibiotic properties of the soil fungus *Penicillium* was one of the most important microbial contributions to human health in recent history. Enzymes produced by microbial processes are used commercially to produce sweeteners such as glucose and fructose, and microbial enzymes and secondary metabolites are used industrially to produce various antibiotics and other pharmaceutical products. Chemical food additives such as amino acids, riboflavin, B_{12}, and ascorbic acid (vitamin C) are also produced industrially from microbial by-products. Selected species of the single-celled yeast fungus, *Saccharomyces*, are used as baker's yeast for raising bread and for beer and wine manufacturing. Beneficial mutualisms between microbes and plants, animals, and other microbes are common in nature. And, in all natural and agricultural ecosystems, soil bacteria and fungi decompose and mineralize soil organic matter, which recycles carbon, nutrients, and minerals through the biosphere.

Recent biotechnological developments have expanded the possibilities—and risks—of the industrial use of microbes. Genetic engineering of microbial cells is used to modify antibiotic-producing microbes, to produce vaccines against deadly viruses, and to isolate and produce mammalian proteins for medical research. Microbes that degrade pollutants are used in bioremediation of polluted soil and water. Scientists in the field of gene therapy who treat genetic diseases are currently experimenting with microbes that can control the expression of particular deleterious genes. Microbial transgenes inserted into whole plants and animals may also increase agricultural productivity and the nutritional value of food. It is important to note, however, that although genetic engineering holds promise for improving the quality of life for many people, the field is still highly controversial because many possible negative consequences remain unknown. Risks of genetic engineering include the escape of crop transgenes into wild weedy relatives, and risks to human health of ingesting transgenes from allergenic organisms. Long-term research will shed light on both the opportunities for and risks of using microbes in genetic engineering.

Microclimates

MICROCLIMATES OCCUR IN localities where the atmosphere is different from the general climate of the surrounding area. They affect the fauna and flora of the small area enough to create a unique little ecology. Usually they cover a small forest, garden, or town.

Microclimates can be caused by nature or by human activities. They exist in many places. Some are near bodies of water that can cool the local atmosphere. Or some may be in sheltered glens or mountain coves where the atmosphere allows plants to grow that would not survive if exposed to the general atmosphere.

In some localities volcanic activity creates warm conditions that allow fauna or flora to grow where they would not otherwise survive. There are places such as remote, isolated valleys among high desert mountains where fauna and flora thrive sheltered from sun and drought. The Ahaggar Mountains (Hoggar) in the Algerian Sahara have verdant microclimates even though most of the Ahaggar Mountains are waterless regions. Occasional snows supply water to deep ravines in which vegetation grows.

Human activities can create microclimates. When dams are built, land is farmed, forests are logged, or afforestation is implemented, the local climate is sometimes significantly affected. Cities also affect the hydrology of an area because the absence of vegetation and loss of ground area for absorbing run off leads to localized flooding. Also, skyscrapers can create wind changes and a tunnel effect as winds are forced to flow between tall buildings in cities.

Humans also utilize microclimates. Planting gardens on urban rooftops can reduce ambient heat, and gardeners also often position certain plants were the sunshine will favor them. In the American South, fig trees are planted by the sheltered southern corners houses where they will be better sheltered from in winter. Farmers use local microclimatic features to grown crops in small areas when they cannot flourish in the surrounding climate. For example, xeriscaping uses knowledge of drought and desert conditions to promote the growth of decorative gardens. Using the sun-favored southern slopes in the Northern Hemisphere and the sun-favored northern slopes in the Southern Hemisphere plants or homes can take advantage of a local microclimate.

Slopes can also protect frost sensitive plants when they are placed nearer to the top of the slope—colder air sinks toward the bottom of slopes. Cherry trees are planted on the sides of slopes to keep them from standing in water. Gardens that are surrounded by walls are afforded protection from winds that can destroy fruit blossoms or tender leaves; fruit trees grown next to walls can use the heat absorbed by the wall as a radiator to promote ripening.

Some museums create artificial microclimates, such as hot jungles, rain forests, and cold climate rooms that permit storage or exhibition of plants and animals that would not normally thrive in the local atmosphere. Greenhouses, hothouses, or sheltered houses are artificial environments as well as artificial microclimates. By using trapped solar heat plants can be germinated earlier or grown to maturity sooner.

One of the most well-known microclimates is the summertime "urban heat island." Microclimates occur in urban areas because asphalt and concrete streets combine with tall buildings of brick, stone, concrete, or other materials to absorb heat from the sun's rays.

The absorbed energy is radiated as heat that adds to the air in the ambient atmosphere. The effect is to create a heat dome that makes the city locality hotter. Another example often seen is a natural park adjacent to a shopping mall that covers the same area as the natural park. The natural park will be cooler than the adjacent area. Each of these would be separate microclimates: The vegetation in the natural park will absorb the sun's rays in its leaves; the grooves of the mall buildings and parking lot reflect the heat of the sun's rays back into the ambient atmosphere. If solar energy striking urban areas were collected in a systematic fashion it could be harnessed as energy.

Micronesia

AS A UNITED Nations Trust Territory, the Federated States of Micronesia was placed under the administration of the United States after World War II. In 1986, Micronesia attained independence through a Compact of Free Association. In addition to marine products and deep-seabed minerals, Micronesia's natural resources include forests and high-grade phosphate. The Micronesian economy suffers from a 16 percent unemployment rate. Less than 6 percent of the land is arable; however, most people survive by subsistence farming and fishing. Less than one-third of the population lives in urban areas even though two-thirds of Micronesians work for the government.

With a population of 108,105, Micronesia has a fertility rate of 4.4 children per woman. The per capita annual income of $2,000 means that Micronesia ranks 180th of 232 nations in world incomes. Almost 27 percent of the population lives below the poverty line. Without subsidies from the United States, which are scheduled to end in 2023, and other grants, Micronesians would find life even more difficult. While 96 percent of the residents do have access to safe drinking water, 72 percent have no access to improved sanitation. Many people have no knowledge of basic environmental protection measures. Due to lack of data, Micronesia is not ranked by the United Nations Development Programme Human Development Reports.

Made up of only 271 square miles (702 square kilometers) of land area with no freshwater resources, Micronesia comprises four major island groups: Pohnpei, Chuuk, Yap, and Kosrae, totaling 607 islands. Bordered entirely by the North Pacific Ocean, Micronesia has 3,789 miles (6,112 kilometers) of coastline. The tropical climate leads to heavy rainfall throughout the year, particularly in the eastern islands. The typhoon belt in the southern edge of the federation occasionally suffers serious ecological and property damage. The terrain of the islands varies from mountainous to low coral atolls. Volcanic outcroppings are present on Pohnpei, Kosrae, and Chuuk.

The largest of the 607 Micronesian islands is home to 100 species that live nowhere else on the planet.

In addition to creating economic problems for Micronesia, overfishing has damaged ecosystems, as have pollution and global warming. Military activities of the past have left legacies that include contamination of marine food supplies; hot spots have been identified in Micronesia where hazardous chemicals such as transformer oils and pesticides have been stored, used, or discarded.

There are more rare, endangered, threatened, and endemic species per unit of land in Micronesia than anywhere else in the world. Consequently, some Micronesians have banded together in the Nature Conservancy to promote environmental protection and biodiversity. The focus of this work is on Pohnpei, the largest of the Micronesian islands. Pohnpei, which is home to 100 endemic species that live nowhere else on the planet, contains the largest intact upland rain forest in Micronesia and is one of the greenest wetlands in the world.

In order to promote sustainable development, the Environmental Protection Board and the Department of Human Resources are given authority under the Environmental Protection Act to promote environmental responsibility in Micronesia. Yap and Kosrae have also passed state environmental legislation. The U.S. Department of the Interior also works with Micronesian officials on the Micronesia Water and Wastewater Training Project to promote the operation, maintenance, and management of local water and wastewater utilities. In addition to government programs, the University of Oregon established the Micronesia and South Pacific Program in 1988 to work with the University of the South Pacific and the College of Micronesia-FSM to further promote sustainable development on the islands. Micronesia's commitment to the global environment is basically limited to participation in the following economic agreements: Biodiversity, Climate Change, Desertification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, and Ozone Layer Protection.

Migration

THE RELATIONSHIP BETWEEN the environment and migration is most often addressed through two major issues: the ways in which environmental change relates to decisions to move, and the ways in which migrants either leaving or arriving in a particular place affect the environment. Recent literature addressing both of these issues, while building upon long-standing debates on migration and the relationship between population and the environment, now focuses on case-specific understandings of the local social relations that give the environment and natural resources value and meaning in particular places.

MAXIMALIST VERSUS MINIMALIST

Historically, the study of the relationship between the environment and the decision to migrate has taken shape through debates about the definition and legal standing of environmental migrants and environmental refugees. The debate about what constitutes an environmental refugee is largely divided into two camps. The first of these takes a maximalist point of view to the role of environmental change in migration decision making, in which environmental degradation is a cause of insecurity that "displaces" people by causing them to seek out settings of greater safety and certainty. This approach to understanding the relationship between migration and the environment works best in situations of sudden, dramatic change, such as coastal inundation or volcanic eruption. In cases of gradual environmental change, however, the decision to move is often considered alongside of, or in combination with, other factors such as the economic and social situation of the decision maker. Writers who recognize this complexity follow a second, "minimalist" approach to the relationship between environment and migration, arguing that one cannot separate the political and the economic from the environmental when considering migration decision making. This argument arises most clearly when researchers question what constitutes a "legitimate" push for migration, but while they point out the complex links among environment, economy, and politics in migration decision making, very little of this work systematically engages how the environment, as one of a suite of drivers in a specific context, becomes integrated with economic and political concerns.

While the minimalist and maximalist literatures continue to inform scholarly and legal debates over the definition and status of those who move, at least in part, due to reasons of environmental change, this discussion limits the ways in which this relationship is conceptualized and therefore does not speak to the intersection of larger political ecological and migration issues that will better inform our understanding of the environmental change/migration nexus. Recent work in migration, however, runs closely parallel to contemporary interests in political ecology, suggesting new paths for the consideration of the migration and environment nexus.

NEOCLASSICAL VERSUS POLITICAL ECONOMY

The broader migration literature has been dominated by two conceptual camps: neoclassical/rational choice and political economy/Marxist. While seemingly opposed approaches to understanding migration decision making, with the neoclassical/rational choice emphasis on individual maximization and the political economy/Marxist focus on structural shifts in the economy, a number of authors have pointed out their shared shortcomings. Vinat Gidwani and Kalyanakrishnan Sivaramakrishnan offer the broadest critique of both schools, arguing that neither offers any interrogation of a modernist rationality that reduces the migrant and migration to a "necessary, if sometimes unfortunate, subplot in the unfolding of history."

The problems that neoclassical/rational choice and political economy/Marxist approaches to migration share have prompted a number of critics to offer their own alternatives to these dominant schools. Many of these critiques aim to understand, as Gidwani and Sivaramakrishnan put it, "how migrants apprehend, negotiate, and transform the social structures that impinge on their lives." The diverse approaches that result from these critiques range from efforts to explore the transformative power of consumption to exploration of the voices of migrants.

These alternative migration approaches are important parallels to contemporary work in political ecology, especially feminist political ecology, that focuses on uneven access to and control over resources. Specifically, these literatures share an understanding of the importance of local social relations in human perception and decision making. These social relations, therefore, serve as a point of contact between the migration literature, which attempts to understand migrant subjectivity, and the political ecological literature, which attempts to understand the social construction of natural/environmental resources and their use. This point of contact creates the potential for a link between environmental change and migrant subjectivities.

ENVIRONMENTAL DEGRADATION

The other major area of concern with migration and the environment is the relationship between migration and environmental degradation. Historically, little attention was paid to this issue within population and refugee studies, with organizations such as the office of the United Nations High Commissioner for Refugees (UNHCR), the Red Cross, and the World Food Program conducting environmental assessments of potential refugee camps only since the early 1990s. Due to the paucity of data on the subject, there is no definitive understanding of the relative environmental impact of forced migrants versus those who elect to move, as case studies arguing both sides have been generated. For example, while circular migration has long been recognized as an important strategy for adding resilience to livelihoods, it may also serve as a means by which local land uses remain sustainable if farmers do not have to overexploit soils to make a living. However, the migration of labor to work in new areas, such as in the expansion of cocoa plantations in West Africa across the 20th century, may contribute to rapid environmental transformations as new land is brought under cultivation, enabled by the new supply of labor. In more extreme cases, the sudden arrival of large numbers of migrants or refugees into new areas, especially in the context of natural disaster or armed conflict, may overtax various local environmental functions and contribute to environmental degradation.

The contemporary focus on the relationship between environment and migration, regardless of whether one's concerns are for environmental pushes or pulls, or for the environmental impact of migrants, is on making sense of the social relations through which the environment is understood in particular cases. For example, in the context of environmental migration, Edward R. Carr has constructed a minimalist framework focused not on the study of environmental conditions that drive migration, but on local intersections of power and knowledge in which environment, ecology, and politics are understood. In this framework, the ways migrants negotiate and transform their context, and the objectives behind such negotiation and transformation, are the condition and result of this understanding.

Sara R. Curran, in examining migrant impact on coastal ecosystems, focuses on the ways in which these migrants' resource use and access is a function of the ways in which they are incorporated into social relations that define resource value and access in the new setting. These and other studies are part of a rethinking of the relationship between environment and migration that uses comprehensive understandings of complex local situations to build a foundation for future efforts at generalization.

Minamata

MINAMATA IS THE name of a neurological disease that closely resembles cerebral palsy. It develops from poisoning by methyl mercury that enters the food chain from industrial wastewater. It was first identified at Minamata, Japan. The expression "mad as a hatter" derives from the use of mercury compounds that affect the human brain that were absorbed by tanners who made top hats from rabbit fur using mercurous nitrate. Somewhat similar symptoms developed in the people of Minamata from the seafood they ate, which was drawn from Minamata Bay.

Minamata Bay is located on the western side of Kyushu, the southernmost of the four main Japanese islands. The bay is part of the Shiranui Sea, which is abundant in fish, clams, crabs, and other sea creatures. Fish has long been the main protein source of the people of the area. The Chisso factory was located between Hyakken Harbor and the Minamata River. Chisso ("nitrogen") was originally a fertilizer company. The factory had opened in 1907 at the request of the townspeople who were farmers and fishermen. By the middle of the 1920s Chisso was dumping its industrial wastes into Hyakken Harbor and Minamata Bay. To compensate for the damage, it paid off the people who were opposed to the polluting.

The practice of dumping was acceptable to the town because in Japanese culture solidarity is an important value. The townspeople who worked at the factory accepted Jun Noguchi, the owner, as a paternal protector, which was a common attitude toward elites in prewar Japanese culture. During the prewar and wartime eras Chisso was making acetaldehyde and using mercury as a compound in the manufacture of drugs. However, after World War II it moved into petrochemicals related to the manufacture of plastics. It prospered and expanded operations, and its polluted wastewater discharges into Minamata Bay increased. The new products led to the discharge of methyl mercury, which is an organic compound that carries the heavy metal mercury.

Minamata disease was first noticed in the area when cats, fed fish from the bay, began to exhibit strange symptoms: They would dance and then die. So bizarre were the symptoms that the idea spread that the dying cats were engaging in "cat suicides." No one was aware that the deaths were being caused by mercury retained in the body from locally caught fish, and that the cats were victims of mercury poisoning. The mercury was causing an encephalopathy. Symptoms in humans included numbness, blurred vision, slurred speech, involuntary movements, and other abnormal neural behaviors. Some people thought that they were going crazy and would shout in an uncontrollable manner. Some lapsed into a coma. Others committed suicide, in part because the Japanese view of medicine held that illness was due to a personal defect that warranted ostracism. Some people suffered brain damage.

The number of babies born with congenital defects increased dramatically. In addition, because mercury settles in the nerves of the human body, it affected children between the ages of five and 11 severely. In all, at least 3,000 people were severely affected by Minamata disease. The last straw came when birds that had also been poisoned from eating the contaminated fish began to fall from the sky.

For years Chisso refused to acknowledge that a problem existed, or that they were the cause of it. By 1963 the Japanese public health service had traced the disease to Chisso's mercury discharges. Payments were made, but the settlements were slim compared to the suffering endured. In the late 1950s, the people of the area organized a "Mutual Help Society." They engaged in grassroots politics, but with little success. Minamata Bay remains polluted with sediment riddled with mercury.

Minerals

THERE ARE SEVERAL thousand minerals in the world, but only about 100 are common. Minerals are inorganic, homogeneous, crystalline solids with definite physical properties and chemical composition. They are commonly defined by their chemical composition. Elements are minerals such as gold or copper that are composed of a single kind of atom. All other minerals are compounds of two or more elements. Minerals are chemically bonded in their atomic structure by the sharing of electrons. They are commonly classified by the negative part of their chemical bond (negative ion) into groups such as: sulfides, halides, oxides, borates, silicates, carbonates, sulfates, phosphates, and chromates.

Minerals are crystalline and can be classified by their crystallographic characteristics. The atoms in minerals have properties that organize them into geometrical forms (crystals) such as cubes like halide (common table salt) or sheets (mica). Mineral crystals are classified into seven systems: isometric, tetragonal, hexagonal, trigonal, orthorhombic, monoclinic, and triclinic.

The physical characteristics of minerals used to identify a specimen include luster, cleavage, hardness, and color. The luster of a mineral is the manner in which its surface reflects light. The luster may be either metallic or nonmetallic. Minerals like gold nuggets or lumps of "fool's gold" (iron sulfides or pyrites) have a shiny metallic luster. Minerals have a nonmetallic luster if the surface looks vitreous (glassy like quartz), pearly (talc), resinous, silky, or is dull and clay-like. The Mohs hardness scale classifies minerals by their hardness on a scale from 1 to 10. The color of minerals depends on their chemical composition. Mineral colors range from white to black with the colors of the rainbow in between. However, the color of a mineral may have been affected by chemical impurities in the formation process.

Some minerals may be recognized by their habit (general appearance). Streak tests are used to identify minerals. After a mineral is rubbed across a rough porcelain plate, the streak it produced is examined for its color. Flame tests to identify minerals use a bit of the mineral specimen ground into a powder. When the mineral powder is burned the color will aid in identification. Chemical tests are used to identify minerals, even in the field.

Minerals are usually formed in various kinds of solutions. The core of the earth is molten magma. As magma wells up from the center of the earth it fractures the crust, melts the rock in its vicinity, and superheats water. As the liquid rock solutions cool, crystals form. Crystals also form when they precipitate out of solutions of hot gases or hot water in fracture veins. Crystals also form from sublimation in cooling volcanic vapors, by chemical reactions to air, water, or other minerals, and by the evaporation of salt lakes or seas.

Mineral deposits are classified by their manner of formation. Igneous actions produce magmatic and pegmatic minerals such as diamonds or corundum. Mineral deposits can form by metamorphic contact (metasomatism), or from magmatic gases (pneumatolysis). Sedimentary action can produce iron ores. Evaporites, such as gypsum, salt, and potash, are solid remains from evaporation. Some deposits are the residue of erosion or other forces. Miners and others seek mineral deposits to work for commercial gain; for them, these include some substances such as granite, oil, gas, opal, and amber that are not true minerals.

Mining

MINING IS THE removal or extraction of rocks, minerals, ores, gemstones, or other geological materials from the earth, typically from an ore body, seam, or vein. Mined materials include diamond, iron, tin, bauxite (aluminum), precious metals (gold, platinum, silver), lead, nickel, and rocks like coal, limestone, marble, salt, and uranium. Mining can also include the extraction of petroleum, natural gas, and water.

The earliest known mine operated 43,000 years ago in Swaziland, Africa, where iron ore (hematite) was removed and ground into a red pigment called ochre. Other early operations mined turquoise in ancient Egypt and in pre-Columbian America in Cerrillos, New Mexico. The first mining operation to use gunpowder was in Slovakia in 1627.

SURFACE MINING

Mining techniques can be divided into two basic extraction types: surface and subsurface. Surface mining removes or extracts deposits of rocks and minerals that are near the surface. First, the land is prospected to locate rock, minerals, and ores. The extent and value of ore is determined and the quality of the material is estimated. A feasibility study is conducted to valuate the proposed mining project. Access to the ore is established to extract and remove the important rock. In large commercial operations, heavy equipment like backhoes and earthmovers first remove the overburden (the soil, gravel, or rock above the valuable deposits). Next, huge backhoes called tower or dragline excavators extract the mineral and redeposit the materials into trucks or onto conveyer belts. Then it is taken away to be crushed further and/or to be extracted from attached rock (gangue). Finally, the land is reclaimed to make the mined environment suitable for use again.

Surface mining results in the production of large piles of waste rock called spoil banks, until the area is recovered through mandatory mitigation policies. Because surface mining techniques remove overlying material, large portions of the countryside may be altered, and the mining operation often destroys the local ecosystem.

There are five techniques for surface mining. Open-pit mining removes rocks or minerals from an open pit because the material is close to the surface and the overburden is thin or the earth is unstable for tunnels. Strip-mining is similar to open-pit mining and extracts ore by removing all overburden. It is a practical technique when the ore is near the surface. Strip-mining generally leaves spoil banks until the area is reclaimed. This technique can have enormous negative environmental effects. Quarrying uses shallow open pits for removing building materials, such as limestone, marble or granite.

Placer mining is accomplished using water pressure (hydraulic mining) or surface excavating equipment to separate and remove materials in alluvial or loose deposits of sand and gravel in stream beds where the material is typically unconsolidated and cannot be tunneled.

Natural processes have separated the valuable materials from the original veins or deposits through stream action, weathering, or erosion and they can then be extracted from stream beds where their greater density permits separation using running water in sluices or pans. This technique was particularly effective during the California Gold Rush in the 1850s and is used today for gem mining in Southeast Asia and gold mining in the Yukon, Alaska, and British Columbia. Because of the large amounts of sediments that are disturbed, placer mining is considered environmentally destructive, so many placer mines now use settling ponds to capture these silts.

Mountaintop removal is a relatively new form of mining in which the earth is destroyed or restructured to reach deep rocks and minerals (less than 1,000 feet [305 meters]). It often requires the complete removal of all timber (clear-cutting) to level the mountain with explosives. In many cases in the United States, this destructive practice has been ruled illegal by the Clean Water Act (1972).

SUBSURFACE MINING

Underground or subsurface mining uses techniques to remove or extract valuable minerals, ores, or other geological materials from beneath the surface, involving equipment and/or miners that work underground. Greater risks are involved with underground mining because the overburden is not removed but lies above. Subsurface coal mines, for instance, are commonly at risk to fires smoldering for years since they can be nearly impossible to control or extinguish.

There are four types of underground mining. Shaft mining uses shafts or tunnels that are vertical or inclined. On the surface above the shaft lies the pithead or hoist and winding apparatus that raises and lowers the cage within the shaft. This cage carries minerals, miners, and equipment. Drift or slope mining cuts into the side of the earth, rather than tunneling downwards. This technique creates access to the material (e.g., coal seams) at slanted or horizontal angles. Hard-rock mining techniques are used to mine ore bodies by digging underground rooms or stopes that are supported by timbers or pillars of standing rock. Hard rock mining is used to extract ores that include gold, zinc, copper, and diamonds. Borehole mining remotely extracts minerals through the use of boreholes and high pressure water and can be used in hillsides, open pits, underground mines, or from floating platforms. Currently the world's deepest mines are for gold extraction and exceed 12,000 feet (3,658 meters).

In 2005, there were nearly three million jobs in the American mining industry and extracted materials were valued at about $30 billion per year or nearly 4 percent of the U.S. Gross Domestic Product.

Mississippi River

ITS TRIBUTARIES SPANNING Montana to New York and its main channel from Minnesota to Louisiana, the Mississippi River is the biggest in North America and the second largest in the Americas behind the Amazon. The river drains much of the interior of North America and shapes the land through sediment erosion and deposition, building an al-

Barge traffic is increasing, but some argue the Mississippi is already overburdened by navigation demands.

luvial landmass from Cairo, Illinois down to the marshes of South Louisiana. At its mouth, where thousands of square miles of land owe their tenuous existence to the whims of the river's choice of outlet, the river builds up and abandons deltaic lobes every few centuries. Every day hundreds of thousands of tons of sediment are moved by the river off the continent and into the Gulf.

The Mississippi valley was the site of the largest urban populations in pre-Columbian America, the Cahokian mound-building states. The river was a crucial transportation link connecting the middle United States to the rest of the world in the 19th century. New Orleans became the hub of this vast commercial system made possible by the introduction of steamboats that could move against the river's current. This "destruction of space by time" greatly accelerated travel throughout the region and connected forestry and farming across a vast expanse to markets.

The steamboat revolution also resulted in hazardous travel on the Mississippi, as the large number of trees pulled into the river by erosion formed many snags that were hard to detect and readily sank boats that ran into them. In the 1830s the entrepreneur Henry Shreve operated a fleet that pulled up many of these snags and directed crews of loggers who cleared riverside trees. This widespread deforestation made steamboat navigation much safer while it accelerated the rate of soil erosion along the river, already increased by expanding agriculture and land clearing throughout the river's eastern reaches. Thus by the 1840s the river was already greatly shaped by human action, but was certainly not tamed.

Levees along the river were constructed from the time of French colonization of Louisiana in the 18th century, and gradually expanded in length and height. Periodic severe floods overwhelmed levees, leading to increasing federal involvement. In 1849 and 1850, the Swamp Land Acts gave federal land to the states for the purpose of funding levee improvements to reclaim the vast swamps in the river valley and protect existing development.

Proponents of a "levees only policy" won a long and sometimes bitter engineering argument on the proper means of controlling flooding. Levees-only proponents argued against the maintenance of multiple outlets for river overflow because keeping the river in a narrow channel would keep the river scoured of obstructions and deepen it to accommodate floodwaters. The levees-only approach also served to maximize the area that could be reclaimed from swamps for plantation agriculture and coincided with the confidence proponents felt that science and technology could make the river do their bidding.

Such confidence in engineering was bolstered by the success of James Eads in 1876 opening up the sandbars that blocked deep draft ship access to the mouth of the river. By means of a jetty that constricted the river's flow at its mouth, the river pushed away the bars and opened the channel without costly dredging, allowing for an explosion of shipping tonnage at the port of New Orleans that placed that city on par with the largest ports in the world.

On the upper Mississippi, as railroad trusts expanded into the Midwest and plains from Chicago, farmers sought relief from their monopolistic practices and turned to river transport. Making the river channel at least four-and-a-half feet to handle barges was key to this strategy. The Army Corps of Engineers built wing and closing dams to constrict the channel and thus deepen it. By 1906 rising rail fees and declining river traffic led to a push for a six-foot channel. Agricultural crisis and problems of soil erosion caused by excessive constriction of the river led to a movement for a nine-foot channel. The channel was later created by locks and dams that raised the entire river level, and was completed by 1940.

Throughout this time, growing conservationist interests lobbied for protecting the river's water quality and wildlife, sponsoring the creation of wildlife refuges and working against channel deepening. The nine-foot river did not create the ecological disaster some opponents predicted, but the upper Mississippi's compartmentalization into reservoirs greatly reduced sediment loads going downstream, blocked the migration of fish, and reduced the seasonal expansion and contraction of the river by keeping water levels constant. Barge traffic on the upper river carrying coal, soybeans, and corn down river has expanded so much that traffic backups are increasing costs for farmers competing in world markets. This has led to a new showdown between proponents of expanding the lock and dam structures for more traffic and environmentalists who argue the river is already too burdened by the demands of navigation.

The security afforded by levees against flooding was always fragile, as crevasses again and again broke through levees in the years after the Civil War. Flood heights increased as levees continued to climb and constrain the channel, but after 1900 people seemed to be getting the river under control. In 1927 the river showed this was not the case. Heavy rains upstream led to record flood heights and massive levee breaks that marched southward as millions of acres of land and homes were flooded out from Kentucky down to the Arkansas and Mississippi delta and huge stretches of Louisiana.

The callousness, brutality, and inadequacy of local and federal response led to the resurgence of populist politics in the country, from Huey Long's gubernatorial victory the following year in Louisiana to the activist New Deal replacing Hoover's lukewarm response to the flood and the Depression. This political upheaval was motivated by actions like the New Orleans city fathers' decision to dynamite a levee east of the city and flood out rural St. Bernard parish and the holding of black sharecroppers on the tops of levees without supplies or clean water, surrounded by flood waters, instead of evacuating them to higher ground, for fear they might leave Mississippi altogether if given the chance.

The 1927 flood forced the Army Corps to build outlets into its flood control strategy even as the 1928 Flood Control Act gave the Corps more power to intensify control over the river. Presently, the lower Mississippi has several outlets such as the Bonne Carré and Atchafalaya spillways.

The Atchafalaya, a distributary of the Mississippi, now threatens to take the main flow of the river away from New Orleans and is only prevented from doing so by the Old River Control Structure, a massive dam complex that almost failed in a 1973 flood.

The industrialization of the river has led to serious problems of water quality as complexes like the chemical corridor in Louisiana have located on the river's shores. Since the 1930s, Louisiana's coastal wetlands have declined in size by some 1,900 square miles, in part due to the loss of upstream sediments and their diversion into the open gulf by the channelizing of the delta, as well as the effects of oil and gas development and wetlands reclamation in the region.

A "dead zone" of hypoxic water averaging 4,800 square miles caused by nitrogen and phosphorous enrichment from fertilizer use in the upper valley forms each year offshore of the Mississippi's outfall. Despite efforts to compartmentalize the Mississippi river system, it continues to be a linked system, and solutions to the problems facing the river and the people who depend on it require the scaling up of efforts to match the interconnectedness of all the river's parts.

Modernity

MODERNITY, IN ITS sociological usage, generally refers to the social and cultural characteristics describing the period of history in the West since the 17th and 18th centuries. Typically, modernity is described in terms of contrast between the modern period and the feudal era that preceded it, especially in terms of changing capacity for understanding, harnessing, and transforming the nonhuman world.

Although there have been dramatic improvements since the feudal era, most sociological discussion and analysis has focused on the negative aspects of modernity. Scholars have raised many issues in their attempts to characterize modernity. Some of the more common characteristics of modernity include: the replacement of religion by science as the major social institution establishing truth; rapid social, economic, and political change; the nation state; global commerce, capitalism, and industrialization; totalizing political ideologies; a highly specialized and mobile workforce; the breakdown of community and increasing individualization; uncertainty and reflexivity; normlessness; the ascendancy of instrumental reason in all social arenas; centralized administration and bureaucracy; the idea of progress; and the domination of nature.

These various, but interlinked, characteristics of modernity could be roughly grouped into those seen by some to be progressive, such as the replacement of superstition with rationality and science; while others seem more problematic, such as the loss of community and increasing normlessness. Social progress is a concept that forms a central aspect of modernity. But grave doubts began to arise in the 19th century among existentialist philosophers such as Friedrich Nietzsche, which intensified in the 20th century. After two world wars, the Holocaust, increasing social estrangement, and the increasing awareness of what the application of science and engineering was doing to the environment, radical doubt increasingly developed regarding the progressive ideal of modernity.

This later period, especially since World War II and extending to the present, is sometimes categorized as "high," "late," or "reflexive" modernity. The spirit of open inquiry and questioning of traditional institutions that form a major aspect of modern social change have increasingly been directed at the institutions of modernity itself. This period is characterized by chronic and pervasive doubt and uncertainty, which has replaced the sometimes brash confidence in social progress that was the zeitgeist of earlier "classical" modernity. Sociologist Anthony Giddens states "modernity effectively involves the institutionalization of doubt."

However, critique of the institutions of modernity has been around from the beginning. The Romantic movement of the 18th and 19th centuries rebelled against many of the changes, and 19th and early 20th century sociologists made in-depth analysis of the negative aspects of social change that had occurred since the feudal period. Much of the focus of this analysis was on the disruption of traditional communities and the commodification of labor. German sociologists such as Ferdinand Tönnies, Max Weber, and Karl Marx are particularly noted for analyzing and describing these changes.

Postmodernists (those arguing that modernity has ended and a new historical period has begun) and neomodernists (who see the current social problematic as only an acceleration of social schemas characteristic of modernity) both maintain that it is an age of radical uncertainty and doubt, including the questioning of the very institutions associated with modernity, such as science, reason, and the possibility of human progress through the application of efficiency and scientific knowledge. The neomodernist perspective expressed by sociologist Ulrich Beck argues that the rise of new social movements and the critique of modernist institutions such as science and technology, "does not stand in contradiction to modernity, but is rather an expression of reflexive modernization."

This radical doubt coupled with the lack of any ultimate source of truth and the hyper-individualization of modern society, where individuals are cut loose from the moorings of community and traditional norms, raises the anxiety-producing responsibility of each individual to figure out how they should live. This heavy responsibility on the individual to construct his or her identity occurs within a social context of unlimited choice, which creates a problem. On the one hand, one of the manifestations of Ulrich Becks's "risk society" was the spawning of the contemporary environmental movement where pollution and other perceived assaults on nature by modern industry and the application of science were questioned. It is characteristic of the risk society attitude that change is no longer viewed as inevitable, but the product of human agency (intentional human action), thereby creating the perception that individuals and institutions are responsible for perceived risks.

On the other hand, environmentalists have evoked a modernist view of science as representing a true and inerrant picture of reality, and use science to argue against perceived environmental insults against some scientifically determined standard for what nature should be. This perspective is in contradiction to the doubt about the modern project among some scholars. For example, even putting aside the epistemological issues of claims to scientific certainties about the environment, the science of ecology now posits nature as highly context specific, driven by chance, and subject to continual and dramatic change, not a perpetual "balance" that can be determined by scientific research and then maintained.

Late modernity's realization of the dramatic limitations to human knowledge and ability problematizes the project of controlling or restoring human caused change in nature, much less resolving the perennial conflict among human groups over which "nature" is the right one. In a brilliant essay addressing this issue, sociologist Bronislaw Szerszynski states that "the world-picture at the heart of the modern problematic [is] that of a lonely humanity faced with the task of pure self-assertion in a meaningless world which no longer tells them/us what to do." As such, according to Szerszynski, there is no absolute referent regarding the goals of environmental stewardship or nature preservation, and "ecology, while seeming to promise a re-embedding of human choices and judgments within a framework which transcends mere human wishes, fails to do so, and always leads us back into the nihilistic condition of groundless self-assertion in a world without purpose and meaning." This condition of late modernity exposes the pretense of using science to justify some absolute standard for the environment that should be imposed on others who disagree, and leaves the debate on environmental protection and restoration where it belongs—in the political arena. With no absolute standard for nature, and given the wide discrepancies among individuals in the power to influence political decision making, the most socially just process for decision making is paramount.

Given the ever-changing nature of revealed reality due to technological, social, and scientific change, it renders impossible any absolute standard of how nature should be. Much as Nietzsche dramatically pointed out the existential (and terrifying) freedom of modern man in the social and moral realm by the metaphor "God is dead," the same problem of radical freedom is faced in attempts to manage or maintain natural systems in a particular way. There is no absolute standard to be found in nature for any objective, absolute criteria to direct our natural resource or environmental policy. As modernity relativized personal moral and religious beliefs, so it has with the use and character of the natural world.

Modernization Theory

THEORIES OF MODERNIZATION define and position "modern" societies at the positive end of a linear development spectrum. Contemporary modernization theories draw on 19th and early 20th century European and U.S. sociology, including social Darwinism and theories of social order in the shift from community to society associated with urbanization and industrialization. Writing during the optimistic boom of the 1950s and emergent Cold War, economic historian Walter Rostow famously formalized modernization theory as stages of economic growth in a book subtitled *A Non-Communist Manifesto*. The stages span from traditional society through "takeoff" industrialization to a mass consumer society. The change from one stage to the next, in linear succession, was argued to be based on both an inherent societal tendency toward optimal paths of growth and a naturalistic concept of diffusion. Optimal paths would be determined by consumer demand, entrepreneurship, and technical knowledge, while diffusion would take place from high-growth Europe and North America to the global South.

Modernization has been most widely developed and deployed in sociology, rooted in Max Weber's idea of the rational individual and Talcott Parsons's concept of structural-functionalism. Parsons constructed a general model of society based on systems theory and biology. He argued that society existed in equilibrium with its environment and should be understood through the ways it adjusted to external pressures. The relative stability of society was achieved through "pattern variables" that created the context for individual rational action, theorized by Weber to be consistent with the reproduction of the "modern" social system. Although put forth as a general theory, Parsons determined the set of phenomena necessary to reproduce society primarily based on his observations of the United States.

In essence, the "blueprint" of modernization is a Euro- and U.S.-centric one that pervades contemporary thinking. Widespread use of phrases like "backward societies" (prevalent in the heyday of modernization theory) and "less developed countries" (still in use today) reflect and re-inscribe the West as the model of society. By dividing the world into categories of traditional, transitional, and modern, this way of thinking characterizes widely distinct societies as the same type and inhibits an understanding of relations between societies. By assuming that all societies follow a similar path to the same destination, modernization theory also implies that societies are infinitely pliable and devoid of their own histories and cultures.

Modernization theory has been highly influential in postwar development policy and is a precursor to structural adjustment policies developed in the 1980s. In the 1990s theories of modernization reasserted themselves in environmental terms in the closely related fields of environmental economics and ecological modernization. Theories in these fields were developed in response to environmental movements' demands for alternatives to the modernization paradigm and the associated process of industrialization. These fields respond by arguing that the solution to environmental damage as a result of modernization is more modernization. In economics, this argument is often tied to the Environmental Kuznets Curve (see Industrialization).

Ecological modernization, a growing literature primarily in sociology, argues that modernization causes industry to be more "ecologically rational," that is, to take into account environmental damage and to minimize it. According to this school of thought, this process is driven by institutional restructuring, greener technologies, market forces (like consumer demand for green products), and environmental movements. Ecological modernization theories are largely oriented toward responses to environmental pressures in urban contexts in the United States and Europe.

Modes of Production

KARL MARX DEFINED modes of production in *Das Kapital* (1867) as the means (e.g., labor and materials) and relations (e.g., property and power) that when combined enable people to change their environment into useful objects (e.g., food and transportation). Marx defined several modes of production (kin-ordered, Asiatic, slave, tributary, capitalist, socialist, and communist). Of these modes of production, three (kin-ordered, tributary, and capitalist production) have been most useful in understanding the political economy of current cultures around the world.

In kin-ordered production, kinship relations are the basis of labor, which is categorized by marriage and/or other kinship relationships between individuals. For example, husbands may hunt with other men of their patriline while wives work in gardens with their sisters. Use is the basis of production rather than exchange. In these classless societies, there is a reutilization of social control. Sharing is a norm and surpluses are not stored, but consumed. Eric Wolf identified two subtypes of kin-ordered production. The first is the equivalent of a band society, which does not modify the landscape, but gathers resources and consumes them. The second subtype is where the environment is subject to transformation through social labor; the environment itself becomes a means of production, an instrument on which there is expenditure of labor.

Tributary production occurs when peasants produce their own food, but rulers extract tribute politically or militarily. The state usually owns the property and the peasants have little, if any, political power. Rulers maintained their elite status by exploiting the peasants, accumulating wealth, controlling the exchange systems and using force to keep peasants in their subordinate position.

The tributary mode of production most often occurs in societies with chiefdom political organization. There are two subsets of the tributary mode: civilizations and mercantile wealth. Civilizations use politics to provide a mode of production within a hegemonic society based on supernatural origins and validation. Mercantile wealth uses merchants to control the profit from the trade of products and goods.

In the capitalist mode of production the means of production (e.g., land and factories) is owned by capitalists (elite class/bourgeoisie). This type of production occurs in modern industrial states. The proletariats (working class) cannot own the means of production and must sell their labor to the capitalists. Capitalists use the sale of surplus commodities to increase their means of production, which increases the divide between the classes.

Of kin-ordered, tributary, and capitalist modes of production, the latter has been most useful in understanding how large states affect indigenous peoples around the world. According to Marx, the continuing repression of the proletariats (people who work but do not own the means of production) occurs when the capitalists control government and make the rules of the society (laws). Members of the capitalist class select representatives who pass laws that serve their own interests. For example, societies such as the United Kingdom and the United States have enacted laws that required people who are not property owners (proletariats) to work for wages and prohibited workers from organizing into labor unions. The police protected the capitalists and suppressed any protest of unfair working conditions.

By controlling the distribution of information, the capitalists can create, for their own benefit, an ideology of their superiority. According to Marx, if the capitalists control institutions that transmit information and ideas, they influence how proletariats view the world. Through institutions such as churches, schools, and newspapers, the capitalists promote the view that the capitalist dominance of society is in the best interests of all. The church, for example, encourages the proletariat to accept its fate because it is "God's will," and/or it teaches proletariats that their poverty is not the fault of the capitalists but is due to the proletariats' "fall from grace."

Similarly, through control of educational institutions and mass communications media, the capitalists convince proletariats that the capitalists use their power to the net benefit of everyone in society. The capitalists use the media to popularize the view that the society would perish without them. In short, the aim of an ideology of class is to convince the proletariat that its position in society is as it should be.

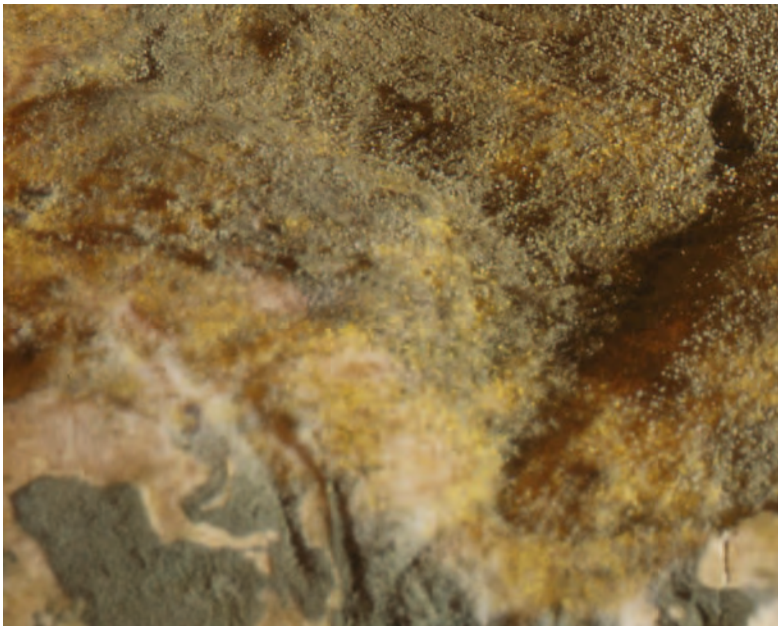
Mold

MOLD BELONGS TO the fungi group and is closely related to mildew, rusts, and mushrooms. As it does not produce chlorophyll, it does not conduct photosynthesis, and so lives on matter made by other plants, by animals, or on decaying matter, as do bacteria and other fungi. Mold develops from a spore, which is a tiny particle broadcast as its seeds. Mold requires a damp or wet organic surface upon which it can feed and grow. When a mold spore lands on a surface, such as a piece of bread in a damp climate, it begins to grow by producing tiny fibers (hyphae). The roots of the mold are the hyphae that become rhizoids. Stolons are the hyphae threads that spread on the surface of the organic material that is host to the mold. If the mold is able to grow to maturity, it will grow hyphae that stand upright and become spore casings. Spores are released from the hyphae that can be carried off by air currents or water to new locations.

Mold can be helpful to human beings. Blue mold, which often appears greenish in color, is familiar to humans as the mold on French Roquefort cheese, Stilton cheese, and many other natural blue cheeses. These cheeses are aged in places where the mold is allowed to grow on the cheese rounds or blocks so that it can give the cheese its flavor naturally. Blue cheese is made artificially by injecting the cheese in a manufacturing process so that the mold grows on the cheese more rapidly. The mold of blue cheese produces a chemical that aided the development of antibiotics. Sir Alexander Fleming (1881–1955) developed penicillin from the mold *Penicillium notatum*.



Toxic mold is a major problem in buildings that have been flooded and has been the subject of growing litigation.

Mold can be harmful to humans or their possessions. In areas of high humidity mold can grow on shoes, clothes, or other surfaces causing damage. It can grow in closed containers where there is no light, such as in the near freezing damp of a refrigerator. Mold can also destroy food. Green mold is familiar to most people as the mold that grows on bread; humans cannot eat this mold. The great Irish Famine (1845–49) was caused by the water mold *Phytophthora infestans*. It produced a late blight of potatoes, destroying the crop and causing millions of the Irish to starve to death or emigrate.

Breathing mold spores may harm human health. If mold can grow in the respiratory tract it can cause allergies. Or powerful toxins may be released and a weakening of the immune system or other major health problems may result. Air conditioning systems may develop mold that causes illnesses. The presence of toxic mold is a major problem in buildings or houses that have been flooded. It has also been the subject of growing litigation against owners who sold houses or buildings to buyers without disclosing the presence of a toxic mold problem.

Moldova

THE EAST EUROPEAN republic of Moldova gained its independence after the collapse of the Soviet Union and is one of the poorest countries in Europe. Since the early 2000s Moldova has been recovering from a long economic recession and completed a successful privatization by the mid-2000s. A significant proportion of the population is living on agriculture; issues related to land use and farming are crucial in the country. The policy framework of Moldova has greatly improved since the early 1990s, however, improvements are still slow and there are a number areas in which the country has been trying to meet European Union practices.

Environmental assessment in Moldova has become transparent, but it is still inefficient and complicated. Therefore it is hard to enforce regulation from the country's limited economic resources. Pollution fines usually go through a long court procedure, which decreases the efficiency of enforcing environmental regulations. Pollution fines are generally low, and violators often ignore penalties. At the same time environmental monitoring has improved but it does not provide full coverage for all waters and lacks a comprehensive nationwide program. Similarly some institutes have increased their activities, but they lack modern techniques to share information with the public.

Around 20 percent of the total labor force earns their living from agriculture; it contributes over 19 percent to the Gross Domestic Product. Increasing soil erosion and decreasing soil fertility affect a significant proportion of the country. During the years of economic crisis followed by the collapse of the Soviet Union, environmental problems concerning agriculture lessened, because the economic crisis led to the reduction of fertilizer use and overgrazing. However, in the near future those problems will probably occur again because of the recent reactivation of the economy and more intensive agricultural production. Inexperienced farmers and the shift to private ownership of land may lead to overgrazing and erosion once more. In addition, environmental protection laws are not legislated and not properly enforced yet. Solutions will have to be developed by farmers, municipalities, and authorities working together.

After independence, industry emissions reduced rapidly due to the economic crisis, but since 1998 industrial output has grown over 30 percent in five years. However, overall emissions seem to have decreased. One must note that this is not the result of the current system of environmental standards—most of these date back to the Soviet era and are inadequate for Moldova's future.

Mongolia

DESCENDED FROM A line of 13th-century conquerors, modern-day Mongolia won independence from China in 1921 and adopted communism three years later under Soviet pressure. Democratic rule was restored in the early 1990s. Surrounded by China and Russia, Mongolia is landlocked with limited freshwater resources in some areas. The climate varies from desert to continental with large daily and seasonal temperature variations. The terrain ranges from semidesert and desert plains to grassy steppe in the mountains of the west and southwest. The well-known Gobi Desert is located in south-central Mongolia. The country is subject to natural hazards that include dust storms, grassland and forest fires, drought, and harsh winter conditions known as *zud*. Extensive natural resources include oil, coal, copper, molybdenum, tungsten, phosphates, tin, nickel, zinc, fluorspar, gold, silver, and iron. Less than 1 percent of the land is arable.

When the Soviet Union dissolved in the early 1990s, Mongolia lost one-third of its Gross Domestic Product (GDP). This economic shock was followed by deep recession and natural disasters in the first years of the 21st century. Three harsh winters were followed by summer droughts that led to extensive loss of livestock. With a per capita income of $2,200, Mongolia is ranked 174th of 232 countries on income levels. The economy is heavily dependent on remittances from Mongolians who work abroad. Considerable income disparity exists with the wealthiest 10 percent of the population holding 37 percent of resources while the bottom 10 percent possesses only 2.1 percent. Forty-four percent of Mongolia's 2,791,272 people are engaged in herding and agriculture, and 36.1 percent of the population live below the national poverty line. Around 28 percent of the people are malnourished. The United Nations Development Programme Human Development Reports rank Mongolia 114th of 232 nations on overall quality-of-life issues.

Like most former Communist countries, Mongolia is experiencing the aftereffects of rapid industrialization and rapid growth unaccompanied by environmental responsibility. Nearly 57 percent of the population live in urban areas where air quality is poor, partially because of coal-burning power plants. Rates of respiratory illnesses among children are increasing. Overgrazing and deforestation in conjunction with the clearing of virgin land for agricultural use has increased the pace of soil erosion beyond what is normal for Mongolia. The country loses an estimated 148,266 acres (60,000 hectares) of forest each year, and only 11.5 percent of the land is protected.

Other environmental issues include desertification and the aftermath of intensive mining. Some 38 percent of Mongolians do not have access to safe drinking water, and 41 percent lack access to improved sanitation. Mongolia has one of the worst waste management systems in Asia, resulting in extensive surface and groundwater pollution. Of 133 endemic mammal species, 14 are endangered, as are 16 of 274 endemic bird species. In 2006, a study by scientists at Yale University ranked Mongolia 115th of 132 countries on environmental performance, below the relevant income and geographic groups. Particularly low rankings were received in the categories of sustainable energy, air quality, water resources, and environmental health.

In the 1980s the Soviets pressured Mongolia to take action in Hovsgol Nuur, where a wool-scouring plant was releasing industrial waste that eventually made its way to Lake Baikal in the Soviet Union. As a result, Mongolia began paying more attention to the environment, closing the plant, banning truck traffic on winter ice, and halting the transportation of oil in barges on area lakes. Government officials were also forced to deal with deforestation in the Hangayn Nuruu, where toxic agricultural runoff, industrial waste, and untreated sewage had polluted the waters and reduced the flow of northern rivers. The desert area of the Gobi had expanded, encroaching on pasturelands.

In 1987, Mongolia created the Ministry of Environmental Protection and began a conscious effort to raise public awareness. Currently, some 4,000 employees work under the Ministry of Nature and Environment, but there is little coordination among agencies, and all agencies are underfunded. Furthermore, environmental laws are not uniformly enforced. Mongolia participates in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Ozone Layer Protection, and Wetlands.

Monitored Retrievable Storage

MONITORED RETRIEVABLE STORAGE (MRS) is a temporary facility used to store radioactive materials. MRS installations are for holding High Level Waste (HLW) radioactive materials that are very "hot," or radioactive, because they are usually spent fuel rods from a nuclear power plant. The term *Monitored Retrievable Storage Installation* was defined by Congress in the Nuclear Waste Policy Act (NWPA) in 1987 (as amended). The Nuclear Regulatory Commission was given authority to monitor all MRS installations and the Department of Energy (DOE) is responsible for operating MRS installations.

The Code of Federal Regulations uses the term MRS to mean an installation with a complex designed, constructed, and operated by the DOE "for the receipt, transfer, handling, packaging, possession, safeguarding, and storage of spent nuclear fuel aged for at least one year, solidified high-level radioactive waste resulting from civilian nuclear activities, and solid reactor-related GTCC [Greater than Class C] waste, pending shipment to a HLW repository or other disposal."

A Monitored Retrievable Storage installation includes any installation that meets this definition. GTCC waste is "low-level radioactive waste that exceeds the concentration limits of radionuclides established for Class C waste." The regulations also establish requirements, procedures, and criteria for the issuance of Certificates of Compliance approving spent fuel storage cask designs. Current law requires all federal agencies to fully support the DOE's efforts to site and license MRS facilities. In addition, they are charged with fully supporting the Nuclear Waste Negotiator's effort to locate sites for MRS facilities.

Current law also restrains endless litigation efforts that would attempt to block timely locating and development of MRS facilities. Because HLW nuclear waste will be dangerous for centuries to come, the political phenomenon of NIMBY ("Not In My Back Yard") has hampered attempts to build MRS facilities. Governors of states and antinuclear interest groups routinely oppose efforts to transport waste, citing dangers from possible accidents that could permanently damage the natural environment.

Proposals to locate sites on Native American reservations have raised issues of sovereignty because of the status of tribal lands. A proposal by the Mescalero Apache Indians that their lands could host MRS facilities raised issues regarding political sovereignty, democratic consent, and environmental justice.

Monoculture

A MONOCULTURE REFERS to the repeated cultivation of a single crop on an area of land and describes the practice of relying on a population of plants or animals derived from a single genotype or a very narrow genetic base. This implies an agricultural practice without any crop rotation or mixed intercropping. In forestry it refers to planting of single species tree crops instead of encouraging a diverse canopy of trees, so that biodiversity that would provide a suitable habitat for a number of different species cannot be provided. Monoculture is characterized by the absence of diversity and can occur on various scales: a plot of ground, a natural community, a landscape, or a large geographic region. Its correlative, polyculture, indicates that two are more crops or herds are part of the system, which is also scale dependent. For instance, a peanut field might be regarded as a monoculture, but fruit trees planted as wind breaks make the system a polyculture, as does any system that grazes animals on field stubble to refertilize the soil.

Monocultures in agriculture have been introduced to maximize the productivity of a single crop. Monocultures perpetuate and even exacerbate the general impacts of agriculture on ecosystems, such as narrowing the genetic base of the system by replacing the natural vegetation, destroying habitats for the natural fauna, increasing vulnerability to erosion by the decline of humus content, aggregating stabilities of soils as a consequence of soil tillage and conversion of virgin land, interrupting and simplifying the natural food web, and underutilizing the variety of niches of an ecosystem with subsequent loss of homeostasis and self regulation mechanisms of the system.

The practice of replanting the same species over years leads to additional yield declines that are due to autotoxity and monoculture injury. Explanations for this include: growing the same crop species in the same soil year after year leads selectively to a deficiency in one or more plant nutrients that would not be limiting to other crop species; the crop plant builds up a toxicity to itself, leading to self-inhibition; or, growing the same crop species in the same soil in subsequent years enriches the soilborne pathogens of the roots of those crops. This helps lead to complete crop failures. The most well-known among these is the Irish potato famine in the beginning of the 20th century, which was due to the expansion of the fungus *Phytophtora infestans* in potato monocultures.

Nevertheless, about 70 percent of the world's food crops are grown in monocultures. The world's agricultural landscapes are planted mostly with some 12 species of grain crops—especially wheat and corn—23 vegetable crop species, and about 35 fruit and nut crop species; that is, no more than 70 plant species cover approximately 1,440 million hectares of presently cultivated land in the world. Reliance on such a small number of crops has reduced the global genetic diversity to an extent that there are fewer and fewer varieties to draw upon for adaptive genes. For instance, in the United States, 60–70 percent of the total bean area is planted with two to three bean varieties, 72 percent of the potato area with four varieties, and 53 percent of the cotton area with three varieties.

Despite the vulnerabilities of monocultures, continuous productivity increases have been achieved through the introduction of improved varieties, mainly promoted by the Green Revolution, accompanied by measures needed to compensate the weaknesses of the system and sustain it, like chemical fertilizer and pesticide inputs, irrigation where farmers have access to supplemental water, hygienic techniques like soil fumigation, and even genetic modifications of organisms.

A well-known argument in relation to biodiversity loss and other negative ecological impacts of monoculture is the land-sparing impact of modern farming practices, which refers to the trade-off of the amount of land that needs to go into production according to different levels of productivity. For example, if yields of the six major crop groups that are cultivated on 80 percent of the total cultivated land area had remained at yield levels farmers achieved in 1961, it would require an additional 1.4 billion hectares of land to meet global food demand in 2004. The key ecological question is therefore whether environmental services other than food production at regional and global scales would be enhanced by focusing food production on less land under intensive management with high yields, versus expanding cultivated area in lower-yielding systems that use farming practices that seek to preserve environmental services at the field and local levels. Although there are many case studies that challenge the productivity argument of the Green Revolution and provide case studies for the high productivity of small-scale farms, mixed cropping, and mixed farming systems, this argument needs further research, since these systems have mainly been neglected by previous research priorities.

Other critical arguments can be summarized as critiques of the mindset behind monoculture and its rationale, which is related to concepts of elimination of diversity not only in regard to nature, but overall. This approach would replace principles of diversity with principles of intolerance and exclusion by prioritizing commercial interests over ecological integration, by ignoring the relation between ecological diversity and the diversity of livelihoods, cultures, and belief systems. This is supported by the fact that the establishment of large-scale monocultures like cotton plantations in the United States, Africa, and India were only possible on the basis of slavery and colonialism, perpetuated by international corporations until today. These corporations externalize harmful side-effects like contamination by chemicals and soil erosions to adjacent areas that are considered peripheries, or to future generations, leaving the farmer without any freedom of choice. For this reason, national action plans of many countries aim at the reduction of monocultures, since there is doubt that sustainable monocultures will ever exist.

Monsanto

THE MONSANTO CORPORATION, based in Missouri, is one of the world's leading suppliers of agricultural inputs created with advanced biotechnology. Monsanto transformed from a predominately chemical company to a seed company focused on a few staple crops and royalties from patents. Using this strategy, Monsanto experienced rapid growth from 2003 to 2005, after roller-coaster gains since 1996 when it began commercial production of genetically modified (GM) seeds. Monsanto's recent gains have not been homogenous around the globe—the company has reported economic losses in the United Kingdom. Monsanto's greatest sales are in North America, followed by Latin America. The main crops, based on acreage, are soybeans, corn, cotton, and canola.

GMOs

Monsanto is a frontrunner in controversial genetic engineering. Transgenetic seeds are spliced with extra-genetic (foreign) information to create desired characteristics, such as drought resistance or pesticide tolerance. Monsanto officials suggest that they prepare genetically modified organisms (GMOs) to end world hunger. Critics charge that after a decade of GM crops, companies are still not able to demonstrate results to help the poor or reduce malnutrition. They argue that Roundup® Ready technology and similar chemical packages represent short-term problem solving.

Although use of this type of agricultural technology may reduce the necessity to till, and therefore reduce soil erosion, it also increases herbicide and pesticide use. The toxic chemicals in pesticides move up the food chain and their increased use creates a public health concern. Excessive use of herbicides could lead to resistant weeds. The impacts of

GM crops on biodiversity are currently unknown, but they could spur significant loss of native species when genes drift to wild areas.

A segment of the public is concerned that transgenetic seed will become the sole agricultural option. To reduce this possibility, or at least stall the process, activists have repeatedly destroyed experimental GM plots, often by uprooting crops. GM critics also charge that it currently profits a small number of transnational corporations and increases their control over the food production chain. Large conglomerates often control seed supply as well as the purchase of agricultural harvests. Firms can now even stop a farmer from collecting seed from his or her own field.

Monsanto lawyers maintain a constant stream of litigation in global courts. The company has sued dozens of farmers for patent violations and won hundreds of thousands of dollars in compensation. After years of court battles, there were mixed results in one of the most infamous cases that pitted Monsanto against an individual Canadian farmer named Percy Schmeiser. Monsanto Canada sued Schmeiser for patent infringement and eventually won the case, but he was not held responsible for reparations.

The elderly farmer grows canola on a large farm in the province of Saskatchewan. He did not sign a Grower's Agreement or Technology Use Agreement with Monsanto for the use of Roundup® Ready canola found on his land. Schmeiser claims he acquired the genetically modified canola through a process of wind drift or cross-pollination. He saved his seeds, as he had done customarily, and planted a new generation. Patent law states that the offspring are the product of Monsanto. Thus, standing patent law does not sufficiently protect non-GMO farmers as they are restricted from planting any seed that becomes contaminated with bioengineered traits.

CONTROL OF SEED PATENTS

Monsanto is involved in extensive litigation over issues of intellectual property rights. In several countries, such as Brazil and Argentina, there have been growing incidences of seed smuggling. Although Monsanto requires the use of contracts that prohibit the sale of future seeds derived from seeds originally purchased from them, seed smuggling is widespread. Companies developing GMOs have the technology to create a type of terminator gene so that reproduction in subsequent generations is impossible; however, there is concern that such a trait could escape into the wild. Drift of modified traits also has the potential to contaminate surrounding conventional and organic agriculture. Recent studies suggest that genetic drift may occur at longer distances than previously thought. Further investigation is necessary.

Monsanto is one of the most visible seed biotech companies, but it is only one of many. Corporate rivals include Syngenta, Dupont, and Dow Chemical. Monsanto had an early advantage over others because it developed methods to "stack" seeds with more than one genetic trait. The company was able to patent traits to sell to other agribusinesses. Because other companies are currently developing competitive patents, Monsanto has recruited aggressively to gain the early advantage around the globe.

Monsanto's rapid global expansion of seed sales has been tied to the strategy of creating economic dependence in new markets. The company introduces its technology at lower prices. Once producers have transitioned to Monsanto products as a cost-saving device, Monsanto raises its price, especially in countries without major competitors for similar products.

However, in locations where Monsanto is fighting for market share with other biotech companies, the firm is more willing to keep prices low. Corporate policies lead to questions of international justice because farmers in some developing countries pay more for seed traits than their counterparts in the United States. Large corporations with the ability to pay Monsanto's prices may receive short-term advantages from their ability to lower productions costs. The greatest savings often comes from labor costs, but greater mechanization in production also leads to a reduction in most agricultural employment.

Monsanto is one of the largest corporate lobbyists in the United States. A policy that the company very actively opposes is required product labeling with GMO use. Monsanto is a significant contributor to research and development in private companies and academic institutions. Long-standing support from some members of academia lends legitimacy to Monsanto's GM seeds and chemical packages.

Monsanto's herbicide called Roundup® was the world's highest selling until the patent approval expired on the original generation. Subsequent generations of Roundup® Ready crops continue to be developed. Other well-known Monsanto products include recombinant bovine growth hormone (rBST) and the artificial sweetener Nutrasweet. Monsanto was also previously one of the producers of the defoliant Agent Orange and paid medical compensation to thousands of victims in South Korea. The company also paid to clean up dioxin and PCBs surrounding U.S. factories that produced the defoliant.

Monsoon

THE WORD MONSOON originates in the Arabic term *mausem,* which means season. Monsoon is generally used to refer to the seasonal change in wind patterns between land and ocean, usually associated with well-defined periods of heavy rainfall. While monsoons can occur in North America and Asia, the dramatic weather pattern in the Indian subcontinent (South Asia) is the more well-known monsoon; it largely affects India, Bangladesh, Pakistan, and Sri Lanka. These seasonal changes in wind and rain patterns are very distinct and the South Asian monsoon is generally associated with heavy rainfall in the summer (often accompanied by floods) and dry spells in the winter months. The spatial coverage and intensity of the South Asian monsoon is not seen in the other monsoons. Rainfall of up to 10,000 millimeters can be experienced in parts of India, and most of the annual rainfall occurs during the summer monsoon season.

Monsoons occur due to the difference in specific heat of landmasses compared to oceans. In the summer, as land heats up faster than ocean water, the heat causes air to rise above landmasses, producing a system of low pressure. Air from the ocean moves in, and brings with it high moisture content. The difference in temperature between land and sea can be up to 20 degrees C. In the winter, as oceans retain more warmth and land cools down faster, the reverse occurs and wind blows from land to sea. In the South Asian monsoon, the summer monsoon (June–September) involves winds blowing landward from the southwest (Arabian Sea, Indian Ocean, Bay of Bengal) bringing considerable cloud cover and rainfall; while the winter monsoon (December–March) is a dry period with winds blowing in the opposite direction from the northeast toward the ocean. Monsoons can thus be thought of as very large, constant, and powerful sea breezes, involving large landmasses and oceans, forming one of the more enduring weather patterns seen.

Forecasting the arrival and retreat of monsoon fronts is important for societies in monsoon-dependent areas. It is important to understand regional differences and specificities in order to analyze, model, and forecast local weather patterns and implications of climate shifts. Monsoons can vary by time of onset and withdrawal, frequencies and intensities of storms, spatio-temporal variability of rainfall, duration and timing of monsoon "breaks" (i.e., days without rain), and tele-connection to larger systems of the El Nino Southern Oscillation (ENSO). Monsoons are thus linked to broader patterns such as the ENSO, but also to more local patterns such as the formation of tropical cyclones (typhoons or hurricanes), which are most common in the pre- and post-monsoon times (i.e., just before the monsoon front moves in and after it retreats, in the months of April–May and October–November, respectively). Tropical cyclones form over oceans and move landward, often bringing with them heavy rainfall, gusts, and storm surges.

The advent of monsoons in South Asia is generally associated with much-needed rain as a welcome relief from the dry heat, as well as for agricultural production that depends on the rains. Monsoons have inspired poetry and literature, and the seasons are an integral part of life and culture. As clouds roll in, rain is often welcomed with ceremonies.

Drought can seriously affect agricultural production, which is the mainstay of livelihoods of much of the South Asian population. The prolonged and heavy rainfall, however, can also lead to floods and ensuing damage and destruction. Rainfall and swollen rivers (from both rainfall and increased summer melting of Himalayan glaciers that feed the rivers) can result in devastating floods that cause damage to lives and property and displace millions of people. For instance, the devastating floods in Bangladesh in 1987 and 1988 resulted in most of the country being submerged under water for months, causing considerable suffering and loss to agriculture, industry, and homes, as well as to the economy. Heavy rainfall in general can also make life and business come to a standstill for days in most parts of South Asia. Monsoonal climates generally result in some levels of adaptation, but the inherent variability of the system means that it is difficult to predict when rain will occur or when floods may ensue and with what intensity. As such, South Asian societies are heavily dependent on and influenced by the monsoonal climatic system.

In the United States, the monsoon season affects the southwest between June and September.

In the United States, the monsoon season is generally between June–September, and affects the southwestern part of the country. It is generally known as the North American monsoon, but is often also called the southwest monsoon. The moist air coming up from the Gulf of Mexico brings with it rainfall, and there are associated thunderstorms in the southwestern deserts as well as the areas around the Rocky Mountains. While this monsoonal system is less pronounced and intense than the South Asian monsoon, it is still a distinct seasonal climatic system.

According to scientists, climate change is likely to affect monsoon systems. Climate simulation models predict that climate change from global warming will lead to increased rainfall; heavier storms; floods from rain and melting snowcaps/glaciers; increasing intensity of tropical cyclones; and changes in the monsoon-ENSO connection. Such changes are likely to affect localized weather patterns considerably in monsoonal zones. The increased sea surface temperature, as well as mean air temperature, will likely lead to greater events of extreme tropical cyclones (and associated storm surges) as well as flooding in the Indian subcontinent. This is assumed to be a result of greater temperatures leading to greater moisture, which will lead to a more intense hydrological cycle, and thus greater monsoons. Climate variability is thus likely to result in greater floods and droughts that may make short-term forecasts difficult and adaptation harder. Climate forecast models can predict certain trends but both short- and medium-term changes can be unpredictable.

With large populations in the tropical and temperate monsoon areas directly dependent on land and water resources for lives and livelihoods, changes in monsoonal patterns thus pose a greater concern to these societies. A dramatic change in monsoon cycles, or advent of monsoon rains themselves, can result in failures of the agricultural production cycle dependent on the monsoons. Increasing floods and tropical cyclones also pose threats to people living in coastal areas and floodplains along the hundreds of rivers that exist in South Asia; and high levels of poverty and lack of access to forecast information further compound the ways by which monsoonal unpredictability can affect lives and livelihoods.

Montreal Protocol

THE MONTREAL Protocol on Substances that Deplete the Ozone Layer is the international environmental agreement designed to protect the stratospheric ozone layer, which shields the earth's surface from radiation in the ultraviolet spectrum. An increase in the intensity of UV-B rays reaching the surface may augment skin cancer rates in humans, decrease plankton production in the oceans, and negatively affect agricultural production throughout the world.

The Montreal Protocol, as it is often referred to in short, provided the framework for phasing out the production of the main ozone depleting chemicals (chlorofluorocarbons [CFCs], halons, carbon tetrachloride, methyl chloroform, hydrofluorocarbons, and methyl bromide). These chemicals were widely used as refrigerants, coolants, aerosol propellants, and industrial solvents.

CFCs were invented in 1928 by Thomas Midgley, Jr. (who also invented the lead additive to gasoline) and were applied widely due to their low costs of production and desirable chemical properties. Global annual reported production of CFCs rose from 544 tons in 1934 to 812,522 metric tons at the height of their use. In 1974, Mario J. Molina and F. Sherwood Rowland published a research paper highlighting the threat of CFCs to the ozone layer in the stratosphere. Their testimony before the U.S. House of Representatives in December 1974 led to a review by the National Academy of Sciences that confirmed the scientific validity of their CFC hypothesis.

In March 1978 the United States, followed by Canada, Norway, and Sweden, banned the use of nonessential aerosols. A number of international scientific conferences were held to study the consequences of ozone depletion. Under the leadership of the United Nations Environmental Programme (UNEP), an ad hoc working group began to negotiate a convention on research, monitoring, and data exchange in 1982.

In March 1985, 43 nations convened in Vienna to complete work on the first international ozone convention, which was later titled the "Vienna Convention." This nonbinding convention requested participating nations to "take appropriate measures" to protect the ozone layer, but more importantly called for renegotiations for a binding agreement.

Two months later, British scientists published data that showed a seasonal "hole" in the ozone layer over Antarctica. The first round of negotiations for a binding protocol were held in Geneva in December 1986, and after two more rounds of negotiations in Vienna and Geneva, the final version of the protocol was opened for signature in Montreal on September 16, 1987. The document is widely recognized as setting a precedent for preventive instead of corrective environmental action on a global scale.

The Montreal Protocol is considered by many as "perhaps the single most successful international agreement to date" (Kofi Annan, Secretary General of the United Nations). What ultimately led to the tremendous success of the negotiations for the final agreement is debatable. The negotiations were expertly directed and greatly influenced by the executive director of UNEP, Dr. Mostafa Tolba.

As Richard Benedick, the chief negotiator for the United States, argues in his seminal account of the negotiations, there were seven components that made a consensus possible. First, the powerful scientific discovery of the underlying chemical process was supplemented by successful collaboration between scientists and policy makers. Second, powerful education campaigns informed public opinion and governments, which resulted in changing negotiation positions for several countries. Third, the role of a multilateral institution (UNEP) in shaping consensus reflected a great degree of sensitivity to individual parties' interests. Fourth, the progressive policies by the major producer of ozone depleting substances, the United States, combined with its central role in international research and leading the way by adopting voluntary controls, provided a strong push toward international consensus. Germany was essential in solidifying the European Union's support of the agreement. Fifth, the involvement of industry and environmental groups played a major role in informing the public and negotiators about the costs and benefits from reduction in CFC production. Sixth, the process leading up to the final negotiations broke the larger issue into manageable pieces (e.g., scientific versus economic issues), which proved to be crucial in obtaining consensus. Finally, the Montreal Protocol has flexible components that allow its adaptation to new scientific and economics findings.

At least 11 countries, making up at least two-thirds of global consumption of the controlled substances, had to ratify the treaty for it to go into effect. This relatively low requirement was met at the earliest allowable date, January 1, 1989, with 30 parties responsible for 89 percent of global consumption having ratified the treaty. It has been amended five times since 1987 (London, 1990; Copenhagen, 1992; Vienna, 1995; Montreal, 1997; Beijing, 1999). By 2006, there were 189 parties to the Montreal Protocol.

The original text specified cutbacks be made relative to 1986 levels. A baseline year in the past was chosen to minimize the possibility of strategic production behavior. The original schedule required developing countries to maintain emissions at 1986 levels until 1992, followed by a 20 percent reduction from 1993 to 1998 and 50 percent reductions by 2000. The 1990 amendments moved the 50 percent reductions up to 1996, followed by a complete phase-out by the year 2000. The 1992 Copenhagen amendments specified a complete phase-out by 1996, which was the schedule the United States had adopted in the 1990 Clean Air Act amendments. The speeding up of the phase-out process was partially motivated by new evidence of the impacts of the regulated substances, but also by the availability of good cheap substitutes. It is generally thought that United States producers were a step ahead of their European counterparts in developing substitutes, which were revealed at a trade fair in 1988. DuPont announced a phase-out of CFC production six months after the signing of the protocol, in March 1988.

Developing countries involved in the negotiations were concerned about regulating products whose benefits embodied the lifestyle their growing populations aspired to obtain. In order to encourage developing countries to sign and ratify the agreement, concessions were made. In the 1987 document, Article 5 specified that any developing country with per capita consumption below 300 grams on the date or within 10 years of entry into force may delay the encoded reductions by 10 years, provided it doesn't exceed the 300 grams per capita threshold.

While the original document included language encouraging direct transfer of technology and aid from developed to developing countries, only the 1990 London amendments established an actual funding mechanism. The Multilateral Fund for the Implementation of the Montreal Protocol was designed to assist Article 5 countries in meeting the reductions. As of April 2006, over U.S. $2 billion in contributions to the fund have been made.

To prevent the leakage of production to non-participating nations, the protocol banned trade in substances covered under the agreement with non-parties. Finally, the parties identified some essential uses for the regulated substances, considered necessary for "the health and safety of society" and for which there were no feasible alternatives. These substances were exempt from the treaty, but the provision is subject to annual review.

Overall, global production of CFC-11 and CFC-12 has gone from 748,511 metric tons in the baseline year 1986 to 15,681 tons in 2003, which is a 98 percent reduction in annual production.

Moral Economy

THE MORAL ECONOMY is an extremely powerful and influential concept that has far-reaching analytical, but also normative, implications. The term is difficult to define precisely, and continues to be used in a wide variety of contexts across multiple disciplines, including anthropology, sociology, geography, history, development studies, and political ecology. The gist of the moral economy is to point to the myriad ways in which economic behavior and institutions are constituted by and embedded within cultural and political norms, often with a high degree of historical and geographical specificity. This can be a primarily theoretical conceptualization drawing attention to the ways in which particular norms, values, traditions, and social relations constrain (and motivate) economic activities (broadly defined). But it can also be used in a more normative manner, advocating for particular regulations and constraints based on overt or implicit moral principles. In both its analytical and more overtly normative connotations, the concept has wide purchase in scholarship and policy discussions concerning the politics of environmental change, not least in terms of how political and cultural sensibilities about environmental transformations and their implications inform the social regulation of economic activities.

Many locate the idea of the moral economy in Aristotle's distinction between production for use and production for exchange. Aristotle was quite critical of the latter, arguing that economic production purely for gain was immoral. This anticipates Karl Marx's more formal distinctions between use value and exchange value under capitalism, and his excoriation of capitalism as a political economy founded on greed and accumulation for accumulation's sake. However, Aristotle also anticipates and is invoked explicitly by Karl Polanyi who similarly criticized what he called market society, i.e., one in which the market is the main institution governing allocation and social distribution. Polanyi argues in *The Great Transformation* and elsewhere that only in a market society do we find the pretense of exchange unmediated by social and cultural constraints. Other (in Polanyi's view prior) societies were characterized by economies *embedded* within and conditioned by social norms and mores—hence the moral economy.

There is some inconsistency in Polanyi with regard to whether or not he actually thought market society itself, even in the minds of its liberal advocates, was truly disembedded, or whether free market orthodoxy itself necessarily turns on moral arguments, e.g., that the pursuit of self-interest unmediated by state interference is an inherent good. What is clear is that Polanyi felt that the "economy" should be conditioned by social and cultural norms other than greed, since a truly market-centered society featuring unchecked production for exchange would tear itself apart by destroying the social and environmental conditions of its own reproduction.

The moral economy idea was developed and deployed by James Scott in his study of the politics of resistance to colonialism in Southeast Asia. Why, Scott asks, did peasants not rise up more often against their colonial oppressors, given evident political and economic exploitation? His answer, in part, relies on the notion that justice is historical and relational, not objective and absolute, particularly vis-à-vis access rights to natural resources and land. He argues that many peasant communities were motivated by the right to subsistence and by attempts to minimize the risk of starvation, rather than to accumulate surplus. According to Scott, only close attention to the particular, localized material conditions and cultural meanings of food production could reveal this ethic and its influence on political action.

Similar notions of a prevailing moral economy order that shapes historically and geographically specific politics and social movements animate E.P Thompson's work, including his widely influential study of Britain's Black Act. Thompson examines the ways in which complex, specific, and overlapping rights of forest access distributed across complex social strata came under threat by changing political and economic conditions in England after the Hanoverian ascension. He argues that only by looking at the world through the eyes of those involved (to the extent this is possible), particularly those who resisted what they perceived as forest enclosures, could the sometimes violent resistance of the "Blacks" (as they were known) be understood. Among the implications, Thompson shows powerfully that various property rights to forests were not only material economic assets, but also powerful rights in a moral and symbolic sense of the term, the maintenance of which underpinned notions of justice, identity, and a morally acceptable economic order.

These ideas continue to have wide influence in political ecology, and at the intersection of development and environment. This is because the concept points to the need for understanding locally specific social relations, institutions, and cultural constructs prevailing over resource access and resource use. For instance, the idea of moral economy has been a powerful influence on attempts to understand and critique so-called coercive conservation, wherein traditional rights of access considered integral to subsistence among local peoples have been violated by attempts to institutionalize parks and protected areas. Considerable NGO and scholarly effort is also being invested in the positive formulation of moral codes and standards by which to govern the global economy, hopefully to steer it toward more socially and environmentally sustainable outcomes based on notions of fairness, equity, and ecological viability. This requires overt discussion of what principles of economic and environmental justice can be institutionalized at international scales of interaction in pursuit of a moral economy in a positive sense of the term. This is no mean feat, and begs a question that goes all the way back to Aristotle: if greed is not acceptable as the moral foundation of economic relations and institutions, what is?

Morocco

MOROCCO IS A country on the western edge of North Africa (or as some would claim, it is the westernmost country of the Middle East). It has an area of 172,413 square miles and a population of

Land Tenure in Morocco

Up until the 1880 Treaty of Madrid, all land in Morocco was owned by the sultan. This meant that sale of any land to a European had to be approved by the sultan himself. There was no landed aristocracy, and Arab nobility was based on blood rather than on possession of estates.

The French took over a large portion of Morocco, which they held until independence in 1956. During that period, they divided land into five categories. Much of the land was *makhzen* land, which meant that it was owned by the sultan personally, and also in his capacity as head of state. There was often no discrimination between the two, and the sultan quite often sold land belonging to him in his capacity as head of state. The next category was *habous* property, which was land left to religious or charitable institutions and administered by *nadir*s appointed by the sultans. Some of it had been held for many centuries as *habous* property, and by 1912 vast amounts of land throughout the country was in this category. Much of it was farmland, but it also included much urban property. A law was introduced in 1913 that allowed French settlers to rent it for up to ten years.

Guich land, was the land that was held by the sultan and handed over to various tribes for them to administer as they sought fit. A 1914 law declared this land inalienable, even though much of it was wanted. Indeed, some of it was taken for distribution and sale to French settlers. Collective lands were lands held by tribes, largely by right of force, and were not recognized by either Andulasian or Moroccan laws. Occasionally these holdings were recognized by the sultan. The last category was *melk* lands, which were privately-held properties that accounted for much of the land holdings in the cities.

30.7 million (2005 estimate). Currently, the capital of the country is Rabat, although there are three other "imperial" cities—Marrakech, Fes, and Meknès—that have also served as capitals. Morocco is bordered by Algeria, the Mediterranean Sea, and the Atlantic Ocean. To the south is the disputed territory of Western Sahara. Although claimed by Morocco, the international community does not recognize Western Sahara as part of Morocco.

Three mountain ranges dominate Morocco: the Atlas, the Anti-Atlas, and the Rif. These mountains collectively influence weather patterns coming off the Atlantic Ocean and channel surface rainwater back into Morocco. On the eastern side of the Atlas Mountains, the desert environment of the Sahara predominates. This phenomenon has frequently given rise to a comparison of Morocco with California; Morocco has many, though not all, of the agricultural possibilities of that state.

The population is frequently classified as Arab/Berber although the two groups are not as intermixed as that label might appear. The official language of Morocco is Arabic, but there are also many Berber dialects spoken in the mountains and the south especially. French is also a widely used second language. Religiously, the overwhelming majority of the population is Sunni Muslim. The once large Jewish minority has mostly left for Israel and other destinations.

Historically, the earliest inhabitants were Berbers, but Morocco also had a strong Roman presence. The Arabs conquered the area in the late 17th century. After Moroccan independence in 788, a succession of dynasties ruled Morocco, including the Almoravids and Almohads who ruled both Spain and Morocco. King Mohammed VI is the latest monarch of the Alouite Dynasty, which has ruled Morocco since the mid-17th century. Morocco was also a French protectorate in the early 20th century, which heavily impacted development and gave Morocco its unique urban flavor of old *medinas* set next to French-inspired *villes nouvelles*.

Morocco's economy is heavily dependent on agricultural production, especially for the lucrative European market. Many areas grow high value, water intensive crops like tomatoes, melons, and cut flowers for export. Over the past three decades, the Moroccan government has spent a substantial amount of their capital expanding agriculture both in places that have historically concentrated on agriculture, such as Marrakech, and in new areas, such as around the southern city of Agadir, where aquifers have been accessed. Environmental problems have resulted as saltwater intrusion has increased and the government has been forced to spend more money on protecting, and where possible, augmenting flow back into aquifers.

Service industry jobs employ roughly the same amount of the population as agriculture with industry employing only about a quarter of the amount of people as either of those two sectors. Unemployment remains high and has fueled migration of Moroccans to Europe, particularly to France and Belgium. Unemployment has also created dissatisfaction with the government and a minority Islamist presence has emerged in recent years.

Mosquitoes

TWO THOUSAND FIVE hundred species and 1,000 subspecies of mosquitoes thrive across diverse ecological niches from the arid desert to the subarctic tundra. The life cycle, habitat preference, and temporal behavior of mosquitoes is therefore highly variable and species dependent. Over its life cycle, a mosquito hatches from an egg, develops through aquatic larval stages into a pupae and finally an airborne adult. Larval mosquitoes inhabit almost all temporary natural, human altered or anthropogenic water holding bodies on land. Extraordinary larval habitats include salty water, hot springs, tree holes, inside of plants (e.g., pitcherplants, bromeliads) and even water in between plant cellular tissue. Mosquitoes that transfer diseases to humans preferentially breed in disturbed environments (e.g., burrow pits, hoof prints) or containers (e.g., potable water jars, tires) close to or inside human dwellings.

Only a small fraction of eggs survive environmental hazards, resource scarcity, predation, disease, and competition to develop into adults. Reproductive strategies vary from laying individual eggs or egg clusters across multiple locations to depositing all the eggs in one location as a mosquito raft. Depending on the species, eggs are either deposited into a water body and rapidly develop or are deposited on a surface previously submerged in water. Subsequently re-submerging the eggs combined with other environmental cues initiates hatching of the mosquito into a suitable habitat. The cold-blooded mosquito's rate of development is strongly influenced by the temperature and moisture characteristics of the ambient environment. In general, warm conditions expedite mosquito development while hot or cold conditions stymie mosquito maturation.

Nonpredatory larvae extract and/or browse for food and nutrients from the aqueous environment and store the food for future development. Larvae mature, grow, and shed their exoskeletons three times before metamorphosis accelerates in the pupae stage. Pupae larval muscles and the midgut are completely reconstructed into adult body parts. Pupae are morphologically distinct from larvae, cannot consume food, float at the water's surface, and can survive outside of water. Adult mosquitoes consume nectar, fruit, and honeydew for sustenance and can be important pollinators of plants. Mature males swarm together and attract viable females to copulate and complete the mosquito life cycle. Inseminated females store the sperm and only fertilize their eggs prior to deposition. Of the mosquito species that extract blood, only the females actively seek out blood meals to provide protein for the development of the eggs. Each species has a preferred time of the day to vigorously seek blood and this circadian rhythm informs strategies to minimize mosquito and human contact. Favorable host seeking times of the day are either the nighttime, daytime, or during the twilight dusk and dawn hours. The degree to which a mosquito hunts for human (anthropophilic) or other vertebrate blood (zoophilic) sources is largely species dependent; however, significant intraspecies variation exists.

Female mosquitoes employ a diverse array of tools to identify appropriate sources of blood and extract plasma without alerting the unwitting victim. She is attracted to the heat our bodies continually emit, carbon dioxide and water vapor we exhale, lactic acid excreted in our sweat, and our body movements. Mosquito repellant masks the body's excretions and makes us less appealing blood sources. Upon landing, the mosquito finds the optimal extraction site by touching and chemically "smelling" the skin with her antennae and mouthparts. She proceeds to find blood, insert her mouthparts, and inject chemical filled saliva similar to a drug cocktail administered to a patient before an operation. Saliva chemicals stop blood clot formation, keep the blood vessels enlarged, and thwart any host inflammatory immune response.

Infectious viruses, protozoa, or worms (nematodes) in the biting mosquito may be transferred with the saliva to another host to complete or start a new reproductive cycle.

Agents responsible for a large proportion of the global disease burden such as malaria, dengue, Rift Valley fever, yellow fever, elephantitis, and encephalitides are transmitted during this exchange. The female mosquito ingests two to three times her weight in blood and finds a safe habitat to process the blood.

EXTERMINATION OR CONTROL

Mosquito management historically combines source reduction, surveillance, targeted biological and chemical control, public education, and legislative action at the region, village, household, and individual levels of organization. Multiple remediation activities target the life cycle specific ecological associations of medically important and nuisance mosquitoes. Insecticide application—Dichlorodiphenyltrichloroethane (DDT)—became the dominant method of mosquito control from World War II until it was banned in Western nations in the 1970s.

Mosquito-borne diseases include malaria, dengue, Rift Valley fever, yellow fever, and encephalitides.

Top down military eradication efforts of the mid-20th century are in the process of transitioning into more participatory, community supported, and holistic management activities. Technical "magic bullets" singularly focused on a component of disease transmission have proven costly, inflexible, and detrimental to other management strategies. Divergent conceptions of society's relationship to the mosquito underpin historical shifts from mosquito and disease extermination back toward mosquito mitigation, management, and control. Integrated mosquito management currently attempts to reduce the level of disease transmission by decreasing mosquito abundance.

Source reduction eliminates standing water required for larval development by draining wetlands and marshes or emptying water in man-made containers. Effective source reduction also includes the active management, engineering, and alteration of mosquito habitats.

Channeling, stabilizing, and diverting waterways, controlling the height and motion of standing water, removing invasive or marginal groundcover, and planting trees along waterways historically controlled malaria vectors.

Biological mosquito control intentionally introduces a mosquito predator, parasite, or organic toxin to reduce larval populations in aquatic environments. Predatory mosquito fish (e.g., *Gambusia*, *Tilapia*) consume larval mosquitoes as well as change the habitat vegetation structure to be inhospitable to certain mosquito species. Microcrustacean predatory copepods, carnivorous *Toxorhynchites* mosquitoes, parasitic nematodes, and pathogenic protista are other biological control methods of varying effectiveness.

The mosquito's rapid reproductive cycle and large number of offspring naturally promote genetic resistance against insecticides. Mosquitoes are adapted to the current generation of pesticides such as organophosphates, carbamates, and pyrethroids and all medically important species are resistant to at least one pesticide. Entirely novel pesticides have not been developed in 15 years and significant financial and safety barriers to chemical generation and introduction exist. Indoor residual spraying is a neighborhood level intervention that applies pesticides inside households on surfaces where medically important mosquitoes rest. This strategy targets the infectious females who may transmit a disease to other household members.

Successful household and individual level interventions focus on mosquito-proofing households, personal protection, and behavioral changes. Households that actively replace standing water, have indoor plumbing, door and window screens, and access to running water decrease their interaction with mosquitoes. To avoid mosquitoes that blood-feed nocturnally or during the twilight hours, individuals can shift their outdoor activities to the daytime hours. Changes in activity patterns may be mandated by state policies like the historic nighttime curfew imposed during malaria transmission season in Israel. Distributing insecticide-coated bed nets similarly capitalizes on the nocturnal feeding preference of *Anopheles gambiae* (malaria vector) to provide personal protection. For mosquitoborne diseases (yellow fever, Japanese encephalitis) with effective vaccines, disease management focuses on vaccine manufacturing and distribution, and building and maintaining public health infrastructure instead of mosquito control. Transmission of diseases with vaccines persists in environmentally disturbed and politically and economically disenfranchised or disadvantaged regions.

Mountains

MOUNTAINS ARE LANDFORMS that are characterized by their elevation and slope. A broad description is any landscape feature that is over 600 meters in elevation change with steep slopes. The United Nations International Year of the Mountain (2002) separated mountains into two major categories—mountains extending above 2,500 meters and between 2,500 and 300 meters. Lands that have topographic relief of more than 5 percent within 7 kilometers are also considered mountains.

Mountains are formed in a process known as orogeny of which there are three major activities: island arcs and trenches—along the subduction zones of two oceanic plates; cordilleran-type mountain ranges—along the subduction zones of an ocean and continental plate; and the collisional mountain belts—the convergence and subduction of an arc or another continental plate in contact with the overlaying plate of the subduction zone. In addition, erosion over time creates topographic relief mountains. The island arcs and trenches are both submerged below ocean floors and rise above the ocean in island chains throughout the Pacific, Indonesia, and the Caribbean. The long mountain chains along coastal regions demonstrate the cordilleran-type mountains, best illustrated by the Andean Mountains of South America. The Himalayas are being formed by the collisional-mountain process, the contact of one plate with another. The sedimentary forelands formed on the subduction plate can create a different set of mountains resulting from the folding and faulting of the sedimentary layers. Examples of this type of mountain range are the Front Range of the Rocky Mountains, the Appalachian Mountains, and the Subandean Range in Argentina.

Approximately 24 percent of Earth's surface area is mountainous. South Asia is covered by almost 54 percent mountains, the other continents by less: North America (36 percent), Europe (25 percent), South America (22 percent), Australia (17 percent), and Africa only 3 percent. There are over 130 recognized mountain ranges worldwide, with peaks of varying elevations. Mount Everest is the highest mountain above sea level (8,848m), while Mauna Kea is the actual highest mountain measured from its base on the ocean floor to its crest above sea level.

Mountain elevation change has a dramatic effect on local, regional, and global climate. Air moving along Earth's surface is forced upward with mountain contact. As the air climbs the mountain it decreases in temperature at an average rate of 6.5 degrees C per 1,000 meter, the adiabatic rate. Moisture in the atmosphere condenses as it cools and forms clouds and eventually precipitation, rain, or snow. As the air continues over the mountain it contains less moisture and on the descent down the mountain it warms at approximately the same or higher adiabatic rate forming dry, warm winds. The upslope movement of air is on the windward side of the mountain and the downslope movement is on the leeward side. Thus, the mountain will have cooling, wetter conditions on the windward side and drier, warming conditions on the leeward side. The weather station on the windward side of Mount Waialeale is located at 1,569 meters and receives an average of 1,234 centimeters of precipitation; in contrast, the leeward side receives only 50 centimeters. The mountain side (face) is also influenced by its orientation to the sun and its latitude. Sun-facing slopes will be warmer and usually slightly drier than slopes facing away from the sun. Similarly, east-facing slopes will receive the morning sun and be cooler than the west-facing slope.

Mountains are the water towers for the land surface. Because of their orographic effects, mountains are the headwaters of almost all of the major rivers in the world. The Ganges, Indus, Yangtze, and Huang Ho rivers have their headwaters in the Himalayas. The Amazon is fed from the Andes, the Blue Nile from the Ethiopian Highlands, and the Colorado from the Rocky Mountains. Mountain runoff is a function of snow accumulation and precipitation patterns. Changes in stream and river flow will have an impact on the water received in the valley or the delta area of the river drainage. Mountains are the source of over 50 percent of the fresh water humans consume.

Vegetation and wildlife respond to the differences in temperature and precipitation caused by mountain ranges. A zonal pattern occurs with increase or decrease in elevation, however, the pattern is influenced by the windward/leeward side of the mountain, the mountain face aspect, latitude, and continentality (whether it is a coastal or mainland mountain range). Overall, the vegetation in mountain areas is a vertical pattern of the horizontal vegetation change through the latitudes from the equator to the poles. There are five major categories of vegetation: tropical rain forest, temperate deciduous forest, coniferous forest, tundra, and ice and snow.

Correspondingly, there are animal, avian, and insect habitats that associate with each of the different vegetation categories and the multitude of species can be combined to create a species richness index. Research has found that the species richness index decreases with an increase in elevation, similar to the changes identified with an increase in latitude. However, the changes in species richness are amplified in the mountain environment because of the compressed distance to transition from one vegetation zone to another. The Andes are an example of this species richness, with over 45,000 plant species in an area that is only 20 percent of the size of a similar richness in the Amazon forest.

Although 24 percent of the world land base is in mountainous terrain, more than 500 million people (12 percent) live in this region. Though more than 80 percent live below 2,500 meters, human activities extend to the highest reaches of mountains. Major activities on mountains are agriculture, logging, and livestock production. These activities can be found at most elevations; however, agriculture will be limited by growing season length and crop type. Logging will be determined not only by forest type, but also by access to transportation. The timber industry is directly related to a transportation system that can deliver the logs to the mill and to the market.

Two other activities that are also dependent on transportation access are mining and tourism. Because of the orogenic activities that created mountains, they have the potential for a variety of marketable mineral deposits and rock structures, from precious metals to construction materials such as marble, granite, and copper.

Tourism has created a new type of activity that brings over 50 million people to the mountains for passive and activity recreation. Overall, 15–20 percent of the global tourism industry is associated with mountain recreation—hiking, skiing, climbing, and observation. Finally, another form of mountain activity is the spiritual pilgrimage, a combination of religion, spirituality, and tourism. Specific sites have significance to particular religious or cultural groups, for instance Amdo to Tibetans, Kii Mountain to the Japanese, and mountainous Blue Lake in the southern Rocky Mountains for the Taos Pueblo.

The mountain region is a fragile environment and change can have immediate impacts. There are two scales of change that are the most evident—global and local. Global climate change is having an immediate effect on snow accumulation, glacial retreat, solar radiation, and runoff. In Glacier National Park, of the 150 glaciers recorded in 1850 there are now only 27 glaciers remaining. Over this time period around the world the temperature has increased .45 degrees C (±.15 degrees C).

In addition, nitrogen in the atmosphere has increased and this has led to a shift in mountain vegetation patterns. At the local scale, devegetation of the hillsides leads to rapid erosion of the slopes. More than 40 percent of the slopes in Nepal have been abandoned by farmers because of the loss of fertility. In Ethiopia, mountain forests covered 75 percent of the land, but deforestation decreased that number to only 4 percent.

In other situations, it is not just deforestation that is destroying the landscape, but rapid development. The desire to visit, the need for comfortable accommodations, and the disposable mentality are taking their toll on the mountains. In South Korea, although the mountains account for only 4 percent of the area, over 30 million visitors come to the mountains for recreation. In the high elevations of the Himalayas the more than 225 lodges need to keep their guests comfortable and over 1,000 tons of firewood are burned daily to keep them warm. New tourism in the Himalayas is also leaving its mark on the landscape in the form of rubbish. It is estimated that over 17 tons of materials are left behind per one kilometer of trails into the mountains.

The increase in the intensity of local mountain activities and the impacts of global climatic change are changing this fragile environment. Through United Nations initiatives, national government policies, and successful local strategies the mountains may be saved for future generations of humankind to experience.

Movements, Environmental

TO IDENTIFY A movement, or movements, as environmentally oriented is to cast the politics of environmentalism in terms of social movement theory. Other notable social movements include the labor, women's, civil rights, peace/antiwar, student, animal rights, and antiglobalization movements, all of which have at times been linked to environmental movements. Classically, social movements are considered to have a type of life cycle. They germinate in order to challenge some form of oppression within society, they build and mobilize affinity groups around issues of solidarity common to an oppressive cause, culminating in success or failure. If social movements fail, theorists have charted how other movements may attempt to revisit the failed issue or reorganize collective actors previously associated with the failed movement as part of a resurgent political strategy. If social movements are victorious, social movement theory has tended to represent them as inevitably ossifying and fragmenting, with leading movement intellectuals and organizations often cementing the movement's overall bureaucratization and rigid institutionalization through their demands for its rigid formalization.

Environmental movements do not appear to accurately reflect this model. Instead, such movements have remained vital and capable of adjusting to meet the dynamic needs of differing social, cultural, political, and historical conditions. They have celebrated many great and small victories without having become either de-radicalized or sclerotic. Likewise, environmental movements have been dealt innumerable setbacks and have arguably been defeated in the large, if one is to judge them by the ongoing exponential growth of global human population, the continued development of unsustainable economic systems, and the ever-burgeoning planetary ecological crises of the last 30 years. Still, this has not led to the marginalization or evaporation of environmental movements. Rather, environmental movements are flourishing as they never have before and remain poised as central agents of sociopolitical change during the 21st century.

Environmental movements involve collective activist networks of individuals, groups, formal and nonformal organizations, and institutional bodies that struggle for social transformation around environmentally-related causes such as global climate change, antitoxics, the conservation of natural resources, population growth problems, the end to nuclear arms and other weapons of mass destruction, the protection of pristine wild places and biological species, corporate accountability, and the promotion of environmental justice principles. Environmental movements work at local, regional, national, transnational, and global levels, and can be structured as loose affiliations of a transient nature, or as longer-term alliances that consist of well-established corporate and noncorporate organizations, including political parties such as the international confederation of Green parties. While environmental movements have played crucial roles in lobbying politicians, as well as in getting governments to produce and enforce sound environmental legislation; having a professional environmental policy approach is only one function of environmental movements. Environmental movements work in legal and illegal ways to transform mainstream values, educate the public about social problems of an environmental nature, create sustainable cultural alternatives, and block environmental harms through myriad forms of protest and direct action.

Sometimes it is implied that the wide variety of global environmental movements are facets of a larger, all-inclusive ecology or Green Movement that has the gestation of a planetary consciousness, the mass proliferation of appropriate technologies, and the broad democratization of science as its goals. Others fold even this larger environmental movement into the emergent movement for global justice, which is often called the movement of movements because of its ability to signal the need for radical change on many fronts. Yet, at least in an Anglo-American context, the terminology of *environmental movement* is most often used to denote the rise of modern environmentalism in advanced industrialized nations since the 1960s; though scholars also frequently extend this time frame to include previous American movements such as the conservation, preservation, and transcendental movements of the 19th and early 20th centuries as important foundations of contemporary environmental activism. A singular environmental movement exists, but the manner in which this movement is made manifest and experienced throughout the world differs significantly, with singular movements sometimes working in contradiction to each other's immediate aims. The environmental movement can refer to anything from a history of localized green activism, to a theorized worldwide revolution predicated on ideas of ecological well-being.

The American environmental movement is often hailed as the birthplace of environmentalism. While nothing resembling an environmental movement existed until the mid-19th century when both the conservation and transcendental movements took root amongst sectors of society concerned with the consequences of the Industrial Revolution, a legacy of ecological harms can be traced all the way back to the initial colonization of North America by European merchant ships, which brought with them a variety of highly invasive species and plagues through the Columbian Exchange.

NATIVE AMERICANS

Native Americans, Mesoamerican tribes, and many Canadian First Peoples who had been living in relative ecological harmony with the land for millennia continue to bear the oral traditions of this history, the living testimony of the perilous environmental and social legacy of colonization. Native voices play an increasingly prominent role in the environmental movement, where they offer articulations of and legitimation for alternative cosmological visions and sustainable living practices. Notably, Winona LaDuke, a leading spokesperson of the indigenous peoples' movement, ran for vice president of the United States as the U.S. Green Party nominee in 1996 and 2000.

If American indigenous societies have tended to produce place-based ecological knowledge and promote a general conservation ethic in their cultural practices, it is only recently that they have more widely practiced public forms of environmental activism. This is in contradiction to the false images of Native American environmental activists that have been fostered by white environmentalists since the 1970s in order to better ground the movement in cultures that appear to represent land-based alternatives to modernity. The most infamous example of this practice was when an 1854 speech by Suquamish leader Chief Seattle was entirely rewritten by screenwriter Ted Perry to support the message of the 1972 environmentalist film *Home*. The so-called Perry version of Chief Seattle's speech has since been quoted by political leaders at Earth Day celebrations, by environmental ideologues such as Joseph Campbell and Bill Moyers, and has served as the basis for a best-selling environmentally-themed children's book, *Brother Eagle, Sister Sky: A Message from Chief Seattle*.

19TH CENTURY AMERICAN MOVEMENTS

The first nonindigenous movement for American environmental conservation began in earnest during the mid-19th century. Thomas Jefferson is sometimes considered the father of the American conservation movement because of his founding work as a naturalist and his call in the book *Notes on the State of Virginia* for the country to be inhabited as a series of small-scale, subsistence-styled farms, a vision more recently defended by important environmentalists such as Wendell Berry. However, Jefferson's late 18th century book was known to only a few people and did not exert much popular influence.

On the contrary, Ralph Waldo Emerson's *Nature*, published in 1836, was widely read and established the transcendental movement that demonstrated the manner in which the American environment should be extolled and utilized as a rich spiritual and aesthetic resource for deepening the American experience of the world. This idea represented a dramatic shift from the long-standing tradition in which the American wilderness was perceived as base, threatening, and requiring the improvements offered by civilization.

Over the next two decades, transcendentalists such as Emerson, Henry David Thoreau, Margaret Fuller, and Bronson Alcott published their work in the *Dial* journal, which became a key movement mouthpiece. Under the transcendentalists' influence, various forms of nature writing became commercially successful genres, and romantic painterly depictions of the American West, such as those produced by the Hudson River school artists, generated enthusiasm about the country's natural wonders. Further, the transcendental movement linked its environmental outlook to a larger social consciousness that radically critiqued political issues of the day, such as the federal government's treatment of Native American populations, the horror of slavery practices, the national passage of the Fugitive Slave Act, the war between the United States and Mexico, women's civil rights, animal welfare, and the social effects of industrialism. The transcendental movement also experimented with utopian forms of community such as Brook Farm, Fruitlands, and Walden.

THE CONSERVATION MOVEMENT

By the mid-19th century, those living on America's eastern seaboard were beginning to see the effects of deforestation, depopulation of species, soil erosion, water issues, and urban pollution in the large cities. Science and technology were also beginning to make revolutionary breakthroughs, including in previously uninvestigated domains such as the science of conservation ecology as represented by the work of George Marsh. A conservation movement arose that sought to combine the culturalism of transcendentalism with science and technology's ability to measure and limit human impacts on the environment as part of a progressive social vision for rationally managing natural resources for human betterment. This movement has an enduring legacy and notched many accomplishments including the creation of the world's first national park system, beginning in 1872 with the formation of Yellowstone National Park, along with the adoption of conservation policies instituting state and national wildlife refuges, forests, and protected species.

The presidency of Theodore Roosevelt is often hailed as a central moment of the conservation movement and is notable for the historic clash between Gifford Pinchot, considered the father of American conservation forestry, and John Muir, the founder of the Sierra Club. A debate erupted over whether to place a dam, a common conservation project undertaken during the early 20th century, in Yosemite Park's Hetch Hetchy Valley in order to create a reservoir to support the city of San Francisco. Muir called for the valley's preservation at all costs and defended nature in transcendental terms as equally important, if not more so, than civilization. Pinchot spoke of the utility of the project and counseled for its approval as long as the park (as with other natural resources) was conserved and managed scientifically for the public's good. Roosevelt ultimately approved the project, despite great controversy and debates about whether to preserve natural places or to manage them for human use.

THE 1960s AND 1970s

Muir's new preservation movement fought against the further desecration of national lands and was successful in preventing further encroachments on the national parks. Especially notable in this respect is the Wilderness Society, created in 1935, which has since protected over 100 million acres of land from development through the passage of the Wilderness Act of 1964. This legislation designated specific areas as "wilderness," or as areas "where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain."

As a result of legislation such as the Wilderness Act, the National Environmental Policy Act, the Endangered Species Act, and the Clean Air Act, the 1960s are often seen as the era that birthed the contemporary environmental movement. In 1962, Rachel Carson's *Silent Spring* shocked the country by exposing the environmental dangers of ubiquitous pesticides such as DDT. In 1969, a massive oil spill off the Santa Barbara coast became the first extensively televised environmental disaster, generating public outrage, anti-oil activism, and demands for marine protection culminating in the Marine Mammal Protection Act. Finally, in 1970, the first Earth Day was conducted in San Francisco, and the American environmental movement began to have global effects.

After the 1970s, the environmental movement's mainstream organizations grew increasingly powerful and global, often partnering with corporations and governments to promote policy change toward sustainable development, implementing industrial reforms, marketing green consumption strategies, and purchasing large land grants as part of private and private/public conservation initiatives. A prominent organization of this type is Friends of the Earth International, founded in 1969 by the former Sierra Club Director, David Brower, which now links organizations from 70 countries.

