JÜRGEN RENN

PREFACE

The transition from classical to modern physics in the first half of the twentieth century by quantum and relativity theories affected some of the most fundamental notions of physical thinking, such as matter, radiation, space, and time. This transition thus represents a challenge for any attempt to understand the structures of a scientific revolution. The present four-volume work aims at a comprehensive account of the way in which the work of Albert Einstein and his contemporaries changed our understanding of space, time, and gravitation. The conceptual framework of classical nineteenth-century physics had to be fundamentally restructured and reinterpreted in order to arrive at a theory of gravitation compatible with the new notions of space and time established in 1905 by Einstein's special theory of relativity.

Whereas the classical theory of gravitation postulated an instantaneous action at a distance, Einstein's new relativistic kinematics rather suggested an analogy between the gravitational field and the electromagnetic field, propagating with a finite speed. It is therefore not surprising that Einstein was not alone in addressing the problem of formulating a theory of gravitation that complies with the kinematics of relativity theory. The analysis of these alternative approaches, as well as of earlier alternative approaches to gravitation within classical physics, turns out to be crucial for identifying the necessities and contingencies in the actual historical development.

It is the profound conceptual transformation associated with the establishment in 1915 of a relativistic theory of gravitation that shows that the genesis of this theory, Einstein's general theory of relativity, was a genuine scientific revolution in its own right. The restructuring and reinterpretation of the fundamental concepts of classical physics involved in the development of the theory was a long and complicated process with far-reaching consequences. First of all, the new concepts had to be presented and transmitted to a wider scientific community. The new theory also created the need to reconsider all branches of physics in light of its new concepts and to look for possible experimental confirmation. It gave rise to new conceptual problems and new research programs, such as finding a unified field theory and integrating general relativity with quantum theory. Finally, the revision of the concepts of space and time by general relativity had a considerable impact on epistemological and philosophical discussions, attracting the attention of a non-specialized public and placing relativity theory and its creator at the focus of public discussion.

Einstein's path towards establishing the general theory of relativity has been an important topic in the history of twentieth-century physics. Our reconstruction of his

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 1
Einstein's Zurich Notebook: *Introduction and Source*.

unpublished research notes and our examination of the broader intellectual context of the relativity revolution has led to a reassessment and a deeper understanding of this process as a transformation of a comprehensive system of knowledge. These volumes document the results of a joint effort at an in-depth analysis of a scientific revolution undertaken by a group of scholars over more than a decade. The aim was to reach a systematic understanding of both the knowledge base in classical physics that formed the point of departure for Einstein and his contemporaries and the nature of the process through which their research eventually overcame some of the conceptual foundations of classical as well as special-relativistic physics.

For this purpose, it was necessary to cover not only Einstein's individual pathway towards general relativity, but also other approaches to the problem of gravitation before and after the advent of special relativity. The aim was to reach an assessment of the "horizon of possibilities" of reacting to the crisis provoked by the conflict between the understanding of gravitation in classical physics and the challenge presented by the special theory of relativity. The horizon of possibilities is determined by the shared knowledge available to the historical actors. The reconstruction of this shared knowledge and its transformation is based on new approaches for describing the architecture of knowledge and for explaining its developmental dynamics, including the interaction between collective and individual processes.

We have thus attempted to provide a broader context to the reconstruction of Einstein's singular achievement. We surveyed the approaches to the problem of gravitation that existed in late classical physics, to examine the intellectual resources on which the different approaches relied, to determine the extent to which they were adequate to the task of responding to the crisis of classical physics, to explore alternative pathways that could have been but were not realized, and finally to evaluate the reasons why Einstein's general relativity eventually came to be accepted as the resolution of the crisis. The results of our reconstruction are documented in the form of detailed commentaries on the historical sources and in the form of new interpretations of the early history of general relativity.

The four volumes of this work comprise two sets. The first two volumes are dedicated to general relativity in the making, that is, to a detailed reconstruction of the research that led Einstein from special to general relativity in the years between 1907 and 1915. At the center of this reconstruction is the detailed "Commentary" on a key document written between 1912 and 1913, Einstein's so-called "Zurich Notebook." In the first volume this notebook is presented in its entirety for the first time. It is reproduced in facsimile accompanied by a new transcription. The second volume presents the comprehensive "Commentary" so that the reader may directly relate interpretation and historical source. The first two volumes furthermore comprise essays on the development leading up to the period documented in the notebook, assessments of the work documented by the notebook itself, and an analysis of the conclusive period of Einstein's search for the gravitational field equation. Taken together, the work assembled in these two volumes offers an encompassing view of Einstein's contributions to the genesis of general relativity.

The second set of two volumes is dedicated to theories of gravitation in the twilight of classical physics in a more general sense. In this part of the work, alternative approaches to the problem of gravitation around the time of Einstein's work are reviewed in terms of interpretative essays and English translations of key sources. The third volume deals with the tensions between the tradition of mechanics, the canonical place of the problem of gravitation, and the newly established tradition of field theory that raised expectations for a novel solution to this problem. These expectations were then strengthened by the advent of special relativity and led to an intense discussion about a relativistic theory of gravitation that forms the other nucleus of this volume. The fourth volume takes a closer look at possibilities for the establishment of a theory like general relativity along pathways that differed from Einstein's in that they employed more sophisticated mathematical means. The volume thus covers both a reassessment of David Hilbert's work and the suggestion of a fictive but historically plausible scenario for such an achievement.

The work presented in these volumes was originally pursued in the context of the *Arbeitsstelle Albert Einstein*, directed by Peter Damerow and myself, funded by the Senate of Berlin from 1991 to 1996, and hosted by the Max Planck Institute for Human Development and Education, at the Center for Development and Socialization headed by Wolfgang Edelstein. I am deeply grateful to the Berlin Senate, in particular to the former Senator of Science, Barbara Riedmüller, as well as to the former Senate Director, Jochen Stöhr, for the courageous and generous decision to support this unusual initiative, which aimed at exploring Einstein's scientific achievements in their intellectual, cultural, and political contexts. Under the auspices of Wolfgang Edelstein it has served in many ways as a pioneering venture for the foundation in 1994 of the Max Planck Institute for the History of Science. In addition to the collaborators of the *Arbeitsstelle*, Giuseppe Castagnetti, Werner Heinrich, and Tilman Sauer, members of its international scientific advisory board, Hubert Goenner, Michel Janssen, Karl von Meyenn, John D. Norton, Karin Reich, Erhard Scholz, and John Stachel, participated in one way or another in the research process – either by providing helpful comments or by engaging directly in joint projects.

In this way, the *Arbeitsstelle Albert Einstein* soon developed into a meeting point for an international group of scholars working on the history of general relativity and the locus of an unusual cooperation involving both senior experts in the field and young researchers, which continued later at the Max Planck Institute for the History of Science. These meetings involved the core group of authors of the first two volumes as well as the other members of the *Arbeitsstelle* and members of its board. In addition to the names already mentioned, Dieter Brill, Ulrich Majer, James Ritter, David Rowe, Matthias Schemmel, and Dirk Wintergrün also contributed at some point to our co-operation. The innumerable meetings and workshops were unique in their collaborative search for an interpretation of historical sources, with key ideas emerging from lively debate. In a lengthy process, the detailed protocols of these meetings were filtered, reworked, elaborated and reformulated to yield the "Commentary" which constitutes the most distinct outcome of the collective work. In this way, the core group worked together to analyze the sources and reconstruct the knowledge resources that are relevant for understanding the research documented in Einstein's notebooks, his publications, and correspondence. Following ground-breaking papers by John Stachel, John D. Norton, and a few other scholars, the continued investigation and reconstruction of Einstein's discovery process has led to many new insights, among them the identification of two distinct heuristic strategies in this discovery process, a physical and a mathematical strategy. This identification proved to be a breakthrough and an important interpretative tool for understanding Einstein's search for the gravitational field equation, even beyond the phase documented by the Zurich notebook. Our analysis has shed new light on the complex process of interaction between mathematical representation and the construction of physical meaning, a process of crucial importance also in other areas and periods of the history of science. Such epistemological insights were only possible because our joint work was not confined to a painstaking analysis of the historical sources in a traditional sense, but also comprised unusual approaches such as reconstructing the architecture of the shared knowledge at his disposal and actually retracing in detail Einstein's research process in a particular phase of his work. For the epistemological dimension of our discussions and for wider perspectives, the intense participation of Peter Damerow in our research endeavor turned out to be critical. He helped us wherever he could from falling into the traps of specialization and placed our work within the larger framework of a history of knowledge.

As work progressed, it quickly became clear that the clarification reached by deciphering Einstein's research notes from the period 1912–1913 would have serious consequences for our understanding the genesis of general relativity in its entirety. The Zurich Notebook shows that in 1912–1913 Einstein had already come within a hair's breadth of the final general theory of relativity. He failed, however, to recognize the physical meaning of his mathematical results, and turned to the alternative, physical strategy. Eventually he published, jointly with the mathematician Marcel Grossmann, the "erroneous" *Entwurf* ("outline") theory of 1913. Much of our work therefore focused on the question of how Einstein, in the period between 1913 and 1915, was able to overcome the obstacles which at first prevented him from realizing that the correct ansatz was the one obtained in his notebook and not the theory he published in 1913. The answer we found to this question led to the surprising insight that, contrary to what was commonly accepted, the long interval between the publication of the erroneous field equation and the return to the correct equation at the end of 1915 was not simply a period of stagnation. It was rather a period during which Einstein arrived at a number of insights that created the crucial preconditions that made the dramatic events of November 1915 possible. This result made it evident that the establishment and stabilization of the new physical concepts that emerged with general relativity first required an integration of further physical knowledge and a degree of elaboration of the mathematical formalism that went well beyond finding the correct field equation.

Another complementary line of research was, as mentioned above, dedicated to the study of other theories of gravitation before and after the advent of special relativity. In order to identify knowledge traditions that contributed to the emergence of general relativity, the scientific context of Einstein's search for a new theory of gravitation was systematically studied by analyzing a broad range of sources related to the work on alternative approaches, including also the work of less well-known authors.

I am particularly grateful to Michel Janssen who throughout the intricate research and production process leading to these volumes never hesitated to take up whatever challenges arose. He took the main responsibility for bringing the "Commentary," the core of the first two volumes, into the form it is presented here and also helped with critical acumen to sharpen the focus and improve the presentation of other contributions. Matthias Schemmel, who co-edited volumes three and four, and Lindy Divarci, assistant editor of all four volumes, played an essential role in coordinating this extended network of scholarly cooperation. Together with the associate editors, Christopher Smeenk and Christopher Martin, they carefully edited the various contributions, unified and improved the translations of original sources, checked and complemented the bibliographic references, and contributed in many other ways to providing a comprehensive resource for studying the early history of general relativity in context. They were assisted in their editorial work by Heinz Reddner, Stefan Hajduk, Yoonsuhn Chung, Miriam Gabriel, and Shaul Katzir.

The long-term cooperation required to produce the comprehensive analysis of the genesis of general relativity presented in this work was only possible due to the persistent institutional support provided by the Max Planck Society, first at the Max Planck Institute for Human Development and Education and, since its foundation in 1994, at the Max Planck Institute for the History of Science; additional support came from the Archive of the Max Planck Society and its director, Eckhart Henning. The close and ever reliable cooperation with other institutions, in particular with the Albert Einstein Archives at the Hebrew University of Jerusalem and its former Curator Ze'ev Rosenkranz and the Einstein Papers Project at the California Institute of Technology and its former director Robert Schulmann as well as its current director Diana Buchwald, were of great help in the completion of this ambitious project. The authors and editors are particularly grateful for the generous permission to reproduce or quote from Einstein's original documents. Other institutions and individuals offered their generous support as well, either in securing the documentary basis for our enterprise or helping in other ways, among them the Albert Einstein Institute (Max Planck Institute for Gravitational Physics), the Cohn Institute for the History and Philosophy of Science and Ideas at Tel Aviv University, the Institut für Zeitungsforschung, Dortmund, the Manuscript Department of the Staatsbibliothek zu Berlin, the Special Collections Department at the Library of the of the Swiss Federal Institute of Technology Zurich (ETH), the Niedersächsische Staats- und Universitätsbibliothek Göttingen (Manuscripts and Early Imprints Collection) and its director Helmut Rohlfing, the Mathematical Institute at the University of Göttingen, the Federal Archives in Koblenz, the National Science Foundation, the Istituto e Museo di

Storia della Scienza, Florence, and the Besso family (especially Laurent Besso, Lausanne). I also want to thank Jürgen Ehlers, Yehuda Elkana, Paolo Galluzzi, Peter Galison, Gerald Holton, Enrique Junowicz, Ron Overman, and Bernhard Schutz. A special thanks goes to the head of the library at the Max Planck Institute for the History of Science, Urs Schoepflin, who not only assured his team's unfailing support during the many years of work on these volumes, but who was also personally engaged in archival work, in sustaining the scholarly network, and in securing key documents on which these volumes are based.

The volumes appear in sequel to the International Year of Physics and the Einstein Year 2005, celebrating the centenary of Einstein's *annus mirabilis* and the overturn of the classical concepts of space and time. They propose an in-depth historical analysis of the consequences of this revolution for our understanding of gravity and, at the same time, of the structures of a scientific revolution that can be documented in an exceptionally comprehensive way. Yet the scope of the scientific revolution associated with Einstein's name goes well beyond the intellectual work on a new theory of gravity. Its full understanding also requires an analysis of other aspects such as Einstein's contributions to quantum theory or the role of cultural, technological, personal, and political contexts that could only be touched upon in these volumes. They are more amply treated in other publications, among them the three-volume survey *Albert Einstein – Engineer of the Universe* of Wiley-VCH associated with the exhibition of the same title, the *Einstein Companion* of Cambridge University Press, as well as a forthcoming book on the institutional contexts of the emergence of quantum theory to appear in this series, all of them emerging from the same context of collaboration that has made the present work possible. As research on Einstein's revolution of science is still in progress, parts of these volumes are, together with additional sources and interpretative documents and tools, accessible also via the Internet <http://einstein-virtuell.mpiwg-berlin.mpg.de/intro>.

MICHEL JANSSEN, JOHN D. NORTON, JÜRGEN RENN,
TILMAN SAUER, AND JOHN STACHEL

INTRODUCTION TO VOLUMES 1 AND 2: THE ZURICH NOTEBOOK AND THE GENESIS OF GENERAL RELATIVITY

When Albert Einstein died in April 1955, he left a small notebook among his many papers at the Institute for Advanced Study in Princeton. Its faintly gridded pages are covered with calculations. Some are tidy and unhurried. Others are hasty and incomplete. Some are annotated with a cryptic remark; others are unadorned. Some halt with a fragmented formula; others proceed mechanically to their conclusion. They come from another time and place, a silent trace of strenuous work from decades earlier and a continent away.[1]

Most of the calculations in this notebook date from the winter of 1912–1913. In August 1912 Einstein had left Prague, where he had taught for a year and a half, to become a full professor at his *alma mater*, the *Eidgenössische Technische Hochschule* (ETH) in Zurich. This is why the notebook is known among Einstein scholars as the Zurich Notebook. The bulk of it is devoted to a new theory of gravity, in which the ten components $g_{\mu\nu}$ of the metric tensor field encode the geometry of spacetime and double as the potentials of the gravitational field. Many of the end results of the investigations recorded in the notebook were published in the spring of 1913 in a paper Einstein co-authored with Marcel Grossmann, professor of mathematics at the ETH and one of his former classmates. The paper consists of two parts, a physical part written by Einstein, and a mathematical part written by Grossmann. The title modestly announces an "Outline [*Entwurf*] of a Generalized Theory of Relativity and a Theory of Gravitation" (Einstein and Grossmann 1913). Einstein continued to work on this *Entwurf* theory, as it is generally known in the historical literature, for the next couple of years, initially with Grossmann (see Einstein and Grossmann 1914b) and with Michele Besso, another friend from his college days. With Besso he investigated whether the new theory could account for the anomalous advance of the perihelion of Mercury, a well-known problem in Newtonian gravitational theory. They found that it

1 In 1982, the notebook, together with Einstein's other papers, was shipped from Princeton to Jerusalem, where it is now part of the Einstein Archives at Hebrew University (CPAE 1, Publisher's Foreword). Its call number is 3-006. A high-quality scan of the notebook is available electronically at the Einstein Archives Online (www.alberteinstein.info).

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 1
Einstein's Zurich Notebook: *Introduction and Source*.

could not.[2] These collaborations ceased in the spring of 1914, when Einstein moved to Berlin to become a salaried member of the *Preußische Akademie der Wissenschaften*. In the fall of 1914, he published a lengthy article intended as the authoritative, systematic exposition of the new theory. Its title, "The Formal Foundation of the General Theory of Relativity" (Einstein 1914), stands in marked contrast to the tentative title of the original Einstein-Grossmann paper. A year later, however, Einstein's confidence crumbled. In a series of four communications to the Prussian Academy in November 1915, he replaced the centerpiece of the *Entwurf* theory, a set of gravitational field equations of severely restricted covariance, by field equations of broad and ultimately general covariance, solving the problem of Mercury's perihelion in the process (Einstein 1915a, 1915b, 1915c, 1915d).[3] Einstein had thus arrived at the general theory of relativity, the crowning achievement of his career. He consolidated the theory over the next few years. In March 1916, he replaced the premature review article of 1914 by a detailed and self-contained exposition of the new theory (Einstein 1916a). He subsequently applied general relativity to new problems—such as gravitational waves (Einstein 1916b, 1918a) and cosmology (Einstein 1917)—and clarified its foundations (Einstein 1916c, 1917, 1918b, 1918c).[4]

As our joint commentary on the notebook makes clear, the material in the Zurich Notebook holds the key to understanding many aspects of these later developments. To facilitate reading the commentary in conjunction with the notebook itself, we placed the commentary at the beginning of volume two and a facsimile reproduction and a transcription of the notebook at the end of volume one.[5] A number of essays, which make up the balance of the volumes, fill in the background to the research documented in the notebook and address the ramifications of our analysis of the notebook for the reconstruction of the further development of the *Entwurf* theory and the transition to the theory of 1915. These essays are written in such a way that they can be read independently of the commentary and of each other.

The analysis of the notebook was quite a challenge. The notebook consists of working notes and was never intended to be read by others. Its one intended reader needed no narrative to explain the goals and presuppositions of the calculations, their successes and failures, the puzzlements and the triumphs. These would have been all too apparent to Einstein's eyes. They were not to ours. Our commentary reflects our best effort to understand Einstein's calculations and to supply some of the connective

2 See CPAE 4, Doc. 14 and the editorial note, "The Einstein-Besso Manuscript on the Motion of the Perihelion of Mercury," on pp. 344–359. For a popular account, see (Janssen 2003). For a history of the perihelion problem, see (Roseveare 1982).

3 The demise of the *Entwurf* theory and the subsequent developments are detailed in Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153). For analysis of (Einstein 1915c) on the perihelion problem, see (Earman and Janssen 1993).

4 For a concise history of Einstein's struggles with the conceptual basis of his theory and further references to the extensive literature on these topics, see (Janssen 2005).

5 Although the commentary only covers the notes on gravity, facsimiles and transcriptions of notes on other topics are also included. Insights from the analysis of the non-gravitational part of the Zurich Notebook were used in (Büttner et al. 2003).

tissue that he left out. We have reconstructed, as best we can, the content, goals and strategies of the calculations, usually on a line-by-line basis, sometimes even symbol by symbol.

Such efforts cannot hope to recover in full detail what transpired as Einstein made these entries in his notebook. Yet the relative completeness of many of the calculations and the apparent clarity of purpose repeatedly allowed us to discern simple and coherent content in pages that initially looked baffling and disjointed. In another context, Einstein often remarked on a problem not altogether different from the one we faced. Physical theories, he remarked, cannot be deduced from sensory experience. There remains considerable freedom of choice in the concepts and propositions one devises to account for experience. What makes stable theorizing possible is the restricted character of this freedom:

> The liberty of choice, however, is of a special kind; it is not in any way similar to the liberty of a writer of fiction. Rather, it is similar to that of a man engaged in solving a well-designed [cross]word puzzle. He may, it is true, propose any word as the solution; but, there is only *one* word which really solves the puzzle in all its parts (Einstein 1936, 294–295).[6]

Our experience with the Zurich Notebook has been similar. For any given page, one can propose many interpretations. However, when the calculation is relatively complete, and when it connects naturally with other pages, the majority of interpretations fail to solve the puzzle.[7] As readers of the commentary will find, our solution is incomplete in places. It is, however, much more complete than any of us dared hope at the outset. The portions that remain obscure are much smaller than those we now read with clarity. The notebook is open to a new readership.

We should make it clear that we did not have to start from scratch. Norton (1984) had already deciphered several key pages of the notebook before we joined forces. More generally, we drew on research done at the *Einstein Papers Project*[8] and on various studies of the history of general relativity. Many of these were presented at the *History of General Relativity* (HGR) conference series and published in several volumes of the series *Einstein Studies*.[9] Both series were inaugurated by the Nestor of our group, Stachel, who is also the founding editor of the Einstein edition. The anno-

---

6 The handwritten German original has: “Mit dieser Freiheit ist es aber nicht weit her; sie ist nicht ähnlich der Freiheit eines Novellen-Dichters sondern vielmehr der Freiheit eines Menschen, dem ein gut gestelltes Worträtsel aufgegeben ist. Er kann zwar jedes Wort als Lösung vorschlagen, aber es ist wohl nur eines welches das Rätsel in allen Teilen wirklich auflöst” (Einstein Archives, 122–858).

7 In the course of our collaboration, we hit upon what we have dubbed the “chicken scratch rule”: to inspire confidence, a proposed reconstruction should account for every last scratch on the page.

8 All five of us were involved in one way or another with the publication of the relevant Vols. 4 through 8 of *The Collected Papers of Albert Einstein* (CPAE), which appeared between 1993 and 2002.