RADICAL MOVEMENTS

By contrast, a plethora of radical environmental movements have mushroomed around philosophies such as social and deep ecology, ecofeminisim, and ecosocialism. Inspired by these philosophies, and especially the writings of Edward Abbey, the radical group Earth First! was founded in 1980 to critique the mainstream movement's reformist tactics. Instead, Earth First! promoted direct action to protect the earth and celebrated the guerilla eco-saboteur art of monkey wrenching environmentally harmful technologies.

This militant wing of the movement further developed with the rise of the Earth Liberation Front (ELF) as an offshoot of Earth First!. The ELF celebrates anarcho-primitivist philosophies, and has been known to firebomb sport utility vehicle dealerships and commit arson to destroy large developments in areas they believe should remain wild. They believe in harming no living being, but exist to inflict maximum economic damage against environmentally destructive corporations and personages. Their mission is also educational and they routinely release anonymous communiqués explaining their actions after the fact. Earth First! and the ELF have demonstrated solidarity with a range of other social movements. In response, the United States and British governments have engaged in repression and targeting of these groups, labeling them and their supporters ecoterrorists.

ENVIRONMENTAL JUSTICE

A final radical development of the American environmental movement is the recent struggle for environmental justice, which fights against the unequal distribution of environmental harms and hazards across society, and often links environmentalism with urban and civil rights issues. The movement arguably began in 1978 during the Love Canal crisis, when Lois Gibbs successfully organized a campaign that exposed how citizens were becoming mysteriously ill due to the city of Love Canal having been knowingly developed on top of a corporate waste landfill composed of toxic chemicals. As a result of Gibbs's community activism, the federal government created the Superfund Act, which fines polluting companies and provides emergency funds for environmental cleanup. Since Love Canal, the environmental justice movement has grown worldwide, empowering poor and minority communities in a myriad of local struggles, and now represents a significant challenge to the idea that environmentalism is primarily about wilderness protection, resource conservation, lifestyle changes, or population reduction. The environmental justice movement has mounted a critique of mainstream environmentalism as a predominantly white and middle-class movement based on affluent social concerns about how to improve quality of life.

The environmental justice movement's focus on race, class, and gender issues as opposed to the non-anthropocentric environmental concerns developed within the American environmental movement also typifies many of the environmental movements of less affluent countries, where grassroots environmentalism is often concerned with peasant survival issues that arise because communities' access to resources becomes imperiled or displaced by industrial and commercial enterprise. These movements affirm traditional rights and uses of land in opposition to privatization schemes that involve environmentally harmful processes of road construction, clear-cut logging, invasive mining, and industrialized agriculture techniques. Traditional uses, it is maintained, are ecologically sustainable and tend toward the maintenance of the commons. Many of these movements are decidedly radical in their ideology and militant in their resistance, though their protest runs the gamut from forms of Gandhi-inspired, nonviolent *Satyagraha* to armed struggle.

Some environmental movements of the Global South have become internationally renowned, including India's Chipko movement, Kenya's Green Belt movement, Nigeria's Ogoni movement, Brazil's Rubber Tappers movement, and Mexico's Zapatista movement. Chipko literally means "to hug," and the 1970s movement for which it is named featured peasants, especially women villagers, of the Himalayan foothills who hugged the trees, practiced ecological restoration, and undertook national and international lobbying efforts in order to block timber cutting of the local forests. The lasting success of Chipko is debatable, but it has been an inspirational movement that has seeded other movements such as the antigenetic modification of food movement theorized by former Chipko activist Vandana Shiva. The Green Belt movement, founded in 1977 by 2004 Nobel Peace Prize winner Wangari Maathai, focused on mobilizing and empowering women to drive environmental and social change. Through the movement's work, over 30 million trees have been planted, women have been trained to utilize natural resources sustainably and earn a living wage, and ecotourism has been promoted.

Meanwhile, movements such as Chico Mendes's Rubber Tappers movement and the Movement for the Survival of the Ogoni People have achieved measures of success at the cost of their leaders' lives. Mendes, who was influential in organizing union workers and gaining international assistance toward ending illegal destruction of the rain forest, was murdered for his activity. Likewise, the poet Ken Saro-Wiwa was officially executed by the Nigerian state for his role in promoting Ogoni self-determination and protesting against international oil companies such as Royal Dutch Shell that drilled and destroyed Ogoni land without making reparations to the people. The Zapatistas have also been heavily persecuted in their struggle for indigenous rights, which began as a response to their displacement by a proposed bio-reserve. The Zapatista movement enlisted the use of the internet to generate international awareness of their plight and to strategize virtually with a range of organizations and individuals.

Mozambique

IN 1975 THE Republic of Mozambique won its independence after nearly 500 years as a Portuguese colony. The following decades were filled with civil war (1977–92), massive emigration by the white population, economic dependence on South Africa, and severe drought. After Marxism was discarded and a new constitution adopted in the late 1980s, Mozambique began to move toward democracy and the development of a market economy. The United Nations brokered a peace settlement in 1992.

Although Mozambique is still a poor country and remains heavily dependent on foreign aid, the economy has grown dramatically since peace was declared. The size of the foreign debt has been reduced through participation in the International Monetary Fund's Heavily Indebted Poor Countries (HIPC) and Enhanced HIPC initiatives. The Mozambican government has not yet been able to adequately exploit natural resources that include coal, titanium, natural gas, hydropower, tantalum, and graphite.

Just over five percent of the land area is arable, with the most fertile area being located around the Zambezi River in central Mozambique. More than 80 percent of the population is engaged in subsistence agriculture. With a per capita income of $1,300, Mozambique is ranked 200 of 232 counties on world income. Some 70 percent of the population live in poverty, and 47 percent are seriously undernourished. Over a fifth of the labor force is unemployed. The wealthiest 10 percent of Mozambicans share almost a third of the country's wealth, while the poorest 10 percent hold less than three percent of resources. The United Nations Development Programme's Human Development Reports rank Mozambique 179th in the world in overall quality of life issues.

Bordering on the Mozambique Channel in the Indian Ocean, the southeast African nation has a coastline of 2,470 kilometers and 17,500 square kilometers of inland water resources. Mozambique shares land borders with Malawi, South Africa, Swaziland, Tanzania, Zambia, and Zimbabwe. The land area of Mozambique is diverse, with costal lowlands rising to uplands in the central section, high plateaus in the northwest, and mountains in the west. Elevations range from sea level to 2,436 meters at Monte Binga. The climate ranges from tropical to subtropical. Mozambique is subject to severe droughts, and the central and southern areas experience devastating cyclones and floods.

Environmental health is a major issue for the population of 19,686,505. With an HIV/AIDS adult prevalence rate of 12.2 percent, 1.3 million Mozambicans live with this disease, which had killed 110,000 people by 2003. Only 42 percent of the population have sustained access to safe drinking water, and only 27 percent have access to improved sanitation. Mozambicans have a very high risk of contracting food and waterborne diseases such as bacterial and protozoal diarrhea, hepatitis A, and typhoid fever and the water contact disease schistosomiasis. In some areas, the population also faces high risk of contracting malaria and plague.

This susceptibility to disease produces a lower than normal life expectancy (39.82 years) and growth rate (1.38 percent), and higher than normal infant mortality (129.24 deaths per 1,000 live births) and death rates (21.35 deaths per 1,000/population). Women give birth to an average of 5.5 children each. Dissemination of disease prevention information is difficult because less than one-third of adult females and less than two-thirds of adult males are literate.

During the long years of civil war and prolonged drought, many Mozambicans deserted the remote areas of the country for the cities and coastal areas, overburdening the environment. The result has been increased levels of desertification and major pollution of both surface and coastal waters from agricultural runoff and by the release of waste products from the petroleum and refining industries, and the textile, paper, and cement industries. The impact of the mining industry has been massive, producing air, soil, and water pollution that include emissions of toxic gas and destruction of forests and habitats. Soil erosion has been a by-product of coastal erosion and the flooding of mountain and coastal areas. Poachers threaten the elephant population in their pursuit of ivory. It is believed that several hundred thousand landmines may have been hidden in Mozambique, creating major threats to humans and the environment, and the process of removing them is ongoing.

In 2006, scientists at Yale University ranked Mozambique 121 of 132 countries on environmental performance, considerably below the comparable income and geographic groups. The lowest scores were assigned in the categories of environmental health and biodiversity and habitat. Around 39 percent of land area is forested, but deforestation is occurring at a rate of 0.2 percent. Although the government has protected 8.4 percent of land, the rich biodiversity was seriously threatened by the prolonged civil war. Of 179 identified mammal species, 14 are endangered, as are 16 of 144 bird species.

The Ministry of Environmental Affairs and Tourism has the responsibility for implementing and monitoring environmental laws and regulations in Mozambique in conjunction with related agencies such as the Ministry of Health. The framework for these laws was provided by the National Environment Management Program of 2002 that focused on managing the various aspects of the environment to maximize sustainable development and the eradication of poverty. Specific programs targeted air, water, and soil pollution; waste management, hygiene, sanitation, and overall environmental heath. Other government efforts focused on the protection of biodiversity. In 2002, for example, Mozambique partnered with South Africa and Zimbabwe to establish the Greater Limpopo Transfrontier Park that encompasses 35,000,000 hectares spanning Mozambique's Limpopo National Park, South

Africa's Kruger National Park, and Zimbabwe's Gonarezhou National Park. It is one of the largest multinational conservation areas in the world. Mozambique participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change-Kyoto Protocol, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, and Ozone Layer Protection.

Muir, John (1838–1914)

WHEN JOHN MUIR was a young man, few would have predicted that he would become a celebrated preservationist, founder of the Sierra Club, and advocate for national parks. Born in Dunbar, Scotland, Muir showed an early proclivity for mechanical work. His family immigrated to rural Wisconsin, near the town of Portage, in 1849. His father was a strict Calvinist and instructed Muir, the eldest male child, in Biblical teachings, but did not allow any of his eight children to attend school. Muir obtained books from friends and soon developed an interest in science. His mechanical abilities won him recognition at the Wisconsin State Fair where he displayed some of his ingenious devices, one of which was an intricately carved alarm clock attached to a bed that tilted at a predetermined time, heaving the sleeper to a standing position.

Muir studied briefly at the University of Wisconsin. An accident in a carriage parts factory, however, changed his life. Nearly blinded, Muir regained his sight a month later and vowed to train his eyes on the beauty of the natural world. He traveled extensively, walking from Indianapolis to the Gulf of Mexico. Muir intended to visit South America, but a bout of malaria encouraged him to travel to California instead. Arriving in San Francisco, Muir quickly looked for the road out of town. His journey took him to the most picturesque, awe-inspiring place he had yet seen: Yosemite. Muir was astonished by the Sierra Nevada Mountains, spending weeks at a time exploring their plants, geology, watersheds, massive forests, and hidden valleys. Muir argued

John Muir, inspired by Yosemite's wild landscapes, became instrumental in its designation as a national park.

that Yosemite Valley was formed by glacial activity, a position contrary to that held by leading professional geologists. Muir spent years researching in the mountains, discovering active glaciers there.

These wild landscapes, however, were much more than a laboratory to Muir. Influenced by the writings of transcendentalists—particularly Henry David Thoreau—Muir saw a deep connection between nature and spirituality. Natural splendor was part of God's creation, and Muir approached it worshipfully and preached its glories with fervor.

With fellow nature-loving friends, Muir founded the Sierra Club in 1892. Muir was elected president of the group, a position he held until his death. The Sierra Club's goals at its founding were to explore and render accessible the mountain regions of the Pacific Coast, to publicize them, and to work for preservation of the forests and natural areas.

Muir worked tirelessly, using all of his connections to protect wild landscapes in the west and was instrumental in the designation of Yosemite as a national park. President Theodore Roosevelt camped with Muir in the Yosemite region, and Muir impressed upon him the importance of using federal authority to protect such natural temples from the avarice of men.

Muir, though a charismatic and a persuasive naturalist, did not win all of his battles for preservation. After the San Francisco earthquake of 1906, the thirsty city turned its eyes to the mountains. City leaders wanted to create a reservoir at Hetch Hetchy, one of the valleys in Yosemite National Park. John Muir and many of his colleagues from the Sierra Club mounted a campaign to raise public awareness of the threat to the beautiful valley. Gifford Pinchot, a former friend of Muir, was a conservationist and the chief forester. Pinchot was not a preservationist, however, and he believed that the highest use of the valley was to provide water to San Franciscans. Eventually, the dam was built and the valley transformed. A broken-hearted Muir dubbed Pinchot and those who favored his position "temple destroyers."

Few have done as much as John Muir to publicize the grandeur and splendor of the mountain regions of the west and few have done as much to protect them. Earning a place on California's state quarter, John Muir's enthusiasm for nature—from the smallest flower to the grandest vista—has made him an icon of the environmental movement.

Mulholland, William (1855–1935)

WILLIAM MULHOLLAND (1855–1935) is remembered as a central figure in the struggle to make sufficient water resources available to the then nascent cities of California that were to grow into the metropolitan superpowers of Los Angeles and San Francisco. Most notably, he had a pivotal role in changing the course of the Owens River to water Los Angeles, much against the wishes of those people then living on its banks and deriving their living from it. Lives were lost in the subsequent struggle and Mulholland has frequently been held up subsequently as something of a scapegoat, although the extent of culpability remains contested.

The development of the western United States was hampered by insufficient convenient water resources. In order for great cities to be born out of the desert and other unfriendly areas, it was necessary to rearrange the deployment of water resources. This was hampered by technical factors—e.g., the need to build extensive aqueducts to change the course of rivers—as well as human factors, such as the presence of people in the way of development plans. Indigenous peoples were mostly driven away from their traditional homes in a series of military campaigns (one of which Mulholland participated in personally), while so-called "Americans" were dealt with in a variety of different ways. At the beginning of the 20th century, Mulholland shared the vision for Los Angeles, then a humble town, to become a great city. He had arrived in America from his native Ireland having supported himself by a series of low-wage jobs, which may have helped to forge him into the tough and hard-minded individual that some believed him to be. To realize the vision for Los Angeles, it was necessary to divert the course of the Owens River, which flowed more than 200 miles away. Accomplishing this against the wishes of the settlers of the Owens River Valley required extensive and complex negotiations and transactions, including land deals and political wrangling, which were apparently partly facilitated by Mulholland's various connections, although such a substantial undertaking could never be the work of one person alone.

The initial aqueduct was completed by 1913 and Los Angeles began its ascent. However, the water resources provided exceeded what was required by the young city and Mulholland was obliged to enter into a second round of private sector irrigation and dam project dismantling in order to redistribute the water to the extent that it would make the scheme sufficiently profitable. Armed resistance broke out among the settlers in the region who were forced by this drive to move, and a series of environmental problems were unleashed. This led in due course to the disaster of the St. Francis Dam, which collapsed in 1928, allowing a massive flood of water to flow down toward the sea, sweeping away all in its path. Unknown numbers of people were killed, made homeless, or dispossessed by this disaster, for which Mulholland was eventually found responsible; he was obliged to live out his days in disgrace.

Transforming the environment to this extent, Mulholland managed to create both winners and losers, though it was not always immediately obvious who had won and who had lost. Those who proved to be winners by benefiting from the newly organized irrigation systems tend to have louder and more persistent voices than those who lost out in the past.

Multiple-Use and Sustained-Yield Act (MUSY)

THE FOREST MANAGEMENT Act of 1897 limited the purposes of federal forests to "securing favorable conditions of water flows, and to furnish a continuous supply of timber for the use and necessities of citizens of the United States." The Multiple-Use Sustained-Yield Act (MUSY) of 1960 defined the purposes of the national forest to include "outdoor recreation, range, timber, watershed, and wildlife and fish purposes" (16 USC 528). The passage of MUSY marked the culmination of years of efforts by recreational, grazing, and wilderness advocates to secure statutory authority for additional activities in federal forests. The act gives the U.S. Forest Service wide latitude in determining the appropriate uses and yields of any given activity on any given area of the federal forest system.

The decade prior to the passage of the act was marked by increased pressure on the federal forest system by competing user groups. In the 1950s, recreation visits to national forests increased by over 300 percent. During the same period, timber production more than doubled, from 3.5 billion board feet to 8.3 billion board feet. Likewise, throughout the decade, ranching interests repeatedly sought to codify a right to grazing access of national forest ranges. In response to the efforts to increase non-timber uses on forest lands, the timber lobby began to actively campaign beginning in the late 1950s to clarify and confirm the importance of timber in Forest Service management. At the same time, the Forest Service actively positioned itself as the mediators of multiple user demands. As Paul Hirt has argued, in theory and practice, however, Forest Service decision makers worked in tandem with timber interests to protect the preferential position of timber production on forest service land while also insuring that sustained yield remained solely an economic term.

Despite the general support offered to the bill during debate by various interest groups, the resulting act has done little to redefine sustained yield and multiple use or prescribe new procedures for balancing the multiple uses stipulated in the act. Prior to MUSY, timber industry and Forest Service definitions of multiple use were nearly identical. Multiple use was understood to be hierarchical, with timber being the critical and priority use of forest resources. All other uses were subordinate to continued timber harvesting. Although the act required equal consideration be given to each of five resources on the federal system, the act was "supplemental to, but not in derogation of, the purposes for which the National Forests were established as set forth in the Act of June 4, 1897." The Forest Management Act of 1897 was the very same act that privileged timber in the establishment of the forest system

Likewise, prior to MUSY sustained yield was understood to mean the maximum feasible production of timber in any given area. In the act, however, this definition was not redefined. Rather, sustained yield was described as a process of planning for yields of forest resources at such a level as to be sustained in perpetuity without impairment of the productivity of the land. The act defined sustained yield as "the achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forests without impairment of the productivity of the land." The bill received support from timber, grazing, and wildlife advocates among groups as disparate as the American Pulpwood Association and the National Wildlife Federation. In practice, the act codified the set of practices and policies already in use on the national forests. Though the Forest Service claimed the authority previously to manage the national forests for multiple uses, the act provided the statutory authority necessary for the Forest Service to defend policies that limited, privileged, or restricted certain activities on federal lands.

Following the passage of the act, the Forest Service engaged in multiple-use planning on federal forests throughout the system. Forest and district-level multiple-use plans were prepared. Despite language in the act that required equal consideration be given to all five uses of the national forest lands, Forest Service budgets remained tied to timber production targets and thus received the largest portion of funds. Though the act codified the rights for non-timber uses of Forest Service lands, the decade following the passage of MUSY saw increased timber harvesting and clearcutting controversies in the national forest system. The budget environment and timber revenue generation guaranteed the continued dominance of timber production in the national forests following the act.

Mumford, Lewis (1895–1990)

LEWIS MUMFORD WAS a humanistic intellectual, social and urban historian, urban planner, and journalist. Born on October 19, 1895, in Flushing, New York, he went on to take undergraduate courses in various subjects that interested him but never actually completed a university degree, being forced to abandon formal education after a diagnosis of tuberculosis. By the time of his death in Amenia, New York, on January 26, 1990, he had established himself and his school of thought, which examined urban morphology and city culture and experience in systematic terms—the city as a human environment and a living thing in its own right.

He began writing commentaries for numerous publications, among them *The Dial*. In 1919 he became an associate editor of that magazine, and the next year Mumford moved to London to work as acting editor of *The Sociological Review*, organ of the Sociological Society. While in England, he became acquainted with the ideas of Ebenezer Howard, including the garden city, and met the protagonists of the town planning movement. From 1931 to 1963, he became a critic on architecture for *The New Yorker*, writing the column "The Sky Line," which was a platform to disseminate his views of urban and social processes.

He was very influenced by the work of Patrick Geddes, a biologist who produced innovative ideas in urban planning and the shaping of modern city that considered the social implications and the ecological integration of the city in the environment. Mumford corresponded extensively with Geddes and adopted the regional survey as a method to explore the city and understand its processes.

Mumford reflected on the shaping of the urban civilization and the role of technological change—technics, in his words—in social processes. He adopted a historical perspective, with natural resources and kinds of energy key factors. From an early optimistic vision, which considered the favorable contribution of technology to improving environmental, social, and economic conditions, he evolved to a rather distrustful perspective on uncontrolled technology and some contemporary urban plans.

In *Technics and Civilization* (1934) Mumford divides the history of technology into three phases: *eotechnics*, *paleotechnics,* and *neotechnics*, each with different resources and energy and identifiable transformations in nature and cities. Technology is not always the same; when armonic and in balance with human nature it is polytechnic, and when disharmonic it is monotechnic. He also introduced the concept of *megamachine*, designating the large hierarchical political organizations that handle humans as simple components. His more pessimistic view of technology was reflected in the double volume *The Myth of the Machine I: Technics and Human Development* (1967) and *The Myth of the Machine II: The Pentagon of Power* (1970).

Mumford called for mobilization against the totalitarian threat in Europe and supported the intervention of the United States; however, after the death of his son Geddes in the conflict he became less optimistic. He wrote and spoke out against atomic weapons and fought United States participation in Vietnam.

In *The Culture of Cities* (1938) Mumford examines the character of a city and writes a history of urbanism. He contributed to the revival of the concept of regionalism with his ecological perspective, recognizing the region as a space integrated with the city. He critically observed the process of suburbanization, proposing recentralization—understood as decentralized planning of small, dispersed, well connected centers, with a low housing and population density, and interspersed green areas—following the principle of bringing the city into the country and the parks into the city. He was awarded the National Book Award in 1962 for *The City in History* (1961), essentially an updating of *The Culture of Cities*.

In 1939, the American Institute of Planners produced the film *The City*, commissioning Lewis Mumford to write the commentary and Aaron Copland to create the musical score. The film is a synthesis of Mumford's vision, displaying the contrast between the effects of urban congestion and life in new planned garden cities such as Redburn, New Jersey, or Greenbelt, Maryland, and portraying the challenges of the modern city.

Mutation

A MUTATION IS a permanent change in the genetic material of a cell, as represented by the genes that compose the deoxyribonucleic acid (DNA) molecules that determine the nature and structure of organic material. The cause of the mutation may be internal and result from a malfunction in the process of transmission from one cell to its successors, or it might be stimulated by an external source such as the proximity of chemicals or radiation.

In accordance with the principles of evolution, it is possible that a mutation may represent a better ability to interact with the environment and more chance of long-term survival with the opportunity to pass the genetic change to subsequent generations. However, it is much more likely that a mutation will be detrimental to the organism's long-term survival chances, since organisms have generally passed through large numbers of previous generations, each of which has offered the small opportunity to adapt better to the environment.

HUMAN MUTATION

Consequently, mutation within humans is most commonly seen in the malformations or deformities caused by the spraying of Agent Orange in the Vietnam War, or the release of nuclear radiation at the Chernobyl power plant. Conditions such as sickle cell anemia are examples of mutations within blood cells.

The process of mutation occurs when codons, which are the genetic codes that specify the number, type, and location of amino acids within the DNA molecule, are altered. Since the molecules are so complex and some amino acids are replicas of each other, a mutation may be unnoticeable or at least trivial in nature. It is also possible that the effect of a mutation may be recessive, in other words, overpowered by the dominant gene that is provided by one of the two parents. While some mutations simply substitute one amino acid for another, others insert a new element repeatedly and these can be very destructive of the cells formed with such DNA. Others produce a localized effect within part of an organism, while different types of mutations affect sex cells that may then be transmitted to new generations. Mutation can be deliberately used in the attempt to create more successful organisms, such as in the case of genetically modified organisms (GMOs), which offer a better yield for farmers. This process has been used as crossbreeding for many centuries and has resulted in the wide variety of dogs and cats, as well as many different strains of rice.

Viruses in particular are liable to mutate themselves through response to environmental conditions that are not predictable or controllable. For example, there is a significant risk of the H5N1 virus known as avian influenza (more commonly "bird flu") mutating from its current form into one that can be transmitted between humans, at which point it would have the capability to cause a pandemic disease.

More positively, genetic modifications may be able to help reduce or eliminate the threat of congenital diseases and conditions and to augment human beings (and other creatures) both physically and mentally through mutation. These issues are controversial.

People who believe that the structure of human life is divinely ordained or that genetic mutation will be used in an inappropriately eugenic way, or who fear the unintended consequences of such changes, oppose genetic modification. Opposition to GMOs is very strong in many countries, especially in Europe, because of a range of ethical, commercial, and health issues.

Mutual Aid

MUTUAL AID IS a term used in a number of areas of life including biology, social relations, economics, and politics. It refers to help that is given by one party to another. The party may be nonhuman or it may be human. In the case of humans, it is usually aid given according to prior agreements. In biology, mutual aid is termed mutualism. It describes the mutual benefit and the interactions that take place between two or more species. The mutualism between two species can be lifelong contact that is physical or chemical. If the mutualism between them is lifelong, it is referred to as symbiosis. Clown fish live in symbiotic relationship with sea anemones. On the other hand, pollinators such as bees that interact with flowering plants have a nonsymbiotic relationship.

The mutual relationship may be obligate (necessary for both to live). Legumes such as alfalfa, clover, peas, beans, lupins, and peanuts are nitrogen-fixing plants that produce nodules rich in nitrogen with the mutual aid of rhizobia bacteria. The relationship is also of mutual aid to gardeners and farmers whose land is enriched with nitrogen in a second mutual benefit. Facultative (either partner can live alone) relationships are nonobligate. The relationship between people and pets is nonobligatory. However, in the case of a seeing eye dog that aids a blind person, the relationship is obligatory. The development of mutual aid relationships between species has been a subject of concern to biologists who specialize in evolutionary developments. One set of relationships that is not mutual aid is parasitism, because the benefit for one is at the expense of the other.

In politics mutual defense pacts are a form of mutual aid. The Constitution of the United States is a mutual defense pact between the states where an attack upon one is an attack upon them all. Historically, all of the American states have had militias that could be called upon to repel an invasion. The principle of mutual aid has guided their organization. Mutual defense can also mean responding to disasters or emergencies. Fire departments in rural areas often have mutual response agreements.

Numerous mutual aid societies have been formed over the years that are aimed at helping people who belong to the group. Insurance is a form of mutual aid. Participants are aiding those who need help while guarding themselves from the risk against which they are insured. Mutual aid groups are often sponsored by social workers to help people who are oppressed, vulnerable, or in need of help to overcome social, economic, or ecological ills. For example, when the Japanese town of Minamata suffered from Minamata disease, many residents and other sympathizers formed a mutual aid society to comfort, aid, and advocate for the redress of grievances of the victims.

Politically, mutual aid has been a principle idea of anarchism and libertarian socialism. Pierre-Joseph Proudhon was a French anarchist and an advocate of mutualism. Russian Prince Peter Kropotkin advocated the development of mutual aid societies. He believed that government was the cause of all social ills. The solution was the abolition of all government. In his anarchistic "state of nature" people would voluntarily join together for mutual benefits and then would trade their products for those of other people in other groups. Kropotkin's vision of a system of voluntary associations that would create an economy where mutual exchanges took place was described in his book *The Conquest of Bread*. He was influenced in his thinking by Darwin's theory of evolution and by the development of mutualism in biology.

Myanmar

A MILITARY JUNTA has ruled Myanmar, commonly known as Burma or the Union of Burma, ever since General Ne Win gained power in 1962. His successors have ruled the country with an iron fist ever since. A tropical country in the path of seasonal monsoons, Burma is about the size of the state of Texas. Its population of 50 million people lives under one of the most oppressive governments in the world.

Although Myanmar's official environmental policy is good (it signed the Kyoto protocol and various other international agreements), high levels of corruption and mismanagement have exposed large swaths of Myanmar's jungles to rampant deforestation. The highly secretive and controlling nature of the Myanmar government makes it difficult to find reliable environmental statistics.

The French oil company Total has developed oil fields in the country and allegedly provides hundreds of millions of dollars in funds to the military government. Oil money has been linked to Myanmar's purchases of arms from China and Russia, though Total denies these allegations and claims that the money is used for economic development.

Although Total and other international companies working in Myanmar would have their own internal environmental regulations, the military junta would have little reason to enforce strict environmental controls. Nobel Prize winner and leader of the democratic opposition Aung San Suu Kyi is being held under house arrest and has been kept incommunicado. With a military government that stifles all dissent it seems unlikely that basic human rights concerns—let alone the social and environmental concerns of the population—will be addressed under the current status quo.

Nader, Ralph (1934–)

RALPH NADER IS a renowned and effective crusader for consumer rights, advocate of general public rights, and environmentalist. His opposition to big insurance companies, "corporate welfare," and the "dangerous convergence of corporate and government power," constantly brings him into conflict with business and government. He was born to Nathra and Rose Nader (both of Lebanese origin), on February 27, 1934, in Winsted, Connecticut. It was probably Nathra Nader's love of politics that inspired Ralph to become a lawyer and a political scientist. Ralph graduated magna cum laude from the Woodrow Wilson School of International Affairs of Princeton University in 1955 with a major in government and economics. He continued at Harvard Law School and graduated in 1958 with honors. As a student at Harvard, Nader became interested in the automobile industry and researched the design of automobiles. In his article "The Safe Car You Can't Buy," published in *The Nation* in 1959, he concluded, "It is clear Detroit today is designing automobiles for style, cost, performance, and calculated obsolescence, but not… -for safety."

After finishing his studies, he served in the United States Army for six months in 1959 before working as a lawyer in Hartford and teaching at the University of Hartford. In 1964 he began work in the office of then Assistant Secretary of Labor Daniel Patrick Moynihan.

Nader continued his earlier research on the automobile industry and in 1965 published *Unsafe at Any Speed*, a study that illustrated the unsafe designs of many American automobiles, especially those of General Motors. General Motors retaliated in part by surveilling Nader. Nader filed suit and, in a case decided by the New York Court of Appeals in 1970, he received a public apology and net settlement of $284,000. He also became an advisor to a Senate subcommittee on automobile safety.

Nader was successful in getting Congress to pass the National Traffic and Motor Vehicle Safety Act in 1966, the Wholesome Meat Act in 1967, and the Clean Air Act and Freedom of Information Act in the 1970s. He also played a key role in the creation of the Environmental Protection Agency, the Occupational Safety and Health Administration, and the Consumer Product Safety Commission. In the early 1980s Nader spearheaded a powerful lobby against Federal Drug Agency approval for mass-scale experimentation with artificial lens implants. He went on to create an organization of energetic young lawyers and researchers known as "Nader's

Raiders." They produced systematic exposés of industrial hazards, pollution, unsafe products, and governmental neglect of consumer safety laws. He has also continued to work for consumer safety and for the reform of the political system through his group Public Citizen.

Nader launched a third party in 1990 focused on the issues of citizen empowerment and consumer rights and to address campaign finance reform, worker and whistle-blower rights, and class-action lawsuit reforms. Nader ran for president as an independent candidate in 1992. In 1996 and 2000, he ran as a nominee of the Green Party with Winona LaDuke as his vice-presidential running mate. In 2004 he ran as an independent with Green Party activist Peter Miguel Camejo as his vice-presidential nominee.

Naess, Arne (1912–)

ARNE NAESS, KNOWN as the father of deep ecology, is a Norwegian ecophilosopher, naturalist, environmental activist, and professor emeritus of philosophy at the University of Oslo. He is the founder of *Inquiry: An Interdisciplinary Journal of Philosophy and the Social Sciences* and the author of more than 30 books. Deep ecology, the movement Naess is credited with founding, critiques mainstream environmentalism and proposes a set of new metaphysical, ecological, spiritual, and sociopolitical alternatives.

Naess's conference paper "The Shallow and the Deep, Long-Range Ecology Movement," given in Bucharest in 1972, was the first recognized formulation of the principles of deep ecology. This paper rejected the idea of the separation of humans and nature in favor of a "relational, total field" image of nature based on "biospherical egalitarianism" in which all ecological beings have an equal right to exist. Naess's work also contrasted his vision of deep ecology with the contemporary or "shallow" environmental movements of the 1970s and 1980s, which he accused of being concerned only with superficial institutional fixes for pollution and resource depletion for the benefit of affluent sectors of society in developed countries, and of thus being anthropocentric.

Other elements of Naess's deep ecology include the principles of diversity and symbiosis, an anti-class posture, the fight against pollution and resource depletion, complexity in place of complication, and local autonomy and decentralization. Sources and spiritual inspiration for deep ecology philosophy are found in Eastern spiritual traditions, Native American traditional religions, Ghandian nonviolence, and selected thinkers from Western religion, philosophy, and art. Deep ecology is a normative value system based on personal change and the transformation of values and understanding toward an alternative way of thinking about the relationships between individuals, society, and nature.

Naess's 1989 theory, Ecosophy-T, his own personal application of the principles of deep ecology and ecological wisdom, involves the achievement of ecological harmony or equilibrium through a fundamental principle of self-realization, or the placement of self as part of nature through the eradication of boundaries between human and ecosystem activities. Naess developed a four-level system to represent his deep ecology framework that is depicted in what he calls the *apron diagram*. Level one encompasses a broad set of philosophical and religious principles such as Buddhism, Christianity, or other sets of norms that influence action and that inform the eight-point Deep Ecology Platform outlined in level two of the apron. These principles, or discussion points, were developed in collaboration with George Sessions, another key deep ecology thinker, and are broadly seen as the unifying features of the deep ecology movement. Combining philosophical ideas with action, the platform's third level expresses the general consequences of the principles in society. Level four expresses the concrete decisions made by individuals in particular situations.

While Naess and extensions of deep ecology philosophy have been criticized as being biocentric and even misanthropic, the anticlass and self-questioning posture within deep ecology seeks to transform human-to-human relationships as well as those between humans and nature. Along the same vein, the stance against pollution and resource depletion is a normative stance based on the idea that all beings—humans included—must be able to satisfy vital needs through the preservation of the diversity of all life forms.

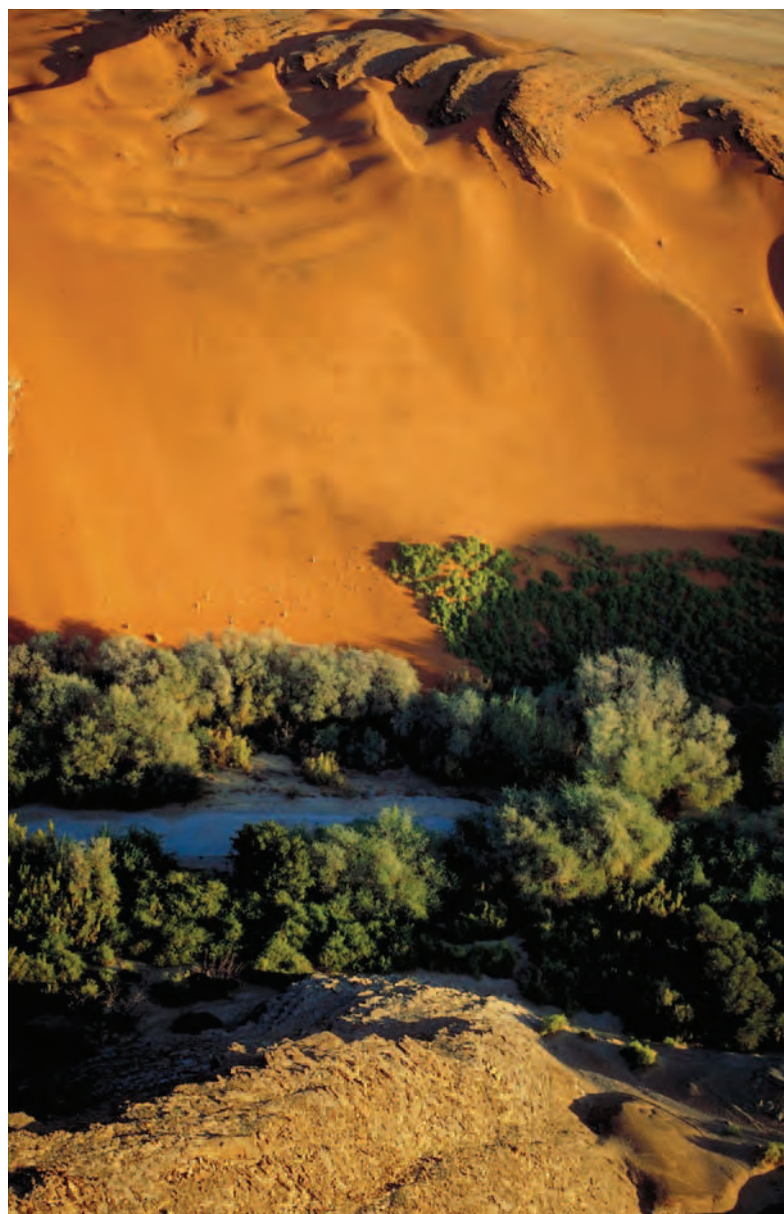
Namibia

NAMIBIA IS A relatively small southern African country of two million inhabitants, but has a rich and diverse cultural and environmental landscape. Formerly known as South West Africa, present day Namibia has four major population groups: the Khoisan (including Bushmen), who are the original inhabitants of southern Africa; the Ovambo, Bantu-speakers largely concentrated in the northern part; the white settlers, mostly of Dutch and German origins; and the Coloreds or Basters, the people of mixed race. These diverse groups were brought together under a single nation state by the colonial boundary-drawing exercise known as the "scramble for Africa" and South West Africa came under German control.

After the end of World War I, the defeated Germans had to cede their colonies to the League of Nations, which passed on the responsibility for administration of South West Africa as a mandate to South Africa. The white minority-ruled state in South Africa decided to rule it as part of its own territory, even after the United Nations rejected South Africa's plea to formally annex South West Africa. Due to years of internal resistance led by the

With 14 percent of its land protected, Namibia is the first country to include environmental protection in its constitution.



South West Africa People's Organization (SWAPO) and external pressure, South Africa finally ended its occupation in 1990 and the independent nation of Namibia came into being.

Namibia is unevenly endowed with natural resources. A large part of the country is desert, and only about one percent of the land is arable. However, the country has huge reserves of nonfuel minerals like diamonds, uranium, lead, zinc, and tin. Mining is a large part of the economy, accounting for more than 20 percent of the country's Gross Domestic Product (GDP). Though its per capita GDP makes it a medium income country, income distribution is highly unequal. From its Gini coefficient, Namibia has the most unequal distribution of wealth in the world—the richest 10 percent of the country's population account for 65 percent of its wealth.

During colonial times, and especially during apartheid, which was extended to Namibia by South Africa, the local population's access to land was extremely limited. Arable land is already scarce and largely restricted to northern Namibia, where the dense Ovambo population is dependent on agriculture. These factors have led to extreme pressure on land in the north, which has made land degradation a serious issue.

The Namibian state has taken environmental issues seriously and in 1992 developed a Green Plan to tackle these problems. The plan seeks to ameliorate problems such as desertification, land degradation, pollution, and biodiversity loss. One of the major programs has been the National Program to Combat Desertification (NAPCOD), which has been operational since 1997 in the entire north-central region of Namibia.

Namibia is the world's first country to include the protection of the environment in its constitution, and more than 14 percent of the country's land is protected. However, not everyone is happy with the current state of affairs. Conflicts have emerged between the state and communities such as the seminomadic Himba, who have been displaced as a result of a large hydroelectric project on the river Cecene.

Narmada Dam

FOR DEVELOPING COUNTRIES, big infrastructure such as buildings, industries, and dams are synonymous to development—the bigger the infrastructure, the more developed a country looks. In the same vein, the first prime minister after independence in India, Shri Jawahar Lal Nehru, had a dream of building dams across large rivers in India. He believed that dams were the temples of modern India and would bring prosperity to rural India through the Green Revolution. The prosperity Nehru envisioned did come to some parts of India.

The Narmada River flows through central India for 1,290 kilometers and divides north and south India. The Narmada Dam Project, another of Nehru's visions, involves construction of a series of dams on the Narmada to support increasing demand for water for irrigation (especially in drought-prone areas of India) and to produce hydroelectricity. Although the idea was first conceived in the 1940s, the project did not begin until 1979.

The government plans to build 30 large, 135 medium, and 3,000 small dams to harness the waters of the Narmada and its tributaries. The height of the largest dam, named the Sardar Sarovar Dam after the first home minister, Sardar Vallabh Bhai Patel, has led to a controversy. With a height of 163 meters it will be the third highest dam in India. The dam is also located in an area with high seismic activity. Social issues, such as relocation of people and allocation of land, add to the concerns about this dam.

Groups that support the building of the dam maintain that the plan would provide large amounts of water and electricity, which are desperately needed for development in the region. Some of the benefits expected from the implementation of the Sardar Sarovar Project are: irrigation, increased drinking water supply, power generation, and some employment. After submerging some agricultural land, it is estimated that building of this dam will allow irrigation of about 1,792,000 square kilometers of land. The water will be spread to about 3,393 villages in Gujarat (75 percent of this area falls in drought-prone areas) and to about 730 square kilometers in the arid areas of another state, Rajasthan (mainly a desert area, but agriculture has flourished where water has been brought in). The dam will also produce electricity and provide drinking water facilities to about 8,215 villages and 135 urban centers in Gujarat.

Although there are benefits to this dam, there is still resistance to its development. The Narmada Bachao Andolan, or Save Narmada Movement, questions the basic assumptions of the Narmada Valley Development Plan and believes that the cost-benefit analysis is greatly inflated in favor of building the dam (and development) and that the plans are based on untrue and unfounded assumptions about the hydrology and seismology of the area. The opposing group believes that the planning of the project does not take all the environmental factors into consideration. They also feel that the construction is leading to large-scale abuse of human rights and the displacement of many poor and underprivileged people who will lose both their land and their livelihoods.

The Sardar Sarovar Project controversy ended up in the Supreme Court of India in the form of a lawsuit decided on October 18, 2000. In a two-to-one majority judgment, the Supreme Court allowed immediate construction of the dam up to a height of 90 meters. It further authorized construction of up to 138 meters in increments of five meters, subject to approval by the Relief and Rehabilitation Subgroups of the Narmada Control Authority. This unfettered clearance from the Supreme Court, despite major unresolved issues on resettlement, the environment, and the project's costs and benefits, was seen as disturbing, especially considering the fact that the World Bank has withdrawn some project funding based on new facts.

A memorandum to the executive of the Operations Evaluation Department (OED) of the World Bank, leaked in 1995, admits serious shortcomings in the environment, resettlement, and rehabilitation components, the project's appraisal, and supervision performance. The evaluation supports most of the conclusions of the Morse Commission on environmental issues and resettlement of people, and rates the World Bank appraisal and supervision as unsatisfactory. Citing problems with the resettlement process, the OED states, "substantial obstacles still remain."

The World Bank had imposed basic conditions such as identifying the number of people to be displaced and completion of resettlement plans, which were supposed to be fulfilled as far back as 1985. On the issue of resettlement, the evaluation reveals that World Bank conditions, which the government of India failed to meet in March 1993, have still not been met. This will cause further delays in dam construction.

In spite of the court ruling allowing construction to proceed on the dam, the struggle continues. Leaders of Narmada Bachao Andolan, most prominently Medha Patkar, insist on their principles of justice, human rights, democracy, and equitable and sustainable development. In 2006 Patkar and others went on a massive hunger strike. The court and government proceeded with the project nevertheless.

The survival of a project of this sort, with its lack of international support and great local controversy, demonstrates the political and ideological momentum of dam building itself and the complex relationships between mastery of rivers, nationalist ideology, and resource politics.

Nash Equilibrium

THE NASH EQUILIBRIUM is the central equilibrium theory in noncooperative game theory. A Nash equilibrium is an outcome where no individual would be better served by changing his or her strategy, considering the strategy choices of all other players thinking the same way. It is the outcome of all individuals in a scenario, their decisions interact and they all seek to maximize their own welfare or utility knowing that others do so as well. John Nash, a mathematician, defined and proved this result in his 1950 dissertation. The Nash equilibrium concept is typically applied to situations in which two or more individuals are making decisions, one or more of their outcomes are influenced by the decisions of others, and they incorporate the decision making of others into their calculations when making their own decisions. Some assumptions underlie the Nash equilibrium, including rationality and, usually, a degree of knowledge regarding other players' wants and beliefs.

The Nash equilibrium has been applied to a variety of situations including imperfect competition in markets, social interaction, animal behavior, and international policy. Nash equilibria are not always socially desirable. Often, on topics of environmental concern, the Nash equilibrium is a typical or likely outcome, but not optimal. For cases of public goods and common property resources dominated by individual decisions rather than government oversight, the socially desirable or socially efficient outcome is not achieved because individuals mostly pursue their own welfare. Individual utility maximization can lead to Nash equilibrium outcomes in which everyone is worse off than if they had cooperated. These outcomes often arise when costs from behaviors are borne by society or a larger group, while the benefits of those behaviors accrue to individuals.

Such is the case for environmental scenarios as varied as maintaining a community garden or the Atlantic cod fishery. In such cases it is typically in an individual's best interest that all other players make choices contributing to the socially optimal outcome, while they themselves make a choice that benefits the individual, a behavior known as "free-riding." In the case of fishing, for example, an individual fisherman may ignore legal or conventional fishing limits, knowing (or hoping) that other fishers will not, thereby maximizing his fishing take at the expense of others. Since all fishers act with the same knowledge and motivation, in theory the result is one in which all fishers behave in this way—reaching a Nash equilibrium that is undesirable, since it leads to overfishing and depletion of the resource for all involved. This is the theorized reason that unregulated fishing, hunting, logging, or other resource extraction can lead to rapid depletion. Government intervention can often improve these situations by limiting individual options.

Efforts to control climate change are an example of individual behavior leading to a socially undesirable outcome. Carbon dioxide emissions on their own do not have negative local impacts. When there are positive costs to limiting carbon dioxide emissions, the costs must be borne by individuals or individual nations, but the benefits of carbon dioxide suppression are spread across the entire planet. Without a powerful authority capable of enforcing a socially optimal agreement among nations, this reduction is unlikely to occur when free-riding options exist or individual priorities differ.

Much research has been done regarding means of achieving a social optimal that differs from a Nash equilibrium. Researchers in cooperative game theory posit that binding contracts, possibly involving side payments, might help, and theoretical and behavioral social research suggests that punishment for cheating or free-riding can be useful when games are repeated.

National Environmental Policy Act (NEPA)

THE NATIONAL ENVIRONMENTAL Policy Act (NEPA) of 1969 is an important procedural land use planning statute followed by all federal agencies as well as local (state, county, city, or industrial) projects that require a federal permit or receive funding from federal agencies. Often referred to as the "Magna Carta" of U.S. environmental policy, the statute also empowers any member of the public to take part in many decisions that affect federal public lands through information gathering, commenting, and even agency appeals. When President Richard Nixon signed NEPA into law on New Year's Day, 1970, he hailed the Act as providing the "direction" for the country to "regain a productive harmony between man and nature."

In December 2005 the House Resources Committee's NEPA Task Force proposed weakening NEPA.

PURPOSE AND PROVISIONS

Agencies such as the Bureau of Land Management, U.S. Forest Service, and U.S. Fish and Wildlife Service must comply with the various levels of the NEPA planning process before federal actions are undertaken. A multitude of actions on federal public lands such as timber sales, mining permits, grazing permits, road building, land sales, wildlife management, ski area development, water developments, and even agency-wide planning that guides entire geographical regions are subjected to the NEPA planning process.

Under NEPA, federal agencies are required to analyze and disclose environmental consequences of proposed actions on federal public lands. For instance, in Section 102 of the law, agencies are required to reveal: (1) the environmental impact of the proposed action, (2) any adverse environmental effects that cannot be avoided should the proposal be implemented, (3) alternatives to the proposed action, (4) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, and (5) any irreversible commitments of resources that would be involved should the action be implemented.

The NEPA process thus requires the federal agency proposing an action or project to produce an environmental assessment (EA). If the proposed action is found to be of a less significant nature, agencies will issue a "finding of no significant impact" (FONSI) and a decision notice (DN).

Citizens and the public (towns, nongovernmental organizations [NGOs], chambers of commerce, tribes, businesses, and so on) can supply comments in the scoping and draft phases of these projects. For instance, the public can identify important resource concerns they may have, identify alternatives to projects (as well as oppose agency plans outright), and appeal and refute the FONSI and DN by concisely and thoroughly stating how they feel the federal action will, for instance, violate a Land and Resource Management Plan (in the case of the U.S. Forest Service) or harm endangered species of plants, insects, or animals. There is no geographical restriction placed on public comments; residents of a state can comment on federal actions in any other state or U.S. territory.

If the federal action is found to be of major consequence, one that broadly and significantly affects the quality of the human environment, the agency must undertake an extensive environmental impact statement (EIS). According to Robert Dreher:

> Analysis of alternatives is the "heart" of an EIS. Comparing the environmental impacts of an agency plan with the impacts of alternative

courses of action defines the relevant issues and provides a clear basis for choosing among options. By considering and, where appropriate, adopting reasonable alternatives that meet agency objectives with less environmental impact, federal agencies can achieve NEPA's environmental protection goals while implementing their primary missions.

After completing an EIS, it is also possible that an agency will abandon all or part of its proposal.

Although NEPA is an impetus for an agency to carefully examine the consequences of its decision for other resources and values, NEPA does not *require* that an agency change its decision to take action even if its final choice is in fact detrimental to the environment. Many federal agencies have eventually made environmentally disastrous decisions even after their completion of the NEPA process showed that they may potentially be breaking other environmental laws, such as the Endangered Species Act. Federal agencies have wound up fighting thousands of lawsuits brought by public interest environmental organizations that wish to overturn harmful agency decisions.

NEPA also created the President's Council on Environmental Quality (CEQ), which is responsible for advising the president and vice president on national and international environmental policy matters. The council also ensures that federal agencies adhere to NEPA guidelines.

ACCOMPLISHMENTS

Some of the more important aspects of NEPA are that its requirements have added greater public accountability for federal agencies, as well as increased the visibility of, and accessibility to, federal agency decision making. It is "action forcing," requiring agencies to study the potential impacts of their actions before environmental damage can occur, rather than allowing nuisance laws to resolve the problems after the damage is done. It calls on federal agencies to use the science of ecology and look more holistically at cumulative impacts of proposed actions.

Before the implementation of NEPA, federal agencies (with little or no advance notice or public debate) were able to embark upon massive timber cutting programs that destroyed entire ecosystems, and even dam valleys to the detriment of homes, businesses, farms, and habitat. With NEPA, the public has a useful tool for staying informed and influencing potentially harmful decisions that affect themselves and the environment.

NEPA has resulted in prominent success stories. In 1971 environmentalists stopped the Army Corps of Engineers from dredging the Cache River in Arkansas, where the recent sighting of the ivory-billed woodpecker, once thought extinct, later occurred. In the mid-1980s, the Pacific Northwest experienced a severe gypsy moth invasion. The U.S. Department of Agriculture (USDA) proposed to spray the town of Salem, Oregon, with the toxic pesticide carbaryl. Concerned citizens suggested the alternative biological insecticide B.t. (*Bacillus thuringiensis*). When the USDA refused to consider this alternative in its EIS, the citizen group sued the USDA in court and won. The agency later reported that B.t. use led to one of the most successful moth eradication programs in the history of the agency.

At the time of this writing, NEPA is under attack. In December 2005 the Republican staff of the House Resources Committee's NEPA Task Force released 13 draft proposals to amend and rewrite important definitions within NEPA. These reforms were supported by agency officials who feel that their decision-making autonomy is restrained by NEPA provisions, resource extraction and user industries (resorts, motorized recreation, and so on), and their political allies who would like expedited decisions and easier access to resources.

Some of the proposals to reform NEPA include: (1) exempting large categories of government activity from the NEPA environmental review process; (2) restricting the substance of environmental analysis under NEPA, in particular by allowing federal agencies to ignore environmentally superior alternatives to a proposed action; and (3) limiting opportunities for the public to comment on and challenge agency decisions.

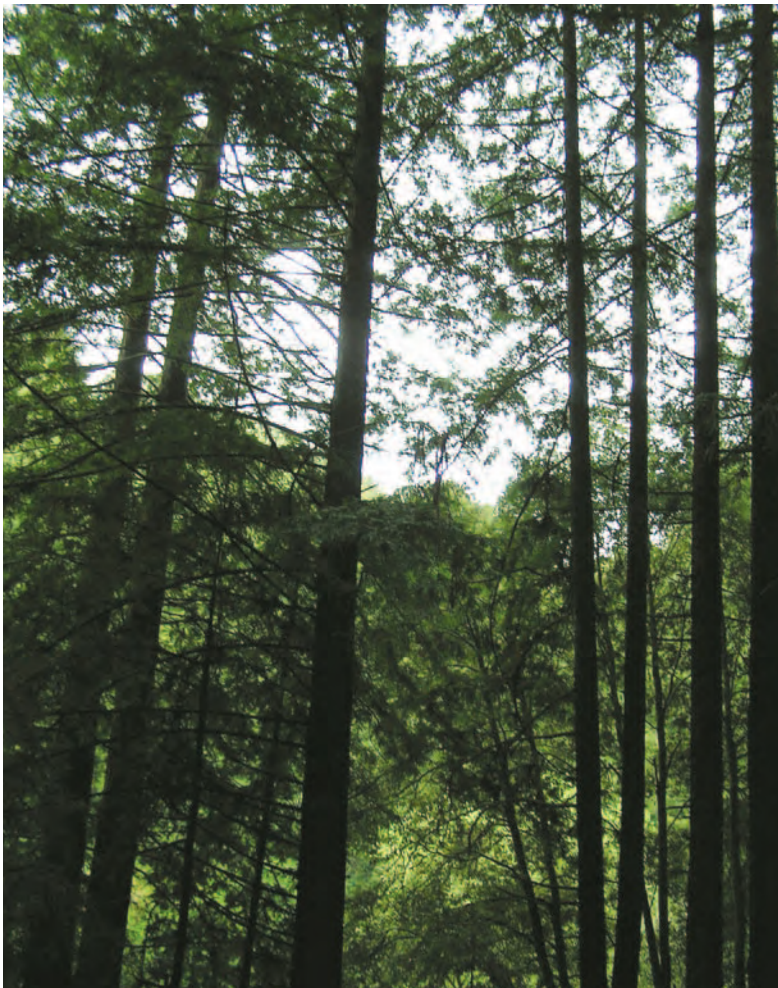
National Forest Management Act (NFMA)

THE NATIONAL FOREST Management Act (NFMA) of 1976 (NFMA) is the principal statute governing the administration of the national forests. The act is an amendment to the Forest and Rangeland Renewable Resources Planning Act of 1974, which called for the management of renewable resources on national forest lands. The 1976 legislation reorganized and expanded the 1974 act, requiring the Secretary of Agriculture to assess forest lands and develop and implement a resource management plan, regularly revised, for each forest unit. NFMA also set standards and procedures for timber harvesting.

The amended act emerged out of controversy over clear-cutting practices in the Monongahela National Forest in West Virginia and the Bitterroot National Forest in Montana. Throughout the late 1960s, efforts by West Virginia legislators and conservation organizations culminated in a successful legal battle to stop clear-cutting practices in the Monongahela. During the same period, a University of Montana study led by Arnold Bolle concluded that management of the Bitterroot National Forest was focused almost solely on maximum timber yields, leading to serious ecological problems. In the years after these debates, courts throughout the United States applied the Monongohela decision to shut down timber sales elsewhere in the national forest system. Facing a serious challenge to its ability to govern national forests, and an equally serious challenge to the viability of commercial timber production on federal lands, the U.S. Forest Service (USFS) pursued a comprehensive legislative remedy to the problem of timber harvesting practices on federal land.

Two competing legislative solutions sought to resolve the problem of timber production in the national forests. One, sponsored by West Virginia Senator Jennings Randolph and written with the help of Arnold Bolle and others, enjoyed the broad support of conservation organizations such as the

In 2005 the USFS created a broad categorical exclusion from its Environmental Impact Statement obligations.



Sierra Club, which saw in the act a means to increase public participation in forest planning, increase transparency in USFS decision making, and reduce the power of the timber lobby in setting forest planning agenda. However, the bill that ultimately became NFMA was one sponsored by Senator Hubert Humphrey and strongly supported by the timber industry.

NFMA added prescriptive requirements related to the identification of various uses and provided specific limits to timber harvests of the national forests. In January 2005 the USFS issued a new forest planning rule creating a sweeping categorical exclusion from its previous obligation to conduct an Environmental Impact Statement (EIS) during forest planning. These new standards release the USFS from meeting specific environmental outcomes in operation, and instead dictate process standards. In regard to public lands management, the changes have been presented as an attempt to streamline forest planning and direct resources away from lengthy planning processes prescribed by NFMA.

National Geographic Society (NGS)

THE NATIONAL GEOGRAPHIC Society (NGS) is the world's largest nonprofit scientific and education institution. Established in 1888 under its first president, Gardiner Greene Hubbard, the NGS aims to increase and disseminate geographical knowledge of the natural and social world. Headquartered in Washington, D.C., the Society is involved in a wide range of activities. Principal among these has been the production of the *National Geographic Magazine,* which for over a century has brought information on the environment, nature, society, and culture to millions of people in an accessible form. Now published and distributed in 30 languages, it has a worldwide circulation of nine million copies, of which 2.1 million copies are published in local languages other than English. As its average reader in the United States is aging—the majority are over 50 years of age—or moving to the internet, the NGS has evolved into new media and new markets. In association with the broadcasters NBC, FOX, and BSkyB, the National Geographic Channel is broadcast in 25 languages and claims to reach more than 200 million households in 146 countries. Its Web site claims an average 55 million page views a month. Earnings from these activities have provided grants for scientific and interdisciplinary field research, conservation and education projects, and expeditions. As a consequence, the NGS can be regarded as a powerful media organization that must balance the commercial realities of publishing and television with its educational and scientific mission and the demands of environmental politics.

Historically, the *National Geographic Magazine* embodied society's interest in advancing and disseminating knowledge as part of its contribution to public education and civic improvement. But the Society originally cultivated an outlook that reflected Western supremacy over the rest of the world. Scholars have suggested that the Society exercised a kind of conservative humanism that celebrated diversity and promoted universal values while permitting it readers to consign non-Western peoples to an earlier stage of progress. This comfortable armchair geography, shaped in the neo-imperialist contexts of the 20th century, typically obscured Western relationships with the Global South. Other critics have suggested that today the Society presents uncritical reflections on the consequences of globalization and tends to commodify nature for human spectacle.

Despite these criticisms, however, the NGS is an unrivalled advocate for the natural world, maintains a firm commitment to conservation and preservation, and continues to ensure geographical issues remain a focus of public debate. It has not taken a conservative approach to debating climate change, for example, nor has it balked from underlining the relationships between consumption and resource and environmental exploitation around issues such as diamond production. Somewhat paradoxically, despite the NGS's awesome media presence, Americans' knowledge of basic world geography is among the poorest in the Western world according to the National Geographic–Roper Survey of Geographic Literacy. In response, the NGS has developed programs to address "geographical illiteracy" in American schools and introduced a range of other publications including *National Geographic Explorer Classroom Magazine* and *National Geographic Kids Magazine*. This ongoing interest in education reveals its commitment to progressive change and demonstrates its continuing faith in geography as a path to both self-knowledge and responsible use of the planet's natural and cultural resources.

National Marine Fisheries Service (U.S.)

ESTABLISHED IN 1871, the National Marine Fisheries Service (NMFS) is the oldest conservation agency in the United States. Originally called the Commission of Fish and Fisheries, this federal agency was later renamed the NMFS and reorganized as part of the newly-established National Oceanic and Atmospheric Administration (NOAA) in 1970.

The commission initiated the nation's first scientific studies of fish species and biology in Woods Hole, Massachusetts, and was devoted to the protection, study, management, and restoration of fisheries. Although fisheries research began in Woods Hole as early as 1871, a permanent station did not exist there until 1885. A center of marine science, Woods Hole was conceived and implemented largely by one man, Spencer Fullerton Baird, who was the first U.S. Commissioner of Fisheries.

Also known as NOAA Fisheries, the NMFS is housed within the Department of Commerce and tasked with the mission of "stewardship of living marine resources and their habitat through science-based conservation and management and the promotion of healthy ecosystems." As such, NOAA Fisheries has an obligation to conserve, protect, and manage living marine resources in a way that ensures their continuation as functioning components of marine ecosystems. Its mission also includes providing economic opportunities and enhancing quality of life for the public so that "the American people may enjoy the riches and benefits of healthy and diverse marine ecosystems." This requires managing valued marine resources in such a way as to protect the health and biodiversity of important aquatic ecosystems while also maintaining and enhancing current and future opportunities for their sustainable use.

Many factors, both natural and man-made, affect the status of fish stocks, protected species, and ecosystems. Although these factors cannot all be controlled, the agency strongly influences many of them through the use of best available scientific and management practices. Maintaining and improving the health of marine systems is a difficult task that involves balancing a diverse array of public needs and interests without compromising the long-term biological integrity of coastal and marine ecosystems.

NOAA Fisheries is responsible for the management, conservation, and protection of living marine resources within the United States's Exclusive Economic Zone (from state waters to 200 nautical miles offshore). NOAA Fisheries also plays a supportive and advisory role in the management of living marine resources in coastal areas under state jurisdiction, as well as providing scientific and policy leadership in the international arena and implementing international conservation and management measures as deemed appropriate.

NOAA Fisheries derives its mandates and authorities from numerous statutes, most importantly the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the Endangered Species

Act (ESA), and the Marine Mammal Protection Act (MMPA). Under these acts, NOAA Fisheries assesses and predicts the status of fish stocks, ensures compliance with fisheries regulations, and works to recover protected marine species (i.e., salmon, whales, and turtles) without unnecessarily impeding economic and recreational opportunities.

With the help of six regional offices and eight councils, NOAA Fisheries works with local communities and proximate land management agencies on a diverse array of fishery management issues. Through such means as collaborating with commercial and recreational fishermen for the collection of biological data and coordinating science and management strategies with regional and state interests, NOAA Fisheries continually strives to balance competing public needs and interests in the use and enjoyment of the nation's ocean resources.

National Monuments

A NATIONAL MONUMENT is a historic or natural landmark, a historic or prehistoric structure, or other object of historic or scientific interest set aside by a national government for public enjoyment or edification. Ireland, Scotland, Singapore, and Wales have national monuments or systems of national monuments. The most extensive system is that of the United States.

In the United States, there are nearly 100 national monuments covering more than 70 million acres and ranging in size from less than 1 acre to 11 million acres. National monuments are different from national parks in that national monuments are usually smaller areas established to protect specific features of historic or scientific interest rather than spectacular natural areas with a wide variety of features (although the 11-million-acre Wrangell–St. Elias National Monument proclaimed in 1978 was larger than any national park). Hunting, mining, and other consumptive uses such as grazing are permitted in national monuments, but are generally prohibited in national parks.

While only Congress can legislate national parks, a process that may take many years, the president can proclaim national monuments, a process that takes only the stroke of a pen. Since 1906 presidents have proclaimed more than 100 national monuments, many of which Congress has subsequently converted to national parks. Grand Canyon, Grand Teton, Zion, Bryce Canyon, Capitol Reef, and Olympic National Parks all originated as national monuments. Congress has also created 38 national monuments. The National Park Service has responsibility for administering most of the national monuments. The U.S. Bureau of Land Management (BLM), the U.S. Fish and Wildlife Service, and the U.S. Forest Service are the primary agencies that administer the rest.

The president derives the authority to create national monuments from the 1906 Antiquities Act, which authorizes the president to proclaim national monuments on federal lands that contain "historic landmarks, historic and prehistoric structures, and other objects of historic or scientific interest." The president is instructed to reserve "the smallest area compatible with the proper care and management of the objects to be protected." The original purpose of the act was to protect objects of antiquity, such as cliff dwellings, pueblos, and other archeological ruins in the southwest. Its sponsors assumed that national monuments would be small in area and confined to the southwest. The act proved to be loosely written, however, and enterprising presidents have been able to apply it to a wide range of sites. Although its use has been challenged in court, it has become a powerful executive tool for shaping sometimes controversial conservation policies in the United States.

That the Antiquities Act would not be used in the limited way its sponsors had intended became immediately evident when President Theodore Roosevelt used the reference to "objects of…scientific interest" to proclaim a natural geological feature, Devils Tower in Wyoming, as the first national monument in 1906. President Roosevelt continued to interpret the act broadly and in 1908 used it to proclaim an even larger "object of scientific interest": the 800,000 acre Grand Canyon National Monument.

This expansive use of the Antiquities Act encountered no significant congressional opposition until 1943, when President Franklin D. Roosevelt created Jackson Hole National Monument in Wyoming. The president saw this as a way to accept a donation of lands acquired by John D. Rockefeller, Jr., for addition to Grand Teton National Park after Congress had declined to authorize the park expansion.

Critics protested that the president was using the Antiquities Act to circumvent Congress. Congress passed a bill to abolish the monument, but the president vetoed it. The state of Wyoming also challenged the proclamation in court. When the monument was finally incorporated into Grand Teton National Park, as a concession to opponents, the legislation prohibited further use of the Antiquities Act in Wyoming without the approval of Congress.

For decades afterward presidents used their authority to create national monuments sparingly and usually with advance congressional consultation and support. The next substantial use of the proclamation authority came in 1978, when President Jimmy Carter proclaimed fifteen new national monuments in Alaska after Congress had adjourned without passing a major Alaska lands bill strongly opposed in that state.

The presidential proclamation authority was not used again until 1996, when President Bill Clinton proclaimed the 1.7 million acre Grand Staircase–Escalante National Monument on public land managed by the BLM in Utah. This action was controversial in Utah and several cases were filed challenging the designation of the monument on a number of grounds. The president directed that the monument should continue to be managed by the BLM, making it the first national monument that the BLM would manage. President Clinton subsequently used the presidential proclamation authority to establish 14 more new national monuments and significantly expand others. In 2001 the BLM created a National Landscape Conservation System to administer these new national monuments and other areas already under its jurisdiction.

National Oceanic and Atmospheric Administration (NOAA)

AS A SERVICE to all American citizens, the National Oceanic and Atmospheric Administration (NOAA) plays an important role in daily life. The stated mission of NOAA reads: "to understand and predict changes in the Earth's environment and conserve and manage coastal and marine resources to meet our nation's economic, social, and environmental needs."

In the early 19th century Thomas Jefferson set up the first science-based agency in the United States, called the Survey of the Coast. It was formed primarily to make sure that coastal areas were protected during times of hostility and war. The Survey of the Coast, the Weather Bureau, and the Bureau of Commercial Fisheries, along with other agencies, merged and evolved into NOAA over the course of almost two centuries. On October 3rd, 1970, then President Richard Nixon established NOAA under the Department of Commerce to help serve a national need for resource protection and weather knowledge for "better protection of life and property from natural hazards" and "for a better understanding of the total environment…[and] for exploration and development leading to the intelligent use of our marine resources." In order to accomplish its main goals, NOAA operates through six major organizations: the National Weather Service; the National Ocean Service; the National Marine Fisheries Service; the National Environmental Satellite, Data and Information Service; NOAA Research; and Program Planning and Integration.

Some of the agency's major functions are regulating the use of natural resources of marine and coastal ecosystems; understanding and interpreting weather and changes in climate so that other agencies can relay information and citizens can respond properly; providing the data necessary for weather forecasts and water cycle events like floods, storms, or droughts; and providing information about the weather to commercial and individual transportation agencies in order to keep transport systems running effectively. Through the National Weather Service, NOAA also acts as an impartial supplier of environmental information about the weather and the oceans.

NOAA information and recorded data is a valuable national resource. National Weather Service and NOAA environmental and weather satellites gather vital information beyond current temperatures and weather. Data is collected from many different domains, such as oceans, coastal areas, agricultural regions, and forest fire zones, which often leads to early, sometimes life-saving detection of forest fires and new volcanic ash. Also, NOAA serves as a provider of environmental stewardship services in the course of managing the environments of coastal and marine areas by regulating land use, supervising fisheries and marine facilities, and protecting endangered species.

Besides physically monitoring resources in coastal and marine areas, NOAA researches ecosystems, climates, weather types and systems, water and the water cycle, and transportation and commerce. Data collected by NOAA is used to study important phenomena such as hurricanes, solar flares on the sun, tornadoes, ocean tides and currents, and holes in the ozone layer. Through the recognition of the close link between the world's oceans and its delicate atmosphere, NOAA has harbored the same philosophy of protection and conservation of natural resources since its creation in the early 1970s.

National Parks

NATIONAL PARKS ARE widely recognized as an American invention and export, created in the 19th century western United States and eventually adopted in nearly every country in the world. Wallace Stegner once remarked that national parks were the best idea America ever had. Perhaps, but by the end of the 20th century, scholars had begun to critically reassess the idea of national parks as an unmitigated good, contributing new insights to our understanding of nature-society relations.

THE YELLOWSTONE MODEL

The world's first national park was created in the western United States, though it is debatable whether it was Yosemite or Yellowstone. Yosemite was actually the first federally designated protected area, created by a Congressional act signed by President Abraham Lincoln in 1864. However, it remained under the jurisdiction of the state of California and did not become part of the federal national park system until 1890. Yellowstone, which the U.S. Congress established in 1872 as a federally controlled park, is thus generally acknowledged as the world's first.

Since Yellowstone became the prototype on which parks in other countries would be modeled, its enabling legislation is significant. Congress declared the territory in present day Wyoming and Montana to be:

> hereby reserved and withdrawn from settlement, occupancy, or sale under the laws of the United States, and dedicated and set apart as a public park or pleasuring ground for the benefit and enjoyment of the people; and all persons who shall locate, or settle upon, or occupy the same or any part thereof, except as hereinafter provided, shall be considered trespassers and removed therefrom.

The legislation further called on the executive branch of the federal government to establish regulations that "provide for the preservation, from injury or spoliation, of all timber, mineral deposits, natural curiosities, or wonders within said park, and their retention in their natural condition." Key elements of the legislation, which have subsequently come to define national parks worldwide, are the placement of ownership and administration with the central government, prohibitions on settlement and occupancy, emphasis on public recreation, mandate to preserve natural conditions, and state's right of eviction. These provisions, which have proven over time to be frequently contradictory and controversial, collectively provide the legal definition of a national park.

The national park idea was quickly adopted in other European settler colonies, particularly in the British Dominion territories. Between 1879 and 1890, Australia, New Zealand, and Canada all created their first national parks. Countries in other regions were slower to embrace the national park idea. Sweden established Europe's first in 1910, Belgium's King Albert, following a visit to Yellowstone, created Africa's first in 1925 in the Belgian Congo, and in South America, Argentina led the way, designating the first park in 1934.

COLONIALISM

The forces behind the historical development of a global national parks movement were complex, but have much to do with the rise and fall of European colonial empires. As European empire reached its height at the turn of the 20th century, hunters, scientists, and philanthropists in Europe created a variety of international organizations concerned with nature protection in the colonies. One of the more prominent was the London-based Society for the Preservation of the Fauna of the Empire (SPFE), which designed and promoted international agreements among European colonial powers. By the 1930s it had pushed through an international convention for African colonies that emphasized national parks, explicitly modeled after Yellowstone, as the primary instruments of conservation. The onset of World War II, however, delayed any serious progress in the creation of national parks in the colonial world.

THE GLOBAL MOVEMENT

Postwar international politics and the rise of institutions of global governance transformed the global national parks movement. Beginning with the founding of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1947, there was a proliferation of organizations with direct interest in national parks. Chief among these is the International Union for the Conservation of Nature and Natural Resources (IUCN, later renamed the World Conservation Union). Established in 1948 under UNESCO auspices, the IUCN was delegated, among other duties, the task of coordinating and monitoring a global network of protected areas. It established the United Nations List of National Parks and Equivalent Reserves, adopted a global biogeographic classification system that is used to assess, map, and plan protected area coverage worldwide, organized a series of decadal world congresses on national parks, and created a global protected area classification system. Under the IUCN's classification system, a national park is defined as a "natural area of land and/or sea, designated to (a) protect the ecological integrity of one or more ecosystems…(b) exclude exploitation or occupation…and (c) provide a foundation for spiritual, scientific, educational, recreational and visitor opportunities…" Administration and control is ideally placed in the hands of each country's central political authority.

The IUCN's definition substantially reflects the legislation that established Yellowstone National Park. But not all of the world's national parks conform to this model. One of the reasons that the IUCN sought to standardize the definitions of protected areas is because the meaning of the term *national park* varied geographically. In some European countries, for example, national park laws allow occupation and exploitation and as a result parks may include towns, villages, agricultural fields, mines, and logging operations. Such international variations in national parks hint at the importance of the specific political, cultural, and historical context in shaping their meaning and purpose.

NATIONAL IDENTITY

A wide range of cultural and political impulses led to the emparkment of Yosemite and Yellowstone. Most important was a prevailing interest among the American political and cultural elite in constructing a coherent national identity, rooted in the landscapes of nature and distinct from settlers' origins in Europe. For writers such as Ralph Waldo Emerson and landscape painters such as Thomas Moran, the source of American's unique national identity could be found in what were perceived to be North America's abundant and monumental natural landscapes. The idea that these landscapes could be preserved in national parks as expressions of American national identity has two components. First, that these monumental landscapes are uniquely North American and that settlers' encounters with them have forged a distinct national identity. Second, that by preserving them, Americans can renew their common sense of national self through periodic visitation. In the 1860s, with the federal government seeking to reunify the United States and forge a common national identity following the Civil War, the national park idea's time had come. Their landscapes soon "became symbols of American national identity."

National parks were also important to the formation of national identity grounded in nature and natural landscapes in the European settler colonies of Africa. Kruger, established in 1926 as the continent's second national park, played an important role in the formation of a collective national identity among white settlers in the early years of the South African Republic. In Southern Rhodesia (now Zimbabwe), the location of Cecil Rhodes' grave in Matopos National Park helped mark the rugged landscape as a symbol of (white) nationhood and "the ceremonial heart of the Rhodesian nation."

TOURISM

The early national parks movement also found support among business interests, particularly in the railroad and banking industries. Business interests hoped to profit from increased railroad passenger traffic and helped lobby for national park establishment. Tourist traffic increased quickly in Yosemite Valley in the years immediately following its designation as a park, and grew exponentially after the completion of the transcontinental railroad in 1869. Critics soon began complaining about crowds and the damage they caused to the park's environment. Thus one of the central contradictions in the national park idea was evident from the beginning. Which is, the more parks are treated as a "pleasuring ground" or managed for "recreational and visitor opportunities," the more likely that pursuit of tourism profits will conflict with the goals of nature preservation.

Outside North America and the British Dominion territories, the movement to create national parks came later and under very different circumstances. During the height of European colonialism, efforts to create national parks began to develop after 1930, mostly promoted by such groups as the SPFE and their equivalents in other European metropoles. Questions of nationalism and national identity played less of a role in park creation in those colonized territories without significant settler populations. Following World War II, the number of national parks created in the colonial territories of Africa and Asia increased, though slowly. Wildlife conservation was an important motivation, but new political and economic interests were emerging.

As the colonial world headed toward political independence from Europe in the 1950s and 1960s, international conservationists grew uneasy, wondering if the new governments would be sympathetic to the national parks idea. International conservationists sought to convince the emerging independent governments that establishing national parks would be a sign of their political maturity, marking their entry into the global community of "civilized" countries. Perhaps a more convincing argument to cash-strapped Third World leaders was that a lucrative international tourism industry could be built on a foundation of national parks. To rally political support among their national citizenries—which, by and large, were from rural, agrarian backgrounds and held interests often at odds with the national park model—the newly independent governments used advertising and school curricula to convince the masses that their parks and wildlife should be a source of national pride.

RECENT CRITIQUES

In the years following decolonization a veritable global conservation boom occurred, marked by an enormous increase in the number of national parks in the world. More than half of the world's national parks, which numbered 3,881 by 2003, have been created since the 1970s and most of these were established in tropical Third World countries emerging from colonial rule. While the number and areal coverage of national parks have expanded and their ecological importance grown, scholars from a variety of disciplinary perspectives have begun to critically examine the history, cultural transferability, social distribution of costs and benefits, and ecological efficacy of the Yellowstone model.

Influenced by a broad range of theoretical positions, including postcolonialism, post-structuralism, and nonequilibrium ecology, scholars have begun to challenge the moral certitude of mainstream histories of the national park movement. Earlier "definitive" histories treated the preservation of national parks as a story of moral and political triumph. While supporting the goal of environmental conservation and biodiversity protection, recent studies have taken a more critical approach, suggesting that the Yellowstone model for national parks raises serious questions of social justice and ecological efficacy.

FORTRESS CONSERVATION

One of the principal themes in recent critiques is that many, if not most, national parks have been created through a process of displacement of local populations, the enclosure of local commons by the state, and the dispossession of the territorial claims of sovereign nations. Scholars refer to the Yellowstone model as "fortress conservation," whereby nature is locked away inside the boundaries of the national park and society is locked out. The implementation of this approach in most cases required the curtailment of local resource use and access and in many cases the eviction of entire communities, thus constituting a form of enclosure.

Historically conservation enclosures have been conducted with minimum involvement of resident populations and the state has often resorted to force in enforcing evictions and curtailing access. In east Africa, for example, pastoralists have lost over 20,000 square kilometers of grazing commons to national parks and game reserves in Kenya and 3,234 square kilometers in Tanzania's Mkomazi Game Reserve alone. Historians recently have linked the establishment of U.S. national parks to the concept of "manifest destiny" and the dispossession and removal of Native American peoples to a system of reservations.

EFFECTS OF POPULATION DISPLACEMENT

The issue of displacement suggests a second theme in recent critiques, which is that advocates of fortress style parks have tended to disregard historic human occupation and its effects on the ecology and landscape of territories targeted for preservation. In contrast, critical studies of U.S. parks detail how various Native American tribes had occupied, used, and significantly shaped the ecology of such iconic parks as Yosemite, Yellowstone, and Glacier. In south Asia and sub-Saharan Africa as well, research has identified areas of critical wildlife habitat in national parks that are the product of past occupation and use. Where east African pastoralist land use practices have helped to create favorable wildlife habitat conditions, their exclusion could actually be detrimental to biodiversity. Often park managers must implement practices such as controlled burning, wildlife culling, and brush clearance in an attempt to slow undesirable ecological change, in effect mimicking the influence of evicted populations.

CLASS AND RACE

A third theme in the critical literature concerns the role of national parks as symbolic landscapes in the construction of national identities, which tended to be restricted and exclusionary. Early ideas regarding U.S. national parks appealed to white, bourgeoisie identity, suggesting that only the cultivated classes of certain "races" could fully appreciate the wild grandeur of nature. Native Americans resident in the national park territories were seen at best as too culturally backward and uncultivated and at worst too degenerate and savage to appreciate the natural landscapes. Black Africans did not belong inside colonial-era African national parks, which had little or nothing to do with reaffirming black African identity. During the Apartheid era in South Africa, black residents were legally restricted from entering such powerful symbols of white South African identity as Kruger National Park.

BIODIVERSITY

Finally, critics of the fortress conservation model argue that it is based on the notion of steady state or stable equilibrium ecology that has been challenged by new ideas of nonequilibrium ecology. Attempts to bound and "preserve" nature through management interventions to halt ecological change have been ineffective where "biodiversity depends directly upon natural patterns of disturbance." The fortress model is based on the idea that biodiversity conservation can best be achieved by creating protected areas where ecosystems can be maintained in perpetuity, undisturbed by human activities. However, nonequilibrium ecology suggests that flux, dynamism, and nonlinear and unpredictable change, not some idealized "natural" stasis, are the ecological norm.

In sum, critical assessments of fortress approach to national parks suggest that it is deeply flawed for reasons of ecology, politics, and social justice. In ecological terms, global biodiversity losses have accelerated during the same period in which the number of

More than 125 years after its creation, Yellowstone National Park began working with the Native American tribes to identify, protect, and provide access to sacred and ceremonial sites within the park's boundaries.

parks and equivalent reserves increased exponentially. The emphasis on the Yellowstone model has meant that communities are displaced and local commons enclosed on principle, raising questions of social justice. Efforts to address these problems are evident in some of the current trends in national parks.

CURRENT TRENDS

Three somewhat interrelated current trends in thinking on national parks are worth noting. The first has to do with biodiversity conservation. The 1992 Convention on Biological Diversity now provides the framework and rationale for international efforts to stem biodiversity loss, focusing on *in situ* conservation in national parks and protected areas. So-called biodiversity hotspots—geographic concentrations of high biodiversity—are being mapped worldwide and targeted for national park or similar protected status. Because national parks are viewed as the primary containers of the world's biodiversity, their number and importance will continue to grow.

A second trend involves new initiatives to resolve or mitigate the historic displacements of communities from national parks. For example, more than 125 years after its creation, Yellowstone National Park hired its first staff anthropologist to begin working with the Native American tribes to identify, protect, and provide access to sacred and ceremonial sites within the park's boundaries. In Australia, the government in 1985 officially recognized Aboriginal ownership of four national parks that had been under state ownership and control.

The final trend is the spread of transboundary parks, sometimes called peace parks, now evident in nearly every world region. These parks are formed when two or more neighboring countries agree to jointly manage national parks that are contiguous, but lie on opposite sides of an international border. In some regions they are part of a larger effort of sociopolitical integration and the suppression of national and ethnic conflicts. In effect, transboundary parks reverse the 19th-century emphasis on linking natural landscapes to distinct national identities, stressing instead commonalities and cooperation among peoples. Europe now has the largest number of transboundary parks. Their worldwide numbers doubled in the 1990s and will likely continue to increase significantly.

National Park Service (NPS)

CREATED IN 1916 by an act of Congress, the National Park Service (NPS) is a federal agency within the Department of the Interior that manages all U.S. national parks, many national monuments, and historic and conservation areas of various designations. The NPS employs over 20,000 people and extends over 84.4 million acres of land in 49 States, the District of Columbia, American Samoa, Guam, Puerto Rico, Saipan, and the Virgin Islands.

The stated goal of the NPS is "to conserve the scenery and the natural and historic objects and the wild life therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations." From the outset, the NPS was charged with a true paradox: To find a balance between preservation and public enjoyment.

In 2006 the national park system controlled 390 park units, 58 of which are designated as national parks. The remaining units include national historical parks, monuments, memorials, preserves, historic trails, outdoor recreation areas, wild and scenic rivers, lakeshores, seashores, battlefields, and cemeteries. The national park system is the oldest in the world and is often called "America's best idea." It has served as a model for national park designation and protection worldwide, as the success of the U.S. national park system spurred other countries to follow suit.

It was concern about the impact of development on the native people, wildlife, and wilderness of the American West that prompted the concept of national parks; artist George Catlin is often credited with the idea. Two of the cornerstones of the early park system were those crown jewels of the West, Yosemite and Yellowstone National Parks. Yosemite was first designated a state park in 1864 and made a national park in 1906; Yellowstone became the first national park in 1872.

Many national park and national monument designations soon followed. However, national parks were established before a system to manage them was formed. This caused numerous problems at the outset, as there were no funds to maintain, enforce, and protect the parks from looters, vandals, poachers, and unruly tourists. Some of the first park superintendents worked without pay or used their own funds to finance management of parks. Congress continued to create parks without securing funds to manage or protect them—causing problems for park managers for years.

Without a management system, competing interests caused further debates. Utilitarians, who believed lands should be used for irrigation, urban water supplies, and hydroelectric dams, clashed with preservationists, who wished to protect the aesthetic beauty of these places. Finally, in 1916 President Woodrow Wilson signed legislation creating the NPS, and Stephen Mather was named the first director.

Over the next several decades the NPS continued to expand, acquiring lands primarily in the western United States. Reorganization of the system in the 1930s expanded NPS further, allowing for the service to take over the management of all present and future national monuments and the War Department's historic parks and monuments. The NPS now managed both historic and natural sites across the United States and increased its presence in the east. Franklin D. Roosevelt's New Deal in the 1930s created the Civilian Conservation Corps (CCC). The CCC employed thousands of jobless young men during the Great Depression in conservation, rehabilitation, and construction projects in both national and state parks. Today many of the structures that they built remain among the most impressive in the system.

Park visitation and developmental pressures continued to increase during the 1950s through 1970s. Americans were becoming more attached to their automobiles and wanted to experience the beauty of the parks by car. Rampant road building prompted the passage of the Wilderness Act of 1964. This act created additional protection from roads, vehicles, and other forms of human disturbance on federal lands. From the 1970s through the 1990s the expansion and growth of the NPS outpaced any previous time period. Ninety-seven new parks were created during this period alone. Park visitation also has steadily increased, with 4.6 million visitors in 2004. A steady stream of visitors and encroaching urban areas take their toll on park lands. Since 1980 the service has focused on improving protection of the parks' natural and cultural resources while continuing to accommodate increasing numbers of visitors.

As with any social institution, the NPS's objectives are often dynamic, guided by the values, ideals, and concerns of society. Over the years, the NPS has expanded its role from park enforcement and management to a wider range of goals. A recent mandate involves increasing ethnographic research to document cultural, religious, or subsistence connections of Native Americans and other diverse cultural groups to park land. The NPS is also emphasizing education and interpretation activities, using parks as classrooms to help increase public understanding of the importance of ecosystem health and protection. By educating the public about land stewardship and conservation, the NPS hopes to ensure that the next generation will be able to experience the beauty of this country's public lands.

National Wild and Scenic Rivers Act

IN RESPONSE TO the alarming rate of damming, dredging, diking, diverting, and destruction of many rivers and free-flowing water sources in the 1960s, Congress created the National Wild and Scenic Rivers Act (1968). Human destruction and indifference toward the nation's system of rivers in the late 20th century was becoming a crisis and government intervention was deemed necessary to prevent further spoilage of natural river environments. However, the act does not designate rivers as national parks—it merely serves to protect their ecological and aesthetic integrity. The goal behind the national system is not to stop the progress of development of rivers but to defend their character and require that any or all development ensures the security of the free-flowing water.

When the National Wild and Scenic Rivers Act was signed by President Lyndon B. Johnson on October 2, 1968, immediate action was taken to improve the function and the value of many polluted or clogged rivers and other free-flowing bodies. The act defines a river as "a flowing body of water or estuary, or a section, portion, or tributary thereof, including rivers, streams, creeks, runs, kills, rills, and small lakes." "Free-flowing," in turn, is defined as "existing or flowing in natural conditions without impoundment, diversion, straightening, rip-rapping or other modification of the waterway." In addition to government intervention, many volunteers were enlisted near affected areas to restore contaminated rivers and to keep unaffected rivers in a more natural state, which is often described as a "living landscape." The actual policy of the act is to make certain that selected rivers possessing remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values are preserved in free-flowing condition and that they and their immediate environments shall be protected for the benefit and enjoyment of present and future generations.

The National Wild and Scenic River Act classifies each included river as wild, scenic, or recreational. Wild rivers are those that are generally only accessible by trail and are free of impoundments. In most cases, these rivers are unpolluted and are taken to be a representation of pre-Columbian America. Scenic rivers are similar to wild rivers in that they are free of pollutants and impoundments, but are accessible by both trails and roads. Recreational rivers are denoted by easy accessibility by road, railroad, or both; having or not having had impoundments in the past; and having or not having development along shorelines. The act also indicates specific rivers that are protected and the methods and agendas for adding

After the Wild and Scenic Rivers Act was signed in 1968, immediate action was taken to improve polluted rivers.

additional water bodies to the act. Agencies that manage the rivers covered by the act include some state agencies, the U.S. Bureau of Land Management, National Park Service, U.S. Fish and Wildlife Service, and the U.S. Forest Service, among others.

While a majority of the included rivers are located in the wildernesses of Alaska and the northwest portion of the United States, other rivers covered include the Rio Grande (New Mexico and Texas portions); Michigan's Au Sable, Pere Marquette, Black, Bear Creek, and Manistee; and selected segments of the Delaware.

Native Americans

THE NATIVE AMERICANS in the United States are the indigenous people of the continental United States and their descendents, covering a large number of tribes and communities. For simplicity, many scholars divide them into the following main cultural groups: the Native Indians of the eastern Woodlands covering New England and eastern Canada; of the southeast; of the plains covering most of the Midwest; of the plateau west of the Great Plains; of the southwest; and of the predominantly fishing communities in modern-day California. There are still major cultural differences between the tribes within these areas.

It is believed that the origins of the Native Americans go back to about 50,000 years ago when some hunters and their families from Siberia crossed the Bering Straits into what is now Alaska. Gradually they moved south until they populated North and South America.

THE NORTHEAST

The Native Americans who moved to what is now New England and eastern Canada developed into woodland farmers, and the tribes there include the Abenaki, the Susquehannock, the Massachuset, the Narraganset, the Delaware, the Powhatan, the Iroquois, the Huron, the Algonkin, the Ottawa, the Menominee Sauk, the Potawatonmi, the Erie, the Miami, the Illinois and the Shawnee. On the island of Labrador was the Beothuk tribe, which differed slightly in customs from those on the mainland. Archaeological work has found items at settlements dating back to between 200 B.C.E. and 400 C.E. located alongside the rivers of the northeastern and midwestern United States. Known as the Hopewell culture, these were the ancestors of the communities that were the first to come into contact with the Europeans. Many accounts of their lifestyle survive.

The woodland Indians lived in small settlements, and planted crops of corn, beans, and squash. Women tilled the fields while the men hunted deer, rabbits, bear, and other wild animals including the woodland buffalo. The men also collected wild fruits and vegetables, with artichokes, cherries, grapes, onions, persimmons, and potatoes all forming an important part of the diet.

The method of agriculture was what became known as "slash and burn," by which the tribes would clear a part of the forest, slashing bark from the trees, and then burn the undergrowth. This cleared the land for planting crops, but the method rapidly depleted the soil, forcing the people to move to another area about every 15 years when crop production started to decline. They did use some fertilizers, but not enough to allow the soil to recover. Environmentally it has proven not to be a good system, but with a very small population living in the woodlands, it was easily sustainable as the woodlands would regrow gradually, reestablishing themselves.

Leadership of the tribes was entrusted to chieftains, with some of these becoming known as kings in early English accounts. Powhatan was the ruler of a large part of what is now Virginia, and had contact with the Jamestown settlement. He controlled some 200 villages and was able to raise a force of several thousand warriors quickly, using them to attack and subdue other villages. His daughter Pocahontas married the Englishman John Rolfe and accompanied him to London, where she was presented to Queen Elizabeth I.

As a result of the fighting between some tribes, many of the villages were protected by stockade fences, as shown in early paintings by artists such as John White who captured many scenes of the region. The crops planted and harvested by the women—the corn, beans, squash, and tobacco—were located within these enclosures. The women were also involved in making clothing from animal skins, with deerskin cloaks used for warmth in winter. As these tribes were the first to come into close contact with the European settlers, they were also the first to assimilate.

Some, like the Wampanoags in Massachusetts, welcomed the Europeans. However, of the 10,000 who were probably living there when the *Mayflower* arrived in 1620, nine-tenths of the population succumbed to smallpox and other diseases introduced by the settlers. In 1636 a number of English settlers attacked the Pequots, who retaliated, and in the following year the English allied with the nearby Narragansets and killed most of the Pequot nation.

THE SOUTHEAST

Southeastern communities were also farming settlements, and archaeological work at Poverty Point, Hardaway, and Etowah has shown strong variations from the Hopewell culture. These tribes were the Cherokee, the Catawba, the Creek, the Choctaw, the Chickasaw, the Caddo, the Natchez, the Timucua, and the Calusa. As with their near neighbors to the north, they also lived in small communities, practicing slash and burn techniques. The men hunted wild animals, especially deer, and were involved in skirmishes with the Spanish.

THE GREAT PLAINS

The Native Americans of the Great Plains were very different, and although they did farm in river valleys, they also hunted the buffalo and other animals, moving as the herds roamed the Great Plains. These tribes included what became the Sioux Confederation, and also, from the north to the south, the Sarcee, the Blackfoot, the Crow, the Cheyenne, the Pawnee, the Arapaho, the Kiowa, the Osage, the Wichita, and the Comanche. Archaeological work has been done on their early settlements at Huff Village and Simonsen.

The Indians of the Great Plains had connections with nearby tribes, although the differences between the Blackfoot in the north and the Comanche in the south were marked. Many of the communities in this part of North America consisted of 20 to 30 families. They lived in tipis, which could be easily dismantled, and they followed the buffalo herds, which they hunted with great skill.

Most often, a number of hunters would creep up on an individual buffalo and kill it with arrows. All parts of the buffalo were then used, with the meat feeding many families, and the leather being important for clothing and for tipis. Occasionally a large number of Indians from the Great Plains would gather together to plan a *piskin,* or communal drive.

The drive involved the preparation of traps, or the use of natural features, such as a rocky outcrop, and then a large group would make as much noise as possible and force the buffalo to stampede toward the trap or cliff. This often resulted in the deaths of many buffalo, providing enough meat and leather to last a long time. The number of buffalo killed as a percentage of the overall herds was very small and every part of the buffalo was used. Unlike the wanton killing by European Americans in the 19th century, the hunts did not endanger the buffalo population, which flourished alongside the Indians for centuries.

In the societies of the Plains Indians, many women enjoyed a high status, but the work undertaken by men and women was strictly delineated. Men hunted and prepared meat. Women looked after the home, preparing it for transport when needed, and raised the children. Women were also involved in much of the craftwork, such as matting, making and stringing beads, and piecing together clothing.

THE SOUTHWEST

In the southwest, the Pueblo Indians were probably the most settled of the Native American groups, with the most well-known being the Apache. The other tribes were the Pueblo, the Navajo, the Hopi, the Mohave, the Papago, the Pima, and the Coahuiltec. Much evidence about their early life comes from the archaeological work carried out at Mesa Verde, Tyuonyi, and Pueblo Bonito. To the west were tribes of desert gatherers, with archaeologists finding remains of their lifestyle at Hogup Cave and Danger Cave. These were the tribes known as the Ute, the Paiute, and the Shoshone. To the north of them were the Nez Perce and the Shuswap.

These tribes lived in one of the least hospitable parts of what became the United States, and as a result the tribes were smaller and the communities produced some of the most adept hunters, who pursued deer, elk, and mountain sheep. The Nez Perce of this region famously refused to hand over their lands by treaty and managed to evade U.S. forces until cornered at Yellowstone River, Montana.

THE WEST COAST

Along the west coast of North America, the communities predominantly lived off the sea, but also had small agricultural concerns along the coast. The tribes around modern-day Washington State, Oregon, and adjoining parts of Canada are the Kwaktutl, the Nootka, and the Chindok. In California and Baja California (in modern-day Mexico) were the Yurok, the Karok, the Pomo, the Yokuits, the Chumash, and the Cochimi. In some parts, especially along the northwest coast of modern-day British Colombia, there were battles over control of fishing grounds, and many warriors wore armor made from wooden slats and built walls around their encampments.

THE REVOLUTIONARY WAR

In the early years of British settlement in North America, land was taken from or ceded in various treaties by the Native Americans. Some tribes supported the British; others were allied to the French. The particularly brutal manner in which some tribesmen fought was regarded as repugnant by Europeans, who recoiled at the concept of scalping the defeated after a battle. Nevertheless, both sides were anxious to create alliances. During the American Revolutionary War, the British managed to get the support of many Native Americans who had hoped that a British victory might end further colonial expansion westward.

When the British signed the Treaty of Paris in 1783 at the end of the war, they ceded Native American lands to the new United States without informing the inhabitants. The new U.S. government tended to regard the Native Americans as having been conquered, but as they had not actually been defeated in battle, the occupation of their lands was a long process as the Native Americans did not recognize the Treaty of Paris.

THE INDIAN WARS

The Indian Removal Act of 1830 compelled many Native Americans to move westward, and those who refused were taken on forced marches. In one horrendous march, known as the "Trail of Tears," some 4,000 Cherokees died. After the American Civil War, the westward expansion of the United States saw a massive encroachment on Native American lands, ushering in the "Indian Wars." Although the Native Americans had victories, such as the Battle of the Little Bighorn in 1876, they were defeated on most occasions. The treaties they signed were not honored by the U.S. government, which pushed the tribes into reservations where sometimes brutal forced assimilation programs were introduced.

At the same time, the destruction of the buffalo herds ended any hope for Plains Indians to return to their former lifestyle. The U.S. government and state governments encouraged the settlement of Indian lands. The lands taken were opened up for cultivation after World War I, and with so much of it marginal agricultural land, it was not long before the Dust Bowl forced many of the new farmers off their lands.

In recent years Native American lifestyles and cultures have been recorded in detail. There were 2,786,652 Native Americans recorded by the U.S. Census Bureau in 2003, with 413,382 living in California, 294,137 in Arizona and 279,559 in Oklahoma, with the others in the remaining 47 states, the District of Columbia and the territories. The U.S. government currently recognizes 563 tribal governments.

Native Species

NATIVE SPECIES ARE the species of plants, animals, and insects that have inhabited a given area or region prior to human disturbance. These original inhabitants are adapted to the specific environmental conditions of their area. They make up the various interdependent parts of the food chain and are an integral part of the regional web of life. Most species have a resident natural predator within the food web that keeps populations of native species in check.

Native species have received a lot of attention in the last decade in two main interest areas: (1) landscaping in an increasingly energy- and water-restricted world; and (2) nonnative invasions. Conventional landscaping traditionally uses exotic plants to enhance an area with colors and shapes from a standard toolkit of vegetative materials. The act of conventional landscaping produces an artificial ecosystem to the extent that earth is often scraped clean and a full array of plant materials is placed to live upon it. Although such plantings are culturally accepted and even expected, they are energy- and water-intensive. As a result, in the last decade there has been more and more interest in native species plantings, since these plants are already adapted to the nutrient and water regimes of the area and therefore require little, if any, added inputs of energy (e.g., petroleum-based fertilizer and insecticides) or water. Additionally, native plantings tend to attract the native fauna and insects, benefitting pollination and the local ecosystem overall.

One area of particular interest within the native landscaping movement is grass-free lawns. Conventional lawns require large amounts of water and fertilizers, insecticides and pesticides to stay green. In many drought-stricken areas of the United States, homeowners are replacing their green lawns with hardy native groundcovers that require no extra irrigation.

Nonnative invasions are another reason why native species have received a lot of recent attention. The introduction of nonnative species is nothing new—ever since humans have colonized new areas, they have consciously or unconsciously brought nonnative species with them. Ecological imbalance occurs when nonnative species take over the niches of native species because of a lack of natural predators in that ecosystem. They simply out-compete native plants and animals for space, food, or water. In some cases, nonnative species make it difficult or impossible for native species to survive by fundamentally altering natural disturbance regimes and other ecological processes.

Nonnative species are introduced via deliberate and nondeliberate acts of human disturbance. Several prominent historical examples of the unintended introduction of nonnative species include the Japanese beetle, Japanese honeysuckle, and rats brought from the Old World to the New World in ships' hulls. Humans have also intentionally introduced invasive species in attempts to deal with ecological issues, but with negative repercussions for the rest of the ecosystem, such as in the introduction of the zebra mussel to the Great Lakes and the cane toad to Australia. Nonnative species continue to spread largely due to lack of public education. Nurseries continue to sell invasive plants as landscape materials and exotic plants and animals remain popular. Nonnative species endanger the earth's already threatened biodiversity. In the process of invasion, nonnatives can push rare species to the edge of extinction.

There are many actions that people can take to help forestall the invasion of nonnatives. First of all, they can become informed about the status of their local native species—the extent to which development and invasive species are threatening or have diminished the native species makeup of their region. Usually there is a local chapter of Audubon or Sierra Club involved in such matters. They can also become versed in the conventional landscape materials that nurseries continue to sell and advocate for the replacement of invasive species with suitable substitutes. Lastly, they can choose to landscape their spaces with native species and to educate the public about the many benefits of native propagation.

Natural Capital

NATURAL CAPITAL IS a term that has emerged to describe the relationship between human means of production and the earth's ecosystem. More specifically, numerous academics and scholars have sought to consider environmental and natural resource features within a Marxist theoretical framework. For Marx, capital represented not simply material wealth, but control over the means of production in society. This rather abstract way of thinking came from Marx's own work with dialectical materialism, an analytic approach that involves seeing the world in a constant state of emergence from different antithetical processes. As such, for Marx, capital is not a thing, but rather a process or set of force relations. Reiterated more precisely, capital is not simply a thing that one possesses; it is a process of production and exchange in whichever greater amounts of capital accrue to the capitalist class, for example, the bourgeoisie. Those who control the means of production are thus able to control the capitalist system by continually exploiting the labor power of the proletariat masses.

The more efficiently the owners of the means of production can exploit the labor power of their workers, the more surplus value they derive, and consequently, the more capital they are able to accumulate. In this way, capital is manifested in material wealth as well as in the process that perpetuates it.

In a majority of his work, Marx considered the process of capital from the standpoint of industrial capitalism. For this reason, capital has most often been thought of in terms of material objects, structures, or institutions that have been manufactured by humans such as mechanized equipment, factories, government institutions, and schools. The means of production, however, are not limited to the material or social apparatuses that people construct.

Capital may also be bound in the naturally occurring objects of the environmental landscape. Marx first explored this idea in a section of his book *Das Kapital*. In this section, which focuses primarily on the concept of ground rent, Marx explains the ways in which a capitalist may use the natural landscape to more efficiently exploit the labor of the proletariat class, thus increasing his own capital returns. A river, for example, is often something that exists naturally, yet can be added to the means of production in order to increase productive outputs.

Natural capital, therefore, is a term that considers the earth's natural resources within the context of a capitalist mode of production. It is often used to signify the productive potential of a given ecological resource or environmental feature. Places may be said to "have a lot of natural capital" if they are rich in natural resources that make them productive and economically valuable. For example, a piece of farmland with nutrient-rich topsoil, consistent precipitation, easily harvestable fields, and transport access has more natural capital than one with poor soil, frequent droughts, and unstable or impassable terrain. From this perspective, natural capital is any naturally existing phenomenon that facilitates the expanded circulation and accumulation of capitalist processes.

In the continuously expanding body of literature that has emerged from scholars investigating issues of natural resource management, conservation, economic impacts upon the environment, and political ecology, natural capital has come to be synonymous with natural resources in many ways. By viewing the quantity or quality of resources such as timber, water, or oil within a given area as the natural capital of that space, some researchers have worked to measure natural capital more precisely. This arguably provides a more quantifiable method for comparing the natural capital of one space or object to another.

While this approach has yielded a number of fascinating insights, one must be careful not to conflate the idea of natural capital with a simple natural resource commodity. For example, a forest, mine, or petroleum reserve is a natural resource, not an all-telling measure of natural capital. Natural resources may comprise an important element in the make-up of natural capital, but they are not the sole indicator: natural capital refers more to the relationship between the environment and capitalist accumulation than it does to a specific natural object or element. In this way, it is most accurate to think of natural capital as the way processes of capitalist production affect and are affected by the natural environment.

Natural Gas

NATURAL GAS, A highly flammable fossil fuel, is an important nonrenewable energy resource. Less polluting than other fossil fuels like coal and oil, natural gas is deemed relatively environmentally-friendly, helping to increase demand for the fuel in recent years. As a hydrocarbon, natural gas is primarily composed of methane, a colorless, odorless, lighter-than-air gas.

Methane is the simplest of all the hydrocarbons in molecular makeup, consisting of one atom of carbon and four atoms of hydrogen. While natural gas is relatively clean-burning, methane itself is a greenhouse gas, more efficient at trapping heat than even carbon dioxide (the major offending gas in the enhanced greenhouse effect). Burning natural gas, as with all hydrocarbons, releases carbon dioxide into the atmosphere. Increased levels of methane and carbon dioxide in the atmosphere are thought to contribute to global warming and such related potential environmental hazards as climate change, polar ice melting, glacial retreat, and the rise in sea levels.

As is the case with other fossil fuels, natural gas is thought to have been formed hundreds of millions of years ago, with dead organic matter sinking to the bottom of ancient seas. Plankton and algae, thought to be the source material for natural gas, sank to the bottom of the seas, and slowly began to be covered in silt and other sedimentary materials. Over many millions of years, the weight of the accumulating sediment, combined with the weight of ocean water, exerted tremendous pressure on the organic material. With the pressure, heat also acted on the organic source materials and over millions of years transformed these materials into hydrocarbons in the form of natural gas. This process is similar to the formation of crude oil, and natural gas and oil are often found at similar locations today. Over time and under extreme pressure, oil and gas were forced into relatively porous sandstone or limestone, referred to as reservoir rock. Subsequent deformation of the earth's crust acted to trap oil and gas into pockets under impermeable cap rock like marble or granite.

The three major geologic forces trapping oil and gas into pockets within the earth's crust are folding, faulting, and pinching out. Folding results from horizontal pressure being exerted on the cap rock, forming a fold (or anticline). Faulting represents a fissure in the cap rock, with a large section of cap rock slipping down, forming a hydrocarbon-trapping cavity. In the pinching out process, impermeable rock is forced upward into the reservoir rock, resulting in pockets trapping oil and gas. In each case, as gas is lighter than oil, natural gas migrates to the top of these deposits. Geologists are able to locate oil and natural gas deposits, often deep within the earth's crust, by looking for evidence of these geologic processes.

HISTORY

While the history of natural gas extends back hundreds of millions of years, its status as a natural resource of practical use by human beings is a relatively recent phenomenon. Gas seeping from the ground would occasionally be ignited by a bolt of lightning, producing a flame that confounded early civilizations. One such inexplicable flame, from around 1000 B.C.E., was found on Mount Parnassus in ancient Greece. Around 500 B.C.E., in what may mark the first human use of natural gas as a fuel, the Chinese harnessed the energy from these flames to boil seawater. The Chinese were also the first to employ a rudimentary system of piping gas by forging together sections of bamboo shoots.

The first well drilled specifically to extract naturally occurring natural gas (as opposed to gas produced from coal) was constructed in 1821 in Fredonia, New York. The well's builder, William Hart, is widely considered the "father of natural gas" in the United States. In 1859, in what is considered the birth of the oil industry in the United States, Colonel Edwin Drake, using a derrick and drill, struck oil and natural gas nearly 70 feet below the earth's surface. A 5.5-mile pipeline was built connecting Drake's well to nearby Titusville, Pennsylvania.

During the 19th century natural gas was used primarily as a source of illumination. As electricity gained prominence in the late 19th century as a source of light, a much-needed market emerged for natural gas. In 1885, Robert Bunsen invented the Bunsen burner, enabling the safe control of a burning flame. Soon a market emerged for natural gas in cooking and heating homes.

After World War II, an extensive pipeline system was built, allowing natural gas to be shipped to individual households in the United States. Today, natural gas accounts for approximately 25 percent of total energy consumed in the United States. Natural gas is used to heat and cool homes, to generate electricity, and to provide fuel for residential cooking stoves. Natural gas is also being developed to power vehicles, offering an environment-friendly alternative to gasoline-burning modes of transportation.

EXTRACTION AND SUPPLY

Moving natural gas from its location in the earth's crust to the end user requires an elaborate process of exploration, extraction (production), processing, shipment, storage, and further transport to local demand points. As the easiest and closest natural gas reserves have been exploited, exploration continues in deeper, more difficult to reach locations. The primary exploration technique involves the use of seismic shock waves, which are sent into the earth's crust, reflect off underground geologic formations, and allow geologists to map the crust's interior. Once produced by dynamite and other explosives, seismic waves are now primarily produced by vibrator trucks that "stomp" the ground.

Recent computer technology has enabled geologists to construct three- and four-dimensional images of the crust's geology. Extraction of natural gas is similar in many ways to the extraction of oil. A drilling rig is constructed, and a hole is drilled in the earth's crust down to the natural gas deposit, allowing the gas to be brought to the surface and collected. Since natural gas from the ground often includes other compounds (gasses, oil, and water), processing removes impurities and other substances, yielding the methane that is piped to markets. Other substances removed during the processing of natural gas include ethane, propane, butane, pentane, and sulfur. Underground gas pipelines transport the processed natural gas to underground storage facilities near markets, and when needed, it is then distributed to homes and businesses.

Natural gas is not a ubiquitous resource. Some countries have a plentiful potential supply while others do not. The largest proved reserves of natural gas in the world are found in Russia (27.2 percent of the world total). The unequal distribution of natural gas in the earth's crust is demonstrated by the fact that over 57 percent of the world's proved reserves are found in three countries (Russia, Iran, and Qatar). Other large, but proportionally smaller reserves, are found (in descending order) in Saudi Arabia, the United Arab Emirates, the United States, Algeria, Nigeria, Venezuela, Iraq, and Kazakhstan. Examining natural gas production (exploitation of reserves) yields a more accurate picture of current supply. The world's largest producers of natural gas are Russia (22 percent of world production) and the United States (20 percent of world production). Other major producers include (in descending order) Canada, the United Kingdom, Indonesia, Algeria, Iran, Norway, the Netherlands, and Saudi Arabia.

Natural Landscaping

NATURAL LANDSCAPING IS a minimalist strategy for beatifying the grounds of homes or professional buildings. The basic technique of natural landscaping is not to simply allow a space to return to its natural state, but instead to design a garden, yard, or grounds so that it is in harmony with nature. The design of natural landscapes is one that imitates areas found in nature such as meadows, wildflowers, trees, plants, and native grasses. This design technique creates environments that are easy to maintain and have economic and environmental benefits. Among

Natural landscaping uses native species to create privacy screens and local rocks to beautify islands of trees.

these is a marked reduction in mowing of traditional lawns, water consumption, and fertilizer use and the restoration of habitat.

The use of xeriscaping (landscaping that maximizes water conservation) as a form of natural landscaping can reduce water use by two-thirds. It also means that in times of drought the natural landscape area will be more drought resistant than landscapes that use plants that require much more care and water.

Professional landscapers who seek to achieve a natural look will use native species to hide utility buildings or other work areas. They will also work with holes or other unsightly areas to fashion them into an area that looks like a natural park. If the area to be landscaped is small, then the design will use borders that create a natural feel to the landscape area. In addition using plants native to the area can create privacy screens that give the feeling that the home or residence is sheltered in a remote wooded area when it is actually in a suburban or urban area.

Natural landscaping design techniques create shady, hidden places that add not only interest to small areas but also habitat for birds and other small mammals such as chipmunks and squirrels. With planting of perennial native grasses and flowers, these animals will find abundant feed. Natural rocks from the property or imported from close by can also beautify islands of trees or the borders of plantings.

Natural Regulation

MOST OFTEN USED in environmental and natural resource policy discourse, natural regulation is generally understood to mean environmental conditions not directly altered by humans. Often, the term is used to contrast areas with minimal direct human influence, such as congressionally designated wilderness areas on federal lands in the United States, with directly managed areas such as commercial forest land used to produce timber for lumber and paper.

Within the context of natural resource management, natural regulation is based on the rationale that nature knows best, and will therefore achieve an ideal state if left alone. The concept is fueled by the belief that an ecosystem is in need of repair because man has used it too intensively for self-gain (or sustenance) for reasons such as logging, mining, hunting, and urban development. Other contributing factors are outmoded management policies such as fire suppression, wolf extermination, and elimination of woody debris from streams that have proved to cause more problems than they solved because of man's ignorance of nature's complexities.

The *Merriam-Webster Dictionary* makes *natural regulation* sound like an oxymoron, when "natural is based on an inherent sense of right and wrong, not artificial, and untouched by the influence of civilization and society," while "regulation implies a prescription by authority in order to control an organization or system." Connecting such words reveals a teleological notion that is unscientific according to contemporary ecological science, as it contradicts the current chaos paradigm that has largely overturned the related concept of balance of nature. Depending on the spatial and temporal scales at which nonhuman-controlled environments are studied, nature appears anything but regulated (for example, consider natural disasters such as Hurricane Katrina in 2005, and the series of tsunamis from the 2004 Indian Ocean earthquake). As some scholars of natural resource management policy have suggested, there tends to be a confusion of the term *natural regulation* to describe an empirically verified state of nature, when in fact it delineates a human value preference for what should or should not be done to an environment.

Frederic Wagner of the National Center for Ecological Analysis and Synthesis suggests that "much of the debate on natural regulation fails to distinguish between the [management] policy and [scientific] hypothesis" that make up the term. Part of the problem can be traced to junk science, blamed for simplifying and distorting scientific claims for personal motivations, whether it be as innocuous as a reporter complying with a word count limit for a newspaper article, or as deliberate as a lawyer constructing a case to win a lawsuit.

An applied policy example of natural regulation is in the western United States in Yellowstone National Park (YNP) by the National Park Service (NPS) on the recommendation of a 1963 report by the National Academy of Sciences to return the area to what it was like before Euro-American settlement. A founder in the development of our understanding of ecology, V.C. Wynne-Edwards, brought some of the supporting concepts for natural regulation to the forefront in 1962 with the book *Animal Dispersion in Relation to Social Behavior*, suggesting that certain species thrive by regulating their own populations via group selection to use their resources sustainably. Three and a half decades later, ecologist Mark Boyce supports natural regulation policy based on the belief that humans can learn from environments in which they are not involved, and are likely to mess them up if they become involved.

In 2002, the National Academy of Sciences put out a review of the natural regulation in YNP in recognition of it being one of the most contentious management issues in the park since its inception. Alston Chase's 1985 book *Playing God in Yellowstone* is a commonly cited source of criticism that sparked considerable backlash from the NPS. Other well-known critics are political scientist Charles Kay and Richard Keigley of the U.S. Geological Survey, who both have associated natural regulation more with politics than science. Biogeographer Amy Hessl illustrates the inevitable limitations of applying natural regulation in that political boundaries such as land ownership don't coincide with ecological processes operating at different spatial scales. However, she implicates support for such an evolution in policy at YNP when she calls attention to management actions connected with declines in aspen populations, identified as the most important indicator species of biological diversity there.

Given that ecosystem boundaries don't correspond with legal boundaries, a policy of natural regulation may actually threaten the ecological values inside of a protected area. Although fire suppression is blamed for wiping out aspen cover in some areas, permitting prairie fires and unlimited wild ungulate grazing can also drastically reduce biodiversity. And as pointed out in the May 1998 UNESCO *Courier*, natural regulation does not absolve managers (or policy makers) from setting objectives, because change is going to take place regardless of their decision to intervene. The quandary becomes one between biocentric and utilitarian goals, and if humans can be a part of ecological sustainability.

Another aspect to take into account with natural regulation implementation is its feasibility, when arguably nothing left on the earth is untouched by humans. If everything is connected, then some human-related development can eventually be found to have initiated a domino effect on what was even thought to still be natural. Many wilderness designations, which the Wilderness Act of 1964 describes as lands to be protected in their "natural condition, untrammeled by man," have been made after (and contingent upon) the destruction of historic buildings.

Discussion of natural regulation also highlights dramatic differences in what people view as acceptable ecological conditions based on what initiated the changes that shaped the character of a place. For example, a lightning-caused wildfire that burns 500 acres of marketable timber would be beneficial according to an environmentalist, but a tragedy to a logger. But if arson were identified as bringing about the same result, the two would likely agree it was a crime. Similarly, the appropriate response to such an incident could range from nothing, to harvesting any salvageable trees that remain.

Environmental philosopher Ernest Partridge speaks to such distinctions in his analysis of what he calls the old and new ecologies. In his successful 1998 proposal to the National Science Foundation on "Implications of Disequilibrium Ecology for Environmental Ethics and Policy," Partridge cites Aldo Leopold's belief, published in 1949, that "a thing is right when it tends to preserve the integrity and stability and beauty of the biotic community; it is wrong when it tends otherwise" as an example of the traditional view, and Daniel Botkin's assertion that although this standpoint forms the basis of federal and state environmental laws and international agreements, it is inaccurate as an example of the current paradigm. New ecology contends that the environment is in constant change, and therefore there is nothing to preserve. Petitions for wilderness restoration are thus left with unfounded assumptions about what condition they are advocating.

Partridge's main contribution to this exploration of natural regulation lies in his rebuttal to the new ecologists about ecosystems being better or worse (that is, healthy versus degraded) than others, as correlated with their being natural or cultivated by human societies. His argument is based on the belief that undisturbed nature manages itself, which to him basically means remaining as is. He does not deny the new ecology claim that all is flux, but tempers it with the qualification that change within natural ecosystems is slow and self-healing, while anthropogenic effects are abrupt and damaging. Such reasoning, however, ignores cataclysmic natural events such as volcanic eruptions, hurricanes, fires, and asteroid impacts. Like most theories, there are some instructive points that remain in both old and new ecology concepts, even after considering their criticisms.

Within the natural regulation context, scientists need to be cautious about mixing science with their personal preferences when making formal recommendations on resource management. Which returns to Frederic Wagner's observation about the shortcomings of using the term *natural regulation*, in that it inextricably links questions of scientific fact that are subject to tests of evidence with sociopolitical value and policy questions: Specifically whether humans are a part of nature, and if so, what their role should be in shaping it.

Natural Resources Conservation Service (NRCS)

AN AGENCY OF the U.S. Department of Agriculture (USDA), the Natural Resources Conservation Service (NRCS) is a unique and rather poorly understood part of the U.S. government. It plays a major role in the management of the nation's rural lands, but unlike its more famous federal land management counterparts (e.g., the National Park Service, U.S. Forest Service, Bureau of Land Management, and U.S. Fish and Wildlife Service), the NRCS neither owns nor administers land. Indeed, it is generally disallowed from working on federal land, and it is the only federal agency specifically authorized to work on private lands. While its principal work activities involve agricultural extension, the NRCS also conducts soil and flood control surveys, inventories national land use and land cover, monitors snowfall to forecast water supplies, and administers grants to conserve wildlife habitat, soil and water, and agricultural land.

Although often perceived among environmentalists as "captured" by farmers and ranchers, the NRCS was never intended to be a regulatory agency. Rather, it was designed to work cooperatively with states and counties as well as private landowners, and in several ways it pioneered approaches to conservation that have more recently been "rediscovered," such as public-private partnerships, community-based conservation, and watershed-scale restoration.

Prior to October 1994, the NRCS was called the Soil Conservation Service (SCS), which was created in April 1935 under Public Law 46. The name change was intended to communicate a broader conception of the agency's mandate, but the mandate itself had always been far-reaching. Public Law 46 declared "that the wastage of soil and moisture resources on farm, grazing and forest lands of the nation, resulting from soil erosion, is a menace to the national welfare." It proclaimed "the policy of Congress to provide permanently for the control and prevention of soil erosion and thereby preserve natural resources, control floods, prevent impairment of reservoirs, and maintain the navigability of rivers and harbors." The SCS formalized and made permanent within the USDA the activities of the Department of the Interior's Soil Erosion Service, which had been formed on an emergency basis two years earlier in response to the combined effects of the Great Depression and the Dust Bowl.

The director of the Soil Erosion Service and first chief of the SCS, Hugh Hammond Bennett (1881–1960), is today regarded as "the father of soil conservation." Bennett joined the USDA's Bureau of Soils in 1903 and spent his early career producing county soil surveys. In the course of fieldwork in the southern United States, Alaska, and overseas, he became convinced that soil erosion was not only widespread and severe but also a peril that required coordinated government action. In 1928 he coauthored "Soil Erosion: A National Menace," a bulletin that popularized the issue and led to the formation of the Soil Erosion Service. Bennett worked from the premise that soil erosion was both a social and an ecological issue, one that required political organization as well as scientific information.

One of the first actions of the Soil Erosion Service was a watershed scale demonstration project in the Coon Valley of southwestern Wisconsin, where local farmers petitioned for technical assistance and agreed to lead the project. Erosion integrated the watershed, touching on everything from farming and grazing practices to land use patterns and wildlife. With input from an interdisciplinary team of technicians, over 400 farmers participated in a comprehensive analysis of the watershed's natural resources and implemented treatments on creeks, forests, and pastures as well as croplands.

This approach was institutionalized in conservation districts enabled by a federal law passed in 1937. Districts are technically units of state government, created and run by elected boards of local cooperators with support and technical assistance from the NRCS. Although the federal legislation permitted districts to assume jurisdiction over planning and zoning, very few states included these powers in their laws. Some 3,000 conservation districts exist at present, although their potential as vehicles for "new" ideas in conservation has scarcely been tested.

Natural Resources Defense Council (NRDC)

THE NATURAL RESOURCES Defense Council (NRDC) is a nonprofit environmental advocacy organization. Originally funded by the Ford Foundation, it was founded in 1970 by public interest lawyers seeking to create an organization that would focus specifically on environmental protection.

The NRDC is one of several national environmental organizations to emerge in the 1970s. These groups are distinct from the conservation organizations that existed prior to this period, such as the Sierra Club and the Audubon Society. At the time these longer established organizations had more of a recreational and hobbyist orientation and were less engaged in political mobilization. The NRDC and other environmental organizations that formed during the 1970s emerged from the political mobilizations of the 1960s and took on a more explicitly political orientation. In later years these large national organizations would converge in terms of their political activities, although some differences in strategy are still evident.

Given that it was founded by public interest lawyers, the NRDC's main political strategy is to use litigation against public entities and private corporations in order to force compliance with and enforcement of environmental laws and regulations. The NRDC Action Fund is an affiliated organization with a different tax status that allows it to dedicate all of its resources to lobbying and political mobilization, while the main nonprofit organization carries out a combination of research, education, and political mobilization.

It its early years the NRDC played a role in the passage and enforcement of the Clean Air Act and Clean Water Act. The NRDC was also key in the fight against ozone depletion caused by the release of chlorofluorocarbons (CFCs) into the atmosphere. A 1978 lawsuit filed by the NRDC led to a ban on the use of CFCs as aerosol propellants. Under threat of further legal action, the U.S. Environmental Protection Agency (EPA) later restricted other uses of CFCs. Other issues on which the organization has focused include forest protection, acid rain, and the removal of lead from gasoline.

Some have criticized the NRDC and similar professional organizations for their close integration into the policymaking system and their relative lack of connection with grassroots activists, especially those from disadvantaged groups. In the 1970s, some NRDC leaders went on to assume positions in the Carter Administration. In the early 1990s the NRDC and other large national environmental organizations were criticized by civil rights organizations that claimed that large professional environmental groups failed to pay ample attention to issues of environmental justice.

Today the NRDC has over one million members and works on a wide range of issues, including global warming, forest preservation, and endangered species protection. It continues to use litigation as its primary strategy and it typically has over 100 lawsuits filed against polluters at any given time. The NRDC also seeks to involve members and activists in its lobbying activity primarily through online and direct mail appeals to write and telephone elected officials. The organization is headquartered in New York City and has offices around the United States. It employs a staff of over 100, including lawyers who carry out the litigation function of the organization and scientists who conduct research and provide technical expertise on environmental matters.

Nature, Social Construction of

MANY PEOPLE CONSIDER nature to be whatever it is they see through the window of an automobile while passing through rural areas. Looking out they see fields, forests, birds, and perhaps a mammal such as a deer. This common view of nature as whatever the individual happens to see of the world is without critical awareness. It can be considered a form of naïve realism that believes that what one sees is what one gets. However, questions about the accuracy of this picture of "reality" have been with us since the beginning of Western philosophy and continue to be raised in modern studies by sociologists.

The philosophic question "what is real?" is an issue because some human experiences are of things that appear to be real, but when examined are found to be only appearances or illusions. All humans have experienced appearances, perhaps as mirages or startling shadows. Distinguishing appearances from reality is a central question in metaphysics. Until the advent of the Copernican Revolution in astronomy, the general belief was that the solar system was geocentric: The sun moved and the earth was stationary. Certainly for an observer on earth the sun does appear to move every day of the year. However, this is now known to be an appearance, and reality is just the opposite. The discovery required major adjustments in thinking about the nature of the universe. It required, as Francis Bacon urged in his writings, a reorganization of knowledge.

The picture of "reality" that people carry in their heads is not just a response to a nature that is out there, but also an artificial construction in the human mind. Animals may be part of nature, but the names by which they are known are a human social construct. Interestingly, the first words used by babies are nouns for naming things, but this is a social act because the names are those given by the language of the society.

The knowledge of the names of the animals is not just that of an isolated person, because humans are by nature social. People may choose at some time to live isolated from human contact; they may die alone; but no human has ever been born alone. Children acquire a language that is filled with deep structures and images that carry the thinking and feelings of many people over generations. The deep structures will include ideas and feelings about nature.

Sociological theories of the "social construction of reality" say that the way in which humans act is a product of their life experiences. In other words, the perceptions of reality that people have are colored by their beliefs and backgrounds. Thus, the attitudes that someone would have about being lost in the deep forests of Canada would be different if that person had grown up on a farm in a rural area as opposed to having been reared in an apartment in New York City. The attitudes of people from rural areas on guns and hunting will differ from those who are from urban areas. The former may have eaten at times thanks to the game they shot and killed. The urbanite may never have handled a gun, and may have usually been fed from local grocery stores or restaurants where the prepared meat or fish is not recognizable as the animals they once were.

An example of the social construction of nature is in the attitudes that Americans have had toward wolves. These attitudes were shaped by European stories of the "big bad wolf," which have often been viewed as true depictions of reality, even though the origins of the story and the intentions of the storytellers may have been very different. In the American West wolves were hunted to extinction because of hostile attitudes shaped more by these images and attitudes than by reality. This occurred despite scientific studies showing that wolves do not live up to their bad reputations. The Thomas Theorem applies because in this case wolves are perceived as bad so their consequences were real.

The social construction of nature also affects scientists. While expected to have clear pictures of reality, studies of their theories have shown that since at least the pre-Socratic teachings of Heraclites of Ephesus, scientists have used images or metaphors to interpret their finding. These models of reality have on a number of occasions created enormous mischief.

Many students of the history of science believe that the Darwinian image of life as a struggle for survival was an interpretation of nature that reflected the savage manner in which society in England at the time operated. If life had been organized in another way, the theory of the mechanisms of nature would have been illustrated differently, and therefore the theory would also have been different.

The pictures of nature that humans carry in their heads are in part an eisegesis of nature. That is, part of human understanding of nature is "read into" nature from the social perspective of the viewer of nature.

Nature Conservancy

THE TERM *nature conservancy* reveals the particular way that society relates to "nature," or what is thought of as the physical and natural environment that surrounds and hosts human activities and life on earth. The relationship between early societies and the natural environment was good, as societies made use of natural resources without causing large-scale depletion. As a whole, indigenous societies such as the Mayas in Peru didn't provoke great environmental conflicts; instead, many ancient societies developed sustainable ways of living.

However, during the early 18th and 19th centuries the relationship between humanity and nature became strained with the beginning of the Industrial Revolution. Nature was often seen as an endless source of raw materials to feed the increasing needs of industrial countries. At the same time the environment served as a container for industrial waste. In this way, industries grew based on natural resource exploitation at very large scales, which gradually depleted the resources.

Early conservation initiatives were led by naturalists in the United States who were worried about extensive land-clearing and the rapid loss of wildlife. As conservation ideas gradually gained support, results appeared. In 1872 Yellowstone National Park was established in order to protect an area of incredible natural beauty. Later on the Forest Reserve Act of 1891 authorized what would become known as National Forests, and the Lacey Act of 1900 established the first wildlife protection measures by restricting commercial hunting and the trade of illegally killed animals.

Throughout the 20th century many other initiatives appeared in the United States. The conservation movement had a high point in the 1960s as books such as *Silent Spring* by Rachel Carson raised public concern about the health and environmental hazards of pesticides and other toxic chemicals used by industry.

In 1972 the United Nations (UN) Environment Programme was formed to encourage international cooperation in conservation and development strategies. Collaboration on environmental conservation issues included the 1987 Montreal Protocol to protect the ozone layer; the 1992 UN Conference on Environment and Development (UNCED) in Rio de Janeiro, Brazil; and the 1994 UN Conference on Population and Development in Cairo, Egypt.

More recently, the idea of conservation has been closely connected to that of sustainable development. Conservation does not simply mean preservation anymore—it means the fostering of economic activities while taking into account and respecting the dynamics of natural ecosystems. That is the basic idea of sustainable development: a triangle between economics, society, and ecology.

Today there are hundreds of agencies, nongovernmental organizations, and other groups whose goals involve the conservation of nature. The biggest and most renowned ones are: the World Conservation Union or International Union for the Conservation of Nature (IUCN), the World Wildlife Fund (WFF), Greenpeace, Conservation International, and The Nature Conservancy (TNC). Some of these organizations have significant budgets. For instance, TNC had a 2005 budget of more than $600 million.

Nature Writing

THE NATURE WRITING style of nonfiction prose about the natural environment often draws from scientific discoveries and facts about nature, commonly in a first-person narrative, and usually includes philosophical reflections on the natural world.

Some early writers mentioned animals in their texts; the descriptions of crocodiles by the Greek writer Herodotus (c. 485–25 B.C.E.) are probably the best-known in ancient literature. However, it was Gilbert White (1720–93) who was the first nature writer in the modern tradition. He was born in the village of Selborne, Hampshire, England. Trained as an Anglican clergyman, he returned to Selborne as the village curate. During his 20 years there he wrote a large number of letters about observations from his garden, from which 110 were collected and published as *The Natural History and Antiquities of Selborne* (1789). The book quickly became popular and has remained in print ever since.

The next nature writer was the American William Bartram (1739–1823), son of the Pennsylvanian botanist John Bartram (1699–1777). The father was hailed by Linneaus as "the greatest natural botanist in the world," and his son wrote *Travels* (1791) which influenced many English writers of the Romantic period. John James Audubon (1785–1851), worked on his famous *Birds of America*, which was published between 1827 and 1838 in 87 portfolios. At the same time, British ornithologist John Gould (1804–81) put together his multivolume books *Birds of Europe*, *Birds of Australia*,

This engraving of Rush Creek Glacier in the Sierra Nevadas accompanied an 1875 article by John Muir.

Birds of Asia, and *Birds of Great Britain*. However, the works of Audubon and Gould are better known for their pictures than their text.

Even though Bartram's work predates that of Henry David Thoreau (1817–62), Thoreau is recognized as the father of American nature writing. He was from Concord, Massachusetts, and as a teacher was fond of long walks studying nature. His book *Walden, or Life in the Woods* (1854), became an American classic, with further works, including his daily journal, being published posthumously.

A number of explorers also wrote about nature. German naturalist Alexander Humboldt (1769–1859) worked with Aimé Bonpland (1773–1858) with Humboldt's book *Kosmos* gaining him wide notice. Humboldt's work was largely technical in nature, and quite unlike the nature writing of Charles Darwin (1809–82) and Lord Alfred Russel Wallace (1823–1913). Darwin described his voyage around the world in his book *Journal of Researches into the Geology and Natural History of the Various*

Countries Visited by HMS Beagle (1839) and later put together his ideas about evolution through natural selection in *On the Origins of Species* (1859).

Although his books never sold as well as those by Darwin, Lord Alfred Russel's *Palm Trees of the Amazon and Their Uses* and *Narrative of Travels on the Amazon and Rio Negro* (both published in 1853), and *The Malay Archipelago: The Land of the Orang-Utan, and the Bird of Paradise* (1869), remain important in their descriptions of Latin America, the Malay Peninsula, and the Indonesian Archipelago.

Others associated with the concept of nature writing include U.S. writers Ralph Waldo Emerson (1803–82), Aldo Leopold (1887–1948), and John Muir (1838–1914). Edward Abbey (1927–89), author of *Desert Solitaire* (1968) and the novel *The Monkey Wrench Gang* (1975) about environmental guerilla warfare, specifically rejected the term *nature writer* for himself, although others give him that title.

Rachel Carson's (1907–64) early books *Under the Sea-Wind* (1941) and *The Sea Around Us* (1951) were nature writing, and she became famous for *Silent Spring* (1963). Another important nature writer was William Henry Hudson (1841–1922), who was born in Argentina to American parents. He wrote a number of books about South America, with a heavy emphasis on ornithology.

Other recent American nature writers include Rick Bass, Wendell Berry, Christopher Camuto, Annie Dillard, Gretel Ehrlich, John Elder, Bernd Heinrich, Sue Hubbell, William Kittredge, Barry Lopez, Bill McKibben, John McPhee, Sy Montgomery, Gary Paul Nabhan, Richard Nelson, Sam Pickering, Michael Pollan, Richard Proenneke, Robert Michael Pyle, David Quamme, Janisse Ray, Scott Russell Sanders, Gary Snyder, Edwin Way Teale, and Terry Tempest Williams.

Nauru

THE TINY OCEANIC island of Nauru was geologically endowed with unusually high phosphate deposits, a resource that would prove to be the island's ecological ruin. Starting in the early 20th century with the intervention of a German-British consortium, and onward for nearly 100 years, phosphates were regularly mined and aggressively removed. The result of a century of exploitation has been the virtual destruction of the island and its native ecosystem.

Nauru achieved independence in 1968, making it the smallest independent republic in the world; the island is only eight square miles (21 square kilometers). Nauru joined the United Nations (UN) in 1999. The climate is tropical with a monsoonal pattern. Periodic draughts pose significant threats to the island's ecosystems and accelerate the need for freshwater. The rainy season lasts from November to February. Nauru is relatively flat, and most of the island is covered by sandy beaches, with a fertile ring around the raised coral reefs. The phosphate plateau is located near the center of the island. The 30-mile (48-kilometer) coastline of Nauru is surrounded entirely by the South Pacific Ocean.

None of the land on Nauru is presently arable, and the only resources are phosphates and fish. The entire country is urbanized as there are no rural areas. Most essential items are imported from Australia. The island has a population of 13,048 people and a fertility rate of 3.19 children per female. With a per capita income of $5,000, Nauru is ranked 135th out of 232 nations in income. Ninety percent of the population are unemployed. The remaining 10 percent mine phosphates or work in public administration, education, and transportation.

The ecological devastation of the island has led to a number of stopgap economic measures. Following the depletion of most of the phosphate resources, the economy shifted during the 1990s to become an offshore tax haven for foreign individuals and firms, and a center for money laundering. Even more radically, in 2001 it became the offshore detention site for asylum seekers attempting to migrate to Australia. These efforts have yielded limited economic benefits and added to ongoing destabilization.

With phosphates virtually depleted, Nauru is facing a major economic dilemma. Although funds were set aside for this eventuality, the fund has been almost bankrupted by indiscriminate government spending. Consequently, the government has invoked a wage freeze, privatized government agencies, and reduced government staff. Australian subsidies currently keep the Nauruan economy afloat. The UN Development Programme Development Reports do not rank Nauru due to lack of data.

Without a natural source of freshwater, Nauruans use roof storage tanks to collect rainwater. However, most water is derived from the one aging desalination plant available on the island. The major environmental problem for Nauru is the aftermath of the intensive phosphate mining. This exploitation has turned 90 percent of the central section of the island into a wasteland and has caused some damage to the remaining land area.

The coastal area is generally filled with pandanus and coconut palms. In the area around the Buada Lagoon, Nauruans have managed to grow some bananas and vegetables. The island produces 23,810 pounds (10.8 metric tons) of carbon dioxide emissions per capita. The global warming trend that is affecting the rest of Oceania is also causing sea levels to rise on Nauru, leaving low areas exposed to flooding and tidal surges. The habitats of many birds have been destroyed by mining and other ecological damage. Consequently, some species, such as the bristle-thighed curlew and Finsch's reed warbler, are threatened. Other species have completely disappeared. The government plans to reclaim some former mining land for use in housing, public utilities, and recreation.

Nauru is divided into 14 districts, and the national government is composed of a president, an 18-member unicameral legislature, a Supreme Court, and various government agencies. There is no minister or agency exclusively assigned to the environment, and environmental laws are virtually nonexistent. Despite its small size, Nauru has committed itself to protecting the global environment by signing the following international agreements that impact on its own environment: Biodiversity, Climate Change, Desertification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, and Ozone Layer Protection.

Needs and Wants

OUR SOCIAL, ECONOMIC, and political arrangements are supposed to serve the fulfillment of human wants and needs; our concepts of wants and needs, and the methods by which we try to fulfill them, have profound environmental and social implications. We need those things without which we would suffer greatly; we want things that would be desirable, but that we can fairly easily do without.

The distinction between needs and wants can be very fuzzy and politically contentious, especially because degrees of suffering are not simply determined by external circumstances, but also by human psychological states. Furthermore, particular desires may point to underlying unacknowledged needs, for example, an eating disorder involving excessive food cravings or an obsessive desire to lose weight may be a response to an unmet need for love.

IS ENVIRONMENTALISM A LUXURY?

The science that most directly studies human needs is psychology. For example, Abraham Maslow, one of the founders of the subdiscipline of humanistic psychology, recognized a hierarchy of needs, beginning with physiological needs (such as for food) at the base, and progressing to needs for safety and security, love and belonging, esteem, and finally, self-actualization. He classified all but the last as "deficiency needs," the absence of which inhibits growth and development, and postulated that these deficiency needs had to be met before people could devote themselves to self-actualization, a "growth need." Other psychologists conceptualize needs somewhat differently, but it is important to note that "nonmaterial" needs are widely recognized as basic to healthy human development.

Much cruder hierarchical models of human needs than Maslow's are at the basis of claims that the desire for environmental protections is a "post-material" want that becomes important only once a society has reached a certain level of affluence. According to this conception, environmentalism is a luxury that the poor cannot afford; they are served best if pollution of air, water, and land is condoned as a necessary price of progress. Hence, the siting of polluting industries in poor countries and neighborhoods helps both the rich (who can indulge in NIMBYism) and the poor (who gain by an increase in employment opportunities).

Critics of this conception point out that even (and especially) the poorest people need such things as friendship, social solidarity, and a sense of identity. For example, Manfred Max-Neef developed a matrix of human needs for subsistence, protection, affection, understanding, participation, idleness, creation, identity, and freedom, each of which involves being (e.g., the subsistence need of being healthy), having (e.g., the need to have peace of mind as a part of idleness), doing (e.g., the need to participate by cooperating and dissenting), and interacting (e.g., the need for a setting in which one belongs as part of identity). He posits these needs to be nonhierarchical and finite. According to this conception, there is no necessary reason why "material" needs should be prioritized over "nonmaterial" needs; hence, for example, we should not wait until needs for food and shelter are met before talking about the need for a clean environment.

AN ENVIRONMENTALISM OF THE POOR

The very distinction between "material" and "nonmaterial" needs is erroneous, however, in the sense that material needs include natural resources that are not provided by the market. Thus, as argued by Ramachandra Guha and Juan Martinez-Alier, there is an "environmentalism of the poor," which focuses on the needs of the poor for access to resources such as clean water and air, fuelwood, fodder, medicinal plants, grazing land, and fertile soils. If these resources are taken away from them and managed for the benefit of elite interests (e.g., timber for the wood industry), the results typically include the intensification (or creation) of poverty and unsustainable resource management.

It is in the interest of the poor to ensure that their local resources are used sustainably, because they know that they and their children will not be able to move to another place in order to exploit resources there. This environmentalism of the poor may differ from that of the rich (which may focus on beautiful views, for example), but is no less real.

ECONOMIC GROWTH VERSUS LIVING SIMPLY

Neoclassical economics is based on a conceptualization of needs going back to late 19th-century positivist approaches, which treated needs and wants as beyond the reach of scientific inquiry because of their irrationality. It ignores any distinction between needs and wants by treating them both as wants. These wants are posited to be infinite, in the sense that a person's wants can always expand beyond the present capacity to fulfill them—and usually do. Hence, people are believed to live in a condition of perpetual scarcity.

Markets are believed to be capable of fulfilling most human wants—or at least, they are believed not to interfere with the fulfillment of any important wants. If a market transaction does interfere with the fulfillment of others' wants, this is considered an "externality," usually regarded as an exceptional occurrence. The problem of ranking different people's wants is to be performed by the market: the amount people are willing to pay for a commodity (its exchange value) is supposed to be an accurate indicator of their desire for that commodity (demand) balanced against the difficulties of supply. Political processes of ranking different people's needs and wants are regarded as an unnecessary and counterproductive interference in the workings of the invisible hand of the market. These claims help justify the universal "need" for continuous economic growth and for minimal government regulation either to protect the environment or to promote social welfare.

In opposition to these claims of neoclassical economics, various critics have pointed out that both wants and needs are constantly being created. The multimillion-dollar advertising industry exists solely to stimulate desires where they may not have existed before; likewise, shopping environments are designed in an attempt to stimulate wants of the customers.

Needs, and not mere desires, are being created by what Illich has called "radical monopolies." For example, urban environments are transformed to the point that people can no longer reach their destinations by walking or cycling, so that they need mechanized transport. If, furthermore, public transport is allowed to decay, people need cars and have lost important freedoms.

In the words of Peter Hershock, "the better we get at getting what we want, the better we get at wanting; but the better we get at wanting, the better we get at getting what we want, though we won't want what we get." According to such arguments, economic growth as we know it is incompatible with the satisfaction of people's most important needs and leads to senseless environmental destruction. Nonmarket mechanisms are needed in order to direct economic development in ways that actually allow people to reach their highest goals (such as for self-actualization).

On the basis of similar critiques of the concept of unlimited needs, sometimes based in religious ideas (for example, monastic traditions in Buddhism, Taoism, and Catholicism), some people seek freedom through the elimination of wants, either individually or collectively. Their goal is to "live simply so that others may simply live," such as in intentional communities that seek to live in harmony with their natural surroundings. Efforts to reduce people's needs may also focus on larger scales, such as the promotion of "livable cities" that reduce reliance on cars and other energy-demanding technologies.

Neem

THE NEEM TREE, or *Azadirachta indica*, has been used by people for centuries because of its many beneficial properties. This evergreen, which can reach up to 66 feet (20 meters) in height, originates in the Indian Subcontinent and Myanmar but has spread to Africa and the Caribbean. In addition to providing shade and firewood and halting desertification, neem has been highly valued for its pest-resistant properties. Neem's extremely bitter seeds and leaves can act as natural pesticides that do not kill pests but alter their behavior so that they do not feed on the tree. Even sprinkling neem extracts on certain crops can help these crops develop immunity to certain pests as they incorporate neem extracts into their system. Neem has helped protect farmers from losing crops to pests for centuries in India and is now used in various other parts of the world.

Neem also has benefited human health, especially since the seeds and leaves contain compounds with demonstrated antiseptic, antiviral, and antifungal activity. Neem also possesses anti-inflammatory, hypotensive, and antiulcer properties. It can disable fungi from producing aflatoxin, the most powerful carcinogen known. Its bark, leaves, flowers, seeds, and fruit pulp have been used to treat diseases and ailments such as malaria, leprosy, diabetes, ulcers, skin disorders, and constipation.

Neem has been used for dental hygiene because twigs of neem have antiseptic compounds in the bark that prevent tooth decay and inflammation of the gums. Oil from neem also has various purposes. It can be used for contraception because it is a spermicide. In addition, the oil has been used for heating, lighting, and crude lubricating jobs. Neem has been used in soaps, cosmetics, disinfectants, and other industrial products. The ability to have exclusive rights over neem have, however, been contested for a decade.

In 1994, W.R. Grace, a U.S.-based multinational agribusiness, fought to patent the intellectual property rights over neem oil. It was not until 2005 that they lost this patent with the aid of the Green Party of the European Union (EU) Parliament; Dr. Vandana Shiva of the India-based Research Foundation for Science, Technology and Ecology; and the International Federation of Organic Agriculture Movements. They challenged the European Patent Office by protesting W.R. Grace's claim to novelty over neem oil, which is required in order to patent an item under the Trade Related Intellectual Property Rights agreement. Those challenging the patent point out that neem oil has been part of public traditional knowledge for centuries in India. The success of the patent challenge of W.R. Grace is an example of how biopiracy, in which corporations from the North claim ownership of resources without permission or providing compensation, can be fought.

Nepal

THE KINGDOM OF Nepal adopted a cabinet system of government in 1951 after dispensing with a hereditary monarchy. Since 1996, however, Nepal has been threatened with political unrest resulting from a Maoist insurgency and a drug-motivated murder-suicide among members of the royal family in 2001.

At least 13,000 Nepalese have died in continuing political strife. In 2005, the new king dissolved the existing government and declared a state of emergency. The following spring, some 300,000 Nepalese took to the streets to protest the king's usurpation of governmental power, forcing the monarch to agree to reinstate Parliament, offering hope for Nepal's future.

The landlocked country is surrounded by China and India. Southern Nepal is made up of a flat river plain known as *tarai,* which gives way to the Himalayan Mountains in the north and the hills of the central region. Elevations range from 230 feet (70 meters) at Kanchan Kalan to 29,035 feet (8,850 meters) at the top of Mount Everest. Including Everest, Nepal is home to eight of the 10 highest peaks in the world.

Southern Nepal experiences subtropical summers and mild winters, but the mountainous northern areas are prone to severe winters and cool summers. When Nepal's summer monsoon season is intense, severe thunderstorms, flooding, and landslides occur. In 2003, 300 people died from such disasters. Conversely, drought and famine may result from lighter-than-normal rainfall in the summer months.

With a per capita income of only $1,500, Nepal is one of the poorest and least developed countries in the world. The high fertility (4.1 children per woman) and infant mortality (65.32 deaths per 1,000 live births) rates combine with a rising HIV/AIDS (0.5 percent) rate and high incidences of diseases such as malaria and tuberculosis to create low life expectancy (60.18 years) in Nepal.

The low literacy rate (45.2 percent), particularly among females (27.7 percent), makes it difficult to lower the poverty level (31 percent) and educate the people on how to care for themselves and their environment. While 84 percent of Nepal's population have access to safe drinking water, only 27 percent have access to improved sanitation. The United Nations Development Programme Human Development Reports rank Nepal 136th of 232 countries in overall quality-of-life issues.

Over a fifth of Nepal's land area is arable (21.68 percent), and more than three-fourths of the population is engaged in subsistence agriculture. In their struggle to survive, some Nepalese farmers have turned to producing cannabis and hashish for the domestic and international markets. The 6 percent of the population that is involved in the industrial sector are chiefly employed in agricultural-related manufacturing, including the jute, sugarcane, tobacco, and grain industries.

Political unrest presents a major threat to Nepal's essential tourist industry. Natural resources include quartz, water, timber, hydropower, and small deposits of lignite, copper, cobalt, and iron ore. A largely unskilled labor force has led to high unemployment (42 percent) in key areas and technological backwardness.

The practice of using wood for fuel has left Nepal with depleted forests and has contributed to the loss of wildlife among rich ecosystems, which range from tropical jungles to frozen valleys. Nepal is home to some 735 documented species of birds, 25 of which are endangered, and 500 species of butterflies. Of 181 endemic mammal species, 31 are endangered. Approximately 7,000 different species of plants have been identified in Nepal. In 2005, English scientists implemented a project in which samples of each plant species have been transplanted to Britain to ensure survival.

Although the Nepalese government has protected approximately one-fifth of the land area, political considerations continue to threaten the environment. Consequently, nongovernmental organizations (NGOs) play an essential role in conservation efforts. Problematically, the tourism upon which the economy of Nepal so heavily depends further exacerbates ecological problems, since trekking posts make heavy demands on wood fuel to accommodate cooking, baths, and other amenities for foreigners.

Severe water pollution has resulted from improper disposal of human and animal wastes, agricultural runoff, and industrial effluents. Although only 15 percent of Nepalese live in urban areas and carbon dioxide emissions are minimal when compared to industrial nations, urban residents in Nepal are exposed to unhealthy levels of vehicular emissions. In 2006, scientists at Yale University ranked Nepal 81st of 132 countries on environmental performance, above both its geographic and economic counterparts. The lowest scores were received in the categories of air quality and environmental health.

Climate change throughout the world is believed to have contributed to a thawing of snow and glaciers in the Himalayas, with at least 26 glacial lakes at risk. Scientists are especially concerned about the changes taking place at the Tsho Rolpa glacial lake near the capital city of Kathmandu, where the lake has expanded from 0.23 square kilometers to 1.7 square kilometers since 1950.

The Kawari glacial lake at the foothill of Annapurna II Mountain has also caused alarm after bursting in 2003 at a cost of five lives and $100,000 in property damage. Such climatic changes increase the intensity of natural disasters in Nepal. Additionally, the government has noted a haze that appears in the breadbasket of the southern plains during the winter, adversely affecting crops.

In 1956 Nepal began a program of environmentalism by passing the Ancient Monuments Protection Act. A series of acts followed, including the Aquatic Protection Act of 1960, the Plant Protection Act of 1964, the Soil Conservation and Watershed Management Act of 1982, the Wild Life Conservation Act of 1987, and the Environment Protection Act of 1996. Since 1993, the government has operated under the Nepal Environment Policy and Action Plan, with implementation and compliance assigned to the Ministry of Population and Environment. Nepal participates in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, Ozone Layer Protection, Tropical Timber 83, Tropical Timber 94, and Wetlands. The Nepalese government has signed but not ratified the agreement of Marine Life Conservation.

Netherlands

BORDERING ON THE North Sea, the Netherlands has 280 miles (451 kilometers) of coastline. The country is also located at the mouths of the Rhine, Maase, and Scheld Rivers. The temperate and marine climates result in cool summers and mild winters. The Netherlands is chiefly comprised of coastal lowlands and numerous polders—land that has been reclaimed from the sea—with some hilly sections in the southeast.

The process of land reclamation began in the 17th century when windmills were used to drain lakes in the north. In the southwest, land was built up over time as tides deposited sand and silt on the shore, allowing the Dutch to reclaim the land with dikes. Around Groningen and Friesland, the government built dams out into the sea to promote the accumulation of sand and silt. In 1930, the government drained the first polder at Wieringermeer. Today, some 5,000 polders cover the Netherlands, and dikes and pumps maintain the water level at around three feet (0.91 meters) below ground level for purposes of cultivation.

As a result of its unique geography, the Netherlands is extremely vulnerable to flooding. This vulnerability was tragically illustrated in what became known as the "Battle of the Floods," which began on January 31, 1953, when a violent storm on the North Sea ravaged the country. The land where hundreds of people lived below sea level had been protected for centuries by 700 miles (1,127 kilometers) of dunes, dikes, and pumping systems, but none of these could withstand winds of 100 miles (161 kilometers) per hour and waves several feet high. In the middle of the night, as the raging tides reached shore, church bells rang and sirens wailed. Within a few hours, the country had been cut in two.

Some 100,000 people were successfully evacuated from low-lying areas, but 1,800 people died. The port city of Rotterdam was under water, and many small towns and villages became islands. Others were totally washed away. Ultimately 332,500 acres of cultivated land was under water, and tens of thousands of livestock drowned. Some 143,500 houses were flooded, and another 20,000 were damaged. Eighty breaks were identified in the dikes, some over 600 feet (183 meters) wide. Others simply crumbled away. To prevent a repeat occurrence, the government launched the Delta Project, constructing a series of dams, sluices, bridges, and canals and erecting a movable water surge near Rotterdam. Unfortunately, fisheries were negatively affected by these protective measures. With global warming expected to cause sea level rise by as much as a meter over the next century, further sea wall construction is ongoing. This climatological reality has also caused enhanced Dutch participation in climate change control treaties and alternative energy exploration.

Today the Netherlands is ranked as the 21st richest nation in the world, with a per capita income of $30,500. The United Nations Development Programme Human Development Reports rank the Netherlands 12th in overall quality-of-life issues. Chiefly located in the delta of the Rhine, 26.71 percent of the land area is arable, and the Netherlands is a major exporter of agricultural products. Other natural resources include natural gas, petroleum, peat, limestone, salt, and sand and gravel.

Some 16,407,491 Dutch live in an area of only 16,033 square miles (41,526 square kilometers). Nearly 66 percent of those live in urban areas, and there are 384 cars for every 1,000 people. The Netherlands produces 0.6 percent of the world's carbon dioxide emissions. Other environmental problems derive from heavy industrialization, with food processing, chemicals, petroleum refining, and electrical machinery enterprises dominating the industrial sector. Consequently, water sources are polluted with heavy metals, organic compounds, and various nutrients that include nitrates and phosphates. A 2006 study by Yale University ranked the Netherlands 27th of 132 countries in environmental performance, below the comparable income and geographic groups. The lowest ratings were received in the categories of biodiversity and air quality.

Environmentalism was first placed on the Dutch agenda in 1970 in response to public concern. In 1970, the Staten-Generaal passed the Surface Water Act and followed it up two years later with the Air Pollution Act. Both acts were designed to check pollution at the local level and force industries to be environmentally responsible. Despite these efforts, pollution remained widespread throughout the 1980s. Tests revealed that groundwater was polluted with nitrate from agricultural runoff, and soil samples contained high levels of chemicals. The entire ecosystem of the forests was threatened by acid rain.

In 1989 the Dutch conducted the Concern for Tomorrow study and identified problems at all levels, setting goals for combating each problem. Under the leadership of the Ministry of Agriculture, Nature and Food Quality, the government established the National Environmental Policy, the first comprehensive national plan geared toward a sustainable economy. The long-term plan, covering 1990 to 2010, established 10 targets that ranged from agriculture and industry to research institutions and consumers, charging each group with cutting pollution and/or developing new technologies for protecting the environment.

Under the 1990 Nature Policy Plan, the Dutch set up the National Ecological Network to promote biodiversity and protected 14.2 percent of the land area. The protected land includes 19 national parks, including the Hoge Veluwe, the Veluwezoom, and the island of Schiermonnikoog. Of 55 mammal species endemic to the Netherlands, 10 are endangered; however, only four of 192 endemic bird species are threatened.

The Netherlands supports the global environment by participating in the following international agreements: Air Pollution, Air Pollution–Nitrogen Oxides, Air Pollution–Persistent Organic Pollutants, Air Pollution–Sulfur 85, Air Pollution–Sulfur 94, Air Pollution–Volatile Organic Compounds, Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Marine Life Conservation, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling.

New Caledonia

THE SEMITROPICAL ARCHIPELAGO of New Caledonia lies 930 miles (1,500 kilometers) east of Australia and 11,160 miles (18,000 kilometers) from Metropolitan France, of which it is an overseas possession. Just off the northeast coast of the main island, Grande Terre, lie the Loyalty Islands, raised coral atolls. Grande Terre is 248 miles (400 kilometers) long by 31 miles (50 kilometers) wide and is a piece of Gondwanaland that broke away from Australia 60–80 million years ago. This island contains great mineral wealth, including about 25 percent of the world's nickel reserves, and is the third-largest producer of nickel, which represents over 90 percent of its export revenues.

The rare plants that have managed to adapt to the soil's high mineral content are unique to New Caledonia. The archipelago therefore exhibits extremely high levels of floral and faunal (terrestrial and marine) endemism. There are 3,200 plant species, of which 79 percent are found only there, while the islands and surrounding lagoon are home to many species of bats, birds, and lizards, as well as the dugong and five species of sea turtle. New Caledonia is considered a conservation priority by the World Wildlife Fund (WWF), Conservation International, and the World Conservation Union (IUCN), for both its coral reef (the world's second largest) and its unique dry forests. Few fragments of the original habitat remain, however, due to uncontrolled fires; nonnative cattle, pigs, and deer; urban and industrial activities; and, of course, mining, which began in 1874 and intensified greatly in the 1950s. The environmental impacts of strip-mining, which include soil erosion, sedimentation of rivers and beaches, and coral reef damage, were virtually unregulated until the 1970s. Although mineral extraction is less damaging today, abandoned mines continue to undergo serious erosion and leaching into watercourses. Meanwhile, the archipelago's sole nickel refinery is its main source of atmospheric pollution, and two more are planned.

Melanesians reached New Caledonia around 3,000 years ago (as marked by the Lapita pottery site), and a complex system of exchange relations and chieftaincies emerged, supported by traditional yam farming and fishing. Captain James Cook and his crew landed on Grande Terre in 1774 and named the archipelago. However, France took possession in 1853, and over the next century the original inhabitants, the Kanak, saw their most fertile lands seized while they themselves were forced onto reserves, to the detriment of their culture and languages.

Today, Melanesians make up the main ethnic group, at 45 percent of the total population, estimated at only 231,000 in 2004. Another 34 percent of New Caledonia's inhabitants are people of European origin, many being the descendants of former French prisoners banished to Grande Terre in the late 19th century. Other minority ethnic groups originate from the Pacific and Asia. Due almost entirely to financial transfers from Metropolitan France, New Caledonia's high Gross Domestic Product (GDP) places it among the 20 wealthiest nations in the world. However, this wealth has traditionally been concentrated in the capital, Nouméa (home to over 60 percent of the population) and is skewed toward those of European descent. French is the lingua franca, although over 20 Kanak languages are still recognized.

Grievances over colonial dispossession of Kanak land rights and their economic disadvantage have persisted. Most recently an organized Kanak pro-independence movement emerged in the 1970s, and the 1980s saw violent uprisings against settlers and France. The Kanak leader, Jean-Marie Tjibaou, signed the Matignon Accords with the loyalist leader, Jacques Lafleur, in 1988, assenting to restitution of customary lands, promotion of Kanak culture, preparation for a future New Caledonian élite, rural development activities, and a referendum on independence after 10 years. Tjibaou was assassinated by a Kanak separatist in 1989, and the 1998 referendum did not sanction full independence. Instead, the Nouméa Accords gave further recognition of Kanak land rights and economic integration. It also provided for gradual devolution of some administrative powers to the territory, which—although remaining a part of France—became an "Overseas Country" (*Pays d'outre-mer*) in 1999. Kanak now have political majorities in two of the three provinces, and another referendum on independence is scheduled to occur between 2013 and 2018.

New Urbanism

NEW URBANISM, A movement in architecture and planning, grew out of a belief that postwar suburban sprawl in the United States would not be able to sustain growth without adversely affecting the environment. It was a response to urban development accompanied by environmental degradation, a declining public realm, and the rise of edge cities. The principles of new urbanism were delineated by a group of architects, planners, developers, scholars, and elected officials between 1993 and 1996 and defined by the Congress of New Urbanism (CNU) Charter, which summarizes each of the 27 new urbanist design principles. These design principles are organized into three main categories that guide development at various scales: The region (metropolis, city, and town); neighborhood, district, and corridor; and block, street, and building.

The key idea behind new urbanist design principles is to promote organized development in the form of neighborhoods that are diverse, compact, mixed use, pedestrian-friendly, and transit-oriented. The neighborhood is a crucial building block within which there are different housing types, shops, services, and civic spaces and amenities. Buildings are low- to mid-rise and high densities create a compact urban form suited to pedestrians. This helps to reduce auto dependence and promote the use of alternative forms of transportation. Civic institutions and parks occupy prominent sites. In dense urban areas, the neighborhood center is usually the commercial corridor and residential areas are arranged in semicircular patterns radiating from the center. Such patterns are often modeled on traditional U.S. villages, towns, and cities, some of which were built before World War II, including historic sections of Annapolis, Maryland, and Savannah, Georgia. The principles also emphasize that it is essential for new developments to take into consideration the local history, culture, geography, and climate of a place so as to create a distinct architectural style that is unique to the place.

Many cities and counties in the United States are beginning to incorporate new urbanist design principles not only in new suburban developments but also in urban infill developments and urban transit-oriented developments. New urbanist design principles also resonate with environmental protection, sustainable development, historic preservation, smart growth, and pedestrian and bicycle planning programs. In the field of housing, new urbanism got a major boost when Henry Cisneros, former Secretary of the U.S. Department of Housing and Urban Development (HUD), signed the CNU Charter in

May 1996. Cisneros also initiated the Homeownership Zone program, which offered grants and loans to cities for redevelopment based on new urbanism. Principles of new urbanism have also been adopted in Hope VI, a HUD program that uses public and private development resources to replace distressed public housing with new mixed-income housing.

New urbanism may help minimize land consumption through increased density. Moreover, the emphasis on environmentally sensitive building techniques and on transit-oriented development may conserve energy. New urbanists point out that the combined effect of the two most important characteristics of new urbanist projects—pedestrian-oriented design and infill development—could have an ecological footprint that is almost 20–30 percent less than that of conventional suburban developments. Although such claims have yet to be proven by empirical research, studies have found new urbanist projects to protect and restore ecologically sensitive areas and reduce impervious surfaces, which have helped improve watershed protection.

Although the principles of new urbanism recognize that physical planning means going beyond just interesting architecture and good site planning, one of its major criticisms is that it tends to rely on the long-discredited concept of "physical determinism" and discounts the importance of developing social relationships for creating a sense of community. Other criticisms relate to social equity and gentrification of inner-city neighborhoods, which displaces low-income and minority households. For instance, critics note that celebrated new urbanist projects such as Seaside, Florida, have become gentrified, high-priced resorts for the rich. New urbanist projects also face opposition in the form of NIMBYism as high-density and mixed-use developments are contested by neighboring communities.

New Zealand

NEW ZEALAND COMPRISES two main and several smaller islands totalling 267,707 square kilometers. There are over 200 peaks in excess of 2,300 meters. Situated on the boundary of the Indo-Australian and Pacific plates, the land is tectonically active. It has been shaped by volcanism, glaciation, and subsequent erosion. Located in a zone of prevailing westerly winds, the climate is temperate. Prior to settlement the land was largely forested, and as a result of its long biogeographical isolation, New Zealand had many endemic species, including numbers of flightless birds. Apart from bats, it had no land mammals and few predators.

As one of the last islands to be occupied by humans, the rate of environmental change, particularly over the last 200 years, has been dramatic. Estimates of first settlement range from 600 to 1,500 years ago, though 1,000 years ago is widely accepted. Volcanic eruptions and related forest fires modified the vegetation, a process accelerated by the Maori people's burning and clearing. Even so, the Maori land ethic of *kaitiakitanga* approximated that of stewardship. Over half the country remained forested at the time of European colonization in 1840. Some 34 bird species including the Moa (Dinornithiformes order) had become extinct by 1840 from hunting. Another nine became extinct after 1840 under pressure from predators and habitat loss; forest cover was reduced to 25 percent of land area by 1900.

Navigator James Cook mapped the islands in 1769 when the Maori population totalled about

86,000. He noted forests of trees suitable for ships' masts. A sealing, whaling, and flax and timber gathering bonanza followed in the 1790s through 1810s. Britain incorporated New Zealand into its empire by way of treaty in 1840. British settlers privileged permanent occupation and cultivation of land and regarded apparently unoccupied spaces as lands going to waste. By 1858 the 59,000 settlers had exceeded the dwindling Maori population.

An export economy developed around extensive pastoralism based on wool production for British markets. On leasehold tussock grasslands in the South Island, regular burning was an environmentally-damaging management tool. Gold rushes in the 1860s provided addition revenues, but by 1890 the settlement focus shifted to the more heavily forested North Island. Government-purchased Maori land was rapidly transformed into small farms for dairying and livestock. Refrigeration technology became vital to the process of agricultural intensification and converted New Zealand into one of Britain's imperial farms. Subsequently, huge amounts of phosphates were imported from Nauru and along with the perennial rye grass and clover pastures enabled further gains in agricultural productivity in the 1920s and 1930s.

From 1840 to the present, 80 animal species and 1,800 plant species have been introduced to New Zealand. Some were for economic purposes, others became weeds, and rabbits introduced for sport quickly became noxious pests. A peak of forest destruction in the 1890s helped trigger the setting aside of national parks and reserves that totalled 8 million hectares, or just under 30 percent of the land area, by 2004. By 1911, 50 percent of the population was urban, although the Maori population remained predominantly rural until 1966. From one million in 1908, the population doubled by 1952, reached three million by 1973, and rose to over four million by 2006. The Auckland urban area constituted 29 percent of the total population by 2001, contributing to its transport infrastructure problems.

The government led the way in forestry and soil and water conservation from the 1920s to 1940s. By the 1980s neo-liberal reforms witnessed the privatization of forest plantations and left soil conservation to regional governments. The Resource Management Act of 1991, regulating on the basis of sustainable management and adverse environmental outcomes, replaced over 50 acts. At the same time, international tourism, promoted by slogans such as "100 percent pure," now contributes significantly to the economy. Agricultural exports remain important to the economy. New Zealand today is highly urbanized, with rural landscapes that have scenic qualities but are still the result of over 100 years of rapid and extensive environmental transformation.

The Lord of the Rings

In 1997, film director Peter Jackson acquired the rights to produce a film version of J.R.R. Tolkien's great work, *The Lord of the Rings*, which had originally been published in three volumes (1954–55). The bestselling books drew much from Tolkein's interest in Saxon England—he was a professor of Anglo-Saxon (Old English) at Oxford University.

Although present in the books, the environmental message of the story is much more obvious in the film version. The films were made in New Zealand in largely pristine wilderness. The Hobbit characters, who live in the green Shire, are pleasant, cheerful, and naïve, though some of their supporters are more worldly-wise. The enemies of the Hobbits, especially the Orcs, are warlike environmental vandals. In *The Two Towers* (2002), the second film of the trilogy, the Orcs saw down trees to build machines of war; their industry despoils the countryside, leaving a trail of environmental devastation in their wake. The Hobbits form an alliance with the Ents, who are tree spirits, a concept common in some Anglo-Saxon legends. The Ents attack the Orcs, whom they blame for the wanton destruction of the forests. The environmentally conscious are depicted as forces of good, while despoilers of the environment represent forces of evil. It is a statement made far more overtly in the films of the early 2000s than in the books of the 1950s.

Nicaragua

ROUGHLY THE SIZE of New York state and with 5.6 million people, Nicaragua is the largest country in Central America and its least densely settled. Paradoxically, it is also one of the poorest countries in the Western Hemisphere. Fifty percent of its population lives below the poverty line, and a third is younger than 15 years old. Nicaragua can be divided into three environmental regions: the tropical, dry Pacific coastal plain, the Central Highlands, and the Caribbean Coastal Plain. These regions share common social and environmental concerns but also have specific problems of their own.

Deforestation is an issue throughout the country. An expanding agricultural frontier east of the more densely settled Pacific region responds to ebbs and flows in markets and governmental priorities. In the 1960s relocation projects sought to "bring light to the jungle" by moving peasants into the rain forest. Ongoing road building and illegal timber extraction continue to bring colonists and speculators to the indigenous lands of the Caribbean Coastal Plain. Another important cause of deforestation is fuelwood gathering. At least 90 percent of Nicaragua's rural population and 60 percent of its urban population relies on wood or charcoal for cooking and heating. This unsustainable activity has no quick remedy in a country with no natural gas production.

Ninety percent of Nicaragua's watersheds drain to the Caribbean through 11 major rivers. Their silt loads maintain the Nicaragua shelf, one of the most productive marine environments in the hemisphere. Traditionally providing an abundant livelihood for indigenous peoples, Nicaragua's Caribbean fisheries have become big business. Poorly regulated exports of lobster averaged $25 million a year through the 1990s. Fishing canneries provide jobs but are not sustainable. Offshore coral reefs are noticeably declining.

Perhaps the biggest marine problem is the rapid decline of coastal mangrove forests, particularly along the Pacific coast. Here, shrimp farmers are clearing mangroves to make new ponds. In 2001, Nicaragua was the world's 17th largest producer of farmed shrimp. Mangroves in the Gulf of Fonseca and elsewhere have also been cleared for firewood.

Water pollution linked to agriculture and ranching, untreated sewage, and soil erosion plague the 10 percent of Nicaragua's fresh water that drains toward the Pacific, where two-thirds of the population lives. The most egregious water contaminants of lime, cyanide, and mercury associated with gold mining in Caribbean watersheds have been addressed, but problems of regulation and enforcement remain.

National parks and forest reserves abound in the Caribbean coast—on paper. The Bosawas Reserve in the northeast, home to Mayangna and Miskito Indians, is one of the largest contiguous areas of tropical rain forest north of the Amazon basin. Like its southern partner, the Sí-a-Paz (yes to peace) Biosphere Reserve, it is part of an innovative binational effort to protect shared borderlands. Both reserves are also central to the Mesoamerican Biological Corridor, a linked series of protected areas designed to spur isthmus coordination and reduce ecosystem fragmentation. Nicaragua is the linchpin in the corridor.

Environmental awareness is growing in Nicaragua, but meanwhile, poverty demands solutions. One project designed to deal with poverty is the so-called dry canal, a high speed rail and port system that would offer cargo ships willing to unload and reload an alternative to the Panama Canal. The

The "Volcano" Stamp

The idea of a canal through Central America goes back to 1534. Charles V, the Holy Roman Emperor and King of Spain, felt that a canal would open up new lands and provide a faster route between Spain and Lima, Peru, the Spanish capital in Latin America. However, the nature of the task meant that it was not until the 19th century that the idea could be seriously entertained. Various surveyors plotted out possible routes for a canal. The two that seemed easiest were either through the narrowest part of Central America in what is now Panama, or through Nicaragua, making use of Lake Nicaragua and the San Juan River. It was partially in support of the latter scheme that William Walker tried to seize parts of Central America in the 1850s.

In the 1880s the French tried to build a canal in Panama, then a part of Colombia, but failed to see it through. As a result, in 1887 a U.S. surveying team went to Nicaragua to see whether a route through that country was more feasible. Two years later the U.S.-based Maritime Canal Company decided the Nicaraguan option was preferable. However, when the company's share price collapsed in 1893, work ceased. Still, Congress chose the Nicaraguan route in 1897, and again in 1899.

On January 1, 1900, Nicaragua brought out a series of postage stamps, printed by the American Bank Note Company of New York, that depicted Mount Momotombo, a volcano in Nicaragua close to the city of Léon. It had erupted several times in the past; in 1610 it buried a nearby Spanish settlement. When Congress had to vote on the route of the canal again in 1902, supporters of the Panamanian route circulated the Nicaraguan postage stamps to all members of Congress to warn them of the danger of a volcanic eruption so soon after the eruption at Martinique in the Caribbean, in which 30,000 people died. Congress changed its mind and voted for the Panamanian route. Work began in 1904 and the Panama Canal was completed in 1914.

proposed route cuts through the Sí-a-Paz Reserve and Rama Indian lands on the Caribbean coast—it is a desperate gambit intended to clear some forest to save the rest.

Nietschmann, Bernard Quinn (1941–2000)

BERNARD Q. NIETSCHMANN was a pioneering environmental scholar and indigenous rights activist. Throughout a professional career that spanned three decades, Nietschmann demonstrated that cultural and biological diversity are inextricably linked, but that the future of both was under threat from global markets and state-centered geopolitics.

Born in Peoria, Illinois, in 1941, Nietschmann received a doctorate in geography under the guidance of William Denevan at the University of Wisconsin at Madison in 1970. After teaching at the University of Michigan for seven years, Nietschmann moved to the University of California at Berkeley in 1977 and remained there until his death from esophageal cancer in 2000.

The publication of Nietschmann's 1973 book *Between Land and Water: The Subsistence Ecology of the Miskito Indians, Eastern Nicaragua,* and his follow-up marine work among both the Miskito and indigenous peoples in Torres Strait, Australia, brought him to the attention of society-environment scholars around the world. Based initially on his doctoral field study in the late 1960s, Nietschmann's seminal work examined how the Miskito adapted seasonally and spatially to resource availability. His scholarship was ground-breaking and contributed greatly to the vibrant field of cultural ecology.

Nietschmann's study of the Miskito and their coastal-marine habitats made at least five important contributions to our knowledge of society-environment dynamics. First, while some societies might be remote, neither they nor their ecosystems have been isolated from world market forces for at least several centuries. Second, subsistence groups respond to social and environmental change by making cultural adaptations to remain viable; indeed, many social practices result from successful cultural adaptation. Third, subsistence ecologies exploit a diverse resource base that makes them efficient, flexible, risk averse, and sustainable. Fourth, for the Miskito—and by extension all subsistence peoples—social relationships and economic exchange are inseparable. And fifth, it follows that accelerated market integration disrupts adaptive dynamics and social obligations, and can lead people into an economic and ecologic cul-de-sac that they are powerless to influence directly. As Nietschmann described it, many subsistence societies have had to "change to remain unchanged," to alter some lifeways in order to retain others.

"MAP OR BE MAPPED"

Beginning in the 1980s, Nietschmann's work tended toward human rights, geopolitics, and participatory mapping among indigenous, or what he called Fourth World, peoples. During the civil conflict in Nicaragua in the 1980s, for example, he wrote passionately about how Miskito ideas of their past underscored their armed resistance to the Sandinistas. His work advocated indigenous autonomy in Nicaragua's Caribbean half, and while rarely popular, this position proved to be the solution to the conflict in 1987. After the war, he promoted what he called "conservation through self-determination." To these ends, he helped Miskito turtlers map their marine territories and establish baseline environmental data on their fisheries. An outspoken environmentalist, Nietschmann became vocally opposed to top-down and outsider-led conservation initiatives that disregarded local indigenous knowledge and resource management practices.

In the 1990s, Nietschmann helped form GeoMap, a small group of Berkeley cartographers, to assist Mayan communities of Southern Belize to produce a first-ever indigenous atlas. In writing about this mapping experience, Nietschmann argued that indigenous peoples must "map or be mapped." Through his fieldwork and writing, Nietschmann sought to empower indigenous people by helping them to defend their ancestral homes and sustain their ecosystems and livelihoods.

Niger

AFTER ATTAINING INDEPENDENCE from France in 1960, the Republic of Niger was subjected to three decades of single-party military rule until Nigeriens propelled their country toward democracy and multiparty elections in 1993. However, a military coup in 1996 plunged Niger into political turmoil until democracy was restored three years later. With a per capita income of only $800, Niger is the 12th poorest country in the world. Ninety percent of the population is engaged in the agricultural sector, which is concentrated in the savanna of the south.

The uranium deposits of Niger are among the largest in the world. Other natural resources include coal, iron ore, tin, phosphates, gold, molybdenum, gypsum, salt, and petroleum. Frequent droughts and fluctuating uranium prices have slowed the economy, and in 2000 Niger qualified for the Highly Indebted Poor Countries initiative and was approved for participation in the Fund on Poverty Reduction and Growth Facility. Over 60 percent of the population lives in poverty, partly in response to food shortages that resulted from drought and locust infestation in 2005. Consequently, 34 percent of Nigeriens are severely undernourished. The United Nations Development Programme's Human Development Reports rank Niger 177th in the world in overall quality of life issues.

Landlocked Niger has only 300 square kilometers of inland water resources. Borders are shared with Algeria, Benin, Burkina Faso, Chad, Libya, Mali, and Nigeria. In northern Niger, four-fifths of the land is desert plains with sand dunes and hills. The southern area is savanna, with flat to rolling plains. Elevations range from 200 meters at the Niger River to 2,022 meters at Mont Bagzane. Niger's dry, dusty desert climate is one of the hottest in the world. In the extreme south, the climate is tropical. As part of the Sahel region of Africa, Niger is prone to prolonged droughts.

In large part because of poverty, Nigeriens are susceptible to a number of factors that affect environmental health. Approximately 46 percent of the population has sustained access to safe drinking water, but only 12 percent has access to improved sanitation. The population of 12,525,094 faces a very high risk of food and waterborne diseases such as bacterial and protozoal diarrhea, hepatitis A, typhoid fever, and the respiratory disease meningococcal meningitis. In some areas, there is a high risk of contracting malaria. There is also concern about the 1.2 percent HIV/AIDS adult prevalence rate that has killed at least 4,000 Nigeriens. Around 70,000 others are living with this disease.

As a result of health factors, Nigeriens have a life expectancy of only 43.76 years. Infant mortality is a major indicator of environmental health, and Nigeriens have an extremely high rate, with 118.25 deaths occurring among every 1,000 live births. Likewise, fertility rates are indicative of the standard of living, and Nigerien women give birth to an average of 7.46 children each. Niger has one of the lowest literacy rates in the world (17.6 percent). Less than 10 percent of adult women and only one-fourth of adult men are literate. Less than one-fifth of children attend school regularly. Consequently, disseminating health and environment information is difficult.

Large areas of vegetation have been destroyed by fires to clear land for agricultural purposes, and mismanagement has led to overgrazing and soil erosion. Deforestation is occurring at a rate of 3.7 percent each year, and the desert is encroaching on other lands. The rich biodiversity of Niger that includes elephant, hippopotamus, giraffe, and lion populations has been threatened by poaching and the destruction of habitats. Only 1 percent of Niger's land area is forested.

The government has protected 7.7 percent of the land area. Of 131 identified mammal species, 11 are endangered, as are three of 125 bird species. A study by scientists at Yale University in 2006 ranked Niger near the bottom of all countries ranked on environmental performance, with a score that was roughly half that of comparable income and geographic groups. Low scores were received in the areas of air quality and biodiversity and habitat, and Niger received only a single point in the category of environmental health.

In large part because of its status as a poor nation and its weak infrastructure, the government of Niger has made slow progress toward promoting sustainable development. In 1998 Niger adopted the National Environmental Plan for Sustainable Development and began working with the World Bank to rehabilitate its infrastructure and establish a framework for environmental policy. The Ministry of Hydraulics is involved with the battle to check desertification, and the Ministry of Health is responsible for dealing with environmental health issues. Niger has partnered with Benin and Burkina Faso to establish the "W" National Park that encompasses 826,254 acres of Nigerien land. Several game reserves have also been established.

Niger participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Ozone Layer Protection, and Wetlands. The Law of the Sea agreement has been signed but not ratified.

Nigeria

DESPITE HAVING ONE of the world's largest petroleum reserves and a wealth of natural resources—or perhaps because of it—the Federal Republic of Nigeria is plagued by dire poverty, poor governance, and environmental crises. Although the country adopted a new constitution in 1999 as part of a peaceful transition to civil government after almost 16 years of military government, the flow of resources out of the country continues unabated, while corruption and mismanagement plague the state. Attempts to rebuild damaged infrastructures and provide political stability have been threatened by ongoing tensions, as portions of the largely disenfranchised population turn to radicalized religious and political action. This volatile situation was much in evidence in 2006 when repercussions from a Danish caricature of the Prophet Muhammad led to the deaths of 100 Nigerians as Christians and Muslims attacked one another. Militants in the Niger River delta, protesting the massive poverty amidst resource wealth, have attacked pipelines and kidnapped workers.

Nigeria's natural resources include natural gas, petroleum, tin, iron ore, coal, limestone, niobium, lead, and zinc. Industry remains focused on oil, which accounts for 20 percent of the Gross Domestic Product, 95 percent of foreign exchange earnings, and around 65 percent of government revenues. Nigeria's other valuable resource is arable land (33.02 percent); and 70 percent of the workforce is engaged in mostly subsistence agriculture, which provides only 26.7 percent of the Gross Domestic Project. Nigeria's population has outstripped agricultural production, however, and much of the food supply is imported.

Major economic reforms were instituted in 2003 that nationalized four oil refineries and implemented International Monetary Fund reconstruction and growth measures. In 2005, initial debt relief from the Paris Club paved the way for billions more. At present, however, Nigeria remains a poor country with a per capita income of only $1,000, which places the country 211th of 232 countries in world incomes. Sixty percent of Nigerians live in poverty. Nigeria is ranked 50.6 on the Gini Index of Inequality, with the richest 10 percent holding 40.8 percent of wealth, and the bottom 10 percent sharing 1.6 percent of resources. The United Nations Development Programme's Human Development Reports rank Nigeria 158th in the world in overall quality of life issues. This is despite the fact that oil exports have earned revenues in excess of $340 billion over the last four decades; roughly nine percent of U.S. oil imports originate in Nigeria.

Bordering the Gulf of Guinea and the Bight of Benin in the Atlantic Ocean, Nigeria has a coastline of 853 kilometers and 13,000 square kilometers of inland water resources. A good deal of this water comes from the Niger River, which flows southward through tropical rain forests and swamps on its way to the Gulf of Guinea. Nigeria shares land borders with Benin, Cameroon, Chad, and Niger.

The southern lowlands give way to hills and plateaus in central Nigeria and to mountains in the southeast and plains in the north. Elevations range from sea level to 2,419 meters at Chappal Waddi. The climate of Nigeria is varied. Southern Nigeria is equatorial, and the north is arid, while central Nigeria is tropical. Nigeria is prone to periodic droughts and flooding.

Nigeria's population of 131,859,731 is experiencing a major HIV/AIDS epidemic. With a 5.4 percent adult prevalence rate, 3.6 million Nigerians are living with HIV/AIDS, which has killed 310,000 people since 2003. Forty percent of Nigerians do not have sustained access to safe drinking water, and 62 percent do not have access to improved sanitation. Consequently, Nigerians have a very high risk of contracting food and waterborne diseases that include bacterial and protozoal diarrhea, hepatitis A, typhoid fever, the vectorborne disease malaria, and the respiratory disease meningococcal meningitis.

Nigeria is also a highly endemic area for Lassa fever, which is contracted from contact with contaminated aerosolized dust or soil. Through the efforts of the Carter Center of Emory University, founded by former President Jimmy Carter, Nigeria is almost free of Guinea worm disease. In the 1980s, Nigeria was reporting 650,000 cases. By 2005, only 121 new cases were identified. In 2006, the Carter Center finally traced those cases to the Sacred Pond of Ogi in Nigeria, paving the way for eradication of the disease worldwide. High disease rates in Nigeria have led to low life expectancy (47.08 years) and growth (2.38 percent), and high infant mortality (97.14 deaths per 1,000 live births) and death (16.94 deaths per 1,000 population) rates. Nigerian women bear an average of 5.8 children each. A female literacy rate of 60.6 for females makes disseminating birth control and disease prevention information somewhat difficult.

ENVIRONMENTAL ISSUES

Nigeria is the most populous country in Africa and the tenth most populous country in the world. Rapid urbanization has led to a severely overburdened environment, particularly in the area of waste management. Soil degradation has occurred as a result of ill-advised agricultural practices that are compounded by natural disasters such as flooding. Deforestation is occurring at a rate of 2.6 percent per year due to logging and slash-and-burn agriculture. Desertification is extensive. Nigeria is experiencing air, water, and soil pollution that is derived in large part from the polluting practices of the oil and mining industries and from the overuse and misuse of pesticides. Biodiversity is at risk because of habitat loss and the practice of poor Nigerians eating bush meat to supplement diets poor in protein.

Oil spills have created major environmental damage, and gas flaring in Nigeria is affecting climate change throughout sub-Saharan Africa. Toxic chemicals released in the flaring process have created major health hazards, such as cancer. The Nigerian Senate ordered Shell Oil to compensate local residents who had been affected by the pollution, but Shell challenged their authority to do so. In 2005, the Federal High Court of Nigeria entered the fray, declaring that Shell had violated the constitutional rights of Nigerians and ordered the oil giant to cease all gas flaring in Nigeria.

In 2006, scientists at Yale University ranked Nigeria 123rd of 132 countries on environmental performance, below the relevant income and geographic groups. The lowest scores were received in the categories of environmental health and biodiversity and habitat. Around 15 percent of Nigeria's land remains forested, but the government has protected only 3.3 percent of land. One of these areas is the Afi Mountain Wildlife Sanctuary set up to protect the Cross River Gorilla and other primate species.

In 1978, the Nigerian legislature passed the Land Use Act. A decade later, the government created the Federal Environment Protection Agency and the Natural Resources Conservation Council and charged them with implementing and monitoring environmental laws geared toward sustainable development. The following year, the Council Act initiated legal conservation measures and overturned traditional ownership practices, placing ecologically important land under the guardianship of federal and state governments. In 1992, the legislature enacted the Environmental Impact Assessment Act and instituted the Acacia Tree Plan Experiment to check the spread of deforestation. In 1999, the Nigerian government revised existing environmental laws and broadened their application.

Nigeria participates in the following international agreements on the environment: Biodiversity, Climate Change, Climate Change–Kyoto Protocol, Desertification, Endangered Species, Hazardous Wastes, Law of the Sea, Marine Dumping, Marine Life Conservation, Ozone Layer Protection, and Wetlands.

Nile River (and White Nile)

THE NILE RIVER is the longest river in the world and flows northward from its sources in eastern Africa toward the Mediterranean Sea. It spans 4,000 miles (6,700 kilometers), beginning at Lake Victoria, which is perched in the highlands of east Africa on the equator and is just one of the three sources of the Nile. The branch of the river that starts from Lake Victoria is known as the White Nile. This branch provides the greatest volume of water to the Nile River as it flows year round. However, not much of the Nile's waters reach Egypt due to evaporation across the desert.

As the Nile passes through the Sudan, the gradient, or slope, becomes so gradual that the water spreads out to form swamps called *sudd*. Millions of years ago, long before the Nile found its way out to the Mediterranean Sea, it is believed that there was an inland lake in the Sudan into which the White and Blue Nile used to flow. However, once this lake filled up, the Nile found itself flowing north on its present course to the Mediterranean Sea.

For Egypt, the most important tributary is the Blue Nile, whose source is Ethiopia's Lake Tana. This tributary, swollen by monsoon rains in the highlands of Ethiopia, has for centuries been the main source of floods to the surrounding valley of the Nile every year between June and September. These floods were heralded by the people along the Nile in Egypt as they brought in rich silt and water for irrigation. It is due to these floods and rich soils that the ancient Egyptian civilization achieved its grandeur. A lesser tributary of the Nile is the Atbara River, which flows from a source in the Ethiopian highlands; it joins the Nile in the vicinity of Khartoum, like the Blue Nile. The Atbara flows only when there is rain in Ethiopia and dries very fast.

The word *nile* comes from the Greek word *neilos*, which means "river valley." The ancient Egyptians called the Nile *iteru*, meaning "big river." Indeed, its large size is signified by the expanse of its drainage basin, which covers an area of 1.26 million square miles (3.25 million square kilometers), about 10 percent of the area of Africa. On its flow from Khartoum northwards, the river experiences a series of rapids, or cataracts, as it meets hard igneous rock beyond Aswan in Egypt.

Nubia, the region from Khartoum to Aswan, was the home of the Nubian civilization, which rose thousands of years ago alongside the Egyptian Pharaonic civilization. In Egypt, the river divides the country into two sections, Upper and Lower Egypt. Upper Egypt, also known as southern Egypt, is in the desert plateau from Aswan to Qena. Here, the Nile has dug a deep, wide gorge in the desert

Stanley and Livingstone

Henry Morton Stanley (1841–1904) was a British-American explorer who was best known for his search for the Scottish explorer David Livingstone and his famous phrase, "Dr. Livingstone, I presume." Stanley served as a soldier in the American Civil War, and then worked on merchant ships and in the U.S. Navy. After a short time as a journalist, he volunteered himself as a war correspondent for the New York *Herald,* eventually ending up in the Middle East. In 1869 he heard of the disappearance of Dr. David Livingstone, who had gone in search of the source of the River Nile three years earlier.

Stanley sailed for Zanzibar, gathered together a small group, and headed for Lake Tanganyika, which was the last place Livingstone was reported to have visited. There, at Ujiji, on the shores of the lake, he found Livingstone, ill and short of supplies. The two became friends and seem to have planned further exploration, but Livingstone died a year later. In the meantime Stanley had made his name as a journalist with *How I Found Livingstone,* which was published in 1872 and won the Patron's Gold Medal of the Royal Geographical Society.

Stanley later returned to Africa to continue Livingstone's search for the source of the Nile. With money from the New York *Herald* and the London *Daily Telegraph*, he led an expedition into modern-day Uganda. He mapped Lake Victoria, but killed a number of local tribesmen in a skirmish, an action heavily criticized in the British press. Livingstone had believed that there was a link between the Nile and the Congo, but this was found to be untrue. Stanley described his travels in his 1878 book *Through the Dark Continent*.

plateau. Downstream from Qena the Nile flows northward into the Nile Delta on the Mediterranean Sea. This upstream region (the northern portion of Egypt) is known as Lower Egypt. The Nile Valley's floodplain covers a total area of 4,250 square miles in a wide canyon before it reaches the Nile Delta, which itself measures some 8,500 square miles.

The delta represents 63 percent of the inhabited area of Egypt, extending about 120 miles (200 km) from south to north and roughly 250 miles (400 km) from east to west; the area supports about 72 million people. Almost all of Egypt's population is crowded along the Nile Valley and the delta, which comprise only five percent of Egypt's land. This area is exceptionally productive from the rich alluvial soils, controlled irrigation, and a long tradition of advanced farming practices.

The flow of the Nile is controlled by numerous 20th-century dams. The intense dependence of the Sudan and Egypt on the waters of the Nile has resulted in the building of two large dams, the Sennar Dam on the Blue Nile in the Sudan and the Aswan High Dam in Egypt. The Sennar Dam and others account for 80 percent of the Sudan's power supply. The Sennar Dam also delivers water to the Gezira plain, irrigating over 2 million acres of land. The Gezira Scheme, one of the most successful agricultural schemes in Africa, was begun in the 1920s under British colonial rule. It was later nationalized by the post-independence Sudanese government in 1956 and the area is now famous for the production of high quality cotton, wheat, and animal feed crops.

Egypt built its own huge dam, the Aswan High Dam, just north of the border between Egypt and the Sudan, which has resulted in the creation of a sizable lake christened Lake Nasser. This lake provides much-needed energy and water for irrigation and ensures that Egypt has some control over the flow of Nile waters toward its more fertile delta near the Mediterranean.

The fact that the Nile flows through several countries, including Uganda, the Sudan, Ethiopia, and Egypt, is a source of both conflict and cooperation. Ethiopia's population is on the increase and it too wishes to harness the waters of the Blue Nile; Uganda needs the waters of the Nile to generate much-needed energy. Demands on the waters of the Nile are increasing, not only by these four countries but also by others in this region. The fear is that these pressures might result in interstate armed conflict. Already there have been a number of posturing statements and numerous skirmishes between Sudanese and Egyptian troops over the waters of the Nile.

NIMBY

NIMBY STANDS FOR "not in my backyard," a term used to describe the reaction people have to the possibility of a "locally unwanted land use"—known as a LULU—being located in their communities. The term gained currency in the late 1970s and early 1990s.

Episodes like Love Canal and Times Beach created considerable fears that, if similarly unwanted uses for land were pursued in their communities, the community would suffer greatly. As the *Christian Science Monitor* noted in the first published reference to the term *NIMBY*:

> People are now thoroughly alert to the dangers of hazardous chemical wastes. The very thought of having even a secure landfill anywhere near them is anathema to most Americans today. It's an attitude referred to in the trade as NIMBY—"not in my backyard."

Wealthy communities often resist LULUs; the environmental justice movement seeks fairer distribution.

This logic was then extended to any sort of facility that might lower property values, from factories, to airports, to group homes for the disabled.

The 1960s and 1970s saw remarkable social change. One of those changes was the greater likelihood that people would at least temporarily join together to fight against an undesirable change in the character of their communities. This sense of empowerment has been translated into much more active community participation in planning and zoning—but only when a community senses a threat. There is considerably less mobilization when an opportunity is presented to a community to build desirable land uses, like parks or other open space (indeed, some people consider these kinds of developments LULUs as well).

Thus, any LULU can be a "negative externality." In economics, an externality is a benefit or a cost that accrues to nonparticipants in a transaction. For example, buyers and sellers of gasoline benefit, the buyer from having motor fuel available, the seller for being able to produce and sell the product profitably. However, a refinery in a residential neighborhood may also emit pollution, pose safety hazards, or just be too loud. The refinery therefore creates a negative externality, and the plant's neighbors benefit from being able to buy gasoline at less than the neighbors' cost—but pay the price of lower house values, impaired health, or the lessened enjoyment of their property—from the operation of the undesirable land use.

The challenge is in finding a way to fix the value of the externality to internalize the costs in the transaction and to compensate those suffering from the negative externality. It is often hard to find the right price to compensate people for having a prison, a factory, an airport, or a group home for disabled people located near their homes or businesses.

Another argument runs that people need to accept these facilities in their neighborhoods as other people do, as part of the costs involved in being part of a complex, interdependent society. The problem with this argument is that neither NIMBYism nor LULUs are evenly distributed. Usually, people of wealth and other means are able to successfully resist LULUs in their community, which then often are forced into lower income, often racially segregated communities. Indeed, this phenomenon is at the heart of the "environmental justice" movement, which seeks to more fairly locate or distribute LULUs so that poorer, less powerful people and neighborhoods do not disproportionately bear the costs of these facilities.

The terms NIMBY and LULU have spawned some colorful and often highly descriptive terms, such as BANANA (build absolutely nothing anywhere near anything), NOPE (not on planet earth), and even YIMBY (yes in my backyard), a term that applies either to the positive benefit of a particular type of development in one's "backyard" or the position taken by people who understand that the societal benefit of a LULU may be more important than the locally-felt costs.

Nitrogen Cycle

THE NITROGEN (N) cycle describes the transformation of nitrogen into its various organic and inorganic forms and its movement between different deposits in the atmosphere, soils, vegetation, and living organisms of the micro and macro fauna. The nitrogen cycle is one of the most important nutrient cycles within the world's ecosystems, since nitrogen is indispensable for the constitution of living organisms, which synthesize proteins, peptides, amino, and nucleic acids from nitrogen. However, the nitrogen cycle has to be managed carefully, since abundance of nitrogenous forms like nitrates in water or food can cause adverse effects on human health. Reactive nitrogenous gases in the atmosphere can contribute to climate warming and the destruction of the ozone layer. The terrestrial nitrogen balance of the nitrogen cycle with its major components can be described by the following equation:

$$dN/dt = N(R) + N(F) + N(bio) + N(H) + N(M) - N(P) - N(L) - N(D) \pm N(Er) - N(fix).$$

t = time
N(R) = nitrogen content in precipitation
N(C) = nitrogen input through combustion
N(bio) = nitrogen fixed by the nodules of leguminous plants and autotrophic bacteria
N(F) = nitrogen in organic and inorganic fertilizers
N(M) = mineralized nitrogen from soils
N(P) = nitrogen uptake by plants
N(Er) = nitrogen in- and out-flow by erosion
N(L) = leached nitrogen
N(D) = gaseous losses of nitrogen through denitrification
N(fix) = nitrogen fixed in clay minerals

Nitrogen (N) constitutes 78 percent of the atmosphere, and the whole atmospheric store is about a million times larger than all other N stocks. Atmospheric nitrogen inputs into the nitrogen cycle enter the soil-plant-water system through electrical processes, fires, combustion, and precipitation, processes by which molecular nitrogen, N_2, is combined with H_2 or O_2. The main natural nitrogen input from atmosphere to soil is induced by biological nitrogen fixation, which refers to the fixation and incorporation of atmospheric N_2 by the nodules of leguminous plants through a symbiosis with bacteria of the species rhizobium, as well as by nonsymbiotic fixation by autotrophic microorganisms as blue-green algae.

Nitrogen mineralization is the transformation of organic nitrogen mainly located in the topsoil into inorganic forms as ammonium NH_4^+ through the process of ammonification, frequently followed by the subsequent process of nitrification, which means the oxidation of the ammonium ions into nitrate, NO_3^-. The processes are mainly performed by species of *Nitrosomonas* and *Nitrobacter* and its kinetics are mainly dependent on the soil temperature.

The reverse process is immobilization, which refers to the transformation and subsequent incorporation of inorganic nitrogen forms into proteins, peptides, and amino acids of micro- or macroorganisms in the soil fauna. Mineralization is also frequently considered as the resulting net rate of all these processes. The highest mineralization rates in the history of soil ecosystems have been created by large-scale transformations of virgin land into arable land due to population pressure. In general this releases about 50 percent of the nitrogen that has been organically bound in soils.

Transport of nitrogen-containing soil matter through erosion can add to or reduce the amount of nitrogen cycling in a system. Further reduction of nitrogen in soils occurs through the fixation of ammonium in a biologically unavailable form in certain expanding clay minerals and, in higher quantities, through nitrogen uptake by plants. In natural ecosystems, the nitrogen uptake by plants is adjusted to the mineralization rate, which is the same if fertilizers are added to soils in combination with agricultural crops. If nitrogen in the soil solution is below the demands of the plant cover, the plants will be undernourished; if it exceeds the demands of the plants, it will either be leached into the groundwater or be denitrified. It can also be enriched in the plant solution.

All nitrogen that is not absorbed by sinks as vegetation, soils, and micro- and macro-faunae is available for leaching into groundwaters. From there, dependent on physical conditions, it flows into adjacent aquifers that determine the general water flow in soils. Denitrification involves the metabolic reduction of nitrate (NO_3^-) into nitrogen (N_2) or nitrous oxide (N_2O) gas. Both of these gases then diffuse into the atmosphere. Soluble carbon is used as an energy source; therefore the denitrification rate is limited by its amount and favored by anaerobic conditions. Denitrification can take place in every part of the soil profile where these conditions prevail and also in groundwater. Similar processes occur in marine ecosystems; however, there are still uncertainties about them, and estimates of N fixation by organisms vary, ranging from less than 30 to more than 300 teragrams (million tons) per year.

Human activities have interfered with the natural nitrogen cycle, which was in a dynamic equilibrium in preindustrial times. Then, annual fluxes of nitrogen from the atmosphere to the land and aquatic ecosystems were 90–130 teragrams per year. This was balanced by reverse denitrification, since the C and N ratio necessary for denitrification was also in equilibrium because almost all inputs were from organic origins.

Industrial combustion increases the emission of reactive N gases (NO_x) to the atmosphere, where they contribute to the production of tropospheric ozone before depositing either as a gas in the form of nitrate or ammonia ions, a nitric acid dissolved in precipitation, or as dry aerosols on land or sea.

Production and use of synthetic nitrogen fertilizer, produced by the Haber-Bosch process, together with expanded planting of nitrogen fixing crops and the deposition of nitrogen-containing air pollutants, have created an additional flux of about 200 teragrams a year, only part of which is denitrified. The addition of a major new flux from atmosphere to land, by way of industrial and crop nitrogen fixation, has created an imbalance leading to increased flows to the ocean. In the process this contributes to eutrophication of rivers and lakes. Some of the nitrogen oversupply leads to increased emissions of N_2O and NO_x, which are increasing in the atmosphere and contributing to global warming, tropospheric pollution, and stratospheric ozone depletion.

Nitrogen Fixation

NITROGEN FIXATION IS the process by which nitrogen, a gas at atmospheric temperatures that represents approximately 80 percent of the total atmosphere of the earth, becomes a chemical compound that is somewhat more reactive than the almost-inert gas form. Fixation takes place through atmospheric phenomena such as lightning, ultraviolet rays, and microscopic soil organism activity.

As agricultural science began to reveal the importance of fixed nitrogen in the soil as a fertilizing agent, the efforts of farmers and technicians to increase and control nitrogen fixation have also multiplied. Intensive agricultural systems rely on artificially fixated nitrogen, and this intensive use has created a number of new problems. This has added chemical forms of fixation to atmospheric and biological fixation processes.

The majority of natural nitrogen fixation—more than 90 percent—comes about as the result of microbial soil organisms. Two principal groups of organisms are involved: the first is nonsymbiotic or free-living bacteria, such as cyanobacteria (blue-green algae); the second are the symbiotic bacteria that are commonly associated with cereal grasses and legumes. Symbiotic organisms live in contact with certain plants and encourage free atmospheric nitrogen to become fixed as nitrates; the plant then uses these as nutrition. Considerable efforts have been made to understand and document the processes involved in nitrogen fixation, and to determine ways to reduce unpredictability and increase yields. This has led to various attempts to stimulate nitrogen fixation, the creation of nitrogen-rich fertilizers, and the development of inoculation techniques to ensure that food plants grow in optimal ways rather than organism-driven growth patterns.

In some fruit and vegetable markets in the developed world, marketing motivations require almost perfectly identical specimens, and this has implications for the removal of organisms that affect specimen growth and nutritional value. The majority of plants, even important food plants, have not been fully investigated for the nodule-creation process by which symbiotic organisms fix nitrogen. Consequently, it is possible that major breakthroughs in reducing world hunger are possible, as well as less welcome side effects. There are known to be three sets of factors that affect the process: climatic factors, management factors, and edaphic (soil-related) factors.

Although less well-known than the soil-based version, nitrogen fixation also takes place in water, primarily through the actions of lake or river plants that convert gaseous forms of nitrogen into solid forms, which are then attached to plants in a symbiotic fashion. Artificially stimulated waterborne nitrogen fixation might become important in increasing the food yield of water resources and in helping to remove pollution. This may be of increasing utility as freestanding sources of clean water decline as a result of global warming, and the amount of edible fish may fall drastically.

Human involvement with nitrogen fixation is an example of the significant yet largely unnoticed ways in which humanity has converted the planet into an engine intended to be more conducive for human habitation.

Nitrogen Oxides

NITROGEN OXIDES ARE a group of chemical compounds involving the elements of nitrogen and oxygen in different configurations. They include nitric oxide (NO), which usually takes a gaseous state and is the most stable of the oxides. Nitric oxide and other oxides are created when vehicle fuel is burned at high temperatures and they are significant pollutants. The oxides can be highly mobile and may be responsible for creating smog and ozone.

The other nitrogen oxides that can be formed include nitrogen dioxide (NO_2), nitrous oxide (dinitrogen monoxide N_2O), and the unstable compounds dinitrogen trioxide (N_2O_3), dinitrogen tetroxide (N_2O_4), and dinitrogen pentoxide (N_2O_5). The amalgamation of oxides created by the internal combustion process is referred to in entirety as NO_x. The oxides are not all dangerous or useless: nitrous oxide, for example, is better known as laughing gas and has important medicinal uses, even if it is poisonous in uncontrolled quantities.

Various types of technology have been employed to try to reduce the creation of nitrogen oxides. One of the most successful and influential of these has been the catalytic converter, which is now compulsory to have fitted onto most forms of automobile at manufacture. However, this is inappropriate for the alternative sources of NO_x production, which include factory and industrial plants burning coal or natural gas. The rapid industrialization of China is of particular relevance in this case because large numbers of Chinese factories rely upon Chinese-sourced coal for power. The nitrogen oxides produced contribute to such phenomena as acid rain, the production of toxic chemicals, and global warming. The compounds can hurt living creatures directly by leading to respiratory problems and illnesses, such as asthma. Climatic conditions and industrialization patterns mean that certain urban areas are particularly potent threats to health. Some claims have been made for clean coal consumption, which offers much lower NO_x production.

The Kyoto Treaty and other international agreements address the worldwide production of nitrogen oxides as a pollutant. Most developed countries have state-level regulatory agencies to monitor the level of atmospheric pollutants and take actions of some sort against heavy polluters. In the United States, the Environmental Protection Agency is the body responsible for this task.

Nixon, Richard Administration

RICHARD MILHOUS NIXON (1913–84) was the 37th president of the United States, serving from 1969 to 1974. A member of the Republican Party, he previously served as vice president under President Dwight D. Eisenhower. Nixon defeated his Democrat opponent Hubert Humphrey in a narrow vote by mobilizing a coalition of southern social conservatives organized by Strom Thurmond. In 1974 Nixon became the only U.S. president to resign from office.

In office, Nixon's administration was widely, and somewhat unfairly, believed to be primarily motivated by foreign affairs and to have little interest in domestic policies. Nixon inherited the American involvement in Indochina and this ended during his administration. Another notable event occurred when he visited Chairman Mao Zedong, leader of the Chinese Communist Party, in Beijing.

Nixon's environmental legacy is remarkable, and perhaps unmatched by any later presidential administration. Most of these policies were forced on Nixon's administration by an environmentally active Congress and a growing environmental movement, but his presidency presided over some of the strongest and longest lasting reforms of federal legislation regarding environmental issues. While he was reluctant to sign some environmental legislation, many experts suggest that, for a conservative Republican administration in the midst of domestic and international crises, the political costs appeared to outweigh the benefits.

Most notably, in 1970 Nixon established the Environmental Protection Agency (EPA), the first coordinated federal agency to manage the mounting crises of the period. Consumer and environmental groups had been lobbying for years on behalf of many different environmental and health issues and this had resulted in a mishmash of laws at several levels of government. The complexity added to legal costs and also provided loopholes and inconsistencies that could be exploited.

The EPA was established to harmonize these different laws and regulations and to determine a suitable method of policing them. The EPA has been responsible for a significant proportion of the reduction of pollution in and from the United States. Nixon also signed the Clean Air Act of 1970, the Clean Water Act of 1972, and the Endangered Species Conservation Act of 1969. He also oversaw the introduction of catalytic converters for automobiles, perhaps the first serious federal intervention into industrial production for consumer health and air quality. Nixon also oversaw the creation of the Organizational Health and Safety Administration (OHSA), which extended environmental protection to workers in the workplace, ranging from exposure to hazardous materials to dangerously high levels of noise pollution.

The decline of the Nixon administration was rooted both in the drawn-out end to the war in Vietnam and in the Watergate scandal, in which the President and members of his administration were accused of the breaking and entering of Democratic Party headquarters, illegal wiretapping, and other criminal acts. Threatened with impeachment, Nixon eventually resigned and was succeeded by Vice President Gerald Ford, as his previous Vice President, Spiro Agnew, had already resigned after another scandal. Nixon's administration eroded trust in politicians and in the political process.

Nevertheless the environmental agencies and laws established during the Nixon presidency remain the bedrock of contemporary environmental management in the United States. While the effectiveness, funding, and commitment of later administrations to these innovations would wax and wane, the Nixon legacy for U.S. environmentalism is undeniable. In the years following his resignation until his death, Nixon produced extensive writings on the presidential process and on foreign policy. However, some critics maintain that in doing so he revealed his indifference toward the details of public policy and obscured his administration's important role in helping protect and improve the environment.

Noble Savage Myth

NOBLE SAVAGE IS a concept that idealizes the virtues of the primitive "other" who dwells in nature according to the doctrine of natural law and without the burdens of civilization. Innocent and free from corruption, the noble savage was seen as a romanticized ideal representing the innate goodness of natural man in contrast to the artificial goodness of civilized man. While the notion of the noble savage is most commonly attributed to Jean-Jacques Rousseau, anthropologist Ter Ellingson traces the origin of the noble savage to Marc Lescabot, a French lawyer and ethnographer who invented the concept in 1609, nearly a century and a half before Rousseau's writings.

THE ECOLOGICALLY NOBLE SAVAGE

A contemporary expression of the noble savage emerged in the late 20th century as the "ecologically noble savage." Environmentalists, in their critique of the unsustainable nature of capitalist growth, focused their attention on indigenous people who were seen as natural conservationists who used resources in ways that were nondestructive, sustainable, and attentive to the needs of future generations. By the 1980s indigenous people living low-impact lives in remote areas were portrayed as far more civilized than people in the industrialized world whose lifestyles had resulted in unprecedented species extinction and disruption of ecosystem processes. Environmentalists were able to marshal evidence from ecological anthropology to support their views of indigenous people as effective guardians of valuable habitats, highlighting the richness of traditional ecological knowledge and the efficacy of local resource management systems.

Embedded in the search to prove the ability of indigenous people to sustainably manage their own resources is a critique of Western capitalism. The environment has been damaged by the growth of global capitalism, and many of the world's regions of high biodiversity remain in areas occupied by indigenous people. This critique of capitalism, coupled with a romanticization of indigenous people, gave rise in the late 1980s to new alliances between indigenous people, eco-activists, and socially conscious "green" businesses such as Ben and Jerry's ice cream, Shaman Pharmaceuticals, and the Body Shop. These businesses promoted images of Amazonian Indians and their environmental knowledge as embodying qualities of purity, simplicity, and living in harmony with nature. The alliance between indigenous people and green companies was a politically potent critique of Western cultural dominance. However, this simplified representation of indigenous people had negative repercussions when it was shown that many native people are just as eager to reap short-term benefits from their natural resources as their neighbors in the industrialized world. Indigenous people had been placed on a moral and ecological pedestal that ultimately crumbled, resulting in a backlash against native people and their ability to manage their lands.

Conservationists Kent Redford and Allyn Stearman sparked an academic debate in the early 1990s by questioning whether indigenous people have a conservation ethic or whether their historically low impact on the land stems from low population density and lack of access to technology. This debate prompted a flurry of research aimed at objectively testing the hypothesis that indigenous people possess an intimate knowledge of their environment, resulting in effective conservation. Research showed that there is abundant evidence that indigenous people can be successful stewards of their resources.

However, for every example of indigenous knowledge with positive conservation outcomes, there is a counterexample of other indigenous practices that have resulted in loss of biodiversity. As a result, many conservationists see national parks as the only places where biodiversity can be preserved. For them, indigenous people should not be expected to conform to a preconceived stereotype of being natural guardians of the forest. Yet the process of protecting biodiversity in national parks almost inevitably results in the removal of indigenous peoples from their lands. As such, this debate over the conservation ethic of indigenous people glosses over the long history of oppression in which indigenous people have struggled for self-determination and recognition of traditional land rights.

While conservationists and scientists devote energy to proving or disproving the ability of indigenous people to conserve their own resources, the debate has not advanced the cause of conservationists or indigenous people. Critical opportunities for collaboration are lost when indigenous people are not given equal authority or negotiating power in decisions regarding their lands, making the possibility for fruitful and critical partnerships between indigenous people and conservationists difficult to achieve.

Nongovernmental Organizations (NGOs)

WHILE COMMON PARLANCE now, the term *nongovernmental organization* (NGO) was not officially coined until 1945 when the United Nation's (UN) Economic and Social Council (ECOSOC) clarified its relationship with intergovernmental specialized agencies and international private organizations in the UN Charter. ECOSOC decided that an "international NGO" (INGO) was "any international organization that is not founded by an international treaty." The UN also determined that NGOs should be given suitable arrangements to be consulted on key issues. The status of NGOs was confirmed in the three conventions arising from the UN Earth Summit in Rio in 1992.

It is important to distinguish between NGOs and not-for-profit agencies. Unlike NGOs—which tend to emerge specifically to address certain issues, offer specific services, or advance a cause—nonprofit agencies may also include other organizations, such as museums, universities, and hospitals, service-based organizations that are not necessarily independent of government or campaigning for a cause. An NGO should not be mistaken as a social movement *per se*, despite the fact that it may perform an important functional role within such movements.