9 (Howard and Stachel 1989) for HGR1 at Osgood Hill (1986) [Don Howard and Stachel are also the series editors for *Einstein Studies*]; (Eisenstaedt and Kox 1991) for HGR2 in Luminy (1988); (Earman, Janssen, and Norton 1993) for HGR3 in Johnstown (1991); (Goenner, Renn, Ritter, and Sauer 1999) for HGR4 in Berlin (1995); and (Kox and Eisenstaedt 2005) for HGR5 at Notre Dame (1998) and HGR6 in Amsterdam (2002). A volume for HGR7 in Tenerife (2005) is in preparation.

tation of the gravitational part of the Zurich Notebook in CPAE 4, which appeared in 1995, incorporates elements of (Norton 1984) as well as some of the early results of the work of our group.[10] Our joint commentary, however, is the first comprehensive analysis of the gravitational part of the Zurich Notebook. As such, it provides new insights on pages that were not deciphered before and important correctives to the interpretation of pages that were.

Our most important new results are highlighted in sec. 1 of the commentary. Here we want to draw attention to a few that are crucial to understanding the essays complementing the commentary in these volumes. Most of the material in the notebook documents Einstein's search for field equations for his new metric theory of gravity. Two strategies can be discerned in this search. We have labeled them the 'mathematical strategy' and the 'physical strategy'. Each of us would probably flesh out the distinction between the two somewhat differently, but the operative notion is fairly straightforward. Pursuing the mathematical strategy, Einstein scoured the mathematical literature (with the help of Grossmann) for expressions containing derivatives of the metric that could be used as building blocks for gravitational field equations. Pursuing the physical strategy, Einstein tried to find such building blocks drawing on the analogy between the gravitational field in his new theory and the electromagnetic field in the classical electrodynamics of Maxwell and Lorentz. Einstein vacillated between these two approaches in the notebook. The importance of this simple observation for our reconstruction of the research recorded in the notebook can hardly be overstated. The same is true for the reconstruction of the subsequent elaboration of the *Entwurf* theory and of the transition to general relativity in November 1915. The distinction between the two approaches plays a key role in two essays in these volumes, "Pathways out of Classical Physics: Einstein's Search for the Gravitational Field Equations" (this volume) and "Untying the Knot: How Einstein Found His Way Back to Field Equations Discarded in the Zurich Notebook" (volume two).

Another new result that came out of our analysis of the notebook and that needs to be mentioned here is more subtle. One of the requirements constraining the choice of gravitational field equations for Einstein was that they reduce to the field equation of Newtonian theory in the case of weak static fields. Einstein was searching for field equations of broad and, if possible, general covariance, i.e., for equations that have the same form in a broad range of spacetime coordinate systems. Newtonian theory—at least in the standard formulation, which Einstein was using—is formulated in such a way that its equations only retain their simple form under transformations from one inertial frame to another. To compare the equations of broad covariance of Einstein's theory to the equations of limited covariance of Newton's, we nowadays temporarily relinquish some of the covariance of the former. This is done by impos-

10 See CPAE 4, Doc. 10 and the editorial note, "Einstein's Research Notes on a Generalized Theory of Relativity," on pp. 192–199. Preliminary results of the work of our group can be found in (Castagnetti et al. 1993), (Janssen 1999), (Norton 2000), (Renn 2005a, 2005b), and (Renn and Sauer 1996, 1999, 2003).

ing extra conditions on the metric field. Such extra conditions are known as coordinate conditions. Once a coordinate condition is imposed, various terms in the Einsteinian equations vanish and the resulting truncated equations can readily be compared to the simple Newtonian equation. As this brief characterization of the role of coordinate conditions shows, they are not essential to the theory. They have the same status as gauge conditions in other field theories. Their purpose is simply to facilitate comparison with Newtonian theory. For the application of the theory to other problems it may in fact be convenient to impose a different coordinate condition. In all of this, the equations of broad covariance remain the fundamental equations of the theory, not the truncated ones obtained with the help of some coordinate condition.

What we found in the Zurich Notebook, however, is that Einstein used such conditions in a manner that deviates sharply from modern usage. He used them to truncate equations of broad covariance and looked upon the resulting truncated equations as the fundamental equations of the theory or candidates for them. The original equations of broad covariance were important to him only in that they made the covariance properties of the truncated equations more tractable. Starting from equations covariant under a well-defined, broad group of transformations, one can, at least in principle, find the covariance group of the truncated equations by determining the covariance properties of the condition used to do the truncating. This is what we see Einstein do over and over again in the notebook. We therefore introduced a special term for such conditions. To distinguish them from modern coordinate conditions we call them *coordinate restrictions*. During the period covered by the notebook, Einstein labored under the impression that coordinate restrictions were needed not just to recover Newtonian theory in the appropriate limit, but also to ensure that the theory be compatible with energy-momentum conservation. It was only in the course of developing the *Entwurf* theory in 1913–1914 that he came to realize that the covariance of the field equations automatically yields energy-momentum conservation, thereby anticipating an important application of one of the famous theorems of Emmy Noether (1918) relating symmetries and conservation laws.[11] Recognizing the role of coordinate restrictions is crucial not only for reconstructing the calculations in the Zurich Notebook, but also for understanding the subsequent elaboration of the *Entwurf* theory and the obstacles that had to be overcome before general relativity as we know it today could be formulated.

The older literature (e.g., Pais 1982, 222) routinely explained Einstein's initial rejection of generally-covariant gravitational field equations by supposing a lack of understanding of the need to use coordinate conditions to compare such equations to their Newtonian counterpart in the case of weak gravitational fields. Then Stachel (1989b) pointed out that Einstein actually compared his *Entwurf* theory's field equations with the field equation of Newtonian theory in the case of weak, *static* fields and that Einstein had presumed an excessively restrictive form for the metric representing

11 For details, see "Untying the Knot …" (volume two).

such fields.[12] Einstein expected that the metric tensor for weak static fields would have just one variable component, which would behave like the Newtonian field. This one component would govern the chronometry only. Since the remaining components were assumed to be constant, the spatial geometry would just be ordinary Euclidean geometry. This expectation contradicts the generally-covariant field equations Einstein finally adopted in 1915 and could by itself preclude their adoption. The suspicion that this was the real reason for Einstein's rejection of generally-covariant field equations was reinforced when Norton (1984, 117) drew attention to a page of the Zurich Notebook, on which Einstein rehearsed the now standard mathematical computations needed to reduce generally-covariant field equations based on the so-called Ricci tensor to the Newtonian equation by means of what is known as the harmonic coordinate condition. Presuming that Einstein used this condition as a modern coordinate condition, Norton conjectured that Einstein had rejected generally-covariant field equations based on the Ricci tensor because his expectations for the weak, static field were incompatible with the harmonic coordinate condition.

Einstein's difficulties with the static metric left unexplained, however, why he subsequently abandoned another, apparently serviceable set of gravitational field equations of near general covariance examined in the Zurich Notebook. Our analysis of the notebook makes clear that these gravitational field equations were abandoned largely because Einstein was not then using modern coordinate conditions but coordinate restrictions. Over the next two years, he worked energetically to develop a better understanding of the covariance properties of his *Entwurf* theory. The more sophisticated mathematical methods resulting from these efforts are central in his return to broader covariance in November 1915. That return involved his adoption of modern coordinate conditions. He concluded that the gravitational field equations of near general covariance rejected in the Zurich Notebook were acceptable after all and rushed them into print (Einstein 1915a). Freed of coordinate restrictions, Einstein now needed only weeks to discover his mischaracterization of static fields. He made some final modifications to the field equations published in (Einstein 1915a) and thus arrived at the familiar generally-covariant field equations of general relativity.

Not surprisingly, given this turn of events, Norton's essay, "What was Einstein's "Fateful Prejudice"?," in volume two analyzes the role of coordinate restrictions in Einstein's work. The essay carefully lays out the case for their presence in the notebook. It also reviews why Einstein's use of them is credible, even though they differ so much from the routine modern usage. Two considerations are key here: First, Einstein's use of coordinate restrictions is not unnatural in view of the historical development of his theory. His special theory of relativity was covariant just under Lorentz transformations. His goal was to expand that covariance to embrace transformations to accelerated frames of reference. General covariance goes well beyond this, includ-

12 In (Stachel forthcoming) it is shown that Einstein was seriously handicapped in the comparison of his theory to Newtonian theory by the mathematical tools available to him. In particular, he lacked the concept of an "affine connection" (see Stachel's "The Story of Newstein …" in vol. 4 of this series).

ing covariance under transformations not associated with a change of the state of motion, such as transformation from Cartesian to spherical spatial coordinates. So equations of broad covariance could plausibly be used by Einstein purely as an intermediate mathematical step, from which the final equations could be recovered by some harmless restriction of the covariance. Of course, what Einstein found again and again in the notebook was that he needed restrictions that seriously compromised his goal of extending the relativity principle. Second, as already indicated above, Einstein found that the coordinate restrictions he applied were closely associated with energy-momentum conservation in the weak-field limit of the theory. This naturally suggested to him that the full theory could only be made compatible with energy-momentum conservation at the expense of restricting its covariance.

More speculatively, Norton suggests that Einstein's use of coordinate restrictions may have been supported by a tacit reification of spacetime coordinates. In an addendum to the reprint of the *Entwurf* paper in the *Zeitschrift für Mathematik und Physik* in January 1914 (Einstein and Grossmann 1914a), Einstein advanced his notorious "hole argument" [*Lochbetrachtung*] against the physical admissibility of generally-covariant field equations. By his own later admission, he fell into this flawed argument because of just such a tacit reification. What if Einstein tacitly reified spacetime coordinates in just the same way during his calculations in the notebook? If he did, Norton argues, the reification would have forced him to restrict the covariance of the theory, even had he known full well how to use coordinate conditions in the modern sense. The conjecture is that Einstein did indeed reify coordinates in this way. It is essential to the conjecture that this reification remained beneath Einstein's conscious awareness, just as he later admitted it did with the hole argument. Had he been able to formulate it explicitly, he would presumably have recognized its inadmissibility right away.

Norton suggests that Einstein had the modern understanding of coordinate conditions all along, even though, for the reasons laid out above, he used coordinate restrictions in the notebook as well as in the further development of the *Entwurf* theory. In "Untying the Knot …" (volume two), however, Janssen and Renn suggest that Einstein only arrived at the modern understanding of coordinate conditions when he replaced the *Entwurf* field equations by equations of much broader covariance in (Einstein 1915a). This paper contains the first unequivocal example of Einstein applying a coordinate condition in the modern sense.

This disagreement is one of a number of disputes that have not been resolved as these volumes go to press. We make no apologies for this. It is a sign of the vitality of Einstein scholarship. We publish our book on the history of general relativity in the same spirit as Hermann Weyl published his famous book on the theory itself. As Weyl wrote in the preface to the first edition of *Raum-Zeit-Materie*:

> But it was definitely also not the intention of this book to turn the life, which manifests itself so forcefully today on the field of physical knowledge, with axiomatic thoroughness into a dead mummy at the point it happens to have reached this moment.[13]

The reader will note that only the introduction and the commentary are authored by all five of us. The rest of the volume consists of essays by one or two authors. In part, this reflects division of labor and differences in expertise. But it also reflects a lack of consensus about the interpretation of the material. Points of contention, besides the issue of coordinate conditions versus coordinate restrictions, are the relative importance of the mathematical and the physical strategy in the genesis of general relativity (as well as the interpretation of this distinction), the nature of Einstein's *modus operandi* as a creative scientist, and the extent to which the analysis of this particular episode provides insights into the practice of scientific theorizing, its conditions and mechanisms, in general. The first two of these disagreements call for some further comments.

The breakthrough to general relativity of November 1915 has been portrayed as a triumph of the mathematical strategy, prematurely abandoned in the Zurich Notebook in favor of the physical strategy that led Einstein to the problematic *Entwurf* theory (see, e.g., Norton 2000). This portrayal certainly fits nicely with the way in which Einstein presented his new results in November 1915. It is also how he came to remember his own achievement in later years, as has been documented in great detail in (Van Dongen 2002). In "Untying the Knot …" (volume two), Janssen and Renn nevertheless argue that Einstein made the transition from the *Entwurf* field equations to the field equations of November 1915 following the physical strategy. They reconstruct the developments of that eventful month taking Einstein at his word that the definition of the gravitational field in the *Entwurf* theory as the gradient of the metric was "a fateful prejudice" ("ein verhängnisvolles Vorurteil," Einstein 1915a, 782) and that replacing this gradient by the so-called Christoffel symbols was "the key to [the] solution" ("Den Schlüssel zu dieser Lösung," Einstein to Sommerfeld, 28 November 1915). With this substitution, the variational formalism for the *Entwurf* theory, developed in (Einstein and Grossmann 1914b) and (Einstein 1914) in close analogy with classical electrodynamics, leads almost automatically to the theory of November 1915. In an appendix to "Untying the Knot …," this insight is used to clarify the mathematical relation between the Einstein field equations and the *Entwurf* field equations.

Concerning Einstein's *modus operandi*, not all of us agree with Janssen's claim in "What Did Einstein Know and When Did He Know It? A Besso Memo Dated August 1913" (volume two) that more room needs to be made for the role of prejudice, wishful thinking, and opportunism in Einstein's work toward general relativity than was done in the accounts we started from (Norton 1984, Stachel 1989b).

Janssen's claim is based primarily on Einstein's handling of what we shall call the problem of rotation. An important test to which Einstein subjected candidate field equations in the notebook is whether they allow the Minkowski metric in uniformly rotating coordinates as a vacuum solution. The point of checking whether this rota-

13 "Es lag aber auch durchaus nicht in der Absicht dieses Buches, das auf dem Feld der physikalischen Erkenntnis heute so besonders kräftig sich rührende Leben an dem Punkt, den es im Augenblicke erreicht hat, mit axiomatischer Gründlichkeit in eine tote Mumie zu verwandeln" (Weyl 1918, vi).

tion metric, as we shall call it, is a vacuum solution was that Einstein wanted to make sure that his theory extended the relativity of uniform motion of special relativity to accelerated motion such as uniform rotation. When Einstein published the *Entwurf* field equations, he had satisfied himself that they met this important requirement. It turns out they do not. It took Einstein some time to discover this and even longer to accept it. As part of his collaboration with Besso on the Mercury anomaly shortly after the publication of the *Entwurf* paper, he made a half-hearted attempt to double-check that the rotation metric is indeed a vacuum solution of the *Entwurf* field equations. He was so convinced they were that he missed some factors of 2 and a minus sign in just the right places to bring about the outcome he expected.[14] This error and its eventual discovery in September 1915 are recounted in (Janssen 1999). The conclusion of this paper was that Einstein had simply been unlucky in not discovering his error sooner. However, a memo in Besso's hand bearing the date August 28, 1913, discovered in Switzerland in 1998 by Robert Schulmann, shows that Besso had clearly warned his friend in 1913 that the rotation metric is not a solution. Einstein initially accepted this verdict. He changed his mind again in early 1914.

The reconstruction of this episode in "What Did Einstein Know …" depends crucially on allowing a certain opportunistic streak in Einstein's general methods. Einstein's handling of the problem with the rotation metric is the most clear-cut case, but the Besso memo provides another example. The memo shows not only that Einstein had the key idea for the hole argument sometime in August 1913, but also that he had already taken important steps toward its eventual resolution in 1915. Janssen argues that it is partly because of opportunism that Einstein did not pursue this resolution in 1913. After all, such a resolution would be a most unwelcome reversal after Einstein had tried for months to make the lack of covariance of the *Entwurf* field equations more palatable. The exposure of such opportunistic moves by Einstein should not be seen as damning to his reputation as a scientist. What it shows rather is that creative science is messier and more complicated than many philosophers of science and science educators like to think.

The material discussed so far focuses on one phase in the genesis of general relativity, Einstein's search for field equations in the period 1912–1915. This phase is extremely well documented and has accordingly been discussed extensively in the recent literature on the history of general relativity. Yet, the field equations were only the capstone on the edifice of general relativity. Much of the foundation had been laid before Einstein started looking in earnest for field equations. The cornerstone of the theory—dubbed the equivalence principle in (Einstein 1912, 360, 366) and later singled out by Einstein as "the most fortunate thought of my life" ("der glücklichste Gedanke meines Lebens," CPAE 7, Doc. 31, [p. 21])—dates from 1907. Stachel's essay, "The First Two Acts" (this volume), examines all Einstein source material per-

14 This calculation can be found on [pp. 41–42] of the Einstein-Besso manuscript on the perihelion motion of Mercury (CPAE 4, Doc. 14). For further discussion of Einstein's struggles with rotation, see (Janssen 2005).

taining to the early stages of the genesis of general relativity.[15] "Act One" concerns his recognition of the close connection between acceleration and gravitation in Newtonian mechanics, based on the equality of inertial and gravitational mass, and his extension of that connection to all physical phenomena, which he called the equivalence principle. He took this principle, which he believed extended the relativity principle to accelerated frames of reference, as the key to any future relativistic theory of gravitation. In the crucial "Act Two," the quest for generalization of the relativity principle, which distinguished his efforts at a theory of gravitation from those of his special-relativistic competitors, had led him by late 1912 from a scalar to a tensor description of the gravitational field. In the theory for which he was looking, this tensor was to play a dual physical role, serving both as the metric in the line element $g_{\mu\nu}dx^{\mu}dx^{\nu}$ [16] describing the chronometry of time and the geometry of space (by then he had adopted Minkowski's four-dimensional viewpoint), and as the potentials for the inertio-gravitational field. It is at this point that the Zurich Notebook begins. In this reckoning, the search for the field equations, the focus of much of the rest of these volumes, comprises only the third act.

The genesis of general relativity, however, did not quite unfold in the form of a classic three-act drama between 1907 and 1915. The story begins before 1907 and continues well beyond 1915. In the essay that opens this volume, "Classical Physics in Disarray," Renn examines the state of knowledge about gravitation from which Einstein had to start. The work on gravity undertaken on this basis eventually culminated in the publication of the Einstein field equations (Einstein 1915d). This publication, the last of the four communications to the Prussian Academy of November 1915, marks the dramatic end of "Act Three". But the dust did not settle until 1918. Both the status of general covariance and the status of energy-momentum conservation in the theory remain unclear as "Act Three" draws to a close. Einstein himself tied together some of these loose ends in correspondence and further publications.[17] Several contributions by others helped clarify key aspects of the theory. The seminal paper of Emmy Noether (1918) on symmetries and conservation laws already mentioned above grew out of discussions among Göttingen mathematicians around David Hilbert and Felix Klein over energy-momentum conservation in general relativity.[18] The astronomer Karl Schwarzschild (1915)[19] replaced the approximate solution for

---

15 This is the only essay in these volumes that has already been published (Stachel 2002a, 261–292). This collection of Stachel's work on Einstein also contains a reprint of an important earlier paper on "Act Two" (Stachel 1989a)

16 The indices μ and ν run from 1 through 4 (corresponding to the spacetime coordinates $x^{\mu} = (x, y, z, t)$) and are summed over.

17 The status of general covariance is clarified in letters to Besso and Paul Ehrenfest in late 1915 and early 1916 (CPAE 8, Docs. 173, 178 and 180). For historical discussion, see, e.g., (Stachel 1989, 1993, 2002b), (Norton 1987), (Howard and Norton 1993), (Howard 1999), and (Janssen 2005). The status of energy-momentum conservation was clarified in (Einstein 1916c, 1918c). For discussion, see "Untying the Knot …" (volume two).

18 For further discussion, see (Rowe 1999), (Sauer 1999, 2005), and Renn and Stachel's "Hilbert's Foundation of Physics …" in vol. 4 of this series.

the metric field of a point mass that Einstein had used in his paper on Mercury's perihelion by an exact solution. The mathematicians Gerhard Hessenberg (1917), Tullio Levi-Civita (1917), and Hermann Weyl (1918) introduced the notion of parallel displacement, thereby clarifying the geometrical meaning of curvature representing gravity in the new theory.[20] This in turn led to the introduction of the notion of an affine connection, which provides a much more natural way to implement the equivalence principle than the metric tensor, with which Einstein had to make do in the development of the theory.[21]

The longest and most ambitious essay in these two volumes is "Pathways out of Classical Physics …" (this volume) by Renn and Sauer. This paper elaborates on "Classical Physics in Disarray" (this volume) and presents a comprehensive version of "Act Three" of the genesis of general relativity within a framework of historical epistemology that integrates historical analysis, epistemology, and cognitive science. This framework builds on efforts to integrate cognitive science and history of science by Peter Damerow (1996) and is based on adapting such concepts as "frames" and "mental models" introduced by Marvin Minsky (1975, 1987) and others to the needs of an historical analysis of knowledge. Damerow was closely involved with our group's efforts to decipher the gravitational part of the Zurich Notebook and to explore the ramifications of the results for the reconstruction of the genesis of general relativity. One of the advantages of the framework adopted by Renn and Sauer is that it allows them to trace continuities across sharp conceptual divides that separate various stations on Einstein's journey from classical physics to general relativity. The hope is that the application of the framework of historical epistemology to the genesis of general relativity will tell us more about conceptual innovation in general and about related issues in—to use a geological metaphor—the plate tectonics of knowledge.

CLASSICAL PHYSICS IN DISARRAY

The Emergence of the Riddle of Gravitation

1. INTRODUCTION

1.1 A Creation ex nihilo?

The genesis of Einstein's special and general theory of relativity is an odd event in the history of science. From today's perspective, Einstein's theory represents the basis for modern astronomy, astrophysics, cosmology, and cosmogony. It comprises a broad range of observational and theoretical knowledge, covering, among others, phenomena related to planetary astronomy, to black holes, and to the expansion of the universe. Yet little of the knowledge that makes relativity theory a central asset of modern physics was available at the time when Einstein completed it by publishing his paper on general relativity in late 1915. Neither the bending of light in a gravitational field nor the expansion of the universe, let alone gravitational waves or black holes, were even suspected by contemporary astronomers. How then was it possible for Einstein without this knowledge to formulate a theory that has since withstood not one but several revolutions of astronomy and its instrumentation, including the development of radio-, X-ray, and space-borne astronomy?