The term *nongovernmental organization* implies independence from government, which often enables NGOs to promote, or expose, activities and events in ways a government cannot. NGOs rely heavily on fundraising, grants, and sponsorships to fund their activities. To some NGOs it is important to maintain financial independence from government at all times; Greenpeace does not accept donations from governments or corporations but relies on contributions from individual supporters and foundation grants. Nonetheless, many NGOs depend in part on government funding. For example, the British government and the European Union donated a quarter of Oxfam's budget (U.S. $162 million) for famine relief in 1998. Medecins Sans Frontieres (MSF) operates with almost 50 percent of its budget coming from government sources.

There are thousands of active NGO organizations operating at local to international scales. According to one estimate, some 37,000 organizations now qualify as international NGOs (with programs and affiliates in a number of countries), up from less than 400 a century ago. Active international organizations include the Red Cross, CARE, and the World Wildlife Fund (WWF). Most NGOs operate within a single country and often function within a purely local setting. Many are essentially neighborhood groups established to promote local issues such as community improvement or street safety.

The 2002 United Nations Development Programme's Human Development Report notes that nearly one-fifth of the world's NGOs were formed in the 1990s. A 1995 United Nations report found that the United States has an estimated 2 million NGOs, Russia has 65,000 NGOs, and that in countries such as Kenya, up to 240 new NGOs come into existence every year. NGOs are significant employers. In 1995, CONCERN, which is an international NGO campaigning against poverty, employed 174 expatriates and over 5,000 national staff across ten developing countries in Africa, Asia, and Haiti.

NGOs have wide scope and appeal. Lesser-known acronyms for the different types of NGOs include:

INGO: International NGO; BINGO: Business NGO; RINGO: Religious NGO; QANGO: Quasi Autonomous NGO; and ENGO: Environment NGO. Religious NGOs include Caritas International, the World Jewish Congress, and the International Muslim Union; examples of political NGOs include the Inter-parliamentary Union and Socialist International. There are active cultural groups as well, such as International PEN, a literary organization. The activities of Amnesty International in the human rights field, as well as those of Greenpeace in the field of environmental protection, are well known. Many NGOs, such as the WWF and Friends of the Earth (FoE), investigate issues that affect human and environmental welfare, and often the nexus between the two.

In the human rights and environmental field, NGOs have served as agents of change and forces for the public good for the protection of human and environmental welfare. Amnesty International and WWF, while international NGOs, operate by working locally to achieve specific goals in specific regions. FoE recognizes that human rights and social justice and environmental issues are intertwined and need to be addressed together. FoE operates as a federation of autonomous environmental organizations from all over the world, and has a membership of 1.5 million in 70 countries. While FoE campaigns on many issues, it is currently focusing on climate change, which it identifies as the biggest environmental threat to the planet.

While NGO activity is often thought of as picketing, protests, and demonstrations, and some NGOs, such as Greenpeace, do employ spectacular and unilateral actions in order to broadcast their message, many NGOs focus on education, research, or diplomatic work to achieve their goals. NGOs are active on committees, in meetings, and in undertaking detailed studies that help inform and promote policy debate. For example, Earthwatch promotes community involvement and awareness of environmental issues with field research trips.

NGO collaboration, lobbying, and public awareness-building methods, including the effective use of media and scientific research, helped ensure that the Australian Government rezoned the Great Barrier Reef World Heritage Area to protect 33 percent of the Great Barrier Reef Marine Park (GBRMP) in a network of no-fishing sea sanctuaries, or "green zones." This was a major achievement, as previously only 4.5 percent of the GBRMP was fully protected from fishing.

NGOs are powerful players in the international policy arena and leverage their access to policy makers to good effect. The NGO-led International Campaign to Ban Landmines (ICBL), first initiated in 1992, laid the groundwork for the UN 1997 International Mine Ban Treaty. Over 140 countries throughout the world have since ratified the treaty. Scholars have also argued that NGOs were "particularly effective in hardening the European Union's position on genetically modified food," and that NGOs had a major influence on the WTO meeting in Seattle by affecting the negotiating positions of governments. The formation of the Kyoto Protocol on Climate Change (1997) is often credited to the pressure brought to bear on governments by environmental NGOs. Many argue that NGOs have been successful in ensuring that policy debate is now framed in environmental terms and have changed the status of environmental issues from being the domain of a politicized few to being in the general interest of civil society.

Some NGOs are developing partnerships with industry. The Marine Stewardship Council initiative has brought together the WWF and the multinational company Unilever PLC, one of the world's biggest buyers of frozen fish. Together they have worked to address the global issues of overfishing, and have developed an eco-certification scheme for major fisheries. Over 40 fisheries are part of the MSC program, which constitutes about 3 million tons of seafood. Fourteen of these fisheries, such as the Pacific cod fishery, are now certified by the MSC as having attained a sustainable eco-standard.

CRITIQUES

The NGO movement, however, has significant critics. Many question the accountability and effectiveness of NGOs. For example, World Vision's coordination of the relief effort for countries impacted by the December 26, 2004, tsunami in Southeast Asia has been attacked by critics arguing that the millions of dollars of donated monies were not reaching the intended victims.

Many NGOs working in developing countries are partly funded by their own government and have been criticized as being a front for foreign government policy. Critics argue that this makes NGOs accountable to their funders, not the people they work with. This issue has often been characterized within a debate about "Northern" (i.e., Western) versus "Southern" (developing world) NGOs. For example, many African governments see NGOs from Western countries as Trojan Horses, designed to promote neo-colonialist agendas.

Many developing countries also resent the fact that international NGOs will enter their countries and establish programs, rather than funding local NGO groups to undertake the same work. As such, the arrival of NGOs can be perceived to actually deny local individuals, councils, and industries of employment—and other opportunities that now flow to and from the foreign NGO—while creating upheaval in local power relations in culturally inappropriate ways. Some countries such as Zimbabwe, Eritrea, and the Sudan have gone so far as to pass laws that effectively limit the operations of foreign-funded NGOs within their borders.

In some cases, NGOs have been accused of ignoring the effects of their activities on other areas. For example, environmental NGO work can focus on biodiversity imperatives at the expense of cultural heritage or social justice needs. In Australia, the biodiversity work of environmental NGOs has been called blinkered in relation to cultural heritage priorities, constituting another form of indigenous dispossession.

NGO dependence on donors also exposes them to criticisms that they are not able to be independent, and thus may be inappropriately partisan. CARE International came under attack for not acting to oppose the war in Iraq, with critics claiming this was due to CARE's dependence on funding from the U.S. government. Oxfam has been accused of diluting its campaign against poverty in Africa as a result of being too close to the British government.

Overall, while NGOs rarely have formal powers within international or local decision-making structures, they have successfully advanced many human rights, social justice, and environmental agendas. This has included promoting and developing core environmental agreements and policies; strengthening the rights of women, children, and the disabled; advancing indigenous rights; establishing programs to address health, education, and poverty; and significant measures in the area of disarmament and peace negotiations.

Nonpoint Source Pollution

POLLUTION IS THE release and spread of contaminants that degrade the environment and impair human health. Point source pollution has a discrete source, like an effluent pipe or smokestack, while nonpoint source pollution cannot be traced to a specific point of origin. Examples of nonpoint source pollution are pesticides from a farm field washing into a stream and soil erosion at a construction site. Controlling this type of pollution is challenging because there is no specific location to target and because inputs of nonpoint pollution are often intermittent.

Sources of nonpoint pollution are varied: streets and highways, farm fields and pastures, construction, logging, mining, lawns, and even pet wastes. Most pollutants from these sources are carried in runoff following a rainstorm or snowmelt. Nutrients, sediments, toxins, and pathogens are pollutants prevalent in runoff.

Phosphorus and nitrogen—essential nutrients for plant growth—become pollutants when excessive amounts of either enter an ecosystem. Sources of nitrogen and phosphorus pollution are agricultural and lawn fertilizers and animal wastes. In the United States and Europe, approximately 30 percent of phosphorus and 18 percent of nitrogen in agricultural fertilizers are taken up by crops. The remainder builds up in soils, washes into surface water, or leaches into groundwater.

Under naturally occurring conditions, nitrogen and phosphorus are relatively scarce in aquatic systems, thus limiting the growth of algae and plants. Populations of algae or of cyanobacteria (blue-green algae) often proliferate following increases in nutrient levels. These algal blooms cloud water and limit light to submerged plants. Then, when these populations of algae die, the decomposition process uses much of the water's dissolved oxygen. Lack of oxygen kills fish and clams, and alters the microorganism and invertebrate composition of the community. In marine ecosystems, nutrient enrichment leads to loss of biodiversity in seagrass beds and kelp communities. These ecosystems, when healthy, provide spawning ground and nurseries for many fish species as well as shelter and food for many marine mammals, so damage impacts many species.

Blooms of some microorganisms produce toxins. Red tides are overgrowths of aquatic microorganisms, so-named because they turn the water red or brown. These organisms synthesize toxins that damage the nervous system, can kill marine mammals and fish, and contaminate seafood. Some cyanobacteria responsible for freshwater algal blooms also produce toxins.

Excessive phosphorus is the primary cause of eutrophication, or premature aging, of lakes in the United States. Nitrogen is responsible for eutrophication in most estuaries and coastal waters. Marine areas that are highly impacted by eutrophication include the Gulf of Mexico, Chesapeake Bay, Long Island Sound, and the Florida Keys in North America, and the Adriatic, Baltic, Black, and North Seas in Europe. Extreme nitrogen enrichment in coastal waters results in what are called "dead zones," or areas with very low oxygen that no longer support the life once found there. The Gulf of Mexico, which receives nutrient inputs from the Mississippi River, has a dead zone that expands to about 4,800 square miles (20,000 square kilometers) in the summer, an area the size of New Jersey.

Particles of silt, clay, and sand particles transported by water are called sediment. These soil particles are washed from fields, construction sites, and logging operations. As with algal blooms, sediment clouds water, blocks light, and limits plant growth. Some sediment particles block the gills of fish and aquatic insects, and bury clams, oysters, and other bottom dwelling organisms. Deposition of sediment in waterways and ports interferes with boat traffic and fishing. In addition, sediments often contain nutrients, which enrich the waters, as previously discussed.

Sediment deposition in Chesapeake Bay has increased four- to fivefold since the 1800s due to urban development, timber harvest, and agriculture. Research in the Chesapeake Bay watershed revealed that the most sediment is produced in the agricultural portions of the watershed, while the lowest input comes from the forested portions. In urban parts of the watershed, sedimentation is highest during building, but established developments continue to contribute sediments.

Pesticides usually enter surface water through runoff, but drifting spray from pesticide application also contributes to water contamination. Mining operations expose sulfur-containing rock to water and air, and this leads to the formation of sulfuric acid. The acid dissolves heavy metals, including mercury, lead, and copper, introducing these materials to runoff. These heavy metals are toxic to humans and wildlife.

Disease-causing bacteria and viruses enter water from manure, pet waste, and improperly treated human waste. These pathogens can contaminate seafood and render water unfit for human use. According to the National Resources Defense Council, 75 percent of U.S. beach closings in 2005 were due to unacceptable levels of bacteria.

Economic and social costs of nonpoint source pollution are high: fisheries are less productive, tourism is damaged, public health can be impaired, water treatment costs increase, and property values decrease.

Monitoring, at both the local and national levels, can provide vital information for water quality management. The National Water Quality Assessment (NAWQA) program is run by the U.S. Geological Survey (USGS). This long-term project monitors nutrients and pesticides in rivers and aquifers. The data gathered helps municipalities, agencies and scientists make management decisions for specific watersheds. Another monitoring program, run by the National Oceanic and Atmospheric Administration (NOAA), is the National Estuarine Eutrophication Survey.

Managing nonpoint pollution requires a variety of methods, depending on the source of pollutants. Vegetated buffer strips along water bodies trap sediment and remove nutrients from runoff. Efforts by farmers to determine levels of nutrient in their soils, then applying fertilizers only to meet current needs, reduces nutrients inputs. Construction site erosion is managed by silt fences to trap sediment and straw and hay mulches are used to hold soil in place until grass is established.

Nontimber Forest Products

ALSO CALLED SPECIAL forest products and minor forest products, nontimber forest products (NTFPs) are renewable forest resources that can be sustainably extracted. Typical NTFPs include gums, resins, oils, sap, nuts, wicker, rattan, bamboo, dyes, incense, fungi, mushrooms, fruits, berries, bark, roots, plants, insects, honey, and eggs. Human beings have relied upon and managed NTFPs for fuel, fodder, food, fiber, medicine, art supplies, and building materials for millennia.

Even today, NTFPs are gathered seasonally and across the spectrum of tenure possibilities by a diversity of people in all countries. Indeed, they play an essential economic and cultural role in the livelihoods of about one-fourth of the world's population, not counting those who retail and consume NTFPs in metropolitan areas.

Regional and global trade in NTFPs is in the hundreds of millions of dollars. Many environmentalists and human rights advocates seek to link global demands for NTFPs in ways that promote forest conservation through sustainable extraction and meet the economic needs of forest peoples and neighboring communities.

Forest peoples worldwide developed ways to manage and regulate access to NTFPs to ensure sustained yield. By their nature, most NTFPs are common property resources, or resources held in common by a defined collectivity. Traditional knowledge of desired NTFPs and their ecologies both shaped and reflected the customary rules of forest access and harvesting practices.

As more distant markets for NTFPs developed, and colonial and state regimes expanded their authority into ever more remote areas, customary rights of forest access blended with or gave way to the imposition of codified rules and regulations enacted in cities. In addition, many NTFPs were purposefully moved to facilitate their production under private, scientific, and colonial control. The most famous example of this was when the British naturalist Walter Bates smuggled the seeds of natural rubber (*Hevea brasilensis*) out of the Brazilian Amazon in the 19th century. Passing through botanical gardens, the seeds facilitated plantation rubber production in British colonies in south and southeast Asia, temporarily ending the demand for the Amazon's wild rubber.

Beginning in the 1970s awareness of new and alarming rates of tropical deforestation prompted thinking about alternative forms of rain forest development. By the 1980s two issues moved NTFPs to center stage in a search for unorthodox solutions. In 1985 the Rubber Tappers National Council of Brazil proposed extractive reserves, or collective long-term land-use rights to forested areas. This plan sought to defend rubber tapper livelihoods against expanding timber and ranching interests in the Amazon basin. The high-profile 1988 murder of Chico Mendes, the charismatic leader of the National Council, by a rancher opposed to his activism only served to galvanize the institutionalization of extractive reserves in Amazonia. By 2006 there were over 120 extractive reserves in Brazil cared for by 200,000 people.

A benchmark 1989 article demonstrated that a hectare of tropical rain forest contained a variety of NTFPs of approximately equal value to timber from the same hectare. The implication was that the sustainable extraction of NTFPs would be worth more over time than a one-time timber clearing. If given the opportunity, rain forests could pay for their own protection by giving forest peoples and national governments an economic incentive to protect them—this was before the growth of ecotourism, which has a similar objective. Recognition of the economic viability of healthy forests strengthened governmental willingness to grant usufruct rights to forest peoples dwelling on ostensibly "national lands."

By the 1990s one important outcome of this convergence was global awareness about the problem of tropical deforestation, and a willingness of industrial-world consumers to buy products that supported or collaborated with NTFP producers. By the early 1990s, however, scholars were already documenting the limits of NTFP extractivism for achieving environmental, economic, and social objectives, as extractors continued to live in poverty and had limited abilities to confront colonists or traditional extractive enterprises, including bioprospectors.

Nontimber forest products play important social and environmental roles in temperate countries as well. For example, it is estimated that up to one-quarter of the entire population of Scotland collects wild edibles. Meanwhile, recent Latino and Southeast Asian immigrants to the Pacific Northwest region of the United States are actively involved in NTFP extraction from National Forests. Permits for a single plant, beargrass, suggest that the activity is worth $10 million annually. Mushrooms, floral greens, evergreen plants, ginseng, and berries are also sought from national and private forests across the United States. The economic importance of NTFPs in industrialized countries will likely continue to grow as rural logging economies restructure and new legislation is passed intended to improve NTFP management.

Nontraditional Agricultural Exports (NTAEs)

NONTRADITIONAL AGRICULTURAL exports (NTAEs) are agricultural products that have not previously been consumed or planted as cash crops in a country. NTAEs include fruits, vegetables, flowers, nuts, and spices. NTAEs are growing in importance globally because of their economic value; they make up the overwhelming majority of trade taking place in the horticultural and floricultural sectors of both producer and consumer countries. Fruits, vegetables, and flowers have formed the bulk of this new trade. Traditional agricultural exports (TAEs) vary from country to country as do the value of NTAEs. However, NTAEs are growing in great volume and value while TAEs are growing at stable rates. For example, between 1997 and 2001, soybean and sugar exports from Brazil, which are TAEs, grew 55 percent. In this same time period, however, Brazilian NTAEs of cantaloupes, grapes, mangos, and other crops grew 145 percent.

In recent years, most agricultural production in Central America and the Caribbean has been consumed locally. However, new crops of NTAEs in these areas have grown enormously. For example, the production of asparagus, eggplants, onions, shallots, green peas, green beans, and tomatoes have exploded in volume and value as trade items. Many of the NTAEs produced today are not traditional foods in the areas in which they are produced. This means that these foods are exported to urban markets in some of the wealthier, industrialized countries of the Northern Hemisphere. The positive result is that Third World countries have a new source of income that does not compete with foods consumed locally.

East Asia is a region new to the production of NTAEs. Historically Japan, Korea, China, and the Philippines have been large producers of fruits and vegetables for local consumption. However, great volumes of fruits such as pineapples, cantaloupes, citrus fruits, and vegetables such as asparagus are now being grown for export.

Countries in Southeast Asia, including the Philippines, Thailand, and Malaysia, are great producers of mangos, which were once not considered a fruit for the wider market. However, the introduction of the mango into colder regions of the world has created a new export market; as a result, a common and traditional fruit has become a new NTAE.

In Central and South America, many new crops that were never grown in the area before are now being grown as NTAEs. NTAEs have a limited market appeal in these regions. As a result, trade links between these nations and the United States and Europe are growing exponentially. The impact of NTAE production in Central America is noteworthy as local farmers have profited from the growth significantly. For example, Mayan Indians, who had no exports previously, are growing broccoli, snow peas, cauliflower, and berries in the Guatemalan central highlands.

Researchers have studied the production of NTAEs and have found that despite some problems, local farmers are positive about the opportunity to produce for export. South America is now a growing center of NTAEs that are counter-seasonal. Apples, pears, grapes, and other fruits are grown in the spring-summer-autumn, which is opposite to the autumn-winter-spring of the Northern Hemisphere. As a result, many traditional foods consumed in the Northern Hemisphere are available fresh during normally off-seasons. The health benefits of fresh produce available counter-seasonally is a significant factor in their marketability.

NTAEs are often the subject of import regulations and tariff restrictions. As long as traditional fruits, such as apples, are imported counter-seasonally, import tariffs are kept low unless they are opposed by domestic producers who want to protect their own production centers. The export of fresh, cut flowers has evoked some opposition from Northern Hemisphere growers who produce cut flowers in hothouses. For example, Colombia is now the world's second-largest exporter of flowers after the Netherlands. Because floriculture is labor intensive, the higher labor costs in the Netherlands are challenged by lower cost floriculture production in Mexico, Costa Rica, Honduras, Peru, Bolivia, and various African and Asian countries.

The Uruguay Round of Agricultural Agreement (URAA) discussions sought to limit the growth of trade restrictions on NTAEs, as many countries have developed complex, restrictive trade policies. To reduce restrictions so that freer markets can exist has been the subject of many international discussions. The European Union has been a leader in restricting imports or in creating trade barriers such as import quotas.

Other concerns expressed by many interest groups in the Northern Hemisphere are fears that exploitative labor practices or the unregulated use of pesticides and herbicides will affect the conditions of production in Third World countries. Testing for residual levels of pesticides or herbicides in accordance with the standards set by the *Codex Alimentarius* is being used to restrict the importation of NTAEs in some instances. Many countries are applying sanitary and phytosanitary (SPS) measures to food imports. More than 270 SPS measures were adopted for fruits and vegetables between 1995 and 2000. The basic rules for using these heath standards have been established by the World Trade Organization (WTO).

In an unusual move, in many countries the public laws on food safety are being surpassed by importing companies. Grocery stores have a vested interest in food safety. A single outbreak of an infectious agent sold in their stores could have a devastating business impact in the near future and the long term. Resulting liability suits can also be very expensive. Therefore, private agencies are creating inspection standards far exceeding those followed by public authorities.

While many observers predict a bright future for NTAE growth, some critics of capitalism and globalization argue that NTAEs have negative social consequences. The "market friendly" orientation of increasing export conditions has led to domination by small numbers of international export companies in many NTAE sectors. The flood of these products simultaneously onto global markets has also resulted in dramatic price declines. While this is a boon for the relatively wealthy consumer in the developed world, to a farmer in the underdeveloped world, it means more effort and energy in export-oriented production for less return. Whether a boon or bane, NTAE expansion has definitely resulted in the ubiquity of historically unusual products stocking supermarket shelves.

North American Free Trade Agreement

IN 1947, IN the aftermath of World War II, 23 nations signed the General Agreement on Tariffs and Trade (GATT). Over time the number of signatory nations grew and by 1986, the year of GATT's eighth round of trade negotiations (known as the "Uruguay" round), there were 75, including Mexico, which joined that year.

In 1989, at a time when market-based, low-tariff trade of goods and services between countries was being touted as a driver of investment and economic growth, the United States and Canada negotiated the U.S.-Canada Free Trade Agreement (CFTA). Soon after, Mexico, then governed by newly-elected, neoliberal president Carlos Salinas de Gortari, signaled a strong interest in enlarging the U.S.-Canada agreement.

After four years of tripartite negotiations, the expanded North American Free Trade Agreement (NAFTA) became law on January 1, 1994. NAFTA thus established the world's largest free trade area—comprising the United States, Mexico, and Canada—populated by some 440 million people and producing about U.S. $12 trillion worth of goods and services.

As a commercial treaty, NATFA's goals were to remove tariffs and nontariff barriers; enhance fair competition; promote investment; protect intellectual-property rights; institute practical procedures for resolving disputes; and facilitate trilateral, regional, and multilateral cooperation.

But while the agreement itself was intended as an economic instrument, NAFTA's legacy may rest in its innovation in another domain: environmental protection. Prior to U.S. congressional approval, U.S. environmental groups, most of which initially resisted the accord, argued for institutional safeguards for the continent's environment and especially the fragile, water-scarce U.S.-Mexico border region. To placate this influential sector of civil society, the signatories agreed to soften the potential environmental impacts of the expected growth in trade and economic activity by chartering three new environmental institutions: the trinational Commission for Environmental Cooperation (CEC), created through a side agreement amending NAFTA; and two binational institutions, the Border Environment Cooperation Commission (BECC) and the North American Development Bank (NADBank), negotiated between the United States and Mexico. This "greening" of a trade treaty was a novel idea in 1993 and it remains the most prominent instance of such a procedure.

The new triad of CEC, BECC, and NADBank was meant to fill significant lacunae in protecting the North American environment. In this, they joined a host of existing international institutions (treaties, organizations, and cooperative agreements) already addressing certain aspects of environmental protection. Most prominent among these are: the International Boundary Commission (IBC), created in 1889 and changed to the International Boundary and Water Commission (IBWC) in 1944, to resolve boundary issues between the United States and Mexico; the International Joint Commission (IJC), an analogous organization established in 1909 to deal with U.S.-Canadian water-related issues; the Colorado River Compact of 1922, which allocates use of that river and forms the basis of what has become known as the "Law of the River"; the 1944 United States–Mexico Water Treaty, governing the Colorado, Rio Grande, and Tijuana Rivers; the 1983 La Paz Agreement (or "Reagan–de la Madrid Accord"), the first comprehensive environmental treaty between the United States and Mexico; the Border XXI Program (1996–2000), a binational cooperative workplan designed to implement the terms of the La Paz Agreement; and Border 2012 (from 2003), the successor to Border XXI.

Among the three new institutions, CEC was the only one that was officially part of NAFTA (and is sometimes referred to as the "NAFTA Environmental Commission"). It was created under the North American Agreement for Environmental Cooperation (NAAEC) to address regional environmental concerns, help prevent potential trade and environmental conflicts, and promote effective enforcement of environmental law. Officially directed by the three participating nations' environmental ministers, CEC operates via a secretariat based in Montreal, Canada, and is guided by three governmental advisory committees, three national advisory committees, and a trinational joint public advisory committee (JPAC).

Since 1994 CEC has addressed the state of the North American environment, the relation between trade and environment, and specific issues such as pollutant releases and registries and eco-regions. In its early years, its greatest influence was achieved through its judgments on enforcement matters under Articles 14 and 15 of the NAAEC, which allow nongovernmental organizations or individuals to file submissions claiming that one of the three countries is failing to enforce an environmental statute.

The Border Environment Cooperation Commission (BECC), headquartered in Ciudad Juárez, Chihuahua, and the North American Development Bank (NADBank), based in San Antonio, Texas, were designed to operate in tandem to improve environmental infrastructure—especially with regard to water—in the U.S.-Mexico border region (defined as a zone 100 kilometers on each side of the boundary). BECC was to encourage needy border communities to submit proposals for projects and then certify those projects meeting the commission's criteria. NADBank's role was to facilitate financing, that is, provide loans for the development, execution, and operation of BECC-certified environmental-infrastructure projects.

BECC has been managed binationally and, until 2006, directed by a board comprising representatives of each government and at-large community members. By its first year of operation, it had devised progressive criteria that required binationality; openness and transparency; bottom-up operation, with requirements for public participation at all levels; and assurances of environmental and financial sustainability. Although by some accounts the BECC process was initially slow, as of July 2006 it had certified 113 border environmental infrastructure projects—a total investment valued at $2.5 billion (not all these funds became available, however), affecting some 11 million residents.

Like BECC, NADBank is managed binationally, but its board—prior to 2006—consisted of the secretaries of the treasury, external affairs, and environment of Mexico and the United States. When the bank was created, it was capitalized at up to $3 billion in financing, with $2.55 billion in "callable" capital and $450 million in "paid-in" capital; but needs for border environmental infrastructure were estimated to be far higher. NADBank has provided about $350 million for projects providing cleaner water, land, and air in border communities. The bank also has administered $500 million in funds from the U.S. Environmental Protection Agency (EPA) through its Border Environment Infrastructure Fund (BEIF).

But while many residents benefited from the projects, the amounts expended remained well below the bank's initial capitalization and far short of perceived needs. Thus, beginning in the late 1990s and accelerating in early 2001, during the first months of the George W. Bush and Vicente Fox administrations, many in Washington and Mexico City considered NADBank to be unsuccessful and BECC less than optimally effective. In September 2001, Presidents Bush and Fox agreed that "immediate measures were needed to strengthen the performance" of the bank and its sister commission. In March 2004, over the objections of environmental interests who feared that the called-for "reforms" would deemphasize BECC's progressive features, the U.S. Congress enacted a bill, H.R. 254, which altered the mandate and structure of the bank and the commission. The zone of operation was expanded from 100 kilometers on each side of the border to 300 kilometers in Mexico; projects would no longer be restricted to the original charter of air, water, and waste; and most significantly, the two boards were to be replaced by a single one with representation from the two federal governments, the border states, and the public.

The changes were effected soon after but the new joint board did not meet until June 2006; the last time the NADBank board met was October 2003, and the last time the BECC board met was June 2004. In the meantime, hostility to the newly-reconstituted NADBank continued, especially in the U.S. Department of the Treasury and Mexico's Secretaría de Hacienda y Crédito Público. During the first half of 2006, rumors of NADBank's demise were rife. But the bank, and by extension, BECC, seemingly survived following strong expressions of support by the "Border Caucus" of the U.S. Congress, Texas and New Mexico federal senators, influential border-states governors, and advisory councils such as the Good Neighbor Environmental Board.

It is difficult to assess whether positive NAO index values since 1980 reflect human influence or random variations.

North Atlantic Oscillation (NAO)

THE NORTH ATLANTIC Oscillation (NAO) refers to a large-scale oscillation of atmospheric mass observed across the North Atlantic Ocean. The NAO was first identified in the 1920s by Sir Gilbert Walker. This oscillation is between the two prominent North Atlantic pressure centers: the Azores high, centered in the North Atlantic, and the Icelandic Low, centered between Greenland and Iceland.

It is now firmly established that fluctuations in the NAO influence weather and climate variations around the world, especially in the North Atlantic region. The NAO is a major controlling factor in basic meteorological variables such as surface wind, temperature, and precipitation, which have large socioeconomic impacts on energy, agriculture, industry, and human health across Europe and eastern North America. Changes in the NAO also significantly impact North Atlantic ecosystems through its influence on oceanic convection, deep-water formation, food availability, plant phenology, and the distribution patterns of fish and shellfish. Although this pattern is evident throughout the year, it is most pronounced during the winter months.

The phase of the NAO can be determined using a simple index, defined as the difference in sea level pressure between Lisbon, Portugal, and Stykkisholmur, Iceland. Instrumental station pressure, temperature, and precipitation measurements along with paleoclimate indicators have been used to construct a monthly times series of the NAO index dating back several hundred years. Depending on the direction of the pressure intensification, a NAO event is considered either positive or negative. Positive values of the index indicate a stronger-than-average Icelandic Low and Azores High, while negative index values signify weaker-than-average pressure centers.

Positive values of the NAO index are associated with stronger-than-average westerly winds across the middle latitudes of the Atlantic onto Europe, with anomalous southerly flow over eastern North America and anomalous northerly flow across western Greenland, the Canadian Arctic, and the Mediterranean. The positive phase of the NAO reflects below-normal heights and pressure across the high latitudes of the North Atlantic and above-normal heights and pressure over the central North Atlantic, the eastern United States, and Western Europe. During times of a high NAO index, the axis of maximum moisture transport shifts to a more southwest-to-northeast orientation across the Atlantic and extends much farther to the north and east onto northern Europe and Scandinavia.

Strong positive phases of the NAO tend to be associated with above-average temperatures in the eastern United States and across northern Europe, while northern Canada, Greenland, and oftentimes southern Europe and the Middle East experience below-average temperatures. Storm systems travel on a more northerly track across the North Atlantic, resulting in drier-than-normal conditions over much of central and southern Europe, the northern Mediterranean countries, and west North Africa. At the same time stronger westerlies result in wetter-than-normal conditions from Iceland to Scandinavia. Wetter winters in the southeastern United States and more frequent cold, dry air outbreaks from the Labrador Sea have also been found to be associated with the positive phase of the NAO.

When the NAO index is negative the westerly winds are weaker than normal, resulting in fewer and weaker winter storms crossing the North Atlantic on a more west-east pathway. North Atlantic sea surface temperature anomalies are above average while steering winds shift southward during low NAO index phases. More frequent and longer-lasting atmospheric blocking patterns across the North Atlantic are associated with low NAO index values.

The negative phase of the NAO brings moist air into the Mediterranean and cold air to northern Europe. As a result northern Europe usually experiences colder winters while wet and mild conditions prevail from the Mediterranean eastward into the Middle East. Greenland experiences milder winter temperatures when the NAO index is negative. The negative phase of the NAO is associated with colder winters and increased snowfall across eastern North America. The southern United States usually experiences colder winters and more variable weather during times of a low NAO index.

The NAO exhibits considerable variability across various time scales. The NAO oscillates week to week as much as it does from year to year or decade to decade, and does so unpredictably. An average of two to three NAO events occur per winter, and prolonged periods of both positive and negative phases of this pattern are common. Variability of the NAO dominates the climate of the North Atlantic and surrounding continents on interannual to decadal time scales.

The NAO has displayed considerable long-term variability since the late 19th century. From the turn of the century until about 1930, with the exception of the 1916–1919 winters, the NAO index was high. Decadal variability in the NAO has become especially pronounced since about 1950, although the causes for such variability are not clear. The NAO was generally low from the early 1940s until the mid 1970s and then abruptly switched to the positive phase. The strong positive NAO index values that have been observed since 1980 have contributed much to the observed warming in the Northern Hemisphere surface temperatures.

The NAO is currently generating intense scientific interest because of its climatic importance. It is difficult to assess whether the observed changes in the NAO reflect a human influence or random climatic variations. Observations suggest there is some predictability in the early winter NAO, which may be of considerable socioeconomic benefit. These sea-level pressure variations may be predictable, provided the sea surface temperature anomalies themselves are predictable.

Northern Spotted Owl

THE NORTHERN SPOTTED owl (*Strix occidentalis caurina*) became the focal point of a singular struggle in the annals of North American environmentalism when it was listed as threatened under the U.S. Endangered Species Act (ESA) in June of 1990. The listing signified and drew widespread attention to the conversion of old-growth forests to younger, ecologically simpler forests, and to a brewing scientific and political controversy. This controversy raised questions about the legitimacy of industrial forestry and state forest policy dedicated to ecological conversion and simplification for the purposes of commodity production. Yet, it also threw into sharp relief the scientific, political, and cultural underpinnings of Western environmentalism. The fight over whether or not to save the owl should in these respects be seen as a crucial episode in the politics of biodiversity conservation, and as an important case study of environmental regulation in liberal capitalist societies.

The northern spotted owl is found primarily in the so-called Douglas-fir region, running west of the Cascade Mountains, and south from southern British Columbia, Canada into northern California. Until the mid-1970s, very little was known to science about the owl, yet early surveys suggested its nearly unique dependence on relatively large, contiguous areas of old-growth forest. A key reason the owls require this habitat is that they tend to nest in the broken tree tops and snags that form in mature stands (stands with a preponderance of trees 175–250 years old or more).

State-sponsored and independent biological research in the 1980s tended to confirm that the owl was highly dependent on old growth, and also that populations were declining in parallel with the loss of old-growth forests due to industrial logging. This science, together with the naming of the owl as an "indicator species" by the U.S. Forest Service in the mid-1980s, provided the basis on which a sustained campaign was mounted by a loose coalition of environmental groups aiming to reign in logging and thereby preserve remaining stands of old growth.

This campaign gained considerable momentum when the owl was listed as officially threatened in 1990, but also from key judicial decisions forcing changes in the management of extensive federal forest lands in the U.S. Pacific Northwest where most of the remaining old growth was and is located. In 1993, a Forest Summit was convened by then U.S. President Bill Clinton and Vice-President Al Gore to attempt to resolve the pervasive stalemate, widely if somewhat erroneously framed as a jobs versus environment issue. A resulting federal plan prescribed reductions in annual timber sale quantities in affected federal forests by approximately 75 percent, while at the same time embracing ecosystem management principles.

The economic and ecological implications of this episode are still unfolding, and the fight is by no means over. While Canada has no comparable federal endangered species legislation to the American ESA, the owl is considered in peril in southwestern British Columbia. More broadly, the fight over the spotted owl in the 1990s precipitated considerable soul searching in academic and policy circles about the approach to environmental regulation institutionalized by the ESA, and the cultural politics of nature that underpin it.

Champions of strong biodiversity protections argue that mandatory preservation with real legal teeth, as evidenced by the 1973 ESA, provides the only means of arresting species and habitat loss. Critics argue such measures put nature—particularly charismatic creatures like the owl—before people (and jobs), denigrate work, and reflect dualistic views of nature and culture. These may be valid critiques. But it is also important to note that saving the owl was prescribed not only by the ESA, but by prior federal forest policy that designated it as an indicator species, a canary to the coal mine of Pacific Northwest temperate, old-growth forest ecosystems. This has been somewhat lost by the emphasis on individual species retention institutionalized by the ESA, and is ironic given that the longer term fallout from the owl's listing has been a more substantive embrace of ecosystem management in federal forest policy.

It also bears noting that the ESA, for all its shortcomings, provides one of the few ways in which commercial exploitation of biophysical nature for the purposes of commodity production may be checked. Nevertheless, a search for ways to transcend the dichotomies of commodification and preservation is ongoing in the aftermath of the spotted owl crisis in the Pacific Northwest, and beyond.

Norway

AFTER REMAINING NEUTRAL in World War I, Norway underwent a five-year German occupation during World War II and joined the North Atlantic Treaty Organization (NATO), subsequently developing close political and economic ties with other Western nations. Norway has refused to join the European Union (EU) but voluntarily contributes large sums to the EU budget.

Oil and gas were discovered in Norway in the late 1960s and Norway is now the third-highest oil producer in the world; oil and gas comprise one-third of all Norwegian exports. Other natural resources include iron ore, copper, lead, zinc, titanium, pyrites, nickel, fish, timber, and hydropower. With a per capita income of $42,400, Norway is the third richest nation in the world. Planning for a time when oil and gas reserves run out, the government has placed over $150 billion in the Government Petroleum Fund.

Despite its wealth and high quality of life, Norway suffers from extensive water pollution that threatens marine life.

North Sea Oil

The oil reserves in the North Sea are one of the largest non-OPEC oil production areas in the world. Much of the oil lies beneath waters that belong to Norway and the United Kingdom, with some fields belonging to Denmark, the Netherlands, and Germany. North Sea Oil was discovered in the early 1960s but it was not until 1971 that it came on line, being piped ashore to the northern English industrial town of Teeside. Soon afterward oil was also pumped ashore in the Norwegian sector.

The Norwegian government administers licenses to the North Sea through their Norwegian Petroleum Directorate, and North Sea oil forms a major part of the economy. Norway has also located and tapped large fields of natural gas. It produces about 3.33 million barrels of crude oil per day, as well as 65.4 billion cubic meters of natural gas.

The North Sea is rough and dangerous throughout the year, but especially in winter. Extracting oil from the North Sea has been extremely expensive, pushing oil industry technology to its limits. However, the oil price rises experienced during the 1970s made Norwegian North Sea oil commercially viable, and the money earned by the Norwegians led to a massive boom in their economy during the late 1970s and the 1980s, although a recession in 1981 did lead to an election defeat for the Norwegian Labor Party, the DNA.

With recent increases in the price of oil, the British government signed a major agreement by which it would buy up to 20 billion cubic meters of natural gas from the Ormen Lange field in the Norwegian sector of the North Sea starting in 2006—bolstering an otherwise flagging Norwegian economy.

The United Nations Development Programme Human Development Reports rank Norway first in the world on quality-of-life issues, in part because of extensive social welfare programs.

Bordering on the North Sea and the North Atlantic Ocean, Norway has 15,592 miles (25,148 kilometers) of coastline, including those along fjords (steep-sided inlets), minor indentations, and more than 50,000 islands. This coastline is one of longest and most rugged in the world. Along the coast, Norway's climate is temperate, with rain occurring all year on the western coast. The rest of the country is colder, even in summer; the north is arctic tundra. Because the land was formed from glaciers, around two-thirds of Norway is made up of mountains interspersed with high small valleys and scattered plains. Rockslides and avalanches are common. Around 97 percent of the land is nonarable.

As a heavily industrialized nation, Norway suffers from extensive water pollution that threatens marine life. Oil discharges from petroleum production have risen recently, particularly in 2003 when discharges from the Draugen field increased substantially. Because of intense urbanization (78.6 percent) and vehicle emissions, air pollution is also a chronic problem. With 417 cars per 1,000 people, Norway produces 0.2 percent of the world's carbon dioxide emissions. Acid rain has damaged forests and upset the ecosystems of lakes. In 2006, a study by Yale University ranked Norway 18th among 132 nations in environmental performance, slightly below income and geographic group averages.

The Minister of Environment works with a number of departments and agencies to promote environmental responsibility in Norway. As a result, discharges of plant nutrients in the North Sea have decreased, along with acidifying substances. Improved methods of dealing with large amounts of domestic and industrial waste have also been instituted. Air quality has improved in Norway due to technological improvements, stricter emission standards, and the closure of some chemical and metallurgical plants.

Despite the use of more environmentally friendly vehicles and fuels, emissions of greenhouse gasses have increased because the number of vehicles on Norway's roads has multiplied and drivers are traveling greater distances. Norway continues to explore the use of alternate sources of energy such as hydropower and wind production. While production of hydropower has declined, two new wind farms were opened in Møre og Romsdal and Finnmark in 2003.

The Norwegian government has protected 6.8 percent of the land. Of 54 mammal species endemic to Norway, 10 are threatened with extinction, and two of the 241 endemic bird species are in a similar situation. In the North Sea, the stock of cod is rapidly depleting, and the capelin stock in the Barents Sea has collapsed. On the other hand, the stock of spring-spawning herring is considered biologically safe, and the spawning stock of the Northeast Arctic Sea is increasing.

Norway promotes the health of the global environment through participation in the following international agreements: Air Pollution, Air Pollution–Nitrogen Oxides, Air Pollution–Persistent Organic Pollutants, Air Pollution–Sulfur 85, Air Pollution–Sulfur 94, Air Pollution–Volatile Organic Compounds, Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Seals, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling.

No-Till Agriculture

NO-TILL AGRICULTURE IS a farming method in which crops are cultivated without plowing, thus minimizing disturbance to the soil. Instead, the farmer plants seeds in a slot created by equipment that uses disks or chisels to create a narrow furrow in which the seed can be injected and then covered. This method of farming yields a number of environmental benefits relative to conventional farming. It preserves soil and, in most cases, generates higher crop yields than conventional farming.

Conventional tilling loosens and disturbs the soil, which allows for greater erosion. Plowing breaks up clods that naturally form from organic matter, such as roots and plant remnants, left in the soil. As this organic matter is churned up, it is exposed to the atmosphere where it quickly decomposes, releasing nutrients such as nitrogen and phosphorus that are easily carried away by wind and rain. The no-till method not only prevents soil erosion but also helps with the retention of nutrients, thus reducing the need for additional fertilizer. Fertilizer use can be further reduced by equipment that injects fertilizer in with the seeds as they are planted, thereby eliminating the need to fertilize the entire field. Naturally forming clods in the soil also help to retain water, which reduces the need for irrigation.

No-till methods also offer promise for reducing global warming, an increase in the temperature in the earth's atmosphere caused in part by the release of carbon dioxide into the air. Elevated carbon dioxide levels are caused primarily by the burning of fossil fuels, but conventional agricultural practices also contribute to this problem in other ways. Plants remove carbon dioxide from the air, but the carbon accumulates in plants and decomposition of the plant returns some of it to the atmosphere. The remainder is sequestered in the soil as organic matter. This is significant as soils contain roughly twice as much carbon as land plants or the atmosphere. The amount of carbon sequestered in the soil is greatly reduced when forests and grasslands are converted for agricultural purposes. Carbon in the soil is easily transferred into the air. Conventional plowing disturbs the soil and allows organic matter to decompose more quickly as it is regularly exposed to the atmosphere into which the carbon dioxide is then released. The no-till method allows the undisturbed soil to retain much of that carbon. No-till methods also greatly reduce the use of fossil fuels by limiting the need for fertilizers and reducing the number of times farmers must go over their fields. Fewer trips across the fields also decreases soil compaction caused by tractors.

Although extensive testing of no-till practices is ongoing, the environmental and economic benefits of no-till agriculture appear to be significant. Higher yields, and savings in terms of labor time, fuel, fertilizers, and irrigation mean fewer costs and higher returns for farmers using this method. Ecologically, no-till methods prevent soil erosion, pollution runoff, the use of synthetic fertilizers, and carbon dioxide releases.

On the other hand, no-till methods still require herbicide usage for weed control and there is some evidence that demand for herbicides may actually increase under a no-till regime. The use of no-till methods in the United States is increasing significantly. By one estimate, in 1990 seven million acres were farmed using the no-till method; by 2002 that number had increased to over 50 million.

Nuclear Power

NUCLEAR POWER IS electrical power generated from a nuclear reactor. Electricity is produced by the heat released from the atomic core though a controlled nuclear chain reaction. Waste products include heat and spent nuclear materials.

Nuclear power plants use a nuclear reactor, which is also called an atomic reactor or an atomic pile. Nuclear reactors have seven primary parts. Some of these are systems and some are protective parts. These primary parts are the atomic core, the moderator, control rods, a coolant system, a pressurized vessel, and a biological shield. In addition there are safety systems and a containment unit to house the reactor.

The atomic core is the center of the reactor. It is where nuclear fission takes place. Nuclear fission, which is also called atomic fission, occurs naturally when atoms that are high in the scale of chemical elements decay or split into smaller elements and at the same time give off energy. Albert Einstein's famous formula $E = MC^2$ says that energy is equivalent to mass times the speed of light squared. The splitting of atoms involves the transformation of small portions of the matter into energy in the nuclear reaction.

When the nucleus of an atom splits, its component protons and neutrons are released. The atom that is split separates into nuclei; free neutrons, photons, and gamma rays are also usually generated. Of the photons, gamma rays are usually the most common form. There may be other particles generated, such as alpha particles and beta particles. The atomic reaction produces energy in the form of gamma rays and kinetic energy in the form of heat. The amount of heat released is millions of times the amount of energy released from chemical reactions that occur from the burning of fossil fuels such as coal, gas, or oil.

Radioactive atomic materials release neutrons naturally. There are radioactive materials that are not used as nuclear fuel in nuclear reactors. Some of these are the waste products of nuclear power plants, while others, such as radium, are used in medicine. Atomic energy was recognized shortly after the discovery of radioactivity. In the case of radium, it was noticed that its decay created heat that naturally surrounded quantities of it. In 1939 the discovery of uranium fission made possible the development of the atomic bomb and, after World War II, the development of nuclear power.

The radioactive material used in atomic reactions is generally referred to as special nuclear material (SNM). The term comes from a definition used in the United States Atomic Energy Act. The special nuclear materials used most commonly in nuclear reactors are plutonium, uranium 233 (U233) and uranium 235 (U235). Uranium is widely distributed in the earth. It was originally formed in a star that was a part of the material that formed the earth. About 99 percent of the uranium on earth is uranium 238 (U238). Less than one percent is U235.

UNCONTROLLED REACTIONS

A nuclear reaction, if uncontrolled in a unit of special nuclear materials, will cause a chain reaction. The neutrons that are causing radioactive decay naturally will continue to increase rapidly so that as a neutron strikes the nucleus of an individual atom the split atom also releases free neutrons. These increase rapidly in number releasing increasing quantities of energy.

Creating an uncontrolled chain reaction of nuclear fission is the principle used to create an atomic explosion. Oddly, a nuclear weapon is designed so that a controlled set of induced atomic reactions is used to create an uncontrolled chain reaction in unstable U235 resulting in a huge explosion with its attendant atomic blast, radiation, and enormous heat.

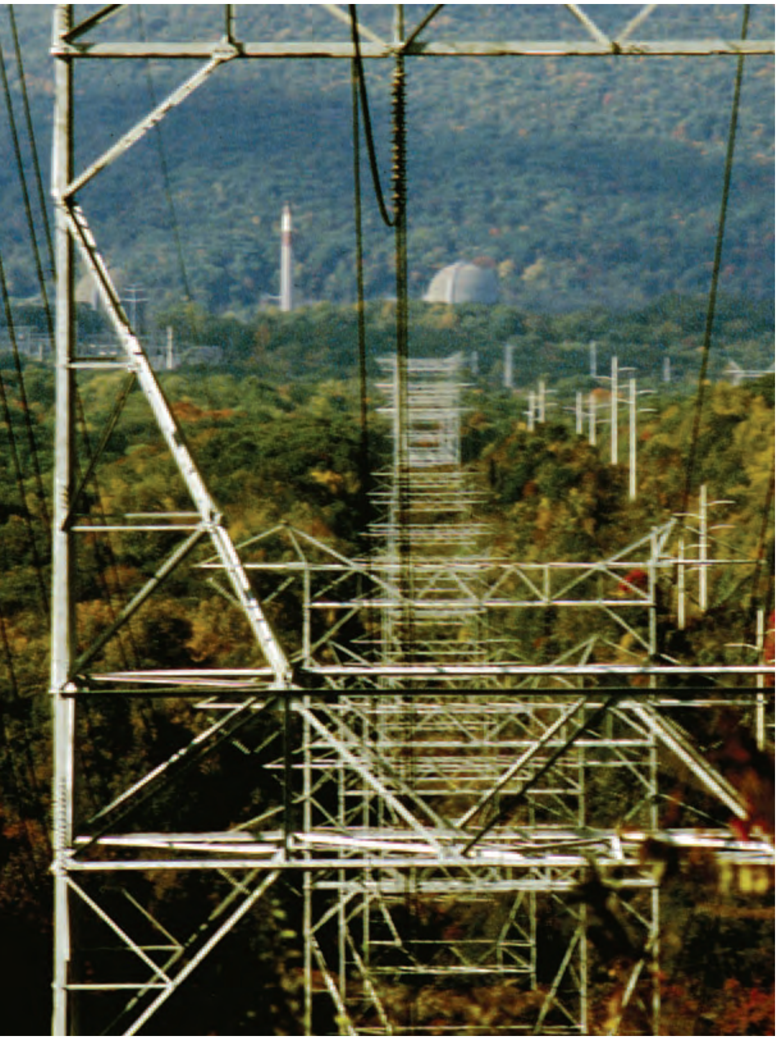
If an uncontrolled reaction occurs in a nuclear power plant an atomic meltdown can occur. The atomic core of the reactor becomes so hot that it melts. If the pressure vessel is not able to contain all of the heat and steam produced, then a terrible accident can occur. This happened at Chernobyl in the Ukraine in 1986. The radioactive materials released were spread over northern Europe. The area around the Chernobyl nuclear power plant for some miles distant, including the city of Chernobyl, had to be abandoned. The health consequences since have been very serious: A much higher rate of cancers, birth defects, and other illnesses caused by exposure to high amounts of radiation.

CONTROLLED REACTIONS

The nuclear reactions generated in an atomic core are controlled. The core is part of a nuclear power plant that contains the nuclear fuel; nuclear fission reactions take place in the core. The core is composed of nuclear material—usually pellets of uranium oxide (UO_2). These are put into tubes to form fuel rods, and the fuel rods are then arranged into fuel assemblies in the reactor's core.

The core's reactions are managed by control rods, which regulate the rate of chain reactions. Control rods are usually made of boron, cadmium, cobalt, europium, gadolinium, hafnium, indium, silver, or other materials that can absorb neutrons without becoming fissionable. These elements capture neutrons at different rates so their use as control rods is guided by the spectrum of the kind of nuclear fission reactions the atomic core is designed to generate. The reaction is started, slowed, and stopped by means of the control rods. The rods are slowly removed from their positions in the core. Nuclear reactors are designed so that the rods effectively cover the top and sides of the fuel rods. The fuel rods rest on a floor of neutron absorbing material.

As the control rods are pulled upward from covering the fuel rods, the nuclear reaction begins to take place. The neutrons are no longer absorbed by the moderator material in the control rods. This allows free neutrons to create fission reactions and more neutrons, which then drive the reaction. By manipulating the control rods the reactor is turned on or off. The effect is like that of allowing more oxygen to enter a fire so the fire burns hotter. The removing of the control rods allows the atomic reaction to occur. The further the rods are removed the faster the reaction increases.



In the United States 20 percent of the electrical supply comes from nuclear power plants.

Nuclear power plants are operated with a large number of monitors that measure the heat being generated. Special instruments measure radiation levels in the core as well. The moderator in mater reactors is a material used to stimulate nuclear chain reactions. Moderators may be composed of several different types of materials. Most moderators have used graphite or heavy water. Water is hydrogen oxide (H_2O); however, heavy water is the common name of an uncommon isotope of hydrogen called deuterium.

The moderator material captures the free neutrons and allows them to be evenly available to the fissionable material. U238 is not atomically unstable like U235 so it will normally absorb the free neutrons. The principle is that when an atom of U235 is hit by a neutron it creates a high probability of fission. The U235 atom splits, and on average produces about two or more neutrons. The effect is to create a self-sustaining chain reaction. No additional neutrons are needed.

The fissionable reactions can be held constant if the surplus neutrons escape from the system. However, if they are allowed to increase, the reactions diverge. In nature the probability that a high energy neutron will directly cause fission in another atom is low. To create the fission reactions in a nuclear core, enriched uranium is used. An increased amount of U235, which is expensive to produce, is consolidated in the nuclear fuel. What the moderator materials do is slow down fast neutrons so that slower neutrons have a better opportunity to be captured in the core's fuel. The moderator becomes a medium for reducing the velocity of fast neutrons so that they are changed into thermal neutrons that can sustain nuclear chain reactions.

Nuclear power plants are built and named after the kind of moderator material used. The most common forms of moderators are water and heavy water. Light water reactors use water; heavy water reactors use deuterium. To be useful as a moderator a material should have the lowest atomic number possible and resist absorbing neutrons to a very high degree. Besides deuterium and graphite, beryllium and hydrocarbons have been studied for possible use. Deuterium has the disadvantage of being expensive; huge quantities of water have to be processed to capture the deuterium atoms.

TYPES OF REACTORS

Another way of naming nuclear power plants is after the type of reactor used. Nuclear fission reactors use a critical mass of fissionable material. There are currently several types of these reactors: Generations I, II, and III, and other subtypes. All of these types use a reactor cooled by pressurized water. The water is under immense pressure, which allows it to absorb greater quantities of heat than if it were at open atmospheric pressure. Most nuclear power plants have pressurized water reactors. In the opinion of nuclear experts, these are the reactors with the most reliable technology. Some of these are fast-spectrum and others are thermal-spectrum reactors.

Usually the fast-spectrum reactors produce waste with a shorter half-life (the time it takes for half of the radioactive material to completely decay).

Fast reactors can also be designed to act as breeders of even more radioactive material. Thermal reactors cannot produce reusable radioactive material. Most reactors in use in power plants are thermal-spectrum reactors and pressurized water reactors. These types of reactors have proved to be the safest and the most reliable, even though the Three Mile Island plant in Pennsylvania was the site of an accident.

Boiling water reactors are water pressure reactors, but the pressure is less and the water is allowed to boil in the reactor. A problem with this type of reactor is that the boiling water in the reactor stresses the components. This increases the risk of an accident that will permit radioactive water to escape. However, the use of this type of thermal reactor is widespread.

Another type of reactor is the Pressurized Heavy Water Reactor (PHWR). This type of reactor uses heavy water as a coolant and also as a moderator. This type of reactor uses hundreds of pressure tubes to hold the fuel, rather than housing it in a single large containment vessel. An advantage of the Pressurized Heavy Water Reactor is that it does not have to be taken off line to be refueled. Canada has developed this type of reactor and has sold units to a number of countries, including Argentina, China, India, Pakistan, Romania, and South Korea.

The former Soviet Union built a number of plutonium reactors. These have proven to be dangerous and unstable. They are water cooled, but use graphite as a moderator. An advantage is that they can be refueled while in operation. However, they are too large to have containment buildings. The Chernobyl plant was of this design. Gas Cool Reactors were been developed in Great Britain. They use a graphite moderator with carbon dioxide as a coolant and have high thermal energy efficiency.

Reactor designs have been advancing since the first reactor went on line in the 1950s. A Generation IV reactor design is being developed. This type of reactor will be like a light water reactor, but it will allow the water to be heated to a critical level so that the thermal efficiency is very high. The critical level is the point at which liquid water under pressure acts like a gas.

Some reactors are liquid metal fast breeder reactors. The liquid metal acts as both moderator and as coolant. There are two types—lead-cooled and sodium-cooled. Several reactors using liquid metal have been built in France. Another type of reactor is the radioisotope thermoelectric generator. It produces heat through passive radioactive decay. Space probes, unmanned lighthouses, some pacemakers, and other devices have been designed to use micro nuclear power plants.

The coolant system in a nuclear power plant distributes the heat generated in the nuclear reactions to where it can be used. The other systems of the nuclear power plant use the heat generated to cool the nuclear reactor and to produce electricity. Cooling the reactor is vital to avoid major accidents. Materials used as coolants in nuclear reactors include gases, liquids, and liquid metals. In light water reactors the moderator also functions as coolant. Heavy water reactors use a different system.

The pressure vessel or a set of pressure tubes hold the core in a nuclear power plant. The core is covered by a very strong vessel. Usually some kind of robust steel is used to contain the reactor core, the moderator, and in systems where the moderator is also the coolant, the coolant as well. Sometimes the pressure vessel is a series of pressure tubes. The tubes hold the fuel and move the coolant through the moderator.

The electrical production in a nuclear power plant comes from steam generation. The portion of the cooling system that diverts heat delivers it to sources of water that can be converted to steam. The steam is used to drive turbines. It can also be used to do mechanical work as well. The turbines in nuclear ships drive the ship's propeller blade as well as supplying electrical power. Nuclear power reactors have been used by several of the world's navies; submarines and aircraft carriers have been atomic powered since the 1950s.

SAFETY FEATURES

The containment structure surrounds the reactor core. It is designed to protect the core from outside intrusion. Storms or other invasive disruptions of the core's reactions could cause a major nuclear accident. Another important function of the containment structure is to act as a biological shield to protect the outside world from the deadly effects of radiation. The material used to make the containment is usually very thick concrete and steel. The structure is often more than a yard (meter) thick. This thickness is needed if a malfunction or accident should occur.

The safety system is really a series of systems to handle emergencies so that serious accidents can be prevented. In general the safety systems act to stop the atomic reaction or cool the core. Safety rods in the core are a very important feature. They will stop a reaction very rapidly and will be automatically inserted into the core if a rapid increase or abnormal amount of neutrons is detected.

Another safety action to stop the atomic reaction is the employment of samarium oxide balls. The balls are made of oxygen and samarium. If dropped into a core they will immediately stop the reaction by absorbing the neutrons. Emergency core cooling systems seek to prevent an accidental meltdown. If the normal coolant is lost or if the coolant system fails then the emergency cooling system can be employed. It floods the core with water that absorbs heat to prevent a nuclear core meltdown.

BENEFITS AND RISKS

Today a growing portion of the world's electrical supply is coming from nuclear power plants. Nuclear power plants are supplying 15 percent of the world's electricity. In the United States 20 percent of the electrical supply comes from nuclear power plants. In France the percentage is 80 percent.

The great benefit of nuclear power is that enormous quantities of electricity can be produced at a lower cost. They also have the benefit that they do not produce smoke or carbon dioxide, which contributes to global warming. However, the great drawbacks are the waste products and the threat of destruction posed by accidents and nuclear weapons.

The enormous quantities of heat generated by nuclear power plants can be handled with appropriate engineering. Uses of waste heat include cogeneration or supplying heat to winter agriculture in northern climates or other practical uses. The key problem is preventing any contamination by radioactive materials, because these can pose serious health problems.

The problem of storing nuclear waste is a major issue. Temporary sites where materials are buried must be supervised to prevent leakage of radioactive materials. Eventually a permanent site where radioactive materials can be kept for thousands of years has to be developed.

The fact that nuclear reactors can be designed to produce nuclear materials that can be used in nuclear weapons is a grave concern to the world. As the knowledge of nuclear fission spreads it is becoming easier for countries or even private corporations to develop these. Many supporters of nuclear power argue that the knowledge is now so widespread that to not use atomic power because it will allow nuclear fissionable materials to be created is folly.

Nuclear Regulatory Commission (NRC) (U.S.)

THE NUCLEAR REGULATORY commission (NRC) is the federal agency charged with the regulation of nuclear power and other uses of nuclear energy in the United States. Five commissioners lead the NRC, one of whom is the chair, appointed by the president and confirmed by the senate for five-year terms. Its regulatory activities address three aspects: materials, reactors, and waste.

Materials include nuclear fuel, as well as nuclear materials used in industry, medicine, and academic settings. Reactors include power reactors and experimental reactors at research and academic institutions. Waste involves the containment, transportation, and disposal of nuclear waste products—the last phase in the nuclear fuel cycle. High-level waste products are often highly radioactive, and therefore require careful handling. The NRC is at the forefront of efforts to develop a high-level nuclear waste disposal facility in Nevada.

The NRC's history is rooted in the history of its predecessor, the Atomic Energy Commission (AEC). The Atomic Energy Act of 1946 established the AEC as the agency that would promote, develop, and regulate nuclear power. The Atomic Energy Act of 1954 clarified the AEC's role in promoting efforts to build and operate nuclear power plants. But the AEC was unable to gain the interest of utilities to build nuclear power plants until the enactment of the Price Anderson act in 1957; this act limited the liability of utilities in nuclear plant accidents. This overcame utility concerns that, in the case of a power plant accident, their liability would be unlimited, making insurance virtually impossible to obtain. With the passage of Price-Anderson, the first civilian nuclear power plant went on line in Shippingport, Pennsylvania, and, in 1959, the first civilian nuclear plant built without government funding began operations.

The AEC and Congress's Joint Committee on Atomic Energy (JCAE) governed civilian nuclear power until the mid-1970s. Because of concerns about one agency promoting and regulating nuclear power, and because of concerns about centralized power in the JCAE, the Energy Reorganization Act of 1974 abolished the JCAE and the AEC. It created the NRC, which began its functions on January 19, 1975. The parts of the AEC that were not incorporated into the NRC were formed into the Energy Research and Development Administration (ERDA), which became the core of the U.S. Department of Energy (DOE) when it was formed in 1977. DOE also encompassed many of the military programs of the former AEC, while the NRC focused on the civilian uses of nuclear power. Congressional oversight over nuclear power was distributed among several congressional committees.

Since Three Mile Island in 1979, there has been no major nuclear power plant accident in the United States.

The NRC was created during a period of turmoil in the nuclear power field. In 1975, the Tennessee Valley Authority's (TVA) Browns Ferry, Alabama, nuclear plant experienced an accident that led to continued calls to subject nuclear power to scrutiny.

In this accident, candles were used for illumination during an inspection of cables; the cables ignited, leading to a fire that cut off the control room from the reactor.

This incident was described on TV's *60 Minutes*, and motivated interest groups, led by the Union of Concerned Scientists (UCS), argued that government estimates of the safety of nuclear power plants had been inaccurate. As a result, and because of methodological problems with the original assessment, by 1979 the NRC had fully repudiated the AEC's primary document that described the risk and probability of a major nuclear accident, the Rassmussen or WASH-1400 report. Also in 1979, the NRC confronted the Three Mile Island nuclear accident, the most serious civilian nuclear power accident in the United States.

Since Three Mile Island, there has been no major nuclear power plant accident in the United States, due to experience with operating reactors, more aggressive regulation by NRC, and reminders, such as the Chernobyl accident in the Ukraine in 1986, of the hazards of nuclear power and the need for continued regulation.

Today, the NRC's major challenge is in finding a suitable site to secure highly radioactive waste from nuclear power plants and other facilities. The need has become acute as some power plants begin to run out of space for storing spent fuel, and as concerns have grown over maintaining security over any radioactive materials at power plants. Reactor licensing renewals are also important tasks, and sometimes engender considerable debate as local community members voice concerns over plant safety and security.

Nuclear Weapons

NUCLEAR WEAPONS ARE among the most destructive devices ever created by humanity and continue to represent a significant threat to human security. Nuclear weapons are also occasionally referred to as thermonuclear weapons or atomic weapons, although all function in approximately the same way. Fission weapons are based on the principle that a sufficient mass of appropriately treated uranium or plutonium will, once it has reached a critical mass, spontaneously explode. Consequently, two masses of the appropriate metal are, to trigger the detonation, forced together by some means. Fusion weapons aim to create conditions in which a thermonuclear fuel such as deuterium will be ignited, through using a fission-based triggering detonation, in a similar process to that which takes place in stars (these are known as hydrogen bombs).

The enormously powerful explosions produced by nuclear weapons mean that it is necessary to project the weapon some distance away to strike against an enemy without endangering the home territory and assets. This means that nuclear weapons are mostly designed to launch via missiles, with the warhead in which the subcritical masses are contained riding this vehicle and programmed to explode at a distance.

Airplanes, submarines, or satellites launch missiles, and these are usually strategic in nature, which means they have a large payload (explosive capacity) and are designed to launch over thousands of miles. The American Cruise Missiles are archetypical strategic nuclear missiles. In addition to strategic weapons, tactical nuclear weapons have been designed that are intended for battlefield usage against hardened or fortified targets with a comparatively low destructive level, although still far more destructive than nonnuclear or conventional weapons systems. As of 2006, the only nuclear weapons that had been exploded in warfare were the two atomic bombs dropped by the United States on the Japanese cities of Hiroshima and Nagasaki during World War II. These weapons killed many thousands, both through the effects of the blasts themselves, but also subsequently from cancers and similar diseases resulting from radioactive fallout. Since then, fear of nuclear weapons has resulted as much from the threat of horrible wasting diseases as the possibility of instant death.

There has been a considerable amount of secrecy concerning which nations possess nuclear weapons and which do not. In addition to the United States, Russia (formerly part of the Soviet Union), France, the United Kingdom, and China also have the ability to launch nuclear weapons. India and Pakistan were permitted by U.S.-led world opinion to obtain such devices at the beginning of the 21st century. It is widely believed that Israel and South Africa also possess weapons, but neither has formally acknowledged this. Some concern exists as to the possibility that North Korea or Iran will pursue a nuclear weapons program.

The International Atomic Energy Authority (IAEA), part of the United Nations, manages regulation of nuclear energy and weapons programs around the world. In general terms, the IAEA permits states to pursue nuclear energy programs, but not nuclear weapons programs outside of exceptional circumstances.

The need to control the proliferation of nuclear weapons started during the Cuban missile crisis of 1962, in which the possibility that the Soviet Union would place nuclear weapons on the territory of its ally, very close to the continental United States, in response to American deployments of weapons close to Soviet territory, nearly brought about a nuclear war.

During the decades of the cold war, the prevailing ideology was that of mutually assured destruction (MAD), which was based on the understanding that, owing to the many thousands of warheads that had been stockpiled over the years, any attack by one side would inevitably lead to the annihilation of everyone concerned. During the 1970s, a series of bipolar negotiations managed to ease tension and provided for the reduction of nuclear warheads in some categories. This included the Strategic Arms Limitation Treaty (SALT) and the Strategic Arms Reduction Treaty (START). In 1986, after the ending of the cold war by Soviet Premier Mikhail Gorbachev and the dissolution of the Soviet system, the world has been moving toward a new ideology to minimize the likelihood of the use of nuclear weapons in an essentially unipolar world.

Much anxiety exists about the possibility of terrorists obtaining nuclear material that could be used as a weapon, which would be more likely to be left as a bomb to be exploded remotely rather than launched by missile. A missile would require a higher level of technology than it is imagined that terrorist organizations could deploy and it would provide more of a warning for potential targets. Nevertheless, there remain considerable concerns about the security of old and decommissioned weapons and the possible environmental impact of weapons new or old releasing radioactive material into the atmosphere.

Nuisance Law

NUISANCE LAWS STARTED just after the Norman Conquest and have been heard in the English courts since the 12th century. The basic assumption is that everyone has the right to the use and enjoyment of his or her land. Nuisance laws were for centuries the major method of regulating land use. When an action or inaction affects that use or enjoyment, it can be identified as a nuisance.

A nuisance can be categorized as either private or public. A private nuisance is a situation that affects the enjoyment or use of an individual's property without a trespass or physical invasion. A public nuisance is a condition endangering public health, morals, safety, comfort, convenience, or welfare of community members. The same nuisance, however, may be enforceable in both situations.

Nuisance laws or ordinances are generally defined at the local government level with a broader description at the state or province level. In some situations, there may be a fine distinction between nuisance and pollution law relative to the definition of the activity, standards, amounts, and location.

Nuisance laws concerned with the environment can be classified into three general categories: public health and well-being, environmental protection, and land use. Public health nuisance laws are designed to protect and preserve the public and infractions can range from smoking in nonsmoking areas to maintaining a yard that could breed infectious insects or vermin.

Well-being is a broad term and has many definitions; however, it generally relates to the perception of safety, comfort, happiness, and convenience. Nuisance laws protect that perception in several ways; one example is by controlling the use of land and structures that conduct illegal activities. An example of impinging on our convenience is to regulate activities that obstruct traffic and thus create traffic congestion.

Nuisance laws that protect the environment are generally associated with land, water, and air pollution. The laws vary and may regulate the dust or erosion from a construction site, the limits of sediment in a stream, or the amount of light emittance skyward. Overall, the nuisance laws protecting the environment are the regulations that control activity at the local level and reflect the community's environmental concerns.

Production and services are needed to sustain a local economy and these activities are conducted in factories, processing plants, and power stations. In addition, food and livestock production are necessary to feed the population. Nuisance laws attempt to mitigate the impacts of factory and agricultural production to the surrounding landholders as these activities can cause discomfort, inconvenience, and visual blight to neighboring landholders.

Nuisance laws endeavor to support these activities and at the same time provide protection to residential and commercial lands. These land uses are generally not a nuisance if conducted in suitable locations and following proper management procedures.

Nuisance law pertaining to land use is a balancing act between economic activity and community quality of life. Each community defines its quality of life and what is a suitable area for different land use activities. Thus, there are no standards to define minimum or maximum for land use interactions.

A nuisance is an unreasonable interference with the use or enjoyment of land. A frequent paradigm for determining whether a nuisance exists is the weight of the gravity of the harm to the landowner or public against the utility of the use or the nuisance. The main points to consider are the character of the harm, the social value of the use, the suitability of that use to the character of the area, and the impracticality of avoiding the harmful invasion. In other words, is it reasonable for the action or inaction to take place in that location or does it impede the individual landowner or the public from using or enjoying the land?

Nutrients (as contaminants of water)

NUTRIENTS IN WATER are chemicals such as calcium, oxygen, nitrogen, phosphorus, various trace minerals, salts, and even decomposing organic material. Some nutrients occur naturally in water in varying amounts. However, chemicals that can serve as nutrients that are due to runoff from farms, urban areas, industrial waste, or sanitation effluent can create significant pollution problems as well as long range health problems for both humans and the environment.

Natural nutrients are produced by the naturally occurring chemical action of water and other elements or compounds that leach into the watershed. The farther downstream it is from the watershed at mountain peaks, the more water is likely to contain oxygen, carbon dioxide, dissolved calcium compounds, and other substances. If the water in a stream begins in an area where it moves through petroleum seeps, coal beds, sulfur beds, iron bearing rocks, or other kinds of rocks with water soluble minerals, it will contain more naturally occurring nutrients.

The mineral content may make the water heavy in iron so that it clouds the bottom of ice water glasses in the summer as it combines with dissolved calcium carbonate to form a precipitate. Or it may be that the water is acidic, salty, or naturally fluorinated. If a strong basic solution is dissolved in the water, such as in the alkali waters of the western United States, the water will have an unpleasant taste.

As natural nutrients are cycled through natural ecosystems they have an important impact. If the ecosystem is naturally rich in nutrients then plants grow rapidly. Among the effects this has is the amount of carbon that is put into plant life and the amount of oxygen given off by plants. There may be consequences from this ecological balance that affects even the global climate.

All of the dissolved chemicals and organic material in water provide nutrients. Some, however, may be pesticides or herbicides that have an immediate and long term negative impact. These will ultimately be degraded in the environment; however, they are not the chemicals that are usually included when referring to nutrients.

Eutrophication occurs when increases in chemical elements lead to population explosions of microorganisms such as algae and blue-green bacteria. These become so thick that light is blocked. The light dependent organisms die, which creates a cultural eutrophication. As plants in nutrient deficient areas are exposed to polluting quantities of nutrients, their roots grow in response and their intake of other plant nutrients is increased. The varied growth rates of plants can produce situations in which some plants crowd out others that were a part of the natural system.

Vegetation that grows in rivers and in the waters that cover the continental shelves of the world respond to nutrient changes in several ways. The slower growing sea grasses, the phytoplankton, and other parts of the food chain change in quantity affecting the natural character of the ecosystem.

Nutrients can be readily consumed by a variety of microscopic plants and animals and cause their growth in watersheds. In effect, they act as fertilizers or food boosters that stimulate growth, which is often harmful to the environment's natural balance when some of these enter into the food chain. Consequently, of great importance to the health of water supplies, including the vast oceans, are the great quantities of industrial and urban wastes that enter water streams. Paper mills are a major source of nutrient chemicals. Their effluents often can be detrimental to riverine food webs and are also capable of reducing oxygen content, thus resulting in fish kills.

The presence of polluting chemicals that act as nutrients and come in large volumes from human sources poses a significant threat to human life. The volume of renewable fresh water on Earth is a small fraction of the total volume of water; about half of all fresh water is currently in use in some fashion around the globe. Fresh water supplies are basic to terrestrial life and to freshwater ecosystems. Great numbers of agricultural and industrial users of water depend upon clean fresh water. Among the chemicals that are of serious concern are ammonia, phosphates, and nitrates.

In 1991, the U.S. Congress directed the U.S. Geological Survey (USGS) to develop a National Water-Quality Assessment (NAWQA) Program. It works with federal, state, and local governments and agencies to examine the water quality in the United States. In its studies, the program has found that in some areas pollution has been a positive addition to a nutrient poor watershed. However, the reverse is more often the case.

One effect of dissolved organic matter in polluted water is that it acts to deplete both nitrogen and phosphorus from timberlands. Agriculture is a major source of polluting nutrients in watersheds. Farming and other agricultural activities take place on the best lands; the margins are usually less productive and are often adjacent to wetlands that connect with the watershed. Water, moving toward lower elevations, carries nutrients like fertilizer toward wet areas where the excessive nutrients will move into the watershed.

The effects of polluting nutrients are most observable when they produce dramatic toxic effects on the aquatic life. Watersheds can recover from occasional polluting, but long term damage occurs with prolonged exposure. As the polluting continues, the habitat traps and processes the nutrients. The buffering zones along riparian areas are overcome and the fauna and flora of an area are affected. The food chain is soon involved because chemicals are absorbed and passed up the chain with significant toxic effects.

When polluting nutrients affect an area, ecologists and conservationists may seek to restore the area to its natural state. This requires elimination of the nutrient pollution at its source(s), removal of excessive growth, and restoring native species. Elimination of nutrients that affect the food chain in systems in which sewage plays a role generally requires bacteria, molds, and other microscopic organisms. Sewage systems that use ponds for aeration will not become nutrient polluting sources if they are not overworked. If their systems are kept balanced then a healthy environment is the result.

Oasis

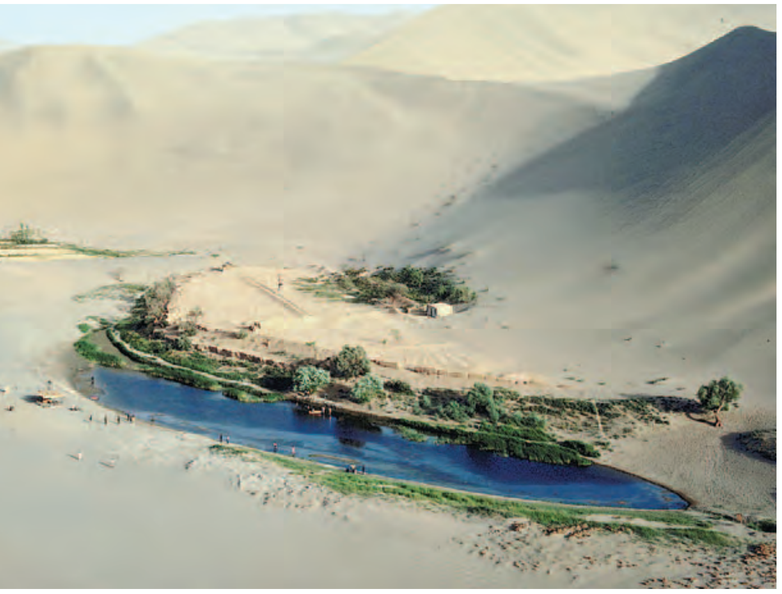
THE EARTH ITSELF is an oasis: An island of life in a vast and, as far as is known, mostly sterile solar system. Most envision the oasis as the classic, palm-filled area of land, an island in the desert. This is the type of oasis that will be described here, along with the unique environmental and social challenges faced by these fragile pockets of water and life.

What makes an oasis is not necessarily that it has life and a consistent source of water, but the fact that it is surrounded by a dry or largely lifeless expanse. Thus, what makes the oasis an oasis is not necessarily what grows within it but the desert surrounding it. An oasis must be disconnected from other regions with water to be considered a true oasis: A region of concentrated life and water standing alone. Like the earth, the oasis is dependent on water for its survival.

Most oases are small and uninhabitable watering holes where Bedouin or yearly migrants bring their livestock. Larger oases that have enough water to support life are rarer. These large oases have been exploited by social groups who use the desert as a shield and flee from central authority. Many simply wish to take advantage of the natural resources available in the oasis. Yet with such a small, contained ecosystem these societies face many environmental challenges; often the costs of isolation outweigh the benefits. While some oases are sustained by human ingenuity, many other oases and their water supplies are exploited beyond their capacity by human inhabitants, leading to the destruction of oasis habitants. Thus, in many ways, oases provide environmentalists, sociologists, and anthropologists an isolated microcosm of humanity's struggles with environmental scarcity.

Most oases are formed when land is low enough, or the ground porous enough, to allow a spring or pool to form from the aquifer: A region below the ground where water from far away, or from long ago, had reached the bedrock. The spring either naturally supports flora and fauna, or the water is exploited by humans; it is sent into channels and used for the irrigation of crops. Thus, by exploiting water humans can vastly expand the natural limits of an oasis, at least in the short to medium term.

There are three major, long-term human activities in oases, however, that can lead to the destabilization of oasis habitat and desertification, the advance of the desert into the oasis. These three activities are deforestation, overcultivation, and overgrazing. Deforestation, driven by a need for fuel and energy from wood, leads to erosion on the edge



Oases arise when low-lying land or porous ground allows a spring or pool to emerge from an aquifer below.

of the oasis. Overcultivation, the growing of food crops and cereals, also leads to the cutting of trees and the clearing of land. Often the land is rotated and allowed to lay fallow, but overpopulation can lead to overexploitation of the land. Without any cover, fertile soil can be blown away by the wind. Overgrazing by livestock, not only within the oasis community, but also by the large livestock brought into oases by migrating tribes, leads to the creation of permanent pasture out of once lush and fertile land. This also leads to conflict between settled agricultural and migratory tribes, a conflict that has come to a head today with the crisis in Darfur, Sudan. The Janjaweed, who have recently been driving villagers off oases are, for the most part, from migratory tribes. Indeed, as the current crisis of oasis communities in the Sudan suggests, it is in the best interests of the human population in general to come to an agreement over the sustainable use of the largest known oasis: the planet Earth.

Obesity

OBESITY IS THE condition of being overweight. The specific definition of obesity may vary depending on source, but is frequently characterized by individuals who are at least 20 percent above their ideal body weight, based on age and height. Obesity has been linked with medical conditions such as diabetes, high blood pressure, strokes, and coronary heart disease. Worldwide, the number of obese people continues to rise.

Historically, obesity was an uncommon feature of social life. Through much of human history the primary dietary concern was the pursuit of adequate nutrition. In preindustrial environments obtaining and/or growing food was a difficult endeavor. In some societies in the past, being overweight or obese served as a marker of status; the ability of an individual to obtain high-caloric and excess food was affiliated with a higher socioeconomic position.

In the 20th century, the existence of obesity has emerged as a social issue in both developed and developing countries. The increased incidences of being overweight or obese vary in the developed world. The United States, in particular, appears to be facing a growing epidemic, with more than a third of Americans being overweight. In contrast, European nations tend to have lower incidence of obesity; however, the numbers of overweight individuals in many of these nations are also on the rise.

Traditionally, it was believed that obesity was only an issue in developed societies, but it is becoming apparent that obesity is affecting populations in developing societies. One correlation that appears to be associated with growing incidences of obesity in the developing world is the increasing likelihood of a Western diet, which is often more inclusive of meat and carbohydrates, as well as high calorie processed foods. Still, many underdeveloped nations continue to face famine and undernourishment, which are strongly influenced by economics. In these societies, obesity emerges primarily among higher socioeconomic groups.

Industrialization and increasing dependence on and use of technology are affiliated with this shift toward obesity. Technology first enabled the expansion and further development of agriculture, which improved the availability of crop foods for consumption. New means of transportation eased the distribution of food goods within a nation and between nations. Increased supply of diverse food sources, particularly within nations able to afford them, has expanded the choices and palates of many within the developed world. Technology has also fostered the transformation of food crops into high calorie processed foods. The consumption of calorie-dense foods, such as snack goods and soda, has been strongly tied to obesity.

Technology has also changed the types of work people do. In developed nations, many people no longer do much manual labor. This transformation of work has led to decreased calorie spending and has been complimented by increased calorie consumption, leading to obesity. Finally, technology, particularly media such as television, has led to more sedentary leisure activities (also often accompanied by increased calorie consumption) which may also lead to obesity.

Ob-Irtysh River

THE OB RIVER originates in the Altai Mountains in southern Russia and flows northwest across the Western Siberian Lowland, a vast expanse of flat land surrounded by mountains on three sides and the Arctic Ocean to the north. The Irtysh River begins in the highlands of China's Sinkiang Province, flows to the northwest, and joins the Ob near the town of Khanty-Mansiysk well within the Western Siberian Lowland. To the east of the Ob/Irtysh Basin and along the foothills of the Central Siberian Highlands the Yenisey River flows north to its mouth on the Arctic Ocean. Both of these river systems move considerable volumes of water across the flat expanse of the confined lowland.

Because the rivers flow north, they freeze in the fall of the year from their mouths southward precluding the free flow of water within its channel. When the spring thaws begin, water is first liberated along the southern extent of these mighty rivers. The physical outcome in both seasons is the accumulation of millions of gallons of water on the surface of the lowland. Some of the water is absorbed into the ground, but most of the accumulation stays on the surface creating a literal swamp comparable in size to approximately one-third the area of the contiguous United States. In winter the swamp turns into an enormous field of ice. In the warm season the standing water makes transit across the plain nearly impossible. In addition, much of the lowland is underlain with permafrost, a condition that limits the amount of water that can be absorbed and renders the surface impractical for the construction of road beds and rail lines. The Trans-Siberian Railroad, which runs from St. Petersburg to Vladivostok, crosses the Ural Mountains at Yekaterinburg and then proceeds south and east in order to avoid the swamp conditions on the lowland.

Both the Ob and Irtysh are navigable during the warm seasons. Since 1933 the Russian Northern Sea Route has operated large vessels on the ice-free waters of the Arctic Ocean near the Siberian coast and in the major rivers for four months a year. The city of Omsk is an important river port on the Irtysh, and Novosibirsk, home of the world famous Academ Gorodok (Science City), a cluster of national research institutions, is located on the

Ob. Both cities are key points on the Trans-Siberian Railroad. A number of hydroelectric generating plants have been built at points in the Ob-Irtysh river basin and a dam was constructed on the Ob at Novosibirsk, creating the Ob Sea, the largest artificial lake in Siberia.

The Ob River has been identified as a possible source of water to refill the decimated Aral Sea, which has dried to about 10 percent of its original size. The demise of the Aral Sea is one of the most serious environmental catastrophes in recent years. The Davidov Plan, conceived during the Soviet era, envisioned the construction of water diversion channels leading from the Ob River to the Aral Sea and other areas within the deserts of Kazakhstan. However, the plan was shelved following the introduction of glasnost in the 1980s and the Aral Sea continues to shrink.

Oceanography

THE TERM *OCEANOGRAPHY* refers to a descriptive science of the marine environment. Within the study, there is a wide variety of separate fields of scientific study, such as geology (including studies of marine and coastal sediments and studies of submarine tectonic plates and processes that affect coastal land forms), biology (for example, marine zoology, ecology of marine species, and marine microbiology), geography and meteorology (particularly oceanic processes that affect weather and climate), astronomy (the effects of astronomical bodies on tidal forces), physics (including fluid dynamics, currents, the behavior of waves, the effect of temperature on marine waters, and the behavior of sound in water), and, finally, chemistry (for example, the density of marine water bodies and the study of dissolved substances in seawater and chemical pollution in marine waters).

Oceanography can entail studies in the open ocean environment (oceanic) or in the coastal environment (neritic), on the sea bed (benthic) or in open waters (pelagic). Studies of the estuarine environment (enclosed areas where freshwater meets the marine environment) are also covered by the term. As such, oceanography encompasses a very broad field of scientific research.

The physical area encompassed by the field is also substantial, i.e., 71 percent of the world's surface is covered by oceans, with the Pacific Ocean encompassing an area equal to that of all continents combined and covering half the planet's surface. The importance of the marine environment is also emphasized when one considers that marine areas actually make up 99 percent of the known biosphere. However, 80 percent of the world's oceans remain effectively unexplored.

The scholar Rupert Riedl divides the history of exploration of the marine environment into four principal eras. First was the time of seafarers, which began either circa 2500 B.C.E., with the Polynesian exploration of the Pacific, or circa 1200 B.C.E., with the journeys of the Phoenicians. These ancient mariners sailed the eastern Atlantic as far north as the British Isles and as far south as the tip of southern Africa. Later came the expeditions of the Norse explorers to Greenland and North America in the late 10th century, and later still those of famous European explorers such as Columbus and Magellan.

One individual who stands out in this era of exploration is Captain James Cook. Starting in 1768 he made three voyages to map the world's oceans and landmasses, discovering New Zealand, Tahiti, Australia, and South Georgia; exploring the Southern Ocean; and charting the Hawaiian Islands, the west coast of North America and the Bering Sea. He became the first person to sail in both polar seas. In addition, Cook also recorded important oceanographic information such as ocean depths, prevailing wind directions, surface currents, and water temperatures.

The second era was the era of major oceanographic expeditions. Probably the most famous of these was the British Challenger Expedition (1872–76). Six scientists undertook a four-year voyage on the HMS *Challenger* to study the chemical composition of seawater and the distribution of marine animals, to record coastal and ocean currents, and to map ocean basins. This expedition made 362 soundings in the Atlantic, Pacific, and Indian Oceans, mapped major currents, and collected 7,000 marine specimens. The researchers identified 4,417 species new to science. The data accumulated from the expedition took 20 years to analyze and was published in 50 volumes as the *Challenger Reports*.

Marine expeditions were followed by the era of marine laboratories and research stations. The oldest marine station in the world was established in Kristineberg, Sweden, in 1830, followed by stations in Concarneau, France (1859), Naples, Italy (1872), St. Andrews, Scotland (1884), and Plymouth, England (1888). These United Kingdom (UK) stations were preceded by the oldest British marine laboratory, the *Ark*, which was a floating barge converted into a laboratory that was first moored in Scotland at Granton near Edinburgh (1884), then moved to Millport near Glasgow in 1885.

In the United States, the U.S. Commission of Fish and Fisheries (now known as the National Marine Fisheries Service) began a station at Woods Hole, Massachusetts, which still exists as the Northeast Fisheries Science Center, and in 1888 Alpheus Hyatt established the Woods Hole Laboratory. The current Woods Hole Oceanographic Institution was established in 1930. In 1903 on the West Coast of the United States, a marine biological laboratory was established in San Diego, which in turn became part of the University of California in 1912 and was renamed the Scripps Institution of Oceanography.

The fourth era of marine discovery was the era of field studies. This was greatly aided by the invention of the self-contained underwater breathing apparatus (SCUBA) by Emile Gagan and Jacques Cousteau in 1943. SCUBA allowed researchers to directly observe marine species in their natural environment. However, only about two percent of the ocean's volume is accessible to scientists using SCUBA equipment; manned submersibles have increased the depths humans have been able to reach to study organisms and features in the field. Remotely operated vehicles (ROVs) have been used underwater since the 1950s and are also an important means by which researchers study oceanographic features and marine organisms. ROVs are unmanned submarine robots with umbilical cables transmitting data between the vehicle and researcher. They have the advantage of being able to operate for longer periods and at greater depths than human divers and do not involve risk to human operators. They are also considerably less expensive to operate than manned submersibles.

Satellites are increasingly being used as another means of gathering data in oceanographic studies. They can be used for mapping marine habitats such as coral reefs, tracking marine life tagged with sensors to determine migratory patterns, and gathering data such as sea surface temperature—which in turn can provide information on currents, cold water upwellings, and climate. Satellites can also observe the color of the ocean, giving information on chlorophyll abundance and, hence, oceanic productivity. It could be argued that we are entering the oceanographic era of remote observational studies.

The scholar Michael Stachowitsch has suggested that there is an additional (current) era of marine/oceanographic research, one in which scientists are studying deteriorated marine ecosystems. He writes that almost all marine ecosystems have been disturbed and damaged by human activities. Indeed, examining the global extent of marine pollution, assessing stocks of marine species depleted by overexploitation, and evaluating the current effects of global warming on oceanographic processes and marine life are all becoming major areas of marine research.

Oceans

OCEANS COVER 71 percent of the earth's surface and contain 97 percent of the planet's water. Over 20 percent of the world's petroleum is derived from offshore sources, and 95 percent of world trade by weight—or two-thirds by value—is carried by ship. Eighty percent of the world's fish catch comes from the ocean, supporting the livelihoods of 140 million people. Economists have calculated that the world's oceans provide services to humanity valued at 21 trillion dollars, as opposed to only 12 trillion dollars provided by land.

Yet the ocean has emerged as an area of environmental concern only recently. In the European tradition of marine management, it was long believed that the ocean's resources were inexhaustible and that its environment was invulnerable to damage from human activities. These beliefs contributed to 17th-century jurist Hugo Grotius's assertion that, beyond the coastal zone, the ocean should be immune to possession by states, a legal principle that continues to inform the law of the sea.

By the mid-20th century, however, it was becoming clear that the ocean demanded the attention of environmental scientists, activists, and policy makers. Economic competition was breeding technological innovations that were increasingly endangering the marine environment. For instance, competitive pressures were leading fishers to adopt new technologies. These new technologies not only enabled higher catch rates, but they also led to a situation wherein fishers *had* to catch more fish in order to pay for their expensive equipment. Similar dynamics were occurring in the emergent industry of offshore petroleum drilling. At the same time, an increase in the volume of shipborne trade—from 996 million tons in 1959 to 6,760 million tons in 2005—was increasing the potential for ship-generated pollution.

As the 20th century proceeded, more effluents from industrialization, urbanization, and chemical agriculture on land were finding their way to the sea, joining waste products that were being dumped there intentionally. As oceanographers gained a better understanding of ocean currents and marine geophysics, they realized the magnitude of the connections among the world's oceans: What seemed like a local environmental problem could have global implications. Indeed, environmental scientists today usually speak of one world-ocean rather than several smaller oceans.

In addition, as climatologists have learned more about periodic climactic events (e.g., the El Niño Southern Oscillation and the North Atlantic Oscillation) and global climate change, they have gained an appreciation of the ocean's role as both an indicator and regulator of trends in the world's climate. An increase in the atmospheric temperature, for instance, would raise the temperature of the ocean. This, in turn, could lead to disastrous impacts for fish stocks, human populations (because of increased storm activity), and ocean circulation systems. Alterations in the ocean circulation system, in turn, could further impact local climates, creating a vicious cycle of climate change in which the ocean would play a leading role.

Increased scientific understanding of (and concern for) the marine environment has been joined by a growth in public awareness. The adventures of celebrity-explorers like Jacques Cousteau, the writings of environmental travel writers like Carl Safina, the interventions of policy advocates like Sylvia Earle, and the warnings of environmental muckrakers like Rachel Carson have all alerted the public to the world's endangered marine environment. To raise environmental consciousness, environmentalists have used a number of images that highlight the ocean as a space deserving protection: The image of the globe from outer space, which illustrates the significance of water on the "blue planet"; the romantic ideal of the ocean as a pristine space of nature that is free from the institutions and influences of human society; and the exotic character of iconic marine fauna and flora, such as whales, manatees, and coral reefs.

MANAGEMENT PROBLEMS

Despite the upswell of support for protecting the environment, it has been difficult to achieve effective ocean governance. In part, this is because marine resources are common property resources. Individuals have little incentive to effectively manage a resource if they believe that others will benefit from their sacrifice. Proponents of this "tragedy of the commons" scenario contend that all fishers have an incentive to overexploit a fishery, because if they were to show restraint it would only aid their neighbor's catch. Compounding this problem is the fluid nature of the ocean as a physical space. Put simply, fish and pollutants move. If one individual (or one country) chooses not to fish a certain species in order to conserve it, that fish will likely move into another individual's (or country's) territory, where it can be caught. Most pollutants are similarly mobile in the ocean (as they are in the air). One has less of an incentive to curtail marine pollution if one believes that others will bear the bulk of the cost.

These problems are exacerbated by the fact that much of the ocean lies outside the territory of any state. To implement any restrictions in international waters, all states (or at least all sea-going states) would have to agree to curtail the behavior of their ships. This rarely happens, given the competitive nature of the global political-economic system in which states are central actors. But even if all states were to adopt a program for effectively managing the ocean, there still would be the problem of enforcement. Under international law, the High Seas (the area of the ocean beyond the borders of any state) are considered the territory of no one.

A ship on the High Seas is treated as an extension of the territory of the state whose flag it is flying (a ship not flying any national flag is legally designated as a pirate ship and can be seized by any other ship). This means that if the world's states were to agree to marine environmental regulations, they would have two options for enforcement: Either each state would be responsible for policing the environmental behavior of its own ships or all states (or at least all sea-going states) would have to cooperate together to patrol the High Seas. Either option would be tremendously expensive. Even in a state's territorial waters (or in its Exclusive Economic Zone [EEZ], the zone between 12 and 200 nautical miles from shore in which a state has exclusive rights to its resources), many states are unable to mount effective patrols. As a result, many countries lose substantial revenues due to resources that are "poached" from their EEZs or territorial waters. In international waters, policing is nonexistent. Thus, even if all of the world's sea-going states were to agree on a marine conservation strategy, they also would need to devote tremendous resources to patrolling the seas so as to prevent rogue states (or rogue ships) from "cheating."

Finally, efforts to develop a comprehensive regime for managing the world's marine environment have been hampered by the fact that the most important use of the sea, in terms of economic value, is associated with its function as a surface for shipping. Shippers (and the world's navies) depend on the sea being a relatively open space—with few boundaries, few rules, and few policing authorities—and they have long been wary of efforts to govern and patrol the ocean, for fear that these efforts might encroach on the "freedom of the seas" that they enjoy.

FISHERIES MANAGEMENT

Notwithstanding these obstacles, there have been many efforts to manage the marine environment at a number of scales. Historically, many fisheries have managed themselves. Common property resources have not always been constructed as open access. In some instances, new entrants have not been allowed to fish existing areas. In other cases, all fishers have agreed to limit their technology. Knowledge may be tightly guarded, effectively barring new entrants from an existing fishery. Seasonal restrictions and catch limits are common as well. In some communities, fishers obtain formal tenure rights over aquatic resources. In Japan, for instance, no conceptual distinction exists between land holdings and land tenure and sea holdings (or sea tenure) and fisheries enjoy a legal status equal to that of land ownership.

When these techniques have been adopted by state fishery management agencies, they typically have been aided by calculations regarding a fishery's Maximum Sustainable Yield (MSY). To determine a fishery's MSY, ecologists examine population dynamics in a fishery and model the changes that are likely to occur from increased or decreased fishing rates and from changes in the marine environment. Using these models, one can estimate the maximum rate of extraction that will allow the fishery's population to remain stable.

MSY is not without its critics. Some have noted that MSY calculations typically revolve around sustaining the viability of a specific species and not that of an ecosystem. Allowing one species to thrive through partial protection may lead other species' populations to expand or decline, which could precipitate a cascading series of unforeseen circumstances that may—in the end—endanger the survival of the very species that one was initially trying to protect.

Others have noted that MSY models are based on the principle of sustaining fish and not the communities of humans that depend on those fish. Still others note that MSY models are informed by the assumption that local environments are essentially stable and tend toward equilibrium, and they charge that this assumption may not represent the actual dynamism of local ecologies.

Once an MSY is established, governmental agencies (in some cases at the national scale and in other cases at more local scales) typically implement a number of strategies to reduce annual fish catch to this level. In some cases, governments attempt to reduce the size of regional fishing fleets through voluntary means, for instance by offering to buy back fishing equipment and to train fishers for new livelihoods. Sometimes governments will resort to more top-down measures, such as prohibiting the use of certain technologies, shortening the fishing season, banning the harvesting of juvenile fish who have not reproduced, or setting seasonal or daily catch limits.

There also have been efforts to give consumers the lead role in mandating sustainable fishing practices. This involves "green labeling" fish that have been harvested from sustainable fisheries. If consumers refuse to purchase fish or fish products that do not bear this label, then fisheries will have an incentive to modify their practices so as to obtain certification.

Another means for managing fisheries involves the institution of Individual Transferable Quotas (ITQs). ITQs effectively transform a fishery from a common property resource into individual property. In a typical ITQ system, each fishing vessel is given an ITQ, which essentially is a license to fish a percentage of the MSY. In theory, over time the less efficient fishers will sell their ITQs to more efficient fishers, creating a fishery that is both economically profitable and environmentally sustainable.

In practice, however, outside interests often end up buying and controlling large fleets of vessels, disrupting what previously may have been a self-governing fishing community. Because they can choose to sell their ITQs and take their investments elsewhere, these outside interests may be even less devoted to the sustainable management of the fishery than were the local fishers who had been fishing it as a common property resource.

MARINE PROTECTED AREAS

Perhaps the most sweeping technique for managing the oceans is the establishment of Marine Protected Areas (MPAs): bounded territories in the ocean in which certain marine activities are not allowed. These may be established as a temporary measure (for instance, to allow a species to rebound after years of overfishing) or as a permanent measure (for instance, as an underwater national park).

MPAs cause dramatic dislocations in existing fishing (and other ocean-going) communities, and some critics have also questioned whether MPAs are truly designed to support the ocean environment or whether they are simply a strategy used by one ocean-using industry to remove the presence of a competing ocean-using industry. For instance, in the waters of the coast of Florida much of the pressure for drawing boundaries around an area in which offshore drilling is prohibited has come not from environmentalists seeking to preserve the marine ecosystem but from the tourism industry, which is dependent on attracting beachgoers and sport-fishers and which would be devastated by a coastal oil spill. Likewise, several tropical islands in the Caribbean and the Indian Ocean have established MPAs where fishing is banned. Critics charge, however, that this is being done not so much to preserve local fish stocks as to create protected spaces for scuba-diving tourists.

The UN estimated that as of 2000, approximately 50 percent of the world's fish species were being harvested at their maximum sustainable yield and 25 percent were overfished.

INTERNATIONAL AGREEMENTS

As heavily-capitalized fleets began fishing distant waters, whether on the High Seas or near to another country's coast, fisheries regulation entered the arena of international treaty law. Some of the first international fishing regulations were bilateral treaties governing specific fish stocks that were known to swim between two adjacent countries' territorial waters, such as the 1830 English-French accord on fishing in the English Channel and the six-state North Sea convention of 1882.

These were followed by multilateral treaties that—although covering larger areas and extending into portions of the High Seas—were still regional, including United States–Canada accords on North Pacific halibut and salmon, signed in 1923 and 1930, respectively, and a 1943 eleven-state accord governing fishing of various species in the Atlantic and Arctic. While some treaties like these remain important, others have become obsolete as the standard breadth of a state's territorial waters has grown from 3 nautical miles (the norm until the 1960s) to 12 nautical miles (the norm since then), and as states have claimed EEZs out to 200 nautical miles. These expansions of state authority in the sea were legitimated by the 1982 United Nations (UN) Convention on the Law of the Sea (UNCLOS), and, in some cases, they have obviated the need for international accords and facilitated state efforts to manage fisheries.

Even with these extended territorial waters, however, there are still some species that defy unilateral or bilateral control because they are harvested in waters beyond the 200 nautical mile limit or because they migrate over several states' EEZs. International policy makers realized early on that conservation of these species posed a particularly difficult problem, and some of the early multilateral marine treaties—including a 1926 whaling convention and a 1949 tuna convention—were specifically directed at these highly migratory species that often are harvested beyond the continental shelf.

In 1995, just as UNCLOS was coming into force, the UN passed a side agreement "relating to the conservation and management of straddling fish stocks and highly migratory fish stocks" that encouraged the establishment of regional fishing associations among states whose vessels fished an area of the High Seas and adjacent EEZs.

The side agreement required that states belonging to a regional fishing association ensure that their vessels follow whatever rules might be agreed to by these associations as well as follow any rules that had been established by global treaties restricting the harvesting of a specific species. Membership in a regional association (or in a global treaty) is voluntary, however, and neither individual states nor the UN has the authority to remove a ship flying the flag of a nonmember state from a High Seas fishery.

Amidst this patchwork of regulatory frameworks, efforts to manage the world's fisheries have been only partially successful. The UN Food and Agricultural Organization (FAO) estimates that, as of 2000, approximately 50 percent of the world's fish species were being harvested at their MSY, 25 percent were being overfished, and 25 percent could be fished at higher rates.

The FAO also notes that the percentage of fish species being overfished has increased significantly since the early 1970s. Furthermore, declining populations of some species are leading fishers on a race, quite literally, to the bottom, as fishers redirect their efforts to the ocean's depths where they are harvesting cold-water species that previously had evaded their attention. These fish, which often are culinary delicacies, typically grow and reproduce at very slow rates and hence are extremely vulnerable to population collapse and even extinction.

SHIPPING

While global fishery regulations, for the most part, have been organized by states (operating on their own or through the UN), the shipping industry has largely regulated itself. Individuals and corporations that trade goods via ship require that ships carry insurance, and insurance companies require that ships are manufactured and operated according to certain standards, so as to maximize the likelihood that the ship will deliver its cargo safely. Industry-associated institutions include Lloyd's of London, which, since 1834, has been classifying ships according to their construction standards and operating conditions, and the Comité Maritime International (CMI), an association of national maritime-law associations created in 1897 to facilitate the creation of universal industry standards.

Historically, however, few of the self-regulations adopted by the shipping industry have concerned the marine environment through which ships sail. Instead, the industry has focused on such issues as: Ship owners' liability, duty to tender assistance, salvage rights, mortgages and liens on ships, safety of navigation, immunity of state-owned ships, treatment of stowaways, status of ships in foreign ports, and registry rules. Ship owners have largely ignored the marine environment for the simple reason that, unlike fishers, the degradation of the marine environment would have minimal impact on their business.

Nonetheless, shipping can impact the environment, both from wrecks (most notably of oil tankers) and from normal operations (e.g., discharge of bilge water). The National Ocean Industries Association, a U.S. industry group, estimates that 44 million gallons of petroleum are released into the ocean annually by tanker ships, and additional quantities of petroleum and other pollutants are released by ships transporting goods other than petroleum. Discharged ballast water also can endanger the marine environment by introducing invasive species that have been transported from a distant area of the world-ocean.

Ship owners (and their insurers) have begun to pay more attention to the environmental impacts of shipping, as they recognize that they risk liability if pollution generated by a ship causes environmental damage to a coastline or a state's territorial waters. There is no remedy, however, if a ship pollutes the High Seas, so long as it is not violating the laws of the state under whose flag it is flying or the conditions of an international convention to which that state is a party.

MINERAL EXTRACTION

A third major use of (and potential threat to) the marine environment is mineral extraction. Although salt has long been extracted from the ocean, the most economically significant mineral resource in the ocean today—petroleum—began to be extracted from offshore locations only in 1937. In a sense, mineral extraction is the simplest marine activity to regulate because it occurs at fixed points. Additionally, because miners must make investments in the sites where they mine, they require states to govern their activities (for instance, by setting up leasing systems whereby mining companies make royalty payments to governments in return for exclusive rights to mine an area).

This dependence on governmental regulation gives states a degree of leverage over miners' environmental impacts that they do not have over fishers or shippers. State regulation of marine mining activities also has been facilitated by the fact that, for now at least, all marine mineral extraction takes place on the continental shelf and thus falls within a state's territorial waters or EEZ.

In the 1960s, it appeared that this aspect of marine mining was about to change, as economists calculated that it would soon become profitable to mine the seabed outside of EEZs. Specifically, miners were attracted to the possibility of mining manganese nodules, potato-sized concentrations of manganese, nickel, cobalt, and copper that coat the surface of the seabed in certain areas of the ocean, beyond the continental shelf.

The potential for manganese nodule mining posed a number of environmental and legal dilemmas. Environmentally, it was not clear what impact the scraping of the seabed over a large swath of space would have on the surrounding marine ecosystem (most other marine mining is undertaken by digging downward, not by scraping the surface). Legally, miners were faced with the problem that they wished to mine in a zone that was the territory of no one. While in one sense this was ideal for miners (there would be no one to make royalty payments to) it was unsettling to potential investors who feared that there would be no political authority to guarantee a company's legal right to mine a surveyed area.

In the end, the UN established a regime under which, for these purposes only, it would behave much like a state, with the High Seas as its territory. The UN's International Seabed Authority claimed the right to manage extraction of resources from the seabed beneath the High Seas, because the seabed's resources were "the common heritage of mankind."

For various reasons, High Seas manganese nodule mining has never occurred at a commercial scale. Nonetheless, the establishment of a global regime for managing and extracting resources from this global space has led policy makers and environmental activists to look to the ocean as they consider new models for environmental management. Whether one focuses on "traditional" ocean tenure systems through which communities have managed their local fisheries or the international seabed regime established by the UN for managing production in a space outside state borders, the interconnectedness of the world-ocean forces one to consider how an environment can be managed both as a distinct space of social and natural relations and as one component of an interconnected, global ecosystem.

Odum, Eugene P. (1913–2002)

SOMETIMES CALLED THE father of modern ecosystems ecology, Eugene P. Odum helped to make *ecosystem* a household word in the United States in the late 20th century. Beginning in the 1950s, Odum developed radiation ecology, later ecosystems ecology, as a science of interconnections among interlocking human and natural systems. This helped make ecological perspectives, which focus on interrelations and interdependence among elements of the whole, nearly synonymous with holistic views of nature and environment among varied communities of scientists, environmental managers, and environmentalists. However, these groups often understood the implications of the new ecology differently.

Odum wrote *Fundamentals of Ecology*, the university textbook that introduced the ecosystems perspective to generations of ecology students over the run of five editions between 1953 and 2004. In 1960 he founded the University of Georgia's Institute of Ecology. In the same year, on the grounds of the U.S. Atomic Energy Commission's (AEC) Savannah River Plant, he also established the Savannah River Ecology Laboratory. Odum was more than just "the father of modern ecosystems ecology": his contributions to environmental science, thought, and values were significant and complex.

Gene Odum, as he was known, grew up in Chapel Hill, North Carolina; his father was the eminent sociologist Howard W. Odum. Eugene earned two degrees in zoology at the University of North Carolina before moving to the University of Illinois, where he was awarded a doctorate in zoology in 1939 for an innovative research thesis measuring the heart rates of birds in terms of a "physiological ecology." The following year, Odum joined the zoology faculty at the University of Georgia, where he would continue to work, later as an active emeritus, for more than six decades.

In collaboration with his younger brother, the ecologist Howard T. Odum, Eugene became increasingly interested in using the new language of cybernetics—developed during the 1940s as an interdisciplinary language of systems and feedback loops for creating electrical circuitry, control systems, computing, and artificial intelligence—to describe the relations among organisms, species, and environments.

The development of atomic sciences and technology in the United States following World War II provided resources for ecologists. The Odum brothers took advantage of the opportunities presented by government funding for large scale nuclear projects during the cold war era, along with the practical needs for environmental and waste management that these projects produced, to secure both funding and key experimental sites for what would become pathbreaking research on the modeling of ecosystems.

In 1954 the Odums studied the effects of radiation on a coral reef at the U.S. Pacific nuclear proving grounds in the Marshall Islands, seeking to better understand the interrelations, or metabolism, of the whole ecosystem by tracing its energy flows. The results of the study suggested the importance of symbiotic relations between organisms in the reef, a mutualism that reinforced long term tendencies toward ecological stability. For the Odums, nature thus had lessons to offer to society, which the ecosystems perspective helped to decipher. In 1955 they wrote:

> Since man is having great difficulty in establishing symbiotic relations with the plants and animals which he requires for his existence, we certainly have much to learn from the way nature has accomplished this on the coral reef.

Eugene Odum also worked in less exotic places. In 1951 he initiated a long-term ecological research program near the Savannah River in rural South Carolina, in what had become the 300-square-mile nuclear buffer zone surrounding the Savannah River Plant, an AEC industrial site for the production of tritium and plutonium for use in nuclear weapons. Observing nature coming back in the farmlands evacuated to create the buffer zone, Odum and a team of graduate students added to theories of ecological succession and contributed a wide range of population ecologies based on long-term observation in the new wilderness at the species level. In 1960, the Savannah River Ecology Laboratory was established on the site, administered by the University of Georgia but funded chiefly by the AEC (and through the present day by the U.S. Department of Energy).

Amid the explosion of federal scientific funding in the United States during the 1950s and 1960s, Eugene Odum built an ecosystems ecology, both conceptually and institutionally, around America's Cold War nuclear architecture. Throughout his career he would continue to stress the necessity of ecological research and education for solving practical environmental problems, including ecological applications both in the management of radioactive and industrial wastes and in conservation practices. Odum was among the influential scientists who brought the atomic age together with the age of ecology, and he remains an important figure in the history of both.

Ogallala Aquifer

THE OGALLALA AQUIFER is one of the world's largest aquifers, which are layers of underground rock containing water that may be tapped for human use. Located under portions of eight U.S. states, it is centered under the Great Plains region, notably the high plains of Texas, New Mexico, Nebraska, Kansas, and Oklahoma, and covers around 174,000 square miles. Use of the aquifer began in earnest at the beginning of the 20th century; subsequently, depletion of the water resource has become considerable as the usage of aquifer water now exceeds the ability of natural sources of rainwater to replenish it. This leads to three significant negative outcomes: First, the water resource will in due course be exhausted; second, the ground above the aquifer will begin to sink, which causes many problems, especially in urban areas; and third, it is possible for seawater to seep into the spaces vacated by freshwater, exposing the aquifer to salination that would make the resource unusable for human purposes. Depletion of the water resource has unleashed various legal battles aimed at determining rights to exploit and own water resources that reside on or under publicly owned ground.

The Ogallala Aquifer, which was named by Nelson Horatio Darton in 1899, was formed in ancient times (possibly the Miocene period). It was a byproduct of the creation of the Rocky Mountains, which resulted in part in a band of porous, sedimentary rock being created to the eastern and southeastern sides and below the newly forming ridges. The band measures up to 558 feet (170 meters) at its deepest and still contains some water dating back to the last ice age, since the recharging water tends to occupy the space vacated by water already pumped from the aquifer. The shape and depth of the aquifer varies considerably across its extent as a result of different pressures exerted during its creation.

It is believed that the extent of depletion of aquifer water in the United States greatly exceeds its repletion rate, as is common throughout most of the developed and industrializing world, although it is difficult to calculate exactly the rate of this occurrence. Reasons for the increased depletion rate include the intensification of agriculture across the region and the greater use of water for both domestic and industrial use. In states such as Texas, residential development increases demand for water for sprinklers and other gardening purposes as residents set out to change the character and appearance of the land.

The U.S. government has been concerned about depletion of the aquifer since the 1970s and has legislated various measures to reduce the impact of too-rapid depletion. These measures include the return of agriculture to previously employed dry land methods, which is planned to be completed by 2020. Since current agricultural activities have proven to be unsustainable, they will in the future either have to be supported by water diverted from elsewhere (which is believed to be impractical in currently foreseeable conditions) or else be scaled back or ended completely. This will inevitably have an impact on the local economies that are currently supported by these activities. It may also lead to economic and social problems among existing communities, probably sparking migration to cities or other regions where water resources are more abundant. Falling land prices resulting from the declining attractiveness of agriculture will require the courts to try to identify who, if anyone, is responsible for this loss of value and whether compensation would be required.

Oil Spills

OIL SPILLS CAN hurt wildlife, the scenic beauty of coasts, and people's livelihoods. For these reasons, government, industry, and environmental groups have sought to find ways to prevent and respond to oil spills to avoid environmental damage while minimizing the costs of moving crude oil and refined products. Oil spills do not constitute the majority of oil pollution in the oceans. A report of the National Academy of Sciences found that "nearly 85 percent of the 29 million gallons of petroleum that enter North American ocean waters each year as a result of human activities comes from land-based runoff, polluted rivers, airplanes, and small watercraft." Nevertheless, these spills are generally dispersed—attention-grabbing oil spills are the ones that are large, near the shore, and do visible damage.

The damage done by oil spills is a function of at least three things: the nature of the oil spilled; the proximity of the spill to the shore where most marine life lives; and the nature of the weather, current, and tides. For example, when the *Argo Merchant* spilled seven million gallons of fuel oil (which is thicker than crude oil) in the waters near Nantucket in 1976, the damage was minor because currents took the oil out to sea. On the other hand, smaller oil spills from barges, pipelines, and small tankers can do significant environmental damage.

Thicker oil near shore does more damage than oil offshore, and refined petroleum products like gasoline or kerosene, while highly toxic, tend to evaporate when spilled into water. Large oil spills far out to sea tend not to do a great deal of environmental damage, because the oil "weathers" and breaks up before it reaches a shoreline. The worst sort of spills, and the ones that receive the most attention, are of crude or heavy fuel oil in bad weather near a shoreline.

RESPONDING TO OIL SPILLS

Oil spill responses are designed to contain or disperse oil before it does damage. Methods for containing oil include booms, which are floating barriers that keep oil from moving across the water; skimmers, which are boats with equipment designed to skim the oil out of the water; and chemical dispersants and detergents that break up the oil into smaller parts that will then disperse in the water column. This latter technique is very controversial: some argue that the dispersed oil still does damage while it is in the water, while others argue that it is best to disperse the oil before it can do worse damage on the shoreline. Other promising techniques include bioremediation, in which particular strains of bacteria are introduced into the water to eat the oil. In addition, some absorbent materials are showing promise in soaking up spilled oil. To reduce the impact on wildlife, responders may set off loud noises to scare animals away so they are not exposed to the oil.

Regardless of the response technique, large oil spills are complex environmental events that require expert management. Since the passage of the U.S. Oil Pollution Act in 1990, the Coast Guard and the Environmental Protection Agency (EPA) are in charge of oil spill cleanup in the United States; other federal agencies are asked for help as needed. Response costs can be recovered from the spiller. In the end, it is very rare to recover all or even most of the spilled oil, particularly in poor weather or when heavy oils are involved.

HISTORIC OIL SPILLS AND PUBLIC POLICY

Oil spills did not receive much attention until the late 1960s, when the environmental movement gained prominence. In World War II, many tankers were sunk along the East and Gulf coasts by German submarines, spilling their loads of crude oil and refined products on beaches. These spills were not viewed as problems because the nation was at war. Even contemporary wars that spill oil receive relatively little attention compared with the war itself: Actions taken by the Iraqi regime during the 1991 Gulf War spilled thousands of gallons of oil into the Persian Gulf, and the Israeli bombing of a power station in Lebanon in 2006 resulted in a significant spill of fuel oil in the Mediterranean Sea.

The first major oil spill to receive worldwide attention was the *Torrey Canyon* spill off the United Kingdom. The response to the spill—including the attempt to set fire to the oil, and the use of detergents to break it up—was widely seen as inept, although international liability regulations for oil tankers did change because of the spill. The first major oil spill to gain similar attention in the United States was the 1969 Santa Barbara, California, oil spill, in which 200,000 gallons of oil spilled from an offshore well, killing wildlife, and leading to a famous picture of President Nixon walking along the oily beach. This spill was small by historic standards—less than 20 percent the size of the *Exxon Valdez* spill—but the spill came just as the modern environmental movement was finding its voice, and it was used by environmental groups as evidence that oil spills could do substantial damage. The Santa Barbara Spill resulted in a drilling moratorium on state lands in Santa Barbara Channel, and has greatly affected public perceptions of offshore drilling worldwide.

The next major oil spill to occur in the United States was the *Argo Merchant* spill off Nantucket. This spill did not do as much environmental damage as its size—7.7 million gallons—would suggest. However, the spill did initiate a 14-year-long debate over how oil transport should be regulated, and how liability should be assigned. This debate was brought to a swift conclusion when the *Exxon Valdez* ran aground on a reef in Prince William Sound, Alaska, spilling 11 million gallons of oil in one of the richest marine environments in the world. The *Exxon Valdez* spill was only the 35th largest in world history; the sheer size of the spill was less important than the nature of the oil and the damage it caused.

Before 1970 there were no laws to make oil spillers liable for cleanup costs and damages. The only tool available to make claims against shipping was the Limitation of Liability Act of 1851. When applied by the courts, this statute often resulted in absurdly low liability limits. However, the law also provided that if the spill occurred intentionally or if the ship owner knew it could happen, the limits could be surpassed. Still, the complexity of this statute made this law unsuitable for forcing shippers to clean up oil, and did not cover offshore drilling at all.

The inadequacies of the Limitation of Liability Act led to the enactment of what is popularly known as the Clean Water Act of 1972. Section 311 established liability limits for owners of oil facilities and ship owners at $8 million for fixed facilities and the lesser of $100 per gross ton or $14 million for ships. Amendments in 1978 raised only ship owners' liability to $150 per gross ton for ships and $125 per ton for barges. This limit was still seen as low, and did not serve as an effective incentive for ship and facility owners to operate more safely.

Section 311 also required that a national oil spill contingency plan be established with a fund to cover costs incurred by the federal government in cleaning up oil spills. This fund never reached its authorized size of $35 million, reaching at most $24 million in 1985. In 1973, the Trans-Alaska Pipeline

Authorization Act created a similar fund for the Trans-Alaska Pipeline System (TAPS), funded by a five cent per barrel tax on oil, with a $100 million cap. This level was reached in 1981, but investments raised its balance to $250 million. This fund was not called upon to clean up the *Exxon Valdez* oil spill, as Exxon chose to rely on its resources, but it is important to note that the fund was far smaller than the costs of cleaning up the *Exxon Valdez* spill. Other liability regimes were created by the Deepwater Port Act of 1974 and by the Outer Continental Shelf Lands Act Amendments. Safety regulations were enacted in the Tanker Safety Act of 1978 (Public Law 95-474), which addressed technical aspects of tanker equipment and personnel and was inspired by the *Argo Merchant* spill.

For years Congress was unable to agree on a comprehensive solution to the problem of oil spills, in large part because of disagreement between the House and Senate over whether federal liability laws should "preempt" state laws. The Senate generally favored retaining the state laws to create a greater incentive to avoid oil spills. The House sought a uniform national standard in large part to reduce the potential costs of transporting oils. The *Exxon Valdez* spill was the event that tipped the balance in favor of more stringent oil spill legislation. The spill, and Exxon's response to it, caused so much public and congressional anger that the House ended up dropping its insistence of federal preemption of state law. With the preemption issue out of the way, oil spill legislation passed relatively easily, and President George H.W. Bush signed the Oil Pollution Act (OPA) into law on August 18, 1990.

The OPA provides for vastly tougher penalties and liability for spillers of oil, allocates more resources for dealing with spills, and places more responsibility on the executive branch to respond to oil spill incidents promptly. The creation of the spill cleanup fund in the OPA was also a major accomplishment. The fund consolidated three smaller funds to create a bigger fund than ever before. At $1 billion, such a fund may not be sufficient to clean up the largest spill, but it still comes closer to the costs of cleaning up a spill of the magnitude of the *Exxon Valdez* than did any of the other funds.

A final feature of the OPA was its requirement that oil companies phase in the use of double-hull tankers in U.S. waters. Such double hulls are said to be able to withstand collisions or groundings (the cause of both the *Torrey Canyon* and *Exxon Valdez* spills), although some experts have questioned their effectiveness. Since the OPA, the incidence of major oil spills in the United States and worldwide has dropped significantly. There has not been a major oil spill from a tanker or an offshore oil platform in U.S. coastal waters since 1990.

Old Growth Forest

OLD GROWTH FORESTS, also referred to as ancient, late-seral, or late-successional forests, are found throughout the world and are extremely rich in biodiversity and natural resources. A universally accepted definition of old growth forests is diffi-

After years of legal and political disputes, the U.S. Northwest Forest Plan was signed in 1994.

cult to resolve, but most experts would agree that several key features characterize these ecosystems. These forests are not exclusively comprised of older, gigantic sized trees, nor are they always left unaffected by natural or human disturbances. They exhibit a multilayered canopy, which is created by tree species of varying sizes and ages. These forests typically need to be anywhere from 100 to 350 years old to be classified as old growth and will vary in composition depending on the area in which they are found. Fallen trees, woody debris, and dead standing trees (snags) are common attributes that contribute to high biomass. Canopy openings, pits, and mounds are other classic characteristics.

Old growth forests house diverse plant and animal species, some of which may be endemic or endangered and only thrive in these unique habitats. For example, some wildlife species may be dependent on old growth conditions for optimal nesting grounds because conditions might be more specialized than in younger stands. Small-scale, infrequent natural disturbances such as fire, disease, insect infestation, and storms are crucial in preserving genetic diversity, and old growth areas demonstrate resilience in maintaining ecosystem equilibriums. However, this resiliency has a limited capacity; if heavy degradation takes place and thresholds are crossed, unfavorable consequences are bound to arise.

Old growth forests help sustain healthy environments. Research has shown that old growth forests carry out important ecological functions such as climate regulation, soil and water conservation, maintenance of hydrological cycles, storage and cycling of nutrients, and breakdown of pollutants. Forestry products, fish and animal stocks, and recreational activities are some of the more tangible human benefits.

In spite of their ecological, economic, and social significance, these forests are vulnerable to increasing harmful anthropogenic disturbances; they have already suffered immensely on a global scale. Illegal logging practices, clear-cutting, and deforestation for agriculture, housing, and industry are major threats because they disrupt, if not completely destroy, forest equilibrium. These activities may also displace local or indigenous populations who rely on forest resources for everyday subsistence. Social and environmental implications have been severe as these forest tracts steadily decline. There has been great contention among politicians, scientists, industries, environmentalists, and citizens over the need to protect these forests and the desire to exploit them for short-term economic gains.

It takes a significant amount of time for old growth forests to reach their optimum state; it is likely that once biodiversity is lost it cannot be regained. Possible remediation efforts include restoration—a long-term process that can be implemented in order to encourage old growth features within a forest. Although mimicking natural features can accelerate this process, it is best achieved by leaving the forest alone for a substantial amount of time.

In recent years, public concern has resulted in calls for appropriate policy and management strategies to help prevent further devastation. Much attention has been focused on protecting these habitats so that rare species can survive and flourish. Perhaps the best known example in North America is the case of the northern spotted owl of the Pacific Northwest. This bird began to decline in numbers in the 1980s as a result of habitat destruction and was declared a threatened species.

Environmental organizations argued that extensive logging of the forest needed to be reduced, if not halted, while the timber industry stated that unemployment levels would rise, crippling the local economy. After years of legal and political dispute, the Northwest Forest Plan was signed in 1994 with the intent of executing more sustainable and environmentally friendly logging practices in old growth woodlands. The "jobs versus owls" controversy highlighted the complexity of finding a balance between human needs and those of the environment. Furthermore, it symbolized the wider social, cultural, and ecological implications of how to understand, manage, and protect forests. While there is now heightened appreciation for these forests, more pertinent scientific research must be conducted to truly understand how they function and respond to both short- and long-term changes.

Olmsted, Frederick Law (1822–1903)

FREDERICK LAW OLMSTED was one of the principal architects and landscapers of the early modern United States. Combining his design work with research and writing, Olmsted became known as an influential force in forging the combination of aesthetic and technical issues that have become established as the dominant paradigm in urban and rural planning concerns. Popularly, he is more well-known for being the designer of such famed parks and open areas as the lands surrounding the Capitol Building in Washington D.C., Central Park in New York City, and the Niagara Reservation near Niagara Falls. Generations of Americans have benefited from the recreational and health-promotional opportunities provided by parks envisioned and planned by Olmsted.

Olmsted's career encompassed foreign travel and an investigation into the slave trade in the southern United States. His experiences in the South, in Britain, and in China helped him to understand the importance of egalitarianism in designing public parks.

In most hierarchical societies, the ability to gain access to public goods such as parks was limited to various degrees. European societies had tended to limit the access to these goods to wealthy elites, while overseas imperial possessions were restricted on the grounds of ethnicity. Colonial Shanghai, for example, was infamous for its (apocryphal but symbolic) signage "No Dogs or Chinese" in supposedly public spaces.

Olmsted was committed to identifying ways in which such discrimination would be impossible to sustain and the methods by which he worked have become guidelines for the industry he helped to create. Not just people but the physical environment too was to be integrated into the design scheme. He realized the importance of maintaining the quality and good health of the land on which parks were to be built in order to ensure they could be sustained for future generations.

He was able to come to this understanding due to, at least in part, his wide range of experiences and travel: among his accomplishments were commanding a unit in the American Civil War (1861–65) and managing a gold mine in California. Nevertheless, the apparent rationality of his ideas belies the fact that at the time his approach was considered not just unusual but extreme and slightly improper. Ultimately, rationality and systematization won out over romanticism.

The combination of skills that Olmsted helped bring together for the field of landscape design, together with noted colleagues such as Calvert Vaux, have helped him to become known as the father of American landscape architecture. It also brought to bear a systematic and scientific approach to the discipline that underlines the general American ideology of subjugating, or at least transforming, nature to fulfill the will and desires of the people, variously defined. This tradition is reflected in American political ideology as it has often been expressed toward the land and the environment.

Oman

THE SULTANATE OF Oman has been involved in a modernization program since 1970 when Qaboos bin Said Al Said toppled his father's regime. The new Sultan began developing strong political and military ties to Britain and thereafter established Oman as a moderate among Middle Eastern nations. Oman's status as an oil-producing nation has raised the country to middle-income status with a per capita income of $13,400. The United Nations Development Programme Human Development Reports rank Oman 71st in the world in overall quality-of-life issues.

In addition to petroleum, other natural resources include copper, asbestos, marble, limestone, chromium, gypsum, and natural gas. Less than one percent of the land area is arable. Oman's population of 3,001,583 people includes approximately 577,293 nonnationals. In an effort to curb the 15 percent unemployment rate, the government has launched "Omanization," a program designed to replace foreign workers with locals who have been trained in information technology, business management, and the English language. Other economic goals are focused on developing and expanding gas resources, metal manufacturing, petrochemicals, and international transshipment ports.

In addition to land borders with Saudi Arabia, the United Arab Emirates, and Yemen, Oman has a coastline of 1,297 miles (2,092 kilometers) that borders the Arabian Sea, the Gulf of Oman, and the Persian Gulf. The climate of Oman ranges from dry desert to hot and humid along the coast. Although the interior tends to be dry, the far south experiences a distinct summer monsoon season from May to September.

The rugged mountains of the north and south give way to central plains in other areas. In the midst of periodic droughts, Oman's summer winds frequently produce large sand and dust storms. These winds carry desert sands into cultivated areas, resulting in extensive desertification.

Like many of its neighbors, Oman has almost no natural freshwater resources. Twenty-one percent of Omanis lack sustained access to safe drinking water, and 11 percent lack access to improved sanitation. Industries have polluted groundwater in many areas. The soil of Oman is becoming increasingly saline, particularly in the coastal plains of Batinah. The presence of large, oil-spilling tankers has also led to major beach pollution. In 2006 a study by scientists at Yale University ranked Oman 60th among 132 nations in environmental performance, slightly above its geographic group but well below the average for other middle-income nations.

Low-ranking categories included air quality and biodiversity and habitat.

Nearly 78 percent of the population have become urbanized, leading to a marked increase in air pollution. Between 1980 and 2002, carbon dioxide emissions in Oman rose from 5.0 per capita metric tons to 12.1. Efforts to improve biodiversity in Oman sometimes conflict with entrenched traditions, such as the practice of wearing rhinoceros horns as status symbols. Outsiders have also depleted Omani wildlife. For instance, the Arabian oryx, a large desert antelope, was hunted to the point of extinction. Over time, international efforts managed to reintroduce oryx bred in captivity into their natural habitats. Strict policies concerning the protection of wildlife are now enforced in Oman, and nature preserves have been established to protect animal life that includes 13 species of whales and dolphins and 400 species of birds.

The Ministry of Regional Municipalities and Environment and Water Resources is responsible for drafting and implementing laws and regulations concerning sustainable development and conservation of resources and for monitoring compliance with all laws. Responsible for specific aspects of Oman's environmental policies, the ministry is divided into the Departments of Inspection and Environment Control, National Conservation Strategy, Pollution Control Operation Center, Environmental Planning Permits, and Chemical Substances.

Oman participates in the following international agreements: Biodiversity, Climate Change, Desertification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, and Whaling.

One Child Policy, China

CHINA HAS THE highest population of any country in the world. Mid-2006 estimates set China's population at just over 1.3 billion; its rate of natural increase (RNI) is 0.6 percent per year. This rate is one-half that of the world and only one-third of India's RNI (1.7 percent). There is every indication that India will pass China in total population some time between 2030 and 2040. Despite its relatively low RNI, China has chosen to continue its often criticized official policy of one child per family, which has been reauthorized through the current five-year plan (2006–10). The Chinese government justifies the extension of this policy by stating that it continues to be consistent with the country's basic plan for population growth, a plan that reflects an insistence on slow growth. Along with the statement reauthorizing the one child policy was a proclamation that it would stay in place permanently.

The one child policy was initiated in 1979, when the Chinese government identified it as a short-term measure. At the time of implementation there was great concern that the growth of China's population would get out of hand. The country's arable land was limited, and over 60 percent of the population was approaching childbearing age. The prospect of high population increase and the potential inability to produce enough food for growing numbers provided the impetus for the policy. The legislation included several requirements in addition to the one child provision. Included was the insistence on later marriage, a policy long in place in some Scandinavian countries, and on the spacing of children in situations where more than one child was allowed. Other exclusions covered families in which a child was disabled, both parents worked in high-risk industries, or the parents were only children. In addition, there were special provisions in place for rural families. Generally, a second child was allowed after number of years, especially if the first was a girl. In some severely underpopulated regions of China, a third child was allowed.

The one child policy includes provisions for the awarding of economic incentives for families in compliance, and penalties and fines for not adhering to the rules. Some of the more severe sanctions include the loss of personal property and dismissal from work.

Within the one child policy is the acceptance of various means of birth control through contraception and abortion. This approach is similar to conditions in Japan following the end of World War II, when the country was stripped of overseas territorial acquisitions and was back on its four-island homeland. Almost overnight, the rate of population increase in the country declined to low levels and overall population growth was curtailed.

The one child policy was implemented despite an already sharply declining total fertility rate (TFR), defined as the average number of children born per woman in the childbearing years. In the early 1970s, the TFR in China was nearly six, which would indicate a high rate of population increase if it persisted over many years. By 1979, the year in which the one child policy began, the TFR was down to approximately 2.7. The mid-2006 estimate for TFR in China is 1.6, well below the replacement rate of 2.1 and the world average of 2.7. Despite these reassuring figures, the Chinese government insists that the one child policy is within the long-term interests of the country.

Of great concern is the fact that without the policy in place, there could be a dramatic increase in population within a generation, even though the TFR is significantly below the replacement rate. This is because of the high percentage of the population still in the childbearing age group. In short, the Chinese government does not want to run the risk of bringing on a baby boom similar to the ones experienced in the 1950s and 1960s. The government insists that the Chinese population not exceed 1.4 billion by 2010 and that total numbers begin to decline before mid-century.

The ratio of males to females in China is 1.2, reflecting the traditional preference for male children.

On the plus side is the change in attitudes toward large families occurring as a population becomes more urbanized. Although China's urban population is only 37 percent of the total, the move to urban areas is occurring at a rapid pace. This transition is expected to continue well into the future as the country continues to build its manufacturing and industrial base, economic thrusts that are largely based in cities. Also, there is every indication that families in China are becoming more attuned to having small families without the need for enforcement of the government-imposed one child policy. There is evidence as well that the traditional preference for a male child is not as prevalent as in past years. Incidences of female infanticide or the aborting of female fetuses have dramatically declined. Nonetheless, the ratio of males to females in China is 1.2, a reflection of the long-held preference for male children. This current male/female ratio portends serious problems as a generation of boys grows to marriage age with a significant portion of them having limited prospects for finding wives. The impact of this demographic on the political and social conditions of China in the next few years remains unknown.

Opium (and Heroin)

IN THE PHARMACEUTICAL industry, opium is derived from a natural substance extracted from the poppy plant and serves as the raw element for painkillers such as morphine and codeine. The illegal drug heroin, also a derivative of opium, is possibly the most addictive drug in the opiates family.

Opium has been the subject of popular fascination for centuries. Two reasons might explain this phenomenon: First, opium and heroin create a fast and strong addiction in their users, and second, images of opium have been much used by European artists and writers in the last two centuries in their representations of an exotic Far East. Literary representations include Thomas De Quincey's *Confessions of an English Opium Eater* (1821), Jean Cocteau's *Opium* (1928), and even an illustrated book for children, *The Blue Lotus* (1936), by Belgian author Hergé, features some scenes set in an opium house in Shanghai. Nowadays, the word *opium* has become a part of everyday life, even though it still represents a real danger. For example, Opium is the name of a long-standing, luxury Yves Saint Laurent perfume. In 1967, the U.S. rock group Velvet Underground released a song titled *Heroin*; in 1969, the Rolling Stones recorded a song cowritten with Marianne Faithfull called *Sister Morphine*.

In the 19th century, England traded opium in China against the Chinese state's will, and that conflict was a contributing factor in the Anglo-Chinese War (1839–42), also known as the Opium War. The Second Opium War (1856–60) was also known as the Arrow War or, in China, the Anglo-French War.

Presently, Afghanistan is the largest world producer and exporter of illicit opium, while India—and to a lesser degree Turkey—produces most of the "legal" opium used for medical and pharmaceutical purposes through a licensing system.

According to the United Nations Office for the Coordination of Humanitarian Affairs (UNOCHA), and other sources, thousands of Afghan farmers grow and harvest opium poppies in rural zones. The International Monetary Fund has found that opium accounts for up to 50 percent of the Afghan economy.

Although sometimes part of an underground economy, farmers involved in poppy cultivation may run a family business or a small enterprise, and reinvest the annual profits into equipment, machines, and buying new fields, as in any mainstream business. They do not worry much about ethical issues, citing the fact that they live in a poor region without many resources. However, the risks are high because these farmers can easily become addicted to their product in a country where solutions to drug-related problems (like detoxification clinics) do not exist.

According to UNOCHA, the harvest of an average of just six kilograms of opium poppies provides the equivalent of about $3,000 to an Afghan farmer for a year of work, making it much more profitable than any other crop in the country. Apart from profitability, poppy cultivation also has social meanings

Khun Sa

A Burmese (Myanmar) warlord, Khun Sa has long been a prominent opium trader in the "Golden Triangle"—the area of land where the Thai, Burmese, and Laotian borders meet. He was born into a Chinese family in 1933 and named Chan Shi-fu; when his mother married a prince from the Shan States in Burma, he adopted the name Khun Sa ("Prince Prosperous").

Khun Sa initially served with the Chinese Nationalist soldiers in Burma who had escaped the Communists at the end of the Chinese civil war in 1949. Gradually he formed his own militia group known as the Ka We Ye, which fought the Shan rebels for a period. After Burma became independent in 1948, a large number of diverse ethnic groups, including the Shan, were seeking independence or autonomy.

By the mid-1960s Khun Sa had stopped working with the Burmese government and was in control of large parts of remote Burma. There he moved into opium cultivation and production. At the height of his power he had 15,000 men under arms—known as the Mong Tai Army (or Shan United Army)—with weapons brought in from Thailand.

His headquarters were at Homong near the Thai border; there he had his own opium factories, residences for chemists, a power station, street lights, telephones, and brothels. Although Khun Sa did try to develop political dimensions to his operations, inviting tourists to visit and interview him, most saw him as a drug dealer. Khun Sa even once offered to sell his entire opium crop to the United States rather than let drug couriers smuggle it into other countries.

At the end of 1995 Khun Sa surrendered to the Burmese SLORC government after striking a deal with them. He moved to Yangon, then the Burmese capital, and still the major city in the country. The Burmese government has refused to extradite him to face charges of drug trafficking into the United States.

and cultural roles. In Afghanistan, owning a poppy field is a symbol of wealth and can even serve as a gift in marriages.

Introduced in the 1960s in various Asian countries, so-called "opium replacement programs" tried to shift farmers involved in poppy cultivation toward other products, vegetables, and grains. In the current combat against illegal opium production, plans have been created to reimburse Afghan farmers for destroying their lucrative harvests of poppy plant. This is a rare case when the targeted destruction of natural plants on a large scale can have positive effects on mankind.

However, the fight against narcotics faces extensive corruption and poverty in Afghanistan. A 2006 World Bank and United Nations Office on Drugs and Crime (UNODC) report states, "Efforts to combat opium production in Afghanistan have…failed to prevent the consolidation of the drugs trade in the hands of fewer powerful players with strong political connections."

There are also strong links between the illegal drug trade and terrorism in Afghanistan, as opium has become a way for terrorist organizations to access large amounts of money. In other words, it is the drug users and heroin addicts in Western countries who, albeit indirectly, finance some terrorist actions. According to the U.S. Office of National Drug Control Policy, other countries producing illicit heroin include Colombia, Burma (Myanmar), and Mexico.

Organic Agriculture

ORGANIC AGRICULTURE IS a method of producing crops without synthetically derived chemical pesticides and fertilizers. Indeed, soil fertility is the central goal of organic farming, as healthy soil produces abundant crops and diminishes the occurrence of pests. Preemptive measures focusing on soil quality are the main way that organic farmers reduce the need for chemical inputs.

Organic farmers use techniques such as crop rotation (changing the crops grown in a field each season) to build healthy fertile soil that has fewer pest problems. Organic farming techniques may also include the use of beneficial insects such as ladybugs to destroy crop-eating aphids. Likewise, companion cropping of certain plants together helps ward off pests.

Organic farming is also based on diversity: Growing a large number of crops both for ecological diversity and for sales diversity. Organic farming is unique in terms of crop choice, planning, harvesting, and marketing. Marketing is accomplished through specific channels as farmers seek out independent sales outlets, often selling to numerous wholesalers, brokers, or directly to consumers. Such direct marketing activities are exemplified in organic farmer participation in farmers' markets and Community Supported Agriculture (CSA), both of which have increased rapidly in the past decade.

Organic farming is distinct from "conventional agriculture," which is based on chemical applications and large-scale specialized production of one or two crops. Indeed the geographic distribution of organic cropland varies substantially from the patterns of conventional production. For example, 80 percent of U.S. conventional cropland is in just four crops: Corn, wheat, hay, and soybeans, but these crops represent less than half of certified organic cropland. On the other hand, organic vegetables comprise 12 percent of certified organic cropland, compared to only 1 percent of total U.S. cropland.

These cropping variations are seen in regional variation as well, with the Pacific and mountain regions comprising two-thirds of organic cropland, but only one-third of total U.S. cropland. The opposite is seen in the Corn Belt, which comprises only 11 percent of certified organic cropland, but represents 25 percent of total U.S. cropland. Overall, organic farmers grow more types of crops and more diverse crops that are not common among conventional farmers in the same region. It is a challenge for organic farmers to identify reliable, distinct organic marketing avenues that will provide the necessary price premiums on the numerous crops they grow.

Estimates place the growth of U.S. organic markets at 20 percent annually since 1990. The year 2000 marked the first year that more organic foods were sold in mainstream supermarkets than in any other venue. In fact, three-fourths of conventional grocery stores now carry some organic food. Natural food stores and direct marketing continue to play a role in the distribution of organic products. Organic food sales are led by fresh produce, non-dairy beverages, breads and grains, packaged foods, and dairy products. Organic dairy items increased by 500 percent in the 1990s as a result of consumers seeking to avoid rBGH, a genetically engineered hormone injected to increase milk production in convention dairy cows. Sales of organic snacks, candy, and frozen foods have increased by 70 percent in recent years.

Consumer demand for all organic products is likely linked to concerns about pesticide residues and genetically modified organisms (GMOs) in food. Indeed, a study by the Consumers Union shows significantly lower pesticide residues on organic compared to conventional food. Parental concern about food safety often motivates parents to buy organic food for their children. A recent study shows that children who eat organic food have significantly lower levels of pesticides in their urine.

ORGANIC CERTIFICATION

Certified organic is an important term because it signifies a specific process of certification, which varies by country but typically indicates that farmers omit synthetic agrochemicals for at least three consecutive years. Detailed farm histories must be written and every input to the organic fields must be documented. An annual inspection by an independent inspector is required and farms must show soil building through rotation and use of green manure (crops planted and plowed under to fertilize the soil).

According to a United States Department of Agriculture (USDA) report, in 2001 certified organic cropland totaled 2.34 million acres. There are wide variations by crop types, with approximately 2 percent of the major fruit and vegetable crops, apples, carrots, lettuce, and grapes, and 2 percent of all tomatoes, grown by certified organic methods. For grains, these figures are much lower: only 0.1 percent of corn, soybeans, and wheat are organically grown. But significant amounts of specialty grains are certified organic, such as spelt (37 percent) and buckwheat (30 percent).

Geographic variation is seen among the states, as California, North Dakota, Minnesota, Wisconsin, Iowa, and Montana have the largest certified organic acreage (influenced by large areas of pasture and rangeland), and California, Washington, Wisconsin, Minnesota, Iowa, Pennsylvania, Ohio, New York, Vermont, and Maine have the largest numbers of certified organic farmers.

RESEARCH AND STANDARDS

Although consumer demand is high, research and information on organic agriculture is sorely lacking. Even by 2003, when land-grant universities had 885,863 acres of field plots and research lands in the United States, only 0.02 percent (151 acres) were certified organic. This is 100 times less than the 0.2 percent of total U.S. cropland that is certified organic and hundreds of times less than the percentage of some crops; for example, 2 percent of tomatoes grown in the United States are certified organic.

The lack of research attention indicates the general disregard for organic farming within the conventional agricultural research system. Because of this indifference, organic farmers have experimented and developed their own pest management and soil fertility techniques, which they often share with other organic farmers. Current research information is a particularly acute need for organic farmers, as information needs intensify with the adoption of reduced-chemical methods. Even programs in sustainable agriculture have been irrelevant for organic farmers, as exemplified by the most important national initiative for sustainable agriculture (the USDA's Sustainable Agriculture Research and Education Program) of which only 19 percent of the funds are for organic production and marketing projects.

Organic farmers are highly diverse; some have moved from conventional methods to organic methods, others started farming more recently and have only employed organic farming techniques. Demographic characteristics also vary greatly, but in general these farmers have strong convictions that have compelled them to undertake something different. They are independent and innovative, as they try new crop rotations, seek out sources of information, solve pest concerns on their farms, and market their numerous crops to meet growing consumer demand for organic food.

Implementation of organic agricultural policy in the United States has been fairly recent. The 1990 Farm Bill initiated the establishment of a USDA organic farming office to draft standards with the assistance of an advisory board. Finally, in 2002, the National Organic Certification Standards were put into effect. Labeling now indicates three designated levels, with products labeled "100 percent organic" containing only organically produced ingredients. The "organic" label indicates products that are at least 95 percent certified organic and "made with organic ingredients" are for items with at least 70 percent of organic components. Any product containing less than 70 percent of organic ingredients may not be marketed as an organic food. Foods that fall into these organic categories qualify to display the "USDA Organic" seal.

The natural foods retail industry strongly supports the national certification standards. The Grocery Manufacturers of America represents major food producers and they note that national organic standards increase consumer confidence through uniformity of organic products. This highlights the conflict between the market-driven success of organic products and the grassroots ethical concerns of organic farming, as national standards will not necessarily support a locally-based organic food network. It is not clear how these divergent ideas will be balanced within the framework of the national certification standards, but it seems that market growth is currently driving the process.

CORPORATE INVOLVEMENT

In addition to policy issues, business concerns also influence the future of organic farming. As organic farming sees rapid growth in demand, it is pulled into the conventional mode of production. Agri-business corporations realize the large market growth in organic products and are well aware of the trends. For example, several multinational corporations have controlling interests in many organic food labels. In addition, in mid-2006, Wal-Mart made a public statement indicating that they seek to vastly expand the organic products they sell. Wal-Mart is already one of the world's largest retailers of organic foods, so this recent move could further increase their influence on the organic food marketplace.

Such corporate involvement exemplifies the growing pains associated with organic agricultural production and consumption: local versus international; and farmer versus multinational. The organic farming system of producing food based on soil health, innovation, and earlier "hippie" movements, is now becoming big business. The potential negative aspects of this evolution are that it may become dominated by the large scale agri-business corporations seen in conventional agriculture.

On the other hand, the positive aspects of the success of organic agriculture are that more diverse consumers can afford to buy organic products and there are environmental benefits to reduced agrichemical use. In the future, organic agriculture will likely struggle to keep its roots in local farming and sales.

Estimates place the growth of U.S. organic markets at 20 percent annually since 1990.

Organization of the Petroleum Exporting Countries (OPEC)

CREATED AT THE Baghdad Conference on September 10–14, 1960, the Organization of Petroleum Exporting Countries (OPEC) is a multinational consortium whose purpose is to coordinate and regulate petroleum pricing and policies among its member countries. OPEC was created to assure stable prices for member petroleum producers, securing cost-effective and regular supplies of petroleum and distillates to consuming nations with reasonable profits to its members and investors.

The original founding members were Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela, which were later joined by Qatar in 1961, Indonesia in 1962, the Socialist People's Libyan Arab Republic in 1962, the United Arab Emirates in 1967, Algeria in 1969, Nigeria in 1971, Ecuador from 1973 to 1992, and Gabon from 1975 to 1994. The organization located its first headquarters in Geneva, Switzerland, for five years, then moved to Vienna, Austria, on September 1, 1965. Nigeria joined OPEC in 1971 and represents the final member nation.

OPEC rose to international prominence during the 1970s when it dominated its own domestic oil production while increasing its direct influence on global crude oil markets. Prompted by the Arab oil embargo of 1973 and the Iranian Revolution in 1979, the world's crude oil prices skyrocketed (nominal value at $38/barrel), and OPEC's role in the world market became obvious. The organization's first Sovereigns and Heads of State Summit was held in March 1975 in Algiers.

Crude oil prices peaked in the early 1980s, only to plummet, causing a worldwide crude oil collapse in 1986. Prices revived in the following years but never approached the earlier high prices until 2000, when crude oil per barrel prices soared to $36/barrel. Nothing however, prepared OPEC for current price escalation to more than $70/barrel due to recent production problems and conflicts across the Middle East.

With increasing Middle East conflicts, market panic instigated a sudden increase in crude oil prices that was reduced by increased production and output dictated by the OPEC members. Prices remained stable until a collapse in 1998 due to economic recessions in Southeast Asia; cooperative action by OPEC and some non-OPEC producers brought about a relative price recovery. A wave of corporate mergers among the major international oil companies followed, which aggravated price fluctuations until the disastrous attack on the United States on September 11, 2001.

With the consequent Iraq war, crude oil production in Iraq, a major global supplier, halted from warfare-related disruption and sabotage, pushing prices in 2006 to more than $70/barrel. These high petroleum values were then exacerbated with the landfall of Hurricanes Katrina and Rita along the U.S. Gulf Coast in 2005—which kept prices high due to importance of that region in North American oil production and distribution services. Increasing Asian demands on oil consumption also contributed to the price rise.

The foremost aims of OPEC, according to its statute, are:

> the coordination and unification of the oil policies of its member countries and the determination of the best means for safeguarding their interests, individually and collectively; [devising] ways and means of ensuring the stabilization of prices in international oil markets with a view to eliminating harmful and unnecessary fluctuations; [giving due regard] at all times to the interests of the producing nations and to the necessity of

securing a steady income to the producing countries; an efficient, economic and regular supply of petroleum to consuming nations, and a fair return on their capital to those investing in the petroleum industry.

OPEC is administered by a board of governors overseen by the secretary general, who is appointed for a term of three years. The secretary general is the legally authorized representative of OPEC and chief executive of the secretariat and administers the affairs of the organization in accordance with the directions of the board of governors. The secretary general is assisted by the Research Division, the Administration and Human Resources Department, and the Public Relations and Information Department.

Organophosphates

ORGANOPHOSPHATES ARE A class of chemicals (specifically esters of phosphoric acid), many of which act as neurotoxins. Organophosphates are created primarily through reactions between phosphoric acid and alcohol, a process that has been used since the middle of the 19th century. Used as pesticides and chemical weapons, they are among the most toxic substances to humans and other vertebrates. They have been used on an industrial scale as pesticides and on a smaller scale for therapeutic purposes. Organophosphates have also been used as a weapon by some military forces and one form, sarin, was used in a terrorist attack on the subways of Tokyo in 1995, which led to numerous deaths and thousands of injuries. Contact with organophosphates at a low level may have negative health impacts, although the evidence is not fully established. There is considerable research concerning the possible use of organophosphates in treating dementia, including Alzheimer's disease. Other medical and industrial applications are under active consideration.

The use of organophosphates as pesticides is generally controlled by governmental agencies owing to the persistence and severity of the toxicity of the substance. In the United States, the Environmental Protection Agency (EPA) monitors and regulates the use of the chemicals in industrial and domestic terms. Their use has been permitted when fears about the spread of infectious disease have been raised. A well-known example is that of the outbreak of West Nile virus, which led to chemical spraying in New York's Central Park, as well as other parts of the country.

Such decisions are often controversial because of evidence of health concerns from proximate exposure. There is always a measure of conflict between those who wish to use organophosphates or any other form of chemical as effective agents in industrial processes for economic gain, and those who believe that potential long-term risks make this an unwise proposition.

In developing countries, the poorest and most vulnerable rural workers are most likely to be exposed to pesticides, and they are the least likely to receive effective medical intervention. In the developed world, acute exposure to organophosphates among farm workers represents a serious environmental justice issue, as does long-term exposure at lower dosages in urban settings.

Orientalism

ORIENTALISM REFERS IN general to the interest by Western Europeans and Americans in Near Eastern and Far Eastern societies, cultures, art, and architecture, which reached a peak in the 18th and 19th centuries but has long been a facet of European culture. The term also refers to a pejorative, romantic, and colonial habit of thinking, embodied in such academic study and ongoing into the present, which holds that the East is in some way essentially different from the West. This latter meaning of the term is rooted in Edward Said's book of the same name, *Orientalism*, published in 1978.

During the period of the Crusades, many designs and ideas from the Near East, as Turkey and the Holy Land were then known, were taken to Western Europe. Some of these concerned philosophical views, medical science, and geometry. Others concerned art, architecture, and military sciences. With the rise of the Seljuk Turks from the 11th century, and the Ottoman Empire from the 15th century, few people from Western Europe were able to get to China, Marco Polo (1254–1324) being a major exception. His account was, for much of the early modern period, the only one readily available that described Imperial China. It excited the culturally adventurous in Europe, but some recent detractors have argued that he may not have gone to China.

In 1510 the Portuguese had not only sailed to India but captured the city of Goa, making it the center of their power on the Indian subcontinent until 1962. They seized Malacca (in modern-day Malaysia) in 1511 and started trading with China in 1513. They established their base at Macau in China in 1557, and also traded with Japan.

These Portuguese voyages fostered Western European interest in Indian, Chinese, and Japanese foods and artifacts. The Dutch, French, and British soon tried to take control of as much of the trade as they could. In 1671 Louis le Vau built the Trianon de porcelaine at Versailles, France, where Chinese art and locally-made items in the style of Chinese art, were used to decorate a room. The idea quickly spread and the term *chinoiserie* came to represent this European and North American fondness for Chinese-style furniture, pottery, textiles, and interior decoration. Few large houses in Germany were without their "Chinese room."

During the War of Austrian Succession (1740–48) and the Seven Years War (1756–63), Britain emerged as the preeminent military power in India, with great riches flowing back to the country. The fortunes made by Lord Clive and Warren Hastings inspired many British (and other) young men to seek their fortunes in India. Many died there, but others returned, often with a taste for Indian food and art. Among the many places with Indian architectural styles were the facade of the Guildhall, London (1788–89); Sezincote House, Gloucestershire, England (around 1805); and Sanssouci, Potsdam. When the British Lord Macartney went to China to try to open an embassy in Beijing in 1792, it was hoped that this would facilitate trade between Britain and China. The Chinese declined the British offer, but drawings of the meetings, and other similar encounters in India and elsewhere, showed the clothing, furniture, and decorations of the Orient to a public that had sufficient disposable income to purchase oriental items.

By the 18th century, the Orient came to represent anything from the Balkans eastward, including Egypt—not just India, China, Japan, and Southeast Asia. This interest in Eastern art and culture received a boost when Napoleon embarked on his invasion of Egypt in 1798–1801. He took with him many scholars and essentially led to the creation of the discipline known as Egyptology, which involves the study of pharaonic Egypt from 4500 B.C.E. until 641 C.E. Subsequent French interest in North Africa, leading to the invasion of northern Algeria in 1830, led to the formation of a painting school known as the Orientalists, often including painters who had only been to Morocco and Algeria, as well as Egypt and Arabia. Some even saw the Moorish style of Spain as being Oriental.

In 1811, the British sent a massive expedition to the Dutch East Indies (modern-day Indonesia), with the commander, Lord Minto, bringing with him antiquarians and archivists. In the early 19th century, trade between China, India, and Western Europe was vast. Tea clippers brought large amounts of tea to Europe, with tea houses opening in many cities. Some of these were decorated with Chinese artifacts, and it was not long before local copies of Chinese art started to appear on the market, and some buildings inspired by Chinese architecture were built. The Royal Pavilion at Brighton, England, was constructed in 1815–22, and represents the interest in Mogul Indian architecture in Regency Britain. Chinese-style pagodas were built in botanical gardens, including in Kew Gardens in London and the English Gardens in Munich. Large numbers of houses in England and France, and also later in the United States, now had a Chinese room, where items from China, or in the style of these, were displayed. Chinese or Chinese-style furniture was also used to decorate these rooms and other parts of the house.

The 19th century also saw a large number of books written about the Orient. Novels such as Gustave Flaubert's *Salammbo* (1862), set in Carthage (modern-day Tunisia) captured the essence of Orientalism of that period. The opening up of Japan in the 1860s saw an interest in Japanese woodblock prints and Japonaiserie. By the early 20th century books and stories set in the Orient often had a more dangerous edge to them. Agatha Christie's *Murder on the Orient Express* (1934), P.C. Wren's *Beau Geste* (1924), and Sax Rohmer's character, Fu Manchu, set among the Chinese in London, focused on this exotic but dangerous Oriental theme. Nowadays the all-encompassing term *orient* has been replaced with more specific interest in Arab, Chinese, Egyptian, Indian, Japanese, Korean, Mongolian, Persian, Tibetan, or Turkish styles.

The persistence of certain ways of thinking rooted in the colonial era, however, are arguably still present in contemporary "oriental" regional scholarship. This persistence of essentialist ideas, holding the orient to be distant, alien, irrational, and the mirror "other" to the West's rationality, has been pointed to by a large number of postcolonial scholars. Most prominent among them is Edward Said, whose book *Orientalism* points out that domination of colonial nations and peoples around the world was historically not simply a matter of brute force, but also one of ideology. The necessary logic of domination, he suggests, is one where the East is mystical, unknowable, irrational, feminine, and in need of control. The long scholarly tradition noted above, he further insists, deeply reflects and constitutes an academic tradition that cements this vision of the world and justifies foreign rule. Orientalism refers therefore to an academic field as well as a dangerous state of mind.

In terms of environmental issues and ecological history, Orientalism has been arguably influential in the development of modern environmental science. The notion of "tropicality," for example, a discourse that holds that temperate environments are more suited to civilization, is a long-standing tradition in historiography, closely tied to essentialist ideas of the "primitive" or mystical East. Quaint as such ideas may seem, their tacit persistence suggests that Orientalism remains a pertinent issue in human/environment studies.

Orographic Effect

THE OROGRAPHIC EFFECT is also known as the Foehn effect and orographic precipitation or relief rainfall, although these two terms only comprise a part of the process. The orographic effect is the series of changes at a synoptic scale in temperature and humidity as a result of the flow of air masses over mountain ranges or oceanic islands. It may engender orographic precipitation when moisture is captured, cloudiness, and differences in air temperature and humidity between the windward and leeward sides of the range. A large local gradient, or spatial variation, of precipitation and temperature results.

When a moving mass of stratified air containing abundant moisture hits a topographic barrier, the air is forced up. In the upward movement, the air cools adiabatically and becomes increasingly saturated. When temperature falls below the dew or condensation point, orographic clouds develop, water vapor condenses, and precipitation occurs as rain or snow, so that some moisture is removed. Rainfall increases as air raises the barrier. The air keeps rising until it reaches the same temperature as the surrounding air. In the condensation process latent heat is released to the air and this is warmed.

During the descent down the lee side of the barrier, the drier air mass warms adiabatically by increasing its pressure. Precipitation drops radically and cloud coverage dissipates. The heat gained in condensation adds to compressional heating. This dry air mass increases its temperature—about 6 degrees per kilometer—more quickly than leeward moist air decreases when ascending—about 10 degrees per kilometer—so that it reaches a higher temperature at an equal elevation. The warmer dry area to the lee side conforms to a precipitation or rain shadow, although sometimes—depending on wind speed—precipitation is projected leeward, a phenomenon called spillover.

Different types of vegetation respond to the contrasting environmental conditions; while the windward side of mid-latitudes mountain ranges are covered by forests, the leeward side frequently exhibits arid, stepparian vegetation—the grassland in the lee of the Rocky Mountains—or, in certain cases, deserts. Death Valley in California and the Great Basin both illustrate the latter.

Examples of significant descending winds produced by a steady manifestation of the orographic effect over a short time are commonly designated by local names, such as Foehn in the European Alps, Chinook in the Front Range of the Rocky Mountains, or Zonda in Western Argentina. Eventually, surface winds flow very strongly and reach disruptive speeds that are considered to have some effects on human behavior. The Santa Ana wind in Southern California reveals some differences. The dry air mass originating from the north and east high deserts over the Great Basin, or northernmost areas, advances over the San Gabriel Range, where no cloud formation occurs, and descends to the coast. The lower altitude of the Los Angeles area allows the increase of temperature combined with a lower relative humidity. Chinook winds are originated by oceanic air moving over the Cascade Mountains and Sierra Nevada Range, where moisture is drained; then the air mass descends to the lee side, creating the dry Great Basin, and the hot and dry wind progresses to the Rocky Mountains, where it may melt the snow cover.

Other less common types of orographic effects include the feeder-feeder effect and the Puget Sound Convergence Zone. The feeder-feeder effect starts with precipitation from an upper-level cloud over a lower-level orographic cloud that feeds precipitation of the lower, increasing the total precipitation. In the second case, moist air masses from the Pacific Ocean, instead of rising, are blocked, split into two air streams, and deflected by the Olympic Mountains. The two branches converge over Puget Sound (on the leeward side of the mountains), and are forced to uplift—leading to convection—and causing precipitation in the Puget Sound Convergence Zone. Although an orographic process, katabatic wind or mountain breeze originates from differential cooling of high elevation and valley air masses. As soon as solar radiation ceases, top mountain air cools faster than in lower areas, becomes denser, and flows downslope, creating a local high pressure.

Overfishing

OVERFISHING IS, IN the simplest terms, the harvest of more fish from a population than it can bear. Yet, the word takes on multiple meanings in practice and the causes and consequences of, and alternatives to, overfishing are even more complicated.

At a first level of approximation, two kinds of overfishing are possible. Recruitment overfishing refers to the harvest of a species such that its ability to reproduce itself back to its preharvest condition is compromised. This can take the form of destroying broodstock directly or harvesting organisms before they have a chance to reproduce at all. Recruitment overfishing can result in less catches over time and, if sufficiently serious, to crashes in abundance, but this can be temporarily masked by the delay of several years between the culling of one year's breeding population and the resulting hole in the population from the loss of recruitment.

Growth overfishing refers to the taking of fish before they have achieved a size or value determined to be optimal. As a primarily economic issue, it does not bear the same seriousness to the ecology of fisheries, but intense growth overfishing can easily shade into recruitment by harvesting juvenile individuals before they have spawned. The calculation of growth overfishing is contingent on the relationship between natural and fishery mortality, such that the maximum size possible for a given species is seldom achieved in the wild, making harvest of a considerably smaller size perhaps the most remunerative option for fishers.

The consequences of overfishing can be quite severe. Overfished populations can take much longer to rebuild to a healthy condition than it took to degrade them, even if fishing pressure on them is relieved. This can be due to the small number of surviving spawning adults, but can also be because opportunistic species have taken over the habitat. Fishing capacity going unused reduces employ-

The decline of a fishery stock may lead to intensified effort to harvest remaining individuals from it, exacerbating overfishing; or it may lead to the abandonment of fishing for other livelihoods.

ment, creates a crisis of fixed capital investment, contributes to local and regional economic decline, and can—for fisheries crucial to regional food security—contribute to malnutrition. Overfishing in West Africa is believed to contribute to the intensification of the bushmeat trade, which threatens many kinds of wildlife in the region. The decline of a fishery stock may lead to intensified effort to harvest remaining individuals from it, exacerbating overfishing; or it may lead to diversification of effort onto other fisheries (with benign or harmful effects), or the abandonment of fishing for other livelihoods. The specific social, economic, and ecological contexts of a given fishery are important in understanding what a fishery will do when faced with overfishing.

Theories to explain overfishing often converge around the Tragedy of the Commons, which argues common property resources inevitably lead to overexploitation and conflict requiring coercive enforcement and enclosure. This general perspective translated into fisheries implies that with open access situations, where there are no restrictions to harvesting, more fishers will add their effort to the collective effort because their individual gain is larger than the collective loss of that share of the resource, until expenses equal benefits and no profits are gained by anyone.

The generally employed rubric for managing fisheries to avoid commons tragedies is known as bioeconomics, which seeks to establish and regulate the amounts and types of harvest acceptable to sustain fish populations and the profitability of fisheries. Managers use statistical models drawing on data from research vessels or surveys of commercial landings to model the population dynamics of individual species or multiple species interactions. Surplus production models are utilized to understand how much fishing mortality can be sustained by a population and what biomass will generate the highest rate of increase to augment production. These models are used for establishing Maximum Sustainable Yield (MSY), the largest harvest possible that should leave enough individuals to reproduce an equivalent harvest. Yield per recruit models are used to calculate the best harvest size to maximize catches so as to avoid growth or recruitment overfishing.

Managers make use of the conclusions of these statistical tools through a variety of regulations. Basic management measures include setting Total Allowable Catches, limiting entry to fisheries, mandating size and number limitations on catches, controlling fishers' access to certain territories or at certain times, or regulating the use of certain types of fishing gears. Drawing on the ideas of Hardin and others, advocates for fishery rationalization support the implementation of Individual Fishing Quotas (IFQs) to simulate private property rights on the premise that marketizing access will lead to better stewardship and allocation of fisheries, reducing overcapitalization.

Pioneered in New Zealand and now used in some Alaskan fisheries, IFQs can reduce wasteful fishing practices caused by "derby fishing," where a fleet quota is established and fishers compete to bring in the most fish before the quota is filled. They have, however, a tendency to encourage high grading, where fishers throw back suboptimal fish (many of which may die) in order to get the most valuable fish under their IFQ.

Common property theorists pose a counter-narrative to this perspective that stresses that institutions for governing common property, if well-suited to the needs of fish and fishers, can overcome tendencies toward overfishing. Community-based marine resource management is expanding in places like the South Pacific, employing means like conservation education and comanagement by harvesters and the state over defined community territories at sea.

The decline of the groundfish fisheries of Atlantic Canada in the early 1990s is a well-known recent example of overfishing. Many factors contributed to this disaster. More efficient but less selective dragging gear was adopted by a sector of Canadian fishers, which made for more discards. Overcapitalization was encouraged by state support to industrialize the fisheries after the withdrawal of foreign fleets in the late 1970s. A lack of enforcement of fisheries regulations caused more fishers to break rules so as to not lose out on the higher catches that cheating could generate. Overly optimistic projections of fishery populations created false confidence and prevented effective corrective action, and high levels of debt on some vessels mandated that fishers keep fishing or go bankrupt, imposing political economic costs on controlling effort on the fishery.

By contrast, the nearby Maine lobster fishery is considered among the most sustainable fisheries in the world. An informal system of territorial management by fishers gives them incentives for protecting the resource in their areas and disincentives from acting destructively. The gears used are highly selective and allow undersized or egg-bearing lobsters to be returned to the water unharmed. The regulations of the state have evolved over decades to be supported by most fishers because they were seen as beneficial and fair, making compliance rates relatively high. Fisheries like Maine lobster, which have a history of management success, appear to build upon that success, but there is no simple checklist of measures to make the fishery commons less tragic. Careful attention must be paid to the history and contemporary social structure of the fishery as well as its ecology and modifications to it by human action to understand how and why overfishing happens (or does not). One emergent truth is that rules that fishermen feel are counterproductive and unjust do not engender the kind of cooperation that makes management effective, if possible at all.

Overgrazing

OVERGRAZING IS A term without a precise scientific meaning. Yet, it is widely used and its use has enormous implications for the management of livestock and wildlife and for the livelihoods of individuals and societies throughout the world. It is called one of the most destructive human practices on earth. It is said to be harmful to vegetation and wildlife and to cause soil erosion and desertification. But without a precise definition, these claims have no real meaning, nor can they be proved or disproved.

Range management is a profession that uses range science and practical experience to maintain and improve grazing system components (plants, animals, soil, water) and the production of goods and services from rangelands in combinations needed by society. Range management defines grazing as the consumption of standing forage (edible grasses and forbs) by livestock or wildlife, and browsing as the consumption of edible leaves and twigs from woody plants (trees and shrubs) by large-hoofed animals. Forage plants coevolved with grazers and have developed the capacity to recover from grazing. But this capacity depends on how much tissue is lost, when it is lost in the life cycle, and how frequently it is lost. From the individual plant's point of view, *overgrazing* could be defined as exceeding its capacity in any of these ways. However, this is not a definition that can be easily generalized.

Range management does not offer a scientifically validated and agreed upon definition of *overgrazing*. This is because there are many different grazing systems, different ways to measure the effects of grazing that are difficult to measure and calculate in practice (examples are carrying capacity, utilization, and range condition and trend), and different temporal and spatial scales over which the effects could be measured. In addition, since the 1980s, nonequilibrium models of ecology have been replacing the equilibrium models on which the range succession model, which has guided range science since the 1950s, is based. The range succession model posited a predictable, linear relationship between grazing and vegetation change and the existence of an optimal level of grazing that could balance desired outcomes. Nonequilibrium models, on the other hand, emphasize variability and unpredictability, making it even more difficult to define *overgrazing*.

As it is commonly used, the term *overgrazing* indicates damage or harm to vegetation caused by grazing or browsing. For example, wildlife biologists debate whether the decline of willow and aspen in

Yellowstone National Park is due to overgrazing by elk. Most often the term refers to harm to vegetation caused by domestic livestock grazing. It is also frequently used to explain environmental change in regions where ranching or "pastoralism" is practiced. Because the term *overgrazing* does not have a precise definition, its common usage is problematic for several reasons. First, harm is often in the eye of the beholder. For example, rangelands in arid regions can appear to be overgrazed from the perspective of an observer from a wetter climate. Thus, eastern visitors to the western United States might see western rangelands as overgrazed. Or European visitors to Africa might enthuse over herds of nondomestic ungulates grazing the African savannah, but deplore the depredations of native livestock. Second, perceived harm is often attributed to livestock grazing without actual evidence of a causal relationship.

FALSE CAUSE

This is a mistake in reasoning called false cause: It assumes that two events juxtaposed in time or space have a cause and effect relationship. The tendency to make this mistake can be aggravated when there is an awareness of events in the not-too-distant past where overgrazing could be said to have occurred on a vast scale, as in the late 19th century in the American West. Grazing is not harmful, by definition, so overgrazing should require evidence of harm. The third reason that common usage of the term *overgrazing* is problematic is that, when livestock are seen as the cause of overgrazing, the livestock owners are usually blamed. This attribution of blame does not take into consideration the wider social, political, and economic conditions in which livestock owners operate in the present. It may also be informed by colonial and racist pasts. When these types of assumptions underlie the use of the term *overgrazing*, it becomes an example of "received wisdom": A powerful orthodoxy that is taken for granted and rarely questioned. Usage of the term may convey more information about its user's social, geographical, and ideological position than about actual conditions on the ground. To understand why the term *overgrazing* carries this ideological baggage, it is helpful to examine the early development of range management.

Although "pastoralism," a human adaptation to marginal environments that emphasizes the herding of livestock, originated approximately 7,000 years ago, the scientific discipline of range management only began to develop toward the end of the 19th century. Both European colonialism, particularly in Africa, and Euro-American western expansion in North America were central to this development. As a result, the term *overgrazing* carries along with it traces of Eurocentric histories and environments. In Africa, European colonial administrators were charged with managing and making productive vast territories whose climate, landscape, and societies were very different from their countries of origin. They were accompanied by an array of scientists whose job it was to inventory and develop scientific management regimes for their colony's natural resources. Europeans either did not recognize indigenous resource management systems, although these systems may have developed and been sustainable over many centuries, or they considered them unproductive because they were not designed to produce the surplus colonists needed for export.

In southern Africa, a science-based approach to range management began to develop toward the end of the 19th century when colonial scientists tailored climatic theories prevalent at the time, which linked deforestation to climate change, to the arid environment of southern Africa. Their "dessication theory" predicted that grazing could reduce vegetation cover and lead to decreased rainfall, increased frequency of drought, soil erosion, and eventually desertification. Scientific range management was intended to prevent desertification and, at the same time, increase livestock production. When scientific range management failed to live up these expectations, instead of questioning science, colonial administrators blamed African graziers who failed to adopt the new methods. Although it has been brought into question, the belief that there is a cause-and-effect relationship between grazing and desertification is still strong today.

In North America at about the same time, a rapid expansion of livestock herding west of the 100th meridian—into a region where average annual precipitation is significantly less than to the east and farming is not possible without irrigation—was taking place. Fueled by a rapid rise in beef prices, the building of railroads, and an influx of foreign capital after the end of the Civil War in 1865, the western rangelands soon became a "cattle kingdom" where cattle and sheep "barons" built up huge herds and competed for forage on the unregulated public domain lands. Overgrazing serves as the classic example of the Tragedy of the Commons and this tragedy played out in the late 18th century on the American rangelands as a series of droughts denuded the range and were followed by severe winters that killed off a larger part of the weakened livestock population.

The disaster shocked ranchers, the American public, and government officials and contributed to a change in attitudes toward ranchers and toward open range grazing. The damage done to the western range during this period is probably irreversible. Range management became an imperative in the United States in the wake of this disaster. Because of its implication with colonial histories, the term *overgrazing* may carry unavoidable ideological implications.

Modern range management has moved away from the use of the term *overgrazing*, and the retroactive consideration of damage done that it implies, to a more proactive consideration of the ecological processes that sustain range productivity.

Overkill Hypothesis

THE OVERKILL HYPOTHESIS concerns the extinction of megafauna, particularly in the Americas and Australia. Archaeological excavations reveal that a number of species, perhaps more than 100, disappeared within a comparatively short period of time, less than 1,000 years.

Excavations also demonstrate that at least some of those animals were hunted and eaten by newly arriving humans. The hypothesis follows that the migrating humans were responsible for the extinctions because the animals were not frightened of them and so were easily hunted. A contrast is drawn with the megafauna of Africa and Eurasia, where a long period of cohabitation with humans taught the animals to be wary of humans. This hypothesis is controversial because the evidence does not convince all observers, and alternative explanations have been suggested, including the impact of climate change or the introduction of unfamiliar diseases.

The arrival of humans in North America and Australia is closely correlated with the disappearance of many large animal species. However, such correlation does not imply causation; further, reliance upon fossilization for evidence is suboptimal, principally because it is such a random method of preservation that it cannot be certain that those that have been preserved are representative of the population. Extinctions happened so rapidly that they have been conceptualized as a form of blitzkrieg, or lightning war resulting in mass extinctions. Some researchers object to this hypothesis for philosophical reasons, because it suggests that humanity cannot live in harmony with the natural environment.

Others maintain that it is impossible to rule out additional factors that would accompany such extinctions, as for example other creatures that would migrate alongside humans, or some other interaction between people and the environment. This has been observed in more recent examples of mammal extinctions, such as when old-world rats and other aggressive creatures have been introduced into island environments and native life has had insufficient time to adapt. Other problems with the hypothesis result from dating two possibly separate incidents with precision, when that precision is notoriously difficult to obtain.

Nevertheless, the evidence that has been gathered does lend support to the overkill hypothesis. One important finding is that it was not necessary for humans to have hunted down every single representative of a species, merely to kill more than were born, and this is quite possible in a 1,000-year period. In addition, the related Keystone Herbivore Hypothesis suggests that the large species, such as elephants and rhinoceroses, are significant environmental engineers and that their rapid disappearance would have a negative effect on the environment inhabited by large numbers of other creatures, some of whom would follow them into extinction.

New forms of scientific research are helping scientists to distinguish between overkill, disease, and climate change theories. Extraction of DNA and other organic material from frozen mammoths, for example, provides the opportunity to identify the presence of viruses or other disease-bearing organisms. Ice core analysis is able to provide more accurate information concerning climate change.

Overpopulation

OVERPOPULATION IS A situation in which the resource demands of a population exceed the resources available in a given area. The concept of overpopulation may be used in conjunction with the concept of carrying capacity, which originated in the field of ecology and refers to the number of individuals and species that a particular habitat may support. When used in reference to humans, overpopulation is often identified as a causal factor of poverty and a driver of environmental degradation, particularly in the developing world. However, since Thomas Malthus professed his views on the grim consequences of unchecked population growth more than two centuries ago, the concept of overpopulation has not only eluded refinement, it has also proven deeply controversial.

In his 1798 *Essay on the Principle of Population,* Malthus maintained that population, due to people's natural desire to reproduce, will expand at a geometric rate, while the means of subsistence (i.e., food production) will increase at an arithmetic rate. The product of this fundamental tension between population and resources was poverty and misery for much of humanity. According to Malthus, humans had not yet multiplied to fill the earth because of what he termed "preventative" checks (e.g., abortion and postponing marriage) and "positive" checks (e.g., war, disease, and, most importantly, hunger). Positive checks tended to fall most heavily upon the poor, whom Malthus held in particularly low esteem owing to their supposed sexual profligacy.

Malthus's principle of population has been critiqued from a number of angles, including for its obvious conflation of moralist and scientific approaches. An early critic of Malthus was Marx, who argued that capitalism, not overpopulation, was the cause of poverty and that capitalistic laws of accumulation, rather than universal laws of population growth, pushed society to the limits of its natural resource base. Marx further contended that under capitalism, "surplus" population performed a vital function as a readily exploitable industrial reserve army of laborers.

Nonetheless, theories of overpopulation and physical resource scarcity crises remained influential. In the context of the rise of environmentalism and concern about rapid population growth in developing countries, the 1960s and 1970s witnessed a reemergence of Malthusian thought in the North that extended Malthus's underlying premise to include environmental degradation as a consequence of overpopulation.

Influential neo-Malthusians included biologist Garrett Hardin (renowned for his Tragedy of the Commons thesis) and fellow biologist Paul Ehrlich, who in *The Population Bomb* (1968) predicted that the earth would soon experience dire famines due to population outstripping food supply. Also, in 1972 the Club of Rome issued its report *The Limits to Growth,* which concluded that exponential population growth and resource development would eventually lead to resource exhaustion and worldwide economic collapse.

Response to neo-Malthusian models came from several camps. Free-market proponents such as Julian Simon argued that rather than inescapably leading to misery and hunger, growth in human population—considered by Simon the "ultimate resource"—actually stimulated innovation and economic development. Also influential was the work of Danish economic historian Esther Boserup, who concluded that population pressure in agrarian societies promoted agricultural intensification through the mobilization of labor and the application of other inputs. Countering Malthus, Boserup thus argued against the inelasticity of food production, a position buttressed by the substantial per-acre yield increases achieved after World War II with the aid of Green Revolution technologies.

In addition, contemporary Marxist critiques maintain that poverty does not result from Malthusian global resource scarcity crises, but rather from the highly unequal distribution of resources and power inherent to capitalism. Critics from developing countries have, in a similar vein, attempted to shift the debate away from population patterns in the south to consumption patterns in the north. Identifying "overpopulation" in developing countries as a driver of environmental degradation amounts to blaming the poor, these critics argue, while residents of developed countries, in fact, consume the vast majority of the world's resources.

Thus, given the multitude of cultural, political-economic, and technological variables that influence the population-resources dynamic as well as highly uneven geographic patterns of resource production and consumption globally, the concept of overpopulation has proven exceedingly difficult to define. Commentators, notably David Harvey, have nevertheless highlighted the political implications of theories of overpopulation themselves—in particular, the degree to which they may be used as ideological levers to justify class or ethnic oppression domestically or neo-imperialist policies abroad.

Owens Valley

LOCATED IN INYO County in southeastern California, the Owens Valley stretches for approximately 75 miles (121 kilometers) between the Sierra Nevada Mountains to the west and the White and Inyo Mountains to the east. Owens Valley is most notable for an intense battle persisting throughout the 20th and early 21st century between the city of Los Angeles and local residents over land rights and the diversion of the valley's surface and groundwater. Owens Valley provides a significant portion of Los Angeles's water despite being located over 200 miles (322 kilometers) to the northeast.

Prior to the diversions, the region was site to Owens Lake, an important stopover for migratory birds and a navigable water body for recreation. The valley was also home to the Owens River, which supported rare high desert riparian habitat and provided water to local farmers. The Owens Valley "water wars" began when the city of Los Angeles Department of Water and Power (LADWP), under the orchestration of Superintendent William Mulholland, drew up plans to divert water from the Owens River to an aqueduct serving the city of Los Angeles. The LADWP acquired water rights from valley farmers and ranch owners despite their protests. By 1913 the 223-mile (359-kilometer) Los Angeles Aqueduct was complete and began diverting water from the Owens River.

In the years following the initial diversions, 50 miles (81 kilometers) of the Owens River as well as Owens Lake dried up. Farmers in the region gave up their dying crops and orchards and were forced to relocate as the region lost its vegetation cover and productive capabilities. A second aqueduct built in 1970, which was heavily dependent on pumping groundwater from Owens Valley, only exacerbated the desertification process.

By 1970, early environmental regulations began affecting the future of both the Los Angeles Aqueduct and Owens Valley. The California Environmental Quality Act (CEQA) of 1970 required the LADWP to describe the environmental consequences of their diversion projects in an environmental impact report (EIR). In 1972, Inyo County used these stipulations to take LADWP to court over their plans to increase groundwater pumping in Owens Valley. The LADWP submitted two EIRs in 1976 and 1979 that were both rejected by the courts.

Numerous scientific studies and court cases occurred over the next 20 years, and several EIRs were unsuccessfully negotiated. Meanwhile, the city of Los Angeles continued to pump groundwater out of Owens Valley. By 1997, the Owens Valley Committee, the Sierra Club, and others signed a Memorandum of Understanding to outline the rewatering of lower portions of the Owens River. Although the majority of this rewatering has yet to occur, the Owens Lake basin is now occasionally shallow flooded by the city of Los Angeles in order to control air pollution from alkali dust storms. Enough water is present in the Owens Lake vicinity to still be designated a Nationally Significant Important Bird Area by the National Audubon Society.

In 2004, Los Angeles Mayor James Hahn proposed a Conservation Easement for all LADWP land in the Owens Valley. Advocates for this plan argue that it would protect the region from economic growth in neighboring areas, while critics argue that the city of Los Angeles will continue to control a landscape they took from local residents nearly 100 years ago.

Oxygen

OXYGEN IS A normally gaseous, nonmetallic chemical element with the symbol O and the atomic number 8. It is widely prevalent in the earth's atmosphere, in which it is essential for the respiration of humans and other living creatures. It is also widely prevalent across 70 percent of the earth's surface in the form of water (H_2O), of which the most important compound is oxygen.

Oxygen was discovered in the 18th century by Joseph Priestley in England, Carl Wilhelm Scheele in Sweden, and Antoine Lavoisier in France, working independently. Lavoisier was responsible for identifying oxygen as an element and determining its role in combustion, which had previously been attributed to the phenomenon of phlogiston.

Oxygen constitutes approximately 0.03 percent of all atoms in the universe, which makes it the fourth most common element. However, it is the most abundant element on the earth, representing nearly half the mass of the earth's crust, 90 percent of the mass of the earth's water, and 20 percent of the mass of the air. In small quantities, particularly in the upper atmosphere, oxygen exists in the form of O_3 rather than the normal O_2 molecule, when it is known as ozone.

Oxygen first appeared on the earth in free form approximately two billion years ago when it was produced as a by-product of the living process of early anaerobic creatures. This enabled the evolution of modern, aerobic life forms and these subsequently developed photosynthetic processes that have greatly increased the amount of oxygen present. A significant amount of the oxygen reacted with hydrogen to create water, making organic life possible. Without the release of oxygen, therefore, the earth would have remained wholly inhospitable to modern life forms.

While plants absorb carbon dioxide and release oxygen as part of photosynthesis, animals including humans inhale oxygen and exhale carbon dioxide. This means that there is an approximate balance for total amounts of the different gases, although this balance is subject to many other intervening variables. Evidence suggests, albeit inconclusively, that it is the presence of free radicals (atoms or groups of atoms that have one missing electron and are usually oxygen atoms) that results in the aging process.

Oxygen has numerous scientific and technological purposes. Its role in combustion, in which it combines with another substance generally at high temperatures, means it has many uses in equipment for melting, soldering, and burning materials. The role of oxygen in respiration means that it is of great importance in medical science.

Oxygen is also important in regulating the environment in which fish and other aquatic creatures live, since these also need oxygen, and environmental degradation can reduce the oxygen level in water. Oxygen regulation is of great importance in fish farming and related industries. Intensive agricultural activities may have contributed to the lack of oxygen (hypoxia) in some important waterways.

Since oxygen will react chemically with many other substances, it is necessary to find methods to prevent the two coming into contact under some circumstances. This has helped to stimulate the creation of rust proofing and vacuum packing technologies. The opposite use of such technologies has been used in providing pressurized cabins that have enabled flight and space flight at high altitudes. As air pollution has intensified in the modern world, particularly in urban environments, increasing numbers of people have been suffering from asthma and similar conditions and have sought relief from inhaling oxygen. Pure oxygen for sale has become a feature in supposedly chic urban cafes.

Ozone and Ozone Depletion

OZONE (O_3) IS a form of oxygen that forms naturally in the atmosphere and also as a result of some electrical activity. It has a characteristic odor and is an irritating and toxic gas at even low concentrations. Ozone plays a vital role in shielding the surface of the earth from damaging ultraviolet radiation. In recent years, ozone has become increasingly depleted as a result of the emission of man-made chemicals into the air. Fears of widespread damage to the ozone layer—which some believe have led to such diseases as skin cancer—have prompted concerted action to repair the problem.

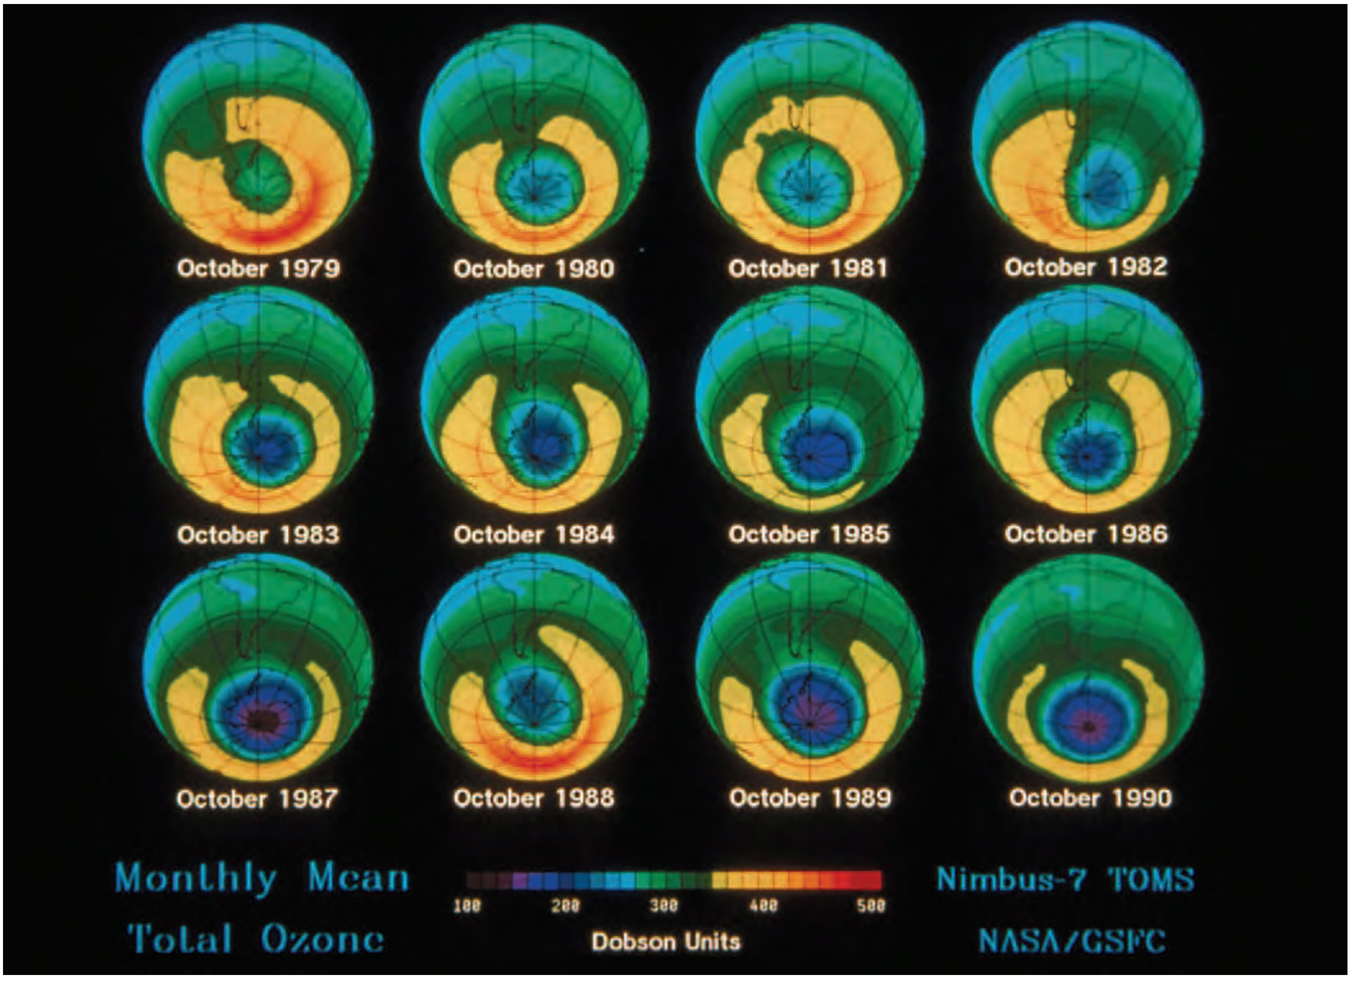
Ozone is present in the stratosphere, which is a layer in the atmosphere from 10 to 50 kilometers above the surface of the earth. This is the height at which airplanes are flown. Ozone in the stratosphere acts as the primary shield against ultraviolet (UV) radiation. Without ozone, severe cellular damage to nearly all forms of life on earth would result. In humans, UV radiation darkens the skin and destroys cells depending on the position within the UV spectrum it occupies. UV radiation is defined as being between 40 and 400 nm, which occupies the space between X-rays and visible light. Excessive UV radiation can lead to the formation of skin cancers and cataracts, in addition to sunburn (erythema).

By passing an electrical discharge through a stream of normal, diatomic oxygen (O_2), ozone may be manufactured. It has a number of industrial applications, including chemical oxidation, organic syntheses, and water disinfection. It can decolorize and deodorize a number of substances, which is useful for consumer goods. Depending on the presence of certain other catalysts, ozone may rapidly decompose at everyday temperatures or at the boiling point of water and above. This and the toxicity of the gas mean that it must be handled with some care.

The amount of ozone in the stratosphere has historically been constant, although processes of formation and destruction of individual ozone molecules is continuous. The total amount has varied within predictable and fairly well-established levels, depending on changes in seasonality and latitude and on the changing prevalence of sunspots. However, it has become increasingly obvious in recent years that the depletion of atmospheric levels of ozone has exceeded all known precedent and may have reached a level beyond which natural restorative processes will replenish it. The reason for this is due to the release of chlorofluorocarbon gases (CFCs) into the atmosphere. CFCs have been used in consumer goods and industrial applications since their development some 50 years ago. They are customarily low in toxicity, nonflammable, and stable and of great value as refrigerants, solvents, and fire retardation agents, among other uses.

Unfortunately, it is the stability of these compounds that causes the problem as it permits the

Despite measures to ban CFCs, the amount of ozone loss is still reaching record levels. According to the most recent data, the ozone layer hole will reach an unprecedented size each year until 2018.



chlorine-bearing compounds to be released into the atmosphere when the substances begin to deteriorate. Although chlorine has been extensively used in human society in such applications as hygiene in swimming pools, this chlorine does not reach the upper atmosphere because it quickly reacts with water in the atmosphere and falls in the form of rain. CFCs are instead driven through the atmosphere by wind action and may pass into the stratosphere. Intense UV radiation can cause the CFC molecules to break down and release chlorine into the upper atmosphere. The chlorine acts as an extremely effective destroyer of ozone; as many as 100,000 molecules of ozone can be destroyed by a single chlorine molecule.

Prevailing winds and usage patterns determine that the flow of CFCs are concentrated more in some areas rather than in others. In 1985, a group of scientists led by Joe Farman, Brian Gardiner, and Jonathan Shanklin published research showing that a hole in the ozone layer had been detected over Antarctica. Subsequent research has shown that the hole appears on an annual basis and has been growing. At its greatest extent, the hole over Antarctica grew to a size that was the equivalent of more than three times the land area of the United States. Clearly, if the hole were to reach heavily populated areas, its impact would be disastrous.

The discovery of the hole led to the creation of one of the first global environmental treaties, the Montreal Protocol of 1987, which bans the production of CFCs. Gradually, the use of these chemicals has been phased out with old kitchen appliances such as refrigerators. Determined efforts have led scientists to predict that the hole is in the process of being repaired and could be fully restored by as early as 2050, assuming current trends continue. Despite measures to ban CFCs, the amount of ozone loss is still reaching record levels. Some 40m tons of ozone have been lost in 2005–06, showing that the ozone layer hole will reach an unprecedented size each year until 2018, according to the most recent data.

At that point, its overall size can be expected to decrease in size and significance. As the Montreal Protocol demonstrates, it is possible for determined human activity—cooperating together and coordinated at the state level—to tackle important, large-scale environmental problems. This may be seen as symbolic of the possibilities of the fight to restore the earth from the dangers of global climate change.

Pacific Ocean

THE PACIFIC OCEAN is one of the largest regions of the world. It spans from roughly 120 degrees east longitude eastward to 90 degrees west longitude for a total span of 150 degrees of longitude, covering almost half the globe. The Pacific Ocean also comprises nearly half the surface area of the earth's oceans. As a geographic region, it spans the Pacific Islands from New Guinea (including both the independent state of Papua New Guinea and Indonesia's Irian Jaya) eastward to Easter Island and Hawaii. Midway Island marks the northernmost island in the region. New Zealand is sometimes considered to be part of the Pacific Region due to its cultural affiliation with Polynesia, but is normally grouped with the Austral Region. The rest of Indonesia and the Philippines are typically considered to be part of Southeast Asia.

With the exception of the continental island of New Guinea, the region is dominated by volcanic high islands and atolls. Despite its vast spatial expanse, the region only hosts a population of roughly 8.5 million people (about 0.1 percent of the world's population) by 2005 estimates. Nevertheless, the region comprises roughly one-fifth of the world's 200-mile coastal exclusive economic zones. The island nations of this region thus have strong claims to fisheries and mineral rights in the region. However, most of these island nations are less-developed nations with little means of enforcing their fishing laws and illegal fishing is common. The fisheries of the region are at risk from overfishing, largely in conjunction with tuna fisheries.

The vast expanse of oceans and predominance of islands has exerted a strong influence on the biodiversity of the realm. The oceans act as filters limiting the numbers of species that are able to disperse between islands, and the relative isolation of the islands gives rise to the evolution of unique biota. Prior to human colonization, the terrestrial species in the Pacific dispersed eastward across the region. In terms of flora, the Pacific's plants show greater similarity to those of Southeast Asia, and hence the region is considered to be part of the Paleotropical Realm.

There is only one genus of mammal native to the region, fruit bats (*Pteropus*), and the fauna of the region is dominated by birds deriving from the area around Papua New Guinea. The Pacific is therefore classed as part of the Austral Realm in terms of its fauna. Given that these are island ecosystems, many of which lacked predators, many bird species evolved out of their ability to fly, leaving them vulnerable to extinction once humans and associated introduced species arrived.

The Pacific region was among the last areas of the globe to be colonized by humans. Although humans had settled into New Guinea and Australia by 40,000 years ago, and had settled into the nearby Solomon Islands by 28,000 years ago, eastern Melanesia (Vanuatu to Fiji), western Polynesia (Tonga and Samoa), and Micronesia were not colonized until roughly 3,500–3,000 years ago. Eastern Polynesia (Society Islands and the Marquesas) was settled roughly 2,200 years ago, and the outermost extremes of Polynesia (Hawaii, Easter Island and New Zealand) between 1,700 and 1,200 years ago.

The immediate impact of ancient human colonization was to transform landscapes and alter species composition of the islands. Polynesians introduced many terrestrial mammals to the Pacific Islands. Pigs and dogs were the primary economic mammal species introduced from outside the region, and rats the primary accidental introduction. Rats especially have been implicated in the extinction of many native and endemic bird species through predation, although human consumption and habitat conversion played a role as well.

The ancient Polynesians introduced many cultivars into the islands, such as taro (*Alocasia esculenta*), and also transported island tree species that were native to one portion of the region to other islands, such as *Pometia pinnata*, which had value as a famine crop. The total collection of all cultivar and forest species that the Polynesians dispersed among the islands is referred to as "transported landscapes." Although the conversion of habitat and introduction of species between islands has been detrimental to endemic species of these islands, many of these introduced species have become naturalized into the native flora.

There are examples, especially from Eastern Polynesia, where the extensive removal of forest cover has resulted in ecosystem collapse followed by collapse of the human societies that depended upon them (Easter Island being the most extreme example). Other Polynesian societies, such as Hawaii, recovered through implementing more intensified agricultural techniques, such as terracing, which helped stabilize soil erosion, among other benefits.

European contact and colonization saw the introduction of many new animal and plant species, accompanied with expansion of habitat loss in conjunction with market linkages. As a result, the South Pacific is considered to be among the most at-risk biodiversity hot spots in the world. Other environmental concerns involve global warming, especially as related to sea level rise (atolls, the predominant island type in Micronesia, with their highest elevations only a few meters above sea level, are especially vulnerable), and loss of coral reefs due to warming ocean waters (both in terms of biodiversity and subsistence for village economies). Conflicts arise over land use practice resulting in habitat loss, detrimental impacts of extractive activities by foreign companies, and perceived insensitivities to the needs of island states on the part of the cosmopolitan core countries in regard to climate change.

Packaging

PACKAGING IS ANY form of material or process used to prepare goods for distribution and sale in the market. It includes tin cans, paper and plastic bags, polystyrene balls, and high-tech covering for human organs transported from one hospital to another for transplanting. From a business perspective, there are many reasons for using packaging. The first and in many cases most important of these is to protect perishable items, such as eggs, from being damaged. A second reason for packaging is to provide needed information for consumers and retailers. This includes guidelines for use in the case of pharmaceuticals, ingredient lists and nutritional information for food items, and advertising for point-of-purchase sales promotion. Increasingly, consumer groups and others are putting pressure on governments to improve the amount and quality of such information on packaging.

The use of tin in the United States on a large-scale basis dates to the American Civil War (1861–65), when the mobilization of large numbers of soldiers required industrialized catering and stimulated the mining of tin in British Malaya and elsewhere. However, packaging has been used since the very earliest days of trade, as items were transported from community to community in clay amphorae or wrapped in banana leaves or other natural items. Ethnic minority groups prior to industrialization have shown considerable resourcefulness in using leaves, bamboo, and other plant or animal parts to create containers and other forms of packaging. These materials have the advantage of being mostly reusable, and rarely have negative environmental impacts when discarded. Even so, excessive use of particular items can lead to unsustainable practices.

The Industrial Revolution and subsequent internationalization of production and distribution massively increased the amount of packaging produced and used around the world and sparked the search for solutions that were lower cost and provided regularity of supply. This led to the exploitation of polymer—long molecular chains with properties suitable for creating moldable products—that were produced as plastics of various types from hydrocarbon by-products. Industrial processes soon found ways to mass produce plastic items in great numbers and at very low cost, and these were attractive to manufacturers and retailers, especially when methods of introducing lettering and graphics on plastic bags were developed. Advertising opportunities on such bags have encouraged redundancy of packaging.

The nature and extent of forms of packaging depend on cultural and geographical considerations. In urban environments such as Australia and the United States, people customarily have spacious housing and travel by car to supermarkets. In these cases, shoppers will buy large amounts of products in large containers or multiple unit packs. By contrast, people living in Hong Kong or Japan, where living space is at a premium, purchase items in much smaller unit sizes and numbers. Manufacturers and retailers must retain flexible packaging systems that can cater to these different requirements. The use of different languages, as mandated by governments importing manufactured items, also causes firms additional expense.

The amount and type of packaging has provoked considerable controversy because of concerns about the waste of resources and the impact that packaging has upon the environment. Some forms of packaging may be biodegradable, but many plastic shrink wrappings and bags remain in a similar form for extended periods. If the packaging is not dealt with effectively, it then contributes to pollution and negative health outcomes. In Bangkok, the propensity for people to throw plastic bags away in the street means they are caught in the canal and drainage system and contribute to flooding during the monsoon season, and the spread of waterborne diseases in the floods. Plastics have negative effects on waterways, rivers, and oceans, damaging and poisoning marine life. Even organic packaging material can contribute to problems.

The main methods taken to tackle the overuse of packaging or the use of unsustainable forms of packaging have included consumer education, recycling campaigns, and regulation and taxation of undesirable products. In developed countries, particularly in Europe and East Asia, most people have become aware of these issues and increasingly participate in systems in which shoppers provide their own reusable shopping bags and shops do not routinely give away plastic bags but will offer them for sale if requested. Using this system has helped in improving the quality and beauty of public spaces in cities such as Taipei. Meanwhile, recycling campaigns in the United Kingdom require most residents to sort their rubbish into one of several categories, including the kinds of plastic bags most commonly associated with packaging. Different categories have color-coded or day-coded means of collection and local councils are responsible for enforcing compliance.

No matter how intense or well-focused government or community support is for the reduction of packaging problems, there are still strong motivations for business to continue to use it extensively. As long as production and ultimate consumption remain separated by wide distances, goods will need to be protected to retain freshness and quality. In modern business, most consumer goods companies also rely on intangible assets such as brands and reputation for the bulk of their profits, and these are sustained by reminders of corporate identity, for which packaging is the most suitable medium.

Pakistan

PAKISTAN IS A low income country in the northwest of the economically poor region of South Asia. For about 200 years prior to 1947 all of South Asia was either directly or indirectly under British colonial rule. When the colonial rule ended in 1947, the British partitioned their possessions in the subcontinent into the two sovereign states of India and Pakistan along religious lines. The modern state of India was predominantly Hindu, while Pakistan was predominantly Muslim. Pakistan has four federating units, Sindh, Punjab, North Western Frontier Province (NWFP) and Balochistan. Pakistan also holds a third of the disputed mountainous region of Kashmir. From the very outset, Pakistan has faced a range of environmental and resource based challenges including, water resources management, environmental hazards (primarily floods, droughts and earthquakes), land degradation, deforestation, rural poverty, and rapid urbanization.

The most important physiographic feature of Pakistan is the Indus basin and its five eastern and one western tributary river. More than 90 percent of Pakistan’s population resides in the Indus Basin, which has almost all the arable land of the country. Also, being a predominantly agricultural country, close to 70 percent of the population of the country directly or indirectly depends upon agriculture. Irrigated agriculture is the backbone of Pakistan’s agricultural economy. The Indus Basin is home to the largest contiguous surface irrigation system in the world covering approximately 16 million hectares. The irrigation system has enabled the largely semiarid country to have significant increases in agricultural productivity. Most of the agricultural productivity has, however, been achieved by increasing the total irrigated area and not by increase in per unit area yield of crops. Nevertheless, green revolution, high-yielding seed varieties coupled with surface irrigated area expansion have allowed the country to be a major producer of cotton, rice, and to a lesser extent wheat and other food crops.

The contribution of irrigated agriculture to total agricultural production is undeniable. However, the Pakistani irrigation system has been characterized by chronic issues of conveyance inefficiencies, inequity in water distribution, water pollution, and irrigation related water logging and salinity. Pakistan’s irrigation system is gravity based where water, diverted from the main stem rivers, flows by gravity to main canals, then to tributary canals, then to individual village water courses. Most of the canals and water courses are unlined, resulting in high seepage losses. The seepage losses in fresh groundwater zones are generally retrieved by farmers by tubewells and water pumps. In brackish groundwater zones, the water becomes unusable once it mixes with the brackish groundwater.

The pervasive water seepage from irrigation channels also leads to raising of the water table

Constantinos Doxiades and Islamabad

The city of Islamabad, the capital of Pakistan since 1967, was designed by the Greek architect and urban planner Constantinos A. Doxiadis (1913–75). His father was a pediatrician who later served as Greece's minister of refugees. Doxiadis graduated from Athens Technical University in 1935 with a degree in architectural engineering, then went to Berlin, where he earned his doctorate from Charlottenburg University.

In 1937 Doxiadis was appointed as the Chief Town Planning Officer for the Greater Athens area, and also headed the Department of Regional and Town Planning in the Ministry of Public Works. As a corporal in the Greek Army, Doxiadis worked in the resistance to the Axis powers, and was a member of the Greek delegation to the San Francisco Peace Conference in 1945. He was subsequently Greece's representative in its dealings with Britain, France, and the United States on matters of Greek postwar reconstruction. Doxiadis then held a number of minor government and diplomatic posts, founding Doxiadis Associates in 1951.

Constantinos Doxiadis was one of the most prominent of the urban planners involved in the ecumenopolis concept, or the movement known as Ekistics. Also known as "high modernism," it led to his plan for building Islamabad in sectors, each containing subsectors separated by parks forming a "green belt." With a strong emphasis on open space and greenery, Islamabad contrasted with Pakistan's previous capital, Karachi. Constantinos Doxiadis died on June 28, 1975, and the Doxiadis Foundation was established in his memory.

which at times can reach the surface, causing waterlogging of the soil. The groundwater on the surface can subsequently evaporate, but as it evaporates it deposits the salts it leeches from the ground by capillary action on the surface. The deposition of a salt layer on the surface through this process is called salinity. Both waterlogging and salinity render the land unusable for agricultural purposes. Every year Pakistan loses thousands of acres of land to waterlogging and salinity, necessitating either abandonment of the land, or expensive groundwater drainage projects.

Strong inequities in water distribution have also been documented in Pakistan. The gravity-based system along the water course is the arbiter of how much water is available. Those at the tail end of the course are typically at a disadvantage in such a system. Recent research on the system demonstrates that it is typically the small and poor farmers, located at the tail end of water courses, who do not get access to water not just because of their location but also because of stronger and richer farmers stealing water through illegal outlets or out-of-turn irrigation.

Groundwater has been significantly developed in Pakistan. In the Indus Basin much of the surface irrigation scarcity has been compensated for by the sinking of electric tubewells and diesel pumps. But the cost of such pumps is very high and only prosperous farmers can afford them. Out of the Indus Basin, primarily in the highlands of Balochistan, groundwater is the only source of water for agriculture and domestic use.

Historically in Balochistan, the ancient karez irrigation system was the main means of groundwater exploitation. *Karez* is an underground water channel starting from a mother well dug directly into the water table. The underground channel is connected by a series of wells, and the water flows by gravity until it reaches the surface, and from there it can be used for irrigation. *Karez* requires a high degree of labor for maintenance and the society had developed well-articulated modes of social organization around the *karez* system. Since the introduction of the tubewell in the arid highlands of Balochistan, the *karez* system is increasingly being replaced by tubewells. Only the richer farmers can afford the them and subsidized electricity for tubewells is inducing those farmers to overexploit the use of groundwater, leading to increasing extinction of *karezes* and abandonment of farms by small farmers who depended on *karez* water.

Back in the Indus Basin, in addition to issues of equity and efficiency, surface irrigation water is increasingly polluted by runoff from farms using of chemical fertilizers and pesticides to maintain yields. Water pollution from agricultural runoff is being compounded by industrial runoff from the growing urban areas of Pakistan. Some of the tributaries of the Indus, for example the upper reaches of the Ravi River by the city of Lahore, are biologically dead because of industrial pollution.

Poor water quality in the Indus basin is accentuated by excessive withdrawal of water for irrigation. Almost 75 percent of the inflow of water into the Indus Basin is withdrawn for agricultural and industrial use, with the result of the Indus delta being under serious threat from salt water intrusion, as are the fisheries and the communities that depend on those fisheries for livelihood. Construction of additional storage structures, in addition to the existing two dams on the Indus Basin rivers, is highly controversial. Furthermore, by the Indus Water Treaty, Pakistan signed away the flow of the three eastern tributary rivers of the Indus to India, accentuating the need for compensatory water infrastructure on the western rivers.

Many of Pakistan's environmental concerns are the outcome of slow development by government and society.

Environmental hazards are another challenge for Pakistan. Powerful earthquakes in northwestern Pakistan have caused significant loss of life and property in recent years. Much of the losses are the outcome of culturally and environmentally inappropriate construction, corruption in the construction of public buildings, and human habitation in vulnerable areas. Flood hazard is another chronic hazard in the Indus basin. Almost every year varying degrees of loss of crops, property and lives are experienced due to flooding. Because of excessive withdrawal of water from the river channels, many channels have lost their original capacity levels, leading to increased flood peaks from even moderate precipitation.

Overall, many of Pakistan's environmental concerns are the outcome of slow development by government and society. Development, narrowly defined as a replication of the West's development trajectory, is leading the country to make excessive demands on its fragile resource base. Also, the complete reliance on modern technology to the neglect of social and environmental considerations is likely to accentuate environmental challenges in the short- to medium-term, unless there is a paradigm shift toward more democratic, socially-responsible and environmentally-friendly conceptions of development.

Paleoclimatology

PALEOCLIMATOLOGY INVOLVES THE reconstruction of past climates prior to the instrumental period. Paleoclimatology focuses on: (1) describing past climates, (2) understanding the natural and anthropogenic processes responsible for these patterns, and (3) using this knowledge of past climates and climate dynamics to identify and understand potential responses to climatic forcing. Detailed views of the modern climate can be obtained using available instrumental records and documentary or historical sources of information, but their short temporal resolution and/or sparse spatial coverage limits their ability to capture the variability that is inherent in the climate system. Paleoclimatology, therefore, extends instrumental and historical records further back in time, enabling the capture of a greater range of variability. This enhances not only our understanding of climate variability in terms of mean conditions, extremes, and states, but also improves insight into the dynamic forces controlling the operation of the climate system.

Examples of research areas that interest paleoclimatologists include: abrupt climate change, hydrological variability, land-cover change, sea-level rise, and modeling the potential response of the climate system to natural and anthropogenic forcing. Paleoclimate research methods involve the testing of specific hypotheses such as how to identify the forcing mechanism(s) or drivers responsible for specific climate events that occurred in the past (for example, the Dust Bowl, Little Ice Age, mid-Holocene aridity in central North America, and the Younger Dryas). One important field of paleoclimate research centers on identifying potential surprise behavior in the climate system, the mechanisms responsible for these nonlinear responses, and ultimately the impacts that may result.

Paleoclimatologists extract paleoclimatological data from a plethora of natural archives, or proxies, such as corals, ice cores, marine and lake sediment, tree rings, and spleothems. For example, ice cores recovered from alpine glaciers located in South America, Africa, and Central Asia and high latitude ice sheets located in Greenland and Antarctica have provided detailed records of atmospheric trace gas concentrations (CO_2, CH_4), temperature (O_{18}, δD), storminess (dust), and volcanic eruptions (SO_x) extending back over hundreds of thousands of years. The European Project for Ice Coring in Antarctica (EPICA) recently completed an ice-drilling project at Dome C, Antarctica that provided a climate record spanning the last 740,000 years. The data from Dome C suggests that a tight coupling between trace greenhouse gases and Antarctic temperature variations has existed for the last four glacial cycles (420,000 years).

Paleoclimate research is increasingly utilizing global and regional climate models to generate simulations of past climates and evaluate the role feedbacks play in the different climate subsystems (atmosphere, ocean, land surface, sea ice, and land ice) at various spatial and temporal scales. A recently completed study, the Paleoclimate Modeling Intercomparison Project (PMIP), systematically assessed the ability of the current generation of general circulation models (GCMs) to simulate past climates that differed significantly from present climate conditions. The output from these models was directly compared to biophysical and geochemical proxy records to evaluate how well models can simulate past conditions. Studies such as PMIP demonstrate that the current generation of general circulation models (GCMs) can simulate known past climatic conditions and events with skill, strengthening their ability to predict future climate change.