A closer look at Einstein's investigative pathway does not resolve but rather complicates this puzzle, which may be called the "paradox of missing knowledge." Einstein first encountered the problem of formulating a relativistic theory of gravitation in 1907 when he was a clerk at the Swiss Patent Office in Bern. In the following eight years he pursued this problem with growing intensity, from 1911 to early 1914 as professor in Zurich and Prague, and from April 1914 as a member of the Prussian Academy and from 1917 as Director of the Kaiser Wilhelm Institute for Physics in Berlin.[1] As early as 1907 Einstein formulated several general conditions for the solution of his problem, among them the famous "principle of equivalence" and a generalization of the "principle of relativity." The first principle allowed him to arrive immediately at a number of surprising conclusions such as that of the bending of light in a gravitational field.[2] Five years later, however, he had to acknowledge that,

Einstein's Zurich Notebook: *Introduction and Source*.

with the mathematical means at his disposal, the problem of formulating a relativistic theory of gravitation could not be solved. To his friend, Heinrich Zangger, Einstein thus wrote around June 1912:

> The further development of the theory of gravitation meets with great obstacles.[3]

Consequently, in the summer of 1912, he turned to his mathematician friend, Marcel Grossmann, who helped him to access more sophisticated mathematical tools, in particular, the absolute differential calculus of Elwin Christoffel, Gregorio Ricci-Curbastro, and Tullio Levi-Civita.[4] But after exploring these tools for about a year, an experience that is documented in the Zurich Notebook, Einstein's conviction grew that the problem he posed in 1907 was actually irresolvable. He thus limited himself to a partial solution, which he first published in 1913 together with Grossmann.[5] Soon after this publication Einstein even believed to have found a proof that his problem could not be solved as originally envisaged. In the following two years, he nevertheless continued to work on a relativistic theory of gravitation largely in isolation from and even against the resistance of the scientific community, which tended to regard his efforts as making little sense. Then, after three dramatic weeks towards the end of 1915 in which Einstein presented to the Prussian Academy week after week a new tentative solution,

3 "Die Weiterentwicklung der Theorie der Gravitation stösst auf grosse Hindern[i]sse." Albert Einstein to Heinrich Zangger, Prague, after 5 June 1912, (CPAE 5, Doc. 406). Unless otherwise noted, all translations are based on those in the companion volumes to the Einstein edition.

4 See (Kollross 1955, 278) according to which Einstein exclaimed: "Grossmann, you must help me or I'll go crazy." ("Grossmann, Du mußt mir helfen, sonst werd' ich verrückt!") See also the preface to the Czech translation (Einstein 1923) of his popular book on relativity where he wrote: "However, only after my return in 1912 to Zurich did I hit upon the decisive idea about the analogy between the mathematical problem connected with my theory and the theory of surfaces by Gauss—originally without knowledge of the research by Riemann, Ricci, and Levi-Civita. The latter research came to my attention only through my friend Grossmann in Zurich when I posed the problem to him only to find generally covariant tensors whose components depend only upon the derivatives of the coefficients of the quadratic fundamental invariant." ("Den entscheidenden Gedanken von der Analogie des mit der Theorie verbundenen mathematischen Problems mit der Gaußschen Flächentheorie hatte ich allerdings erst 1912 nach meiner Rückkehr nach Zürich, ohne zunächst Riemanns und Riccis, sowie Levi-Civitas Forschungen zu kennen. Auf diese würde ich erst durch meinen Freund Großmann in Zürich aufmerksam, als ich ihm das Problem stellte, allgemein kovariante Tensoren aufzusuchen, deren Komponenten nur von Ableitungen der Koeffizienten der quadratischen Fundamentalinvariante abhängen."), (CPAE 6, Doc. 42, 535, n. 4). For more extensive discussion, see "The First Two Acts" (in this volume).

5 See (Einstein and Grossmann 1913).

each revoking the previous one, he eventually succeeded in definitively solving his original problem.[6] How was it possible that Einstein could, without having an idea of the final solution and eight years before actually attaining it, already formulate the conditions it had to satisfy, and how could he persist in his search against the judgement of contemporary experts and in spite of his numerous failures? What was his explicit or implicit heuristics? And what accounts for its success?

The following is an attempt to prepare the answers to these questions by analyzing the roots of Einstein's achievements in the knowledge of classical and special relativistic physics, and by following the development of his theory until, in the summer of 1912, he recognized gravitation as the bending of space and time. As we shall see in this and the following contributions, both the peculiar emergence and the remarkable stability of Einstein's theory of gravitation with regard to the further development of physics and astronomy become plausible only if the genesis of general relativity is understood, not as a fortunate anticipation of future observational discoveries, but as a transformation of pre-existing knowledge. The next section provides a survey of this knowledge, in particular of classical physics as it became relevant to the emergence of a relativistic theory of gravitation. The concluding third section then attempts to explain how this knowledge became effective in laying the foundations for Einstein's successful heuristics.[7] As a prelude, let us look briefly at the long-term development of the knowledge on gravitation, which provided the presuppositions for Einstein's achievements.

1.2 A Short History of Gravitation

What can one possibly learn from a survey of the history of gravitation in order to understand the genesis of general relativity? Certainly, the long-range history of knowledge on gravitation turns out to be as peculiar as the emergence of general relativity. Above all it is characterized by the longevity of certain basic ideas on gravitational effects, as well as by the radical turnover of these ideas in the course of the historical development. For almost two millennia, the understanding of what we consider to be gravitational effects was dominated by Aristotelian natural philosophy. It divides such effects into two distinct classes; the motions of terrestrial and of celestial bodies. The downward motion of heavy terrestrial bodies is conceived as a "natural motion" towards the natural place of such bodies, the center of the earth. In contrast to the "violent motion" of terrestrial bodies, which is caused by a force, natural motion does not require any external moving cause but is the result of an intrinsic tendency of a heavy body acting in accordance with its nature. The characteristic motion of celestial bodies is, on the other hand, categorically separated from that of terrestrial bodies and conceived as an eternal circular motion.[8]

6 See (Einstein 1915a, 1915b, 1915c, 1915d).

7 For an attempt to provide comprehensive answers to the above questions based on the present analysis, see "Pathways out of Classical Physics …" (in this volume).

The Aristotelian account of gravitational effects was eventually supplanted by that of classical Newtonian physics, dominating their understanding for several centuries until the advent of relativity theory. Like Aristotle's natural philosophy, Newtonian physics also introduced a fundamental distinction between types of motion, in this case between uniform inertial motions and motions that are accelerated due to the action of a force. In Newtonian physics, gravitation is understood as a force acting like any other external force causing acceleration, be it human or natural, terrestrial or celestial. Accordingly, the accelerated motion of falling terrestrial bodies and the accelerated orbital motion of the planets are explained in the same way as being due to a universal gravitational force of attraction. This gravitational force acts without intermediary and without time delay through the intervening space between two bodies.

Since the mid-nineteenth century, yet another distinct idea was discussed and gained increasing support: gravitation as a space-filling field, transmitting the gravitational force not instantaneously but with a limited speed through an intervening medium called the "aether."[9] Finally, in general relativity, gravitation is conceived as a field that represents the curvature of the spacetime continuum itself and that is caused by the distribution of masses and energy in the universe. Since gravitation is not understood here as a force, motions of bodies within this field are no longer distinguished according to their inertial or gravitational character. They are rather all "natural" motions governed in the same way by the intrinsic geometry of spacetime.

What made these distinct conceptions convincing while they ruled the understanding of gravitation, and what eventually overturned them? Was the long-term domination of Aristotelian natural philosophy merely the consequence of its adoption as the official doctrine of the Catholic Church? And was the replacement of the Aristotelian concept of natural motion by the Newtonian explanation of the motion of fall in terms of a gravitational force simply the triumph of a newly introduced scientific method? If so, what accounts for the fact that the Newtonian conception itself was eventually superseded by that of general relativity, which returns to the interpretation of the motion of fall as a "natural" force-free motion, as conceived in Aristotelian natural philosophy? How can it be that, even after the establishment of the "scientific method," history of science was not simply dominated by gradual progress and that even the very foundations of the understanding of gravitation could still be overturned? As the following sketch will attempt to make plausible, the emergence and disappearance of such diverse core notions of gravitation—conceived as natural tendency, force, field, or as curvature of spacetime—becomes understandable on the basis of a history of knowledge that studies the extension as well as the architecture of the knowledge sustained by these core notions.

While the history of science has traditionally limited itself to the knowledge embodied in scientific theories and, more recently, also to that represented by experi-

8 For a survey, also of the following, see (Dijksterhuis 1986).

9 For a survey, see the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics" (in vol.3).

mental systems, the knowledge on gravitation here at issue predates considerably any systematic theoretical treatment in the framework of physics.[10] The most basic knowledge on heaviness, force, matter, and motion is based on experiences acquired by human activities almost universally in any culture. It includes, for instance, the perception of heavy bodies and their spontaneous tendency to fall downwards and the fact that their motion usually requires an effort. The outcome of these experiences is an "intuitive mechanical knowledge" embedded in a qualitative physics, which is built up in ontogenesis and guides human activities in their relation to the physical environment. A second kind of physical knowledge, which predates any systematic theoretical treatment, is the knowledge gained by the use of practical tools. In contrast to intuitive physical knowledge, this type of knowledge is closely linked to the production and use of technology by professional groups of practitioners and is hence subject to historical development. For a long historical period, these two forms of knowledge, intuitive and practitioners' knowledge, also formed the principal experiential foundation of scientific knowledge which is characteristically represented and historically transmitted in the form of written texts. Without realizing the extent to which the development of theoretical knowledge of gravitation depends on the reflection on these forms of "shared knowledge," its dynamics remain inexplicable.[11]

The historical persistence of Aristotelian natural philosophy, in particular, is related to the fact that it incorporates knowledge about the natural environment common to all human beings. The knowledge of intuitive physics is structured by mental models, that is, by specific forms of representation that allow inferences to be drawn from prior experiences about complex objects and processes, even if only incomplete information is available about them.[12] One example is the motion-implies-force model" which, when involved in the interpretation of a process of motion, yields the conclusion that the moved object is moved by a force exerted upon it by some mover. While this conclusion is incorrect from the perspective of classical physics, contradicting as it does Newton's principle of inertia, it represents elementary human experiences. In fact, when observing a moving object, for instance a vehicle moving on the street, one usually presumes that there is a mover at work that drives the object by its force, even when the mover itself and its force cannot be directly observed. Mental models possess slots that can be filled with empirically gained information but also with default assumptions, as in the case at hand, when the mover remains invisible.

10 The following outlines some basic notions of historical epistemology as it is pursued at the Max Planck Institute for the History of Science in Berlin; see the scientific reports of the institute (http://www.mpiwg-berlin.mpg.de/en/forschung/reports.html). For contributions to an account of the development of mechanical knowledge to which the following makes reference, see (Damerow, Renn and Rieger 2002; Büttner, Damerow and Renn 2001; Damerow et al.; Büttner et al. 2003; Renn 2001; Damerow and Renn 2001).

11 For the notion of shared knowledge, see (Büttner, Damerow and Renn 2001).

12 For the concept of mental model, see, e.g., (Minsky 1987; Gentner and Stevens 1983; and Davis, 1984). For a view on the potential of cognitive science and cognitive psychology for the history of science to which the present work is much indebted, see (Damerow 1996). This approach is extensively used in "Pathways out of Classical Physics …" (in this volume).

Such assumptions may simply result from prior experience, or may be "inherited" from higher-order mental models. In any case, information is assimilated to the slots of a mental model in the form of "frames," that is, cognitive structures with a well-defined meaning that categorize information as being suitable for the slots of the model or provide such information, if necessary, by their "default settings." In the case at hand, such frames are those which either identify a given object as a mover or as moved or which supply—if suitable empirical information is lacking—default examples of such objects from prior experience. A higher-order mental model may trigger the activation of mental models to interpret the natural environment; it is, in any case, context-dependent. While motions such as that of a vehicle tend to be interpreted in terms of the "motion-implies-force model," other motions, such as the spontaneous downward motion of a falling body due to gravitation, are interpreted by another mental model, the "heaviness-causes-fall model," implying that a heavy body will, without any intervention by a mover, fall downwards once the obstacles to such a motion are removed.

The embedding of a mental model in a theory such as Aristotelian natural philosophy, resulting from the reflection of intuitive physics, imposes further requirements on the explanatory potential of the model, in particular a drive towards universalization, consistency, and precision in the use of the model. In Aristotelian physics for instance, the motion-implies-force model became the foundation for the treatment of the class of "violent motions," whereas the heaviness-causes-fall model serves as the basis for the explanation of the "natural motion" of heavy bodies. Cases that do not clearly belong to one of these two categories, such as the motion of a projectile that is initially propelled by an external force and eventually drops to the ground due to its heaviness, represent a problem for this theory. Which is, in particular, the external force driving the motion of the projectile once it is separated from its original mover? And how does this force interact with the natural tendency downwards in the course of the projectile's motion? The awkward attempts at solving such problems, identifying, for instance, the surrounding medium as the missing external cause of the continued motion of a projectile, illustrate the new kind of challenges encountered by a mental model of intuitive physics when integrated into a theoretical framework.

Problems such as that of projectile motion were the subject of critical discussions and revisions of Aristotelian natural philosophy and eventually led, in the early modern era, to the ascendancy of a new mechanics, but only after such problems had become an important challenge for contemporary practitioners and theoreticians. In the early modern period, scientist-engineers accumulated, in the context of the technical ventures of the time,—from artillery via intercontinental navigation to monumental building projects—a rich base of experiences largely exceeding those of intuitive physics and also of the practical knowledge of antiquity. The bodies of specialized practical knowledge that they assembled were in fact the principal source of empirical knowledge for the new sciences of the Scientific Revolution. The preclassical mechanics and astronomy of Galileo, Kepler, and their contemporaries were constituted by attempts to assimilate the new knowledge resources of this period to the traditional knowledge structures inherited from antique and medieval science.

The early modern period was characterized, however, not only by new bodies but also by new images of knowledge.[13] In opposition to the prevailing Aristotelian worldview, early modern intellectuals searched for a framework in which celestial and terrestrial phenomena would be explained by the same causes. Accordingly, they cherished explanations with the capacity to integrate knowledge from these traditionally separated spheres. Galileo, for instance, attempted to explain the genesis of the planetary system on the basis of a mental model originating in his analysis of projectile motion.[14] This model makes it possible to imagine that projectile motion—or, in the cosmological case, planetary motion—proceeds as if it were generated by a preceding accelerated motion of fall along the vertical which is then deflected into the horizontal, thus producing the parabolic motion of a projectile or the circular motion of a planet around the sun, as the case may be. In his cosmogony, Galileo speculated that there was a fixed point in space from which all planets were originally released so that their deflection into a circular motion after the proper distances of fall—producing their correct distances from the sun—would generate the appropriate speeds of their revolving motions around the sun. While Galileo's model is still shaped by the traditional conceptual framework, interpreting for instance the motion of fall as a natural motion and a projectile motion as violent motion, it nevertheless integrates areas of knowledge that were separated from each other according to the classificatory distinctions of Aristotelian natural philosophy. It shows, in particular, how the "natural motion" of fall can be converted into the "violent motion" of projection and even the "celestial motion" of a planet.

The vision of a unified treatment of terrestrial and celestial physics embodied in attempts such as Galileo's was eventually realized in Newtonian physics on the basis of a new mental model, the "acceleration-implies-force model," which makes it possible to explain the motion of the planets and the motion of falling bodies on earth by the same universal force of gravitation. This model is still rooted in intuitive physics, as is suggested by the anthropomorphic concept of force involved in it and also by its character as a modification of the motion-implies-force model, from which it results by the specification that it is not motion but acceleration that is caused by a force. But clearly the acceleration-implies-force model is actually no longer part of intuitive physics or of practitioners' knowledge, as is made evident by its counter-intuitive consequences such as the implication that a force-free motion will never come to rest. The acceleration-implies-force model as the basic explanatory scheme of classical mechanics emerged rather from a reflection on the extensive experiential basis accumulated in preclassical mechanics and astronomy. The radical change in physical explanations, which it implies when compared to explanations based on the motion-implies-force model, was the result rather than the presupposition of a process of

13 See (Elkana 1981).
14 See (Büttner 2001).

knowledge integration. When considering the origin of the acceleration-implies-force model in the integration of knowledge achieved by preclassical science, the gravitational force of Newtonian physics, with its peculiar properties such as acting at a distance without any intermediary or causing all bodies to fall with the same acceleration, no longer appears to be just the strange but compelling idea of an individual genius. It rather emerges as being supported by the accumulated knowledge of preclassical and then classical science, comprising terrestrial experiences as well as astronomical observations, a circumstance that accounts for its stability for more than three centuries of classical physics.

The emergence of Newtonian physics out of the knowledge-integration of preclassical physics accounts, however, not only for its stability but also for the fact that it could eventually be revised again. In fact, Newtonian physics does not embody, as philosophers such as Kant believed, an *a priori* framework determining the fundamental categories for the further development of physics, but merely represents a temporary structure of knowledge organization subject to historical change. Although the knowledge from which it originated was rather comprehensive and grew steadily with the elaboration of classical mechanics and also with the advancement of technology, it was, after all, only a highly specialized body of knowledge whose specific theoretical structures were transmitted in a tradition of experts, carried on by institutions of higher learning and a sophisticated technical literature. It is therefore not surprising that it did not replace the intuitive physics by which we orient ourselves in our natural environment. In fact, as psychological investigations show, the intellectual means used to address physical problems outside such expert traditions strikingly resemble those at the roots of Aristotelian natural philosophy, although Aristotle's system has long ceased to dominate the academic world.[15]

The fact that Newtonian physics is removed from intuitive physics not only makes it difficult to understand for laymen but also represented, in the course of its history, a potential challenge even for professional science. Newton's concept of gravitational force as "action at a distance," for instance, was criticized by his contemporaries as well as by later scientists because it does not provide a mechanism of interaction compatible with what was to be expected from intuitive physics, that is, an interaction mediated by the contact of a material agent. Numerous attempts were thus undertaken to develop models of gravitational interaction capable of countering or circumventing this objection.[16] An example is provided by the suggestion of the eighteenth-century scientist Lesage, according to which gravitation is an "umbrella effect" by two material bodies apparently exerting a mutual force of attraction but actually only screening each other from an omnipresent "rain" of invisible particles impinging on them from all sides.[17] The net-result of this stream of invisible particles on a single,

isolated body would simply vanish, given that they pressure such a body from all sides. But if this stream on a given body is screened from one side by another nearby body, the impacts of the invisible particles no longer neutralize each other but actually drive the two bodies towards each other.

The tension between classical physics and expectations rooted in intuitive physics served, however, not only to provoke conciliatory attempts such as the one just described but also simply to keep alive the astonishment about the Newtonian doctrine and some of its peculiarities, in particular with regard to the puzzling features of inertial motion. The autonomous character of both natural and celestial motions, showing no noticeable intervention of an external cause, was thus never lost from sight, even long after the Aristotelian world picture had vanished. While Newtonian physics was extremely successful in accounting for the motions of the planets and other celestial bodies it could therefore never completely extinguish objections against its explanations questioning, for instance, the rather artificial split of the orbital motion of a planet into an inertial component due to an intrinsic tendency of motion and an accelerated component due to the invisible gravitational action of the sun. But for a long time such questions were mainly left to philosophers such as Hegel and played no significant role in the development of classical physics.[18]

The situation gradually changed, however, with the steady growth of scientific knowledge and, in particular, with the discovery and exploration of new phenomena outside the range of mechanics, such as those of optics and electromagnetism. Paradoxically, it was the rapid development of the disciplinary specialization in nineteenth-century science which showed that specialization was not just a means of isolating problems from the larger context of knowledge. Specialization also turned out to be a form of the production of shared knowledge that unavoidably creates intersections between different, highly structured bodies of knowledge, making it necessary to review their explicit and implicit foundations. It was precisely such intersections that brought the problems of gravitation and inertia eventually back to the fore. This first happened around the middle of the nineteenth-century—at the time without much further consequence—in the context of philosophical discussions of the structure and role of mechanics, which were triggered by the establishment of other subdisciplines of classical physics. Towards the end of the nineteenth century, a rich discussion had evolved around foundational questions concerning gravity and inertia, which, however, were still largely neglected by mainstream classical physics.[19] The pursuit of foundational questions was then taken up with much greater impact as a consequence of specific new problems that may be characterized as "borderline problems" between the major continents of classical physics. Among those driven by such borderline problems to revisit the foundations of physics and eventu-

19 For a survey, see vols. 3 and 4 of this series.

ally revolutionize the classical understanding of gravitation was Albert Einstein, initially also an outsider on the periphery of established physics.

What can one learn from such a survey of the history of knowledge on gravitation? It specifies the challenge of what it means to reconstruct the genesis of general relativity as a transformation of knowledge. As we have seen, radical breaks in the understanding of gravitation were not due to the invention of new paradigms or the creation of new ideas *ex nihilo*, but rather to the long-term processes of the accumulation and integration of knowledge resources preceding such breaks. It was this evolution of knowledge that also produced tensions within the existing cognitive structures as well as the potential for resolving them: in the course of a reflective reorganization of the accumulated shared knowledge, its architecture could be revised from bottom up. In the following section we will show, by sketching the major building blocks of classical physics and tracing their intersections at borderline problems, how the riddle of gravitation reemerged at the beginning of the 20th century due to the integration of the knowledge of classical physics, which gave rise to a disintegration of its foundational concepts.