With respect to temporal scales, the paleoclimate record reveals that earth's climate varies on a number of different timescales: long-term (106 years), medium-term (104–105 years) and short-term (101–102 years). Long-term changes are generally associated with changes in the distribution of landmasses on the earth's surface, often referred to as continental drift, but more aptly described as plate tectonics. For example, the movement of landmasses from the equatorial region approximately 300 million years ago (Gondwana) to the poles facilitated the development of high latitude ice sheets and led to the last Great Ice Age. Changes in ocean circulation and orogenesis also operate on a similar timescale and impact climate globally. For example, the uplift of the Himalayan and Tibetan Plateau resulted in the development of the Asian monsoon, which affects global atmospheric circulation patterns.

Medium-term changes are associated with the periodic global expansion and contraction of glaciers during the last 2.8 million years (Pleistocene). The cyclical expansion and contraction of alpine glaciers and large continental ice sheets, with an overall periodicity of approximately 100,000 years, has been linked to astronomical forcing. The CLIMAP (Climate: Long-range Investigation, Mapping, and Prediction) Project and SPECMAP (Spectral Mapping Project) helped identify that variations in the earth's orbital parameters (orbital eccentricity, precession of the equinoxes and obliquity) were responsible for the dramatic glacial-interglacial cycles evidenced globally in marine and ice core records. Short-term alterations in climate are associated with changes in the concentration of atmospheric trace-gases, such as CO_2 and CH_4, changes in solar output, and variations in volcanic and anthropogenic aerosol forcing. It appears that slight changes in solar output may explain much of the variability evidenced in the climate system during the past 1,000 years, but the rate and magnitude of warming experienced during the 20th century strongly suggests that this variation has been amplified by human activity.

With nine of the warmest years on record (global land temperatures) having occurred since 1995, global climate change has become part of the lexicon. Changes are occurring in many of the climate subsystems, and many of these changes can be attributed, in part, to anthropogenic forcing. From variations in storm frequency and intensity, to the future of coastal communities and settlements, to changes in local and regional ecosystems, paleoclimatic records provide context and evidence regarding the potentially deleterious effects of climate change.

Questions still remain, however, regarding the degree to which human activity can be implicated as a forcing factor responsible for the modification of the behavior of the climate system. The value of the paleoclimate record lies in its ability to provide a broader context, that is, sufficiently long records to circumscribe baseline conditions and facilitate separating human-induced climate change from natural cycles. It is only with this longer-term perspective that the full range of variability that exists within the climate system can be captured; this will improve the understanding of the dynamic forces controlling the operation of the climate system.

Paleoecology

PALEOECOLOGY IS THE study of extinct organisms or groups of organisms in relation to their environments by means of their fossil records. Through these records we can discover how ancient plants and animals lived, fed, bred, and died. By studying them, we can relate their environments to ours, and try to understand how the world changes with time. Modern paleoecology is a branch of paleontology, the study of fossils. The study of fossils begins with asking four basic questions about fossils: What are fossils? In what time frame did this fossil live? From what organisms did this fossil descend from, and what organisms did it give rise to? Who originally discovered this fossil? Paleoecology begins by asking all of the above questions plus two more: How did the animal originate, and where did it originate? Paleoecology seeks answers to these two most important questions. Thus, paleoecology is the study of the habits and habitats of living organisms from the time they first appeared on earth.

Uniformitarianism is one of the main methods and basis of geological reasoning used by paleoecology. The basis of uniformitarianism is a simple one: study the present environment and its organisms, establish a relationship between them, and then deduce the environment of the past by studying organisms living at that time. We can make educated guesses about ancient environments by studying environments of similar present-day organisms. For example, we know that modern day tropical waters support reef corals within a very restricted range of tolerances, so we can safely assume that ancient reef corals lived under similar conditions in the past, also taking into account the change in lifestyle of reef corals with the passage of time. We can also apply uniformitarianism to the fossil's organic associates. Organic associates can provide a great deal of information about an organism like its eating habits and the type of weather it thrived in.

While uniformitarianism is a powerful tool in paleoecology, it does not apply when no comparisons are available between ancient organisms and modern-day life forms. This is when we make deductions based upon morphology (shape) of the fossil. In other words, when we come across fossils of extinct organisms like trilobites, we have to examine their shapes to make deductions of their lifestyles and their environments.

Another simple but useful tool to study ancient environments is to observe the orientation of fossils as they are found in rock or soil. We are immediately faced with three questions: Is this the natural position of the organism as it walked in life? Is this the natural position of the organism as it lay on the ground or sea floor upon dying? Is it the position in which the dead body of the organism fell? By studying such orientations, we can find out whether the animal lived under water or on land.

Palestine

ORIGINALLY, PALESTINE WAS a geographical term describing an ever-shifting area between the Mediterranean Sea and Jordan River Valley. First controlled by the Romans, it was then ruled by successive empires. By the time of Ottoman control, Palestine was no longer a distinct territory. Palestine reemerged during World War I, denoting an area similar to historic Palestine that was seized from the Ottoman Empire and occupied by Britain in 1917. In 1920, Britain was given the Mandate for Palestine, which incorporated the Balfour Declaration promising the area to both the Jewish people and Palestinians. In the void left by the 1948 British withdrawal, the state of Israel was declared, and subsequent political and military events effectively ended Palestine's existence as a geographically defined entity. Although various wars and partition plans failed to establish a Palestinian state, some still use the term to refer to the Gaza Strip and West Bank, which are administered by Palestinians.

Palestine has many diverse climates: semiarid, temperate, subtropical, and mountainous. Gaza and northward, the Jordan Valley, and the Negev highlands each have their own distinct crops, creating year-round growing seasons and high biodiversity. However, a natural lack of nutrients and high salinity has limited marine life on the shores. Historically, Palestine was among the more prosperous and fertile areas. Crops, such as cotton, cereals, olives, and grapes, were produced in mass quantity and shipped to other areas. With the creation of the British Mandate, population increases put new strains on local resources causing escalated violence. Needing to feed and settle immigrants, Jewish groups primarily created agricultural settlements. The influx brought northern European flora and fauna to Palestine. Some survived, others died, and the rest became hybrid species. New residents also led to the displacement of Palestinian peasants from the land, often causing violent outbursts against the British, Jewish settlers, and Arab nobility.

Political problems and social conflicts influence access to resources and the quality of the environment. The Gaza Strip, only four to five miles wide, is among the most densely populated areas of the world, causing rapid urbanization and placing great strain on the environment. Further, there are few natural resources, most of the agricultural land has been confiscated, and other countries sometimes limit access to resources. For example, international treaties, such as the Camp David Accord, reduced Palestinian fishing rights. The Israeli army has uprooted thousands of olive and orange trees because they obstruct visibility, although the Israeli government spent millions to plant trees. Nonpolitical problems have also caused environmental damage. Overhunting and climate change have led to extinctions and a reduction in biodiversity. Attempts have been made by some Israeli and Palestinian conservation and aid groups to improve environmental conditions. Despite these efforts, with the construction of a security wall and the political unrest in the area, the future for Palestine is uncertain.

Panama

THE REPUBLIC OF Panama is an irregular 30,193-square-mile (78,200-square-kilometer) strip of land connecting Costa Rica and Columbia. Early in the 20th century, the United States backed Panama in seceding from Colombia, paving the way for the construction of the Panama Canal, which provides a gateway between the Atlantic and Pacific Oceans by way of the Caribbean Sea. By the end of the century, the United States had relinquished the canal area to the Panamanians in compliance with the original treaty.

Panama's natural resources include copper, mahogany forests, shrimp, and hydropower. With a per capita income of $7,300, Panama is ranked 109th in world incomes. Some 37 percent of the 3,039,150 people live in poverty. Even though the unemployment rate is 8.7 percent, Panama has a serious shortage of skilled labor. Approximately 21 percent of the workforce are involved in agriculture. Nine percent of the population lack access to safe drinking water, and 28 percent have no access to improved sanitation. The United Nations Development Programme Human Development Reports rank Panama 56th on general quality-of-life issues.

Bordering on the North Pacific Ocean and the Caribbean Sea, Panama has 2,490 square miles (6,449 square kilometers) of coast. The tropical maritime climate is hot, humid, and cloudy. The rainy season lasts from May to January and is followed by a five-month dry season. The interior terrain of Panama is made up of steep mountains interspersed with upland plains. Land along the coast varies from plains to rolling hills. Panama occasionally experiences severe storms, and forests fires are a constant threat in the Darien area in the dry season.

Panama suffers from water pollution caused by agricultural runoff that is also threatening fishing. The depletion of the tropical rain forest is of major environmental concern, as are land degradation and soil erosion. Some 57.2 percent of the population live in urban areas where air pollution is a serious issue. Mining industries have proved to be the biggest polluters in the country. Currently, 38.6 percent of the land area of Panama is forested, and the government has protected 21.7 percent of the land. Panama's forests contain more species of wildlife than any other country in the Americas. Of 218 endemic mammal species, 20 are endangered, and 16 of 301 endemic bird species are threatened. In 2006, scientists at Yale University ranked Panama

37th out of 132 countries on environmental performance, placing the country above both relevant income and geographic groups.

The Institute for Renewable Natural Resources, the Ministry of Agricultural Development, and the Ministry of Health share responsibility for regulating and protecting the environment. The autonomous National Environmental Authority assists in developing strategies that promote sustainable development. Under the General Environment Law, these agencies work with the National Council of the Environment to implement and monitor all environmental laws. These laws are based on the principle that prevention should be the goal in protecting the environment. Consequently, environmental audits of all companies are made every three years. Through the National Environmental Council, relevant government ministries develop environmental polices according to the Constitutional Ecological Regime based on the constitution of 1972. Panama participates in the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling. The agreement on Marine Life Conservation has been signed but not ratified.

Panama Canal

IN 1534 THE King of Spain first studied feasibility for a canal in what would eventually become the center of Panama. While the Spanish never constructed this canal, they paved a road with stones to transport gold and other riches on mules. A New York–based company completed a Panamanian rail line in 1855. It carried tens of thousands of gold seekers until a U.S. transcontinental railroad was completed in 1869. In 1880, French companies began construction of a Panamanian canal, but the project was halted in 1887 due to hardship and disease.

In 1903 the province of Panama declared independence from Colombia. An agreement was quickly signed with the United States to begin construction of a trans-isthmus canal. This shipping canal opened in 1914 to connect the Atlantic and Pacific Oceans. An advanced engineering accomplishment, the United States spent $352 million on construction. Fifty thousand unskilled workers, from as many as 50 different countries, and 6,000 engineers and skilled workers, largely from the United States, were employed during construction. Workers routinely worked 10-hour workdays, six days a week. There were dual tiers of pay for gold workers (skilled) and silver workers (unskilled). Although medical records are incomplete, it is believed that 20,000 workers died during the U.S. and French canal-building initiatives combined. In addition to mosquito-borne illness, injuries from dynamite blasts, railroad accidents, and drowning claimed lives.

The canal required significant ecological change, including flooding to form reservoirs that store water for operation during the dry season. An average ship takes between eight and 10 hours to cross the canal, which is approximately 50 miles (81 kilometers) in length. The canal's complex geography includes two artificial lakes. Lake Gatún is one of the largest artificial lakes in the world. Most of the 52 million gallons (197 million liters) of freshwater needed in the canal's three locks originates from Lake Gatún, which is located at 85 feet (26 meters) above sea level. The water moves by gravity, but electricity is needed to open the gates of each lock.

The Canal Zone is 10 miles (16 kilometers) wide. It slices Panama in the middle, separating the east of the country from the west. The Panama Canal, and the entire Canal Zone, was under U.S. administration until December 1999. In 1977 President Jimmy Carter signed a treaty with President Omar Torrijos that began a highly structured and regulated governance transfer process. Although troop numbers have been reduced, the United States maintains a military presence in the Canal Zone, although now in coordination with other countries of the Americas.

Under Panamanian administration there have been technological improvements to the canal and the introduction of a new fee system based on the size and weight of vessels. It is likely that Panama will expand the waterway before it reaches its maximum capacity in upcoming years. Since 1999 more than 100 different studies have been undertaken to improve canal administration, as Panamanian officials restructure operations. It is possible that a third shipping canal will be added next to the two already existing. There have been other upgrades to canal equipment and investment in complementary transportation infrastructure to better link Panama with rest of Central America, such as the recent Centennial Bridge passing over the canal.

Other shipping locations have been considered for "post-Panamax" vessels, modern ships that surpass the size limits of the Panama Canal locks. Each lock chamber is about 110 feet (34 meters) wide and can accommodate boats less than 1,000 feet (305 meters) long. Other Central American locations have been evaluated for either dry or wet canals, including Mexico and Nicaragua, but construction plans have not been solidified. The Suez Canal, connecting the Mediterranean and Red Seas, is considered to be Panama's major competitor. Although it can accommodate larger boats, the Suez Canal does not serve as many routes. With increases in global trade, many smaller world ports are overburdened. Transportation routes utilizing railroads or roads are not as viable as the Suez and Panama Canals, at least in the short term, due to bottlenecks.

Conservation is important in the Panama Canal watershed to maintain water levels needed to transport ships. A central aspect of assuring the necessary water is forest protection in the Chagres National Park, which has received significant funding from international aid agencies. Deforestation in this area would lead to the quick flow of water down slopes and into the ocean. Forests serve to absorb the heavy rains and release water more slowly throughout the year. Deforestation also in-

George Goethals

George Goethals was the U.S. engineer who oversaw the construction and the opening of the Panama Canal. George Washington Goethals was born in 1858 in Brooklyn, New York, and graduated from West Point in 1880. He then joined the U.S. Army Corps of Engineers, teaching civil and military engineering at West Point until 1888. He served in the Spanish-American War as lieutenant-colonel and chief of engineers of the U.S. volunteers.

In 1907 President Theodore Roosevelt appointed Goethals chief engineer of the Panama Canal. A previous attempt by Ferdinand de Lesseps, backed by French funds, had failed, and Roosevelt believed that Goethals had the determination to see the project through. After changing the original plan several times, Goethals used vast quantities of dynamite to blast his way through mountains and finish the canal.

The Panama Canal opened in 1914, a year ahead of June 1, 1915, the scheduled completion date. For his efforts in the project Congress gave him thanks for "distinguished services in constructing Panama Canal." In recognition of his work he was appointed first civil governor of the Canal Zone from 1914–16. Goethals died in 1928; the Goethals Bridge, linking New York City to Elizabeth, New Jersey, is named for him.

creases siltation, which could lead to build up in Lake Gatún, reducing its water storage capacity.

Papua New Guinea

THE INDEPENDENT STATE of Papua New Guinea is located on the eastern half of the island of New Guinea, with Indonesia comprising the western half of the island. The British took responsibility for Papua New Guinea in 1885 but transferred administration to Australia in 1902. Independence was granted in 1975. In 1990, the island of Bougainville revolted, leading to a nine-year conflict and the loss of 20,000 lives. Bordering on the South Pacific Ocean and the Coral Sea, Papua New Guinea has a 5,152-mile (8,295-kilometer) coastline. The climate is tropical with only slight seasonal variation. The staggered monsoon season lasts much of the year, occurring from December to March in the northwest and from May to October in the southeast. The terrain is generally mountainous interspersed with coastal lowlands and rolling foothills. One of the largest swamps in the world is located along the southwestern coast.

The rich store of natural resources includes gold, copper, silver, natural gas, timber, oil, and fisheries. Two-thirds of all export earnings come from mineral deposits, but the cost of developing these resources has prevented serious exploitation. Crime and government corruption also hamper development. Only a small portion (0.46 percent) of the land is arable. Some 85 percent of the workforce are engaged in the agricultural sector, but agriculture generates only 35.2 percent of the Gross Domestic Product (GDP). Only 13 percent of the 5,545,268 people live in urban areas. With a per capita income of $2,400, Papua New Guinea is ranked 171th out of 232 countries in world incomes. Around 37 percent of the population live in poverty even though Australia contributes to the nation's budget. The United Nations Development Programme Human Development Reports rank Papua New Guinea 137th of 232 on overall quality-of-life issues.

As New Guinea and much of Melanesia sits adjacent to the tectonically active Pacific "Ring of Fire," earthquakes are common and often severe. Droughts, mudslides, and tsunamis pose additional threats to the environment and to human lives and property. Due to the high commercial demand for tropical timber, the forests that cover 75 percent of the land area have been depleted, threatening 60 percent of the rain forest.

Heavy pollution is present wherever mining projects occurred because of open cast mining operations and the practice of directly discharging mining waste into water sources. Corals and sea coasts have proved to be especially vulnerable to this deterioration. Other contaminants, such as Polychlorinated Biphenyls (PCBs), pollute water and soil. DDT, used to control mosquitoes, shows up in samples of mother's milk and marine food.

Environmental threats to human health are very high in Papua New Guinea. Food and waterborne diseases such as bacterial and protozoal diarrhea, hepatitis A, and typhoid fever are common. In some locations, vectorborne diseases such as dengue fever and malaria pose additional risks. HIV/AIDS has also become a problem (0.6 percent). Over 60 percent of the population lack access to safe drinking water, and 55 percent have no access to improved sanitation. Infant and childhood mortality are both unacceptably high, contributing to the 4.1 children per woman fertility rate. Because literacy rate are low (71.1 percent), particularly among females (57.7 percent), the dissemination of environmental and health information is made more difficult. A 2006 study by Yale University ranked Papua New Guinea 96th out of 132 countries on environmental performance,

The Ok Tedi Mine

The Ok Tedi mine is located near a river of the same name in the central part of Papua New Guinea. It was built on a site believed to have the largest copper deposit in the world when it was opened in 1984. The result was a massive economic benefit to the local economy with the town of Tabubil being established—it now has a population of 10,000. Ok Tedi Mining Ltd. was majority owned by BHP Billiton, the world's largest mining company formed from a merger between BHP (formerly Broken Hill Proprietary Company of Australia) and Billiton, a South African mining giant. Since 2002, Ok Tedi Mining Ltd has been majority owned by PNG Sustainable Development Program Limited.

The economic benefits of the mine to both the highlands of Papua New Guinea and the country in general are obvious. However, there has been much criticism over the environmental damage it has wrought. The approximately 2,000 people on whose land the mine was built were well-rewarded for their support with jobs, money, and major infrastructure development, but others nearby who were badly affected were not compensated.

Some 90 million tons of contaminated mine tailings and mine-induced soil erosion pour into the Ok Tedi River each year. With 50,000 people living in about 120 villages downstream of the mine, there have been many complaints over chemicals from the mine killing or contaminating fish and harming all the wildlife associated with the river. Severe flooding has raised the level of the river bed and contaminated plantations of bananas, sago palm, and taro. Copper concentrations in the Ok Tedi River are 30 times the level before the mine was built.

slightly below the relevant income group and considerably below the relevant income group average. Scores were particularly low in the categories of environmental health and biodiversity and habitat. Clan ownership of lands has made it difficult to protect land, and there is no national park system in Papua New Guinea. The country is rich in animal and plant life, including more than 6,000 species of butterflies. Of 214 endemic mammal species endemic to Papua New Guinea, 58 species are threatened with extinction. Likewise, 32 of 414 endemic bird species are endangered.

In 1976, the National Parliament created the Office of Environment and Conservation (OEC) under the Department of Lands, Surveys, and Environment. In 1985, OEC became the Department of Environment and Conservation, charged with promoting sustainable development while advancing environmental responsibility and educating the public. The focus of environmental policy is based on the notion that polluters pay for the damage they do. Local, regional, and international groups are also heavily involved in environmental protection in the country, and projects such as the World Bank's Forestry and Conservation Project offer both funding and expert advice.

Papua New Guinea's commitment to the global environment is demonstrated through participation in the following international agreements: Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, and Wetlands.

Paraguay

THE REPUBLIC OF Paraguay has a long history of political strife. From 1865 to 1870, the country fought in the War of the Triple Alliance, which resulted in the loss of two-thirds of the male population. After decades of economic stagnation, the Chaco War of 1932–35 stripped Paraguay of important land areas previously acquired from Bolivia. At the end of the 20th century, Paraguay threw off 35 years of military dictatorship and held free elections.

With a per capita income of $4,900, Paraguay is ranked 137th in world incomes. Some 32 percent of the 6,347,884 population live below the poverty line. Unemployment is currently 16 percent, and there is a large informal sector that is engaged in the re-export business and various microenterprises such as street vending. Approximately 45 percent of the workforce are involved in the agricultural sector. The United Nations Development Programme Human Development Reports rank Paraguay 88th among 232 nations in overall quality-of-life issues.

The landlocked country has 3,649 square miles (9,450 square kilometers) of inland water resources. Roughly the size of California, Paraguay's climate varies from subtropical to temperate. The eastern section of the country experiences substantial rainfall, but the western section is semiarid. The terrain is also varied, with grassy plains and wooded hills to the east and low marshy plains to the west of the Paraguay River. Elsewhere, the land is dry forest and thorny scrub. From September to June, the southeast is subject to flooding. Because they are poorly drained, the plains are likely to become boggy between October and June. Paraguay's natural resources include hydropower, timber, iron ore, manganese, and limestone.

Environmental problems include massive deforestation, loss of wetlands, and water pollution. Around 17 percent of the population have no sustained access to safe drinking water. Over one-fifth of the people lack access to improved sanitation, and the lack of adequate waste disposal is creating

Migrants to Paraguay

Following the War of the Triple Alliance (1864–70), in which Paraguay fought Argentina, Brazil, and Uruguay, the country was briefly occupied by Brazil. The population and economy had been devastated. The newly discovered 1870 Paraguayan census revealed that as many as two-thirds of the country's population perished in the war. Some books claim that there were only 29,000 men out of a population of 221,000.

To try to rebuild the country, the Paraguayan government encouraged migrants to settle in the country. Francisco Solano Lopez had managed to get some French migrants to come in the late 1850s, but that had been a dismal failure. The new government was keen to attract farmers, and in 1872 a contingent of 888 "Lincolnshire farmers" came out from England. Unfortunately, few of them were actually farmers, and their settlement was a disaster.

In 1887 Bernhard Forster and his wife, Elisabeth (sister of Friedrich Nietzsche, the famous philosopher), organized a more successful German settlement. They established Nueva Germania (new Germany), which continued for a number of years—indeed, some descendants still live on the original farms. Over many years large numbers of other migrants have established "colonies" in Paraguay. These include Australians, Japanese in the 1930s, Russian Mennonites from 1930–32 at "Colonia Fernheim," Poles, Czechs, and many others. Many have prospered and moved to Asunción, Paraguay's capital, or to other countries.

health problems in population-dense urban areas of the south. Around 58.8 percent of land in Paraguay is forested, but the government has protected only 3.5 percent of land area.

The most ecologically significant areas in the country are the Pantanal wetlands, the interior Atlantic rain forest, and the Chaco dry forest. These areas are rich in biological diversity, but the destruction of forests and wetlands has taken a toll. Since the mid-1980s, 19.8 million acres (8 million hectares) of forest have been lost. Ten of 305 endemic mammal species are threatened with extinction, and six of 233 endemic bird species are endangered. In 2006, a study by Yale University ranked Paraguay 62nd of 132 countries on environmental performance, in line with the relevant income group but below the relevant geographic group. The lowest scores were received in the categories of air quality and biodiversity and habit.

The Ministry of the Environment, the Ministry of Agriculture and Livestock, and the National Forestry Service share responsibility for implementing environmental laws and monitoring compliance. Based on an environmental mandate in the National Constitution, Paraguay has a large body of laws designed to protect wetlands and wild areas, implement environmental assessments, and punish those who destroy the environment. However, such laws are not uniformly enforced. In 1999, for instance, the Comptroller General reported that 26,333 hectares of the reserve of the Rio Negro National Park had been illegally allotted to private individuals. Illegal logging continues in defiance of specific guidelines, often with the assistance of government officials.

The United States works with the Foundation for the Sustainable Development of the Chaco Region to provide Paraguay with funding and technical assistance for several areas, including the Biosphere Reserve of the Chaco, the Upper Parana Atlantic Forest (UPAF), and the Northern Block sub-ecoregion of the UPAF. Panama has signed the following international agreements: Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Ozone Layer Protection, and Wetlands.

Parasites

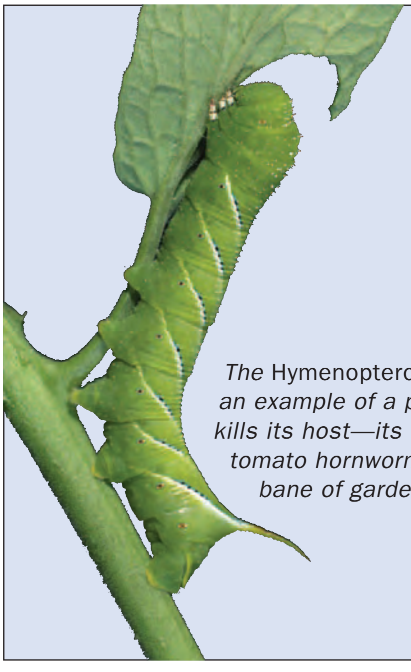
PARASITES OCCUR AMONG virtually all life forms on earth. Almost every plant or animal is subject to parasitism by one or more parasites. Parasitism occurs when the parasite plant or animal lives on or inside of the host plant or animal in order to feed on it. Heterotrophic nutrition is one form of parasitic nutrition. Autotrophic (self-nourishing) organisms synthesize their food either through photosynthesis, or in the case of some bacteria, by chemosynthesis. All animals and fungi and most bacteria feed themselves by some means of nutritional heterotrophy. In the case of animals, they are holozoic heterotrophs, that is, they eat solid particles. In the case of yeasts, molds, or most bacteria, the nutritional form is the saprophytic "eating" of decaying plant or animal matter. Parasites are beneficiaries of the parasitical relationship, usually at the expense of the host upon which it lives or feeds. Some parasites cause little or no harm to their hosts. However, most parasites damage their host. In some cases the parasite may also kill the host. If death occurs from the parasite, the parasitic relationship is called parasitoidism. Parasitoids that kill their hosts include some species of ants, wasps, bees, flies, butterflies, and moths.

Parasites cause a great deal of morbidity among plants and animals. Among humans, parasites cause enormous losses in productive energy. There are millions of human beings, especially in the tropics, who are infected with parasites that prevent them from working at their full capacity. Some parasites such as the *Trypanosoma brucei* cause sleeping sickness in humans. *Trypanosoma brucei* is a parasite of cattle, mostly found in Africa, which is passed to humans by the tsetse fly (*Glossina palpalis*).

There are several other forms of parasitism. Social parasitism is practiced by ants, which herd aphids and exploit them for a secretion that is a food for the ants. Cowbirds and cuckoos practice brood parasitism. They lay their eggs in the nests of other birds that then raise the parasite chick. The chick of the cowbird or cuckoo will usually kill the hatchling(s) of the host bird parents by pushing them from the nest. If a parasite is itself parasitized, the relationship is called hyperparasitism. For example, a hyperparasitic virus may be living on bacteria that are living on a protozoan, which is living in the digestive track of a flea, which is living on a cat.

Parasites can be directly harmful to humans. The parasites that infect human beings begin with the tiniest of viruses. Other parasites in humans include bacteria, single-celled parasites, and multicelled parasites. Common human parasites include pin worms, hook worms, round worms, lice, fleas, ticks, chiggers, yeast infections, and the fungus that causes “athlete’s foot.” In addition, parasites such as fleas may spread diseases like the Black Death (bubonic, pneumonic, and septicemic). Many parasites are spread by fouled water or by animal wastes. Millions of people in the world drink and bathe in streams, rivers, and wells that are sources of parasitic infection. Moreover, many animal and plant foods carry parasites. Usually these can be killed with proper cooking. The U.S. government’s Center for Disease Control estimates that 80 percent of the pathogenic outbreaks in the United States are due to improper food preparation.

An example is trichinosis (or trichinellosis), a painful condition caused by eating meat from animals infected with larvae of the trichina worm (*Trichinella spiralis*). The infection occurs among certain carnivorous and omnivorous animals such as pigs and bears. When the flesh of the infected host is eaten, it infects the new hosts. The larvae mature into males and females in the life cycle of the worm after they are eaten. The adults then breed in the new host and infect its muscles. The larvae cause soreness in the muscles and in humans can be very



The Hymenopterous *wasp is an example of a parasitoid that kills its host—its larvae will eat tomato hornworms, a common bane of gardeners.*

Garden Parasites

While parasites cause misery to millions of people around the world, some forms of parasitism are actually beneficial to humans. For example, the tomato hornworm is a common garden pest that eats the leaves of the tomato plant; however, if a small parasitoid *Hymenopterous* wasp of the Braconid family should lay its eggs on the tomato hornworm, its larva will feed on the hornworm, killing it.

Knowledgeable gardeners allow insect forms of parasitism to benefit their gardens. They make use of predator bugs like praying mantises, spiders, lady bug beetles, lacewings, some kinds of stink bugs, brown damsel bugs (nabid bugs), and pirate bugs.

painful. Infection in humans is rarely fatal, but it causes extreme discomfort.

Parasites can cause significant reduction in food supplies by damaging links in the food chain. Recent studies of food chains have extended the concept to the idea of a food web to express the interlinking of parasites with food chains. Until recently, parasites have not been rigorously included in food chain studies. These new studies have found many more links between parasites and hosts than between predators and prey.

Participation

PARTICIPATION IS AN approach to environmental management and problem solving that solicits groups with locally specific knowledge and skills to contribute to sustainable environmental policies and projects. Sometimes called community-based natural resource management, participation seeks to actively include populations at the grassroots level in access, control, and management of natural resources.

Public participation frequently appears as a framework for facilitating sustainability and actor investment among populations that are (to be) affected by environmental policies. By involving indigenous groups in the creation of management institutions and guidelines, participation is expected to lead to empowerment. Cost and time efficiency are additional benefits to be achieved by facilitating local involvement in projects.

Participation as a precept was codified during the 1992 United Nations Conference on the Environment and Development (UNCED) in Rio de Janeiro, Brazil, as Principle 10, which states: Environmental issues are best handled with the participation of all concerned citizens, at the relevant level. At the national level, each individual shall have appropriate access to information concerning the environment that is held by public authorities, including information on hazardous materials and activities in their communities, and the opportunity to participate in decision-making processes. States shall facilitate and encourage public awareness and participation by making information widely available. Effective access to judicial and administrative proceedings, including redress and remedy, shall be provided.

Principle 10 indicates that participation should be solicited from a variety of actors at many scales (e.g., the state, formal councils, private industry, activists, municipal administrators, consumers, and nongovernmental organizations [NGOs]). It also includes in its definition of participation access to environmental information and citizens' rights to know about potential hazards. Once citizens have this information they are to be included in decision-making processes. The state is also given responsibility for disseminating information to citizens and providing for their access to judicial and administrative processes in relation to environmental issues and citizens' rights.

Compared to "top-down" approaches to environmental planning, participation is expected to increase project success rates and lead to sustainable management practices. Top-down approaches involve allowing powerful groups (e.g., the state or donor institutions) to make decisions without accessing local environmental knowledge or consulting with users' groups. The failure of environmental policies and projects is blamed on lack of community participation and local people's indifference to their success.

Whether participatory approaches are more successful than "top-down" approaches to environmental decision making is debatable, and criticism of participation has grown with its popularity as an approach. Critics argue that participatory approaches are in name only, i.e., there may be much talk about the benefits of participation, but actual public participation is much less widespread. Others suggest that the cost and time efficiencies achieved by participatory approaches are mechanisms that shift state responsibilities onto citizens or lead citizens to self-regulate and monitor.

Another difficulty with participatory approaches is the variety of meanings and practices associated with the term. Participation has been used to validate a range of activities, e.g., justify expenditures, cut operation costs, improve public image, and create new markets. Decision makers and environmental planners may intend stable meanings for *participation*, but these meanings may change throughout planning and implementing phases of environmental management. The opposite problem arises when planners settle on a fixed set of participatory techniques or interventions, which limit flexibility when searching for potential solutions.

TYPES OF PARTICIPATORY APPROACHES

Participatory Rural Appraisal (PRA), Rapid Rural Appraisal (RRA; central to this approach is learning "just enough" from a community to enable decision making and planning), and Participatory Learning and Action (PLA) are names given to participatory approaches in general, and more specifically to techniques and methods of information gathering from local people. Although the term *rural* is in the definition of each approach, its methods are not limited to rural settings.

PRA is founded on the idea that individuals are aware of themselves, their situation, and their problems and, given a chance, they will actively seek appropriate solutions. In contrast to approaches where so-called experts arrive in a community, gather information themselves and then analyze it within their own context, PRA calls for local people to facilitate information gathering and analysis of shared issues among stakeholders. Exercises are often hands-on and action-oriented (e.g., village walks where different types of land use are pointed out and discussed en route). PRA is also intended to facilitate collaborative learning between all stakeholders (not just majority, rich, or powerful groups) and outsiders, who may be state employees, NGO fieldworkers, or development aid donors. PRA uses informal interactions (e.g., brainstorming sessions), mixed group, open meetings, and/or games to draw out community knowledge about resource access and problems from indigenous populations. PRA tools include interviewing, focus groups, preference rankings, mapping, and diagramming. Learning-by-doing, teamwork, and open-ended discussions are central tenets of PRA approaches. Flexibility is key to allowing local knowledge and solutions to surface as part of the process.

PARTICIPATION AS A FORM OF POWER

Flexibility is also necessary if a community participatory approach is intended to address existing power imbalances within and between stakeholder groups. Participatory approaches that accept the status quo in local societies may serve to sustain oppressive power relations existing within communities. Drawing on the work of Michel Foucault, participation has been framed as a discourse and a form of power. In contrast to viewing participation as a set of techniques and then offering advice on better implementation or training, conceiving of participation as a discourse enables participation to be explored for how it is deployed to further or hinder power.

Discourses of participation in different contexts and scales can be interrogated for what they contain and omit, and the ramifications of such inclusions and exclusions for both environments and affected citizens. Within a framework of participation as a form of power, the actions of individuals and institutions, comprising the context in which discourses are created and operationalized, are examined for the ways in which participation might be used in an illegitimate exercise of power. Still further, participation as a form of power interacts with other operations of power. For example, participation combines with patriarchy to reinforce the marginalization of women when participatory approaches address women only in their roles as housewives.

Before participation became popular, approaches to knowledge gathering were criticized for answering the agenda of those who came in from the outside to collect information and for failing to access and question groups on the margins of their communities, e.g., women, the poor. Although participation is now standard as an approach, scholars and practitioners have realized that choices made by local people and participation facilitators are shaped by the relationships and discourses in which they are immersed.

Simply setting a participatory approach in motion may lead to the furthering of a particular environmental agenda held by the facilitators or believed by local communities to be favored by the facilitators. For example, NGO fieldworkers asking questions about forest use may inadvertently steer local people's answers in directions that suit the technical solutions that the NGO can offer. NGO fieldworkers make choices about participatory practices based on constraints and opportunities present within their NGO and the community with whom they are conducting participatory planning. Powerful groups within local communities may try to influence the process. Individuals navigate social pressures within their communities about what to reveal or omit, or whether to speak or stay silent. Strict definitions of participation will not resolve these issues of power. The dynamic social context in which participatory approaches are practiced means that participation will always be influenced by relationships of power.

Participation is also a method of research gathering for scholarly purposes, with many of the same attributes, criticisms, and pitfalls. Ultimately, researchers decide which information is most valuable to report. An analysis of participation becomes further complicated when implementing organizations reflexively begin to take note of their own practices of inclusion and exclusion. Participation may begin as a method imposed from the outside, as part of ensuring long-term resource sustainability. But validating participation as an approach may force organizations to evaluate the treatment of their own employees and examine who has been incorporated and who has been omitted from decision making and planning.

GENDER AND PARTICIPATION

Gendered approaches to participation were also codified at UNCED. Principle 20 states: "Women have a vital role in environmental management and development. Their full participation is therefore essential to achieve sustainable development." Women's participation is widely recognized as critical to sustainable development and environmental management. Women's participatory approaches will access women's knowledge about sustainable environmental practices and draw on women's abilities to protect the environment. In their roles as housewives, mothers, and resource managers, women's participation in resource-use planning will maximize the benefits of intended improvements. Women can also increase project efficiency by contributing their labor.

As the role of the state in resource provision (e.g., water supply) or management (e.g., of forests) has come to be seen as inefficient and expensive, gendered approaches to participation are intended to increase local women's investment in resource control and management. Women's empowerment-through-participation is also sought through a "bottom-up" approach that incorporates women in decision making and planning at its earliest stages. Women's participatory approaches often pursue an agenda of creating lasting social change, e.g., sustainable resource management and social equality through women's participation and empowerment.

Gendered participatory approaches have similar goals to participation in general; but without specific attention to gender, community participatory approaches to natural resource management may increase women's exploitation, constrain self-determined change, and repress local, gendered meanings of resources. Participation may make a difference for women if approaches challenge assumptions about gender, environment, and relationships between women and nature. But participation has been criticized for taking for granted gendered relationships to natural resources, thereby reproducing inequality. Participatory interventions involving natural resources often base themselves on existing gender-resource relations. Women's work and roles involving environmental resources are accepted as the norm, instead of being interrogated for the ways in which they are exploitative. Without calling these assumptions into question, women's work burdens are increased, or their reasons for their practices are misunderstood. Too often women are targeted as a category, i.e., as a unified group with unchanging, essential characteristics, powerless and without agency. Participatory approaches that do not seek to question existing gender roles, nor view women as individuals (e.g., consider class, race, age, etc.) are likely to reproduce existing social inequalities.

Passenger Pigeon

THE PASSENGER PIGEON (*Ectopistes migratorius*) was once probably the most numerous bird on earth but became extinct through an extraordinary case of massive overhunting and habitat loss.

This striking blue-gray pigeon, closely related to the mourning dove, was highly social, living in huge flocks across the great deciduous forests that once covered eastern North America. At the time of the arrival of Europeans, there may have been up to 5 billion passenger pigeons, representing 25 to 40 percent of the entire continent's bird population. Their range stretched from Alberta to Nova Scotia, and south to the Gulf states, covering more than 7.25 million square kilometers. They wintered in the southern states and in the spring made spectacular migratory flights northward to their breeding grounds in the eastern mixed hardwood forests. Migrating flocks over one kilometer wide and 400 kilometers long were commonly observed well into the 19th century. Some great flocks were reported to have darkened the sky as they flew overhead, taking an entire day to pass a single point. Passenger pigeon nesting colonies could contain 100 million birds across 100 square kilometers, with dozens of nests per tree. After breeding season, large flocks of pigeons would move through the northern forests, seeking their preferred food—the mast of beech, oak, and chestnut—but also seeds, berries, worms, and insects.

Passenger pigeons had a significant impact on forest ecology. When hundreds of thousands made a long-term roost in a hardwood forest, they would consume great quantities of acorns and other tree seeds, damage or kill trees with their collective weight, and deposit tons of droppings on the forest floor. It took decades for such areas to recuperate, so the great flocks of pigeons needed vast new areas of hardwood forest each year for food, shelter, and raising their young.

When European settlers cleared the eastern forests for farmland, passenger pigeons began to lose some of the vast woodlands that they needed. It was intense commercial hunting in the 19th century, however, that caused the passenger pigeon to be essentially eaten into extinction.

The birds had long been hunted for food by indigenous peoples. In the 1800s, the demands for cheap food in the growing cities of the east led to large-scale, unregulated hunting for profit. The birds were netted, shot, or gassed with pots of burning sulphur at roost sites. Young squabs were knocked out of nests with long sticks. Tens of thousands of birds were killed daily and shipped in box cars to East Coast markets where they might sell for as little as fifty cents a dozen. Game dealers in New York, for example, took in 100 barrels, or approximately 55,000 pigeons, a day.

Several thousand workers were employed in the pigeon meat industry by 1850. Thousands more were hunters. When observers noted in the 1860s that pigeon numbers appeared to be decreasing, the response was to move further inland to the still game-rich Midwest. Market hunters took advantage of the latest technology, learning the location of flocks through telegraph communications and travelling to nesting sites on the railroad. Season by season, county by county, the "pigeoners" eliminated the birds. One of the notorious last large hunts took place in Petoskey, Michigan, in 1878. Hunters killed over 50,000 birds per day over several months, then tracked and killed the survivors when they attempted a second nesting.

In the 1890s, conservationists pushed for legislation to control pigeon hunting, but it came too late. The gregarious passenger pigeon would only breed well in large colonies. Attempts at breeding the surviving captive birds failed. The last wild passenger pigeon was shot by a 14-year-old boy in Ohio in 1900. The last known bird died at the Cincinnati Zoological Garden in September 1914. The only positive effect of the destruction of the passenger pigeon was heightened public interest in conservation laws. In 1916, for example, the Migratory Bird Treaty was enacted in America and Canada to control the hunting of migratory birds.

Pasteur, Louis (1822–95)

LOUIS PASTEUR WAS a polymath French scientist who made many important contributions to modern medicine, including the use of vaccines for anthrax and rabies. He also contributed to the area of stereochemistry, and the term *pasteurization* carries his name. Pasteur was born the son of a once-indentured tanner and showed early promise as a boy, but primarily in art. He took a second degree in science and then a doctorate, with early work involving crystallography. This work resulted in his discoveries concerning asymmetry within biological molecules and the understanding that the structure of the molecules, as well as their composition, help to determine their properties. This was achieved through dividing crystals into their right- and left-handed states, which were mirror images of each other. Pasteur moved from one topic to the next, steadily progressing through careful science and logical deduction in new but related fields of study.

Pasteur continued his work on molecular asymmetry during his early academic career. When he was appointed dean of the faculty of science at the university in Lille, France, he became involved in the study of alcohol fermentation, since that was an important industry in his new home city. Pasteur's work with asymmetrical molecules had persuaded him that such asymmetry was congruent with the presence of life. Systematic examination of yeasts and other biological inputs helped him to identify the microorganisms that were responsible for impurities that had proven harmful to health and industry. He subsequently determined that heating beer and wine would kill those microorganisms and produce a pure flow of the outputs through the process of pasteurization. His methodical approach led to brilliant results and he was also asked to investigate the silk industry in France, which was close to collapse as a result of two diseases suffered by the silk worms. Pasteur investigated with his microscope and was able to identify the agents causing the diseases and suitable methods for combating them. By helping to create industrial guidelines and supervising the training of workers, Pasteur saved the European silk industry.

Pasteur's work with alcohol fermentation helped him definitively solve the so-called self-generation problem, which had perplexed scientists for thousands of years. This concerned the reason why biological matter should seem spontaneously to come into being, as for example the growth of molds or the eruption of maggots from a corpse. Pasteur identified the presence of microorganisms as instrumental in these events and proved this through systematic experimentation. Using a similar concept as other scientists in the field, he came to the understanding that such microorganisms or germs were responsible for the spread of many diseases and infections. From this understanding and the application of empirical science, Pasteur was able to develop vaccines for anthrax and rabies, among other diseases, that have helped save millions of lives.

Pastoralism

PASTORALISM IS BROADLY defined as a land use system where communities raise livestock, such as camels, goats, cattle, sheep, llamas, or yaks, to make a living. It involves herding on natural pastures and implies that animal husbandry is the dominant strategy in an economic and cultural sense. In reality, pastoralism is more complex to define due to the diversity of pastoralist systems as adaptations to local conditions. The composition of herds, management strategies, and social organization vary significantly between regions. Pastoral societies include the Maasai in eastern Africa, Bedouin in the Middle East, Navajo in North America, Raika in India, Chukchi in Siberia, and Mongols in north-central Asia. There are an estimated 100 million pastoral people worldwide, while Africa has the largest pastoral population with 20 million.

In general, commonly used factors to distinguish pastoral systems are dietary patterns and herd mobility. Pure pastoral systems are those where livestock constitute at least 50 percent of the economic portfolio of a household. Pastoral systems are distinguished by varying degrees of movement of people and herds, ranging from nomadic, to semi-nomadic, to semi-sedentary systems. Nomadic pastoralism is considered the most mobile system, where herders exclusively rely on animal products for subsistence, exchange, and trade. Livestock are not only a source of livelihood, but constitute cultural significance, providing a wide range of functions such as: milk, meat, traction, manure, blood, skin, and religious and cultural meaning. Generally, meat production is a minor component, as this involves killing the investment.

ORIGINS

It is believed that recognizable pastoralist systems date back several thousand years. While the differentiation between wild and domestic livestock in archeological evidence remains challenging, most studies suggest that the presence of domestic cattle goes back at least 6,000 years (for example, in northeast Africa). One of the most prominent views of the origins of pastoralism in the earlier literature suggests that pastoralism is an evolutionary stage in human history, directly derived from hunting and gathering and followed by farming and sedentarization. However, archaeological evidence and historical documents suggest that the origins are more complex. For instance, evidence suggests that agriculture started earlier than pastoralism.

MANAGEMENT

Pastoralists live mostly in marginal areas. They inhabit regions of the world in which the natural environments provide little potential for cultivation due to their rainfall or temperature regimes, or terrain. These marginal areas include drylands, rangelands, savannas, steppes, tundra, and mountains. The natural resource base in pastoral environments is generally characterized by patchiness of resources across time and space. Temporal variation of biomass is closely tied to climatic conditions that are often highly variable and unpredictable; this is particularly true in drylands. Here, vegetation has adapted to variable rainfall by accumulating seed reserves in the soil that germinate when rainfall conditions allow. In cold environments, the limiting factor is temperature and a short growing season restricts access to fodder and requires its conservation for the winter.

The resource management system of pastoralists is considered one of the most effective strategies for utilizing drylands and a well-adapted strategy to sustain human populations in environments with limited resources. The most important component of pastoralist systems is mobility—an adaptive resource use strategy to manage risk by exploiting highly variable natural resources (water and forage). It is aimed at minimizing the effects of drought. A range of other considerations play a role in determining movement patterns: for example, soil conditions, environmental factors (dew, shade, predators), avoiding pests, disease, and damage to crops, proximity to markets, household labor availability, cultural gatherings, territorial boundaries, political insecurity, and social relations. Mobility is determined by a detailed environmental knowledge, and a complex system of rules and regulations that determine whether communities can negotiate access to resources.

Herd management and diversification is also important. Pastoralists keep diverse herds to provide for their needs and to optimally utilize available resources. Diversification increases the range of products and spreads risk. The main aim is to accumulate large herds to have enough females to supply milk. For instance, east African pastoralists commonly keep cattle to provide milk and as a form of investment, and additionally small stock for its meat supply and to be sold on the market. Pastoralist systems can rapidly respond to changing environmental conditions by switching to different strategies (such as other species, or opportunistic cultivation).

SOCIAL ORGANIZATION

The resource management system is closely intertwined with complex social organization that regulates the use of resources. While decisions about livelihood strategies are made at the household level, the community plays a crucial role. Decisions about access to water and pasture are made by the community and animals are often herded communally. Informal and formal institutions govern access to the common resources of pasture and water and act as checks against overuse. Social control mechanisms are enforced through traditional leadership. The concepts of reciprocity and mutual dependence are particularly important during times of scarcity. Individuals will then call upon relatives and alliances in other regions, distributing parts of their herds among them in anticipation of future losses.

PERCEPTIONS OF PASTORALISM

Scientists and policy makers attempted to describe pastoralist systems in the light of three interrelated paradigms—range equilibrium, backwardness of pastoralists, and tragedy of the commons. These paradigms have influenced interventions in pastoral environments. The range model was based on equilibrium, which assumes that livestock density is limited by forage availability that is constant in space and time. When herds expand to exceed carrying capacity, they cause overgrazing and degradation. While this may be an adequate model for temperate zones, it is flawed in its applicability to drylands. The assumptions include that drylands are potentially stable ecosystems, that they are often destabilized by improper use, and that interventions are needed to return these systems to a productive state.

Colonial and postcolonial governments in Africa interpreted pastoralism as a maladaptive, destructive system. Pastoralists' obsessive concern with livestock was called premodern and accused of obstructing development. Policies showed a strong bias toward agriculture, and consequently, pastoralists were relegated to the periphery of economics and politics. Throughout the 1980s the focus remained on the need to modernize and settle pastoralists and turn them into more efficient land users.

Pastoralism was also perceived within the concept of common property resources, coined by Hardin in 1968 as the Tragedy of the Commons. It engages property rights to explain environmental degradation. The Tragedy of the Commons assumes that individual herders maximize profit by fielding as many cattle as possible on common land; this will ultimately lead to overgrazing and stocking densities exceeding carrying capacity. The concept assumes that individuals maximize herd size for individual gains, while bearing only a fraction of the costs imposed on the common resource. Once the resource is exploited, pastoralists avoid the consequences by moving into another area. This scenario led to the conclusion that with limited grazing areas, demographic growth will eventually exceed the carrying capacity of the land.

These paradigms have long been considered a viable way of explaining pastoralism. However, mainly due to the failure of interventions based on these paradigms, they are increasingly questioned. Little evidence actually supports overstocking claims on a wider scale. A new understanding includes that pastoral environments are characterized by non-equilibrium and heterogeneity, that pastoralist strategies are not aimed at maximizing production, and that pastoralism is a sustainable response to harsh environmental conditions. Alternative approaches to common property resources are emphasizing decentralized systems of self-management. Institutions and behavioral norms that have evolved over time in pastoral communities are considered more appropriate than imposing new institutional frameworks.

CONSTRAINTS TO PASTORALISM

Pastoral communities worldwide share a common difficulty of interacting with the state, neighboring land users, and markets. The relationship between them and the state has often been ambivalent, characterized by hostility and suspicion. Pastoralists have become marginalized within national borders due to remoteness from the capital and the segmentation of pastoral groups during the creation of nation-states after colonialism; this has limited their ability to represent their interests at a national level.

The wider economic, ecological, demographic, and political context in which pastoralists operate has significantly changed in recent decades, creating unprecedented pressures and leaving pastoralists more vulnerable. While climate variability is becoming more severe, pastoralists are exposed to more frequent droughts. Their traditional grazing lands are shrinking due to tighter national borders, political conflict, growing competition over land amongst pastoralists, spreading cultivation and conservation areas, urbanization, mining, and notions of private property. There is growing evidence of increasing land degradation at local scales. At the same time, population growth remains high in pastoral areas, adding more people to a system with scarce resources. Mobility is severely restricted, and increasing numbers of pastoralists diversify by incorporating cultivation or migrating into urban areas. National strategies to reduce poverty do not effectively reach pastoralist areas, and access to education, health care, and infrastructure is only slowly improving.

Pastoralists have a comparative advantage in exploiting marginal environments—supplying animal products to meet global demands may be an economic opportunity. Additional opportunities may arise from the production of niche products (like exotic species), comanagement systems of conservation areas, and ecotourism. Realizing these opportunities, however, will require a concerted effort by national and international governments to provide an enabling environment. As long as pastoralists remain marginalized, without access to markets, and perceived as backward, they may not be able to effectively exploit the advantages they have. Moreover, commercialization and globalization will inevitably transform the system with unknown social and cultural consequences. It will also affect the environment, as growing populations are leaving their trace on the landscape, with increasing evidence of resource degradation and scarcity.

Increasing vulnerability and continuing marginalization indicate that pastoralists are not able to respond to the pressures effectively. Recognizing these challenges, there are voices that call for the abandonment of this way of life altogether. Others argue that pastoralism should be supported into the future on the basis of human rights, the right of communities to preserve their cultures, and environmental concerns that argue for pastoralism as sustainable land use. Current vulnerability should be considered as a policy failure, rather than a failure of pastoralism itself. Major shifts in policy are needed to support pastoralists. Pastoralists need to be recognized as rational decision makers. Within the context of decentralization policies an effort has to be made to integrate pastoral communities into decision-making processes. Ultimately, it is for the pastoralists to decide whether their way of living is viable, or whether it will be more beneficial to give up pastoralism for another way of life.

Patkar, Medha (1954–)

MEDHA PATKAR IS one of the world's foremost anti-dam activists and a leading Indian environmentalist. She is the founder of Narmada Bachao Andolan (the Save Narmada Movement). The Narmada River flows through central India; millions of people rely on it for nourishment and economic activities. Large dams built on the Narmada threaten their livelihoods. Patkar, together with a number of like-minded people, has led campaigns against the dams and similar projects. These campaigns have drawn upon the tradition of nonviolent protest pioneered by Mahatma Gandhi. Hunger strikes have hurt Patkar's health but have heightened public awareness and sympathy for her causes. Following one hunger strike, the authorities arrested Patkar for attempted suicide, which is considered a crime.

The Indian government treats nongovernmental organizations with suspicion. In June 2006, the Supreme Court of India ruled that Narmada Bachao Andolan had accepted money from overseas sources and was involved, therefore, in unpatriotic acts funded by non-Indian sources. This accusation is a common tactic among governments of the developing world: Nongovernmental organizations (NGOs) are typically characterized as working to undermine the home country and nationals supporting them are treacherous. This enables the government to take action against identified NGOs and their supporters and to demonize them in popular media. Legislation, either from a previous struggle against insurgents, or else resulting from the war on terror, is then used to suppress public dissent.

Nevertheless, large-scale protests by members of the public, when allied with support from influential political interests and international audiences, can force governments to make concessions. This was the case with the Narmada Dam, as state officials accepted the need for a review of its height and construction details. However, obstructionism and opaque decision making might still be deployed to delay final decisions not favored by funding partners. The struggle for Narmada was not over at the end of 2006 as the government began another attempt to bring the dam into service; more protests were anticipated. Medha Patkar is an example of the modern form of popular protest, employing networks, vivid public demonstrations, and innovative public relations. The use of information technology, particularly the internet, has helped local protests become global in scope and support.

Peasants

THE TERM *PEASANT* is imprecise, but it has much historical significance. It could hardly be otherwise when the defining characteristic of the modern economy has been the gradual transformation of a world dominated by peasants and landlords (of various kinds) into a world dominated by waged labor and capitalists (of various kinds).

The contradictions within the modern project—a project predicated on the expansion and control of national territories and resources, on urban industrial development as the hallmark of progress, and on the construction of certain kinds of citizens—have turned peasants into a contradictory group, both theoretically and in practice. Throughout the modern period they have been alternately seen as backward, ignorant throwbacks to a primitive period (even today, the second definition of peasant in most English language dictionaries is buffoon or simpleton) or as independent, communitarian stalwarts of a more socially just and humane period.

In 1776 Adam Smith bemoaned the loss of the small farmer trained in all the various tasks of the farm, but he believed that peasants would not be able to withstand the competitive advantages of scale reaped by a greater division of labor on large farms. This argument would carry important political and policy weight in the post–World War II development period when industrial development was predicated on the incorporation of "underemployed" rural producers.

A hundred years after Smith, an influential Marxist argument suggested that smallholders were inherently allies of the propertied classes but that as differentiation occurred (the transition to wage labor), small farmers would become proletariats on their own land and would align with the urban worker. Another populist argument suggested that small-scale agricultural (and industrial) production was the best way to guard against the evils of large-scale capitalism. A final argument, rhetorically embodied by Thomas Jefferson but captured in many other countries where territorial settlement figured prominently, such as Brazil and Mexico, suggested that national development would be propelled forward by the small farmer, an independent, hard-working class of subsistence providers who would civilize (and in some cases whiten) the land in the interests of national development and control.

The peasantry as a class became the subject of heated academic debate in the 1960s and 70s when they were rediscovered as active political subjects playing major roles in national liberation struggles from Vietnam to China. One problem inherent in the discussion of the peasantry was the conceptual difficulty of defining exactly who or what was a peasant.

Without reaching a definitive conclusion, peasants are usually defined as agricultural producers who are primarily organized as a family unit geared toward subsistence and characterized by partial, subordinate integration into relatively incomplete markets. Although the generalizing term "peasant" has been disputed, it is still used by peasant activists and by academics attempting to lend analytical or representational coherence to the group.

Interest in the peasantry in the 1960s and 70s paved the way for research analyzing their "moral economy," the circumstances under which peasants would rebel, the political affinities of rural producers, the relationship between the peasantry and the modern nation state, and more. Debates continue about the nature of the relationship between peasants and production, between peasants and political systems, between peasants and the household, and between peasants and the greater society.

Today peasants continue to be important political actors (even as their economic influence has lessened). Antidotes to globalization are often "back-to-the-land" calls for a return to sustainable agricultural production and coherent local communities, rooted in the nostalgia that British Marxist historian Raymond Williams once traced back to the beginning of the first millennia. The Zapatista uprising of southern Mexico in January 1994 is often considered the symbolic birth of the contemporary counter-globalization movement. The Zapatistas are joined by other movements in Brazil, India, South Africa, the Philippines, and more in an umbrella organization called Via Campesina. Local groups within Via Campesina work toward alternative modernities based in sustainable development, agro-ecological production methods, food sovereignty, and coherent local communities. These alternatives are explicitly based in a rejection of industrialized agricultural production that emphasizes output over process and export profits over local nourishment.

Perception, Environmental

LIVING ENTITIES PERCEIVE environments by interacting with them. There is no perception without organism–environmental engagement. Consequently, the basic unit of analysis in the study of perception is always the organism *plus* its surroundings. For many centuries, especially under the influence of Cartesian premises, people in Western societies believed that perception was the result of the brain's processing of raw, concrete, and objective information about the external world that was delivered directly through sensory organs and the nervous system. In the 20th century many studies showed that what reaches the brain is actually information that has already been partly processed by sensory apparatuses and nervous systems. An example of this phenomenon is what happens when the human eye is exposed to images that play with the ambiguity of people's perception. These are images in which, depending on what an eye "chooses" to focus on, a person will either see a young woman or an old lady. Another example are images where the eye can alternate between seeing a vase or the lateral view of two human faces in front of one another.

Whereas in previous centuries philosophers and neurologists believed that the mind was exclusively in the brain, many scholars currently conceptualize the mind as operating within the connections that exist between sensory organs, the things that are being sensed, the nervous system, and the brain. They contend that the mind is immanent in these pathways. Scholars argue that through perception, organisms "bring forth" certain aspects of the world while other aspects are ignored and, therefore, remain unknown. Following this theory one can say for instance, that when interacting with their environments, dogs bring forth a world that is heavily imbued with smells. Humans tend to be more attuned to bringing forth visual aspects of the world and, even then, only in terms of what the human eye is capable of detecting.

BATESON AND SENSORY PERCEPTION

One of the scientists who most contributed to a more complex understanding of perception was Gregory Bateson. Bateson was unsatisfied with the notion that the brain directly receives concrete information about the world, which it subsequently interprets. This would be too simple a process for highly complex organisms. He suggested instead that perception emerges from relations that organisms establish with their world, as well as from relations among sensory organs, nervous systems, and the brain. Bateson was also suspicious of the notion that perception is based on the passive transmission of discrete bits of information from the senses, through the nervous system, and on to the brain. Bateson's point is that perception is not initiated by the arrival of mirror-like images of the world in the brain. Rather, perception is directly associated to the arrival of news of difference and that news of difference is not possible unless the organism interacts with its surrounding environment. These differences are not first detected by the brain, which means that there is some processing of information at the sensory level.

Visual percepts provide an illustration of this idea. Bateson proposed that perception begins with eyes detecting a difference between the white of the page and the black of the text's fonts. The fact that you are reading this text illustrates this argument. When a person reads a text that is typed on a page, the person engages with the text by using his or her eyes in a context where the necessary conditions for such engagement exist (for example, there needs to be enough light in the room for the person to be able to read). Distinguishing between the black text and the white page is a form of information processing that starts in the eye. If there is no significant difference at all between the two, the eye cannot see the text, and the person cannot perceive that she or he is looking at a text.

The same goes for the perception of temperature. Noticing whether a surface is or is not cold entails using the skin's sensory capabilities to compare that surface with others that are hotter or colder—even if it means comparing that with sensory memories of other surfaces and their temperatures. A person who puts his or her hands in lukewarm water after being exposed to extremely low temperatures will sense that water as if it were very hot. Alternatively, if a person is exposed to a smell that stays relatively constant—that is, without oscillations in its intensity—will eventually decrease levels of smell-perception or even stop him or her from smelling it altogether. The assertion that perception is a multilevel system is so fundamentally correct that neurologists have discovered that without sensory engagement with environments, the human mind cannot function properly. Sensory deprivation is—at least for humans—a highly cruel form of torture.

PERCEPTION AND SOCIAL RELATIONS

Social scientists working on the basis of these premises add to this knowledge by explaining the role that culture and social relations play in the mediation of perception. Rather than contradicting the findings mentioned above, they complement them and take them even further. A case in point is the work of the anthropologist David Howes. He has done extensive research on the relations that exist between sensory perception and sociocultural contexts. First, Howes shows that there is a distinction to be made between sensory capabilities and their use. This implies that there is no universal natural sensory state. Instead, sensory potential is exercised differently depending on a person's social background. Each society specifies the appropriate uses for people's senses. For example, in North America it is generally considered rude to sniff a person's smell.

Second, Howes shows that the notion of "sense" is to a great extent cultural. In Western societies people normally talk of five senses, but there are other societies where people refer to the existence of many more senses. There are societies where people are encouraged to use additional senses, including some that allow them to make statements about another person's soul.

Third, Howes's research shows that contrary to dominant assumptions that each sense operates individually, sensory perception actually emerges out of the interaction of various senses. The end result is that perception is more than the sum of the bits of information that are provided by each sense alone. This means that sensory perception is synergistic. Howes's major argument is that any discussion of human environmental perception must begin with an account of the realm of the sensuous in active interaction with surroundings. This in turn must be understood in the context of social practices that lead to particular types of habitual, embodied sensory practices.

INDIVIDUAL VARIATIONS

Tim Ingold, another anthropologist, has studied the ways in which human beings, who are endowed with sensory capabilities and who are influenced by culture, perceive the environments they live in. Ingold argues that notwithstanding people who have disabilities, all contemporary humans are endowed with similar perceptual capabilities. However, the extent to which people actually exercise these abilities is related to the perceptual habits they develop through life as well as to the extent to which the person learns to be aware of his or her perceptual practices. This means that on the one hand, people become accustomed to using some of their perceptual capabilities more often—and better—than they use other capabilities. The possibility is there at birth that people use all of their sensory potential but, as they grow up, they become accustomed to relying mainly on specific combinations. For example, there are societies in which most people develop the habit of using mainly their eyes in order to engage with the world, to the point where information about the world is not real to them unless it can be visually verified.

In Western societies, a person's mood is often determined by looking at the person's face and seeing whether she or he looks happy. This is often taken as more informative than listening to what the person has to say about his or her emotional state. In fact, expressions like "she says she's happy but I can see she is not" are illustrative of how Westerners privilege the visual over the auditory.

On the other hand, as people go through their lives, they become aware of the ways in which they perceptually engage with their surroundings. This allows them to fine-tune their perceptual capabilities. The typical bird-watching beginner is not capable of noticing differences between the sounds of distinct bird species, nor is she or he capable of detecting the physical and behavioral nuances that separate various subspecies from one another. In fact, many beginners are not even capable of seeing birds when they walk through the woods. In time, however, beginners learn how to become aware of more aspects of their surroundings.

LEARNING AND CULTURAL TRANSMISSION

People develop this awareness by learning to discover different levels of perceptual engagement with environments. According to Ingold, and very much along the lines of what Bateson had proposed before him, this information entails more than having images of the world copied into a person's head. It also means that in this process of learning it is insufficient to receive instructions from someone else on how to perceive. This is a process that normally falls under the label *enculturation,* whereby a person is informed of the knowledge and ways of living that characterize his or her society. The person must instead be actively involved in engaging with his/her surroundings and, in so doing, discover how to use his or her perceptual potential. Ingold shows that the latter is a process of *enskillment.* It contrasts with enculturation in that while enculturation occurs by means of information transmission from one person or society to another, it is instead achieved by learning to pay attention to environmental cues. The latter is what Ingold calls a dwelling perspective. It is based on the notion that acting and perceiving are inextricably connected.

A bird-watching beginner, for example, may receive instructions from a teacher on how to proceed toward having a better chance to see birds on trees, or information about how the sounds of different species might best be recognized. Their instructions are helpful, but not enough to render a novice bird-watcher a proficient bird-spotter. Instead, the novice must acquire corresponding perceptual skills in order to see, listen to, distinguish, and appreciate birds.

Ingold's work goes even further by explaining how these processes occur, and what are the related roles that culture and social context play. Ingold considers two main contrasting forms of cultural understanding of perception, identifying two distinct epistemologies or general theories concerning the validity, scope, and anatomy of human-knowledge processes—including perception. First, there is the orthodox Western understanding of perception. As mentioned above, it is based on Cartesian premises.

Cartesian premises assume that there are clearly demarcated boundaries between the external world, a body's perceptual apparatus, and a central information-processing unit—the brain. It is typical of Cartesian thinking to believe that the senses play a minor role in relation to the brain's mental processes. At best Cartesians see the senses as mere vehicles that passively transport direct information from the outside world. For them it is the brain and the brain alone that displays properties of mind: that is, the capability to know the world. From this perspective, it makes perfect sense for Cartesians to argue that human knowledge can be effectively and successively transmitted abstractly in the form of verbal and written information.

To some extent this proposition is indeed true. A good portion of the average Westerner's knowledge is acquired this way. However, humans would hardly be able to cope with living in the world if this were the only way they knew the world. As anyone who ever had problems learning mathematics or abstract philosophy knows, it can be extremely difficult for humans to learn things that they cannot relate to the worlds they are engaged with. In turn, most of the practical knowledge that humans require in order to deal with the demands of their daily lives is embodied knowledge, not abstract and conceptual. One could spend hours describing to someone else all the theory that comes with bicycle riding, but the prospective rider would still fall many times before learning balance.

Ingold contrasts this epistemology that dominates the Western world with the epistemologies of many cultural examples from societies that exist around the world. His work shows that hunter-gatherers, for example, differ from most Westerners in that they understand perception as emerging from the simultaneous conceptual and bodily engagement with the world. They do not operate on the basis that the world is an external reality that passively waits to be known. Following a dwelling perspective in the terms described above, hunter-gatherers conceptualize knowledge as the combined result of thinking and acting within environments. For them, the two cannot be separated; mind and environment are two connected processes.

The process of hunting illustrates this point. In many non-Western societies, such as the Cree of northern Canada, knowledge of how to hunt always entails a reciprocal interaction between hunter and prey. Certain aspects of this knowledge must be passed conceptually from one person or society to another, but the actual hunting encounter will fail for the hunter unless he or she is attuned to the animal's responses and responds accordingly. Certain actions by the hunter will lead to certain responses by the animal. These, however, depend on the environmental context wherein hunting takes place. For instance, animals will respond differently depending on whether they are in the proximity of their herd, or depending on whether it is windy or not. Consequently the hunter must learn to align his or her perceptual apparatuses such that they can be adjusted to oscillating conditions during the hunting event as well as to the animal's responses to both the environment and the presence of a human being. Perceptual knowledge is thus "spread around knowledge" in that it resides in the interactions that take place among the hunter, the prey, and the environment. Clearly, this epistemology contrasts with Cartesian premises that knowledge is fixed in the brain as a set of concepts about an external world.

In short, environmental perception is a complex biological process that entails the active interaction of sensory organs, nervous systems, and the brain. This, however, is only a fraction of the process. A person's biological perceptual systems give him or her the potential to know the world. This potential is not exercised until the person actively engages with the environment. In this process of engagement certain aspects of this potential will be used, while others will not. In so doing people bring forth some features of the environment, while others remain unknown. To a great extent this is the result of culturally acquired sensory habits whereby humans learn to use some senses more than others. In addition, sensory perception tends to be synergistic—different senses cooperate and interact such that perception emerges as a combined product of individual sensory capabilities.

Finally, environmental perception is influenced by social and cultural context. Some societies and cultures operate on the basis of an epistemology that encourages members to be particularly attuned to feedback information from the environment while others do not. Recent scientific studies from neurology, psychology, anthropology, and sociology show that, regardless of epistemological belief, the fact remains that perception is not possible without environmental engagement.

Permits, Tradable

A TRADABLE PERMITS system represents an attempted solution to problems arising from the use of common property resources, such as air and water, either as a source of value or a sink for pollutants or waste. Since such resources are freely available to everyone and costs of their overuse, depletion, or damage are not borne directly by the user, there is a tendency toward unsustainable usage (a Tragedy of the Commons).

A tradable permit system limits the amount of the resource that can be used or the quantity of pollution that can be emitted, but then allows this quantity to be freely exchanged. Tradable permits are licenses issued by a competent authority that give the holders the right to use the resource specified (e.g., producing pollution or catching fish). They may be traded with other institutions or individuals, generally, but not necessarily, for money. Tradable permits have been considered a success in tackling some environmental issues. In theory, their advantage is to create an incentive for increased efficiency, allowing those who pollute less in production, for example, to sell their unused rights for a profit. Tradable permits have been used largely in the areas of water management, fisheries control, air pollution, and land use. The Kyoto Protocol on atmospheric emissions is perhaps the best-known example. The Chicago Climate Exchange has emerged in the United States in anticipation of carbon trading to control global warming.

Market-oriented approaches appeal to those who are opposed to the concept of governmental control of the use of natural resources. Governance is essential for such systems to work, however, since caps and limits must be set and enforced and trading must be organized and regulated. It is necessary to ensure that all participants have confidence in the system and that it is transparent.

There are transaction costs involved in the trading process and inevitable asymmetries of information may make the pricing mechanism inefficient. In order to improve the efficiency of the process, additional features have been implemented in some cases, in the same way that derivative or future options are used in financial markets to enable parties to manage their exposure to risk (such as the inefficient use of resources). These include by-catch quotas, safety values, and zero revenue auctions. These market-based mechanisms can be effective when properly regulated, although there is always the concern of collusion or other disreputable behavior on the part of participants.

Persian Gulf

LOCATED IN A politically volatile region at the center of the world's most important and accessible oil deposits, the Persian Gulf is one of the most environmentally vulnerable bodies of water in the world. Within the past few decades small fishing villages on the Trucial Coast, the coastline of the United Arab Emirates, Qatar, Bahrain, Oman, and Saudi Arabia, have experienced phenomenal economic growth. Dubai, for example, has become a hub for air and sea transport, finance, and trade throughout Eurasia. This development has led to a significant increase in pollution and ship traffic in the gulf.

The Persian Gulf wars in Iraq and Kuwait and Saddam Hussein's destructive environmental warfare have left a harmful environmental legacy. Crisscrossed by oil pipelines, dotted by refineries and sulfur stations, the Saudi coastal oil facilities are a ripe target for terrorists wanting to cause global economic panic. The prospect of conflict with Iran and its development of nuclear technologies have also made the Gulf vulnerable on its northeastern shore.

The Persian Gulf, barely connected to the Arabian Sea by the narrow straits of Hormuz between Oman and Iran, functions almost as its own ecosystem. It is some 1,000 kilometers long and 300 kilometers wide, but is only 35 meters deep on average. Any oil spills or pollutants that enter the gulf take a long time to exit the straits and dilute. With mangroves, salt marshes, mudflats, coral reefs, and sea grass along its shore, the warm waters of the Gulf are home to a great diversity of marine life, one of the richest in the world. Large numbers of migratory seabirds flourish in the warm, shallow marshy habitat. The dugong—a large, rare, slow moving sea mammal—is found in significant numbers near the coast. Sea turtles are also commonly found nesting on the Trucial sands.

The potential for conflict in the Persian Gulf region remains high and the risk of environmental fall out from large-scale warfare does not seem to be ending any time soon. The unbridled development of oil-producing states will continue to threaten fragile marine environments on the coasts. The Persian Gulf is too often referred to as "the Gulf," as a purely political entity and as a potential center of international political crisis and change. The potential for environmental crisis in gulf waters, however, is perhaps just as high. It remains to be seen if either the political or the environmental consequences of recent Western intervention in the region can be managed.

Persian Gulf Wars

THE PERSIAN GULF Wars—the first fought between Iraq and Iran between 1980 and 1988, the second fought between a U.S.-led coalition and Iraqi occupying forces in Kuwait in 1991, and the third fought between the United States and the Iraqi Army in Iraq itself and later against insurgents from 2003 to the present—are no exception to the tragic rules of environment and war.

Success in war is highly dependent on very immediate, short-term considerations. A slight change in tactics or position on either side can have serious consequences for the ultimate outcome of a conflict. Success in environmental policy, in contrast, must develop over the long term. War is fought in highly unstable situations where there is often a lack of clear government. Without a government, there is no way to regulate or to manage environmental crises. Rather than attempting to save the environment, both sides in the conflict may destroy the enemy's environment for immediate tactical advantage.

Destruction of the environment around enemy troops has an ancient history, going back to the destruction of crops and the poisoning of besieged cities' water supplies. One of the most dramatic examples of this was the spraying of Agent Orange in Vietnam by U.S. forces to kill the jungle and root out the Vietcong. When Iraqi dictator Saddam Hussein faced resistance from southern Iraqi Arabs, he drained marshes and destroyed ecosystems. His use of mustard gas against Kurds in the north also had serious environmental, let alone humanitarian, consequences.

The sheer presence of a military can lead to large quantities of garbage and waste. In the case of U.S. troops stationed in the arid zones of Saudi Arabia during the first gulf war, much of the waste was buried or burned. The Iraqi military, without sufficient logistical or planning support, caused serious damage and often relied on burn and run tactics. The most famous image of the first gulf war was of oil fires set alight in Kuwait by Iraqi forces, and possibly by some coalition bombing. Some 600 fires raged after the first war, causing serious respiratory diseases, and the soot from the fires scavenged large quantities of ozone. This has been called one of the worst deliberate environmental disasters, causing an oil slick in the fragile and overstretched gulf ecosystem, one of the most productive marine environments in the world. The dugong, a threatened species of manatee, is especially vulnerable to the destruction of coastal marine vegetation. Several washed up dead on the Saudi beaches after the oil spill. The second gulf war also led to the release of harmful chemicals and pollutants into the gulf.

The bombing of poorly constructed chemical and nuclear facilities led to the leaching of harmful wastes into the Tigris River, source of most of Baghdad's water supply. The present lack of central control in some areas of Iraq has lead to further serious environmental consequences. As insurgents target trash collectors, waste and sewage builds up in the cities and slums. The looting of nuclear and chemical facilities after the U.S. occupation in 2003 has led to serious concerns about the whereabouts of dangerous nuclear fuel and radiation. Some looted nuclear barrels were allegedly used to store milk and food. Even as some areas—such as the marshlands—have been restored, the lack of infrastructure, water, power, and development has led to desperate measures in a civilian population exposed to pollution and poverty.

Peru

FOR MUCH OF its history, Peru has been beset by political strife and government corruption. From 1533 to 1823, residents lived under oppressive Spanish rule. In modern times, governments have vacillated between military and democratic. This political instability has led to a weak infrastructure with major economic and environmental problems. The per capita annual income of Peru's 27,925,628 people is $6,000, resulting in a ranking of 122nd among nations of the world. Inequality is widespread in Peru, and the top 10 percent of the population hold 37.2 percent of resources. At the other end of the spectrum, 54 percent of the population live below the poverty line. The United Nations Development Programme Human Development Reports rank Peru 79th among 232 nations on overall quality-of-life issues. Long an important part of the national economy, the illicit coca leaf crop has declined by about 40 percent over the last decade, further hampering the regional economy.

Bordering on the South Pacific Ocean, Peru has 2,414 miles (3,887 kilometers) of coastline. The climate ranges from tropical in the east to dry desert in the west and temperate to frigid in the Andes Mountains. The terrain is varied: Coastal plains cover western Peru, giving way to the Andes in the center and to the lowland jungle of the Amazon Basin in the east. Earthquakes, tsunamis, flooding, landslides, and mild volcanic activity are common in Peru, and some disasters have a major human impact. For instance, the 1983 El Niño was devastating to Peru. Many people lost their main source of food when fishing was suspended as the river flooded and sea levels rose during five months of nonstop rain.

Two of the world's most significant geographical features are found in Peru. Lake Titicaca (shared with Bolivia) is the highest navigable lake in the world. The Amazon River also reaches its ultimate source on a remote slope of the Nevado Mismi. Peru is rich in natural resources that include copper, silver, gold, petroleum, timber, fish, iron ore, coal, phosphate, potash, hydropower, and natural gas. However, overdependence on minerals and metals has adversely affected the country.

Extensive deforestation in the Amazon Basin of Peru has occurred as peasants migrate into the area, encouraged by land tenure laws that allow five-year occupants of the land to retain it. More problematically, deforestation also follows logging, intensive commercial plantation agriculture, mining, and the state-sponsored road construction that engenders these activities. Municipal growth and mining have resulted in soil erosion and extensive pollution in rivers and coastal waters.

In the industrial area of Lima, air pollution threatens general health. Peru produces 0.1 percent of the world's emissions of carbon dioxide even though there are only 30 cars per 1,000 people. The HIV/AIDS virus is also posing considerable health risks in Peru. With a prevalence rate of 0.5 percent, it is estimated that 82,000 people are living with the disease, and 4,200 have died. Further threats to health derive from the fact that almost one-fifth of the population lack access to safe drinking water and almost 40 percent have no access to improved sanitation.

The impacts of climate change are reaching crisis proportions in Peru. Some scientists believe that the tropical glaciers will disappear by 2015, leaving the population with a shortage of freshwater resources. Environmentalists around the world have campaigned against the Camisea gas pipeline project that became operational in August 2004. The pipeline stretches over the Andes Mountains from the Amazon River to the Pacific Coast. During the first 18 months, three major ruptures occurred. Extending for 700 miles (1,127 kilometers), the project threatens Amazonian ecosystems and poses great health risks to tribal communities in remote areas such as the Nahua-Kugapkakori Reserve.

Approximately 51 percent of Peru is still forested, and the government has protected 6.1 percent of all land. Although Peru continues to maintain biologically diverse ecosystems, many are at risk. Of 460 mammal species endemic to Peru, 49 are in danger of extinction. Likewise, 76 of 695 bird species are threatened. In 2006, a study by scientists at Yale University ranked Peru 65th of 132 countries on environmental performance, in line with the relevant income group but below the geographic group average.

Historically, Peru's environmental protection framework has been weak. During the mid-1980s, enacted legislation proved difficult to enforce. In the early 1990s, Congress passed the Environmental and Natural Resource Code that spelled out environmental policy without providing sufficient funding for implementation. The National Environmental Council was created in 1995 with the authority to levy civil and criminal penalties for noncompliance. Again, enforcement proved difficult. The Peruvian government enacted stiff laws restricting the activities of the timber industry in 1999 and began working with the private sector to develop environmental programs. In 2004, Congress passed a law designed to bring all environmental agencies together in a single tribunal.

Peru has signed the following international agreements: Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Hazardous Wastes, Kyoto Protocol, Marine Dumping, Ozone Layer Protection, Ship Pollution, Tropical Timber 83, Tropical Timber 94, Wetlands, and Whaling.

Pesticides

PESTICIDES ARE CHEMICALS or biological agents (such as viruses or bacteria) used to control or eliminate pests. Pests can be anything that disturbs human life, agriculture, horticulture, or domestic animals. Pests are most often insects, but they may be bacteria, fungi, weeds, unwanted fish, rodents, nematodes (roundworms), deer, or rabbits. Pests may be native to a local environment or invasive species. Pesticides are often classified according to the type of pest they are designed to control or eliminate. There are five kinds of pesticides: fungicides, herbicides, insecticides, rodenticides, and a miscellaneous category.

Fungicides are used against pathogenic fungi to either prevent the spread of the fungus or eliminate the infection. Fungi may infect plants, animals, and humans, damaging crops or human health. The damage may cost great sums of money, cause the loss of plants, damage the health of animals, or even kill humans. Contact fungicides are sprayed or used as an ointment on the infected area(s). Systemic fungicides kill fungi through an absorption mechanism that induces the fungi to absorb the fungicide, then sicken and die. Many cleaning products are fungicides. In some situations, a fungicide may be applied to garden or farm seed as a prophylactic. Usually, seed treated with a fungicide can be easily recognized because it is tinted a bright pink color to alert people to the danger of eating the seed. Fungicides (often containing mercury) have caused death, paralysis, or brain damage when people ate fungicide treated seed.

Herbicides are pesticides that are used to kill unwanted plants. There are two basic types of herbicides—general and specific. General herbicides, such as the commercial product Roundup, are nonspecific: All of the plants sprayed with a general herbicide are killed. Some general herbicides have been developed from plant hormones. They are applied to plants and are able to confuse hormonal growth patterns. Some plants are natural herbicides, such as walnuts (genus *Juglans*). Herbicides are used in enormous quantities in landscaping, landscape turf management, agriculture, and highway maintenance. Herbicides are also used extensively in the management of wildlife areas, in lakes, in forestry, and in pasture management systems. Specific herbicides kill only a specific type of plant; there are many commercial herbicides that can be applied to crab grass, poison ivy, or poison oak. Without these products, whole areas would have to be cleared by hand or with mechanical devices. There are some organic herbicides, which are usually expensive, confined to noncommercial uses, and less effective than synthetic chemical herbicides. Examples of organic herbicides include some spices, vinegar solutions, steam, and fire.

Insecticides are pesticides designed to eliminate crawling bugs, such as cockroaches, ants, fleas, flies, mites, and arachnids—ticks, mites, scorpions and spiders. Spiders and scorpions can be dangerous, and insecticides may be sprayed to make areas safe for human activities. Pyrethrums, which are obtained from chrysanthemums, and piperonyl butozide, derived from sassafras trees, are natural biological insecticides. Synthetic pyrethrums are currently finding wide use. Insecticides have improved human health and longevity by controlling insects that have plagued humans for millennia.

Rodenticides kill mice and rats. Those developed in the middle of the 20th century were usually composed of toxic substances such as arsenic, strychnine, cyanide, and even some chemicals developed for use as chemical weapons. Contemporary rodenticides are those that block the production of vitamin K. This compound plays an important role in coagulation. When rodenticides kill rodents, they may cause secondary poisoning in dogs or cats if they eat the weakened or dead rodent. Warfarrin and other rodenticides are designed to be toxic to rodents, but far less toxic to humans or larger animals.

Rodents carry fleas, which are carriers of numerous diseases. Bubonic plague and some hemorrhagic diseases are spread by fleas on rats and mice or by their droppings. Among rodentborne diseases are arenavirus, hantavirus, leptospirosis, lymphocytic choriomeningitis, murine typhus, plague, rat bite fever, and salmonellosis. Cleansing human habitations and food stocks of pests is important to preserve human health.

The miscellaneous category of pesticides includes slug pellets (molluscicides), which kill snails, and various repellants for insects, birds, and animals. Rabbits in Australia have no natural predators. After their introduction, they multiplied enormously to the point where they were eating much of the existing vegetation. They were eventually controlled with a pesticide in the form of a virulent virus that is deadly to rabbits. Pesticide agents used in swimming pools remove health hazards, bacteria, and algae. A "trick" pesticide used to drive away birds or animals that become pests is to spray areas with the urine of their natural predators. Coyote urine has been used as nontoxic repellant; it is a biochemical pesticide, but also a naturally occurring substance that is otherwise harmless in nature. It has been used to repel armadillos, beavers, domestic cats, deer, elk, and wild pigs.

Without pesticides, crops would be lost and health improvements would be difficult. When crops are infested with a pest such as cabbage loopers, an entire crop can be destroyed or rendered unfit for use. Many localities use mass spraying of insecticides to control mosquitoes. The use of DDT (dichloro-diphenyl-trichloroethane) aided great reductions in typhus, malaria, and other insectborne diseases in World War II and afterward.

In 1962 Rachel Carson, an American biologist, published *Silent Spring,* which claimed that DDT was causing cancer and destroying bird populations. Her work was an important factor in the rise of the environmental movement and efforts to ban the use of insecticides. After the political controversy that arose following the publication of *Silent Spring*, Congress created the Environmental Protection Agency in 1971. It assumed control of pesticide regulation, taking over responsibility from the Department of Agriculture. One of its first actions was to ban DDT in 1972.

Environmentalists' claims that chemical companies and other manufacturers of pesticides are producing dangerous products have been substantiated. Scientists, engineers, farmers and other agriculturalists also have a vested interest in not poisoning the land. Since the 1980s, pesticide research has sought out safer biological controls, such as pheromone traps and microbial agents. Modern pesticides used in urban areas have been found to pose little risk to human populations and are important defenses in the effort to control mosquito-borne diseases and destructive pests. Biological pesticides or those with reduced risks of side effects are being approved by the EPA in growing numbers.

Pests, Agricultural

PESTS ARE LIVING organisms that damage and destroy agricultural produce. Pests include mobile threats such as locusts and other insects, viruses, fungi, and bacteria. The threat of pests has existed for as long as humanity has practiced agriculture, and also affects nonagricultural growth. The consequences of pest infestation are physical and economic, as well as psychological, resulting from fear and panic spread by the influx of pests. Those pests that have led to animal disease, including bovine spongiform encephalopathy and foot-and-mouth disease, have led to the mass slaughter of livestock.

Pests can be very destructive. The *Phytophthora* fungus, which arrived in Ireland from North America in the 1840s, stimulated blight among the potato crop for several successive years. The Irish population, especially the rural poor, had become dependent on a small number of species of potatoes for food. With the almost complete destruction of successive potato crops, compounded by the inadequacy of the British government that administered Ireland at the time, more than one million people starved to death and more than another million people fled overseas.

The example of the potato blight in Ireland reveals the confluence of several factors that make pest infestation particularly severe: The sudden introduction of a previously unknown organism, unusual climatic conditions that enable the pest to flourish to unusual extents, and the reliance on too narrow a range of foods. As globalization of trade increased during the 18th and 19th centuries, international trade in grains increased to feed growing cities. This caused pest infestations to become endemic throughout the world. States were required to introduce new legislation, and government agencies tried to combat such pests. One of the earliest examples of this was the Destructive Insects Act of 1877 enacted in Britain and aimed at removing the threat of the Colorado potato beetle.

Farmers have fought pests throughout history. Early infestations of locusts, as recorded in the Bible, were met by as many workers as could be mustered to pick the creatures off plants by hand and for some quite primitive forms of spraying. Earlier farmers also responded by selecting more resistant seeds for sowing, although in many cases this process was not well understood.

In the early modern age, the application of the scientific method enabled farmers to mobilize more effective means of combating pests, including chemical sprays and pesticides. These technologies have proved very effective in killing many pests, and even people when used in warfare; organophosphate pesticides, in just one example, are the progenitors of modern nerve gas. However, there have been a number of cases when the use of chemical pesticides has produced poor results, either because other, necessary organisms have also been destroyed or else chemical residue has contaminated food. In some developed countries, the routine use of chemicals has led to the regularization of the size and shape of food and vegetables, to the detriment of their nutritional value. Meanwhile, there are dangers that pests will become resistant to the chemicals used to try to eradicate them. Aerial spraying of chemicals also poses a health threat to people caught within the area of spraying.

Petroleum

PETROLEUM, OR CRUDE oil, is a nonrenewable natural resource that has had a tremendous beneficial influence on human society. With a name derived from Latin *petra* (rock) and *oleum* (oil), petroleum represents the world's most important energy resource. Such fuels as gasoline, diesel fuel, jet fuel, heating oil, and related oils power the world's transportation system, provide electrical power for industrial production, and produce heat for human populations residing in cold-weather climates. In addition to its many energy uses, petroleum is also an important raw material resource used in the manufacture of a wide array of products that provide significant societal benefits. Petroleum is the raw material input in the production of many fertilizers and pesticides, which are largely responsible for increased agricultural production and efficiency.

Most of the world's consumer products contain plastics and other materials derived from petroleum. Petroleum has positively impacted most segments of human life; for example, the medical industry has developed life-saving, petroleum-based implants. While the vast benefits of petroleum energy and products are clear, the production and consumption of oil has come at a price to the natural environment (e.g., pollution and oil spills) and to human populations themselves (e.g., war and production facility accidents).

ORIGINS

The formation of petroleum can be traced back hundreds of millions of years to ancient microscopic plants and bacteria. These living organisms were able to convert the energy from the sun directly for their own sustenance. These organisms, residing in the ancient seas that covered the earth, sank to the sea floor upon death. Over time, sedimentary layers of silt trapped the nondecayed organic matter in what would later become source rock. Sedimentary layers accumulated above the organic materials, and combined with the weight of the ocean, exerted great pressure and heat. Over time, this pressure and heat transformed the organic source material into the hydrocarbon we now know as petroleum. This process is similar to the formation of natural gas, which is a reason why petroleum and natural gas are often found at similar locations in the earth's crust today.

Over time and under extreme pressure, petroleum was squeezed into the crevices of relatively porous sandstone or limestone, called reservoir rock. Subsequent deformation of the earth's crust acted to trap petroleum into pockets under dense, impenetrable cap rock like marble or granite. The three main geologic forces trapping petroleum into pockets within the earth's crust are folding, faulting, and pinching out. Folding results from horizontal pressure being exerted on the cap rock, forming a fold (or anticline). The resulting bell-shaped fold in the cap rock serves to trap petroleum. Faulting represents a fissure in the cap rock, with a large section of cap rock slipping down, forming a petroleum-trapping cavity. In the pinching out process, impenetrable rock is forced upward into the reservoir rock, resulting in petroleum-trapping pockets. Each of these geologic formations has the potential to hold reservoirs of petroleum, allowing geologists today to predict the possible locations of underground reserves.

As with other natural resources, petroleum's status as a resource began with its recognized use and value to human populations. Ancient civilizations located petroleum seeping to the surface of rivers and lakes. Over time, medicinal uses for petroleum, such as for skin ailments, were realized, and petroleum was used to waterproof canoes and water buckets and provide a base for paint.

THE MODERN INDUSTRY

While the first oil wells were drilled in China as early as the 4th century, the modern petroleum industry in the United States began in 1859 near Titusville, Pennsylvania. "Colonel" Edwin Drake struck oil nearly 70 feet below the earth's surface using a wooden derrick and drill, and stored the oil in wooden whisky barrels and vats. At this time, petroleum ("rock oil," as kerosene was called) was used primarily as a fuel for illumination, a cheaper alternative to whale oil. By 1879, the development of the electric light bulb by Thomas Edison provided a cleaner, safer alternative for illumination. Soon electricity-generated lighting forced the oil industry to the brink of extinction.

A new market, however, appeared in the form of the automobile. Henry Ford's "horseless carriage" was powered by the internal combustion engine, which in turn was powered by petroleum-derived gasoline. The automobile would come to transform American society, increasing mobility while also increasing dependence on petroleum. The geopolitical importance of oil became fully realized during World War I and II. Oil soon powered ships, planes, tanks, and troop transports. While securing oil figured prominently in Japanese and German war plans, America's plentiful supply of oil proved decisive in allied victories in Europe and the Pacific.

The post-war suburbanization of the United States was largely enabled by the automobile and an improved highway system. During the 1970s, the energy crises stemming from the oil embargo by the Organization of the Petroleum Exporting Countries (OPEC) and the Iranian revolution sent prices of oil and gasoline to new heights, causing global panic. Between 1980 and 1988, the Iran-Iraq war was fought largely for control of oil fields. Iraq's invasion of Kuwait in 1991 was also an attempt by Iraq to garner additional oil fields, as well as to acquire Kuwait's superior port and oil export facilities. The U.S.-led invasion of Iraq in 2003 and the ongoing war has contributed, in tandem with the threat of terrorism in the Middle East, to geopolitical uncertainties that have helped drive up the current price of oil.

EXTRACTION AND REFINING

The process of moving crude oil from its location within the earth's crust to delivering the final product to the consumer is a complicated process involving upstream (exploration and extraction), midstream (refining), and downstream (distribution to customers) activities. Each of these steps takes place in different (and often distant) locations, forming an intricate pattern of trade and capital flows.

Exploration is done to locate possible petroleum deposits. Most exploration is done using seismology, sending a seismic wave through the earth's crust, recording the reflecting waves, and mapping the underground geologic formations. On land, seismic waves are produced by vibrator trucks, which stomp the ground with a large rectangular foot. Offshore, a compressed air gun is used. Technological innovations, using advanced computer developments, have enabled geologists to construct three- and four-dimensional images of the crust's geology, increasing the success rate of finding productive oil deposits. Such computer-assisted exploration is costly; a 100-square-kilometer exploration area costs $1 million.

Refining, which transforms crude oil into usable products, is yet another costly and involved process. Physical (heating and boiling) and chemical (cleaning and additives) processes separate crude oil into its usable products. For a given barrel of crude oil, nearly half ends up in the form of gasoline. Other important by-products are diesel fuel, jet fuel, residual fuel oil, liquefied gasses, petroleum coke, asphalt oil, lubricants, and kerosene. Other by-products serve as "feederstock" for fertilizers and petrochemicals.

SUPPLY AND CONSUMPTION

As petroleum was formed under certain circumstances, and petroleum reserves trapped by certain geologic processes, oil is found in certain locations in the earth's crust. As a result, some countries have sizeable reserves of petroleum, while most do not. An appropriate measure of potential supply is the amount of proved reserves. These represent the amount of identified and usable petroleum that is available at current market prices and under current extraction technologies.

The Middle East houses approximately 67 percent of the world's petroleum reserves, making this volatile region vital for the future supply of oil to world markets. The largest proved reserves of petroleum in the world are found (in descending order) in Saudi Arabia, Canada, Iran, Iraq, United Arab Emirates, Kuwait, Venezuela, Russia, Libya, Nigeria, and Kazakhstan. One measure of current supply is production, the actual extraction of crude oil ready for processing or export. The largest oil producers in the world are (in descending order) Saudi Arabia, Russia, the United States, Iran, Mexico, China, Norway, Canada, Venezuela, and Nigeria.

In terms of demand, the best measure is consumption. The United States is by far the world's major user of petroleum, consuming an astounding 25.5 percent of total world consumption. This figure is particularly large in comparison to the second-largest consumer, Japan, which consumes 6.8 percent of the world total. The other major oil consumers in the world (in descending order) are China, Germany, Russia, Canada, Brazil, India, South Korea, and France. The main variables explaining oil consumption are high levels of industrialization and/or large human populations.

REVENUES AND THE "RESOURCE CURSE"

The extraction, refining, and consumption of petroleum and petroleum-based products have stimulated astounding levels of revenue and wealth. The top oil companies rank among the world's largest and most profitable corporations. The countries of Kuwait, United Emirates, and Qatar owe their placement in the World Bank's "high income" category to the abundant amounts of petroleum that happen to lie underneath their territory.

While the economic benefits may be great, oil wealth has not always translated into economic prosperity. OPEC members Nigeria and Indonesia remain poverty-stricken countries with rampant corruption and instability. Even Saudi Arabia, the world's top oil producer and exporter, has income and development levels far below those expected given its oil endowment. Per capita gross domestic product in Saudi Arabia places this oil-rich country alongside Poland and Latvia in world rankings. The observation that oil wealth is not always a blessing for countries has led to the development of the concepts of the "resource curse" and "Dutch Disease." During the 1960's the Netherlands discovered extensive oil and gas deposits, creating a so-called "oil boom." Despite its newfound source of wealth, the Netherlands experienced slower economic growth and lower economic performance, as well as higher rates of inflation. These symptoms were later termed "Dutch Disease."

Other variants have resulted in countries where an increase in oil revenue has led to economic distortions, resulting in the inefficient use of human and monetary resources. Such distortions include corruption, abnormally high wages, over-borrowing, and complacency that emphasizes short-term gains at the expense of long-term planning. These distortions ultimately lead to economic inefficiencies, resulting in lower economic growth and performance. In many cases, oil wealth is distributed highly unevenly, leading to regional inequalities, and often heightening already existing regional conflicts, occasionally escalating into civil war.

ENVIRONMENTAL EFFECTS

The negative effects of the extraction, transportation, and use of petroleum on the natural environment are substantial. Perhaps the most visual negative impacts on the environment are oil spills from seagoing vessels. One of the most highly publicized spills was the 1989 *Exxon Valdez* spill off the coast of Alaska, which emptied more than 10 million gallons of oil. This was the worst oil spill in U.S. history, killing wildlife, disrupting entire ecosystems, and creating an unnatural eyesore. Images of oil-soaked sea otters and dead, oil-drenched cormorants united environmentalists around the world in their further disdain for large oil companies. Other notable spills include the 1991 deliberate release by Iraq of 240–460 million gallons of crude oil into the Persian Gulf, and the 2002 *Prestige* leak of 20 million gallons off the coast of Spain.

Further environmental problems associated with the burning of oil and gasoline include air pollution, smog, acid rain, and the human-induced greenhouse effect.

Pets

A PET IS not just an ordinary animal; it is an animal conceived, bought, and given a home for the joy of humans. For instance, a white pet mouse in a cage may delight a child, while at the same time unwanted mice running somewhere in the house are a nuisance. Popular pets are dogs, cats, small birds, hamsters, reptiles, fish, and rabbits. Pets can be considered a sociological phenomenon, particularly in places like the United States, where more than half of all households own at least one pet. There are more than 60 million pet dogs and nearly 70 million pet cats in the

United States according to the American Veterinary Medical Association.

Pet ownership can contribute to human health and well-being. Researchers who studied the dynamics in a cat shelter to see how people fared in a place crowded with pets found that they seemed to be calmer. Many veterinarians and researchers have explored the healing effects of animal-assisted therapy (AAT) on various patient populations. They have also found that retired persons living with pets engage in more exercise and have more social relationships as a result of caring for their pets. Some species and breeds of animals are used to assist specific patient populations (such as the blind, the disabled, mentally ill individuals, AIDS patients, and children).

Another social phenomenon is pet loss. The mourning of an animal who was an everyday companion is quite difficult for some pet owners, and not just children. Strong feelings for their lost pets lead people to seek support groups or books to help them through the grief process. Some authors explore psychological dimensions, while other experts question the spiritual issues.

In the United States there are more than 60 million pet dogs and nearly 70 million pet cats.

Businesses exploit the fact that people are responsive toward animals in marketing. An image of a dog, for example, can be very effective in marketing products that have little to do with animals, such as Hush Puppies shoes that bear a Basset Hound as a logo. Animals kept as pets lack freedom, but when properly cared for they gain shelter, regular meals, veterinary care, and protection. In the 21st century, pet owners face similar choices and issues for their companions as for themselves in terms of consumption, health, birth control, vaccines, organic food, and even homeopathic medical care.

There are many organizations dedicated to animal rights and the fight against cruelty toward animals, such as the American Society for the Prevention of Cruelty to Animals (ASPCA). Those who advocate animal rights are often vegetarians. As for cultural restrictions, there is a food taboo against eating cats and dogs in Western civilizations, but not in societies like China. Although no law prohibits it in the United States, very few people eat horse meat. These meals are quite popular in some countries, however, and the meats can be bought in supermarkets in Canada, France, and Japan.

In recent years, people have experimented with nontraditional pets and exotic (and dangerous) animals such as crocodiles, panthers, and boa constrictors. When owners of these exotic animals abandon them, they can introduce hazardous species to new environments, thus disrupting the ecological balance—an example is the thoughtless discarding of living turtles or piranhas in a lake.

Philippines

THE REPUBLIC OF the Philippines is an archipelago of 7,107 islands, approximately 700 of which are inhabited. Its total land area is approximately 300,000 square kilometers (116,600 square miles). The islands are usually divided into three groups, from north to south: Luzon, Visayas, and Mindanao. Luzon has the two largest cities, Quezon City with 2.2 million inhabitants, and Manila (the nation's capital) with 1.6 million people. Both are part of Metropolitan Manila (or the National Capital Region), a large conurbation of 636 square kilometers with 12 million people (a density of 17,751 people per square kilometer). Total population is about 85 million, roughly two thirds of whom reside on the island of Luzon. Population growth is about 1.8 percent per year, with 24.89 births per 1,000 people (2006 estimate).

Since independence on July 4, 1946, the Philippines have experienced economic and political instability. Ferdinand Marcos was elected in 1965, but subsequently extended his power and tenure illegally. In 1986 the People Power Revolution overthrew Marcos, and Corazon Aquino (widow of murdered Senator Benigno Aquino, Jr.) assumed power. Since then, government corruption, ongoing civil unrest, and Muslim separatist movements have continued to hamper the economic and political life of successive democratically elected governments. Gloria Macapagal-Arroyo succeeded Joseph Estrada, who resigned following massive street protests after allegations of government corruption and cronyism.

Total Gross Domestic Product (GDP) is $91.36 billion ($451.3 billion, or $5,100 per capita PPP, 2005 estimate). In 2005 agriculture accounted for 14.8 percent of total GDP, industry 31.7 percent, and services 53.5 percent; 36 percent of the labor force work in agriculture, 16 percent in industry (particularly labor intensive industries including garments and footwear), and 48 percent in services. Forty percent of the population lives below the poverty line. The Philippines suffered less from the 1997 Asian Financial Crisis than its neighbors,

Mount Pinatubo

On June 15, 1991, Mount Pinatubo in the Philippines erupted after 500 years of dormancy. The volcano is part of a chain that stretches across the western part of the island of Luzon. It seemed that an eruption was so unlikely that the United States built their Clark Air Base only 25 miles away. At the time of the eruption there were about 500,000 people living within 30 miles of the volcano, with 20,000 at the air base, and 150,000 at nearby Angeles City.

On March 15, 1991, a number of earthquakes were felt on the northwestern side of the volcano. By April 2, small eruptions near the summit had begun; they continued for a few weeks. By this time scientists were studying the earth tremors closely. In early June the tremors grew more pronounced, and on June 7 magmatic eruptions took place and a lava dome formed at the summit of the volcano.

At 3:41 A.M. on June 12, an eruption began and a large eruption cloud up to 12 miles (19 kilometers) in height appeared; it was followed by other activity. At 1:42 P.M. on June 15 the seismographs at Clark Air Base went wild, and within 45 minutes they had been rendered inoperable. A massive eruption had begun. An ash cloud from the volcano covered about 50,000 square miles, with ash falling as far away as Cambodia and Malaysia. More than two million people were directly affected, and the Clark Air Base was destroyed. The eruption ruined 200,000 acres of rice farmland and killed 800,000 head of livestock or poultry. Because of the early seismic activity and warning, only 300 people were killed; the rest managed to flee.

partly because of remittances from its workers overseas. Over eight million Filipinos live overseas, and the remittances they send back ($12 billion a year) are a very important contribution to the national economy. Since 2002 economic growth has been quite consistent at about five percent per year.

Over 170 languages are spoken in the country, most of them belonging to the western Malayo-Polynesian language group of the Austronesian language family. The 1987 constitution gave Filipino and English the status of official languages. About 92 percent of Filipinos are Christians (81 percent Roman Catholic), and about five percent are Muslims who predominantly live on the island of Mindanao and in the Sulu archipelago.

The archipelago lies on the northwestern fringes of the Pacific Ring of Fire, and is of volcanic origin. There are frequent seismic and volcanic activities, and many active volcanoes, such as Mayon Volcano (a stratovolcano that has erupted around 50 times over the past 400 years), Mount Pinatubo (which erupted in June 1991 after 500 years of dormancy), and Taal Volcano. The highest point is Mount Apo on Mindanao at 2,954 meters. The climate is tropical marine with a northeast monsoon from November to April and a southwest monsoon from May to October. The Philippines have relatively high temperatures (mean annual temperature is 26.6 degrees C), high humidity (between 71 percent in March and 85 percent in September), and abundant rainfall (mean annual rainfall varies from 965 to 4,064 millimeters). Five or six cyclonic storms strike the Philippines each year.

Pinchot, Gifford (1865–1946)

GIFFORD PINCHOT, ARGUABLY the progenitor of modern American conservation and forestry, was born to a wealthy family in Connecticut in 1865. Upon graduating from Yale University, Pinchot went on to the French National Forestry School, learning techniques and concepts that would later develop further through German and British Imperial forestry, and which underpin modern natural resource management. After two years as a member of the National Forest Commission, he later served as the first chief of the United States Forest Service (1905–10). Pinchot also founded the Yale University School of Forestry and was elected governor of Pennsylvania for two terms. Owing to his lifelong efforts to reform management of natural resources, he engendered many controversies. Nevertheless, he helped to bring conservation issues to the forefront of politics.

With the help of President Theodore Roosevelt, Pinchot gave meaning to the word *conservation* and advocated the wiser use of natural resources. Defined in its historical context, conservation was understood to mean management of natural resources to maximize utilitarian benefits (e.g., timber) without depleting them unnecessarily over time. Pinchot asserted that if there was not proper state-led oversight of the use of natural resources, monopolies and corporate control might lead to overexploitation of public goods, especially forests, whose “sustainable yield” might be surpassed by overaggressive logging.

Pinchot was opposed on two fronts. More libertarian views about natural resources, oriented more exclusively toward markets, made conservation unpopular in some political circles. William Howard Taft, who succeeded Roosevelt in the White House, terminated Pinchot for speaking out against his policies as well as the policies of Secretary of the Interior Richard Ballinger. In what was later to be known as the Ballinger-Pinchot controversy, Pinchot showed his shrewd management of public opinion by subverting public confidence in Ballinger’s beliefs and character, forcing the latter to leave office.

On the other side, the dawning preservation movement (most prominently represented by John Muir) challenged the utilitarian philosophy at the core of conservation. The suspicion of preservationists about commercialization of nature caused ongoing public debates with Pinchot, not only over forestry but also the damming of rivers, most prominently in the Hetch Hetchy controversy.

Determined in his beliefs and efforts, Pinchot founded the National Conservation Association and served as its president for the group's first 15 years. In 1914 Pinchot expressed his interest in the U.S. presidency and ran for the Senate as a candidate of the Progressive Party. During his campaign, he ran against President Woodrow Wilson's World War I neutrality platform; Pinchot promoted the American movement to get involved in the war. After Wilson was reelected for a second term, Pinchot turned to Pennsylvania state politics and was appointed the Commissioner of Forestry in 1920. Pinchot's interest, however, was in the office of governor.

Proposing popular reforms, he won a close gubernatorial election. At the end of his first term, Pinchot took a seven-month leave from office but returned when he was elected for a second term. At the age of 72, Pinchot attempted to gain another term as governor but was defeated due to lack of support from the leaders in his own party. Toward the end of his term, Pinchot was hospitalized, and his wife became the acting governor for the remainder of the term. Setting his sights on the Senate, Pinchot failed for the third time to win a seat.

In his final years, Pinchot retired from politics but still gave advice to the president. As a retired politician, Pinchot unflaggingly supported his conservation beliefs and wrote a book about his own life as a forester. He was not only knowledgeable in the forestry field—he also introduced a very useful fishing kit that was later used in lifeboats during World War II. Gifford Pinchot died from leukemia on October 4, 1946, at the age of 81. The Pinchot family left their mansion, Grey Towers in Milford, Pennsylvania, to the U.S. Forest Service to be used as a museum for forestry education.

Plantation

PLANTATIONS ARE FARMS covering a large land area that are usually devoted to growing a single crop that will be sold for cash. They are classified according to the manner in which they employ laborers, or according to the kind of crop that is grown. The crops grown are usually something other than a cereal grain or pasture for cattle. Sometimes, orchards may be classified as plantations, especially if nuts are grown.

The English in Northern Ireland first developed plantations. Colonists were "planted" in Ireland on land that had been lost by the Irish in fighting against the English and the Scots. These and other Europeans and their descendants brought the plantation system to the Americas. These plantations resembled ancient latifundia in the Mediterranean, which were worked by slaves for the growing of olives for oil. In the 19th century plantations were established in Asia and Africa and on many Pacific islands. A common factor in almost all plantations is the necessity of gaining and maintaining a reliable source of affordable labor. The number of laborers required has usually been sizeable.

In the United States, plantations developed during colonial times. African Americans who had been imported as part of the slave trade and free whites worked on these plantations, which often grew tobacco. Tobacco was grown first in Virginia, and then in other colonies. Soon after tobacco cultivation began, slaves were introduced into the Virginia colony. However, many of the laborers on the early plantations were indentured servants who had to work for a number of years in order to pay for the cost of their passage to the New World. However, smaller farms that were sometimes "glorified" with the name *plantation* raised other crops besides tobacco, such as corn. Rice was first grown in the colonies in South Carolina's Low Country plantations. Slaves worked the coastal indigo and rice plantations for generations until the abolition of slavery. After the emancipation of the slaves, freed African Americans continued to work the rice plantations until new rice lands were developed in southwestern Louisiana and eastern Texas, where mechanical rice farming took the place of manual labor.

Cotton plantations developed rapidly in the south after the invention of the cotton gin. Plantations developed on the coastal plain, and later on the southern coastal plain of the Gulf of Mexico. Any plantation that was over 1,000 acres was considered large. As settlers moved inland to the Piedmont Region of the southern states, they established cotton plantations there as well. These upland cotton plantations were somewhat smaller than the coastal plantations, but they were usually devoted to producing crops that maintained the people on the farm, and cotton served as the cash crop of the plantation.

When the Civil War ended, slavery plantations changed from slave plantations to plantations using "free" labor. In effect, the people on these plantations were trapped. They would sell their labor to the owner of the plantation where they worked in exchange for a share of the crop. However, in order to pay for the seeds, fertilizer, farm tools, and other supplies needed to maintain themselves until the crop was harvested, they had to buy on credit. If the harvest was poor, they were still in debt after the harvest. If the harvest was good, they usually found that what they earned from their labor was barely enough to cover their debts.

Around the world, plantations developed to grow other crops. In many Caribbean countries such as Cuba, Haiti, and Jamaica, and also in Brazil, sugarcane was the plantation crop, and slavery was used extensively. The end of slavery did not see the end of plantations. In Hawaii, pineapple plantations developed along with the sugarcane plantations. In Central America, Ecuador, and other countries, banana plantations were developed with free labor.

Europeans developed plantations in the 19th and early 20th centuries in their colonies. The people of India worked many British plantations in Guyana and in the Polynesian Islands. Large numbers of their descendants now populate these areas. Other European countries using plantations included the Portuguese, French, and Dutch. Tea plantations were established in Ceylon, India, and China. Development of the motorized vehicle generated an enormous growth in the demand for rubber for tires. Rubber plantations where the trees could be tapped for their sap arose in Central and South America and in Malaysia.

MODERN PLANTATIONS

Modern plantations continue to produce a great many crops, and there are now even "environmental plantations" devoted to preserving a watershed area. The laborers who work on modern plantations are increasingly well educated and employ machinery in the production of their respective crops. Many of the problems posed by modern plantations are environmental. The development of plantations in places such as Indonesia threatens tropical forests. Palm oil, for example, is produced on land that could be left as wilderness preserves; palm oil could be grown on older, but less suitable land and still be profitable. Developing both policies and a culture that will abide by these policies is an ongoing task.

Industrial plantations are those that are devoted to a single crop (monoculture). In the southern United States, pine tree plantations (tree farms) covering vast areas supply the demands of pulp mills that produce paper. A major problem faced by any plantation is that growing only one crop is a specialization of the species. This single species growth invites different kinds of pests—for example, the boll weevil once nearly destroyed cotton production in the southern United States. The concentration of a single crop on plantations over a wide area requires pesticides to protect the crop, and the use of pesticides can have a negative environmental impact.

Plantation Forests

China, the United States, Russia, India, and Japan grow 65 percent of the world's plantation forests.

PLANTATION FORESTS ARE cultivated through the processes of afforestation (or reforestation). Afforestation refers to tree planting in areas not previously forested, while reforestation refers to tree planting on previously forested spaces. Asia has the highest proportion of plantation forests, comprising 45 percent of the global total. Five countries—China, the United States, Russia, India, and Japan—account for 65 percent of the plantation forests.

Plantations produce wood products such as lumber for construction material, furniture, or pulp for paper production. Most plantation forests use nonnative tree species. The most common species is pine (pinus), followed by eucalyptus. These species have biological and ecological characteristics, such as fast growth, that make them the world's most successful timber trees.

The plantation ecosystems are managed through "silviculture" practices. Most plantations are monocultures, with the trees planted in evenly spaced rows. Due to the heavy management of plantation forests, most researchers do not consider them natural forests; instead, they are viewed as an agricultural product similar to maize or wheat.

Plantation forests are primarily planted to meet the demand for wood worldwide. In addition, plantation forests sequester carbon, and many policy makers are encouraging their expansion to help mitigate our increasing use of fossil fuels. Both business and government organizations advocate tree planting as an activity that could offset many current environmental problems. Many researchers, however, disagree.

Studies on the ecological impacts of plantation forestry focus on the loss of flora and fauna species due to the monoculture nature of plantations. Most of the studies conclude that both flora and fauna biodiversity decrease in plantation forests. Furthermore, other studies show that recovery of the land after trees have been cut can take several years, and even longer if the land is to be restored to its previous grassland state. Pine and eucalyptus plantations acidify the soil, which is toxic to some plants. In many countries where plantations are common, another environmental threat caused by plantations is the spread of species to nonplantation areas. Eucalyptus, for example, is considered an invasive species in many parts of Africa.

Many international organizations, such as the World Bank and the United Nations (UN), have clear policies for their funding programs that support plantation forests. The UN Report on the Environment and Development from the 1992 Earth Summit acknowledges that both natural and planted forests "should be sustainably [*sic*] managed to meet the social, economic, ecological, cultural, and spiritual needs of present and future generations." The World Bank also has a forest policy, revised in 2002, which specifically mentions plantation forests: "The Bank does not finance plantations that involve any conversion or degradation of critical natural habitats, including adjacent or downstream natural habitats." While these organizations recognize the need for plantation forests, they also recognize the possible adverse ecology impacts of monoculture plantations.

Plants

THERE ARE AT least 400,000 known species of plants in the world. Vast numbers of plants have existed in earlier geological eras, a great number of which are now extinct. Of the plants that exist today, most belong to a group of "higher plants" that have roots, stems, and leaves, and that produce seeds in order to reproduce. Plants range in size from a single cell to giant sequoia trees, which can grow up to 240 feet (80 meters) tall.

Biologists have classified all living organisms into two kingdoms—the animal kingdom and the plant (Plantae) kingdom. Plants are distinguished from animals because most animals can achieve locomotion at will, while plants are rooted and cannot move to a new location unless carried by water or wind. Plants compensate for this lack of mobility by giving movement to their seeds. Many plants produce fruits that are eaten by birds and then deposited elsewhere. Some plants simply drop their seeds to the ground where they are moved by water, insects, or animals; others, such as cottonwood and maple trees, use the winds to broadcast their seeds.

Plants also differ from animals in their growth cycles. While animals stop growing at maturation, plants continue to grow until they die. They grow thicker in their stems, their roots deepen, and new growth is added. Some plants have short life spans while others live for centuries. Some trees live for thousands of years; there are trees that are estimated by biologists to be 5,000 years old.

PLANT FOOD PRODUCTION

Another difference between plants and animals is that plants can produce their own food, while animals eat either plants or other animals. The roots, stems, and leaves of plants are used to manufacture food. Roots take in water and minerals like calcium, iron, nitrogen, phosphorous, and potassium, then use these and other chemicals to make food. In order to do so, the water and nutrient chemicals have to reach the leaves. Because the nutrients travel through the stem of the plant the process can be a long journey in tall trees. In most cases the stem has vascular tissue through which the nutrients travel. As the water moves from one cell to another it eventually reaches xylem, which is a complex plant tissue. Xylem is formed into long tubes or vessels through which the water carries dissolved salts of the nutrient chemicals.

Eventually the fresh nutrient supply reaches the leaves of the plant. At the same time, food from the leaves of the plant, often in the form of some type of sugar, moves down the xylem in a liquid watery solution in tube-like cells called sieve cells. These cells have little holes in the wall of the tube that act like a sieve, allowing food to pass to the plant. The sieve cells are supported by phloem cells. These are plant tissues that are in parallel with the xylem tissues. A third type of plant tissue called cambium separates them. This tissue provides support and also keeps the nutrient solution separate from the food solution.

Plants also have a variety of stems—the trunks of trees, for example, are large stems. Some are underground stems, such as rhizomes, which send roots deeper into the soil while forcing branches to the surface, where leaves can grow. Some stems are climbing stems and use tendrils for support, like ivy plants; other plants, such as tulips and daffodils, have bulbs as stems. Plants are the only organisms that can convert inert matter into living matter. Plants absorb nutrients from the earth, from water in which they grow, or even from the air. An example of a plant that absorbs nutrients from the air is spanish moss. Some plants, such as fungi, do not manufacture their own food. Some of these are parasitic, such as the dodder plant, which begins life rooted in the ground, but then grows like a vine around its host plant, sucking water and nutrients from the host. Meanwhile, its own root dies and it becomes permanently attached to its host.

PHOTOSYNTHESIS

The leaves of plants convert carbon dioxide, water, and nutrient chemicals into plant food via a process called photosynthesis. Without this process there would be little or no life on the planet. Most leaves have two parts: The lamina is the leaf's blade; the petiole is its stalk. There are plants that have leaves that grow directly from the stem—these plants do not have a petiole. The petiole extends to the tip of the leaf and branches out to form its veins. Water and chemical nutrients flow through the veins of the leaf where they will be used in the making of the plant's food.

Leaves vary widely in shape and placement upon the stem. A cross section of a leaf would show that it has layers of different kinds of tissues. The epidermis is the leaf's surface. Below the epidermis surface layer are the palisade layers, which have long, food-producing cells containing chloroplasts. There are also palisade cells and spongy cells. Thousands of holes called stoma allow air to circulate between cells. Leaves usually have a glossy or waxy side that faces the sun, and many plants have leaves that can move to face the sun. Sunflowers have a large flowering head that moves with the sun during the day. Leaves absorb sunlight through the lamina, which also takes in carbon dioxide directly from the air.

Respiration takes place continually in a plant as the cells use energy, in the form of glucose, to make food. It happens in a nucleus where a jelly-like substance, cytoplasm, is surrounded by a cell wall. The nucleus uses its coded information to make a new plant, and it also can control energy production in the cytoplasm. Aerobic respiration in plants uses oxygen for the air, as do animals, but plants produce more oxygen than they use. The surplus oxygen is used by other organisms. While some plants use respiration, others do not. There are plants that breathe with anaerobic respiration. This process breaks down carbohydrates to form other chemicals; among the chemical by-products are alcohol and lactic acid.

The food making process of photosynthesis is a complex chemical process that can only take place in daylight. The leaves of the plant trap sunlight with chlorophyll. The green pigment chlorophyll is located in the chloroplasts, where the photosynthesis process takes place. Plants have pigments in their leaves other than chlorophyll, but the green chlorophyll so dominates the leaf that other pigments, such as the reds, browns, and yellows of fall foliage, are not seen until the chlorophyll is destroyed.

The structure of a chloroplast begins with a membrane on the outside. It has a stroma, which is a layer covering the thylakoid and the grana. The thylakoid is composed in sheets, as is the grana, which contains the chlorophyll. Through the photosynthesis process the plant makes carbohydrates and oxygen. The oxygen is expelled through the stoma air holes and the carbohydrates are dissolved in watery solutions that are transported to other parts of the plant to be used as sugars or starches.

FOOD AND WATER STORAGE

Sugars or starches may be stored in the plant as pigments or fats. For example, the avocado plant produces fruits that are fatty in content. Others, such as dates, beets, or sugarcane, are high in sugar content. Plants store food in roots, leaves, and seeds. An example of a plant that stores its food in roots is the potato plant. The mature tubers are very high in starch content, having grown as the plant stored food from the photosynthesis process as carbohydrates in the tubers.

After the plant has converted nutrients, water, and carbon dioxide into food through photosynthesis, it also uses a process called transpiration. The water that the plant has drawn to its leaves is used to make food and also to deliver it to the plant's cells. However, a great deal of the water is breathed out as water vapor through the plant's leaves. A tree can expel or breathe out hundreds of quarts (or liters) of water a day.

Some of the water that a plant transpires is lost through its stem, and some is lost through flowers. However, the bulk is lost through stomata. The water that is lost evaporates, cooling the leaves of the plant and regulating the plant's temperature. The stomata, through which respiration and transpiration take place, are flanked by guard cells that control their closings and openings. Opening allows air to enter into a sub-stomal chamber. The leaves of plants from moist or humid climates have flat surfaces that allow water vapor to easily pass through the stomata opening and into or out of the leaf.

In order to control their use of water, plants have adapted many mechanisms and leaf structures. In the winter deciduous trees lose their leaves and go dormant. The process of shedding leaves annually is called abscission. In temperate and polar seasons the leaves are shed during the autumn in preparation for winter; in wet-dry climates the abscission takes place in the dry season.

Evergreen trees and plants are sometimes called semi-deciduous. In winter, conifers keep their needle-like leaves, which are adapted to continue respiration and transpiration even in winter. In desert climates cacti function well without leaves, storing water in their stems. The waxy surface of the plant reflects the sun and regulates the temperature of the plant, allowing little water to escape.

REPRODUCTION

Gymnosperm plants do not use ovaries to enclose their seeds, while angiosperms have flowers that are pollinated to produce seeds enclosed in an ovary. Conifers such as pine trees and fir trees are the best known of the gymnosperms. They enclose their seeds in woody cones, which are male or female. Ovules form on the scales of female conifer cones, while pollen forms on the scales of the male cones. Wind carries the pollen from the male cone to the female cone.

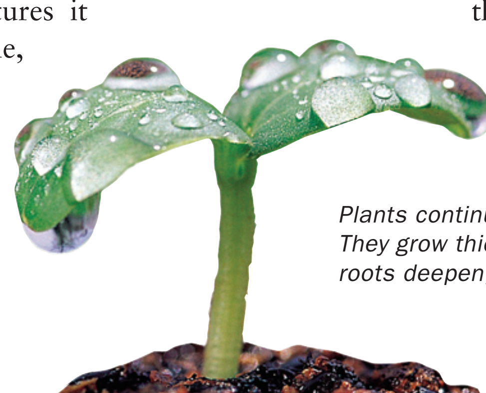
There are two groups of angiosperms. The dicotyledons have two seed leaves; monocotyledons have only one seed leaf. Wheat seeds are monocotyledon because upon germination only one leaf appears at first. However, beans are dicotyledons because as the seed embryo matures it has two seed leaves. For example, roasted peanuts when split reveal what looks like the head of a man with a bow tie—the bow tie is actually two cotyledons, which means the peanut seeds will germinate as dicotyledons.

The flower is the main reproductive part of the angiosperm. When the flower is mature it opens anthers in order to let out pollen grains. Many plants use insects to assist with pollination; others allow their pollen to be carried by the wind. Western junipers and southern pine trees will emit so much pollen that cars and other surfaces will be coated in yellow pollen dust for days during pollination. Some plants are capable of self-pollination, but others need a pollinator. Varieties of plums or pears are good at pollinating, while other fruit trees will not produce unless pollinated. Some trees such as holly have males that provide pollination for the females, which have the characteristic red berries.

A flower usually has a male and a female part. The stamen is the male part and has delicate filaments that hold grains of pollen that contain the active sex cells of the plant. The pistil is the female part of the flower. It has at least one carpel; the carpel has an ovary, inside of which are ovules that contain sex cells. At the far end of the pistil is the sticky surface of the stigma, which receives the pollen grains with the sex cells of the male portion of the flower. Protecting the stamens and the carpels are the sepals and the petals, which together form the corolla. When fertilization takes place, the pollen is transported from the flower's stamen to its stigma. After the pollen falls on the stigma, it forms a long tube that goes down though a structure called a style until it reaches the flower's ovule, where fertilization takes place. Once the ovule is fertilized, the flower will shed its petals.

The ovary takes food from the plant's leaves, and as it does, the seed or seeds develop rapidly. The seed is covered in a tough protective coating and contains an embryo plant made up of a root, a shoot, and one or more shoot leaves (cotyledons).

There are many ways in which the ovaries of plants develop after fertilization. Some dry out. Others become fleshy or develop filaments that are so delicate they can be blown about on the winds—dandelions, for example, use the wind to spread their seeds. Others plants,



Plants continue to grow until they die. They grow thicker in their stems, their roots deepen, and new growth is added.

such as wisteria, use an explosive rupturing of the seed pod to propel seeds some distance from the parent. Plants may also depend on animals such as birds. Birds eat the seed, but only the fleshy outer portion is digested; the seed with its thick protective coating is passed from the bird to a new location where it puts down roots after germinating. Some seeds stick to the coats of animals—burrs and other "riders" may be carried miles before they are dropped.

After the seed reaches a moist spot it germinates. Water softens the coating and allows it to take up the water and begin growing by putting down its tap root and sending up shoots. Sometimes fruit flesh serves as a built-in fertilizer. The fleshy part is covered with a skin. A drupe is a fleshy fruit with a stone-like pit or seed that is covered with a fleshy fruit. The skin is called the epicarp and covers the fleshy mesocarp, which in turn covers the hard shell that contains the seed. The seed is an endocarp and it contains the embryo plant.

A few plants do not produce seeds but instead reproduce using spores. Lichen, which is a form of algae living in a symbiotic relationship with fungi, reproduces with spores. Lichens grow on a number of surfaces including on rocks and tree trunks. Other plants such as ferns or mosses have spore capsules on the underside of the leaves or fronds. When a moss spore capsule is mature it drops to the ground and germinates; each spore then develops a thin branch or protonema on which a bud grows.

ADAPTATION

From mountaintops to seas, from deserts to swamps in the tropics, plants have found ways to adapt to the enormous climatic variations of the earth. They have also adapted to soil and moisture conditions. For a vast number of plants, conditions in temperate zones are nearly ideal, except for the presence of other plants that compete for soil, moisture, and sunlight. In other environments, such as jungles, the hot, moist growing conditions are too favorable. Enormous numbers of plants crowd together to capture every bit of space for rooting, for water, and for sunlight. Taller plants will capture the sunlight and shade out small growing plants. To meet this challenge, some plants grow as vines to reach the sun.

Orchids are epiphytic plants that grow in the heights of trees. Some grow on branches and others on tree trunks in order to reach the sunlight. These types of plants have no roots for obtaining moisture so they get it through their leaves or through fine-haired roots that hang in the moist air. Their aerial roots also capture minerals, especially when the plant is near oceans that cast water vapor into the atmosphere containing salts that the plant can use. Others plants use leaf structure to capture water—the bromeliad has a leaf that forms a basin shape in which water is retained for the plant's use.

Some plants, such as mangrove trees and willows, have adapted to living in or next to water. Others, such as the herb water crest, live in water with their leaves on the surface. Water lilies are rooted in the muck of ponds but have a stem that supports a leaf that floats on the pond's surface. Other plants live completely under water—many seaweeds never reach the surface. In order to gather nutrients in a nutrient-poor environment, plants have adapted a number of strategies. Insectivorous plants feed on insects. The pitcher plant uses a scent to attract insects, then traps them in a watery solution where they drown and are dissolved for their nutrients. Others use traps that spring shut or have sticky hairs that trap the insect much like a spider's web.

CULTIVATION

Agriculture is the human activity of growing plants for use. Because of the usefulness of plants, people have been cultivating them for at least 12,000 years. Cultivation of plants depends upon the character of the plant. For example, viticulture—the cultivation of grapes—involves more that just planting grape vines. The vines have to be pruned each year in order to stimulate growth of grapes. Otherwise all of the growing energy would be put into new vines and leaves. Plants such as coffee or tea are grown for their stimulating effects; others are grown for the intoxication value. Beer is brewed from wheat and a great many other plants such as rice, coconut, chocolate, and fruit juices can be used to produce alcohol. Plants such as marijuana and poppies can produce addictive drugs that can also be used medicinally.

Plants are uniquely important in the ecology of the earth because they supply life-giving materials to other creatures. They make their own food by combining water, carbon dioxide, and mineral salts with sunshine. Green leafy plants are the beginning of the food chain. Some of these exist in the oceans or other bodies of water. Herbivores are animals that eat only plants; they include deer, buffalo, cows, rabbits, and many others. Carnivores, in turn, eat the flesh of herbivores. The waste materials of both are returned to the soil as droppings that can be used later by plants.

Plants also provide humans with food, fiber, and shelter; people have been using plants for the entire history of the human race. The earliest humans gathered nuts and berries and used vegetation for shelter. This is still the case with millions of people living close to nature even now.

Plastics

PLASTICS ARE MATERIALS that can be molded, spun, or shaped to make products for human consumption. Plastics may be natural or synthetic. Natural plastics are materials such as asphalt, bitumen, cellulose, horn, rubber, shellac, tortoise shell, and waxes. Humans have crafted products for millennia using natural plastics. Ancient peoples in all parts of the globe used natural plastics for decorative or functional purposes. The ancient Egyptians soaked the winding cloths for mummies in natural resins to protect the body of the deceased from decay. Musical instruments, parts of weapons, or other devices have been made in part or in whole from the horns of sheep, cattle, or other animals.

In the 1850s, shellac, a resinous secretion of the lac insect, was imported from southern Asia into the United States, where it was patented as a natural plastic. Another natural plastic from southern Asia was gutta percha, which is sap from trees of the same name in Malaysia. It was used to insulate electric wires that were just coming into use. In 1897, milk was used to develop casein plastics. Other natural plastics materials derived from tropical forests, such as rubber, began to be employed by manufacturers.

By 1900, scientists were finding more ways to manufacture modified natural plastics, such as artificial horn, celluloid film, and cellophane. While natural plastics were useful, there were drawbacks to using them. The supply was insufficient and unreliable. They were not always amenable to being molded, and they were prone to degrading or, in the case of celluloid, were highly flammable.

In the early 1900s, developments in the coal and oil industry made available vast quantities of material that could be employed in the manufacture of synthetic plastics. In 1909, Leo Hendrik Baekeland, an American chemist, created Bakelite. Baekeland developed a thermosetting synthetic resin (phenolic resin). His invention was commercially successful and was employed in telephones, pot handles, and many other products. As research into the chemistry of long chain organic polymers expanded enormously, many new ways to combine or modify them to make synthetic plastics were developed. In Germany, the I.G. Farben Company discovered how to make polystyrene and polyvinyl chloride by 1932. In the mid-1930s, it patented polyepoxide (epoxy). In 1937 Friedrich Bayer & Co. invented polyurethane. Du Pont's research team, led by Wallace Carothers, discovered how to synthesize vinylacetylene with chlorine to make synthetic rubber (neoprene) in 1930. In 1935, Carother's team found that a polyamid formed by combining hexamethylene diamine and adipic acid produced nylon. His discovery of nylon made parachutes available in vast quantities.

After World War II, more new plastics were invented. The textile industry began to use many plastic fibers, which were blended with natural fibers and marketed as polyester blends. Among the new products were Tupperware, plastic bottles, film, and safety helmets. Thermoplastics (polysulfone) were used in facemasks or in hospital equipment. Everything from spacecraft parts to artificial body parts are now made with plastics.

While plastic manufacturing has been refined in the last 50 years, biodegradability is still in experimental stages.

MANUFACTURE

Plastics are made from synthetic resins. The resins are made from chemicals manufactured from natural sources such as coal, petroleum, salt, water, and limestone. Chemically, synthetic resins are long chain polymers. Monomers are used to build the polymers by combining them together with chemicals such as ammonia and benzene. The process of polymerization joins the monomers into long chains of atoms and molecules.

Plastic products are manufactured by molding, casting, laminating, extruding, or calendaring. Other methods include vacuum forming and press forming. Molded plastic products are formed by squeezing a molten resin into a mold that will be hardened by pressure and by chemical reactions. Thermoplastic resins harden when they are allowed to cool, while thermosetting resins harden under heat and pressure. Once set, the plastic object is permanently molded.

Casting is similar to molding, but the plastic resin is poured instead of squeezed into the mold. This method is useful when using thermosetting and thermoplastic resins. Other casting resins contain acrylic, polyimide, polyurea, and silicone adhesives. Often, the casting resins are mixed with a hardener. They are used to make semiconductors and insulated parts for generators, transformers, switches, and circuit breakers, and even in artwork. Some photonic and optical equipment made with casting resins use polymers and elastomers. Formica table or counter tops are made with the laminating method of applying plastics. Vast quantities of laminating plastics are sold to businesses and home users.

Extruding forces solid resin material into a heating device that then pushes (extrudes) it out through an opening to form products such as fibers, garden hoses, piping, gaskets, or tubing. The extruded material may be forced through a rectangular opening that will form molding. The textile industry uses vast quantities of synthetic fibers for products such as carpet. Calendaring pushes plastic resins between rollers to coat different products, such as plastic cards used in business or other services. Plastic film is made by extrusion and by calendaring.

ENVIRONMENTAL IMPACT

The amount of plastic consumed every year has grown greatly over the last 50 years. Unfortunately, so has the negative impact of plastics upon the environment. Apart from the petroleum and other materials used to make plastics, discarded plastic products remain in the environment for a long time. Large amounts of waste are dumped into landfills. Also, large amounts scatter as unsightly trash. Efforts to reduce the amount of plastics have focused on recycling. Great quantities of plastics are reused after they have been melted and recast into other products. Plastics are also incinerated for energy.

Some progress has been made toward making plastics much more biodegradable. Nylon naturally degrades in direct sunlight because the light breaks some of the bonds in the polymers; researchers are seeking ways to ensure that more plastics will degrade in sunlight. Another way to ensure that plastics degrade is to add starch-based resins to the formula. However, the "rotting" is only partial. Researchers are also experimenting with plastic-eating bacteria to create biodegradable plastics, and two nylon-eating bacteria have been identified. These methods are in the experimental stage because of costs and the danger that bacteria could evolve and end the age of plastics.

Poaching

POACHING IS THE act of stealing animals or plants from areas in which they are protected. The motive for poaching may be food or economic gain. The latter reason has gained in significance since the beginning of the 20th century, when international trade in animals and plants was stimulated by rising demand and prices and, concomitantly, falling supply of the creatures involved. The intensive poaching of, for example, elephants and rhinoceroses, for ivory and horn respectively, have led to the almost catastrophic decline in numbers of those animals. This has had a broad negative impact on the environment in which they live.

Poaching may provide a profitable living for many people but, in addition to its illegality, it is not a sustainable practice as market forces lead to the extinction of the creatures concerned. In many countries in Africa and elsewhere, there is constant conflict between poachers and local authorities seeking to stop the poaching. Violence is often a part of this conflict because of the availability of weapons customarily used in capturing animals, and because of the high stakes nature of the activity.

Poaching extends around the globe. In Siberia and Myanmar, poachers aim to log precious hardwoods; in many oceans, illegal whaling takes place for culinary purposes. In British waters, fishing boats from mainland Europe and farther away take large catches of the dwindling supply of fish in acts that many people consider poaching. It is estimated by some that there will be no more edible fish in the world's oceans within two decades. However, these figures are contested. Most economically important fish species have quotas imposed to try to prevent overfishing, but while sustainable quota levels are also contested, it is apparent that many involved in fishing are routinely exceeding their quotas, while also destroying many other species through bycatch. The value attached to fish products in some markets justifies the risks that poachers take.

The prices of abalone, shark's fin, and tuna in some East Asian markets represent attractive opportunities for would-be poachers. The same is true for those who seek to kill and harvest body parts from animals for use in traditional remedies and tonics, such as those in Chinese medicine. Although markets have opened in other countries, rapidly rising affluence in China has made it particularly significant in the context of poaching. A number of Chinese people have responded to increasing affluence by seeking to obtain expensive medicines and exotic bush meat. It is believed that the crowding together of so many different species of animals in unsanitary surroundings in southern China brought about the conditions in which the lethal virus SARS first originated.

Designating poaching as illegal requires that property rights of some sort be enacted by the state, both to regulate access to land and to give the state rights to ownership of animals and plants within designated areas. Alternatively, private property rights can be used by landowners to claim the same protection from poaching. In countries such as Britain, where an aristocratic elite has historically dominated land ownership, poaching was legally met with armed responses. Poachers, who were motivated primarily by hunger, were liable to severe punishment and even execution. Landowners' control of the creatures resident on their lands has contributed to popular revolutions in a number of countries. In recent years, attempts to end poaching have focused both on prevention, possibly through the use of armed wardens and high technology monitoring equipment, and on persuading potential poachers to undertake other activities.

Since the absence of suitable alternatives led people to take up poaching in the first place, reducing poaching often means developing new forms of work and income for local people. This can be an expensive undertaking and some people will consider it unfair when extra resources are devoted to people who have turned to crime. An additional way of inhibiting poaching is through education and through ratification of the Convention on International Trade in Endangered Species (CITES), the relevant international contract.

Point Source Pollution

FOLLOWING THE PASSAGE of legislation in the 1960s and 1970s aimed at cleaning the air and waters in the United States, rigorous efforts have focused on point source pollution control. The term identifies sources of pollution that emanate from a discreet and clearly identifiable point. The Environmental Protection Agency lists the following structures that fit the definition: pipes, ditches, channels, tunnels, conduits, wells, rolling stock concentrated animal feeding operations (CAFO), landfill leachate collection systems, water-borne vessels from which pollutants may be discharged.

Point source is distinguished from "non-point" source pollution, such as precipitation runoff from an urban area that is not caught in a sewer system, or agricultural pollution from the seepage into the soil of fertilizers and insecticides. Discharge from a power plant smoke stack is an example of point source pollution. Other sources include discharged waste water from industrial plants and municipalities through pipelines. If the materials that are being discharged are not treated to remove pollutants, the effects on air and water can be degrading. Even treated effluents can still have a measure of pollutant material in them. It is the amount of pollutant material in treated water that demands regulation.

REDUCING WATER POLLUTION

In the case of water pollution, the Clean Water Act established the National Pollutant Discharge Elimination System (NPDES) in 1972. This agency issues permits to regulate the amount of pollutants carried in water discharged from industries and municipalities into surface waters. Under the NPDES legislation, licenses are issued specifying the quantity and quality of pollutants that may be legally discharged. Staff members of the Environmental Protection Agency will periodically monitor the sites and collect sample of the effluent to determine if discharges are within the legal limits. Since the enactment of the NPDES, the amount of point source pollution has significantly decreased nationwide.

A case in point is the reduction in point source pollutants entering the Expansive Chesapeake Bay on the Atlantic seaboard. In the 1987 Chesapeake Bay Agreement, a document that addressed the immense value of this body of water, a goal was set to reduce the level nitrogen and phosphorous by 40 percent by 2000 from the 1985 levels. This degree of reduction of these chemicals would not only cut pollution but also increase oxygen levels in the waters and stimulate the growth and survival of aquatic life. In the 1992 amendment to the agreement, it was agreed to continue the 40 percent reduction in pollutants beyond 2000. The agreement is a complex one given that three states (Pennsylvania, Maryland, and Virginia) and the District of Columbia each developed strategies to achieve the reduction goals.

The process involved in implementing the reduction goals is also complex. Pont sources in each municipality located on Chesapeake Bay were required to implement a Biological Nutrient Removal (BNR) program. In this process, nutrients are removed from municipal waste water in addition to solid waste. The BNR process for removing nitrogen begins with the conversion of ammonia to compounds of nitrites (nitrification), which stimulates the growth of nitrogen consuming bacteria. The next step (denitrification) transforms nitrites to nitrogen gas through the action of nitrite converting bacteria.

Similar reductions in point source pollution have occurred in Texas. Since the enactment of the NPDES, the state has seen a 70 percent reduction in the amount of pollution from municipality waste water. At the same time a number of firms in the state were issued "no discharge" permits due to the degree of pollutants contained in the effluent. In these cases, the retained waste water is evaporated or used in irrigation systems. For a number of agricultural activities in Texas (poultry, dairy and feedlot operations), "no discharge" permits have been issued. This precludes the discharge of animal waste into surface water and mandates its retention in secure ponds.

Poland

HISTORICALLY, POLAND HAS had to struggle to maintain its independence from its more aggressive neighbors. After World War II, Poland became a member of the Soviet bloc; but the Solidarity movement, which gained momentum throughout the 1980s, led to a resurgence of nationalism. After the dissolution of the Soviet Union, Poland instituted major political reforms. Poland's market economy is still evolving. A per capita income of $12,700 places Poland 73rd among world incomes. Unemployment is high at 18.3 percent, and 17 percent of the population live below the poverty line. The United Nations Development Programme Human Development Reports rank Poland 36th among nations of the world on overall quality-of-life issues.

Bordering on the Baltic Sea, Poland has 304 miles (491 kilometers) of coastline. The temperate climate produces cold, rainy, moderately severe winters. Summers are mild with frequent precipitation. Flooding is a common threat throughout the year. Except for mountains along the southern border, Poland's terrain is mostly flat. Around 46 percent of the land is arable, and over 16 percent of the workforce is engaged in the agricultural sector. Other natural resources include coal, sulfur, copper, natural gas, silver, lead, salt, and amber.

The Soviet presence in Poland resulted in heavy industrialization and substantial environmental damage. The true extent of the environmental attrition was revealed only in the post-Soviet era with a legacy of heavily polluted air, water, and soil and severely damaged forests. Some 60,000 tons of banned pesticides continue to be stored in Poland, and 25,000 tons of these are stored on farms scattered around the country, creating a potential ecological disaster.

In 1991 the government recognized that the most extensive damage had occurred in heavily industrialized Upper Silesia, which is home to 11 percent of the Polish population. Studies revealed that infant mortality was nearly five times the rate of Western European nations and that total life span was four years lower than that of the rest of Poland. Cancer rates were also abnormally high. Rates of circulatory and respiratory disease were elevated, and high levels of lead were discovered in the bloodstreams of children in the area. Indiscriminate waste disposal in the area had also led to 29,653 acres (12,000 hectares) of land being declared unfit for future cultivation.

A study in 1990 revealed that 65 percent of rivers in Poland were polluted enough to corrode industrial equipment. The Vistula River carried these pollutants into the Baltic River, spreading contamination. Such contamination meant that river water could not be used for irrigation, and only 5 percent of river water was potable. Acid rain spread further pollution into the lakes and threatened two-thirds of the nation's forests. Major damage had also taken place on military bases where raw sewage had been released and vegetation had been annihilated by heavy equipment.

All national and regional parks and reserves had also been polluted. Today, some 12.4 percent of Polish land is protected. Fifteen of 84 mammal species endemic to Poland are threatened with extinction, and four of 233 endemic bird species are endangered. Overall cleanup costs of the Soviet occupation were estimated at $3.4 billion. Predictably, the Soviets refused to bear any of the expense. However, other countries offered assistance through grants, loans, and debt forgiveness and provided expert and technical advice.

In the 1980s, public activism accelerated in Poland in response to the ongoing environmental situation and to the construction of a Czech coking plant near the Polish border and the Chernobyl disaster in 1986. The government established the Ministry of Environmental Protection and Natural Resources and began passing new environmental laws. In 1990 Poland announced a new policy of "ecodevelopment" designed to force industries to modernize and restructure using environmentally friendly technology. The following year, the national policy was put in place, with an emphasis on polluters bearing responsibility for the damage they caused. With the help of the United States and several European nations, the ministry developed a list of 80 enterprises most responsible for the pollution and placed them on notice that they would be closed if pollution levels were not reduced. The State Environmental Protection Inspectorate was established to enforce environmental regulations.

Despite the new commitment to environmentalist, air pollution from sulfur dioxide is still emitted from coal-fired power plants, posing serious health risks. Acid rain generated from the same source persists in damaging forests and ecosystems. Almost 62 percent of the Polish population live in urban areas. With 259 cars per 1,000 people, Poland produces 1.3 percent of the world's carbon dioxide emissions. Water in Poland is still polluted from industrial and municipal sources. Efforts to meet European Union (EU) standards continue, but the costs of doing so remain high. In 2006 a study by Yale University ranked Poland 38th of 132 nations on environmental performance, in line with its economic group but below the geographic group average. Poland was ranked particularly low on biodiversity and habitat protection.

Poland's commitment to the global environment is demonstrated by its participation in the following international agreements: Air Pollution, Antarctic–Environmental Protocol, Antarctic–Marine Living Resources, Antarctic Seals, Antarctic Treaty, Biodiversity, Climate Change, Desertification, Endangered Species, Environmental Modification, Hazardous Wastes, Kyoto Protocol, Law of the Sea, Marine Dumping, Ozone Layer Protection, Ship Pollution, and Wetlands. The Air Pollution–Nitrogen Oxides, Air Pollution–Persistent Organic Pollutants, and Air Pollution–Sulfur 94 agreements have been signed but not ratified.

Rebuilding Warsaw

The city of Warsaw was badly bombed by the Germans in their 1939 invasion of Poland and suffered greatly during occupation. The German plans to destroy the Jewish ghetto led to the Ghetto Uprising in April 1943; in August 1944 the Warsaw Uprising saw further damage to the city. When the Germans retreated from Warsaw soon afterward their soldiers destroyed much of what had survived. Adolf Hitler, in one of his last speeches to the German Reichstag, declared that Warsaw was no longer a name on the map of Europe. Some 850,000 inhabitants of Warsaw, or two-thirds of the prewar population, were dead or missing. General Dwight Eisenhower described the ruins of Warsaw as the most tragic sight he had ever seen. Some suggested that Poland should reestablish its capital in another city.

Nevertheless, in 1945 planning began for the rebuilding of the city, which took ten years. Much of the heart of the old city was rebuilt, with the master plan involving collecting information on all the historic monuments and buildings in the Old Town so that they could be rebuilt to look as they did before the war. In other parts, ruins were replaced by "socialist functionalism" and large numbers of industrial factories. The need to house tens of thousands of people immediately after the war resulted in many prefabricated concrete apartment blocks, giving some parts of the city a dismal quality. However, it was a remarkable feat of construction, and did provide housing for many people.

In recent years new steel and glass towers have appeared throughout the city, along with many other buildings that are providing colorful contrast to the gray of the suburbs.

Policy, Environmental

ENVIRONMENTAL POLICY CONCERNS the attitudes that states, representing their people, adopt toward the environment and the need to protect or exploit it in different ways. These range from the desire to maintain nature in a pristine state to the desire to exploit all resources of the land and atmosphere without regard for the future or side effects.

Most ideologies, in common with most forms of organized religious belief, derived from a period in which agricultural lifestyles, featuring sustainable use of resources as part of folk wisdom concerning husbandry of the land, were dominant. This might have been expressed either through sacred texts outlining the role of man as part of nature or through practical education such as that provided by Buddhist monks in forested parts of East Asia.

Political ideologies that have derived from more modern history, such as communism or libertarianism, tend to have been created in periods in which industrial activities dominated agricultural activities. They are therefore more likely to support extraction of resources to facilitate more production. In these cases, the purpose of nature is generally seen as supporting mankind's development and ascension.

As modern life has become more complex, environmental policy has both become a more recognized area of concern in its own right and broadened to engage with numerous issues. Solid waste management, apportioning fishing rights, controlling industrial pollution, and addressing global warming are all issues now included within environmental policy. Governments around the world have established specific departments to formulate and implement policies and to monitor changes. Evidence of global warming and the effects of pollution have sparked worldwide interest in environmental issues, leading to increased involvement in voluntary organizations and growing pressure on elected politicians to adopt what are perceived to be environmentally-friendly policies.

RELIGION AND ENVIRONMENTAL POLICY

Most large religions posit that the universe and all the aspects of nature within it are created by some kind of supernatural figure. Consequently, they deem it appropriate for mankind to respect nature and not damage it heedlessly. However, in the case of a religion such as Christianity, the sanctioned sacred text of the Bible explicitly gives wardenship of the earth to humanity and, hence, provides justification for exploitation of the world, although not to the extent of damaging it. Nevertheless, when there is controversy over the meaning of sacred texts and the means of interpreting them, there may be diversity in attitudes toward nature and its use.

Most religions embrace the concept of sacred areas or lands that should be sequestered from public use; these include taboo areas such as graveyards, sacred mountains, and areas where supernatural events are said to have occurred. In some cases, this is manifested in the building of sacred edifices such as cathedrals or temples or the preservation of the area in its original state. In the kingdom of Saudi Arabia, state-sanctioned sacred places are preserved, while those from other traditions are suppressed.

These religious practices demonstrate that belief patterns are held to be directly related to acceptable and unacceptable uses of the environment. Related to this are religious dietary practices and food taboos. Historical patterns of technology use and understanding probably helped inspire beliefs that some foods were taboo. This has led to different patterns of land use insofar as some animals are excluded from entering sacred territory or, as in the case of cows in Hindu India, are allowed to wander freely.

Humanist philosophies or natural religions have often featured a profound reverence for nature that is to be manifested in the unchanging worship of the land and the life that resides within it. The philosophies of Henry David Thoreau may be considered in this light, as might the English poets William Wordsworth and John Keats. The great visionary poet William Blake saw nature as God's expression of paradise on earth and, hence, it was all the better left in an unimproved state.

Chinese painting often depicted the harmonious relationships possible between mankind and nature. This was linked to the concept that the Chinese emperor was provided with legitimacy to rule through the Mandate of Heaven and could only rule as long as the mandate was maintained. Environmental phenomena were powerful signals from heaven that the mandate was at risk or might already have been withdrawn. Earthquakes, disease, or famine could all be symbols that the temporal, the environmental, and the spiritual were all linked. Across most cultures of the world, astrological phenomena such as eclipses or comets were also believed to betoken some kind of important temporal change as mandated by supernatural forces.

A final example of a quasi-religious philosophy is that of James Lovelock's Gaia, which posits that nature and indeed the planet exist in a kind of holistic and self-regulating system. This system can manage itself sustainably within certain parameters, but there are limits to what can be managed. The impact of man upon this system is believed to have exceeded the self-healing limits, making it time for more radical policies to remove or at least nullify that influence. In extreme cases, this has led some people to the position that no more use of environmental resources should be permitted and that all forms of industrialization are now unsustainable and should be ended. This policy would call for a huge reduction in the standard of living of the developed world so as to protect what remains of environmental resilience.

EXTERNALITIES

One of the central aspects of environmental policy is the concept of externalities. This concept refers to all of the additional impacts on the environment that a physical change can have. In terms of environmental change, forests provide a facility for sequestering carbon from the air and for providing aesthetic and recreational services for people. This is in addition to the physical impact of the forest, which provides valuable logging resources and a habitat for wildlife.

Understanding, documenting, and evaluating the existing externalities related to a physical phenomenon and understanding the impact of change and interaction with other physical presences is complex and only partly completed. Since ecosystems have been known to collapse quite suddenly, it is clear that the interaction can be unpredictable and complex. In terms of policy, therefore, the role and value of externalities is contested because of the difficulty in quantifying their importance and value. Simplistically, interests who wish to develop or exploit environmental phenomena on a commercial basis will tend to argue for a low value for externalities, while those opposed to commercial exploitation will argue in the opposite direction.

Attempting to quantify the value of environmental resources has been a difficult and complex task and the various attempts have not been accepted uncontested. However, economics presents some concepts that have been useful in this attempt. This has been assisted by the recognition that many of the world's resources are not only finite, but their final depletion can now be foreseen. In particular, projections that oil resources will be exhausted within 100–120 years, based on current rates of extraction and assuming (as seems likely) that no significant new finds will be made, has focused attention on the need for substitute fuels within a generation.

POLITICAL APPROACHES

While practical implementation of policies to address these issues are only beginning at the end of the first decade of the 21st century, attempts have started to be made to place extra tax on airplane travel and the use of overly large, fuel-inefficient personal automobiles. Tradeable carbon permits are the instrument most commonly used in international agreements; these are starting to become viable, although generally only developed countries are currently expected to have to participate. There is a need for these schemes both to broaden in scope and to become more effective—this will form the basis of many future policy debates.

THE 21ST CENTURY

As it has become increasingly apparent that global climate change and warming are having an enormous impact upon the entire world, environmental policy has focused on both the struggle to persuade climate change deniers of reality and the search for solutions to which all major parties would be willing to contribute. The Kyoto Protocol Treaty, for example, was an attempt to institute a carbon trading scheme to which all developed states could subscribe. The plan was that once leading states had so subscribed, then the treaty details could be expanded in terms of geography and the cost of carbon emissions. However, the refusal of the George W. Bush administration to sign the protocol has hamstrung the agreement, since the United States is the world's leading polluter. Further, it has become difficult to persuade important developing states such as China and India, where pollution and emissions are high and increasing, of the commitment that Western countries have to mutual reduction of emissions.

In the years since the 1960s, the majority of the developing countries of the world have entered into an economic paradigm that focuses on export-oriented growth, generally supported by import-substitution. Almost the sole measure of success has become growth in Gross Domestic Product (GDP), although there have been some exceptions. The consequence has been the dismissal of claims for the environment in promoting growth. Instead, the environment has been viewed as a stage on which GDP growth can be effected.

A coalition of different interest groups has formed to resist this way of thinking, including some faith-based groups who have allied with those ideologically inspired to campaign against the relentless exploitation of the environment. At the same time, as cities around the world develop to the extent that they can provide wealthy lifestyles for their middle-class residents, their populations become increasingly concerned about such problems as access to services for people with disabilities, road safety, and the need for public spaces for aesthetic and recreation purposes. In cities such as Taipei and Seoul, for example, much debate centers on the need to improve not just the immediate environmental vicinity of the cities, but also their hinterlands. There, awareness of the interdependence of environmental systems is beginning to permeate the public consciousness.

Political Ecology

POLITICAL ECOLOGY IS an academic field that seeks to understand human societies and their relationship to nature. Political ecology posits that environmental problems are intrinsically political and need to be understood in a broader framework that takes local as well as global actors into consideration. An important overarching goal of political ecology is to understand and participate in the forces linking social change, environment, and development. Academic studies using political ecology perspectives of analysis are appearing with greater frequency in contemporary environmental scholarship. While geographers and ecological economists have taken the lead in this endeavor, other fields, such as anthropology, history, and sociology, are joining in this collective effort. However, different shades of political ecology draw from a number of academic subdisciplines including: cultural and ecological anthropology, development theory, environmental economics, environmental studies, gender studies, environmental history, human geography, rural sociology, and postcolonial studies. The origin of political ecology was influenced by political economy, which has roots in Marxism, and has drawn on post-structuralism.

Given that an increasing number of academic disciplines are engaging in political ecology frameworks of analysis, explanations of society-nature relations have likewise become increasingly fragmented along disciplinary lines. These explanations are characterized by dualistic thinking that all too often analytically isolates physical and social phenomena. Political ecology is an interdisciplinary, nondualistic strategy that remains under development, and perhaps deliberately so, seeking to describe the dynamic ways in which, on the one hand, political and economic power can shape ecological futures and, on the other, how ecologies can shape political and economic possibilities.

Often identified with political economy, political ecology frequently takes political economy's interest in the expression and influence of state and corporate power on environmental politics and combines this with insights derived from understanding and analyzing environmental influences on social activity. In this manner, political ecology extends theoretical inquiry beyond the insights of the conventional social and natural sciences. Political ecology's ability to engage the philosophy and values of ecological justice has made it attractive to many who expect analysis to facilitate social change.

Political ecology is a fast-growing multidisciplinary field of research. It focuses on human to nature relationships and has a particular interest in connections between politics and environmental change. Human beings have evolved out of and as a part of nature, but with the increasing determinacy of human culture on landscapes, highly visible since the Neolithic period, it is hardly possible to speak of virgin natures. Even the Arctic Archipelago, far from human settlements, is exposed to radiation from the gap in the ozone layer caused by human livelihoods in other parts of the globe. The uneven vulnerability of humanity to environmental crises is increasingly being recognized, as global capitalism affects place-based peoples and transnational, mobile elites in extremely different ways.

FORMS OF POLITICAL ECOLOGY

It is possible to recognize two primary forms of political ecology. The first represents a fusion of its predecessors: human ecology with political economy. The second form, in opposition to the previous form, is a political ecology informed by poststructuralist social theory and represented by the work of Watts, Rocheleau, and others. The first form of political ecology takes as its point of departure the existence of an unproblematic material/ecological base and a series of actors, differentially empowered but with clear interests, contesting the claims of others to resources in a particular ecological context. The second (or poststructuralist) form of political ecology is characterized by the perspective that it takes nature, as well as the identities and interests of various agents, to be both contingent and problematic.

Since the 1970s political ecology has advanced an interdisciplinary approach to complex human-environmental interactions, especially those related to economic development in the third world. A primary objective has been to understand the underlying causes of human and environmental crises and identify ways to ameliorate or eliminate them. Anthropologists, geographers, political scientists, and other scholars generally use the political ecology framework to understand how environmental and political forces interact to affect social and environmental changes through the actions of various social actors operating at different scales (levels of analysis).

Recently, political ecologists have expanded their domain to include considerations of history, gender, social movements, and discursive formations. Much of the analysis centers on the role of power in mediating the relations among diverse interest groups and/or social/cultural actors. Such power is manifest in the relative abilities of actors to control access to and use of environmental resources, to transfer environmental risk to other actors, and to affect certain policies and projects (often partly through the control of public discourse).

Political ecology also acknowledges the coproduction of environmental knowledge and politics and makes use of discourse analysis to explore constructions of nature and human interaction with nature. There are diverse socioecological processes that interact to create different scales of mutual relations, which subsequently result in varied political ecologies. One of the major attributes of political ecology is that it reveals the political aspects of environmental change. The political ecology framework developed by Raymond Bryant and Sinéad Bailey is useful in this regard, as it identifies different actors vying for access to natural resources, and then interprets the political role that actors play in human-environment interactions in three ways: (1) it situates local-level findings into a larger body of theoretical and comparative perspectives; (2) it details the motivation, interests, and actions of different actor groups, focusing especially on the strengths, weaknesses, and relative power they possess in relation to other actors; and (3) it places politics at the center of political ecology, emphasizing that all human-environment interactions are mediated by politics, and that all actors, even weak ones, possess some level of agency with which they pursue their own interests.

Political ecologists critique biologists and other naturalists working for the conservation movement in that they have been unable to solve environmental problems because the nature of the problems themselves are not biological, but rather political, economic, social, and ethical. Political ecologists also note that environmental problems stem from political and economic influences that lead to an inappropriate or unjust allocation of benefits (as well as negative consequences) of natural resources and their use. They also note that policy and market failures concerning sustainable resource use are not accidental, but instead are the manifestation of laws, policies, and institutions that are the product of political, social, and economic forces that benefit powerful actors.

DEVELOPMENT OF THE FIELD

Predecessors to political ecology include a variety of orientations in cultural and human ecology in vogue from the 1950s to the 1970s. The field of political ecology can be traced to Rappaport's 1968 study of the role of ritual in human ecology among the Maori people of New Guinea. In this work, Rappaport established a new framework for examining human-environment interactions in that he examined "extralocal" (or external) linkages to regional systems.

Borne out of Rappaport's examination of larger systems was the field of political ecology, which seeks to inform understanding of how people and their environment shape each other over time. Political ecology then emerged during the 1970s in conjunction with the growing environmental movement of the era. Eric Wolf was among the first to use the term political ecology in his 1972 critique of cultural ecology and ecological anthropology, in which he emphasized the need to contextualize local ecological realities within the broader political economy. The initial step was the infusion, in the 1970s, of cultural and human ecology with considerations of political economy.

Political ecology became more significant during the 1980s and into the early 1990s, as it was perceived to improve on the weaknesses in human ecology and ecological anthropology, as they were practiced during the 1960s and early 1970s. This improvement came via the incorporation of a more rigorous political-economic framework of analysis that was strongly influenced by political economy perspectives, including systems theory and Marxism.

By the mid-1990s however, political ecology began to absorb other elements, including post-structuralist analyses of knowledge, institutions, development, and social movements, and feminist insights into the gendered character of knowledge, environment, and organizations. This resulted in the emergence of a more nuanced account of nature-society relations and political ecology. It highlighted the interwoven character of the discursive, material, social, and cultural dimensions of the human-environment relation. While empirical studies based on these frameworks have been taking place for some years, the theoretical work of political ecology is still in its early stages.

FEMINIST POLITICAL ECOLOGY

Political ecology approaches have been used as a method for analysis for other ecologies that include feminist, deep, and social ecologies. Feminist political ecology treats gender as a critical variable in shaping resource access and control, interacting with class, caste, race, culture, and ethnicity to shape processes of ecological change, the struggle of men and women to sustain ecologically viable livelihoods, and the prospects of community for sustainable development. Feminist political ecology provides an invitation to examine the power relationships that shape the environment through the insights of gender analysis, and a set of frameworks for doing so. In this way, it identifies new ways of examining gendered power relations in the shaping and use of the environment.

EUROPEAN APPROACHES

Political ecology also differs depending on whether it is being discussed within Anglo-American or European contexts. Anglo-American perspectives on political ecology tend to create a distinct dichotomy between people and the environment. European, and especially French, perspectives on political ecology instead tend to use more of a systems approach, which identifies a more holistic relationship between people and the environment. A critique that Europeans have of Anglo-American academicians is that by creating a people-environment dichotomy, they inhibit the expression of new ways of thinking about and framing environmental issues.

Given that the French arrived relatively late to the people versus environment debate, their more holistic perspectives on the environment have allowed them to pursue a variety of strategies that are grounded in systems theory and which are not centered on ecological arguments. From the French perspective, the division of environmental debates into two distinct ontological zones (human and nonhuman) is modern (as opposed to postmodern) behavior leading to purification (which sociologist Bruno Latour uses to define the total separation of nature and culture, which is a primary objective of the modern constitution), which prevents us from fully understanding hybrids of nature and culture.

For Latour, political ecology is a philosophical project with two broad aims. The first is to overcome the concept of nature as an asocial, objective source of truth. In this way, political ecology is a critique of existing environmental politics, which claim to speak for nature. The second aim of political ecology, according to Latour, is to recognize the complex relations between humans and nature and, from that recognition, produce new facts, values, and practices that will allow various actors to speak about common issues of concern. In this sense, political ecology is a critique of current environment politics. According to Latour, the aim of political ecology is not to bring science into nature, but instead to destroy the concept of nature.

OTHER APPROACHES

Anthropologist Arturo Escobar extends the post-structuralist form of political ecology. Escobar defines political ecology as the articulation of biology and history. This definition does not rely on the common categories of nature, environment, or culture (as in cultural ecology, ecological anthropology, and much of environmental thinking) or on the sociologically oriented nature and society (as in Marxist theories of the production of nature).

Equally significant, the form of political ecology Escobar articulates brings together several disparate domains of environmental scholarship, most notably the study of social movements and explorations of the emergence of technonature, and provides a basis for the development of an engaged critical environmental praxis. Examples of political ecology range from those that can be gleaned from the prehistoric past, to the most contemporary and futuristic, from ancient articulations through agriculture and forestry to molecular technologies and artificial life. Each articulation has its history and specificity and is related to modes of perception and experience, determined by social, political, economic, and knowledge relations, and characterized by modes of use of space, and ecological conditions. It is the task of political ecology to outline and characterize these processes of articulation and to suggest more just and sustainable social and ecological relations. Another way to state this goal is to say that political ecology is concerned with finding new ways of weaving together the biophysical, the cultural, and the techno-economic for the production of other types of social nature.

In his treatment of the idea of nature, Escobar transcends the theoretical impasse that has developed over our long-standing adherence to the nature/culture dichotomy. Escobar articulates an anti-essentialist theory of nature, where the view of nature goes beyond the truism that nature is constructed to theorize the manifold forms in which it is culturally constructed and socially produced, while fully acknowledging the biophysical basis of its constitution. In his advocating for an anti-essentialist theory of nature, Escobar notes that it is a necessary condition for understanding and radicalizing contemporary social struggles over the biological and the cultural.

From this perspective, culture and especially discourse are seen as active agents that create and produce nature as well as frame knowledge and related conflicts associated with nature. This constructivist approach, along with its emphasis on discursive formations, has added a significant critical dimension to the earlier work of political ecologists. Especially important have been constructivist examinations of the role of science in environmental campaigns and debates and the role of discourse in framing environmental conflicts related to development, especially in the developing world.

CRITIQUES

Some have critiqued the field of political ecology and many of its research practitioners for being biased and predisposed to finding specific, assumed answers (especially political drivers to environmental problems) before research begins. Vayda and Walters have suggested that the field, whatever its merits, might be more profitably replaced by "event ecology," an empirical and inductive (or abductive) approach to explaining environmental problems.

While this debate continues, a large body of work continues to pursue political ecological research for the analysis of contested environmental issues, seeking deeper insights, avoiding superficial and erroneous conclusions, and challenging the unspoken assumptions, biases, and conventional wisdoms of powerful actors. This analytic lens acknowledges power differences among actor groups and tries to explore the degree to which actors (powerful or otherwise) exercise their agency in their day-to-day actions toward their environment as well as toward each other.

Political Economy

POLITICAL ECONOMY HAS come to represent a lengthy and diverse body of theoretical work often grounded in the nexus of relationships involving governance (i.e., the state) and economic activity. The term was coined by classical economists during the 18th century, notably Adam Smith and David Ricardo, who began to examine the changing production and distribution patterns of the late mercantilist period. Karl Marx (1818–83) is the one most often associated with the idea of political economy, particularly in regards to his critique of work by Smith and Ricardo. Unlike his predecessors of the classical economic era, Marx argued that capitalism as an economic mode of production was an inherently doomed institution. Although Marx openly recognized the productive potential of capitalism, he believed the roots of capitalism's demise lay in many of the same attributes that made it so productive (i.e., the falling rate of profit). He proposed that a new mode of production, heavily regulated by the state, was needed to guide humanity along the path to a communist utopia. The legacy of this line of thought has led many to question the perceived divide between political decision making and economic activity, reasoning that the two are so tightly bound they are theoretically indivisible.

Since Marx's time, inquiries have continued into the theoretical understandings of political economy in both the social and scientific spheres. Questions regarding the relationship between political economic modes of production and environmental issues have been investigated by numerous scholars in a wide variety of academic disciplines. Even Marx himself considered such questions, often remarking upon capitalism's tendency to degrade the natural environment. At a broad level, one could argue that issues of nature and the environment are always inherently bound within the realm of political economy; because modes of production are inevitably connected to environmental conditions in one form or another, a perceived division between political economic decision making and environmental decision making would be inaccurate. Every issue pertaining to the environmental landscape necessarily affects political economy, and consequently, the reverse is also true.

One of the more intriguing (and best-known) ideas within this topic is Neil Smith's notion that nature is something that is "produced" in modern capitalist society. In his landmark publication *Uneven Development* (1984), Smith proposes that nature is not only being materially produced in today's world (e.g., transgenic seeds), but that the *idea* of nature is also being produced for the benefit of capitalist accumulation.

According to this notion, the commonly accepted belief that nature and human society are two distinctly separate entities is one that exists for the benefit of some (i.e., capitalists), and that the way in which the idea of nature has been produced and what nature signifies and represents exemplifies capitalism's influence over ideology. Thus, nature as both an object and an idea can be harnessed by those with power and influence to fortify their dominant position in society.

Regarding environmental and ecological activism, the study of political economy has led to a multitude of different viewpoints regarding the role of economics and state policy in environmental decision making. Whether implicitly or explicitly, most environmental or ecological movements engage in political economic discourses at one level or another. Some examples include, although are by no means limited to, authoritarianism, corporate and state managerialism, pluralistic liberalism, conservatism, moral community, ecosocialism, ecofeminism, and decentralized communitarianism. By appealing to the broad array of issues situated within political or economic practices, these movements are able to ground their concerns within a context to which everyone is linked.

The study of environmental issues from a political economic perspective continues along many fronts in today's academic world. Recent work in political ecology, for example, shows the value in questioning the position of the state and economic modes of production in issues of nature and society. As a theoretical approach, political economy continues to offer fresh insights to researchers in the critical human and behavioral sciences.

Polluter Pays Concept

THE POLLUTER PAYS concept is a principle of international environmental law that argues that those who cause damage to the environment (i.e., polluters) should be liable for the costs of the damage. Although the Río Declaration on the Environment and Development supports this principle, its roots can be traced back to the early 1960s when some of the first instruments were drafted to address civil liability for damage resulting from hazardous activities, such as nuclear energy and oil pollution. The principle is an example of attempting to tackle pollution through economic instruments, internalizing the environmental costs of production. The Río Declaration contains the polluter pays principle only for nations and does not deal with transboundary pollution; the European Union's (EU) polluter pays principle does deal with transboundary problems.

DEFINITIONS

The first express definition of the principle was given by an Organisation for Economic Co-operation and Development (OECD) recommendation in the context of economic policy. In 1972, the OECD Council Recommendation on Guiding Principles Concerning International Economic Aspects of Environmental Policies stated:

> This [polluter pays] principle means that the polluter should bear the expenses of carrying out the [pollution control] measures decided by public authorities to ensure that the environment is in an acceptable state. In other words, the cost of these measures should not be accompanied by subsidies that would create significant distortions in international trade and investment.

This principle does not have a liability on any party, but is more of an economic instrument for allocation of pollution control costs on the party responsible for causing the pollution. The main objective of this fundamentally economic policy is to encourage the free market internationalization of environmental costs in preference to trade distortions effected by governmental subsidies.

An economic system is considered to be efficient when scarce resources are allocated to meet the needs and wants of consumers, though there are different types of efficiencies. If the consumer is willing to pay the price, which equals the cost of resources (price is equal to marginal cost), it means allocated efficiency has been achieved and economic welfare is maximized. Productive efficiency is achieved, however, when the production costs of the firm are applicable both for the short- and long-run—in other words, when producers minimize the waste of resources in their production process.

In this system, there has been no consideration of the cost of pollution, or of pastures that are overgrazed or oceans that are overfished, because they are not owned. Pollution in any form is considered to be an externality—the price of polluting the air or water is not considered or built into producing the goods. The cost to society of polluting the air and water increased in the form of ill effects on human health and well being.

It was a British economist, Ronald Coase, who came up with an elegant idea of creating markets for such goods in 1959–60. If property rights are defined, then the polluters and exploiters could bargain with the victims of pollution or over exploitation until a mutually acceptable solution was found. Depending on who held the property rights, the victims would have to bribe the polluters or the polluters would have to compensate the victims.

As an example, consider two neighbors—one of them likes to have a nicely-cut lawn and cuts it with a lawnmower, which disturbs the other neighbor in the evenings and Sunday afternoons. They negotiate and strike a bargain in which the neighbor who likes to sit on the deck and enjoy the evenings offers monetary compensation to the neighbor who likes shorter grass. In this case, as the property right is vested in the gardener—she has the right to cut grass when she likes—the sufferer has to pay the polluter (although this would not be true if a strict noise nuisance act was in place). Even though it is the body owning the property rights who has to be paid in the example above, according to the principle of polluter pays, the industries causing pollution or contamination are obliged to pay for their damage to the environment.

THE EUROPEAN UNION

In 1973 the EU included the polluter pays principle in its first program of action on the environment. The polluter pay principle in "Principles of a Community Environmental Policy" stated: "The cost of preventing and eliminating nuisances must in principle be borne by the polluter." A subsequent recommendation in 1975 provided guidance for member state implementation, and later endorsements in treaty amendments established a legal basis backed by the OECD instruments.

According to a strict reading of the polluter pays principle, funds collected by a national program from pollution charges, fees, or taxes should not be used as financial assistance to a polluter, as such activities would constitute a government subsidy. Each EU country, however, has developed unique re-interpretations of the polluter pays principle to justify its subsidy schemes as being compatible with the principle.

Differences in national environmental protection policies from country to country may have an impact on international trade. Countries that adopt strict environmental protection measures may increase the costs of production relative to their trading partners, thereby reducing the competitiveness of their manufacturing industries. As a result, cooperative efforts have been made by industrialized countries to equalize production costs by reducing governmental subsidies for private pollution control.

The polluter pays principle has been incorporated in some transboundary instruments such as the Climate Change Convention; the 1990 International Convention on Oil Pollution Preparedness, Response, and Cooperation; and the 1990 Amendments to the Montreal Protocol. Most of the time, the polluter pays principle is considered part of international environmental law.

Pollution, Air

THE STUDY OF air pollution encompasses an examination of pollution emissions from industrial, agricultural, household, and other sources; the fate, transportation, and interaction of multiple pollutants in the atmosphere; atmospheric conditions and ambient air quality levels; the health and environmental effects of air pollution; the political and economic strategies and consequences associated with air pollution legislation; and community level movements and activist responses to air pollution largely in the context of environmental justice.

TYPES OF POLLUTION

Air pollution can be categorized as gaseous or particulate matter, primary or secondary, and toxic or nontoxic. Air pollution and related formal and informal prevention measures are also generally divided between outdoor or indoor environments.

One of the most pervasive outdoor pollutants with serious health and environmental risks is particulate matter. Particulate matter is classified in two ways, having a diameter less than 2.5 micrometers ($PM_{2.5}$) and particulate matter with a diameter less than 10 micrometers (PM_{10}). Although both forms of particulate matter present serious health risks, $PM_{2.5}$ is generally considered more dangerous because of its small size—approximately 1/30 the width of a human hair. When breathed, $PM_{2.5}$ can lodge deep in human lung tissue and even enter the bloodstream, causing severe health problems. Smaller particulate matter also tends to have a longer residence time in the atmosphere. As a result, $PM_{2.5}$ can travel farther and affect a greater population.

The principle sources of $PM_{2.5}$ and PM_{10} include combustion from motor vehicles, power plants, and other industrial sources, as well as biomass burning. One of the most severe sources of particulate matter is diesel-powered vehicles. Airborne dust, soils, and salts are other common forms of large particulate matter that occur in areas susceptible to high winds. The combination of these sources can produce a haze in the sky in both urban and rural areas, often in the late afternoon.

The composition of the earth's atmosphere is 78 percent nitrogen (N_2), 21 percent oxygen (O_2) and

.9 percent argon (Ar). The other 0.1 percent of atmosphere consists of trace gasses such as carbon dioxide (CO_2), neon (Ne), helium (He), methane (CH_4), and water vapor. Except in extreme situations, most pollutants are considered trace gases and do not greatly alter the overall composition of the atmosphere. Even at extremely low levels, however, gaseous pollutants can have serious health and environmental consequences.

Important gas contaminants include: Carbon monoxide (CO), chlorofluorocarbons (CFCs), nitrogen oxides (NO_x), hydrocarbons (HC), sulfur dioxide (SO_2), and carbon dioxide (CO_2).

Carbon monoxide (CO) is formed when carbon-based substances are burned with an insufficient supply of air. The majority of CO in the United States is emitted from motor vehicles due to the incomplete combustion of gasoline. Areas within road and highway corridors are therefore subject to high levels of CO. When inhaled, the health effects of CO include headaches, respiratory illness, and—in extremely high doses—death. Carbon monoxide is a "criteria" pollutant as outlined under the Clean Air Act.

Chlorofluorocarbons (CFCs) were used historically as refrigerants, cleaning solvents, and as propellants in aerosol canisters. CFC use was largely banned under the 1987 Montreal Protocol due to its impact on the ozone layer. The State of Oregon banned CFCs as early as 1975. Their long atmospheric lifetime—ranging from 55 to 140 years—and regenerative capabilities make CFCs particularly devastating to the upper atmosphere.

Nitrogen oxides (NO_x) are a combination of nitric oxide (NO) and nitrogen dioxide (NO_2). Common in urban areas, they are produced from natural sources and fuel combustion. Over half of anthropogenic NO_x in the United States results from motor vehicle activity. The major health effects of NO_x are pulmonary-related. Nitrogen oxides are designated as a "criteria" pollutant under the Clean Air Act and contribute to the formation of acid rain and smog.

Hydrocarbons (HC) are chemical compounds that contain both elemental hydrogen and carbon (e.g., methane). Hydrocarbons such as benzene are varieties of volatile organic compounds (VOCs), which are characterized by their ability to vaporize easily at room temperature. Hydrocarbons are most commonly released into the atmosphere when petroleum fuel is only partially burned or unburned. The majority of this pollution occurs through the exhaust pipe of motor vehicles or as a consequence of fuel evaporation. Hydrocarbons react with NO_x to create smog, and in the case of benzene and other hydrocarbon varieties, may contain toxic compounds.

Sulfur dioxide (SO_2) exists in gaseous form and can react with other chemicals to create tiny sulfate particles. It is one of six "criteria" pollutants under the Clean Air Act. Roughly two thirds of SO_2 comes from fuel combustion at power plants, especially those burning coal. SO_2 contributes to acid rain and can cause respiratory illness when inhaled.

Carbon dioxide (CO_2) occurs naturally in the earth's atmosphere from the combustion of biomass, animal respiration, and outgassing from the earth's surface. Carbon dioxide is also emitted into the atmosphere through the anthropogenic burning of fossil fuels for energy and transportation purposes. While the presence of carbon dioxide at low concentrations is normal, CO_2 is an effective greenhouse gas that can alter the earth's atmosphere.

TOXIC POLLUTION

Toxic air pollutants, commonly referred to as hazardous air pollutants (HAPs), present acute risks to humans and the environment. Possible risks include cancer, birth defects, damage to the immune system, as well as serious neurological and respiratory ailments. While toxic pollution is typically breathed from the air, some toxins like mercury and lead can settle into soils and enter into plants and other animals and eventually be ingested up the food chain to humans.

The U.S. Environmental Protection Agency (EPA) works with state and local governments to regulate and reduce the release of 188 toxic pollutants. Some examples of toxic pollutants include perchlorethlyene, which is a common effluent of dry cleaning facilities; methylene chloride, which is found in many industrial solvents and paint strippers; and benzene, which is found in gasoline. Other common air toxics are toluene, dioxin, and asbestos and metals such as mercury and lead compounds.

Lead (Pb) is another of the six effluents designated as "criteria" pollutants by the Clean Air Act. Whereas in 1970 the vast majority of lead pollution came from motor vehicles, now most lead pollution is the result of metals processing activities such as lead smelters. Today, the biggest concerns regarding lead occur in "hot spots" immediately surrounding these processing facilities. Between 1980 and 1999, ambient lead levels in the atmosphere dropped 94 percent. The overall reduction in lead pollution since 1978 is attributed to the gradual phase out of leaded gasoline. The health effects of lead are severe and include organ, neurological, brain, and cardiovascular damage.

High concentrations of toxic air pollutants in impoverished and minority communities in the face of pro-business city planning agendas have galvanized grassroots environmental justice activists. Environmental justice organizations speak out against the inequitable distribution of air pollution within these neighborhoods. The goal of these movements varies from one to the next but usually promotes private polluting facilities moving to other locations or adopting cleaner practices; holding governments accountable to communities; and public involvement and control over decisions influencing air quality.

In order to gain political traction, these groups provide evidence of environmental injustices. Some communities practice "popular epidemiology" by locating and recording health incidents throughout neighborhoods, while others mobilize around air quality reports using data from Toxic Release Inventories (TRI). The TRI database caters specifically to the public and provides information on facility-specific toxic emissions into the environment.

INDOOR ENVIRONMENTS

In all areas of the world, people spend much of their time inside while at work and at home. The prevalence of indoor air pollution is therefore a serious problem that affects both developed and developing nations. Indoor air pollution consists of gas compounds and particulate matter, as well as toxics and nontoxics. Throughout the world, forms of indoor air pollution include: Radon filtering into the home from below ground; volatile organic compound (VOC) emissions from office supplies; furnishings, paints, and other household solvents; lead particles from dried paint; and particulate matter from wood burning fireplaces and secondhand smoke from cigarettes.

Asbestos is another serious health risk in indoor environments although a number of product bans and reformed building construction codes have eliminated the use of asbestos-based material in homes. Because it is carcinogenic (cancer causing), asbestos was one of the first hazardous air pollutants regulated under the 1970 Clean Air Act.

In developing nations the burning of biomass for heating and cooking purposes is a major health hazard for nearly 2 billion people. The World Health Organization (WHO) estimates that approximately 1.6 million people die each year as a result of exposure to indoor air pollution from biomass burning. The main groups impacted by indoor smoke are women and children because they are responsible for most cooking and heating activities. The 2002 World Summit on Sustainable Development in Johannesburg launched the Partnership for Clean Indoor Air. The principle aim of this coalition of organizations is to reduce indoor air pollution from household energy use around the world.

SECONDARY POLLUTANTS

Secondary pollutants are not directly emitted into the atmosphere. Rather, they are formed when primary pollutants react with other gases, sunlight, or water vapor and undergo a chemical change in the atmosphere. Two examples of secondary pollutants are tropospheric ozone and components of acid rain such as nitric and sulfuric acids.

Tropospheric ozone (O_3) is a photochemical oxidant and is formed through a reaction involving sunlight, NO_x, and hydrocarbons. Ozone is an important component of smog that impacts urban residents around the world. Respiratory and eye irritation are the most common symptoms of photochemical smog exposure. Mega-cities such as Beijing, Los Angeles, Mexico City, and Athens all suffer from pronounced smog levels. Wind and precipitation are two principal means for removing smog.

The formation of smog is aided by the presence of an inversion layer that creates a so-called "lid" trapping pollutants over the city. An inversion layer, which forms when warm air resides over cold air, prevents old, stale, and polluted air from escaping vertically out of an urban system. Under these stable atmospheric conditions, surface level pollution accumulates creating elevated smog levels.

In 2005, the American Lung Association used recent county-by-county air quality data to conduct a "State of the Air" report. County level data on two pervasive pollutants—ozone and particulate matter—were included in the report. According to the study, in 2005 over 52 percent of U.S. residents lived in counties with unhealthful levels of either ozone or particle pollution. (The results were based on the EPA's Air Quality Index.) Despite California's firm commitment to reduce dangerous air pollution, five-metropolitan areas around the state make the top 10 list for short-term particulate matter pollution while six make the ozone pollution top-10 list.

Nitric acid (HNO_3) is an easily soluble, acidic gas. It is formed when nitrogen dioxide (another secondary pollutant) reacts with water. Sulfuric acid (H_2SO_4) is also highly acidic and contributes to the formation of acid rain when reacting with water. Acid rain is typically most severe downwind from major power and industrial plants, although pollution from cities can also lead to acid rain. For example, areas of the Northeastern United States experience acid rain originating from Midwest industrial belts.

SOURCES OF POLLUTION

Pollution sources are both environmental and anthropogenic. Environmental sources include fires, volcanoes and other geothermal activities, livestock, trees (most notably species of pine), the earth's substrate (which can experience radioactive decay), and agricultural fields and deserts, both of which produce dust storms when exposed to high winds.

Anthropogenic sources are categorized as stationary, mobile, or area sources. Stationary sources (commonly referred to as "point sources") are generally fixed to a single location or point. These sources include industrial activity such as combustion-fired power plants, oil refineries, and other wood, natural gas, oil, and coal burning facilities. Other stationary sources include landfills and pollution directly resulting from agricultural activity such as loose soil, chemical applications, and controlled burns. Mobile sources include automobiles such as passenger cars, public transportation vehicles, heavy duty trucks, and mobile construction equipment. Aircraft, locomotives, and marine vessels are other varieties of mobile pollution sources. Area sources include stationary and nonroad sources that are too numerous or small to accurately account for in strict emissions inventories and are therefore assigned to a general area.

LEGISLATION AND MITIGATION

Air quality legislation can focus on the pollution source by regulating single-source or total regional emissions. Legislation is also often based on air quality standards, aiming to limit the ambient level of pollution in the atmosphere over a given period of time. Still other legislation is technology-driven and regulates facilities based on equipment standards. While these regulations ultimately target the polluting facility, they usually operate through a central air quality officer at the national, state, county, or municipal scale.

Air pollution in the United States is regulated at both the national and state scale. National Ambient Air Quality Standards (NAAQS) are established by the U.S. Environmental Protection Agency's Office of Air Quality Planning and Standards (U.S. EPA OAQPS). The standards establish maximum allowable pollution levels for a given area. The NAAQS consists of primary and secondary standards designed to meet human health and nonhuman health (crops, structures, and animals) requirements respectively.

The standards are directed toward six criteria pollutants: ozone (O_3), particulate matter ($PM_{2.5}$, PM_{10}), carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen oxides (NO_x) and lead (Pb). The EPA was instructed to maintain records of ambient air quality levels in accordance with 1990 amendments to United States Clean Air Act of 1970.

The 1970 Clean Air Act (CAA) was a landmark legislative accomplishment outlining federal rules and regulations for stationary and mobile air pollution sources. Aside from mandating the NAAQS, the CAA also created standards for hazardous pollutants through the National Emission Standards for Hazardous Air Pollutants (NESHAPS). Through

In 2005 over 52 percent of U.S. residents lived with unhealthful levels of either ozone or particle pollution.

New Source Performance Standards, the CAA created strict stationary source emissions standards. Perhaps the most significant achievements of the act is that it allows states to devise their own air quality implementation and enforcement plans, assuming they are no less stringent than federal standards. States must submit a State Implementation Plan (SIP) to the EPA in order to demonstrate a capacity to achieve minimum pollution criteria.

California is a notable example of a state aggressively enacting numerous stringent air pollution regulations. For example, in 2002, California passed legislation known as the Pavley Bill, creating vehicle emissions standards requiring that greenhouse gas emissions from new vehicles be reduced by 22 percent by the 2012 model year and 30 percent by the 2016 model year. By 2006, ten other states had adopted these strict California standards, which in turn put pressure on car manufacturers to fill this growing "green" automobile market.

Mobile source emissions are also controlled by regulating vehicle fuel composition. Examples of fuel-based regulation are initiatives to reformulate gasoline by eliminating toxics such as benzene and the 1995 ban on leaded gasoline for passenger vehicles in the United States. Another set of measures intended to reduce mobile source emissions focus on zoning and land use ordinances that reduce total vehicle miles driven. Examples include "smart growth" initiatives such as carpool incentives and urban growth boundary designations.

Because air is fluid and political boundaries are porous (in terms of both the movement and eventual impacts of air pollution) national and subnational regulatory frameworks are insufficient alone. Multilateral Environmental Agreements (MEAs) have been created to govern cross boundary pollution between nations and international air-related environmental problems. One example is the 1979 UN Economic Commission for Europe (UNECE) Convention on Long-Range Trans-boundary Air Pollution. The 1987 Montreal Protocol banning the production of CFCs and the 1997 Kyoto Protocol designed to regulate global greenhouse gas emissions are examples of international accords that emphasize "local" pollution prevention measures to prevent potentially calamitous global impacts.

MONITORING AND ENFORCEMENT

Air quality modeling supports air pollution regulations and increases public awareness by predicting pollution concentrations and levels of human exposure. Pollution modeling requires synthesizing atmospheric inputs with emissions data from the National Emission Inventory (NEI). The EPA compiles NEI data on criteria and hazardous air pollutants from a variety of state and local agencies as well as industry.

A number of programs are used to mitigate pollution by enforcing standards, reducing the financial cost of compliance and improving levels of public awareness. Permitting programs help sources achieve mandated emissions standards. Permitting requirements are outlined under the Clean Air Act in two forms, construction permit programs and operating permit programs. Construction permits include New Source Review (NSR) permits. NSR permits are issued by air pollution agencies and regulate pollution through technological standards. New sources of pollution and significant emission increases at existing sources must satisfy certain state-of-the-art pollution control technology requirements in order to avoid penalties.

Under Title V of the Clean Air Act, operating permits are issued to certain pollution sources. These permits outline industry-based performance standards and require sources to monitor and share with the EPA their compliance with these requirements. A number of source monitoring measures are available for most facilities, although fugitive emissions (unaccounted for effluent releases) present an ongoing challenge to most monitoring efforts.

Emissions trading programs and "command and control" enforcement procedures are both used to enforce air pollution compliance. Emissions trading programs cap total emissions within a given region but allow sources with more expensive control costs to purchase pollution "credits" from sources experiencing cheaper control costs. The goal of these programs is to achieve emissions reduction in the most cost efficient manner. Command and control enforcement relies on government control to achieve emissions reductions. Under these programs, facilities that violate industry standards are fined by government regulatory enforcement bodies.

Pollution, Water

SOURCES OF WATER pollution in lakes, streams, rivers, oceans, and other water bodies include municipal sewage, industrial waste, agricultural runoff, and oil spills, among others. Waste may be dumped in water intentionally or accidentally. Although water pollution is usually caused by human activity, some natural phenomena—like volcanoes, storms, and earthquakes—cause changes in water chemistry. Sometimes, high saline or mineral content of water makes it unfit for certain uses, even though the water is not polluted in the traditional definition of pollution.

Many toxic synthetic chemicals cannot be broken down by natural processes and cause serious harm. These substances may be dissolved or suspended in water or deposited in sediments, but they do not go away. This results in the pollution of water—the quality of the water deteriorates affecting aquatic ecosystems. Pollutants can also seep down and affect groundwater deposits.

Water pollution has worsened since World War II with the advent of what is known as the "chemical age," which has impacted the quality of water worldwide with industrial and agricultural chemicals. Eutrophication of water bodies (caused by nitrates and phosphates from various sources, including fertilizer runoff) has greatly affected the quality of water in large parts of the world. The effects of water pollution are devastating for living beings. Contaminated water destroys aquatic life, reduces its reproductive ability, and results in ecosystems that can no longer support full biological diversity.

SOURCES OF POLLUTION

There are many sources of water pollution, such as city sewage, also known as sanitary sewage or domestic sewage, which refers to wastewater from households. This water contains a wide variety of dissolved and suspended impurities such as organic materials and plant nutrients, and human waste. It contains inorganic products such as synthetic detergents containing phosphates, which affect the health of all forms of life in water. Most cities do not have adequate facilities to treat wastewater and much of it is discharged into water bodies.

Bacterial contamination of surface water from sewage caused serious health problems in major cities in Europe and North America in the mid-19th century. Cities built sewer networks to route domestic waste downstream of drinking water intakes to prevent contamination of the drinking water. These sewage networks and waste treatment facilities expanded rapidly in the developed world. In the developing world, where governments sometimes lack financial resources to expand sewage and water infrastructure, outbreaks of waterborne diseases like cholera still occur.

Industrial waste or effluents, usually containing specific and readily identifiable chemical compounds, are another source of water pollution. Many plants (e.g., paper mills, tanneries, sugar mills, distilleries, and thermal power stations) generating these effluents do not have adequate treatment facilities because these small-scale industries cannot afford enormous investments in pollution control equipment. Major industries have treatment facilities for industrial effluents, yet enough small-scale operations pollute water to counter measures taken by major industries.

Agricultural runoff is another source of water pollution. Intensive cultivation of crops usually involves chemicals (nitrates, phosphates) and pesticides (such as DDT) and water from these fields containing fertilizers and pesticides not only drains into rivers or lakes, but also seeps into groundwater in a process known as leaching. Scientists also believe that massive and largely unregulated use of antibiotics in agriculture and aquaculture may present a great risk to the aquatic environment and human health.

Petrochemicals are also threats to water quality. One of the greatest disasters with petrochemicals was the 1989 oil spill of the *Exxon Valdez,* which contaminated about 1,500 miles of Alaska's coastline. It killed birds, mammals, and fish and disrupted the ecosystem in the path of the oil. Major spills like these are few, but they pollute water and cause damage to the aquatic ecosystem. Ships and tankers also discharge water taken on in one location in other locations, causing transmission of pollutants, diseases transmission vectors, and nonnative species, which can be disastrous for certain delicate aquatic ecosystems.

POINT AND NONPOINT SOURCES

Water pollution sources can be categorized in another way: as direct, or point, sources and indirect, or nonpoint, sources of pollution. Liquid effluents from factories, refineries, and waste treatment plants, which are emitted directly into water bodies, are called point sources of pollution. It is simpler to regulate the standards for such emissions, since they are identifiable and quantifiable. Even though there are regulations governing the emissions, it does not guarantee that these emissions are pollutant-free.

Rain water flowing from improperly disposed of waste, whether domestic or industrial, can also result in water pollution. Leachate from landfill sites also results in water pollution. These are examples of nonpoint source pollution. Indirect sources also include contaminants that enter water bodies from the atmosphere via acid rain, which contains emissions from cars and factories. Both point and nonpoint pollutants and contaminants can be many different types, including organic, inorganic, radioactive, and acid or base.

OTHER TYPES OF POLLUTION

Metals or other elements in water are also of great concern. Mercury can be released into the air by human activities such as metallurgical processing, municipal and medical waste incineration, and power generation from coal combustion. It is also released to the atmosphere by natural phenomena like volcanic eruptions, forest fires, and the weathering of geological formations. Once deposited in or discharged to water bodies, mercury can be converted by bacteria into mercury compounds, such as methyl mercury, which accumulate in the food chain. Fish consumption exposes humans to methyl mercury, as observed in Minamata Bay in Japan in the 1950s. Even though eating fish offers nutritional benefits, caution must be taken to avoid eating too much fish containing excessive levels of methyl mercury or PCBs.

Researchers are detecting trace amounts of pharmaceuticals in water, especially in the developed world, because of high consumption of medicines. Other chemical ingredients from cosmetics, toiletries, food additives, and veterinary drugs have also been found. As a group, these chemicals have been dubbed PPCPs (pharmaceuticals and personal care products). Scientists and policy makers have started worrying about the possible effect and harm to human health and environment of these chemicals, even though the amounts detected are minute—typically between 20 parts per billion and less than one part per trillion for each substance. Many drug compounds dissolve in water, but about one third dissolve only in fat.

This enables them to enter cells and move up through the food chain to become more concentrated. Deformities in the reproductive systems of fish and frogs show that these chemicals are not harmless. Recent research has shown that exposure to even very small amounts of toxic chemicals can be harmful to humans and other forms of life. A developing fetus, an infant, or an adult with a compromised immune system would be even more at risk. The Canadian government is pioneering approaches to the problem of PPCPs under a program called the Environmental Impact Initiative. The program includes research, public education, and the introduction of environmental assessment regulations.

MITIGATION

Both developed and developing countries have to deal with water pollution. In the developed world, different types of pollution occurred sequentially, with the result that most developed countries successfully dealt with major surface water pollution. In contrast, in developing countries (such as China, India, Brazil, and Mexico) both surface and groundwater pollution not only occurred simultaneously but also at such a rapid rate that these countries hardly had financial resources, technologies, or time to cope with them.

Legislatures all over the world have passed laws and developed regulations to combat water pollution. Governments alone, however, cannot solve the problem, especially during the present era when downsizing of governments to conserve funds has resulted in losses of environmental monitoring capability and capacity. Science is also seeking practical solutions to minimize the present level at which pollutants are introduced into the environment and for remediation of past problems. Individuals and communities can help minimize water pollution by planting trees, reducing household waste, disposing of household chemicals responsibly, recycling packages made with polluting dyes, and reducing the use of fertilizers and lawn chemicals. The developed world and developing countries must collaborate to prevent further pollution. Our leaders—whether political or industrial—must think of sustainable development rather than economic expansion.

Polychlorinated Biphenyls (PCBs)

POLYCHLORINATED BIPHENYLS (PCBS) are a class of organic compounds composed of two interconnected phenyl rings, with a number (one to 10) of substituted chlorine atoms attached to these rings. There are a variety of variations, forms or congeners of PCBs, all of which have slightly different chemical properties.

PCBs are a member of a class of pollutants referred to as organochlorines and are conservative contaminants, that is, they persist in the environment for a long time, and they also bioaccumulate: PCBs that are not excreted build up in the tissues of contaminated organisms. As PCBs are lipophilic (fat soluble), they primarily tend to be stored in adipose (fat) tissues of organisms.

PCBs have been produced since the 1930s and have been used in insulating fluid for industrial transformers and capacitors; hydraulic fluids; surface coatings for copy paper; in synthetic resins, rubbers, paints, and waxes; and in lubricating oils, asphalts, and flame retardants. Due to environmental health concerns about this class of chemicals, many countries began banning the production of PCBs in the late 1970s and early 1980s. Until these bans, world production of PCBs was approximately one million tons—most of which has ultimately ended up entering the marine environment.

The structure of PCBs means that they can sometimes mimic hormones, which in turn leads to disruption of biological systems and health effects. As a result, reproductive failures have been recorded in several mammal species fed PCB-laced diets. Other PCB-induced reproductive defects include: altered menstrual cycles, embryo reabsorption, abortions, stillbirth, impaired infant survival or low birth weights, and impaired infant growth. PCBs can also affect the immune system, impacting lymphocyte production and increasing susceptibility to viral, bacterial, and protozoan infections. Other documented effects of PCBs include liver toxicity, thyroid and skin damage, cancer promotion, behavioral changes and impaired neurological development, and "reduced intelligence."

Two well-known outbreaks of disease related to PCB poisoning have occurred. In 1968 rice paddies in Japan contaminated with PCBs led to an outbreak of the disease *yusho,* affecting 1,700 people. Symptoms, which included darkening of skin and acne-like skin eruptions, were recorded with PCB doses of 0.07 milligrams per kilogram of victim body weight. Another PCB-induced disease outbreak occurred in 1979 in Yu-Cheng, Taiwan, affecting 2,000 people. A more recent poisoning event occurred in January 1999, in Belgium, when 500 tons of animal feed contaminated with 50 kilograms of PCBs (and one gram of dioxins) were distributed to Belgian, Dutch, German, and French farms. Very quickly decreases in egg production were noted in some poultry farms, and ultimately over two million chickens were slaughtered due to contamination fears. When the incident was publicized in May 1999, it led to a major political and economic crisis. It has been estimated that due to PCB contamination alone, up to 6,776 extra cancer deaths could occur in the Belgian population.

As noted above, PCBs are lipid soluble, and one notable lipid-rich substance in humans is breast milk. In several areas of the world relatively high levels of PCBs have been reported in human breast milk and concerns have been expressed about the potential effects. One particular concern is that the effects of vitamin K metabolism may result in hemorrhagic disease in newborn infants. However, although some studies have shown correlations between breast milk PCB concentration and thyroid hormonal levels and impaired neurological development in infants, other studies contradict some of these results. Nonetheless the situation is one that requires monitoring and consideration.

Studies showing high levels of human PCB contamination have often noted a high seafood diet. Since the majority of PCBs have ultimately ended up in the marine environment, fish and other marine species with fat-containing tissues are at risk of PCB contamination. In particular, PCB contamination is a problem for marine mammal species as they are often top predators with long life spans, and may bioaccumulate and biomagify higher levels of PCB contaminants in their tissues. The thick blubber layers of many marine mammal species may also act as a PCB store, and their fat rich milk may pass on high levels of contaminants to their offspring. Marine mammal species that consume other marine mammals may be particularly at risk from PCB contamination, and several studies have linked reproductive and immune system abnormalities, high neonatal mortality rates, and even mass mortality events in several species of whales, dolphins, and seals to high levels of PCBs and other organochlorine contaminants. In turn, human communities in Alaska, Canada, Greenland, or other areas who consume high concentrations of whale or seal tissues in their diet may also be at greater risk of elevated dietary intakes of PCB as a result of marine mammal contamination.

Population

AS OF MID-2006, the earth's human population stood at approximately 6.48 billion. In 1 C.E., it is estimated that the global population was between 250–300 million. Humans reached the first billion by about 1804; the second by 1927. The world population hit five billion around 1987, and six billion in 1999. This means that an estimated six percent of people ever born on earth were alive in 2002. The length of time it took to add an additional billion people to the planet shrank dramatically. Whereas it once took millennia to add a billion people, that number was added in just 12 years. The human population is expected to continue to grow for the next 70 years, peaking at 9.22 billion around 2075. At least seven more decades of growth are forecast, mainly because the average person is living longer, and because so many potential parents are already born, also called "population momentum."

Many people consider this inexorable rise in human numbers to be cause for alarm and immediate action to slow population growth. However, the rate at which new people are added to the planet has actually been decreasing for the last several decades. This rate of natural increase (RNI) is determined by the difference between birth and death rates. This rate peaked between 1965 and 1970, when the human population grew at over two percent per year—an astronomical figure unprecedented in human history. Since then, the gap between birth and death rates has slowly been closing; between 2000 and 2005, the global population grew by only 1.22 percent, and the rate continues to decline. This slowdown usually receives less popular attention—and is often confused with—the fact that human populations will continue to rise for the next 70 years or so.

The main reason for this slowdown has been a dramatic drop in fertility rates worldwide. The total number of children that the average woman is likely to have in her lifetime has been declining for several decades, and has done so much more quickly than most experts expected. Between 1950 and 1955, women on average had five children. By 2000–05, the global average had fallen to 2.7; in 2000, 42 percent of humanity lived in countries that had already achieved fertility below the replacement level of 2.1. This ongoing decline in fertility rates worldwide has been described as the biggest revolution in human population history.

There are multiple reasons for this fertility transition. Although it has varied in pace and magnitude by geographical region, a set of intertwined factors are generally recognized to be globally influential. These include: improved access to contraceptives, health care improvements that greatly enhance child survival, women's greater access to education and work outside the home, a widespread shift from rural to urban livelihoods, postponement of marriage, and reduced cultural and religious pressures for large families. In the vast majority of cases, fertility declines reflect women's desires to have fewer children. Only in rare cases has fertility reduction involved coercive practices, as, for example, with China's one-child policy or certain reproductive programs in India.

Fertility decline is the single most important factor for understanding why global population growth is slowing. But mortality rates are beginning to contribute to this slowdown too. Because women have been having fewer children than in the past, the cumulative effect is that the global population is slowly becoming older as children comprise a smaller portion of the overall total. Today, the median age is 26; by 2010, it is estimated to be 44 years. Thus, even as life expectancies continue to rise, the aging of the population will result in higher death rates. As the decline in fertility continues, mortality rates are expected to creep upward.

When the two rates intersect—which is projected to occur by 2075—then the population will stabilize. These estimates are based on recent calculations by the United Nations Population Division, and they represent the most informed answer to date on the perennial question of how large the human population will become.

THE DEMOGRAPHIC DIVIDE

Demographers commonly divide the world into two major regions: more developed (comprising North America, Europe, Australia, New Zealand, and Japan) and less developed (comprising the remainder). These are contested terms—sometimes affluent and poor are preferred. By this categorization, eight out of 10 people on earth currently live in less developed countries, which is why some observers argue they should collectively be known as majority world. China and India, whose status as less developed is currently a matter of debate, are the world's two largest countries, with populations estimated at 1.3 billion and 1.1 billion, respectively, in 2005. Together, they account for almost half of the developing world, and 37 percent of the planet's human population.

In 1950 about 29 percent of world population lived in more developed nations, with 21.7 percent in Europe alone. At that time, Africa's share of world population was only 8.8 percent. These proportions have since changed dramatically as countries have experienced very different birth, death, and migration rates. For example, European women had on average 1.4 children in 2005—well below replacement-level fertility. The region is experiencing negative population growth. In contrast, the average woman in Africa had 5.1 children in 2005—the highest regional rate in the world—and rates of natural increase average 2.3 percent. As a result of these disparities, Africa held 14 percent of the world's population in 2005, while Europe's share dwindled to 11.2 percent.

The differences in demographic structure between these two regions exemplify what is known as the demographic divide, resulting in the separation of demographic issues into two distinct camps with very different attitudes and policy approaches. In Africa, for example, high birth rates mean that populations are young, with some 42 percent of the total population under age 15. Most governments consider their birth rates to be too high, and they may wish to prioritize investments in family planning programs, maternal and child health, and educational opportunities for girls in order to reduce fertility. At the same time, however, these governments face rising mortality rates and declining life expectancies due to HIV/AIDS. This devastating epidemic has in many cases drastically reduced the number of adults able to care for children, and diverted scarce health funds toward HIV/AIDS treatment and prevention.

In Europe, by contrast, the population concerns are far different. Extremely low fertility rates have led some observers to talk about a birth dearth. As populations age and individuals live longer, there is also much social angst about who will care for the elderly. In many cases, governments are reluctant to deal with the thorny social issue of maintaining or increasing their current population size through immigration, and are instead creating incentives to encourage couples to have more children.

THE POPULATION-ENVIRONMENT DEBATE

Whether the growing human population is inherently good or bad for the global environment is one of the most hotly debated issues in science. On one side of the debate are those that see human population numbers, and our rapid recent growth, as the most significant cause of environmental and humanitarian crises. The most famous advocate of this view was Thomas Malthus (1766–1834), an English pastor and economist. In a famous essay first published in 1798, Malthus argued that food supplies grow more slowly than do human populations, and he predicted that without the population checks of disease, death, or delayed marriage, population growth would outstrip food supplies and lead to hunger and misery.

In 1972 a group of scientists known as the Club of Rome recast Malthus's main arguments in ecological terms. They and contemporary neo-Malthusians argue that human populations are growing faster than our ability to support ourselves from finite natural resources such as soil, water, and forestlands. They argue that we will soon exceed, if we haven't already, our limits to growth, or the earth's carrying capacity. The single most important way to prevent further environmental devastation and widespread human misery, they say, is to control the runaway population—to reduce human numbers as quickly as possible. Because they emphasize sheer numbers and densities of peoples in given areas, neo-Malthusians typically focus their attention on less developed countries, where large numbers of people, environmental degradation, and hunger often visibly coexist. To redress such problems, neo-Malthusians advocate policies that prioritize fertility reduction through family planning, enforced control on resource use, and the setting aside of biodiverse areas as off-limits to resource users.

On the other side of the debate are those that feel that the number and density of people—at the global or regional level—is not the principal factor for understanding patterns of use, management, or degradation of the natural environment. They argue that the number of people that can be supported by natural resources depends very much on how humans choose to use, trade, and govern those resources; in effect, resources may be finite, but humanity's ingenuity to find better and more efficient ways to harness and distribute those resources is not.

The Danish economist Ester Boserup (1910–99) is famous for her refutation of Malthus by showing how, throughout human history, growing numbers of people in rural areas stimulated the invention and adoption of more labor-intensive farming methods that allowed for higher yields. In other words, human populations have typically adapted their farming techniques to accommodate their growing populations. The academic Julian Simon (1932–98) also argued that people could be the solution to resource scarcity and environmental problems because of our ability to innovate ways to better use resources.

Recent field studies have also called into question neo-Malthusian explanations for such environmental problems as deforestation, soil erosion, desertification, and overfishing. Researchers repeatedly find very little direct evidence that such processes are the direct result of the number or density of local resource users. Rather, they show that these problems typically arise under specific political, historical, and economic circumstances. They find, for example, that when local users have a long-term stake in the management decisions affecting resources, then forests, wildlife, and biodiversity in general can thrive even at very high human densities.

Most significantly, critics of neo-Malthusian views argue that simple cause-and-effect models of overpopulation and environmental degradation ignore the profound interconnections between people, resources, and capital in the globalized world. They point out, for example, that the colonization of some countries by others has left a legacy of marginalization and inequitable resource distribution whereby peasants starve on tiny plots of marginal land while vast tracts of rich soil are controlled by multinational companies and devoted to the cultivation of export-oriented luxury foods such as coffee. This example shows that there are complex historical reasons for hunger and resource degradation that are largely unrelated to a country's population-to-resource ratio.

AN EMERGING CONSENSUS

Over the past decade or so, the consensus is emerging that human population numbers on their own are insufficient for understanding the human impact on the global biosphere. The equation I = PAT was proposed by ecologist Paul Ehrlich to reflect the fact that human environmental Impact was the product of Population, Affluence (usually measured as income per capita), and the Technologies used to meet everyday needs. Thus the impact of a few wealthy people living in amenities-rich urban luxury would have the same impact as many more people eking out a rural living with their own labor. But the equation still suffers from the misconception that specific environmental impacts are the direct product of characteristics of the local population.

The crisis of global warming helps frame these issues more holistically, and to focus particularly on the consumption side of the population-environment issue. For example, the United States comprises less than five percent of the world's population, but is currently estimated to contribute some 33 percent of human-produced greenhouse gases into the earth's atmosphere. Yet global warming—like most environmental problems—is not inevitable. There are technologies and skills to greatly reduce the reliance on fossil fuels. But economic momentum, political inaction, and everyday consumption choices have to date prevented many from meaningfully addressing this crisis. Doing so in a serious way means making tough choices about where to live (high density cities or sprawling subdivisions), what to eat (locally grown food or exotic imports), the types of technologies to choose (solar panels or coal-fired power plants), where to take vacations, and what clothes to buy.

To reflect the need to more closely examine the role of consumption in environmental problems, the New York–based Population Reference Bureau (which publishes an annual report compiling data on all countries' population trends), has now included information on countries' energy use per capita, as measured by kilograms of oil equivalent. By this metric, the average person in developing nations uses only 20 percent of what the average person in more developed nations does. Put another way: with 80 percent of the world's population, the residents of less developed countries used, collectively, only 44 percent of the energy consumed annually.

Portugal

PORTUGAL IS A European country located on the Iberian Peninsula in the southwestern part of the continent. Portugal has a land area of 35,672 square miles (92,391 square kilometers), including the Atlantic island groups of the Azores and Madeira, and an estimated population of 10.6 million people in 2006. The country may be divided into five main physiographic units that form a succession of hilly terrains and depressions occupied by the large Iberian rivers such as the Douro, the Tagus, and the Guadiana. The climate is cool and rainy in the northern mountains and turns progressively warmer and drier toward the south, with near arid conditions in the Algarve region.

Air pollution is becoming an important issue in cities such as Porto and Lisbon where European Union (EU) standards for air particulates and tropospheric ozone are frequently surpassed. In Porto, for instance, people suffering from chronic obstructive pulmonary diseases (which has been linked to concentrations of particulates in the atmosphere) rank second in number in Europe after London. Traffic and fossil fuel burning (fossil fuels with high sulfur content are still relatively important in the country) are the main causes. In July 2000, the European Court ruled against Portugal for not having passed legislation dealing with 99 hazardous substances and for not having established temporal targets for their reduction. Moreover, acid rain has contributed to the defoliation of part of Portugal's extensive forest cover.