2. GRAVITATION AMONG THE BORDERLINE PROBLEMS OF CLASSICAL PHYSICS

2.1 The Three-Partite Division of Classical Physics

The specific problems addressed by the special and general theories of relativity are rooted in the development of classical physics in the late nineteenth century.[20] In the following we will therefore look at classical physics at this time, surveying its extended and gradually evolving landscape with the double aim of introducing a world not necessarily familiar to modern readers and of locating the structural origins of the problems addressed by Einstein. In the late nineteenth century physics had evolved into three major branches, each treating a set of interconnected physical problems on the basis of characteristic knowledge structures. Such knowledge structures comprise chunks of knowledge embodying basic, often only qualitative rules, which allow the prediction of the essential properties and behavior of physical objects. These chunks are best described in terms of the above-mentioned "mental models." Such knowledge structures also comprise elaborate conceptual frameworks represented by specialized theories, representational tools such as mathematical formalisms, and practical knowledge concerning paradigmatic experimental systems. These knowledge structures were transmitted in the context of the disciplinary organization of nineteenth century physics by school and university training, textbooks, journals, as well as the participation in research projects.

20 For surveys, see (Jungnickel and McCormmach 1986a, 1986b; Harman 1982; D'Abro, 1951a, 1951b; Stichweh 1984).

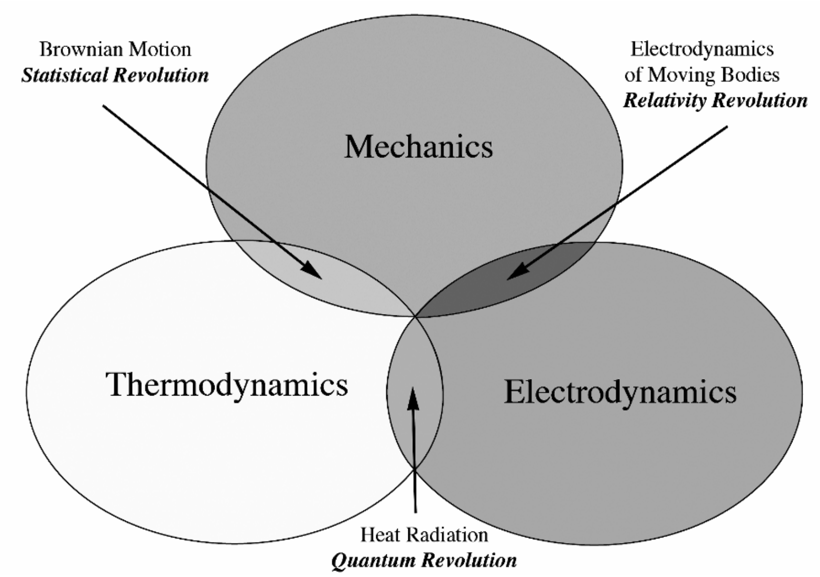

Figure 1: Revolutions at the Borderline Problems of Classical Physics

The most oldest structure of physics is mechanics, established as a major body of knowledge in the early modern period, following a tradition reaching back to antiquity, and brought into its classical form in the eighteenth and nineteenth centuries. Among its elementary mental models is, for example, a lever moveable around a fulcrum that enables a large weight to be lifted by a small force. Among its basic concepts are those of space, time, velocity, acceleration, force, momentum, energy, and mass. Among its outstanding objects of study are the motion of fall, planetary motion, motion along an inclined plane, collisions between elastic and inelastic bodies, and the motion of a pendulum. Its representational tools include, apart from ordinary and technical language, those of mathematics and, in particular, the language of ordinary differential equations.

By the end of the nineteenth century electrodynamics (including optics) and thermodynamics had been established by scientists such as James Clerk Maxwell, Heinrich Hertz, and Hendrik Antoon Lorentz, on the one hand, and Joseph Thomson and Rudolf Clausius, on the other, as specialized knowledge structures similar to that of classical mechanics. In fact, although they share some of their most fundamental concepts such as those of space and time with classical mechanics, they also comprise characteristic mental models, concepts and theories distinct from those of mechanics and transmitted within their own subdisciplinary traditions.

Electrodynamics deals not only with the electric and magnetic interaction of material bodies but also with electromagnetic radiation such as light. Among its elementary mental models is that of a charged body generating an electric field in its vicinity. Among its basic concepts are those of conductor, dielectric, electric charge, electric current, voltage, electric and magnetic field. It accounts for physical processes such as the attraction or repulsion between two charged particles, the generation of a magnetic field by a current, and the induction of voltage by a conductor moving in a magnetic field. Partial differential equations and vector analysis represent the prevalent mathematical formalisms used in electrodynamics.

Thermodynamics was formulated as an axiomatic theory in the mid-nineteenth century by Thomson and Clausius; its objects are all physical processes involving heat and its transformations. Among its elementary mental models is that of a heat-converting engine. Among its fundamental concepts are heat, temperature, energy, entropy, pressure, and volume. Physical processes studied by thermodynamics are the behavior of gases with changes of temperature, pressure, or volume, and the transformation of thermal into mechanical energy and vice versa. Partial differential equations are also an important mathematical tool for expressing the laws of thermodynamics.

The three-partite division of classical physics into mechanics, electrodynamics, and thermodynamics did not result in peaceful coexistence, let alone in a stable harmony of these branches and their theoretical foundations.[21] There were many open problems, regarding both the mutual relation and the internal structure of these sub-disciplinary bodies of knowledge. In fact, even within each field of research, a number of alternative theoretical formulations competed with each other. These alternatives distinguished themselves, for instance, by a different deductive organization of the knowledge, by modifying some aspects of the basic conceptual framework, by focussing on different paradigmatic objects, or by asserting different quantitative laws for some phenomena, which sometimes could be empirically tested.

2.2 Foundational Problems of Classical Mechanics

Even the conceptual foundations of classical mechanics were still being debated in the nineteenth century. Since this debate was particularly relevant to the later development of relativity theory, we will take a closer look at some of the foundational problems of classical mechanics as they were seen at the time. The establishment of physical theories other than mechanics demonstrated to students of mechanics in this period that its foundational concepts could not simply be considered as being intimately linked with the structure of human reasoning about nature, as was believed in the eighteenth century under the impression of the enormous success of Newtonian mechanics, by scientists and philosophers such as Jean le Rond d'Alembert and Immanuel Kant. Also the progress of research in mechanics itself, as exemplified by the contributions of Leonard Euler, Joseph Louis Lagrange, William Rowan Hamil-

21 Here the notion of classical physics is used as a historiographically descriptive term; for its contemporary use, see (Staley 2005).

ton, and others in the eighteenth and early nineteenth century, opened up new perspectives on its theoretical and conceptual foundations.

One elementary mental model of the Newtonian theory of motion is that of a discrete material particle moving in empty space (also called "mass point"); mechanical problems could, in general, be considered as being explicable as complex cases of this basic model. Another basic mental model is the "acceleration-implies-force model," introduced above. This model implies that the motions of material bodies can be divided into two classes, those which require a causal explanation by a "force," and those, called "inertial motions" or motions governed by the "principle of inertia," which do not require such an explanation. The latter class of inertial motions includes the state of rest and the rectilinear and uniform motions of particles, whereas all accelerated motions are to be considered as being caused by a force. Since the same motion may be accelerated or uniform depending on the point of reference, this distinction is only well defined with respect to a given laboratory that is located at a specific place at a specific time and that thus represents a "frame of reference." In Newtonian mechanics, the reference frame to be chosen is either the "absolute space" or any frame of reference in rectilinear uniform motion with respect to it, since such a motion makes no difference to the causal classification introduced above. For the frames of reference that are in rectilinear uniform motion with respect to absolute space the designation "inertial frames" was introduced in the late nineteenth century.[22] The conclusion that the laws of Newtonian mechanics should be equally valid in any one of these inertial frames is usually designated as the "Galilean principle of relativity."

If a body is accelerated with respect to an inertial frame, it must be subject to a force exerted upon it by one or more other bodies. The magnitude of its acceleration depends on the magnitude of the force, but also on the resistance with which it reacts to the force. This resistance is, in classical mechanics, an intrinsic, characteristic property of a body called its "inertial mass." In Newton's original conception it was understood as being proportional to the number of elementary particles composing the body.[23] Apart from this inertial mass, bodies also possess another kind of mass according to Newtonian mechanics, their "gravitational mass." In contrast to the inertial mass, the gravitational mass does not measure a resistance to the action of a force but rather represents itself the origin and source of a force, that of gravitational attraction, which, according to Newton's law of gravitation, is proportional to the product of two gravitational masses attracting each other and being inversely proportional to the square of their distance. Newton claimed that a single body may also have an inertial mass, while it possesses gravitational mass only in so far as it interacts with other bodies.[24] But in spite of the very different conceptual function of the two kinds of masses in Newtonian mechanics, they turn out to be exactly proportional to each other and can thus be considered identical (in the following we will therefore simply

22 See (Lange 1883, 1885a, 1885b, 1886).
23 See (Newton 1999, 23–24, 626).
24 See (Newton 1999). For discussion, see (Freudenthal 1986).

speak of an "equality" of inertial and gravitational mass).[25] For the motion of free fall caused by gravitational attraction, this remarkable coincidence has the peculiar consequence that, independent of their mass, all bodies fall with the same speed. In fact, the strength of the gravitational force exerted upon them, which is proportional to their gravitational mass, changes in exactly the same way as the magnitude of their resistance against this force, which is given by their inertial mass.

Even in Newton's time, the conceptual foundations of his theory of mechanics did not remain undisputed. In the nineteenth century, both the further progress in physics mentioned above and the development of a philosophy of science critical of its metaphysical aspects renewed the interest in foundational questions of mechanics. Among the problems discussed were the meaning of Newton's notion of absolute space and the difficulty of identifying the inertial reference frames in which solely the laws of classical mechanics are valid. Since absolute space itself is not directly accessible to experience, an inertial frame of reference can also only be indirectly identified by studying observable physical processes. If, for instance, in a given reference frame the bodies that are not subject to forces are those which are either at rest or in uniform and rectilinear motions, then the given frame of reference is indeed an inertial frame. But, according to the acceleration-implies-force model, the concept of force itself as a cause of motion is only indirectly defined by its connection to the concept of acceleration, which represents its effect. Therefore the presence or absence of forces can in general only be judged by observing and classifying the kind of motions a system of bodies is performing. But this operation in turn depends on the prior establishment of an inertial frame, so that one has apparently entered a vicious circle.

In practical applications of classical mechanics, however, the situation turns out to be less dramatic since here one mostly deals with forces produced by concrete material arrangements, such as a stretched elastic spring, under conditions in which other forces are either known or assumed to play no significant role. The role of inertial frames of reference for the actual functioning of mechanical knowledge may therefore be conceived as that of "laboratory models," i.e. mental models of physical systems, such as a laboratory with an experimental arrangement, for which the laws of classical mechanics turn out or are assumed to be valid. In practice, a laboratory model might therefore also be embodied by systems that are evidently accelerated as is in fact the case for all terrestrial laboratories. But considerations of this kind are hardly suited to respond to the foundational problems as raised by critics of mechanics, in particular in the second half of the nineteenth century. For instance, according to Newton, absolute space should represent an inertial frame of reference even when only a single body is present in the universe. But can it really make a physical difference, in the sense of the presence or absence of forces acting on the single body, whether or not that body is or is not accelerated in an otherwise empty universe?

25 This equality was discussed in the nineteenth century by Heinrich Hertz as a "miraculous riddle," ("wunderbares Räthsel"), see (Hertz 1999, 122).

Critics of mechanics such as the philosopher Ernst Mach argued that it makes no sense at all to apply the concept of motion or even of inertial mass to a single body.[26] He rather suggested that the entire theory of classical mechanics should be reformulated in terms of the relative motions of bodies with respect to each other and that also the concepts of inertial mass and inertial frame should be redefined along these lines. He argued, in particular, that the centrifugal forces curving the surface of water in a rotating bucket should not, as Newton suggested, be interpreted as being due to an effect of accelerated motion with respect to absolute space, but rather as being due to relative motion with respect to the other bodies in the universe ("Mach's bucket"). A few scientists close to Mach's ideas even demanded that the concept of an inertial frame should be given up entirely since a laboratory that is not subject to external forces and thus capable of providing a material embodiment of an inertial frame of reference cannot exist anywhere in the universe, in particular in view of the universal presence of gravitational interaction.[27] They argued that any frame of reference should be equally suitable for formulating the laws of mechanics. But their demand required a fundamental revision of Newtonian mechanics including the prediction of new effects for which they had little empirical evidence. Following Mach's interpretation of the Newtonian bucket experiment, they conceived, for instance, the effects observed in a rotating laboratory as not being due to the centrifugal forces arising because of its acceleration with respect to absolute space or to the inertial frames of classical mechanics. They rather interpreted such "inertial forces" as a manifestation of an hitherto not well understood interaction between physical masses in relative motion with respect to each other, those of the laboratory and those of the distant stars. But attempts to find direct, terrestrial empirical evidence of such an interaction failed.

Other critics of Newtonian mechanics neither worried about the concept of inertial frame nor demanded an entirely new mechanics but still found themselves dissatisfied with the Newtonian notion of force and the role of the interaction between mass points as a basic model of classical mechanics. The development of continuum mechanics and of analytical mechanics in the eighteenth and early nineteenth century in fact offered alternatives to these fundamental assets of mechanics in its original, Newtonian formulation.[28] Most mechanical arrangements do not resemble collections of point-like masses interacting with each other at a distance, as is the case for planetary astronomy. The interaction between the parts of a mechanical arrangement, such as a machine for instance, is realized by the geometric constraints that the arrangement imposes on the motion of its parts. A body moving along an inclined plane is constrained by the shape of the plane to follow its slope, or, to give another example, the motion of a bead along a curved wire is constrained by the shape of the wire. The deviation of this motion from rectilinearity can, in principle,

---

26 See (Mach 1921, chap. 2, sec. 6) or for an English version, (Mach 1960, chap. 2, sec. 6). For further discussion, see "The Third Way to General Relativity" (in vol. 3 of this series).

27 For extensive discussion, see "The Third Way to General Relativity" (in vol. 3 of this series).

28 For a survey see (Pulte 1989; Lützen 1993).

be explained by reconstructing the Newtonian forces exerted by the wire on the motion of the bead, a task that may become rather involved. But it appears much more natural and also more practical to account for the shape of its trajectory directly by the curvature of the wire, in particular as it turns out surprisingly that such an analysis may yield rather simple laws of motion which, under certain conditions, can be interpreted as a generalization of the principle of inertia.

Analytical mechanics as developed by Leonard Euler, Jean-Baptiste le Rond d'Alembert, Lagrange, and others achieves such an explanation by incorporating the geometric constraints of motion, such as the shape of the wire, into the coordinates used to describe the motion, for instance of the bead along the curved wire. In a suitable curvilinear coordinate system, the curved wire may even be described by what is, in these coordinates, the equivalent of a straight line, now being described in terms of a "variational principle" as the shortest or, more generally, an extremal path in such a coordinate system. The motion of the bead may then be considered as a "natural motion" in the sense of generalization of force-free inertial motion, at least when no other forces, apart from those exerted by the geometric constraints, are present. In short, the description of motion in terms of a Newtonian equation of motion on the basis of the acceleration-implies-force model can be replaced by a description on the basis of the "constrained-motion model" according to which the properties of a motion are explained, at least in part, by the geometry of the constraints imposed on the motion. The forces exerted by these constraints can be neglected as they are accounted for by the introduction of suitable coordinates adapted to the problem at hand. In this way, a considerable step was taken towards the elimination of the concept of force as a foundational concept of classical physics. In order to ban it completely from mechanics, however, one would have to conceive of all forces as being due to rigid constraints. An attempt in this direction was undertaken in the late nineteenth century by Heinrich Hertz who reformulated classical mechanics entirely in terms of such constraints, including invisible ones that were supposed to replace the forces known from ordinary mechanics.[29] However, because of the speculative character of the invisible constraints, this reformulation of classical mechanics did not find many followers.

2.3 Invisible Mechanisms and the Expansion of Mechanics

Hertz's rigid constraints may serve as an example for an "invisible mechanism." Such mechanisms are a characteristic tool for extending the range of applicability of a domain of knowledge beyond the set of problems to which it is directly applicable. Invisible mechanisms are usually conceived in terms of mental models from familiar territories of physical knowledge, in particular also from intuitive physics, such as the model of a rigid body or of a fluid. Under the assumption that what they actually represent is, for a good reason, only partly or indirectly accessible to sense experience,

29 See (Hertz, 1894, 1956).

as is the case for atoms, for instance, they may become the fundamental constituent of an all-encompassing theoretical framework such as atomism. This type of extension of a conceptual framework beyond its immediate range of application was a well-established practice within the tradition of mechanics since the early modern period. In fact, the emerging new science of mechanics had to compete with the all-encompassing Aristotelian word view embraced by the Church, a circumstance that proved to be a major challenge encouraging the elaboration of a mechanical world-view.[30] Furthermore, for a considerable period of time mechanics was without serious alternatives as a theoretical foundation of physics. In any case, the construction of invisible mechanisms involving mechanical models and knowledge remained a common practice throughout the reign of classical science.

The explanation of heat by the motion of atoms in the nineteenth century is a well-known example for such an extension of mechanics beyond its immediate range of application.[31] According to the kinetic theory of heat atoms were conceived according to the mental model of the discrete, more or less rigid bodies of our macroscopic experience, but were taken to be unobservable due to their smallness. Only their bulk effects such as heat or pressure were assumed to be directly accessible to sense experience. The kinetic theory of heat succeeded in representing the relation between the heat, temperature, pressure, and volume of a gas, for instance, by the relation between the motion of these atoms, their energy, momentum, number, etc., that is, by relations determined by mechanical and statistical laws. In this way, mechanics could be conceived as offering a theoretical foundation for thermodynamics as well. Since the early days of classical physics, invisible mechanisms were also considered in order to explain actions at a distance such as that of gravitation, electricity, magnetism, or the transmission of light, which, from the point of view of ordinary experiences with mechanical arrangements, appeared as particularly mysterious.

Invisible mechanisms for the explanation of the transmission of light, for instance, were conceived in terms of the motion of minute particles (in particular by Newton and his immediate followers) but also (first by Huygens and then by most physicists in the second half of the nineteenth century) in terms of the motion of an invisible continuous medium, the optical "aether."[32] The latter was understood according to the mental model of a medium such as water or air, as is familiar from intuitive mechanics. These media demonstrated how the transmission of a physical effect—like a water wave or sound—could be conceived without the transport of material, just by the propagation of a local perturbation from one point to the next. An invisible mechanism based on the model of a continuous medium was therefore, at least in principle, a plausible candidate for explaining the transmission of those physical effects which are not associated with any noticeable transport of material, such as the actions at a distance mentioned above. In the case of light, such an explanation

30 See, e.g., (Renn 2001; Montesinos and Solís 2001).
31 For a historical survey, see (Brush 1976a, 1976b).
32 For historical discussions, see (Cantor and Hodge 1981; Buchwald 1989).

received decisive additional support in the first half of the nineteenth century by the discovery of the wave properties of light, which follow naturally from its explanation as a perturbation of the optical aether.

2.4 The Problem of the Motion of the Optical Aether

By its very nature, an invisible mechanism has more properties than those which are directly involved in the physical processes to be explained by it. Even though, for instance, the optical aether itself was assumed not to be directly accessible to ordinary mechanical experience, it follows from its conceptualization as a mechanical medium that it must be in motion or at rest with respect to the macroscopically observable bodies immersed in it. Now it turns out that, for the optics of moving bodies, the different possible answers to the question of the state of motion of this invisible medium even have distinct observable consequences. In principle, it is possible that the aether locally shares the motion of a body (an assumption proposed by George Gabriel Stokes), or that it remains entirely unaffected by it (an assumption pursued by various scientists such as Thomas Young, Augustin Jean Fresnel, and Hendrick Antoon Lorentz), or that it is partially dragged along by the motion.[33]

A strong argument for an immobile aether was the phenomenon of stellar aberration known since the eighteenth century. If one observes the position of a star in the course of the year from different positions along the orbit of the earth, it is subject to certain regular variations, which if the star is at great distance cannot be due to its parallax, i.e., to the changing line of vision. These variations can, as James Bradley recognized at the beginning of the eighteenth century, rather be explained by the fact that the speed of light originating from the star is composed with the speed of the earth's motion in such a way that the starlight seems to originate from different directions in dependence on the direction of the earth's motion. However, on closer inspection, this simple explanation of aberration requires two specifications: first, if light is assumed to be carried by the aether, the composition of velocities explaining the aberration works in a straightforward manner only if it is further assumed that the aether is immobile; second, if propagation of light through a medium such as the glass of a telescope or water is taken into account, one has to deal with the fact that the speed of light in such media differs from that in the aether so that the effect of aberration should change if stars are observed through them. Observation shows, on the other hand, that aberration is completely independent of whether or not light passes through a transparent medium.

At the beginning of the nineteenth century, Fresnel explained this fact by assuming that transparent media, which move along with the earth through an otherwise immobile aether, carry it along with a certain fraction of their speed. But what exactly does this partial drag of the aether mean? Can it perhaps be observed directly or is it

33 For an extensive historical discussion of the problem of the optics and electrodynamics of moving bodies, see (Janssen 2004; Stachel 2005).

merely a hypothetical compensation in order to explain the absence of deviations from the normal aberration? This question was at the center of an experiment performed by Hippolyte Fizeau in 1851. He studied the propagation of light in flowing water in order to determine the variation of the speed of light in dependence on the speed of the moving medium. His experiment yielded a relation between the speed of light in water and the speed of the flowing water, which indicated a slight drag of the aether by the water, thus roughly confirming Fresnel's aether-drag hypothesis. Towards the end of the nineteenth century, the assumption of an immobile aether became generally accepted as the most plausible assumption about its state of motion, in particular after optics was included in Maxwell's electromagnetic theory, a development to which we shall return. On the basis of this assumption the problem then was to explain the apparent slight drag indicated by the peculiar way in which the speed of light in the flowing water was composed of the ordinary speed of light in the water at rest and the speed of the flowing water.

But a theory based on the assumption of an immobile aether faced much more serious problems. An immobile aether had to be conceived as providing itself a universal frame of reference for the motion of all other bodies, an embodiment of Newton's absolute space as it were. In short, it turned out that electromagnetism, as was the case for mechanics, also had unavoidable "cosmological" consequences. As the aether is a medium with concrete physical properties, the motion of a body with respect to this aether frame should somehow have noticeable effects. Now, if that is indeed the case, the aether model cannot be compatible with the principle of relativity of classical mechanics, according to which physical laws should be the same in two laboratories representing inertial frames and which are moving with rectilinear and uniform motion with respect to each other. Since the aether model entails that the speed of light with respect to the aether must always be the same, independently of the state of motion of the body emitting the light, such a violation of the relativity principle turns out to be an unavoidable consequence of this model. If, for instance, the speed of light is measured in two laboratories in relative motion with respect to each other, the two measurements cannot yield the same result, as at least one of the two laboratories must necessarily move with respect to the aether. An even simpler arrangement would be the measurement, in a single terrestrial laboratory, of the speed of a light ray once propagating in the direction of the earth's motion through the aether and then of the speed of the same ray when deflected by a mirror so that it propagates perpendicular to the direction of the earth's motion. An experiment along these lines was in fact performed by Michelson and Morley with the result that the speed of light is unaffected by the motion of the earth through the aether. Here then the explanation of optical effects by an aether model met with a very serious paradox.[34] On the one hand, the phenomenon of aberration and Fizeau's experiment required the aether to be essentially immobile, while, on the other hand, motion

34 For discussion, see (Janssen and Stachel 2004).

through the aether did not have the physical effects it should have had according to the aether model.

2.5 Foundational Problems of Classical Electrodynamics

In the course of the development of electrodynamics, light was recognized by Maxwell as a particular case of electromagnetic radiation, and optics henceforth became part of electrodynamics. As the electrodynamic theory founded by Maxwell was also based on an aether model, the electrodynamic aether now took over the role of the optical aether. The problems of the motion of the optical aether discussed above therefore became part of a knowledge area commonly referred to as the "electrodynamics of moving bodies." Although the aether represents an invisible mechanism based on mechanical concepts, it turned out to be extremely difficult, if not impossible, to construct a concrete mechanical model of the aether reproducing all physical properties required by the wealth of electromagnetic and optical experiences covered by Maxwell's theory. Even just the explanation of the properties of light required an aether that has the mechanical properties of an incompressible, jelly-like elastic medium and yet represents no obstacle to the motion of huge physical masses such as the earth or the sun.[35]

In fact, however, the aether could serve at least some of its essential explanatory functions, such as rendering comprehensible the transmission of electromagnetic waves, even without being exhaustively described in terms of the laws of classical mechanics. Certain aspects of the aether could instead be captured by the laws of electrodynamics themselves. Thus one could imagine that in the presence of an electric charge, the aether changes its state like an ordinary non-conducting, dielectric medium, which, according to the laws of electrodynamics, becomes "polarized." In this way, however, the aether model ceased to serve as a tool for linking electrodynamics to a mechanical foundation. It rather became itself part of an independent foundation of electrodynamics but nevertheless retained some of the properties due to its roots in intuitive physics, for instance, of having a state of motion—*this being the state of rest*.[36]

By the end of the nineteenth century the most developed theory of electrodynamics —by Hendrik Antoon Lorentz—was in fact based on an aether model whose dynamical behavior was entirely governed by electrodynamical laws, while it was assumed to be absolutely stationary.[37] Lorentz's aether was not even subject to Newtonian laws of motion. In fact, it exerts forces on bodies within it—without being affected itself by a counter-force as required by Newton's law of the equality of action and reaction. In order to describe the electromagnetic behavior of ordinary

35 For studies concerning the concept of aether in classical physics, see (Whittaker 1951–53; Hirosige, 1966; Schaffner, 1972; Buchwald 1985; Darrigol 1994; Warwick 1995; Janssen 2003).

36 The observation that the assumption of the aether being immobile amounts to the assignment of a mechanical property is due to Einstein, see (Einstein 1920).

37 For studies of Lorentz's aether theory, see (Hirosige 1969; Janssen 1995).

matter, which cannot escape the laws of mechanics, Lorentz's theory employed another invisible mechanism in addition to the aether. Matter was conceived to be made up of elementary particles carrying electric charges. While the particles themselves were modelled after the discrete bodies of ordinary mechanical experience and were hence also subject to the laws of mechanics, their charges were supposed to interact with the aether according to a mechanism similar to the interaction between charges and dielectric medium in macroscopic electrodynamics. The presence of charges generates a particular state of the surrounding aether, corresponding to an electromagnetic "field," which then propagates through the aether and thus can affect other charges. The introduction of the field concept had been the result of reflection on the experiments by Hans Christian Oerstedt, André-Marie Ampère, Michael Faraday, and others which showed that interactions involving the environment beyond the connecting line between two particles were characteristic of electromagnetic effects.[38] According to Lorentz's theory, charges interact with each other only via the aether, by generating fields and by sensing a "ponderomotive force" exerted by the field upon the elementary particles carrying the charges. By way of its complicated invisible mechanisms, which refer to two entirely distinct entities, the aether and the elementary particles, Lorentz's theory achieved an integration of the laws of electrodynamics with those of mechanics, albeit at the price of a fundamental dualism.

2.6 The World Pictures of Classical Physics and the Emergence of Borderline Problems

The enormous success of late nineteenth century electrodynamics in explaining physical properties of matter as well as of radiation stimulated some contemporary scientists to search for an electromagnetic foundation of all physics.[39] One could in fact imagine invisible mechanisms, now conceived in terms of electromagnetic processes, offering mental models to understand experiences hitherto explained in terms of mechanics. For instance, it is well known from electrodynamics that an electrically charged body, set in motion by some force, generates a magnetic field in its vicinity which results in an increased resistance against the moving force. Since this resistance adds to the inertial resistance, contemporary scientists wondered whether this process might perhaps serve as a model to understand the concept of inertial mass in purely electromagnetic terms as a kind of resistance against a moving force, thus underpinning a central concept of mechanics with an electromechanical foundation.

Other features of classical mechanics were even more suited to speculations about a possible electromagnetic origin. Since in the case of electricity, magnetism, and light, electrodynamics had been so successful in accounting for actions at a distance by an aether model, it was plausible to also attempt an explanation of the gravita-

---

38 For a survey, see (Darrigol 2000). See also (Steinle 2005).

39 For historical discussion of the electromagnetic foundations of physics, see (Jungnickel and McCormmach 1986a, 227–245).

tional action at a distance by means of the same intervening medium.[40] Newton's law of gravitational attraction between two masses even has the same form as Coulomb's law for the force between two electrical particles at rest. In both cases the force is inversely proportional to the square of the distance between the particles and proportional to the product of the masses in the first case, and the charges in the second. On the background of the electromagnetic aether model, in particular as developed by Lorentz, it was therefore natural to interpret the mass as representing a "gravitational charge" accounting for a perturbation of the surrounding aether and resulting in a "gravitational field," which is then transmitted through the aether and thus acts upon another gravitational charge.

Apart from the difficulty in developing a consistent model for an aether carrying such a gravitational field, either in addition to the electromagnetic fields or somehow produced by them, an aether model of gravitation also implied hitherto unknown features of the gravitational interaction. Consequences of an aether model for gravitation such as a finite speed for the transmission of gravitational interactions and the possible existence of gravitational waves were not only new with respect to classical mechanics but also found little support in the empirical knowledge on gravitation available at the turn of the century. Developing an aether model for gravitation was hence an unwieldy and speculative task comparable to constructing the entire theory of electrodynamics when only Coulomb's law of electrostatic interaction is known.[41]

Scientists in the second half of the nineteenth century not only attempted to construct an electromagnetic foundation of physics but also explored the possibility of extending the theoretical foundation of thermodynamics to the entire body of knowledge of classical physics.[42] The starting point for this line of research was the observation that in all branches of contemporary science the concept of energy played a central role and that different kinds of energy may be transformed into each other, mechanical energy into thermal energy, chemical energy into electrical energy, and so forth. The aim of this research program was therefore to understand all physical, if not all natural processes as transformations of energy. In this way, by overcoming the separation of the objects of the different branches of science, such as bodies in motion, electricity, or heat, all now conceived as different manifestations of energy, the separation of the branches themselves should also be superseded.[43]

In short, the different theoretical foundations of late nineteenth-century physics could be and were in fact conceived as being potentially alternate foundations for the entire body of knowledge of classical physics. Contemporary scientists thus discussed a mechanical "world picture," an electrodynamic world picture, and a thermodynamic world picture. Nevertheless, the dynamics of the intellectual development of physics in this period continued to be governed mainly by the many concrete

40 For further discussion, see the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics" (in vol. 3).

41 This observation is due to Einstein, see (Einstein 1913 1250).

42 For a historical discussion, see (Jungnickel 1986a, 213–227).

43 For historical discussion, see (Kuhn 1977, chap. 4, 66–104; Elkana 1974).

unsolved problems—both theoretical and empirical in character—on which the scientists were working. By the end of the century some of these problems also emerged as being related to more than one theoretical foundation. One such problem was the electrodynamics of moving bodies, which required the application of both the laws of electrodynamics and the laws of motion of mechanics. Another example of this class of borderline problem is heat radiation, which required the application of both the laws of radiation—covered by the laws of electrodynamics—and the laws of thermodynamics. Since these problems fall under the range of application of two different theoretical foundations, they represented not only a potential locus of conflict between fundamentally different conceptual frameworks, but also points of departure for their integration into more developed theoretical frameworks. Thus Planck's law of heat radiation was later seen as the first decisive contribution to quantum theory,[44] while the electrodynamics of moving bodies became, as we shall see, the core of the special theory of relativity.

At first sight, however, the problems of the optics and electrodynamics of moving bodies, as discussed previously, may merely appear to be due to the unfortunate choice of a mechanical aether as an invisible mechanism for electrodynamic explanations. But even Lorentz's renunciation of ascribing any mechanical properties to the aether did not help avoid the paradoxes of the propagation of light through the aether described above. He therefore had to modify his otherwise very successful theory of electrodynamics by additional assumptions about the effect of the aether on bodies moving through it in order to explain the lack of any noticeable effect due to the motion of a terrestrial laboratory through the stationary aether. If one considers, on the other hand, the absence of any noticeable "aether wind," not only from the perspective of the internal problems of electrodynamics, but from that of classical physics as a whole, it emerges in fact as a borderline problem between electrodynamics and mechanics. The absence of any aether wind due to the translatory motion of a laboratory through the aether is simply a confirmation of the principle of relativity of classical mechanics, according to which such a motion should indeed be unnoticeable, at least if acceleration is neglected. But this confirmation takes a form which itself is not compatible with classical mechanics, since the absence of an aether wind requires that the motion of the laboratory has no effect on the speed of light measured in the laboratory. This conclusion is in direct conflict with all ordinary experiences with the speeds of moving bodies, whose magnitude depends, of course, on the state of motion of the observer performing the measurement. The resolution of this paradox eventually required the abolition of the aether model rooted in intuitive physics, and with it, a complete revision of the concepts of velocity, space, and time.[45]

44 See (Büttner et al. 2003).

45 For discussion of the electrodynamics of moving bodies as a problem of classical physics, see also (Renn 2004, Rynasiewicz and Renn 2006).

2.7 The Crisis of Classical Electrodynamics

The existence of partially distinct conceptual frameworks within classical physics provided the substratum for a multiplicity of perspectives not only on its foundational questions but also on various specific research problems, and in particular on the borderline problems mentioned above. We have characterized the electrodynamics of moving bodies as a borderline problem, bringing to light a basic conflict between the notion of electromagnetic aether and the relativity principle of mechanics. But from within the conceptual framework of electrodynamics this conflict may have been perceived differently by contemporary scientists, namely as an unsolved puzzle of perhaps even minor significance. The undetectability of an aether wind could thus appear to them not so much a confirmation of the well-known relativity principle of classical mechanics but rather the net result of several causes conspiring to hide the presence of effects due to the motion of the earth through the aether.

Correspondingly, it was natural for scientists in the late nineteenth century to attack this problem by exploiting the conceptual and technical resources of electrodynamics. Lorentz introduced, in addition to assuming a "local" time characteristic of a physical system moving with a certain speed through the aether, the hypothesis of a length-contraction of bodies along the direction of their motion ("Lorentz contraction") in order to explain the "null-effect" of the aether wind on electrodynamic and optical measurements. The exclusive aim of this hypothesis was to introduce a mechanism compensating the expected but unobserved effects of an aether wind; this consideration also determined the quantitative specification of the length-contraction. Lorentz's qualitative justification for his hypothesis was the behavior of the molecular forces within bodies under motion through the aether, which he tentatively assumed to be analogous to that of the electric and magnetic forces.[46]

From the perspective of the mechanical framework of classical physics the same problem appears quite differently, as indicated above. The carefully and with much experimental effort established null effect, which was so difficult to explain within an electrodynamic theory based on an aether model, turned out to be simply another confirmation of the time-proven relativity principle of classical mechanics. Consequently, it was natural, within this framework, to discard the aether model as the source of the difficulties and to construct instead an electrodynamics based on the relativity principle. While for such an approach the null effect represented no challenge at all, it was confronted, on the other hand, with the task of explaining, in its terms, results that had constituted the triumph of an aether-based electrodynamics and optics since the early nineteenth century, such as the interference of light waves or the Fizeau experiment discussed above.

Since in the beginning of the twentieth century the wave theory of light encountered difficulties, also in other fields of enquiry but in particular regarding the interaction of light and matter, it seemed worthwhile to several scientists of this period, most

46 See (Lorentz 1892, 1895). For discussion see, e.g., (Janssen 1995, sec. 3.2).

notably to Albert Einstein and Walter Ritz, to tentatively reexamine and modify Newton's corpuscular theory of light as a framework within which to explain the new empirical knowledge.[47] Indeed, a corpuscular emission theory of light succeeded not only in accounting for the role of the color of light when setting free electrons of the irradiated matter. This effect was difficult to explain for a wave theory but was concisely described by Einstein's hypothesis of corpuscular quanta, whose energy is related to the color of light.[48] An emission theory was also a suitable basis for incorporating the relativity principle into the foundations of a theory of radiation and perhaps of electrodynamics in general.

The velocity of the light particles should not differ from the way velocities of other particles behave since its magnitude must, of course, depend on the state of motion of the reference frame in which it is measured. The affirmation of a "constancy of the speed of light" can, in this conceptual framework, only refer to the speed measured with respect to the source of light and not to any property independent from the frame of reference. There was, in particular, no need for any "absolute" frame of reference such as that provided by a stationary aether in order to give meaning to this constancy of the speed of light. But apart from the extraordinary difficulty in reconstructing electrodynamics and optics on the basis of an emission theory of light, this approach encountered additional obstacles in explaining other well-established aspects of scientific knowledge such as the properties of reflected light.[49] The available shared scientific knowledge thus decided against an emission theory of light although it evidently represented a promising approach to the special problem of the electrodynamics of moving bodies.

However, also an assessment of Lorentz's solution to this problem depended on the extent to which shared knowledge was taken into account for its evaluation. In fact, his proposal appears even more shaky when viewed not only from the internal perspective of classical electrodynamics but also in the light of new knowledge generated by another borderline problem: heat radiation. In the early twentieth century, the experimental and theoretical studies of heat radiation were recognized as being in conflict with an aether model such as the one assumed by Lorentz. According to the so-called "equipartition theorem" of the kinetic theory of heat, such an aether in thermal equilibrium with matter, should carry electromagnetic radiation of all possible frequencies, with each frequency being attributed an equal share of the total. In fact, the velocity of the light particles should not differ. But since there is, in principle, no limit to the frequencies at which the aether can vibrate, contrary to the case for ordinary matter, the aether with its infinite degrees of freedom will eventually absorb all the energy of a physical system so that a thermal equilibrium between aether and matter becomes impossible.[50]

Hence neither the conceptual framework of electrodynamics nor that of mechanics offered a straightforward solution to the puzzles raised by the electrodynamics of moving bodies. Nevertheless, within the first framework—an aether-based electrodynamic field theory—it was at least possible to develop a somewhat roundabout solution by twisting and stretching this framework to its limits, which is what Lorentz did with his ever new additional auxiliary hypotheses. However, due to this protraction of the theory by auxiliary hypotheses, not only its anchoring in an aether model, but also its relation to the conceptual foundation of classical physics, had become loose. In particular the introduction of special variables describing lengths and time intervals in a moving system augmented the formalism of Lorentz's electrodynamics by elements for which a direct physical interpretation in terms of this foundation had become difficult. And yet the formulae developed by Lorentz to describe the electrodynamics of moving bodies were themselves compatible with all available knowledge, even with the principle of relativity from mechanics, which was otherwise at odds with the foundations of an aether-based electrodynamic theory.

2.8 Birth and Early Development of the Special Theory of Relativity

The elaboration of a consistent electrodynamics of moving bodies on the basis of an aether model was achieved mainly due to the work of Lorentz and Poincaré. As pointed out, the final results of their efforts constituted a new nucleus of knowledge whose linkages to the conceptual foundation of classical physics were problematic. Of course, precisely how problematic these linkages actually appeared to contemporary scientists depended on the range of shared knowledge they could or wished to take into account for their judgement, as we can see from the relevance to this judgement of such apparently unrelated phenomena as the thermal equilibrium of heat radiation. In other words it was the knowledge of classical science as a whole that provided a resource for reflection that could be used in different ways. Such reflections took on the form of different "perspectives" on this knowledge.

In the case at hand, it was precisely the decoupling from the roots of classical physics of the new body of knowledge constituted by the electrodynamics of moving bodies that created the possibility of a novel perspective on the conceptual foundations of physics, in addition to the perspectives rooted in mechanics, electrodynamics, and thermodynamics, respectively. In fact, as we have seen, Lorentz's auxiliary variables describing space and time intervals in a moving physical system could not fully derive their meaning from the concepts of space and time as they were basic to classical physics. Therefore, if the outcome of Lorentz's efforts was itself being considered as anchoring a conceptual framework, the new space and time variables could be conceived as gaining their meaning, not via a specification of these general classical concepts, which anyway was problematic, but primarily from their role within the electrodynamics of moving bodies. But this limited body of specialized knowledge

50 See the discussion in (Einstein 1905b).

was, on the other hand, in itself insufficient to equip the new space and time variables with the meaning of general space and time concepts, at least as long as their implicitly defined meaning within this body of knowledge could not be related to the more universal meaning of these concepts in physical thinking.

Lorentz's theory thus offered a natural starting point for a process of reflection that is repeatedly observable at decisive moments in the history of science. This process implies that marginal elements of a complex architecture of knowledge torn asunder by inner tensions become the starting points for a reconstruction as a result of which a new structure emerges that is, however, essentially composed of the building blocks already available. This process may be designated as a "Copernicus Process." Indeed conceptual turnovers unfold in a similar way to the revolution of Copernicus, who created a new world system by placing an initially marginal celestial body—the sun—into the center, while, instead of starting with a *tabula rasa,* retaining the previously elaborated complex machinery of planetary astronomy. Similarly, the central role of the aether and peripheral role of the new variables for space and time in Lorentz's theory is essentially reversed in special relativity; here the concept of aether no longer plays a role while Lorentz's auxiliary quantities become the new foundational concepts of space and time. Most mathematical details, on the other hand, in particular the so-called Lorentz transformations between reference frames in uniform motion with respect to each other, remain unaffected by this displacement of the conceptual center.

The special theory of relativity, published in 1905 by Einstein,[51] shows that it is indeed possible to embed the new space and time variables of the electrodynamics of moving bodies within such general physical concepts of space and time, with the consequence of also restructuring these general concepts. Einstein carefully defined space and time measurements in a given frame of reference with the help of an elementary procedure conceived in terms of measuring rods and clocks. This procedure involves only a minimum of well-defined physical assumptions, such as the existence of rigid measuring rods, the possibility of synchronization procedures between clocks, etc. In fact, it is the peculiar feature of this procedure that, on the one hand, it is compatible with and makes precise some essentials of our ordinary understanding of space and time measurements but that, on the other hand, little else follows from it without the addition of further assumptions. In particular, it entails nothing about the relation between space and time measurements performed in frames of reference in relative motion to each other. Einstein thus succeeded in demonstrating that the concepts of space and time in classical physics involve at least two layers of knowledge, one that involves elementary mental models of rods and clocks, and a second, clearly distinguished one that introduces the additional theoretical assumptions required for the universal time and space concepts, equal for all physical systems whether in motion or not, which underlie classical physics. Disentangling these two levels he could now replace the layer of additional physical requirements leading to the classi-

51 See (Einstein 1905c).

cal concepts of space and time, such as the assumption of an infinite signal speed or the assumption that the simultaneity of events is independent of the state of motion, by the layer representing the physical requirements embodied by the electrodynamics of moving bodies.

Einstein thus introduced the notion of a "relativity of simultaneity" and identified the ordinary addition of velocities as not pertaining to the elementary level of the concepts of space and time. It was just this ordinary and seemingly self-evident addition rule, however, which led to the incompatibility between the constancy of the speed of light, supported not only by the Fizeau experiment but essentially by the entire body of knowledge incorporated in Lorentz's electrodynamics, and the principle of relativity from classical mechanics. The assumption that velocities along one and the same direction can simply be added or subtracted like numbers in fact immediately leads to the conclusion that, if the velocity of light has a certain constant value in one reference system, it cannot have that same value in another system in relative motion to the first one, but must be augmented or diminished in dependence on the direction of motion. But on account of the epistemological insights associated with the introduction of the special theory of relativity, one could abandon this addition rule as part of the classical understanding of space and time and yet retain the more elementary level of mental models of space and time measurements, on which one could now build differently structured concepts. It turned out to be possible to introduce the constancy of the speed of light, along with the requirements imposed by the relativity principle, as a basic assumption of the new conceptual framework from which then a new addition rule for velocities could be inferred. This addition rule makes it possible to avoid the contradiction between the constancy of the speed of light and the relativity principle, which among other things requires that velocities of bodies depend on the state of motion of the reference frame from which they are observed. Indeed, for the velocities of ordinary material bodies the new addition rule comes close to the classical one, while the speed of light always retains its constancy; the new addition rule furthermore implies that the speed of light plays the role of a limiting velocity for physical interactions. In this way, the special theory of relativity had achieved a synthesis between the foundation of classical electrodynamics, from which the principle of the constancy of the speed of light was taken, and the foundation of classical mechanics, from which the principle of relativity was inherited.