Portugal has also received repeated calls from the EU to curb water pollution. In 1999 and 2000 the country was not complying with the Drinking Water Directive regarding concentrations of fecal and total coli bacteria forms. The European Commission decided to take Portugal to the European Court for failing to declare a sufficient number of protected zones under the Nitrates Directive and thus prevent groundwater pollution, especially in the irrigated agricultural areas of Setúbal and the Algarve.

Soil degradation is one of the most important environmental problems of Portugal, especially when linked to forest fires. In 2002 almost 30 percent of the land was under cultivation, but a substantial part presents diminishing fertility as a result of erosion. In 2000 forests covered more than 40 percent of the total land area. Because of agricultural abandonment, forest areas are growing (140,850 acres [57,000 hectares] of net gain between 1990 and 2000). Portugal exports timber and is the world's largest producer of cork (67 percent of the world total), mostly extracted from the vast forests of the Alentejo. In 2003, about five percent of the land was subject to environmental protection.

Garcia de Orta

Garcia de Orta (1501 or 1502–68) was a Portuguese Jewish physician who detailed cures for tropical diseases. During the 16th century many Portuguese sailors were journeying in the tropics, and some were succumbing to tropical diseases, often bringing back diseases to Portugal. Garcia de Orta, the grandson of Jews who fled persecution in Spain, practiced medicine and was a professor at the University of Lisbon in 1530. He became the chief physician in the fleet of Martin Afonso de Sousa in 1534 when the new viceroy sailed for India. Living in Goa, de Orta became well-acquainted with many diseases and their local cures.

In Goa, Garcia de Orta cultivated a botanical garden full of spices and other medicinal plants. He corresponded with others regarding tropical treatments and published a book on tropical medicine in Goa in 1563. He was the first recorded person to conduct an autopsy in India, and performed an autopsy on a cholera victim, becoming the first European to describe cholera, among other diseases.

In 1543 Garcia de Orta married a relative who had converted to Christianity, but the marriage was troubled. Six years later de Orta managed to have his mother and two aunts sent to Goa after their arrest and persecution for being Jews. Garcia de Orta died in 1568, apparently without having been denounced himself. His sister was burned at the stake for her Jewish beliefs in the following year, and in 1580 de Orta was posthumously convicted of being a Jewish heretic and his body was exhumed and burned—a sad end for someone who contributed so much to medical science.

In 2003 forest fires affected more than 1.05 million acres (425,000 hectares), or five percent of the total land area of the country, during a series of fires that were the worst in Europe in 50 years. Portugal declared the whole country a disaster zone and received monetary aid from the Solidarity Fund of the EU. Despite governmental measures implemented to avoid large fires, the summers of 2004 and 2005 were again tragic. In 2005, during the worst drought experienced by the country in more than 50 years, some 320,000 acres (130,000 hectares) burned and 13 people died in fires in the center of the country.

Coastal urbanization for tourist development, especially in the Algarve, has also raised considerable concern. In this case, one of the more pressing issues is water availability. In 1998 the construction of the Alqueva Dam on the Guadiana River began. Once completed (in 2025), it will have created the largest artificial lake in Europe (97 square miles [250 square kilometers]), with a total capacity of 146 million cubic feet (4.150 cubic hectometers). Though originally designed for irrigation, a growing proportion of the water will go for tourism uses, especially golf courses. The dam's environmental effects are expected to be numerous. The Alqueva Dam will not only submerge prime agroecological land but it is thought that it will also affect fisheries at the mouth of the Guadiana River.

Postcolonialism

POSTCOLONIALISM (also sometimes known as postcolonial theory, or post-oriental theory) refers to the legacy of 19th century European colonial rule. The study of postcolonialism acknowledges that colonialism continues to affect former colonies many decades following their political independence. Postcolonial studies articulate the many and complicated histories through which colonialism is still being reproduced.

Contemporary academic inquiry on postcolonialism owes much to the work of Edward Said. His book *Orientalism,* one of postcolonialism theory's seminal texts, investigates and articulates the means by which colonized peoples are constructed by colonizers. Specifically, Said describes the ways in which the Western world has wrongly depicted the Orient as a strange and exotic place. Said argues that postcolonialism can only be understood by acknowledging the means that reinforce and strengthen colonialism. Specifically, he demonstrates how European arts and literature have negatively represented the Orient as "Other." The result is that the knowledge produced and consumed by Western societies reinforces the superiority of the West over other peoples and cultures.

Another important contribution to postcolonial scholarship is Paul Gilroy's *The Black Atlantic*. This work traces the movement of black people from their native countries to the Western world and how these people, often treated as commodities by the West, have fought to establish their own distinct cultural identities counter to colonizers' dominant constructions of them. Through explorations of music and other art forms, Gilroy argues that this is a process that continues, subtly and not so subtly, to this day. Gilroy's work demonstrates how black culture is not exclusively African, American, Caribbean, or European, but a complex and simultaneous mixture of them all, a Black Atlantic Culture.

After more than two decades of development, postcolonial research is now an interdisciplinary field involving scholars from English literature, history, sociology, human geography, anthropology, cultural studies, and more. Researchers tackle the problems of how the experience of colonization affects those who were colonized; how colonial powers continue to control; what remnants of colonial control remain in education, science, and technology; what forms of resistance were and are being used against colonial control; how colonial education influences the culture and identity of the colonized; how Western science changes knowledge systems in the world; the emergent forms of postcolonial identity after the departure of the colonizers; whether decolonization and a return to the precolonial past is possible or desirable; and how new forms of imperialism might be emerging and replacing colonization.

In recent years, a slight backlash has occurred with certain scholars and journalists beginning to challenge some of the assumptions in postcolonial studies, claiming that previously colonized peoples are not the powerless victims they have been made out to be. These commentators have emphasized the extent to which previously colonized countries have shaped, and continue to shape, their own destinies, sometimes through empire building of their own. Cynics would suggest, however, that the intention of these arguments is to lay a certain amount of blame on previously colonized countries for their current threats to the Western world (such as terrorism). Hence, for many, the backlash is nothing more than another form of dangerous colonial power.

Postcolonial studies have affected everyday language and led to the replacement of marginalizing terms such as *third world*. In academic study and many other engagements between former colonizers and colonies, people—particularly in the Western world—have become more aware of the need to think more carefully about the way in which they act and interact. This is a subtle, but nevertheless important, change.

THE ENVIRONMENT

Postcolonial conditions impinge on the environment in a number of ways. First, postcolonial states often have a legacy of environmental management (e.g., forestry) rooted in colonial governance systems. These may be heavy-handed, out of step with local populations, or otherwise founded on the expropriative ways of colonial tradition. Game park management in Africa and Asia is evidence of such entrenched relations. Second, postcoloniality enforces a state of production and exchange relations in which dependency persists, and peripheral locations continue to exploit primary resources in service of core areas. The flow of value and externalized environmental costs is consistent with historical patterns, even in the early 21st century.

Third, and more subtly, postcolonialism can be seen in environmental knowledge relations, where ideas, systems, and paradigms are exported to postcolonial states where local knowledge traditions, training, and articulation of environmental issues and problems is silenced through the celebration and entrenchment of "expertise."

This last problem, so emblematic of historical relationships between official and lay knowledge, has serious implications for land management, wildlife preservation, and pollution abatement where local traditions are lost amid enthusiasm for environmental modernization. However, postcolonial conditions can conversely engender dangerous romances about indigenous ecological knowledge and traditions. This way of thinking may lead to patriarchal relationships and symbolic participation, reinforcing colonial relationships while claiming concern for preserving traditional environmental knowledge and values—essentially separating East from West or North from South—with all that follows from such distinctions. For these reasons, understanding colonialism is crucial to understanding environmental conditions and problems around the world.

Potatoes

THE POTATO IS an edible tuber originating in highlands of South America. Growing potatoes for food value has spread across the world to the extent that it is now the world's fourth most important food crop, following maize, wheat, and rice. The vegetable (*Solanum tuberosum*) is gaining in importance globally, resulting principally from increased growth in suitable areas of India and China. Global production has doubled over the last two decades and is forecast to do so again by 2020. China has the largest crop of potatoes, with annual production of around 80.5 million tons (73 million tonnes), from a worldwide total of 356 million tons (323 million tonnes). The Russian Federation produces 39.7 million tons (36 million tonnes) per year, and the third largest producer is India, which grows an estimated 27.6 million tons (25 million tonnes). The total value of the crop amounts to around $40 billion annually.

While potatoes are found in a number of different varieties, most share the characteristic of being low in vitamins and other nutrients but comparatively high in carbohydrates, making them a good source of energy. However, potatoes are also characterized by high levels of vitamin C and protein. The combination of ease of growth with the energy value of the plant means that potatoes are particularly important to people who are poor or forced to occupy marginal agricultural land. In recognition of this importance, the United Nations has designated 2008 the International Year of the Potato.

From its origins in the Peruvian and Bolivian plateau known as Titicaca, where as many as 5,500 different varieties have been developed over the years, the potato was taken to Europe by the Spanish and adapted itself to new climates at a time when rapid population increase was fueled by such transfers of technology. This process was not inevitable, nor was it immediately successful. Concerted efforts were required to make the potato popular in, for example, France, where it took nearly two centuries before it became accepted.

When potatoes were introduced in the United States, the wide open spaces of the Midwest states made large-scale production convenient and profitable. The leader in this process was a man named

Luther Burbank, who grew new varieties in the United States in the early 19th century, in particular the Russet Burbank, which remains one of the most popular varieties in the country. The domination of the U.S. environment by human endeavor, including the establishment of large-scale damming and irrigation projects, enabled the economies of scale that now characterize the country's agriculture. The desire to grow ever more quantities of crops such as potatoes has led to the physical transformation of a great deal of the landscape and it is far from clear if the use of water resources is sustainable. This has been accompanied by significant levels of research and development investment into the business of agriculture in the customary pattern of the public sector supporting the private. Despite all of this, new diseases and pestilences are still emerging in those areas around the world in which potatoes are being grown on a large-scale for the first time.

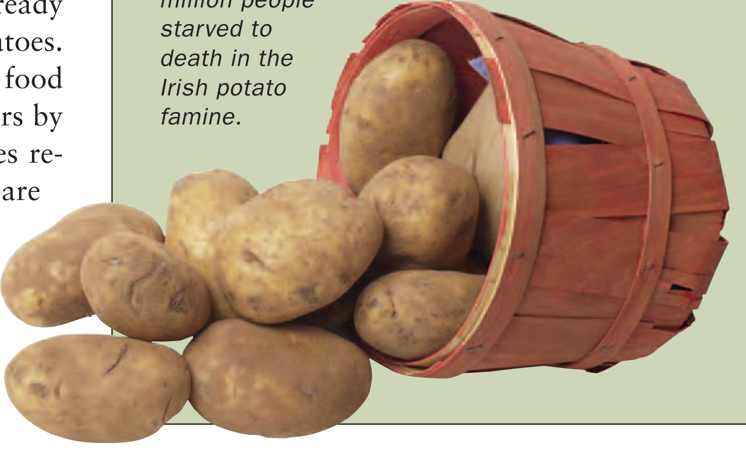
In terms of cuisine, potatoes have been found to be quite flexible in being adapted to local tastes and are prepared in many ways. Cooking is necessary because the raw potatoes contain chemical substances that can have negative health impacts. Care should also be taken about the black "eyes" that develop in potatoes and are also potentially problematic.

In the modern Western world, great quantities of potatoes are eaten in deep fried snack form, often with added salt, artificial coloring, and flavoring. These snacks are believed by some to add to obesity problems in the societies in which they have become popular. They have become part of the standard package of quick meals in leading multiple fast food chains and, for the sake of security of supply and taste, are customarily processed, powdered, and frozen, and such methods further reduce the already limited amount of vitamins within the potatoes. The move to becoming more of a processed food was stimulated among producers and marketers by declining sales led by fears of the health issues related to over-reliance on potatoes. Now there are fears in traditional rice-eating countries such as Japan that, as part of packaged fast food meals, the potato will suppress production of rice and will further contribute to the increasing obesity problem, not to mention the cultural implications. The use of potatoes in distilling vodka in the states of the former Soviet Union and neighboring areas has also contributed to excessive drunkenness as the failure of post-Communist policies has led to widespread popular discontent and despair. Again, a simple vegetable proves itself to have numerous uses into which deep meanings have become embedded to the extent that

The Irish Potato Famine

When the disease known as potato blight struck Ireland in the mid-19th century, it led to a terrible famine. A number of Western cultures had become dependent on the potato as a staple crop, and for many people in Ireland, potatoes were almost the only source of food. The reliance of Irish peasants upon the potato, which was also the principal form of animal fodder, had been intensified by the reliability of the crop, which had adapted well to high rainfall levels prevalent there. The famine was exacerbated by the refusal of British landlords to do anything to alleviate the suffering. Population levels have still not recovered from the subsequent starvation and mass emigration.

One minor consolation of the disaster was that it inspired a wave of scientific exploration aimed at determining the cause of the disease, properly known as *Phytophthora infestans*, which was identified as a fungoid infestation. This wave of research gave new momentum to the discipline of plant pathology.



More than one million people starved to death in the Irish potato famine.

it is almost impossible to separate the original item from its cultural significance.

Poverty

THE RELATIONSHIP BETWEEN poverty and environmental degradation is one of the more contentious areas of sustainable development. The conventional view, often dating back to colonial attitudes, has been that the poor are to blame for environmental degradation. To a great extent this standpoint has been implicitly or explicitly supported by development agencies such as the World Bank and United Nations (UN) and the findings of key development forums, such as the UN-appointed World Commission on Environment and Development (WCED), which, in its 1987 report *Our Common Future,* brought to the fore the close causal links between environmental change and poverty:

> [M]any parts of the world are caught in a vicious downward spiral; poor people are forced to overuse environmental resources to survive from day to day, and their impoverishment of their environment further impoverishes them, making their survival ever more uncertain and difficult.

Similar assertions have been reiterated at subsequent global conferences, such as the Rio Earth Summit (1992), various UN meetings, and the Johannesburg conference of 2002.

However, this somewhat deterministic representation, that the poor degrade their environments and in that case only increased income (at the individual level) or economic growth (at the national level) can lead to more sustainable interactions between people and the environment, has a number of shortcomings. On the one hand such a simplistic poverty–environmental degradation nexus ignores or diminishes the importance of contextual factors. Subsequently this second view, that there is a complex web of factors that result in environmental degradation, of which poverty is only one of many, tends toward examining relationships around resource access (e.g., assets, land, labor, credit, markets), institutions (e.g., land tenure systems, governance) and vulnerability (e.g., seasonal versus long term networks, entitlements). These structural issues may offer a more dynamic and holistic basis of analyzing people's relationships (both poor and wealthy) with their environments as well as more constructive policy opportunities.

THE POVERTY-ENVIRONMENT NEXUS

International development agencies have paid at least some attention to relationships between poverty and the environment for a number of years. Making environmental concerns a more central concern of poverty has, in large part, been driven by the desire of the international community to meet its poverty eradication targets set in the Millennium Development Goals (MDGs). But what is the relationship between natural resources and poverty (or wealth), and what is the impact of poverty (and the poor) on the environment? Despite earlier, enduring, discourses that blamed the poor for environmental degradation and pollution, there is little evidence that such a nexus exists on any significant scale.

Consequently, third world leaders and populations often suspect that governments and environmental movements of the West are trying (through the environment-poverty-development debate) to limit the way they can exploit their own environments, keeping them permanently poor. This was a basis for conflict between developing countries and the West at both the Rio and Johannesburg sustainable development summits. Developing countries have been typically skeptical of forms of sustainable development that aim to protect the environment ahead of the pressing needs of the poor, for example through the creation of conservation parks and marine reserves. For them, poverty, underdevelopment, and global inequality (resulting from unequal terms of trade) are the most pressing problems facing the world and these have to be tackled before environmental problems can be adequately and holistically addressed.

The poverty-environment nexus therefore has a number of contentious aspects. First, there is the view that poverty alleviation is a more serious problem than environmental protection. These views are accentuated by fundamental and significant inequalities in wealth and access to resources within nation states and globally. These inequalities mean that the question of sustainability is framed quite differently for people in different parts of the world: they have contrasting needs, aspirations, resources and constraints. For someone in the West, sustainable development is about securing and preserving an environment in which to enjoy a comfortable standard of living and that can be equally enjoyed by one's descendants (intergenerational sustainability). It may also be about securing enough natural resources to offset global warming through protecting forests and large water bodies, often in developing countries (for example the Amazon basin). For someone below the poverty line in the third world, sustainable development may be about securing one's individual and cultural livelihood and meeting basic needs, and natural resources use is an important means by which to do this.

Consequently, while some argue that poverty is closely linked to environmental degradation, for others increased utilization and exploitation of natural resources, at an even greater rate than today, is the only realistic strategy for meeting current needs and for future development. Forests, agricultural lands, fisheries, wetlands, and rivers all support the livelihoods of people and communities. In fact, some 70 percent of the world's poor continue to live in rural areas and depend on their local environments for their daily survival.

Additional arguments suggest that environmental degradation causes human poverty. In other words, an environment with falling fish stocks, soil fertility, or forest cover can support fewer people. In urban areas degraded environments, primarily from unregulated industrial development and waste disposal, impact on urban communities living in marginal environments through exposure to polluted waterways, infectious and parasitic diseases, and other environmental and health hazards. Equally so these threats have as much to do with the governance of cities and the relative lack of power of the poor to demand provision of safe water, sewage and sanitation services, and access to social goods than poverty *per se*.

The poor are affected much more by environmental degradation and pollution, whether it emanates from their own communities or from the activities of others. A great amount of research has supported the observation that the poor are impacted by pollution and environmental degradation disproportionate to their contribution. Land degradation, desertification, flooding, and other hazards are more likely to impact on the poor, rather than the rich who are better serviced and often distant (or walled off in the case of cities) from degraded environments and industrialization. The poor's greater exposure to the impacts of pollution is accentuated by their geographical and social position and relative lack of influence over politics and policy. They are more likely to be exposed to environmental hazards in the workplace, the home, and in their neighborhoods. In third world cities the poor are less likely to have access to potable water, to have access to sewage and sanitation systems, and often do not have waste (both hazardous and nonhazardous) collected or disposed of safely. Even in wealthier Western cities research has shown that poorer urban citizens are more likely to live downwind of polluting industries and closer to sites of waste disposal.

POVERTY AND DEGRADATION

There is also a strong argument for a reverse connection: That poverty is not just a symptom of environmental degradation but is also a *cause*: Poor people are forced to degrade their environment because they have no other means to survive. This occurs when poor people with limited access to land or other resources are forced to overexploit such resources as they do have to the point where there is long-term damage to the environment. People may be marginalized through environmental conditions, poor soils, remoteness, difficult terrain, a hazardous environment, or socioeconomic reasons, or their livelihoods may have been disrupted or destroyed through their own activities, or the activities and decisions of others (particularly if they are less powerful vis-à-vis other social groups). This can take many forms: cultivating land every year without adequate fallow periods; overgrazing with too many stock for a given area of land; overfishing so that stocks do not naturally regenerate; and settling and using marginal lands that easily erode or lose fertility. As Robert Chambers has noted:

> Poor people in their struggle to survive are driven to doing environmental damage with long-term losses. Their herds overgraze; their shortening fallows on steep slopes and fragile soils induce erosion; their need for off-season incomes drives them to cut and sell firewood and to make and sell charcoal; they are forced to cultivate and degrade marginal and unstable land.

Such damage to the environment then leads to a situation where production falls in future years and fewer people can be supported, exacerbating the original problem of poverty. Poverty and the environment are therefore linked in a multidimensional relationship often referred to as the Poverty-Environmental Degradation Spiral. In this model poverty places unsustainable demands on local environments that lead to environmental damage resulting in resource depletion and declining productivity. Environmental degradation then serves to reinforce poverty, which leads to further environmental decline, and so on.

NATIONAL-LEVEL POVERTY

We can consider these examples at the micro-level, with what individuals or communities do when faced with poverty and falling environmental carrying capacity. Yet these processes also work on a larger scale: Nations suffer from poverty as well as individuals. Countries with massive debt burdens and crippling debt servicing costs face a similar situation to individuals with restricted access to resources. In order to extricate themselves from poverty, they use available resources heavily (for example, by milling rain forests or giving liberal mining or fishing concessions to overseas companies). At a national level poorer countries are more likely to be exporters of resources (such as timber) and sinks for the dumping of hazardous and toxic wastes from wealthier ones. This also includes the greater possibility of high-polluting industries being relocated from countries with stricter environmental standards (typically more developed nations) to states with less environmental standards or laxer regulation (typically developing countries). The environmental costs of development are then transported from wealthy to poorer regions and countries.

WEALTH AND DEGRADATION

It is important to note that poorer societies, and countries, have less of an impact on the environment that wealthier societies and states. Growth is necessary, it is suggested, in order to meet basic needs, but such growth need not be environmentally damaging. Focusing on the impact of the poor on the environment and the world's resources obfuscates the fact that the wealthy use a disproportionate amount of the world's water, energy, forestry, and food resources and, in turn, contribute the greater amount of waste that represents an ecological footprint far beyond the local scale—though research on wealth and environmental degradations across scales is less common.

In turn, promoting economic growth through exports based on monocrops as the answer to poverty and environmental degradation ignores the fact that the shift to more intensive large-scale farming (such as cotton, cocoa, and coffee) actually *increases* ecological impact and decreases benefits to poorer farmers and communities. Research has consistently shown that wealth and development has potentially greater environmental impacts than poverty and the poor.

The argument is often then made that a country's environmental wealth is plundered and impoverished to meet an immediate need and prevent (depending on whether we are discussing households or whole countries) poverty or bankruptcy. Poor or developing countries may then be unlikely to fund environmental protection, regulation, or sustainable development initiatives that inhibit the attraction of industrial relocation or even resource extraction operations. However, in both cases, the actions of the wealthy are as important as poverty as an environmental issue.

There is, consequently, a strong case for focusing on the structural causes of poverty in order to better understand and address environmental issues. This involves a more inclusive addressing of causality at a range of scales, from local to regional and global. It also involves understanding a number of processes, whether they be ecological, social, economic, cultural, or political. For example, the environmental conditions that many poor urban communities face are related to a lack of access to infrastructure, services, affordable land, healthy localities, and a lack of inclusion in urban governance, than purely income.

A SUSTAINABLE LIVELIHOODS APPROACH

A more dynamic approach to the poverty and environment debate is to focus on the factors that impact on people's livelihoods. Recently development agencies and practitioners have refocused on supporting sustainable livelihoods as a means of reducing poverty and the impact of poverty on the environment. Communities around the world are able to lead rich, dignified, and fulfilling lives when they are in charge of their natural resources.

To many of these people, and particularly those who are considered "poor" in the economic sense of the word, a fulfilling life is about much more than simply money or possessions. It is about their access to and control over natural resources and their involvement in decision-making processes about these resources.

For the Bagyeli tribe in Cameroon, for example, the creation of protected areas on their ancestral territories has infringed upon their individual and collective rights, marginalizing and impoverishing them—despite external views that see the creation of protected parks as the basis for sustainability. They believe that any poverty reduction strategy proposed by the government or by external funding organizations must include their participation, and must be based on their collective right of access to land and forest resources. As one indigenous Bagyeli person exclaimed:

> If you do not collect fruits, you cannot have soap; if you do not go fishing, you cannot eat salt; if you do not cultivate plantains to sell you cannot buy clothes. I am dirty and without clothes because I do not do anything. I have already been forbidden from entering the forest.

Among the more holistic and progressive ways to examine the poverty-development-environment nexus is the Sustainable Livelihoods Approach (SLA), which can be used for identifying where constraints or opportunities lie and for developing policy. It is a potentially useful tool for communities and policy makers alike as it views people as operating in a context of vulnerability. Within this context, they have access to certain assets or poverty reducing factors. These gain their meaning and value through the prevailing social, institutional and organizational environment. This environment also influences the livelihood strategies—ways of combining and using assets—that are open to people in pursuit of beneficial livelihood outcomes that meet their own livelihood objectives. The objective of the SLA is to *support* people's livelihoods, increasing the sustainability of people's livelihoods, as a means of eliminating poverty. This is best achieved through promoting more secure access to, and better management of, natural resources rather than excluding the poor from their sources of livelihood.

At a practical level, this means that an initiative must start with an analysis of people's livelihoods and how these have been changing over time; fully involve people and respect their views; focus on the impact of different policy and institutional arrangements on people/households and on the dimensions of poverty they define (rather than on resources or overall output *per se*); stress the importance of influencing these policies and institutional arrangements so they promote the agenda of the poor (a key step is political participation by the poor themselves); bridge gaps between the macro and micro levels, recognize the importance of macro level policy/institutions to the livelihood options available at the micro level; and work to support people to achieve their own livelihood goals.

Another key element of the structural approach is the emphasis on social equity, justice, and liberation. Just as there are basic material needs for people, there are also fundamental social needs and considerations of injustice. Unjust societies are not sustainable societies because they rest on the exploitation or subordination of one group in society by another. Therefore, sustainable development is not possible within the context of an unjust society because large elements of that society cannot survive and function. This approach, then, places stress on the removal of injustices and inequalities within societies. Dealing with these injustices and inequalities is, to the oppressed or poor concerned, their most pressing development need. Talk of sustainability is meaningless when such conditions persist. Consequently, rather than focus on the (static) argument that poverty and the poor degrade the environment, sustainable development must incorporate notions of social justice and be directed at achieving sustainable societies (in an ideal world free of injustice and major inequalities) as a precondition for environmental sustainability. Writers from a political ecology framework argue that poverty and the environment are interrelated around issues of combating poverty, inequality, and injustice. These are essential steps to achieving sustainable development. Such a strategy aims to achieve not just environmental sustainability but also the sustainability of just and equitable societies.

At its most basic level, many of the debates over the poverty-environment nexus revolve around whether human or environmental needs are given priority and whether "development," if it is defined as neo-liberal capitalism, can ever be sustainable. Effectively dealing with poverty, and addressing the causes of poverty, is fundamental to environmental sustainability. The poverty-environment nexus goes beyond a question of degradation and into issues of rights, access, entitlements, local institutions, property rights, and decision making power over the use of resources. The links between poverty and the environment are therefore likely to be context specific and most effectively examined at relevant spatial and social scales. Far from being a straightforward issue of the poor degrading the environment at unsustainable rates, a much more mutually dependent and dynamic relationship between poverty and the environment exists.

Powell, John Wesley (1834–1902)

A CHILD OF America's mid-19th century western agricultural frontier and a celebrated explorer of the Grand Canyon, John Wesley Powell devoted his remarkable career as a scientist and, for a time, powerful U.S. bureaucrat, to the expansion of scientific work in the federal government. He focused on the survey and mapping sciences of geology, geography, and ethnology (i.e., the study of American Indian language and culture). Powell was director of the U.S. Geological Survey (1881–94), founding director of the Smithsonian Institution's Bureau of Ethnology (1879–1902), and earlier, leader of the Geographical and Geological Survey of the Rocky Mountain Region (~1869–79), known as the Powell Survey. In each of these offices, Powell expanded the reach of government-supported survey, mapping, and research projects, and in doing so, sought to bring scientific knowledge to bear, both directly and indirectly, on problems of environmental and resource governance, particularly those associated with American agricultural expansion and settlement in the arid West during the late 19th century.

Though he became a keen spokesman for Washington's emerging scientific community in the 1870s and 1880s, Powell's own expertise was initially built on the success of his Colorado River expeditions and he had a limited formal scientific education. A native of central Illinois, he undertook these expeditions while still a geology professor and museum curator. That Powell piloted the voyages, despite having lost much of his right arm in the U.S. Civil War, remains an astonishing feat. But Powell's contributions to the earth sciences, including his development of general concepts of baselevel of erosion, antecedent and subsequent rivers, and runoff, were also built on skillful synthesis and analysis of observations in the West, including subsequent survey work on the Colorado Plateau in southern Utah.

Operating under the Smithsonian Institution and U.S. Department of the Interior, the Powell Survey joined three other federally sponsored surveys in the West. Some of this work Powell managed from Washington, where he garnered Congressional appropriations in support of ongoing triangulation surveys, topographical mapping, and geological and ethnological studies. Key works produced during this period include Powell's *Explorations of the Colorado River of the West and Its Tributaries* (1875), which blended geological observations with exploration narrative, the *Report on the Geology of the Eastern Portion of the Uinta Mountains* (1876), and the collaborative *Report on the Lands of the Arid Region of the United States* (1878).

In the latter volume, in which the Utah Territory served as a model for U.S. arid lands as a whole, Powell introduced a land use classification system delineating land as (potentially) irrigable, pasturage, or timber regions, based on topographical, geographical, and geological characteristics. While the book intended to "set forth the characteristics of these lands and the conditions under which they can be most profitably utilized," it insisted that these conditions were circumscribed by the limits of irrigation technology and of nature itself in the arid West.

The report called for sweeping reforms of the Homestead, Desert Land, and Timber Cultures Acts, arguing that government distribution and regulation of public lands must better reflect the physical conditions of the region. In his advocacy of more efficient land and resource usage, Powell also criticized Native American land use practices, especially the use of fire to drive game, and he called for the removal of the tribes to federal Indian reservations as a solution to the problems of resource conflict and violence between the white miners and settlers and Native Americans.

Two years after the four western surveys were consolidated into the U.S. Geological Survey (USGS) in 1879, Powell was named to direct the agency. He established goals for an ambitious national mapping program organized around the mission of a complete topographical map of the United States (in 2,600 sheets) which would provide the basis, in turn, for a comprehensive national geological map. The maps were to be widely distributed for public use.

In the late 1880s, Powell also came to direct a federal irrigation survey of U.S. public lands in the western states and territories, in the course of which he attempted to set in place a system of land use classification similar to that he had called for in his Arid Lands Report. The resulting enmity from western senators, who perceived that Powell was slowing the pace of economic development in the West, would kill the irrigation survey, and Powell's land reform plans, before they took shape.

Powell resigned from the USGS directorship in 1894, but his national mapping programs continued; he departed the survey as a pioneer of the sciences in American government and of the geo-coded world.

Pragmatism

PRAGMATISM AS A school of philosophy arose in (and has remained for the most part confined to) North America in the late 19th century. Pragmatism's most well-known and influential early theorists included Charles Sanders Peirce, William James, John Dewey, and George Herbert Mead. Though not as well-known or widely appreciated internationally—or even within American academic philosophy—as many European philosophers, these "classical" American pragmatists continue to inform a diverse and evolving contemporary American pragmatism.

Perhaps most fundamentally, "all [pragmatists] agree in their rejection of foundationalist epistemology." Pragmatist anti-foundationalism should not, however, be thought to reflect an antirealism or antinaturalism. The early pragmatists, particularly Peirce and Dewey, were intensely interested in theorizing the nature of scientific inquiry—in large part for the sake of the development of the practice(s) of natural science. For pragmatists, we *must* continue our scientific investigations into the "truths" of the world; but our explanations must proceed without recourse to a priori, unchanging "laws." This emphasis on experience and *experiment* (and perhaps the near conflation of the two) "led James to call his philosophy 'radical empiricism,'" according to Kelly Parker. All explanation is the product of experience, and experience has proven that our understandings of the world are nothing if not "fallible."

The concept of "fallibilism"—originally theorized by Peirce—is also integral to pragmatism. Human beliefs are necessarily based in certain fundamental constructs. All such constructs—whether guiding natural science or social inquiry—are also necessarily fallible. We can never, in other words, assume that there is any transhistorical correctness underlying a particular concept of belief. Emphatically for pragmatists, however, this should not be construed to mean that no beliefs or constructs are correct or accurate. It is more that, as Larry Hickman puts it, "we *may* be able to get it [a belief or construct] better and better, truer and truer, but we *never* get it completely right" (emphasis added). "May" and "better" are primary qualifiers in this sentence. To anyone who would conflate the pragmatist optimism, inherent in this sentence, that "we may be able to get it…truer and truer," with the Enlightenment "project" of the accumulation of knowledge increasingly nearing absolute Truth, it could be pointed out that we only ever know that we *may* be getting it truer. So there is a point in trying, a necessity for inquiry, to be sure, but it is unverifiable—and therefore a nonissue—to argue whether the development of any particular truth is approaching Truth. To staunch antimetaphysicalists (e.g., most poststructuralists) who might quarrel that "better and better, truer and truer," still harbors an implication that there is a transhistorical end-state toward which we "think" we might be headed, the flat declaration that follows, that "we [know we] never get it completely right," should sufficiently silence this charge.

Pragmatist anti-foundationalism and empiricism are thus based in a desire to explain and understand the world, but in a less epistemologically confident manner than as practiced within predominant modes of Western science.

ENVIRONMENTAL PRAGMATISM

In 1996, Andrew Light and Eric Katz proposed a focused "*environmental* pragmatism" as a solution to a definable problem within environmental philosophy: its lack of practical influence on environmental science, activism, or policy. To remedy this perceived deficiency, they suggest that "the fruits of this philosophical enterprise should be directed toward the practical resolution of environmental problems." Of particular concern to Light and Katz was the observation that environmental philosophy remained mired in a "theoretical dogmatism," with the majority of environmental philosophers committed to the belief that only a nonanthropocentric environmental ethics "will yield a morally justifiable environmental philosophy."

Philosophical and practical opposition to the moral monism that results from dogmatic nonanthropocentrism and theories of intrinsic value in nature is probably the broadest base of common ground between the contributing authors in Light and Katz's 1996 edited collection *Environmental Pragmatism*, defining a subfield of environmental studies that has grown substantially in the decade since.

Prairie

PRAIRIE IS A type of grassland that is characterized by the presence of grasses without many trees and a generally low altitude with few hills or other uplands. The prairie tends to promote the lifestyle of herders or nomads and has in more recent years become home to large-scale and often intensive agriculture which may have required the resettling of indigenous people away from their traditional lands.

Although it is possible to categorize the pampas of Argentina or the steppes of Central Asia as prairie, the term is more usually applied (particularly in the United States) to the rolling grassland that covers more than two million square miles of the central United States and extends into parts of Canada. These lands have become almost mythologized in the American psyche for their role in opening up the west of the continent and as remote, rural agricultural areas.

It is believed that French explorers of what is now the central United States labeled the high plains regions of states such as Kansas, Oklahoma, and the Dakotas, as well as the mid-plains to the east, ranging from Texas to Manitoba in Canada, as prairie or meadow. Almost the entirety of this vast area of land has now been transformed to become farmland, either through dryland techniques or, more recently, by drawing upon the below-ground water resources of the Ogallala Aquifer. The nature of the topography lends itself to economies of scale and scope in agriculture. This was accentuated by the allocation of land as a very cheap resource to settler families. Consequently, the transformation of the land into cattle or crop growing territory has been conducted on a large and uniform scale. This form of agriculture has enabled farmers to provide large amounts of produce of comparatively even quality and low cost. This has had significant impact upon the ability of farmers to feed a growing population and also to export food.

One of the main problems threatening the sustainability of existing living practices in North American prairie regions is the provision of water resources. The depletion of the Ogallala Aquifer and existing above-ground water resources, together with continuing increase in demand for water and the changes being wrought by global climate change, mean that most agricultural and residential practices will have to change significantly.

Since the 1970s the U.S. government has been encouraging and legislating for changes in the high plains regions, in particular, to try to mitigate excessive strain on water resources. This has included changes in agricultural practice and in patterns of urban residential planning. However, these changes as presently manifested are likely to prove insufficient. New regulatory structures and licensing systems might prove to be effective in the short and medium term through trading of water rights and diversion of resources. As climate change leads to alterations in the regular pattern of seasons, changes in demand for power and water will stretch existing preparations for supply and demand management of these goods.

Wildlife supported by prairie regions has been considerably reduced in terms of variety and number as agriculture has spread across the land and transformed it. This makes nature reservations of great importance in maintaining existing stocks and offering the opportunity to rebuild depleted stocks of at least some species. Maintaining reservations against the pressures for commercial development will require strong and well-policed regulation allied with a high level of political will.

Precautionary Principle

THE PRECAUTIONARY PRINCIPLE is a response to uncertainties over potentially harmful impacts to humans and the environment. The precautionary principle can be described in two ways. First, it specifies that it is better to avoid a set of actions if they contain potential serious or irreversible negative outcomes. In a more active form, taking a precautionary approach may necessitate action to avoid the potential negative consequences of delay or inaction.

A precautionary approach is used to manage potentially harmful actions (e.g., illegal hunting), processes (e.g., nuclear proliferation), products (e.g., asbestos) and technologies (e.g., genetically modified organisms). The precautionary principle can be implemented to secure personal well-being in the face of external threats or may be applied altruistically in order to safeguard resources and prevent potential harm to others, including future generations. It is this condition—the difficult task of projecting risks and benefits into the future in order to make informed decisions today—that often draws the ire of antiprecautionary advocates.

The precise origins of the precautionary principle are difficult to pin down, especially in light of the principle's contemporary widespread appeal and seemingly rational "look before you leap" logic (although there are strong counter-sentiments to be addressed below). The term can be traced to the German implementation of the foresight principle, or *Vorsorgeprinzip*, in environmental law during the 1970s. The 1982 World Charter for Nature was one of the first international endorsements of the precautionary principle. In 1992, Article 130r of the Maastricht Treaty noted that newly formed European Union (EU) environmental policies would be "based on the precautionary principle and on the principles that preventive action should be taken, that environmental damage should as a priority be rectified at source and that the polluter should pay."

Managing complex health and environmental affairs in the face of scientific uncertainties has rendered the precautionary principle a common governance axiom. In this context, the precautionary principle suggests that anticipatory action to prevent possible negative outcomes on human health and the environment is worthwhile despite a lack of clear evidence on the risks or the benefits of alternative measures. This is different from "burden of proof" protocols guiding many environmental management decisions where "business as usual" tactics often persist unless there is clear evidence supporting an alternative development path. In the face of scientific uncertainty over potential harms, a "better safe than sorry" approach is usually established by those following precautionary principles.

Precautionary decisions in the policy arena are oftentimes supported by a cost–benefit analysis to measure the risks and rewards of action in monetary, social, and ecological terms. Under this analysis, nonmitigating and mitigating action costs, opportunity costs (or the cost of lost opportunities as a result of a particular chosen course of action), and the option value of putting off action to a later date are all assessed in an effort to find the most efficient path forward.

In the modern-day policy making climate, the decision to apply precautionary principles cannot be reduced merely to an objective debate over the scientific certainty of future events. Instead, decisions involving the management of environmental resources and the well-being of future generations are heavily influenced by politics. Not only is scientific evidence interpreted differently by various interest groups, it is also produced in various capacities to support political ends.

Two notable examples illustrate the use of the precautionary principle. The Montreal and Kyoto Protocols, though different in eventual outcomes, have become widely accepted through the application of precautionary principles. Both the Montreal Protocol, which bans the production of ozone depleting substances, and the Kyoto Protocol, which reduces levels of greenhouse gas emissions, concern themselves with environmental systems that influence a global array of individuals and communities. While the Montreal Protocol is ratified by the major economic powers and exhibits widespread adherence, the Kyoto Protocol lacks the same level of commitment from developed nations, most notably the United States. Nevertheless, the commitment by nations to sign and in some cases ratify these international treaties—especially in the face of significant uncertainties over the accuracy of complex, long-term climate and upper-level atmospheric models—points to the tractability of the precautionary principle in the global policy arena.

Other international protocols, such as the Río Declaration on Environment and Development, signal, at least rhetorically, a commitment to precautionary global environmental governance. Principle 15 of the 1992 Río Declaration specifically states:

> In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

Though the precautionary principle has garnered much support over the past 15 years, a number of criticisms remain. The most vocal concerns come from antiprotectionists, supporters of technological innovation, and libertarians advocating personal freedom. Free trade advocates such as the World Trade Organization (WTO) argue that definitive proof should be required before potential health and environmental hazards precipitate the formation of barriers to trade.

One example is the WTO's position that the EU's six-year moratorium on genetically modified (GM) food imports from the United States is illegal. The EU ban, premised on the uncertain health effects of GM foods, was finally lifted in 2004 under pressure from the WTO to eliminate protectionist economic policies.

Others argue that technological innovation is inhibited by the precautionary principle. A risk-averse society denies the potential for technological developments that could potentially help, not harm, society. In this context, these groups often refer to once controversial, now widely accepted drugs and medical procedures found in the health care industry. Others are particularly concerned with a loss of personal freedom to innovate arising under strict adherence to the precautionary principle. These critics instead follow "proactionary" principles. Coined in 2004 by Natasha Vita-More, the proactionary principle suggests that many of history's great technological achievements were not well understood at the time of their discovery.

Precipitation

PRECIPITATION REFERS BOTH to the process by which particles fall from clouds to the earth below, and to those particles themselves. Owing to various chemical and physical actions, cloud droplets that would otherwise remain in the atmosphere can aggregate around an ice or liquid core until they achieve a mass that causes them to fall from the sky.

The different forms of precipitation that are possible include rain, snow, hail, and sleet. The type that forms depends on the specific weather conditions prevailing within the cloud and during the time between creation of the particle and its arrival on the ground. For example, cloud conditions may be such that ice particles form and start to fall to the ground, but the air conditions closer to the ground are sufficiently warm enough to melt the ice before it arrives. In any case, the process by which particles form and become larger is primarily the result of collisions with other cloud droplets and coalescence into larger particles. The speed with which this occurs depends upon specific local conditions, but it can take only a few minutes for the one million or so collisions to take place in favorable conditions and for precipitation to begin.

In particularly unusual climatic conditions, it is possible for a large group of small animals like frogs to be swept into the air and deposited as precipitation at a distant location. More commonly and predictably, dust or sand from desert areas can be regularly borne aloft and precipitated in other areas, as occurs with the red dust rain that derives from Xinjiang and arrives in Beijing periodically. The distance between the origin and ending of the precipitation process can lead to complex legal issues of responsibility in those cases where precipitation has, through pollution, led to damage to the environment. An example of this has been the acid rain that was produced by industrial activities in parts of Britain and then fell on Scandinavia.

The level, type, and nature of precipitation can have a significant impact upon the fertility of land on which it falls and, therefore, the ability of the land to sustain human and animal populations. The factors that can influence precipitation include the presence of ocean currents such as the Gulf Stream; the topography of mountains, basins, and depressions; wind patterns; and the distribution of banks of air in the atmosphere. These factors interact with each other in very complex ways, which makes prediction of the impact of attempts to modify weather very difficult.

The impact of future climate change is also very difficult to predict, although intensification of many existing meteorological phenomena is likely. Research suggests that human civilization can adapt to climatic changes within a comparatively narrow range but, especially when urbanization has taken place, will collapse when more extreme changes are indicated. The predictions of future climate changes, based on trends that have already been issued, would include some that exceed the narrow range of survivability of human civilization. Significant levels of resources would be required to withstand the more intense hurricanes, rainfall, and extreme forms of weather that may become more common in future.

Land areas that receive less than 250 millimeters of precipitation annually are classified as deserts, irrespective of the ground temperature. Much of the polar regions of the world are deserts, along with the very hot lands of the Sahara and the Kalahari. These lands are very dry and consequently sustain comparatively fewer forms of life than other parts of the world—and those life forms are specialized to deal with the conditions. Approximately one third of nonpolar land on the planet is classified as desert.

By contrast, some areas have very high levels of annual rainfall and this helps them support rainforests or tropical rain forests, which sustain a very diverse set of flora and fauna. These areas receive the majority of their rainfall from seasonal patterns, such as the monsoon rains that water much of south and southeast Asia. This includes various parts of India, which are the wettest places in the world, with annual rainfall exceeding 11 millimeters. The islands of Hawaii can also receive extremely high levels of precipitation because of the specific local conditions. The relatively even temperatures of oceans compared to land also tends to ensure that coastal lands receive more precipitation than falls offshore, as in the case of Ireland, which receives a great deal of the precipitation from clouds that have passed across the Atlantic Ocean.

Human activities can also have an impact upon the nature and level of precipitation. Since undergrowth and forest cover help to trap water in the ground, this leads to a cycle of greater fertility, which means that the larger plants can continue to thrive. Should those plants or trees be cut down for agricultural or commercial purposes, then the ability of the land to retain water will degenerate and this can lead to problems with flooding and mudslides and the desertification of forest land. This in turn affects the specific local weather conditions, reducing precipitation and intensifying the loss of plant life.

Predator/Prey Relations

PREDATOR/PREY RELATIONS REFER to the population dynamics between any heterotrophic species (consumers) and the species that it feeds on. The term "predator" in this usage refers to primary consumers (herbivores) as well as secondary and tertiary consumers (carnivores, top carnivores, and omnivores). The concept is crucial to understanding species demography, trophic hierarchies, ecosystem stability, and biodiversity conservation.

The works of Lotka and Volterra during the 1920s form the basis of much subsequent work. Lotka examined the competitive interactions between species, both in terms of intertrophic competition but also with competition between species for similar resources (interference), in terms of the laws of thermodynamics, bringing the concept of energy flow and efficiency into synthesis with Darwninian competition. This was further elaborated upon by Lindemann, Elton, and MacArthur and ultimately culminated in Odum's concept of the ecosystem. The Lotka-Volterra model of predator/prey relations describes the populations of both predator and prey species as fluctuating together, with the changes to the predator population lagging behind that of its prey in time. In such a model, neither the predator nor the prey become extinct, as predator populations will decline as prey populations decline, and the resultant decline in predators allow the prey population to recover.

The actual variance in abundance of predator and prey populations is affected by specific characteristics of the predator. A predator that has a narrow range of prey species (a stenophagous predator) will have its populations fluctuate in accord with the predictions of the Lotka-Volterra model. The abundance of the prey species in such a situation exerts a greater control on the populations of the predator, and extinction of either predator or prey species is not likely.

Alternatively, a predator that consumes a wide range of prey species (a euryphagous predator), exerts greater control on the overall abundance of each species, with variable effects on biodiversity. A euryphagous predator can reduce the biodiversity of an area by eating one or more of its prey species to extinction because of its wide dietary range and the presence of other species to feed upon. A euryphagous predator can also increase the biodiversity of an area by limiting the overall abundance of each of its prey species and preventing any one of them from becoming dominant. That is, were the predator to be removed from the environment, the abundance of each prey species would be regulated by interference competition, with a greater likelihood that one or more of these species would be driven to extinction by competitive exclusion.

ECOSYSTEM STABILITY

These concepts of predator/prey relations are crucial to understanding dominant ideas of ecosystem stability. The general premise of ecosystem stability states that greater native biodiversity within an ecosystem provides stability, where stability is defined as the maintenance of a constant community structure (that is, an ecosystem is considered stable when the species composition does not change). This statement is further elaborated upon to specify that a high level of biodiversity across all trophic levels provides stability. As the number of predator and prey species increases, according to this argument, intratrophic competition increases. Predators become more efficient in and specialized to a narrower niche and hence are more likely to be stenophagous. With a greater incidence of stenophagous predators, control of overall population numbers shifts to the bottom of the trophic levels (producers), extinctions are less likely to occur, and the higher levels of efficiency mean that all environmental resources are consumed and cycled, making it more difficult for a species from outside the ecosystem to become established within it. Hence, species composition remains stable and the ecosystem is considered stable. This line of reasoning has guided conservation practice throughout the latter half of the 20th century and into the 21st.

SPECIES INVASIONS

In terms of human-environment interaction, predator/prey relations have informed knowledge of the process and management of species invasions. Some factors commonly cited as allowing for the success of an invader in a new environment relate to it often being a generalist predator, and having escaped its natural predators. Hence, some invasive species are seen to drive the extinctions of several prey species that are not adapted to predation by the predator, while the new predator has nothing to keep its own population in check and vastly expands its own numbers at the expense of the native biodiversity.

Managers have used predator/prey models in controlling invasive species, often through biotic control. Biotic control involves introducing a predator species that is stenophagous toward the targeted invasive species, with the reasoning being that this new specialized predator will keep the number of the invasive species down while not preying on the native species in the ecosystem. Nevertheless, examples exist where the biotic control species expanded its dietary range upon being introduced to a new environment, and became a pest as well.

Questions of predator/prey relations also surface in conflicts over conservation efforts, especially in relation to the reintroduction of predators into an environment. For example, during the 1930s wolves were systematically eradicated from the American West because they were seen as livestock pests; this resulted in explosions of populations of primary consumer species such as mule deer and elk. These consumers then were seen to further reduce the biodiversity of the vegetation due to over-browsing. Conservationists have encouraged the reintroduction of predators such as wolves, bears, and cougars, but these measures are often met by resistance over economic and safety concerns.

Prescribed Burning

PRESCRIBED BURNING, ALSO known as "controlled burning," refers to the planned use of fire in different environments for a wide range of reasons, including reduction of wildfire severity, protecting grasslands from forest incursion, and simulating prior fire regimes. Although the term was developed only in the late 20th century, the practice of prescribed burning has been applied throughout human history.

The word *prescribed* is used as these fires are set only once certain environmental parameters are achieved. In industrialized societies, the parameters are generally based on quantitative thresholds for a range of factors such as wind speed and direction, air temperature, relative humidity, and moisture content of vegetative fuels and soil. Together with attributes such as local topography, these influence fire behavior, intensity, and rate of spread. Thresholds are usually determined empirically following research into fire behavior and are established to ensure that the fire can be contained while achieving management objectives.

However, generations of experience also provide the basis for knowing where and when to burn for best results. Indigenous peoples have long employed fire for environmental management. After 40,000 years some Australian Aboriginal communities continue to use fire to achieve a range of habitat and cultural outcomes. For example, fires are set to stimulate germination of grasses that attract kangaroos and other game for hunting and to thin out trees and shrubs to ease movement and habitation. Native Americans also burned selected areas regularly to favor grass species over trees and shrubs and improve grazing for game. Other societies share long histories of using fire as a land management tool. In Europe, fire was used for centuries to clear land, improve its short-term fertility, or bring about changes in vegetation structure to suit farming or hunting objectives.

Central to understanding the environmental consequences of prescribed burning is the concept of the fire regime. This refers to the frequency, intensity, season, and fire types, natural or otherwise, that have occurred in an area over time. Species, especially flora, evolve responses to fire regimes that enable them to persist in the ecosystem in the face of fire, but their adaptive responses relate to the historical fire regime. Therefore, changes to a fire regime, including the exclusion of fire, may cause changes in the species composition of an ecosystem. Prescribed burning imposes human fire regimes on the environment, contributing to the shaping of the landscape as a cultural artifact.

In New World countries such as the United States, Canada, and Australia, colonial settlement and agriculture interrupted fire regimes and ecosystems associated with indigenous environmental management practices. Wary of the threat that wildfires represented to their lives and assets, European settlers tended to suppress fires in the landscape. Ironically, these changes often produced a more wildfire-prone environment. Shrubs and trees replaced grasslands and forest densities increased. Of course, heightened fuel levels meant that when wildfires inevitably occurred they did so with greater severity.

After World War II, research into fire behavior and its role in the environment made clear the need to include fire as an integral part of land management in order to restore or maintain historic vegetation patterns and fire regimes. This represented a paradigm shift, which, together with improvements in the technology to conduct and control prescribed burning, resulted in an increase in its use particularly in silvicultural practice to reduce wildfire risk and to manage forest estates. Its use has also increased as a means of reducing wildfire risk to urban environments. Prescribed burns conducted to reduce wildfire risks are often referred to as “hazard reduction” or “fuel reduction” burns. They are of low intensity so they may be contained; yet they are hot enough to consume the vegetative material that might otherwise become fuel during a wildfire. Hazard reduction burns need to be conducted every few years, depending on the vegetation, to keep fuel levels low.

The advent of frequent hazard reduction burning, particularly to protect urban environments at the wildland-urban interface, has led to concerns that some species that coevolved with indigenous or natural fire regimes will not survive altered fire regimes. As a result, research is now being undertaken to establish fire regimes that support both wildfire hazard reduction and biodiversity conservation, but some regard these objectives as incompatible. Prescribed burning undertaken specifically to achieve conservation objectives, such as preserving threatened ecosystems or particular species, may be referred to as “ecological burning.”

Other concerns about prescribed burning include: the potential for increased soil erosion; the risks of fires escaping containment lines; smoke pollution; and the costs of providing adequate resources to conduct and control burns. More recently attention has also focused on the implications of burning for the carbon cycle and climate change issues. These and other problems drive continuing research into the use of prescribed burning and the parameters associated with fire prescriptions. Prescribed burning remains a contentious and complex issue. Debate is characterized by uncertainty over both the effectiveness of hazard reduction burning and the ecological consequences of prescribed burning.

Preservation

PRESERVATION, OR PROTECTION of ecosystems and biodiversity from injury or harm, is a form of resource management advocating the separation of humans from nature. Since the 19th century, there has been a schism in the American environmental movement over the best way to manage natural resources, with preservationists on one side and conservationists on the other. Preservationists believe that nature should be protected from the simplifying effects of human management. Conservationists believe that natural resources should be adequately used and managed by society in a utilitarian manner to achieve the highest possible benefit for the greatest number of people. The preservationist perspective believes that ecosystems and biodiversity can only be saved through nonuse, or full protection. Preservationists criticize the material aspects of the conservationist approach, arguing that they have compromised conservation values in the name of economic development.

Preservation-oriented policies raise an important corollary issue: what types of ecosystems and species warrant preservation? Most often, the answer is large wilderness areas that can support large carnivores, which are often seen as keystone species indicating overall ecosystem health. The association of wilderness with preservation adds another layer of complexity to the debate surrounding preservation; wilderness has become a highly contested concept as both social and natural scientists have demonstrated that there are no areas in the world that can be called "pristine," or free from the influence of humans. Areas once considered to be "pristine wilderness areas" are often the product of many generations of human management.

The environmental historians Roderick Nash and William Cronon have drawn attention to the need to understand the cultural and historical rationale for preserving certain landscape elements. They demonstrate that associations with the concept of wilderness have not always been positive. In early American and European history there was a strong negative association with wilderness, which drove the desire to conquer or destroy wilderness rather than preserve it. Up until the late 18th century, the most common usage of *wilderness* referred to landscapes perceived as "barren," "desolate," "savage," and "deserted." Nash draws our attention to William Bradford's first impression as he stepped off the *Mayflower* into what he saw as a "hideous and desolate wilderness." Early American pioneers struggling to make a living on the frontier saw little in wilderness worth protecting; instead, wilderness was an obstacle to survival. Wilderness was considered a chaotic and immoral wasteland and the westward progress of pioneers found satisfaction in its destruction.

By the 19th century, however, there was a growing appreciation of wilderness areas in the United States. Yellowstone National Park, established in 1872, was the world's first instance of large-scale wilderness preservation. The emergent national interest in the preservation of landscapes was supported by a variety of different arguments. The Romantic Era, as the period has come to be known, is characterized by the writings of philosopher Henry David Thoreau, who sought inspiration in the solitude of nature. Thoreau felt that the American character benefited from living in the wilderness, a belief that later inspired President Theodore Roosevelt to establish federal protection for almost 230 million acres. Numerous artists, such as Thomas Cole and Albert Bierstaadt, and writers such as James Fenimore Cooper, found their main source of inspiration in wilderness. Transcendentalists such as John Muir, the founder of the Sierra Club, saw connections between religion and nature and sought evidence of the power and goodness of God in nature. Others saw the American wilderness as an important component of the American identity, distinguishing it from Europe. In the words of Michael Nelson, an environmental ethicist, "The United States is a place where the eagle flies, the buffalo roam, and the deer and the antelope play." When making comparisons to Europe, America's natural environment was one of the few areas in which the young nation could claim superiority.

The proposed construction of the Hetch Hetchy Dam, which would provide water and electricity to the arid San Francisco region by damming portions of Yosemite Valley, became a landmark case representing the division between conservationists and preservationists. In 1907 Roosevelt supported the planned Hetch Hetchy Dam under the utilitarian argument that the dam was essential to the material development of the state and would result in the highest possible use of water resources for the growing San Francisco population. John Muir and other preservationists, refusing to accept this decision without a fight, launched an aggressive campaign, arguing that Yosemite National Park—including the valley that would be flooded by the dam—was an important "public playground." The campaign proved temporarily successful and Roosevelt retreated from his endorsement of the reservoir, although it was later approved under Woodrow Wilson's administration in 1913.

By the 1930s other preservationists adopted a more radical view, known as deep ecology, developed by the Norwegian philosopher Arne Naess. In contrast to utilitarian argument, deep ecologists adopt an ethical argument to support preservation of biodiversity: all nature has an intrinsic worth, apart from its benefits to humankind. This view affects the preservationist-conservationist debate by shifting the perspective from anthropocentrism—the belief that man is the center of the universe—to biocentrism, in which mankind has a place equal to all other elements of the natural world.

BIODIVERSITY

Regardless of the philosophical underpinnings that motivate the preservationist approach to separating man from nature, preservation it is not always successful in its primary goal, protecting biodiversity. The growing evidence that humans have had a role in producing supposed "wilderness" areas raises the important question: What happens to the wilderness landscapes when people are removed? An understanding of the role that Native Americans had in shaping the ecosystem that now comprises much of Yosemite Valley in California provides a clue to this question. Ethnoecologist Kat Anderson and anthropologist Michael Moratta have demonstrated that for Native Americans in the Sierra Nevada region, "fire was the most important management tool employed to clear brush, maintain grasslands and meadows, improve browse for deer, enhance production of basketry and cordage material, [and] modify the understory species composition in the forest." Given this knowledge, it is not surprising that the preservation policies in place at Yosemite National Park have resulted in a decline in biodiversity; forest succession, historically kept in check by Native Americans, has begun to overtake the meadowlands. The landscape in Yosemite Valley that American explorers sought to preserve was in part shaped by the management techniques of the Native American residents they expelled.

POPULATION DISPLACEMENT

It is not only the role of people in shaping the landscape that is overlooked by preservationist policies, but also the human and environmental rights of people who are displaced in the name of preservation of natural resources. A critical part of the history of both Yellowstone and Yosemite National Parks, often overshadowed by the magnificence of the landscape, is the fact that the eviction of Native Americans was a prerequisite to establishing the park.

Author Rebecca Solnit points to the fact that the naming of the principal landmarks in Yosemite was the result of the Indian War of 1851, in which Lafayette Bunnell and a battalion of about 200 men captured the Native American inhabitants and marched them to a reservation in the flatlands of San Joaquin Valley. For Solnit, this process of naming the landscape after the very people who were forcibly evicted is a bizarre mixture of romanticizing Native Americans while simultaneously annihilating their culture and settlements from the region. Just as the wilderness areas of United States could only be romanticized once they were "conquered," the "savage" civilizations of the Native Americans could only be romanticized once they were extirpated.

For over a century, Yellowstone National Park became the model by which parks were established around the world. The American ideal of linking landscape, nature, and a national identity was replicated in nearly every country. The global movement to preserve landscapes and biodiversity was largely led by a group of wealthy, elite Europeans and Americans who saw themselves as gentlemen hunters-naturalists. Roderick Neumann, in his exploration of the political purpose that national parks played in colonial Africa, shows that Kruger National Park, established in 1926 in the Southern African Republic, played a significant role in formation of collective (white) national identity. He also persuasively shows that the very idea of wilderness protection in Arusha National Park in Tanzania was a European colonial construct, enforced at the expense of local livelihoods, that simultaneously strengthened the political power of the colonial administration. The preservationist model of conservation, as it is applied in much of Africa, not only evicts local people from their homelands, but also impoverishes them as the local elite invariably claim the profits from the tourism and safari hunting industries. Given this, it is not surprising that local residents resent protected areas and work to undermine the goals of preservation by continuing their reliance on protected areas for their livelihoods.

In other parts of the world, the separation of man from nature in the name of preservation has failed to garner the support it has in America. Ramachandra Guha has gone as far as to call the most extreme elements of the American wilderness preservation model a "frankly imperialist manifesto." Guha and other scholars such as Vandana Shiva and Juan Martinez-Alier argue that wilderness and people should be allowed to coexist in a coherent whole; the separation of man from nature is an artificial dichotomy. They question who gave the conservation movement the moral authority to determine which areas need protection and which people need to be relocated to achieve protection.

ENVIRONMENTAL JUSTICE

In the 1980s wilderness preservation policies received a new critique from within the United States from the environmental justice movement. Environmental justice advocates seek to broaden the environmentalists' perspective to include urban, work, and home environments, and the mitigation of hazardous resources. The goal of this group is to make environmental concerns more meaningful to a wider range of people living in varied environments, not just those who can visit remote national parks for pleasure. By drawing attention to the fact that many urban poor may never visit a national park, the American environmental justice movement emphasizes that the benefits of the traditional conservation agenda are not shared equally. This movement is creating a potential bridge to people in the developing world who feel that they have been unfairly burdened by the creation of protected areas.

ALTERNATIVE MODELS

While the preservationist model of conservation has undoubtedly protected valuable and unique ecosystems and species in the United States, many conservation advocates recognize the poor fit between the American preservationist model and conservation goals of other countries. Consequently, many alternative models of conservation have been developed. These include extractive reserves, joint forest management, community-based conservation management, and integrated conservation and development projects. All of these alternatives promote benefit sharing in an effort to compensate local people for the resources they have given up by distributing income, employment, and other benefits from tourism. There is a growing awareness that conservation does not happen in a social vacuum, and that the preservationist's model of conservation has a limited ability to protect biodiversity. Social and natural scientists are increasingly working together to rethink the traditional preservationist, or "Yellowstone model" of conservation with alternatives that capture a more holistic understanding of mankind's place in nature.

Primates

PRIMATES ARE A group of animals that include human beings. All primates are mammals. There are about 180 species that are members of the primate class. Besides humans, primates include great apes or gorillas, chimpanzees, bonobos, orangutans, gibbons, lemurs, aye-ayes, and macaques. Primates are classified into two main groups. The Anthropoid family includes human beings, apes, and monkeys. The other primates are in the Prosimian family. It includes aye-ayes, galagos, lemurs, lorises, pottos, and tarsiers. There are other species that have been included as prosimians, such as tree shrews, but not all scientists accept this classification.

Primates' similarities to humans have made them a frequent subject for the study of human diseases. The rhesus monkeys (*Macaca mulatta*), of which there are three subspecies, were used in experiments in the 1930s and 1940s. The rhesus antigens in the blood of rhesus monkeys enabled researchers to identify blood groups in humans.

Beginning in 1948, monkeys were sent in rockets into space to study the physiological effects of weightlessness. Rhesus monkeys and chimpanzees were used in a number of space experiments. For example, in 1959 a rhesus monkey named Able was sent on a Jupiter Rocket on a bioflight. He was trained to tap a switch when a red light flashed, to collect data on performance. In 1961 a chimpanzee, Ham, was closely monitored for cardiovascular responses during a Mercury flight. In 1985 small primates were also studied for the effects of space travel during a 13-day voyage aboard the space shuttle Discovery.

Since most primates live in social groups, researchers have investigated their behavior, communications techniques, and organizational patterns. Insights gathered about their behavior have contributed to understanding human behavior. Researchers have found that some primates use tools, and, in the case of chimpanzees, wage war. Jane Goodall studied chimpanzees for many years in the Gombe Stream Game Reserve in Tanganyika (now Tanzania). She observed that chimpanzees are not strict vegetarians. They eat meat for a period and then return to a vegetarian diet for other periods. In order to get meat they will sometimes engage in chimpanzee cannibalism. Dian Fossey, (1932–85), an American ethnologist, studied the highland gorillas for some years, but was killed protecting these great primates.

In contrast, some prosimians live as individuals rather than in groups. Bonobos (*Pan paniscus*), such as Kanzi, at the Language Research Center in Atlanta, Georgia, have been able to communicate with humans to a limited degree using a keyboard and symbols. The study contributed to the educational theory that children who are taught to sign can communicate before they can speak.

Fully half of all primate species are threatened with extinction. The main threats come from humans: The destruction of forest habitat and the hunting of primates as pests, as stock for zoos, for pets, and for meat have reduced the numbers of most primates. The hunting of primates for food—the bush meat trade—is a serious threat. Gorillas, chimpanzees, and bonobos in central Africa are especially vulnerable to commercial hunters, who may engage in the illegal or unregulated slaughter of many wild animals. The price of great ape meat is high because many Africans believe that they draw strength from the meat. The hunting of apes kills more than the total amount currently held in zoos.

Primatology

PRIMATOLOGY IS THE study of primates: Placental mammals of the order Primates best known as apes. Humans are also considered primates but are usually not studied as part of primatology. The discipline is fragmented insofar as primatologists may be found working within a number of different fields and disciplines (e.g., anthropology and zoology) and with a variety of methodologies. It is controversial, since extrapolating lessons about human behavior and communities from other primates is often considered problematic, and because much of the history of primatology has been marked by theories heavily influenced by their social and political contexts.

Primates include two main families, which are the Prosimians and the Anthropoids. The Prosimians include the tarsiers, lorises, and lemurs and are jointly commonly referred to as the lower primates. The Anthropoids are the higher primates and include humans, monkeys, and apes, including chimpanzees, orangutans, and gorillas. The intensely complex forms of behavior and social systems established by the higher primates make them fascinating creatures for study, and they help in understanding many of the bases of human society. Primatology studies the anthropology, biology, psychology, and evolutionary history of primates. Commonality between primate and human forms of behavior has been revealed by this method. The higher primates, in particular, demonstrate forms of behavior such as adultery, diplomacy, apology, and deception that had previously been considered to be uniquely human and to have moral implications.

Studies of chimpanzees have shown the degree to which language is used by primates; this has helped indicate the ways in which thinking has developed within animals. The structure of chimpanzee societies, for example, depends upon the number of animals involved within the group. Chimpanzees

The Sangeh Monkeys

The Sangeh Monkey Forest on the Indonesian Island of Bali is home to a large population of monkeys who are the self-appointed guardians of the Hindu temple of Pura Bukit Sari.

According to local legend, during the Ramayana, when Rama was attacking Ravana, the demon god, the former was helped by Hanuman, king of the monkeys. Hanuman, along with thousands of monkeys, tried to crush Ravana by squeezing him between the two halves of Mount Meru. In that encounter a part of the mountain, along with a large number of monkeys, was flung toward the island of Bali. It crashed into the forest, with many of the monkeys surviving and establishing a large colony. A temple, nestled within a grove of sacred nutmeg trees, was built at Sangeh during the 17th century.

Today the resident monkeys are regarded as sacred and are a major tourist attraction, despite their ferocity. Locals carry sticks to beat them off, as they jump on people, snatch food, and like to steal cameras and jewelry. While they once survived off offerings left at the temple by devotees, they now do much better with the thousands of tourists who visit each month bearing peanuts and other food.

can recognize other members of the group and will have social relations with them. However, should the group—the "monkeysphere"—become too big, it takes too long and too much effort to identify and contextualize all the other members and the society becomes inefficient. In such a case, the group will divide into two smaller groups that represent more efficient societies.

Additional research has focused on the ways in which chimpanzees and human babies learn and develop, and this has indicated considerable levels of similarity in these processes. However, the controversial nature of some findings has inspired criticism of primatology. Some previous examples of research may no longer be considered valid because of the atypical conditions in which the primates were kept and treated.

It is possible to distinguish between Western and Japanese schools of primatology. The former tends toward an objective, quantitative, and scientific approach to the subject, while the latter, as represented most notably by Kinji Imanishi, has more of a subjective and interpretive approach. Japanese primatologists approach their subjects as creatures with whom to establish a relationship that is a form of partnership and that leads to greater levels of mutual understanding. The Western primatologist is more likely to attempt to maintain independence from the creatures and to try to describe and analyze it in isolation from the human relationship.

Prior Appropriation

PRIOR APPROPRIATION IS a legal doctrine for assigning water rights based upon the rule "first in time, first in right." It was first developed in Colorado and is known as the Colorado Doctrine, or officially as the Prior Appropriation System. The doctrine is a system of water allocation for controlling who uses how much water, the kinds of uses allowed, and when the waters may be used. The doctrine of prior appropriation is quite different from the law on riparian water rights originally developed in England and imported into the American colonies. The law on riparian water rights has historically been easy to apply in the water-abundant eastern United States where contention over a plentiful resource has, until fairly recently, been uncommon. However, in the water-scarce west, water wars have occurred that were both physical and legal.

The water referred to under the doctrine of prior appropriation is surface water, that is, water that naturally occurs in the open atmosphere. Surface water includes rivers, streams, lakes, reservoirs, ponds, impoundments, seas, and estuaries. The term *surface water* also includes all springs, wells, and other collectors. Water coming from surface runoff includes precipitation, snowmelt, and even water from irrigation that is in excess of the amount that can percolate into the soil, and is as a consequence held in a small depression.

Claimants to water under the doctrine of prior appropriation include senior appropriators and junior appropriators. Senior appropriators are the owners of water rights that were acquired prior to other right holders on the same stream. Junior appropriators are claimants who acquired water rights after the rights of others on the same stream. Riparian access, which is ownership of land adjacent to a stream, does not give a right to its water. Rather, the historical appropriation of water for a beneficial purpose is what creates prior appropriation.

Water in the doctrine of prior appropriation rejects the idea that anyone may own the water in a stream. Rather, the water must be used for a beneficial purpose such as irrigation or watering livestock. Beneficial use is applied broadly in the doctrine of prior appropriation. It includes using water for homes, cities, agriculture, industry, stock watering, recreation, wildlife, power generation, and mining. Recent expansions of the meaning of *beneficial* have included dust-settling control and snow making. Historically, courts in western states have rejected very few uses of water as unbeneficial. One use not accepted as beneficial has been holding water for ecological uses. The fact that wildlife or a natural body of water needs water retained has not impressed the courts. However, a few courts have begun in recent years to rethink the meaning of *beneficial* and to apply it to ecological needs.

Under the doctrine of prior application, each water right has an annual quantity and drawing date assigned to it. Every year, the senior appropriators may draw out of the water source their full allotment of water. Since water is scarce, it is usually assumed that the water is available for allocation. Then, the next water right, which is the next earliest, may use the full application. In times of drought, the full application may not be used because the water is simply unavailable. In dry years, junior applicants may receive no water at all, although the senior applicant gets the full amount. Water rights may be sold. If they are sold, then the prior appropriation date travels with the sale. Also, only the amount of water historically used can be transferred with the sale. The application of prior appropriation to water used across state lines or across international boundaries often falls under federal jurisdiction.

Water rights under the doctrine of prior appropriation may also be mortgaged or encumbered as if they were rights to real property. In addition, the water does not have to be used on the land on which it originates nor on the land upon which the right is based. If a water right is not used for some beneficial purpose for a period of time, it may be forfeited under the doctrine of abandonment. The lapsing of water rights is rare. The details of the doctrine of prior appropriation vary from state to state. California uses a combination of both prior appropriation and the older common law riparian water rights. The doctrine is important in regions like much of the western United States, where water is a scarce resource. However, as the competition for water in states east of the Mississippi River has increased, the doctrine is beginning to influence water polices.

Prisoner's Dilemma (PD)

THE PRISONER'S DILEMMA (PD) is a concept from game theory that posits a tension between the benefits of cooperation versus noncooperation. In its narrative form, it proposes that two prisoners, both suspects of a crime, are held by the police in separate rooms for interrogation and pressed for either a confession or an accusation against the other prisoner. If both mutually accuse one another, both will serve a moderate sentence. If one accuses the other, who remains silent, the accused serves a lengthy sentence and the accuser goes free. If both remain silent, both serve minimal sentences. Clearly for both players, the best outcome is to remain silent. The temptation to accuse the other prisoner, however, and so gain the best individual outcome, tends to lead to a choice to mutually accuse one another, thus leading to a worst outcome for both.

This perplexing puzzle has long been applied to a great number of real-life problems, including scenarios involving the use of nuclear weapons between two countries. During the early 1980s theorists such as Robert Axelrod began to apply the PD toward understanding the Tragedy of the Commons and the evolution of cooperation. While the Tragedy of the Commons provides a useful model for explaining why overexploitation of community-held resources might occur, it does not shed light on how communities might profitably control the use of the commons, which they have historically done.

The PD is a formal mathematical game model that represents results of an interaction with different payoffs and therefore takes into account the rewards and punishment for different actions. The two-person version of the game is as follows:

1. If both players cooperate, they both receive the same reward payoff (R);
2. If both players defect, they both receive the same punishment payoff (P);
3. If one player defects and the other cooperates, the cooperator gets the sucker's payoff (S) and the defector gets the temptation to defect payoff (T);
4. The temptation to defect must be larger than the reward for mutual cooperation, which must be larger than the punishment for mutual defection, which in turn must be larger than the sucker's payoff (T>R>P>S);
5. The reward for mutual cooperation must be larger than the sucker's payoff plus the temptation to defect payoff divided by two (R>(S+T)/2), so that the benefit to both over several turns is larger than if they would have mutually cooperated.

The best strategy for both players collectively is to cooperate with each other. The individual's best strategy is the temptation to defect for the higher payoff (see Figure 1). Therefore, a dilemma is created with an individual having to make a choice between defection (cheating), which is the best individual strategy (e.g., in Figure 1, the individual would gain 5 points), and cooperation, which yields the higher combined reward for both players (e.g., in Figure 1, the scores would total 6 points).

		Player B	
		Cooperate	Defect
Player A	Cooperate	R = 3	S = 0
	Defect	T = 5	P = 1

Figure 1: Prisoner's Dilemma Payoff Matrix

However, the simplicity of this game becomes more complex as varieties of the game add "real world" rules to the game. In response to this, Axelrod applied the PD toward the explanation of cooperation within groups, which has influenced anthropological research of the Tragedy of the Commons. For example, Axelrod used the following rules in his analysis of iterated (repeated) PD games:

1. Players cannot enforce other players' strategies or commit themselves to a particular strategy;
2. The only history of past actions known to each player is their own history with the specific player, not actions with other players;
3. A player cannot refuse to play or prevent another player from an interaction;
4. A player cannot change the payoffs of another player.

Using these rules, Axelrod tested which strategy would succeed in playing this game by soliciting strategies from game theorists, scientists, and interested individuals. After each turn of the game, the ones with a higher total score would advance and the ones with the lower total would fall back. He found that tit-for-tat (TFT, or cooperating on the first interaction and then doing whatever the other player did on the previous move) resulted in the highest overall score in the tournament. Following Axelrod, other studies using different payoff matrices have found that TFT was not the best overall strategy, but contrite TFT (same as TFT, but if the other player defects, this strategy only defects once before cooperating again) is more stable. In other studies, another strategy was more successful than TFT, namely Pavlov, which continues the previous strategy if the player wins (rewarding cooperation), changing strategy upon losing (punishing defection).

Pristine Myth

THE PRISTINE MYTH may have begun with Christopher Columbus upon his return to Spain after his first voyage. The lifestyle of the natives in the Caribbean region had made it seem like the original paradise to him. As reports of the discoveries in what was eventually seen as the New World filtered across Europe, there arose the idea that the New World was pristine, unlike the Europe that was close at hand. It became a favorite device of social criticism to hold aloft the pristine or innocent natives there as a mirror exposing the faults of Europeans. This same method of social criticism has been practiced in America and elsewhere in the New World.

The reality is that while undeveloped by European standards, the New World as known to Columbus or as later described by Charles Darwin and others was not pristine. It had been modified to a degree by the Native Americans. When the first people came to the Americas, probably 30,000 or more years ago, the continents were indeed pristine. However, by the end of the last Ice Age many species had disappeared. The megafauna of mastodons, saber-toothed tigers, camels, horses, the dire wolf, and other animals vanished. It is now suspected that either hunting or changes in the environment wrought by fires or other means killed off these animals. There is probably no way to know what species of plants may have been lost.

As a consequence, while it is tempting to see the great forests of North America as pristine when the first colonists arrived at Jamestown, or in Canada, the reality is that the Native Americans had already made significant changes to the environment. What these changes were may never be fully known. For decades it has been taught in American schools that when the colonists arrived they found an untouched wilderness; it was a Garden of Eden that was soon spoiled by the settlers. Teaching this way "mirrors" bad practices from good environmental practices.

There is now a growing body of evidence that suggests that the modifications made in the Western Hemisphere in the pre-Columbian era were significant. Some have conjectured that the Amazon rain forest is an artifact of human effort. Increasing numbers of archeologists, anthropologists, geographers, and others are now viewing the Native Americans as less than ecologically pure hunters and farmers.

The pristine myth is important to many environmental groups because their agenda is to restore wilderness areas to an original pristine condition. It allows them to argue that the environment began pristine, was spoiled, and should now be restored.

Private Property

PROPERTY RIGHTS DETERMINE who is entitled to use and dispose of resources, both natural and man-made. Private property is a form of property ownership in which an individual, company, or corporation enjoys the associated rights. It thus differs from common property (where a group of people enjoys those rights jointly), state property (where the sovereign ruler or nation is the presumed owner, with the state managing the property), and open access (in which case no property rights have been established).

The nature of private property varies depending on which rights have been conferred upon resource owners by social institutions such as the state or

While logging may be profitable within the lifetime of a private landowner, replanting that forest would not pay off.

commonly recognized customs. The "bundle of rights" included consists of varying combinations of the rights to use, sell, rent, lease, destroy, give away, and pass on the property as an inheritance, and to exclude others from its enjoyment. These rights may or may not involve reciprocal obligations or duties on the part of the property owner (for example, ownership of water may be contingent on its "beneficial use").

The *de jure* property rights may not always be recognized by others, and thus there is usually a cost associated with the defense of property rights. These costs are especially high if the difficulties of excluding others from the enjoyment of that property are great or if there is little social acceptance of this particular kind of property. For example, intellectual property rights in seed varieties and their propagation can be difficult to defend while enjoying little popular acceptance; the development of hybrid varieties that do not breed true and of "terminator" genes that prevent the reproduction of seeds are attempts to make private property rights more easily defendable.

Some resources, such as air to breathe, are generally regarded as nonexcludable: others could not possibly be prevented from using them. Other resources may be nonexcludable for social or technological rather than physical reasons; for example, where communal grazing rights are the norm, an individual's claim to private property rights to grazing land would not be respected. A resource may also be nonexcludable for reasons of cost, for example, if the costs of fencing land exceed its benefits to the property holder. Hence, private property rights can only emerge where excludability is possible in practice as well as theory.

PERCEIVED BENEFITS

The question of whether private property is desirable is a different matter. From a mainstream economic point of view, private property should be established whenever possible, in order to maximize economic efficiency. The basic argument is that most production involves an investment by the producer to obtain resources and manage them so that they will remain productive in future. If the owner of a resource does not capture all the benefits of that investment, he or she is likely to invest less than is optimal for sustained, maximum production. Hence, for example, a farmer should own his or her land in order to ensure that he or she will invest in protecting soil fertility, building irrigation infrastructure, buying machinery, and so on for the long term. Only long-term security of tenure is thought to encourage this kind of ecologically as well as economically sustainable farming.

On the basis of similar arguments, private property rights have been introduced as a way of minimizing the costs of achieving air pollution standards. In this case, a government authority decides the overall amount of pollution that will be allowed within an area, and then provides tradable pollution permits to polluting industries located there. Tradability of the permits ensures that companies that can cheaply reduce their emissions will sell their permits in order to cut costs; while those companies that cannot easily reduce their emissions will buy permits. This ensures that environmental targets are achieved at minimum cost.

It must be remembered, however, that the government still has to set overall pollution limits and enforce compliance. Thus, although pollution permits are treated as a kind of private property, the protection of air quality remains a function of the state, that is, a form of state property.

DRAWBACKS

The promised benefits of private property rights are not always assured, however. For example, private property in land allows the owner to rent out that land. If tenants are forced to pay excessive rents and can be evicted arbitrarily, they are left without the resources or the incentives to make long-term investments. Meanwhile, the landowners may be more interested in extracting high rent payments from the tenants than in the long-term development potential of the land. In such cases, there will be very little investment in long-term productivity of the land. This problem may be remedied at least partially by land reform that assigns "land to the tiller," and that also provides farmers with the resources they need in order to successfully make a living on the land (as has been done, for example, in South Korea, Taiwan, and the Indian state of Kerala).

Even if tenancy relations create no perverse incentives, land uses that are profitable within the lifetime of an owner may be unsustainable over longer time periods. For example, the intensive use of agrochemicals on highly nutrient-demanding cash crops for export may promise to be profitable in the owner's lifetime but lead to longer-term land degradation as well as off-site ecological impacts (called externalities by economists). The exploitation of minerals may cause extensive ecological impacts both on and off site but still be profitable to the owner. Logging of timber may be highly remunerative to a landowner, but replanting the forest in order to reestablish trees that take many decades to reach maturity will not pay off within the present owner's lifetime. The option to sell the land may exacerbate a short-term orientation. For example, logging companies in Southeast Asia, where tropical rain forests are being cut down at a very rapid rate, often sell deforested land to companies interested in establishing oil palm plantations. Although oil palm plantations may be sustainable in the sense of being able to persist a long time, such land use change does lead to the loss of natural forest cover and associated biodiversity. Some of these issues can at least theoretically be addressed by creating property rights in the resources affected by externalities, for example, by establishing property rights in clean water. However, ecological impacts that are expected to occur only in the future cannot be mitigated in this way; instead, government regulations may be necessary.

Many critics of private property rights also point out problems of inequity. Following Pierre-Joseph Proudhon's tenet that "all property is theft," they have pointed out the injustices in the original creation of private property, integral to the process that Karl Marx called "primitive accumulation." Examples include the expropriation of colonized peoples around the world, enclosures of common property in England and elsewhere, and the privatization of state assets in post-Soviet Russia and eastern Europe. Injustices may persist for an indefinite period of time after the original property rights have been established. For example, the Portuguese colonial practice of assigning huge landholdings to a few individuals in order to lay claim to large territories in Brazil laid the foundations for the present situation in which impoverished people suffer from land scarcity even while population density is low and many landowners do not utilize all of their land. Brazil's Landless Workers Movement (MST) denies the legitimacy of private property that is unused while others have no land at all and occupies unused land in order to force the government to carry out constitutional provisions that call for the redistribution of such land. Extreme inequity in land ownership as found in Brazil may lead to serious ecological impacts in which wealthy landowners use resources wastefully, while marginalized people are forced to eke out a living on unproductive land in unsustainable ways or to migrate into urban shantytowns that lack basic sewage, water supply, and garbage collection facilities.

Environmental protection may also require that some resources be removed from the market altogether, or be made into state property of some kind. For example, the preservation of extensive ecosystems may require the creation of a national park owned by the state. If that land was owned by many separate private landholders, a few might wish to preserve natural habitat, but these areas would usually be small and fragmentary and therefore insufficient for species preservation. In some cases, it may be possible for the state or a private foundation (e.g., a land conservancy) to buy easements, whereby private landowners forfeit some of their land-use rights (for example, to drain wetlands). If such rights are taken away by legislative action ("takings"), many private property advocates resist because they see this as an abridgement of their property rights (e.g., the Wise Use Movement in the United States). Without the abridgement of private property in some form, however, it is unlikely that many areas of high biodiversity and landscape value will be preserved.

INTELLECTUAL PROPERTY

Intellectual property rights, and especially patents, are a particularly controversial form of private property. Patents violate free-market doctrine in that they provide temporary monopolies in the supply of goods involving innovative technologies. These monopolies can be made quasi-permanent by continual minor innovations that serve primarily to extend the period of patent protection rather than to improve the marketed commodity.

The rationale for providing temporary monopolies (not a necessary feature of private property) is to provide an incentive for companies to engage in costly research. However, patents are based on the assumption that an individual or company is solely responsible for the innovation. In fact, often many people were involved in order to create an innovative product, though it can be very difficult to identify each person's contribution. For example, when drug companies utilize the knowledge of indigenous people about medicinal herbs, the common knowledge of a large group of people going back many generations is appropriated, usually with very little compensation. These people may even be prevented from marketing products that they have produced for many years (e.g., the company W.R. Grace attempted to prevent Indian manufacturers of products from the neem tree from selling their products on the Indian market).

Some activists demand methods of repaying communities (and not just individuals) in such cases; more radical proposals call for the reversal of laws passed in the 1980s that first allowed the patenting of life forms. Environmental concerns associated with patenting of genetically engineered organisms relate to the potential dangers of introducing completely new organisms into ecosystems with unpredictable effects, and encouraging more pesticide-intensive forms of agriculture (e.g., via crops resistant to pesticides).

Ultimately, no single form of property can successfully address all possible social, economic, and environmental conditions. Which form of property is favored in any particular instance also depends on how much value people place on total production or efficiency, on social equity, and on environmental protection. All existing societies exhibit a diversity of property regimes; the challenge is to devise effective solutions that satisfy diverse interest groups and provide for ecological sustainability as well.

Privatization

PRIVATIZATION IS THE conversion of state or common property, or of an open-access resource, into private property. The privatization of a common property resource is also often referred to as *enclosure*. Privatization is justified on economic efficiency grounds, with claims that it ensures that owners or investors devote their full attention to enhancing the productivity of the privatized resources because they reap the full returns of their efforts. In addition, it is claimed that private property ensures that the costs of any environmental damage must be borne by the property owner, thus ensuring that such damage is minimized. Critics of privatization, however, insist that it usually serves only to enrich a small elite by handing them a resource formerly owned by all the people in common, without leading to any environmental benefits.

It is impossible to make accurate generalizations about the environmental impacts of all forms of privatization, because private property is suited for some but not all purposes, and, like all forms of property, depends on supporting institutions (e.g., relevant laws and their enforcement). Furthermore, property cannot so easily be classified as "public" or "private," because many kinds of property involve overlapping rights or entitlements—the "bundle of rights" that constitutes property may be unbundled during privatization, with only some of those rights being transferred to private property holders. The result is then some form of "recombinant," or "fuzzy," property in the words of David Stark and of Katherine Verdery (both of whom study eastern European privatizations). Detailed study is needed on such privatizations in order to understand the environmental outcomes. In addition, even if privatization is an appropriate goal, actual outcomes depend on whether it is handled in a transparent manner untainted by corruption. Finally, particularly in the post-Communist context, many social and economic changes occurred at once (including democratization, economic collapse, and in some cases recovery) that can make it difficult to determine which environmental changes are due to privatization rather than other causes.

In some instances, the new property regime is clearly not appropriate for environmental preservation, social equity, or even the creation of a free market. This consideration applies most often to "natural monopolies," such as the provision of water and sewerage services, the construction and maintenance of railway lines (though not necessarily the services of rail transport on the rail network), roads, and electric power grids (though not the production of electric power). In such cases, market competition is either greatly constrained or absent, and poorly conceived privatization efforts can easily lead to negative results. For example, privatization of British rail services was followed by some highly publicized accidents, high prices, and inconvenient connections and ticketing arrangements between lines operated by different companies. Such problems push consumers to prefer car or bus transport over more environmentally friendly trains. To correct these problems, renewed state involvement in the rail system was found to be necessary.

Networks constructed on the basis of private initiative tend to focus only on the most profitable places (sometimes called "cherry-picking"); if the goal is universal provision, this may be insufficient. For example, in 19th-century Britain, private piped water supplies only brought potable water to about 10 percent of the urban population, which not only meant poor living conditions for the other 90 percent, but also greater risk of disease outbreaks (e.g., cholera). In response, piped water supplies were made a municipal responsibility, later centralized in 10 regional water authorities. However, in the late 1980s, continuing concerns about river water quality and the reluctance of the national government under Margaret Thatcher to make necessary investments in water treatment led to a policy of privatization. Since it was recognized that regional monopolies would likely engage in monopolistic practices, price caps were imposed on water charges, while environmental regulations were strongly enforced. The result was improved water quality in rivers, lakes, and beaches, but underinvestment in some aspects of water provision (e.g., in preventing leakage of water) and high returns for shareholders. These were so high, and the water charges increased so much, that the public protested and the subsequent Labour government tightened price controls. This public reregulation has been so extensive that the private water companies actually resemble public services, and some of them have even applied to change their status to nonprofit ventures owned by some or all of their customers.

Privatization of water supplies has also occurred elsewhere in the world, often with far more problematic results. In the Bolivian city of Cochabamba, a privatization program in 2000 turned over the system to a subsidiary of the Bechtel corporation. In contrast to the British case, where the water itself was still regarded as public property, this privatization even extended to rainwater as soon as it fell on the ground within city limits, turning people who collected rainwater in their own cisterns into thieves. A high rate of return was guaranteed to the water company, in part by tying water rates to the value of the U.S. dollar. A massive protest movement declared that the vital resource of water was everybody's property, and forced the reversal of water privatization within half a year. The renewed municipal water company was reformed to ensure direct accountability to customer representatives. More successful water privatization schemes do exist (for example, in La Paz, Bolivia), but include much more stringent regulation of private water companies.

In other cases, privatization is much more likely to lead to environmentally favorable outcomes because a private property regime is in principle well adapted to the resource use in question. This includes the privatization of state-owned or communal agricultural farms in China after 1978, and in eastern Europe and the former Soviet Union after 1989. Privatization in these cases offered the opportunity to reverse some of the environmental damage created by decision making and price setting by distant bureaucrats with little appreciation of local environmental or social conditions (e.g., as analyzed by James Scott). The actual outcomes varied tremendously, however, depending on how the process of privatization was handled. For example, in a study of three villages in China's Henan province, Muldavin found that two villages created corporate institutions to take over indivisible communal facilities (for example, small enterprises processing agricultural commodities), with each member holding a share.

The land, however, was distributed among individual property holders. One of these villages achieved positive environmental outcomes by pursuing a diversified "ecological" agriculture with strong investment in irrigation and biogas facilities, though fertilizer use was perhaps excessively high. The other "corporate" village pursued a high-input agriculture plus industrialization, thus increasing environmental impacts. A third village was completely decollectivized, meaning that indivisible agroindustrial assets were appropriated by a few individuals. Irrigation facilities declined, many farmers ended up with excessively small holdings and overexploited their soils, while others applied excessive amounts of fertilizers to compensate for the lack of irrigation. This study demonstrates how important the process of privatization is in determining outcomes, and that it is essential to build up new institutions to make the new property regime viable.

In the former Soviet Union and eastern Europe, outcomes of privatization of agricultural land have also been very diverse. Where land holdings after privatization were small and fragmented, access to markets was poor after the centralized marketing facilities were dismantled, or the elimination of price controls led to drastically increased prices for agricultural inputs, farmers reverted to more subsistence-oriented production methods, involving small-scale diversified family farms minimizing the use of agricultural chemicals (e.g., in large parts of Bulgaria, Romania, and Poland). On the other hand, where access to markets was good, and where state or collective farms remained as large undivided units (e.g., as joint stock companies), they typically invested in more intensive or specialized farming, while shedding some of their labor force and increasing economic efficiency (e.g., much of Eastern Germany).

An instructive historical example illustrating the importance of the process of privatization occurred in 19th-century Alpujarra (in Spain) and Lucania (in Italy), as described by McNeill in *Land, Property,* *and the Environment* (2002). Although some of the old and complex property regimes in land, water, trees, and animals had been highly inequitable, they did ensure that radical changes in land use required the support of diverse interest groups with overlapping rights, preserving ecologically sustainable land uses. Privatization was marred by widespread nepotism, allowing a few new owners to take over vast acreages. They were able to quickly accumulate windfall profits from the sale of timber, with little concern for the eroding hillsides left behind. Many of the deforested lands were put to the plow in spite of their unsuitability for agricultural purposes, increasing erosion problems. This kind of behavior is often referred to as "asset stripping."

On a much larger scale, asset stripping has occurred in the wake of privatization of large state enterprises in the former Soviet Union and some of the eastern European countries. These activities may have much more important social and economic than environmental consequences, however. Some forms of deindustrialization that happened as a result may be regarded as environmentally beneficial (e.g., reduced greenhouse gas emissions), but others may not (e.g., leaking oil pipelines, abandoned industrial sites contaminated by chemicals).

Those industries that privatize and continue to operate are expected to work more efficiently, that is, minimizing the consumption of scarce (i.e., expensive) natural resources. This can lead to investments in order to become more energy efficient, for example. However, where clean air, water, and soils are treated as if they were expendable (that is, there is no effective regulation of pollution), there is no incentive for private enterprise to take any more care to avoid pollution than the state enterprises that preceded them. Where privatization has stimulated rapid industrial growth (as in China), the result is therefore a significant increase in environmental pollution. This once again shows that it is vital that privatization be accompanied by effective institutions (in this case, appropriate regulations), and that it may be counterproductive if such institutions do not exist.

Production, Conditions of

THE CONDITIONS OF production in agriculture are the environmental factors that affect plant or animal growth. The conditions of production in industry are a form of socioeconomic organization that can lead to the real or apparent exploitation of local labor.

The conditions of production in agriculture are variables that affect yield and are often impossible to control, unlike conditions in industry that can be controlled. In many poor countries of the world, especially in the Southern Hemisphere, weather patterns or disease greatly affect the growing of crops. These and other conditions of production often lead to the loss of crops and independence when farmers have to mortgage their land or farm animals to local money lenders at usurious interest rates.

Historically, scholars have viewed small scale production units in third world countries as inherently efficient because they are the product of many years of hard work by many generations of a single family. It has been widely accepted that these small operations are at their peak of efficiency because all possible opportunities for production efficiency have already been attempted in generations gone by. However, recent studies indicate something more complex, if not the opposite.

Moreover, the growth of global agricultural corporations that can increase production efficiency through economies of scale, access to higher yielding seeds, and cheaper fertilizer are presenting small operations with external challenges to production efficiency and economic survival. Along with that economic challenge is the fact that studies have shown that small plot holders in third world countries do not exercise cooperative actions among themselves to control the spread of weeds and insects, which large scale operations can do with their access to insecticides and herbicides.

The conditions of production in agriculture have been the subject of intense study in the industrially advanced countries. This has led to studies of the growth rates for chickens, hogs, and beef cattle raised for consumption of meat. The feeding of the growing billions of people on the earth is pushing farmers to be ever more productive. For example, studies of dairy cattle have shown that there are optimum ages for productive activity for delivering calves and for producing milk, after which productivity goes into decline. To optimize the production of a dairy operation requires the removal of members of the herd on a regular basis once they reach the declining level of productiveness.

The conditions of production in industry are those natural conditions that affect production such as the weather. However, the organization of production can also greatly affect productivity. Adam Smith, in the beginning of *The Wealth of Nations*, the seminal economic work of capitalism, described the increased productivity of a pin factory that was gained through the division of labor in the manufacturing process. Near the same time that Smith wrote about the enclosure movement, the growing Industrial Revolution in England led to the development of the factory system. This way of organizing production virtually replaced the home cottage industry system. It forced large numbers of people into cities and into working for low wages in factories where the factors of production were rigorously controlled.

Today, with slavery virtually abolished globally, the use of exploitative labor occurs most often agriculturally on plantations and industrially in what are called "sweat shops." In these instances, conditions of production are controlled externally and workers produce goods for lower wages than they would be paid in industrially advanced countries. In some cases the laborers are children.

In the growing agroindustries of the world, the production of living organisms includes not only traditional livestock or traditional food crops, but also the growth of traditionally cultivated insects such as silk worms or worms for fish feed. The production of living organisms includes the industrial production of microscopic organisms such as viruses for the manufacture of medicines and the production of bacteria for use in eating sludge and cleaning up oil spills.

Production of Nature

THE PRODUCTION OF Nature perspective examines the material transformation of nature by human societies, insisting that labor rests at the heart of the social relation with nature. It rejects the notion that nature is external to human societies, but rather stresses the role that human societies have in giving shape to nature through the activities of production, consumption, and the social relations governing these activities—especially under advanced capitalism. By rejecting a dualistic view of society versus nature, it provides an alternative to visualize and understand the relationship between society and nature.

Central to the approach is the idea that the labor process is a social act that transforms both humans and nature, and thereby dissolves the intellectual dualism between nature and society. Building on the work of Karl Marx, it looks to labor—or more generally, production—as a process involving both people and nature, in which people initiate and manage the material interactions with nature resulting in finished goods and infrastructure. Production takes place in nature and involves changes in the form of matter using both human labor and natural forces. People work in nature as a kind of natural force, using muscle, machines, and knowledge to shape nature according to human desires. Production includes far more than an individual's fabrication of an object. It encompasses imaginative work, economic and cultural creation, collective endeavors, and also consumption. As people shape the external world through production, moreover, they also transform their own nature and their own societies.

The Production of Nature does not imply that every atom in an endangered species, cloned sheep, genetically modified salmon, or university building is literally created by people. Instead, the view holds that people's actions affect the location and protected status of the wild animal, the process that led to the birth of the clone, the gene-splicing technology and patents of the salmon, and the location, style, materials, and social purposes of the university building. To differing degrees, all seemingly natural systems have a social framing and context while all seemingly social systems have a natural substrate, much modified by historic processes of producing nature. Meanwhile, environmental problems such as global warming, desertification, and mercury poisoning show that the materiality of produced nature can have unexpected and damaging consequences.

Under capitalism, the process of buying materials, transforming them with added labor, and selling them at a profit is central to the production of nature. Sometimes nature seems to pose certain barriers, however, to this cycle. Seeds, for example, were long a self-reproducing good. Unlike tractors, they were at one time difficult for capitalist firms to own, produce, and sell. In the past 100 years, however, science broke down the barriers to capitalist ownership of seeds through the selective breeding of hybrid, high-yielding varieties and the creation of a legal framework of patents to such seeds. More recently, biotechnology and patent law has extended to the modification and patenting of entire organisms with novel combinations of characteristics. The Production of Nature approach shows how these processes are driven by the dynamics of capitalism, which have promoted narrow and short-term interests at the expense of the precautionary principle, social considerations, or any interest in cultural or biological diversity.

The Production of Nature approach contrasts with more common views that conceptualize nature as separate and external to society. Proponents argue that this is a false abstraction because it is impossible to know nature as external to social structures, belief systems, and social values. There is no pristine, prehuman nature, and the view that nature is external to society is a false ideology usually mobilized to justify social oppression and/or short-sighted environmental domination. In contrast to dualistic views of nature and society, the Production of Nature moves environmental debates beyond the rhetoric of either protecting nature or dominating it. In particular, Production of Nature proponents reject a back-to-nature attitude in environmental debates. It is impossible to stop producing nature, but it is possible to produce nature (and society) along more socially and ecologically progressive lines.

At one extreme, a Marxist politics of nature accepts the proven and potential benefits of scientific and technical transformations of nature and recognizes that nature and society are tightly woven together. In contrast with approaches that advocate better nature management, or a hands-off nature protection, it seeks a revolutionary transformation of capitalism in favor of an economic system that is not driven by the narrow drive to accumulate profits. It advocates a social system in which science and technology is uncoupled from capitalist imperatives in order to serve more socially and environmentally progressive ends.

A more reformist interpretation, in contrast, contributes to debates about genetically modified organisms in agriculture by identifying the corporate control of biotechnology research and development and by promoting a stronger role for publicly-funded, democratically accountable universities in the research development of biotechnology, including more careful assessments of the long-term implications for human health and agro-ecosystem functions.

For critics, the Production of Nature approach overemphasizes production at the expense of cultural processes that also socialize nature, and in which productive processes are always embedded. They also point out that the approach shows much greater interest in how capitalism produces nature and much less in how produced nature affects capitalism; it does not encompass the agency of nature. Furthermore, it portrays nature as nothing more than a means to human happiness, and seems to silence a consideration of nature and natural processes in their own right.

Progressive Party

PROGRESSIVE PARTY IS the name of a number of political parties in the United States and in several countries around the world. Progressive parties are or have been "left of center" parties. They are usually statists, because they advocate actively using the power of government in all manner of public policy areas including ecology. Theodore Roosevelt, who is generally viewed as a Progressive though he initially entered the White House as a Republican, became the president of the United States on September 14, 1901, following the assassination of President William McKinley (1843–1901). He was elected to his own term as president in 1904. In 1912, Roosevelt made another bid for the presidency and created the "Bull Moose Party," or the United States Progressive Party. The nickname "Bull Moose Party" came from Roosevelt's answer to questions about his health and his stamina for creating a new political party—he replied that he was as healthy as a "bull moose."

Important environmental planks in the platform of the United States Progressive Party of 1912 were promotion of country life and conservation. The promotion of country life was a pledge to promote prosperity in rural areas and improvements in rural life. The conservation plank of the platform proposed a policy of conservation that applied to forests, oil, and other natural resources. Conservation would govern development and use of natural resources in a manner that was not destructive.

Homesteading would still be encouraged, but most natural resources still in government hands, either state or federal, were to remain in public hands so that they could be wisely conserved and used for the general welfare. Moreover, it would be a policy in which the government would gain mining fees or lumber profits for the benefit of the people, and not for the benefit of commercial enterprises. The nation's water supply would be effectively nationalized with regular payments to be made to the government for the exercise of water rights by private companies. A similar arrangement was to be made for leases of public lands for grazing rights. Finally, the platform includes the statement that those natural resources necessary for the national welfare should be owned or controlled by the nation. The presidential election of 1912 was a disappointment for the Progressives. They vastly out-polled the Republican Party in popular votes and Electoral College votes; however, they lost the election to the Democratic Party's candidate Woodrow Wilson. By the election of 1916, the Progressive Party had disappeared, but it reemerged in subsequent elections.

In 1924 Robert Marion La Follette, Sr. (1855–1925) organized the Progressive Party so that he could run for president. The party's platform called for public ownership of water power, public control and conservation of all natural resources including coal, mineral ores, oil, and timber lands so that these could be responsibly used for the common good. It carried Wisconsin and disappeared after the election. Henry Wallace was the presidential candidate in 1948 on the Progressive Party ticket. Its platform was in the main written by extreme leftists. Beyond asserting that all natural resources belonged to the people, it had little to say about conservation or the environment. The Progressive Party of Canada was based in Manitoba. It flourished in the 1920s and 1930s, but soon lost public support. It was linked with the United Farmers Parties in several other Canadian provinces.

Several American states have had, or still have, progressive parties. In 1988 Eugene McCarthy established the Minnesota Progressive Party so that he could run for president of the United States. He and the party fared poorly at the polls. The Vermont Progressive Party is a state-level party that promotes left-of-center ideas. The party's stand on environmental issues includes opposition to unregulated development, preservation of the rural environment of Vermont, and pollution prevention. The Progressive Party of Washington State considers itself to be a revival of the original Bull Moose Party of 1912. Organized in 2003, it supports conservation, a search for alternate fuels and energy, small farms and businesses, and respect for the earth. The Progressive Party of Missouri is similar. The New Zealand Progressive Party held some offices in the government in 2006, and is active in conservation and environmental issues. Its achievements include efforts to save the kiwi bird, increasing fishing reserves, and the establishment of preserved or dedicated-use public lands. Other small progressive parties exist around the world.

Property Rights

PROPERTY RIGHTS DETERMINE who is entitled to use and dispose of resources, both natural and man-made. They profoundly affect the decisions people make regarding the use of resources, and hence the magnitude of human impacts on the environment.

Property rights entitle one or more people to use a resource (usufruct), to exclude others from its use, to transfer ownership to someone else (e.g., by sale, inheritance, or gift), or to allow someone else to use the property temporarily (e.g., for rent). Property rights may also allow the owner to destroy the property. These rights are conferred by social institutions (e.g., by government) and are subject to renegotiation. Hence, property rights consist of "bundles of rights" that vary in time and place.

The environmental implications of property rights depend on the kind of property as well as on the type of resource, and the uses that people make of that resource. Important kinds of property include open access (no one owns the resource), common property (owned by a defined group of people), state property (owned by the state), and private property (owned by an individual, or a corporation treated as a legal person). Important characteristics of the resource include whether it is renewable or not, whether it requires human effort to maintain its quantity or quality, and whether it is "excludable" or not. An excludable resource is one from which all others can be excluded; for example, land is an excludable resource but the atmosphere is not. Important characteristics of resource uses are whether they are liable to degrade or deplete the resource. For example, logging can deplete a forest and degrade its soils and is thus a "rivalrous" resource use, while breathing the air or walking on a sidewalk is nonrivalrous. Some resource uses improve the resource, for example, the utilization of knowledge typically adds to the existing knowledge base of society, and nobody loses knowledge when somebody learns.

OPEN ACCESS

An open access regime is appropriate if the main resource uses are nonrivalrous, especially if little or no human effort is required in order to maintain that resource (for example, air to breathe or sunlight). Patent rights (a kind of private property) are intended to provide economic incentives to create new technical knowledge, even though that knowledge is nonrivalrous. Hence, many patents are controversial, especially if they are extended to living things such as genetically modified organisms (GMOs) or are used to appropriate knowledge that was previously in the public domain, that is, open access.