The new concepts of space and time of the special theory of relativity of 1905 are built from combining Einstein's elementary procedure for measuring space and time by rods and clocks, which determine space and time only in one reference frame, with transformation equations relating the measurements obtained in one frame to those in another frame. The specifics of this new, higher-level structure of the concepts of space and time are entirely determined by the knowledge extracted from classical mechanics and classical electrodynamics. From classical electrodynamics it follows, in particular, that the speed of light should be constant at least in one frame of reference. From classical mechanics it follows that the admissible frames should be inertial frames of reference and that the basic physical laws, and hence also the constancy of the speed of light, should be the same in all such frames. From these requirements the so-called “Lorentz transformations” can be derived, which relate the space and time variables in one inertial frame of reference to those in another one.

While similar transformations were initially derived by Lorentz as an artifice for solving internal problems of the electrodynamics of moving bodies, their refinement and reinterpretation by Einstein led to new concepts of space and time whose potential range of applicability was now the entire domain of physics. These new concepts were already so closely interwoven with electrodynamics that it turned out to be rather unproblematic to implement them in this area of knowledge, with little need for major restructurations. The foundational equations of electrodynamics, due to Maxwell and Lorentz, did not have to be modified in order to be compatible with the new prescriptions for transforming physical variables from one reference frame into another. However, this was not the case for Newton’s dynamics which did require such modifications. This difference is not surprising since classical electrodynamics was already conceived as a field theory in which physical actions travel with speeds limited by the speed of light, as required by the special theory of relativity. Newton’s dynamics, on the other hand, allows for instantaneous actions at a distance, such as that of gravitation, and conflicts with the requirement of special relativity that no physical interaction can propagate with a speed greater than that of light. Nevertheless, in the course of a “mopping up” operation in the years following Einstein’s formulation of special relativity, it turned out to be possible to adapt greater parts of classical physics to the new concepts of space and time. The assimilation of ever larger portions of physical knowledge to these new concepts provided them in turn with an ever growing stability, reflected also by the quick acceptance of the special theory of relativity among contemporary physicists.

This restructuration of physical knowledge by new concepts was greatly eased when in 1908 Hermann Minkowski developed a mathematical formalism for representing the totality of physical events in space and time, together with the relations between these events as implied by the special theory of relativity.[52] This mathematical formalism consists of a four-dimensional manifold in which coordinate systems, representing the physical frames of reference, can be employed to characterize each physical event by four numbers, its three space and one time coordinate. If the time coordinate is introduced in such a way that it is always multiplied by the constant speed of light, it also acquires the physical dimension of a spatial variable so that Minkowski’s four-dimensional world becomes even more similar to the three-dimensional Euclidean space familiar from classical physics, being, however, extended by one more dimension.

The mathematical analogy becomes almost complete if in this space the notion of a “metric” is introduced, allowing a determination of the distance between two events in space and time. In ordinary Euclidean space a metric has the immediate physical significance of giving the spatial distance between two points. It can be expressed in

52 See (Minkowski1908).

terms of a “line element,” determining the distance ds between two infinitesimally close points in terms of their infinitesimal coordinate differences dx, dy, dz. In the case of the usual orthogonal Cartesian coordinates one thus obtains according to the Pythagorean Theorem:

$$ds^2 = dx^2 + dy^2 + dz^2.$$

In the case of more general coordinates or of a non-Euclidean three-dimensional space, the line element is given by a more general expression:

$$ds^2 = \sum_{i,j=1}^{3} g_{ij} dx_i dx_j$$

where g_{ij} are the components of the so-called “metric tensor,” which in general may even be functions of the coordinates. In the case of the usual coordinates of the four-dimensional Minkowski’s geometry, the line element is given by:

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2 dt^2,$$

corresponding to the components of a metric tensor with constant components which, represented in matrix form, are given by:

$$g_{ij} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -c^2 \end{bmatrix},$$

where c^2 is the square of the speed of light. In Minkowski’s four-dimensional world, line element and metric do not possess an immediate interpretation in terms of the concept of length; the line element can, for instance, represent a spatial interval in one case and a time interval in another. But line element and metric do represent in a concise way the causal structure of physics according to special relativity. In particular, an event that can causally affect another one must have a distance that is negative or zero as measured according to the metric of Minkowski’s world since two events can only be causally connected by interactions that propagate with a speed less than or equal to that of light.

In addition to the characterization of the causal structure of physics by the metric, the introduction of a distance in the four-dimensional world of spacetime events also offers the possibility of giving a succinct characterization of the Lorentz transformations. In ordinary three-dimensional Euclidean space the notion of a distance enters into the definition of rotational transformations between two coordinate systems. In fact, they can be defined as those linear and homogeneous transformations which leave the distances between arbitrary points invariant. It now turns out that, with the help of the four-dimensional metric that defines distances in Minkowski’s world, Lorentz transformations can simply be defined in terms of four-dimensional rotations and hence acquire geometrical significance.

The mathematical representation of events in space and time by "Minkowski space" or "Minkowski spacetime," as this four-dimensional manifold is also called, and the representation of Lorentz transformations by rotations in this space has far-going implications for the mathematical representation of other physical quantities and relations as well. One immediate consequence is the characterization of the motion of a point particle by a four-dimensional "world-line" in Minkowski space, representing the sequence of events in space and time corresponding to this motion. The usual kinematic description of the motion of a point-particle is thus replaced by a description in terms of the geometric properties of such a line. In a sense, the dynamics of physical changes in a three-dimensional world now becomes a "statics" in the four-dimensional representation. Minkowski thus formulated the requirement that in the mathematical description of physical processes, the time coordinate should not play an exceptional role, but rather be treated on an equal footing with the other three coordinates.

The motion of a particle corresponding to a specific world-line may of course, still be given in terms of relations between its coordinates referring to a given coordinate system, for instance by prescribing the spatial position of the particle with respect to this system as a function of the local time in this system. But the geometric properties of the particle's world-line in the four-dimensional Minkowski space remain independent of any specific coordinate system. All that changes, if another coordinate system is introduced in the four-dimensional world, is the relative position of the curve with respect to this new system, and hence the description of the curve in terms of space and time coordinates. One such coordinate representation results from another one by a Lorentz transformation, provided that both coordinate systems correspond to inertial frames of reference. The use of Minkowski's four-dimensional "spacetime continuum" as a framework for physical theories naturally leads to the requirement that physical magnitudes should be represented by geometric objects in this framework. This requirement automatically ensures that the representation of such a physical magnitude in terms of space and time coordinates referring to a given reference frame is related to the coordinate representation with respect to another frame by a Lorentz transformation. In this case the physical magnitude may be characterized as being "Lorentz invariant."

Minkowski's formalism thus provided not only an elegant representation of the mathematical properties of the Lorentz transformations, but also a heuristic framework guiding the reformulation of physical knowledge in terms of the new concepts of space and time. It offered, on the one hand, a mathematical criterion for immediately deciding whether or not a given physical quantity is Lorentz invariant, and thus conforming to the principles of special relativity; on the other hand, it allowed the creation of a multitude of mathematical objects which were candidates for representing physical magnitudes or laws within special relativistic physics. On the background of Minkowski's formalism it was possible, for instance, to recognize immediately that Newton's law of gravitation is not Lorentz invariant—Newton's expression for the gravitational force does not correspond to a geometric object in Minkowski space—and thus needs to be adapted to the principles of special relativity. The same formalism immediately suggested, on the other hand, a variety of Lorentz invariant force laws that could all be conceived as candidates for a special relativistic modification of Newton's law of gravitation.[53]

Special relativity, in particular after its reformulation by Minkowski, was largely perceived as founding a new kinematics, in the sense of a new spatio-temporal scaffolding for the description of physical processes, which replaces the "absolute" space and time concepts of classical physics. Although the new scaffolding was initially constructed on the basis of knowledge acquired mainly in a specific subdomain of electrodynamics, it tended to be perceived as having or pretending to have the same quasi *a priori* status for physical science as classical kinematics. While in the future physical research would uncover new forces and hence new dynamical relations, it was nevertheless expected that these would fit into the kinematic framework established once and for all by special relativity; in this sense special relativity was conceived as structuring new physical experience in terms of space and time rather than as being itself potentially affected by it. But even in the first years after its formulation the theory already led to far-going conceptual changes in classical physics, beyond the domain of kinematics. Naturally, the dynamical laws of classical physics, such as the relation between force and acceleration or the principle of energy conservation, had to be adapted to the new spatio-temporal framework, as we have already mentioned. Some of these adaptations, however, profoundly changed the understanding of concepts crucial for dynamics such as those of mass and energy. The impact of the special theory of relativity on the conceptual structure of classical physics was therefore not limited to a revision of its spatio-temporal scaffolding.

The special theory of relativity led, in particular, to the consequence that energy possesses inertial mass and that, more generally, energy and mass are but two aspects of a single conserved quantity whose relation is described by the famous equation $E = m \cdot c^2$, where E stands for the energy, m for the mass, and where c^2 is the square of the speed of light. In principle this "mass-energy relation" allows for the possibility that energy may be transformed into matter and matter into energy, in a well-defined ratio, although the equation itself does not specify the processes by which such transformations can be achieved. It follows that, whenever a body loses or gains energy, it also loses or gains inertial mass; furthermore, if energy—in whatever form—is subject to motion it behaves like a body with an inertial mass of the amount $m = E/c^2$. Einstein arrived at these conclusions in 1905 by theoretically studying transformation processes in which a body loses, for instance, energy in the form of radiation.[54] Considering such a process from two different frames of reference in relative motion with

53 For discussion, see the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics" (in vol.3).

54 See (Einstein 1905a).

respect to each other, he could use the Lorentz transformations to determine the effect of the energy loss on the motion of the body—and hence on its inertial mass.

The mass-energy relation is at the root of the striking implications of special relativity for dynamics. It requires, for instance, that stresses be systematically taken into account when considering the effect of forces on the motion of an extended body, even when in classical physics the stresses have no effect on this motion, e.g. when they are produced by a pair of equal and opposite forces acting along the same line. But according to the mass-energy relation, stresses embody energy and thus may change the inertial properties of the moving body. The elaboration of such consequences of special relativity had the effect of changing the fundamental role that the concept of inertial mass played in classical physics. Even when dealing with an extended body, in classical physics it was always possible to describe the effect of forces on its overall motion—leaving aside deformations—by a single quantity, its inertial mass. It was therefore possible, for many purposes, to treat an extended body according to the mental model of a single mass point having the same inertial mass as the extended body. This was another reason why the elementary dynamics of mass points had a more fundamental status in classical mechanics than the treatment of extended bodies, in addition to the fact that theories such as hydrodynamics and elasticity theory could be built on the conceptual basis of particle dynamics. In special relativity, on the other hand, there is in general no single quantity such as mass characterizing the inertial behavior of an extended physical system. The work of Max von Laue around 1911 made it clear that for this purpose no less than ten functions are required, which together form the components of a geometric object in Minkowski space called the "stress-energy tensor."[55]

2.9 Gravitation as a Stumbling Block of Special Relativity

How could gravitation be made to fit into the framework of the relativity theory of 1905? A modification of Newton's law of gravitational attraction was clearly necessary since it implies an instantaneous action at a distance, while the spatio-temporal framework of special relativity requires that no physical action can propagate with a speed faster than that of light. It quickly turned out that it was not at all difficult to adapt Newton's law to this spatio-temporal framework; as the work of Poincaré, Minkowski and others between 1905 and 1910 showed, there were even several possibilities for performing the necessary adjustments.[56] Furthermore, these adjustments could be brought without much difficulty into agreement with the well-known astronomical results confirming Newton's original theory. But while from a purely kinematical view point no essential difficulties arose, these special relativistic gravitational force laws were quite unsatisfactory from a broader perspective. In par-

55 See (Laue 1911a, 1911b).

56 For historical discussion, see the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics" (in vol.3).

ticular, since they took the form of an "action at a distance," even if with a temporal delay, they did not fulfill the ambition to create a field theory of gravitation, in analogy to the theory of the electromagnetic field.

Attempts to construct a relativistic field theory of gravitation could essentially follow the model represented by Lorentz's theory of electromagnetism. In contrast to an interaction between particles that can be described in terms of a mutual force, the "Lorentz model" takes into account that an interaction mediated by a field involves not only the interacting material particles but also their vicinity, in fact, their global environment. As discussed above, the Lorentz model describes in terms of a global field how this environment is affected by matter, considered the "source" of the field, and how this field in turn determines the motion of matter, now conceived as a "probe" exposed to the field. A mathematical representation of physical processes interpreted according to this model therefore necessarily comprises two parts: i) a field equation describing how a localized source, such as a particle, creates the global field or, alternatively, an analogous equation determining the "potential" from which the field can then be derived; in classical physics the corresponding second-order partial differential equation for the gravitational potential was known as the "Poisson equation," and ii) an equation of motion describing how the global field determines the motion of a localized probe; in Newtonian mechanics the corresponding equation is that between acceleration, force, and inertial mass $a = (F/m)$, representing the acceleration-implies-force model.[57]

In order to apply Lorentz's model of a field theory to the case of a relativistic theory of gravitation, one had to identify an appropriate mathematical representation of the gravitational field as well as of its source, and one had to find a generalization of the Poisson equation that was to be Lorentz-invariant. The familiar quantities from classical physics, the gravitational field derivable from a scalar gravitational potential and the gravitational mass, represented the default solutions to the first two problems. In addition, it was not difficult to write down a generalization of the Poisson equation compatible with special relativity. Nevertheless, the most obvious implementations of Lorentz's model of a field theory along these lines turned out to lead to serious difficulties, menacing the very framework of special relativity.

The early attempts at a special relativistic treatment of gravitation were, in particular, confronted with the dynamical consequences of special relativity following from a revised understanding of the concept of mass.[58] As we have seen, in classical mechanics the inertial mass of a body is quantitatively equal to its gravitational mass, although the two masses are conceptually distinct. This quantitative identity leads to the consequence that in a gravitational field all bodies fall with the same acceleration, whatever their constitution ("Galileo's principle"). The transformations that the concept of inertial mass underwent due to the advent of special relativity could not

57 For more extensive discussion, see "Pathways out of Classical Physics …" (in this volume).

58 See "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in vol. 3 of this series).

remain without effect for the understanding of this relation within the new relativistic mechanics. From the mass-energy relation it follows that the loss or gain of energy of a body changes its inertial mass—but does this change also affect its gravitational mass? If so, one would expect that Galileo's principle remains valid also in the relativistic context. It turned out, however, that it was not easy to preserve this principle in a special relativistic theory of the gravitational field since it seemed to follow from a straightforward implementation of the classical gravitational field equation within a special relativistic context that bodies fall with different accelerations in a gravitational field if their initial velocities and hence their inertial masses are different.

This problematic consequence may be glanced from a simple thought experiment, which might have been at the roots of Einstein's 1907 decision to abandon the attempt to find a special relativistic field theory of gravitation. Consider a stone falling vertically and a projectile shot horizontally at the same time the stone is dropped. According to classical physics, both hit the ground at the same time. If this situation is now considered from a moving reference frame, which moves with the same speed as the projectile along the horizontal, the roles of the stone and projectile are reversed. In the moving reference frame, the projectile falls vertically to the ground, while the stone now follows a projectile motion with a horizontal component in the opposite direction. According to classical physics, also within the moving reference frame, the two bodies should hit the ground at the same time. According to special relativity, however, the two events, which happen simultaneously in one frame of reference, cannot happen at the same time—because of the relativity of simultaneity, i.e., its dependence on the state of motion of the reference system—simultaneously in the other reference system moved with respect to the former. Galileo's principle, according to which all bodies fall with the same acceleration, can hence not be valid in both frames of references; it hence cannot be valid at all.[59]

This difficulty amounted not only to a clash between the new theory and a time-honored insight of classical mechanics, but pointed also to an internal conflict between the kinematical and the dynamical dimensions of special relativity that was generated by the attempt to incorporate gravitation into its framework. The dynamical consequences of special relativity, as embodied in the revision of the concept of mass, made it in fact impossible to simply transfer the elements of the classical gravitational field equation into a relativistic kinematic framework. In the classical Poisson equation, the

59 This reconstruction fits with Einstein's remark: "These investigations, however, led to a result which raised my strong suspicions. According to classical mechanics, the vertical acceleration of a body in the vertical gravitational field is independent of the horizontal component of its velocity. Hence in such a gravitational field the vertical acceleration of a mechanical system or of its center of gravity works out independently of its internal kinetic energy. But in the theory I advanced, the acceleration of a falling body was not independent of its horizontal velocity or the internal energy of the system. This did not fit with the old experimental fact that all bodies have the same acceleration in a gravitational field. This law, which may also be formulated as the law of the equality of inertial and gravitational mass, was now brought home to me in all its significance." In (Einstein 1954, 286–287).

mass density of matter acts as the source of the gravitational potential. But what should take its place in the relativistic counterpart of this equation? From the mass-energy relation it follows that any form of energy—even the energy of the gravitational field itself—should act as the source of a gravitational field, at least if the close relation between gravitational and inertial mass is to be upheld also in a relativistic theory. But in which form should the energy of an extended physical system act as the source of a gravitational field? It follows from the mass-energy relation, as we have seen above, that the inertial behavior of such a system in special relativity can no longer be easily characterized by a single function such as the classical inertial mass; it was therefore to be expected that similar difficulties arise also with regard to the gravitational effects of an extended physical system. The relativistic action-at-a-distance laws proposed by Poincaré and Minkowski, referring only to the interaction of point masses were of course, far from coping with such demands on a relativistic theory of gravitation and also for this reason had little impact on the further development of gravitational theories.[60] But also the most straightforward four-dimensional generalizations of the Poisson equation suggested only a single function, such as the mass as the source of the gravitational potential, and therefore encountered similar difficulties caused by the transition from the concept of mass to the concept of mass-energy.

A further, more "kinematical" difficulty characteristic of special relativistic field theories of gravitation is related to a simple mathematical property of Minkowski's four-dimensional formalism.[61] From the fact that, in Minkowski space, the scalar product of the "four-velocity" of a moving body with itself equals the square of the velocity of light, it follows that this four-velocity has always to be perpendicular to its "four-acceleration," since the derivative of the constant velocity of light vanishes. However, this condition imposes unacceptably restrictive conditions on the choice of a gravitational potential in the most obvious four-dimensional theory. In particular, the gravitational potential must be constant along the world-line of a particle, a very restrictive condition indeed. In summary, the framework of special relativity revealed itself as being too narrow for assimilating the knowledge on gravitation that was accumulated in the context of classical physics, at least as long as this framework was not somehow further elaborated or even stretched.

2.10 Exploring the Limits of Special Relativity

The various and partially conflicting demands on a relativistic theory of gravitation form the background of the different approaches to the problem of such a theory pursued by scientists like Albert Einstein, Max Abraham, Gunnar Nordström, and others

---

60 For more extensive discussion, see the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics" (in vol.3).

61 For further discussion of this problem, see "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in vol. 3 of this series).

in the period between 1912 and 1915.[62] Theories in which the gravitational potential is represented by a single function were advanced in this period by Abraham and Nordström, while a theory in which this potential was represented by a more complex mathematical object was pursued by Einstein. In fact, these theories embody the different possibilities offered by the shared mathematical and conceptual resources available at the time to respond to the challenges of a special relativistic field theory of gravitation.

Using earlier hints provided by Einstein's studies of special static gravitational fields, Abraham proposed in 1911 the first four-dimensional field theory of gravitation, obtained by a simple modification of the most straightforward special relativistic field theory.[63] In contrast to this "standard" theory, Abraham's theory assumes the speed of light to be variable. It thus succeeds in avoiding the difficulty related to Minkowski's formalism just mentioned, that is, the orthogonality between four-velocity and four-acceleration implied by the constancy of the speed of light, but, as it turned out, at the price of violating a fundamental principle of special relativity. It was, in fact, soon realized that Abraham's theory is no longer Lorentz-invariant but rather makes the geometry of Minkowski space depend on the variable speed of light which in turn is a function of the gravitational potential. This radical step met with criticism because it led to an internal contradiction. But even apart from this difficulty, Abraham's theory did not offer a response to the "dynamical" problems related to the modification of the concept of mass discussed above.

These problems quickly became the central issue in the development of Nordström's apparently more conservative alternative approach, which was intended to remain within the framework of special relativity.[64] But whether more conservative or not, this approach had the same starting point as Abraham's, the problem of bringing the most obvious four-dimensional generalization of a gravitational field equation into harmony with the most elementary requirements of a theory of gravitation. His solution for avoiding the restrictive conditions on the gravitational potential resulting from the "standard" special relativistic gravitational field theory was to let the mass of a body depend on the gravitational potential, instead of assuming a dependence of the speed of light on the gravitational potential. In this way, it seemed that he had only to introduce a minor unorthodoxy into special relativity, rather than giving up its entire conceptual framework, as was effectively the case with Abraham.

The theory that Nordström first proposed in 1912 did not, however, succeed in avoiding other objections against a special relativistic approach. Like Abraham's theory, Nordström's initial approach was based on considering only the mass as the source of the gravitational field, neglecting other forms of energy. In order to avoid

62 This is discussed more extensively in the introduction to vols. 3 and 4 of this series "Theories of Gravitation in the Twilight of Classical Physics". See also "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation"; "The Summit Almost Scaled …" (all in vol. 3 of this series).

63 See (Abraham 1912).

64 See (Nordström 1912).

this difficulty, a further elaboration of Nordström's theory therefore had to take into account the recent advances in understanding the role of energy for the inertial behavior of bodies. We have seen above that the mass-energy relation implies that in special relativity the inertial behavior of extended physical systems can, in general, no longer be described by the single function "inertial mass" but that this description rather requires a complex, 10-component object, the "stress-energy tensor." Given the demand that the inertial and the gravitational behavior of such an extended system should be governed by the same physical quantity embodying its energetic properties, this stress-energy tensor was also a natural candidate for the source of the gravitational field, thus effectively replacing the classical notion of gravitational mass. Nordström's theory, however, was guided by the default settings for the Lorentz model inherited from Newtonian theory in assuming that the gravitational potential is represented by just one single function which had to correspond to another single function representing the source of this potential. In the classical case, this single function characterizing the source of the gravitational field was given by the gravitational mass. Now, in the light of the new insights into special relativistic dynamics and of the constraints imposed by Nordström's theory, it became necessary to extract such a single function from the complex stress-energy tensor for a physical system acting as the source of a gravitational field.

The attempts, in particular by Nordström and Einstein, to address this problem necessitated further revisions of Nordström's original theory. Eventually Nordström was forced to assume that the gravitational potential influences not only the mass of a body, but also length and time measurements performed under the influence of a gravitational field. However, this further revision implied that Nordström's theory of gravitation had essentially undercut its own conceptual roots in the spatio-temporal framework of special relativity. Indeed, as it turned out, this framework was no longer directly accessible through measurements as these are affected by the presence of a gravitational field.

These and other attempts between 1911 and 1915 to confront the challenge that the inclusion of gravity posed for special relativity led to a situation similar to that of classical aether-based electrodynamics at the turn of the century, when it was confronted with the challenge of incorporating the electrodynamics of moving bodies. In both cases it was possible to cope with these challenges by continually adjusting and modifying the original framework which, however, created tensions between the elaborated theories and their conceptual roots. But further development under the spell of these challenges not only produced internal inconsistencies and a proliferation of possible modifications, it also generated the preconditions for new perspectives as a consequence of the enhanced opportunities to reflect upon the accumulated knowledge. In the case of the electrodynamics of moving bodies, these preconditions were constituted, among other aspects, by the new space and time variables in Lorentz's theory.

In the case of the relativistic field theory of gravitation we have also encountered the emergence of such elements of a new perspective, even though we have reviewed only a small segment of its development. Indeed, a sober look at Abraham's and Nordström's efforts could not only have suggested that a satisfactory field theory of gravitation might transcend the limits of special relativity, but could have also revealed hints as to how such a theory might be constructed: by letting the geometry of Minkowski space depend on the gravitational potential (Abraham); by representing the gravitational potential not by a single function but by a 10-component object on a pair with the stress-energy tensor and having this tensor as its source (Laue and Nordström); and by including an effect of the gravitational potential on the measurement of space and time (Nordström).

In summary, our survey of the evolution of classical physics has shown that the accumulation of knowledge in its highly organized disciplinary structures produced borderline problems which also challenged the classical understanding of gravitation. The fact that the problem of a relativistic theory of gravitation was deeply rooted in a structural crisis of classical physics makes it evident that the genesis of general relativity was not just a one-man affair and a lucky individual discovery but the result of a profound transformation of the extended system of knowledge of classical physics that may well have taken place, albeit under a different form and possibly with a different outcome, even if Einstein had never lived. This survey makes it thus clear in which sense general relativity was not created *ex nihilo*. What remains open, however, is the second question posed in the introduction concerning the success of the heuristics that guided Einstein in its creation. While this survey makes it plausible that this success must have been due to the fact that Einstein's heuristics exploited the knowledge of classical and special relativistic physics, it remains to be clarified how it did so concretely. This is the question at the center of the next section.

3. THE ROOTS OF EINSTEIN'S HEURISTICS IN THE KNOWLEDGE OF CLASSICAL AND SPECIAL RELATIVISTIC PHYSICS

3.1 The Drama of General Relativity

How is Einstein's work on general relativity related to the knowledge resources reviewed in the last section? At first glance it seems that the processes described above merely set the stage for the truly decisive events associated with his struggle for a relativistic theory of gravitation. In fact, this struggle resembles a heroic drama which, according to Einstein's own retrospective account, has three major acts:[65] The drama began in 1907 when he conceived the idea of the so-called "equivalence principle," which was at the origin of his unusual and lonely path towards a theory of gravitation, and with which he was to realize a generalization of the principle of relativity. The drama reached a first culmination in 1912, when Einstein introduced a 10-component metric tensor as a representation of the gravitational potential, substituting its representation in classical physics by a single scalar function. At that point, the

65 See "The First Two Acts" (in this volume).

full extent of the deviation of the new theory of gravitation from classical physics became visible. Finally, in 1915, the drama reached its climax when Einstein, after a desperate search and numerous failed attempts, formulated the gravitational field equation of general relativity as a differential equation for the metric tensor.

However, describing the three steps associated with the years 1907, 1912, and 1915 as turning points of a drama or of an individual biography obviously does not explain why each of them was so successful in advancing the solution of the problem to create a relativistic theory of gravitation, in particular as they do not even seem to lie along a straight path towards such a solution. Einstein's contemporaries strongly objected, for instance, against the introduction of the metric tensor which they considered to be an unnecessary complication with respect to the simple scalar gravitational potential of the Newtonian theory.[66] Even a psychological explanation of the origin of the three breakthroughs in Einstein's thinking can hardly account for their effectiveness in creating general relativity as a durable solution to the problem of a relativistic theory of gravitation, emerging at the dusk of classical physics.

In the following, we shall therefore concentrate on the way in which Einstein's three crucial steps functioned in the transformation of the knowledge of classical science. For this purpose, we will describe what happened in terms of mental models effecting an integration of physical and mathematical knowledge. The emphasis is not on the question of how exactly these models entered Einstein's individual thinking. What matters here is that they originated either in the shared scientific knowledge of the time, such as the model of a field equation taken over from Lorentz's electrodynamics, or resulted from a reflection on conflicts within this shared knowledge of the kind described in the previous section, such as the conflict between Galileo's principle and special relativity.

3.2 Einstein's Realization of the Conflict between Galileo's Principle and Special Relativity

In September 1907 Einstein agreed to the offer by Johannes Stark to write a review article on the theory of relativity which he was expected to complete within two months.[67] At the beginning of November, when he had completed the first half of the paper, he was yet uncertain whether gravitation should be included—at least he did not mention this topic in a letter to the editor Stark which he wrote at that time.[68] When the paper was submitted on the fourth of December, it did comprise a short section on gravitation.[69] The obvious problem confronting Einstein was the reconciliation of Newton's law of gravitation with the requirement of a finite speed of the

69 See (Einstein 1907, sec. V, 454–462).

propagation of physical effects following from special relativity. In a later recollection, Einstein wrote:

> Like most physicists, at this period, I endeavoured to find a "field-law," since, of course, the introduction of action at a distance was no longer feasible in any plausible form once the idea of simultaneity had been abolished.
>
> The simplest way was, of course, to keep the Laplace scalar potential of gravity and to extend the Poisson equation by adding, in such a way as to comply with the special theory of relativity, a term differentiated with respect to the time. (Einstein 1933, 6)

Whatever precise form Einstein had given to his attempt at a special relativistic gravitation theory, he soon encountered the above-mentioned intrinsic conflict between the kinematical and dynamical implications of special relativity for the problem of gravitation, which shifted the central conflict from that between Newton's law and special relativity to that between special relativity and Galileo's principle. The conflict suddenly transformed this long-familiar principle—and the equality of inertial and gravitational mass on which it is based in classical physics—into a touchstone for a new theory of gravitation. It was as if the elaboration of a relativistic theory of gravitation had directed a spotlight onto this previously rather inconspicuous asset of classical physics. This is strikingly confirmed by Einstein's own recollection:

> This principle, which can also be stated as the law of the equivalence of inertial and gravitational mass, impressed me as being of fundamental importance. I wondered how this law could exist, and believed that it held the key to the real understanding of inertia and gravitation. I never seriously doubted its exact validity, even though I did not know about the beautiful experiments of Eötvös, which, if I remember alright, were not known to me until a later date.
>
> I gave up, therefore, the attempt, which I have sketched above, to treat the problem of gravitation within the framework of the special theory of relativity; it was clearly inadequate, since it failed to take into account just the most fundamental property of gravitation. (Einstein 1933, 7)

The ground was thus prepared for reflecting upon this property of gravitation and rethinking the relevant knowledge of classical physics taking into account that the framework of special relativity was evidently too narrow for capturing the problem of gravitation.

3.3 The Synthesis of Knowledge by the Elevator Model

Even within classical mechanics Galileo's principle appears to be an odd coincidence, due to the equality of gravitational and inertial mass rather than a fundamental property anchored in its conceptual structure. However, when Einstein reconsidered it in the context of his attempt at a relativistic theory of gravitation, it somehow seemed to hold the key to a deeper understanding of gravitation and inertia. But what exactly was the question to which Galileo's principle suggested an answer? Einstein eventually noticed that it did fit with Mach's peculiar view on mechanics, questioning the privileged role of inertial frames of reference and the notion of acceleration with respect to absolute space. Mach had claimed that the curvature of the surface of water in Newton's bucket experiment might also occur if the bucket were at rest while the cosmic masses rotated around it. Mach thus established an equivalence between a situation in which a physical effect—the curvature of the water surface—is caused by acceleration, and a situation in which the same effect can be interpreted as being caused by forces exerted on the water by the cosmic masses. If Galileo's principle is now reconsidered from the point of view of such an equivalence relation, it becomes plausible to reduce Mach's argument to a comparison of two much simpler situations; one in which just the usual linear acceleration of free fall is considered instead of a rotational motion, and one in which just the usual gravitational force of the Earth is contemplated instead of a speculative force of moving cosmic masses.

The problem to which Galileo's principle provided a response was, in other words, the generalization of the principle of relativity to accelerated motions which, for Einstein, was associated with Mach's view. He later recalled:

> After the special theory of relativity had shown the equivalence for formulating the laws of nature of all so-called inertial systems (1905) the question whether a more general equivalence of coordinate systems existed was an obvious one. In other words, if one can only attach a relative meaning to the concept of velocity, should one nevertheless maintain the concept of acceleration as an absolute one? From the purely kinematic point of view the relativity of any and every sort of motion was indubitable; from the physical point of view, however, the inertial system seemed to have a special importance which made the use of other moving systems of coordinates appear artificial.
>
> I was, of course, familiar with Mach's idea that inertia might not represent a resistance to acceleration as such, so much as a resistance to acceleration relative to the mass of all the other bodies in the world. This idea fascinated me; but it did not provide a basis for a new theory. I made the first step towards the solution of this problem when I endeavoured to include the law of gravity in the framework of the special theory of relativity. (Einstein 1933, 5–6)

It was evidently the highlighting of Galileo's principle by the problems of a special relativistic theory of gravitation that had linked this principle, in Einstein's mind, with Mach's interpretation of mechanics, and in particular with the idea to generalize the principle of relativity also to accelerated frames of references. According to standard classical mechanics, inertial and accelerated frames of reference have a fundamentally different status. But when, as Galileo's principle implies, all bodies fall in the same way in a uniform and homogeneous gravitational field, an observer falling with them could imagine living, at least temporarily, in an inertial frame of reference although he is himself falling with growing speed. In fact, he would neither feel his own weight nor observe any forces acting on the bodies falling with him. It is as if the gravitational field had been neutralized by his own accelerated motion. His accelerated frame of reference would therefore be indistinguishable from an inertial frame. This indistinguishability between an accelerated and an inertial frame could, in turn, be made into a criterion for the validity of Galileo's principle. If, in particular, the new theory of gravitation were to incorporate this principle, it would have to be also a generalized theory of relativity allowing for accelerated frames of reference. This way of reinterpreting Galileo's principle as the equivalence of a freely falling reference frame with an inertial one, and as the starting point for resolving the problems raised by Mach, must have struck Einstein as a flash-like insight, as is made evident by his later recollections. In his famous Kyoto lecture, for instance, Einstein reminisced:

> I was sitting in my chair in the patent office at Bern when all of a sudden a thought occurred to me: 'If a person falls freely he will not feel his own weight.' I was startled. This simple thought made a deep impression on me. It impelled me towards a theory of gravitation. (Pais 1982, 179)

Other recollections not only confirm the sudden nature of this insight but also hint at the intellectual background that had prepared it and, in particular, at the role of Mach's critique as suggesting the problem to which Galileo's principle, freshly discerned in its significance, provided the striking and unexpected resolution:

> Now it came to me: the fact of the equality of inertial and gravitational mass, i.e., the fact of the independence of the gravitational acceleration from the nature of the falling substance may be expressed as follows: In a gravitational field (of small spatial extension) things behave as they do in a space free of gravitation, if one introduces into it, in place of an "inertial system," a frame of reference accelerated relative to the former. ... The concept of "acceleration relative to space" then loses all meaning and with it the principle of inertia along with the paradox of Mach. (Einstein 1979, 61, 63)

Einstein's rethinking of Galileo's principle was guided not only by his familiarity with Mach's foundational critique of mechanics but also by other aspects of his earlier intellectual experience, such as his recognition, in the context of his work on the electrodynamics of moving bodies, that electric and magnetic fields only have a relative existence depending on the state of motion. In one of his recollections he stressed the analogy of this crucial insight from the context of special relativity with the relative existence of the gravitational field as revealed by accelerated motion:

> At this point, there occurred to me the happiest thought of my life. Just as is the case with the electric field produced by electromagnetic induction, the gravitational field has similarly only a relative existence. *For if one considers an observer in free fall, e.g., from the roof of a house, there exists for him during this fall no gravitational field—at least not in his immediate vicinity.* Indeed, if the observer drops some bodies, then these remain relative to him in a state of rest or in uniform motion, independent of their particular chemical or physical nature (in this consideration the air resistance is, of course, neglected). The observer therefore has the right to interpret his state as "at rest."[70]

---

70 "Da kam mir der glücklichste Gedanke meines Lebens in folgender Form: Das Gravitationsfeld hat an einem betrachteten in ähnlicher Weise nur eine relative Existenz wie das durch magnetelektrische Induktion erzeugte elektrische Feld. *Denn für einen vom Dache eines Hauses frei herabfallenden Beobachter existiert während seines Falles*—wenigstens in seiner unmittelbaren Umgebung—*kein Gravitationsfeld*. Lässt der Beobachter nämlich irgend welche Körper los, so bleiben sie relativ zu ihm im Zustand der Ruhe bezw. gleichförmigen Bewegung, unabhängig von ihrer besonderen chemischen und physikalischen Natur. Der Beobachter ist also berechtigt, seinen Zustand als "Ruhe" zu deuten." (CPAE 7, Doc. 31, 265). English translation in (Holton 1971). See also (Miller 1992, 325; Pais 1982, 178).

The way in which Einstein exploited the knowledge resources available to him obviously depended on his specific perspective on these resources. But in whatever prior experience this perspective was actually grounded, there can be no doubt that his first crucial step towards a relativistic theory of gravitation—the introduction of what he later called his equivalence principle—has its origin in a thorny process of knowledge integration that started with the attempt to assimilate the classical knowledge on gravitation to the framework of special relativity. How exactly did the equivalence principle structure this process?

The equivalence principle states that all physical events in a uniform and homogeneous gravitational field are equivalent to those happening in a uniformly accelerated frame of reference. It is often described, also by Einstein himself, in terms of a "thought experiment" with a closed laboratory, which is also known as the "elevator experiment." However, if it is merely conceived as a thought experiment, then it must remain a riddle why Einstein held on to it for so long and why he made it the central element of his heuristics, even against the resistance of almost all his colleagues. On the other hand, if one interprets it as an operation with the mental model of a laboratory, then it becomes clear that it could have dramatic effects on the architecture of the knowledge of classical physics.

Einstein's laboratory may be considered in two states that, in classical physics, are described by different concepts. In the first case the laboratory is uniformly accelerated by an arbitrary external force with respect to an inertial system. It represents the mental model of a system with inertial forces. Among its slots are the state of motion of the system, the inertial forces in its interior, and the motion of bodies caused by them. In the second case the laboratory is at rest in an inertial system and is exposed to a homogeneous gravitational field. It now represents the mental model of a system with gravitational force. Among its slots are the state of motion of the system, the gravitational force acting on the bodies within the system, and the motions caused by it.

Einstein noticed that the observer in the interior of the laboratory cannot distinguish between these two cases. A laboratory of which it is only empirically known that bodies in its interior fall to the bottom with uniform acceleration satisfies the conditions for the slots of both mental models, which are connected with each other in this way. In fact, the slots for the motion of the bodies within the laboratory are, in both cases, filled with the same empirically given data, while the slots for which no empirical information is available, such as those for the states of motion, can be filled by default assumptions delivered by the interpretation of the laboratory either as being in accelerated motion or as being exposed to a gravitational field. The integration of the two mental models questions or even dissolves essential distinctions of classical and special relativistic physics, in particular that between accelerated systems and inertial systems, and that between inertial forces and gravitational forces.

Even years before the formulation of only the first approach to a generally relativistic theory of gravitation, the integrated model—in the following called the "elevator model"—became the central asset of Einstein's heuristics. In fact, this integrated model allowed him to relate two separate knowledge areas of physics to each other. In particular, it enabled the investigation of special cases of the gravitational field by means of the study of accelerated motion. Accelerated motion, in turn, could be analyzed by methods of special relativity, assuming that the physical effects at a certain point in the accelerated laboratory are the same as those in a laboratory moving uniformly with the same instantaneous speed, that is, in a "comoving inertial frame of reference." On the basis of this successful, if only partial integration of the knowledge of classical mechanics and special relativity, Einstein was able to draw conclusions concerning the empirical consequences of a theory of gravitation still to be formulated, among them the prediction of the deflection of light and of the redshift in a gravitational field,[71] as well as the explanation of the anomalous perihelion motion of Mercury.[72]

The bending of light in a gravitational field, for instance, could simply be inferred from the observation that, in an accelerated laboratory, light rays must be curved as a consequence of the superposition of the motion of the laboratory and of the light. The conclusion that this is also the case for a gravitational field was in accordance with the assumption that energy has not only inertial but also gravitational mass, so that the energy of light should be subject to gravitational attraction. Such straightforward considerations are at the roots of the most striking observational predictions of general relativity, made long before its completion and confirmed only years afterwards. Among them is Einstein's prediction that, during a solar eclipse, one should be able to observe a variation of the apparent positions of stars whose light passes close to the sun and is therefore deflected by its gravitational attraction, a prediction first published in 1911 following up on Einstein's 1907 considerations,[73] and confirmed during a solar eclipse in 1919.[74] Among these striking predictions is also that of the existence of gravitational lenses: distant massive objects which create images and intensify the light of even more distant objects aligned with them. Einstein first determined the properties of such gravitational lenses in 1912, three years before completing general relativity.[75] He later abandoned the idea because he doubted that such objects could ever be observed; an observation that, in fact, was only achieved much later. These examples illustrate how the knowledge resources of classical physics made it possible to identify effects predicted by general relativity even before its formulation. In fact, the deflection of light, revealed as a qualitative effect by the elevator model as early as 1907, could, without much difficulty, be combined with mental models from ray optics involving simple constellations such as that of a solar eclipse or a gravitational lens.

3.4 Conceptual Challenges Implied by the Elevator and Bucket Models

Einstein's elevator model was not only a heuristic device capable of predicting remarkable observational implications of the new theory of gravitation, it also highlighted its incompatibility with special relativity and allowed Einstein to anticipate some of the conceptual changes associated with such a theory. The bending of light in a gravitational field, for instance, suggested that the speed of light is no longer constant, in contradiction with one of the fundamental principles of special relativity. This qualitative conclusion could be underpinned, as Einstein did in his review paper of 1907,[76] by an analysis of time synchronization in an accelerated frame of reference that made it evident that the concept of time in a gravitational field had to be further differentiated with respect to that of special relativity. In fact, time, in the sense of a synchronized network of clocks, could be defined with respect to any of the comoving inertial frames anchored at particular points of an accelerated frame of reference. But since these different "local inertial frames" are in relative motion to each other, two such networks do not coincide since, according to special relativity, simultaneity means something different in each of them. It is hence no longer possible to simply refer to "the time" of an accelerated frame of reference (or of a frame with a gravitational field) since one can no longer expect that two standard clocks, initially synchronized at the same location in a gravitational field, would still remain synchronized when one is transported to a region with a different gravitational potential; in this sense the "homogeneity" of time is lost in a theory of gravitation incorporating Einstein's principle of equivalence.

An extension of the considerations that had led to the elevator model allowed Einstein to arrive at similar insights concerning the necessity of revising the concept of space in the new theory of gravitation. Such an extension of the original model, to include more general cases of accelerated motion and, in particular, the case of rotation, was suggested both by Mach's analysis of inertial effects in classical mechanics and by the Lorentz model. The combination of knowledge resources from mechanics and field theory was, in fact, characteristic of Einstein's work on a new theory of gravitation.[77] The Lorentz model, rooted in the tradition of field theory, made it possible to conceive of gravitation and inertia as two aspects of one gravito-inertial field, in analogy to the unification by Maxwell's field equations of the electric and magnetic field to one electromagnetic field. In a letter to Paul Ehrenfest from spring 1912 Einstein wrote with reference to static gravitational fields:

> My case corresponds to the electrostatic field in the theory of electricity, whereas the more general static case would further include the analogue of the static magnetic field. I am not yet that far.[78]

---

76 See (Einstein 1907, sec. V).

77 For further discussion, see "The Third Way to General Relativity" (in vol. 3 of this series).

78 "Mein Fall entspricht in der Elektrizitätstheorie dem elektrostatischen Felde, wogegen der allgemeine[r]e statische Fall noch das Analogon des statischen Magnetfeldes mit einschliessen würde. So weit bin ich noch nicht." Einstein to Paul Ehrenfest, before 20 June 1912, in (CPAE 5, Doc. 409, 486).

Mach's analysis of classical mechanics, on the other hand, suggested identifying the inertial forces in accelerated frames of reference as being due to an interaction between bodies in motion. His interpretation of the mental model of a rotating bucket, in particular, made it plausible to search for a theory that admits rotating frames of reference in the sense of a generalization of the principle of relativity and to conceive the inertial effects occurring in them as a specific case of this hitherto unknown interaction. In this vein, Einstein wrote, also in spring 1912, to his friend Michele Besso:

> You see that I am still far from being able to conceive rotation as rest![79]

While attempts to formulate a purely Machian mechanics on the basis of introducing such inertial interactions had been hopeless, the combination of this idea with the perspective of field theory could now provide the latter with precise information, otherwise missing, concerning the properties of *dynamical* gravitational fields. In other words, an integration of the Machian bucket model with the Lorentz model made it possible to identify the inertial forces in a rotating frame as the analogon to a magnetostatic field, thus filling the slots of the Lorentz model with specific knowledge about the special case of a stationary gravitational field.

When Einstein began to search for a gravitational field equation in 1912, the bucket model became, next to the elevator model, the second crucial mental model of his heuristics, exploiting the possibilities of analyzing properties of a generalized gravitational field by considering the inertial effects of accelerated motion known from classical mechanics. The bucket model pointed to the effects of Coriolis-like forces on light rays in a stationary gravitational field, which turned out to be such that light rays cannot go back along the same path from one point to the other.[80] From this insight it follows that the force exerted by such a stationary gravitational field is velocity-dependent, in this case changing with the direction of the velocity of light. However, even within the framework of special relativity, the inclusion of rotating reference frames was connected to a conceptual difficulty that had its origin in the length contraction of rapidly moving bodies and the problem of defining a rigid body in special relativity. Einstein and Max Born had already encountered this difficulty in 1909.[81] It had also been found independently by Ehrenfest.[82] Ehrenfest argued that the circumference of a cylinder, which is slowly set into motion around its axis should, according to special relativity, show a contraction with respect to the state of rest, while its radius is not affected by such a contraction since it lies orthogonally to the motion. For the rotating cylinder, the ratio between circumference and radius

---

79 "Du siehst, dass ich noch weit davon entfernt bin, die Drehung als Ruhe auffassen zu können!" Einstein to Michele Besso, 26 March 1912, in (CPAE 5, Doc. 377, 435).

81 See (Born 1910).

82 See (Ehrenfest 1909).

should therefore, from the viewpoint of an observer at rest, deviate from the number π that, in Euclidean geometry, determines this ratio.

This difficulty was related to what became known as the "Ehrenfest paradox" which gave rise to a controversial discussion about the definition and role of rigid bodies in relativity theory. Einstein, however, took this paradox as a hint relevant for a generalization of relativity theory on the basis of his equivalence principle. Immediately after the discovery of the problem he wrote to Arnold Sommerfeld:

> The treatment of the uniformly rotating rigid body seems to me to be of great importance because of an extension of the relativity principle to uniformly rotating systems that is based on a line of reasoning analogous to that which I tried to purse for uniformly accelerated translation in the last § of my paper that was published in the *Zeitschr. f. Radioaktivit.*[83]

When Einstein interpreted the Ehrenfest paradox in terms of the bucket model, it took on a new significance, implying conceptual consequences for the new theory of gravitation which sharpened its conflict with special relativity. In one of his papers published in 1912 (Einstein 1912a), Einstein argued that the ratio between the circumference and radius of a circle or a disk in a rotating laboratory is no longer given by π because, as he later explained in detail,[84] the Lorentz contraction affects a ruler posed along the circumference and moving in the momentary direction of the rotating motion, while it does not affect a ruler posed along the radius of the disk. As a consequence, one needs more such contracted rulers to measure the circumference of the rotating disk which thus exceeds the length of 2π times the radius expected from ordinary geometry. In other words, the spatial properties of a stationary gravitational field no longer satisfy Euclidean geometry.

For Einstein the equivalence principle, and with it the use of mental models such as the elevator and bucket models, was eventually subsumed under a more general heuristic principle, his generalized principle of relativity. According to this principle, the new theory of gravitation should not make a distinction between inertial and gravitational effects, which are rather to be described as effects of an integrated gravito-inertial field. It should, in particular, admit reference frames in arbitrary states of motion and describe the inertial effects occurring in them as the effects of such a generalized gravito-inertial field. As will become clear in the following, this principle played a crucial role in shaping the mathematics employed by Einstein to formulate the gravitational field equation, imposing, in particular, its covariance with respect to general classes of coordinate transformations. However, it follows from the preceding discussion that Einstein's generalized principle of relativity not only had implications

83 "Die Behandlung des gleichförmig rotierenden starren Körpers scheint mir von grosser Wichtigkeit wegen einer Ausdehnung des Relativitätsprinzips auf gleichförmig rotierende Systeme nach analogen Gedankengängen, wie ich sie im letzten § meiner in der Zeitschr. f. Radioaktivit. publizierten Abhandlung für gleichförmig beschleunigte Translation durchzuführen versucht habe." Einstein to Arnold Sommerfeld, 29 September 1909, in (CPAE 5, 210–211).

84 For an extensive historical discussion, see (Stachel 1989). For a modern assessment, see (Vishveshwara 2003).

for the mathematical instruments used in the creation of general relativity, but that it also incorporated knowledge resources of classical physics, in particular, the knowledge on inertial effects in accelerated frames of reference which were traditionally explained as being due to the existence of an absolute space.

3.5 The Synthesis of Knowledge by the Curved-Spacetime Model

Classical physics offered a number of tools for the further exploration of the properties of a generalized gravitational field. Exploiting these tools, Einstein was eventually led to a major breakthrough in his understanding of gravitation. As a result of this breakthrough, gravitation was now conceived as being due to the curvature of space and time. How did this breakthrough come about? In order to describe how gravitation affects motion Einstein first made use of the classical acceleration-implies-force model, conceiving gravitation as a force. In a second step, he then realized that the way in which a gravitational field influences the motion of a body exposed to it could also be accounted for by the constrained-motion model, also familiar from classical physics, wherein the equation of motion is formulated in terms of a variational principle. Finally, in a third step, he realized that an equation of motion thus formulated also perfectly matches the slots of another mental model, this time rooted in the shared knowledge of contemporary mathematics, the "curved-surface model." As a result, these two models were joined to become an integrated model, the "curved-spacetime model," which opened the way for a complete and coherent mathematical description of motion in a relativistic gravitational field by virtue of the mathematical structures associated with the curved-surface model. It follows from this revised description of the effect of gravitation that the gravitational field itself could now be conceived, instead of being a force in the sense of Newtonian physics, as expressing the geometric properties of a generalized spacetime continuum. In fact, this new world generalizes Minkowski's spacetime in the same sense as a curved surface represents a generalization of a plane surface, its geometric properties being governed not by a constant but by a variable metric. This metric, in turn, emerged as the appropriate mathematical representation of the gravitational potential. Because of its origin in the integration of two mental models, the metric tensor embodies both the knowledge of the generalized gravito-inertial field revealed by the equivalence principle, and the knowledge of the causal structure of spacetime following from special relativity and incorporated in Minkowski's formalism.

A closer look at the emergence of this breakthrough reveals it as a rather straightforward implication of the knowledge so far accumulated. Until 1911 Einstein had committed himself mainly to exploring, by means of the equivalence principle, the effects and conceptual changes characterizing a new theory of gravitation, evidently without seriously attempting its construction. Only in early 1912 was he challenged by the publications of Max Abraham to elaborate such a theory, at least for the special case of a static gravitational field.[85] He did so by applying the Lorentz model to the results of his use of the equivalence principle. In particular, he attempted to describe the inertial effects in a uniformly accelerated frame in terms of a field equation for a static gravitational field, and the motion of particles by an equation of motion in accordance with the acceleration-implies-force model. For this purpose he explored how a force-free motion in an inertial frame would look if considered from the perspective of an accelerated frame of reference from which it could then be interpreted, on the basis of the equivalence principle, as a motion subject to a gravitational force.

Having derived transformation equations between the inertial and the accelerated frame of reference compatible with the available knowledge, in particular about the propagation of light, Einstein arrived at transformation equations for space, time, and a variable speed of light. Since in Einstein's theory of static gravitation the speed of light is variable, his results were obviously no longer compatible with special relativity. As discussed in the previous section, Max Abraham had followed an entirely different strategy. He believed to have resolved the problem of gravitation within the framework of Minkowski's four-dimensional representation in a simple and surprisingly elegant way, but Einstein soon recognized that Abraham's use of the Minkowski formalism was not compatible with the assumption of a variable speed of light. In reaction to Einstein's criticism, Abraham became the first, in February 1912, to propose that the four-dimensional line element, defining the infinitesimal distance between points in Minkowski space in terms of a constant metric, has to be replaced by a variable line element whose functional dependence on the coordinates is determined by a gravitational potential associated with the variable speed of light c.

While the appearance of such a generalized line element in Abraham's work is striking, pointing as it does at what was to become a central mathematical object of general relativity, neither Abraham's nor Einstein's contemporary research offered a context for realizing this key role. On the contrary, one of the essential properties of the line element in Minkowski space—its invariance under Lorentz transformations—was lost by the introduction of a variable speed of light, as Einstein did not fail to notice. As a consequence, the formalism introduced by Abraham clearly did not represent a coherent generalization of Minkowski's spacetime. On the other hand, Einstein's theory of the static gravitational field, for the time being, did not offer even a hint at a general framework that would allow him to go beyond the special case of static fields. In addition, it even suffered from a problem of compatibility with the essential physical requirement of energy conservation. In fact, this problem had not only necessitated an adjustment of its field equation but also a restriction of Einstein's central heuristic device, the equivalence principle, to infinitesimally small fields. In short, the attempts at a relativistic theory of gravitation pursued by Einstein and Abraham had met with a dilemma in which neither mathematical formalism nor physical heuristics seemed to provide an indication as how to proceed further.

By the end of May 1912, Einstein encountered at least a partial resolution of this dilemma in the course of revisiting the equation of motion of his theory. This turning

85 For more extensive discussion and references to Abraham's papers, see "The Summit Almost Scaled …" (in vol. 3 of this series).

point—referred to above as the second step in Einstein's realization of gravitation as being due to the curvature of spacetime—is documented in a postscript to his second 1912 paper on the static theory, in which he proposed the modification of its field equation just mentioned.[86] Einstein had also reconsidered the equation of motion of his theory, originally shaped, as mentioned, according to the acceleration-implies-force model. He now successfully attempted to rephrase it, without changing its physical content, according to the constrained-motion model.

The elaborate mathematical formalisms associated with this model in analytical mechanics, such as the variational calculus of Euler, Lagrange, and Hamilton, had proven to be standard tools of classical physics for succinctly representing the structure of complex theories, in particular when these theories could not be interpreted in terms of simple mechanical interactions, as was the case, for example, for optics or electrodynamics. The essential ingredient of such reformulations in terms of a variational calculus is usually the integral of a physical quantity, depending on the trajectory of a particle or of a light ray, whose extremal value is to be determined by a variation under certain constraints. In this way, it is possible to single out among several possible trajectories along a curved surface the one that actually represents the "natural motion" under the given constraints. A direct interpretation of abstract variational formalisms in terms the physical meaning of the constrained-motion model is, under certain conditions, still possible but not essential for the successful development and implementation of these formalisms.

In his reformulation of the equation of motion in a static gravitational field Einstein again followed as closely as possible the precedent of special relativity, just as he had done in his original formulation guided by the acceleration-implies-force model. In this case the precedent was given by Planck's formulation of the equation of motion of a particle in the framework of a variational calculus adapted to Minkowski space.[87] The physical quantity, whose variation Planck had considered, is the integral over the square root of the negative line element along the trajectory of the particle. The requirement that this integral be an extremal has a direct geometric interpretation: the world line of a force-free particle in Minkowski space is given by a geodesic, that is, by the straightest possible line connecting the initial and the end point of the particle's motion. It now turned out that the corresponding expression for the motion in a static gravitational field takes on exactly the same form as that given by Planck for a gravitation-free Minkowski space, the only difference being that the speed of light is now assumed to be variable:

$$\delta\left(\int\sqrt{c^2dt^2 - dx^2 - dy^2 - dz^2}\right) = 0,$$

where δ stands for the variation of the subsequent integral.

86 See (Einstein 1912b, 458).
87 See (Planck 1906a, 1907).

Einstein was not only struck by the simple form of this equation and its complete analogy to the special relativistic case, but also by the possibility it immediately offered for a generalization beyond the special case of static gravitational fields:

> Here too—as was proved by Planck for the usual [i.e., special] theory of relativity —it is seen that the equations of analytical mechanics possess a significance that extends far beyond Newtonian mechanics. Hamilton's equation as finally written down lets us anticipate [*ahnen*] the structure of the equations of motion of a material particle in a dynamical gravitational field.[88]

Nevertheless, according to later recollections,[89] it must have taken Einstein a while before he took the third and final step in his understanding of gravitation as the curvature of spacetime. For some time, he was indeed struck by the dilemma of what coordinates could actually mean in physics given that coordinate differences could no longer be interpreted as being the immediate result of measurements with ideal rods and clocks, as was discussed above in connection with the loss of the "homogeneity" of time in a gravitational field. Only after his return from Prague to Zurich at the end of July 1912 did Einstein realize that a generalization of the equation of motion along the lines indicated by the above quotation, yielding an expression of the form:

$$\delta\left(\int\sqrt{\sum_{i,j=1}^{4} g_{ij}dx_i dx_j}\right) = 0,$$

which now involves 10 variables g_{ij} characterizing the gravitational potential, could be assimilated to the curved-surface model as conceived in Gaussian surface theory and its successive elaborations by Bernhard Riemann, Elwin Christoffel, Tullio Levi-Civita, and others.[90] If considered from the perspective of this model, the components of the gravitational potential g_{ij} can be conceived as those of a metric tensor determining the geometry of a generalized curved surface. In this way, Einstein also found an answer to his question concerning the physical meaning of coordinates. In fact, the differentials of the general curvilinear coordinates dx_i, just serving to number spacetime points, are related to the measurable magnitude ds, representing the invariant line element, with the help of the components of the metric tensor g_{ij}, by means of the following expression:

---

88 "Auch hier zeigt sich—wie dies für die gewöhnliche Relativitätstheorie von Planck dargetan wurde—daß den Gleichungen der analytischen Mechanik eine über die Newtonsche Mechanik weit hinausreichende Bedeutung zukommt. Die zuletzt hingeschriebene Hamiltonsche Gleichung läßt ahnen, wie die Bewegungsgleichungen des materiellen Punktes im dynamischen Gravitationsfelde gebaut sind." (Einstein 1912b, 458)

89 See the preface to the Czech translation of (Einstein 1923) of his popular book on relativity. See also (Einstein 1981, 137).

90 For a historical survey of the mathematical aspects, see (Reich 1994). For the role of Einstein's Machian heuristics in this step, see "The Third Way to General Relativity" (in vol. 3 of this series).

$$ds^2 = \sum_{i,j=1}^{4} g_{ij} dx_i dx_j .$$

This expression corresponds to the term under the integral in Einstein's variational formulation of the equation of motion, as given above, and lends an immediate geometric interpretation to this formulation, which was probably at the roots of Einstein's embracing of the curved-surface model. Indeed, expressed in general curvilinear coordinates, the equation simply represents the condition for a geodesic line on such a surface. The fact that the number of indices is 4 instead of 2, as in ordinary surface theory, could hardly infringe on the plausibility of this interpretation.

Once the curved-surface model was taken into consideration and generalized to a four-dimensional context, the analogy between the generalization of the concept of a straight line to a curved geometry and that of the concept of an inertial motion to a situation in which accelerated frames of reference are admitted, must have been immediate, in particular since force-free motion and geodesics are also closely related in classical physics. A motion along a curved surface, which is not subject to any external forces, proceeds along a geodesic line—the most natural generalization of a straight line for such surfaces. This description can immediately be transferred to the case of a force-free motion that is observed from an arbitrary accelerated frame of reference in a four-dimensional framework. Using the curvilinear coordinates, with the help of which one can describe such an accelerated reference frame, this motion can now simply be represented by a geodesic line in the four-dimensional spacetime. In view of the equivalence of inertial and gravitational forces assumed by Einstein, it was plausible to extend this insight also to arbitrary gravitational fields, including those which cannot be generated by accelerated reference frames.[91]

The assimilation of the equation of motion to the generalized curved-surface model had a number of profound consequences for Einstein's theory. First of all, the curved-surface model consolidated what had merely been a speculative generalization of his equation of motion for the static case to general, dynamical gravitational fields. In particular, it became possible to immediately conclude that force-free motions in general gravitational fields are represented by geodesic world lines, and also that the gravitational potential is, in general, represented by the 10 independent (from a total of 16) components g_{ij} of a metric tensor. Second, the interpretation of Einstein's equation of motion in terms of a mental model embedded in elaborated mathematical theories opened up a plethora of technical resources available to the construction of a relativistic theory of gravitation, in particular for the search of a gravitational field equation. In mid-1912, even though Einstein himself was far from being familiar with these resources, he eventually appropriated them with the help of his mathematician friend Marcel Grossmann. Third, this interpretation had far-reach-

91 By August Einstein had found an expression for the general equation of motion in a gravitational field, see Albert Einstein to Ludwig Hopf, Zurich, 16 August 1912, (CPAE 5E, 501–502).

ing implications for the conceptual understanding of a relativistic theory of gravitation. In fact, Einstein's earlier observations concerning the implications of the equivalence principle for the concepts of space and time could now be systematically related to the newly available concepts of surface theory and its elaborations, such as the concepts of coordinates, line element, metric tensor, invariants, and curvature. As we have emphasized, these and other conceptual implications follow from the fact that the mental model that had guided Einstein's formulation of the equation of motion, the constrained-motion model, could be combined with the curved-surface model to yield the integrated curved-spacetime model. Hence motion under the influence of a gravitational field could now be conceived as a natural motion in the sense of generalized inertial motion, governed by the curvature of spacetime. In this way, it was possible to combine the synthesis of gravitation and inertia prepared by the equivalence principle with the insight into the causal structure of physical interactions represented by the metric structure of Minkowski's spacetime.

3.6 The Lorentz Model as a Problem for the Integration of Physical and Mathematical Knowledge

Einstein's pathway from his first attempt at a theory of gravitation in 1907 to his insight into the general laws of motion under the influence of a relativistic gravitational field in mid-1912 had been an unusual one, involving steps that had led him far from the ordinary course of the adaptation of the knowledge of classical physics to the framework of special relativity. This unusual pathway was marked, in particular, by the heuristics of the equivalence principle that had initiated it and by its preliminary culmination in the no-less singular recognition of the four-dimensional metric tensor as the appropriate representation of the gravitational potential. From this point onwards, the further course was, apparently, well laid out. Einstein had found what was necessary to formulate an equation of motion in a gravitational field. What was lacking was a gravitational field equation determining how this field was created by its sources, matter and energy. In fact, the twin constellation of field equation and equation of motion rooted in the tradition of classical physics and ideally embodied in Lorentz's theory of electromagnetism had directed Einstein's search for a relativistic theory of gravitation at least since he considered the unification of gravitation and inertia in analogy to the unification of the electric and magnetic fields, and certainly since Abraham had published his proposal for a field theory of gravitation, obviously shaped by the same model.

In view of the guidance provided by the Lorentz model, the completion of a relativistic theory of gravitation by an appropriate field equation might have appeared to be a rather straightforward task once the equation of motion had been found. However, the task of finding a field equation turned out to be the most challenging one among all Einstein had ever tackled in his struggle for a relativistic theory of gravitation. First of all, he was confronted with the daunting mathematical problem that the representation of the gravitational potential by the metric tensor requires a field equation not for a single function but for a 10-component object. Second, an acceptable gravitational field equation replacing the Poisson equation of classical physics had to be compatible not only with the various insights Einstein had gathered during his earlier work on the problem, such as the necessity of introducing new concepts of space and time, but also with the immense resources of knowledge on gravitation and its relation to other physical interactions accumulated by classical and special relativistic physics. Einstein had already encountered the vicissitudes of these treasures while elaborating his theory of the static gravitational field. There he had stumbled, as mentioned above, on the unpleasant discovery that what appeared to be a most natural and plausible candidate for a static field equation actually turned out to be incompatible with the inescapable requirement of the conservation of energy and momentum. This episode thus confronted him in effect with the insight that the identification of an acceptable gravitational field equation represented an even more challenging task of knowledge integration than the promising hints and intermediate results obtained due to the heuristics of the equivalence principle could have led him to believe.

In particular, Einstein could not avoid taking into account that the action of the gravitational field under ordinary circumstances was well known and satisfactorily described by Newton's law of attraction. The relativistic field equation of gravitation therefore had to yield the same results as this law under appropriate circumstances. We will refer to this requirement as the "correspondence principle," representing an important building block of the heuristics that guided Einstein's search for a gravitational field equation. The new field equation had obviously to be compatible also with the well-established knowledge on energy and momentum conservation. This requirement, which must have played an outstanding role for Einstein given the just mentioned precedent offered by the theory of the static field, is referred to in the following as the "conservation principle," another crucial building block of his heuristics. But in addition to these well-established knowledge resources, Einstein's earlier research under the guidance of the equivalence principle had revealed a number of insights that were to be covered by the new field equation, in particular, the insight into the unified nature of gravitation and inertia. As pointed out above, this insight was suggested not only by the elevator and the bucket models, but also more generally by the possibility of conceiving inertial effects in accelerated frames of reference as effects of a generalized gravitational field and, accordingly, accelerated frames as being on equal footing with inertial frames of reference. Following Einstein's own terminology, this heuristic building block is therefore called here the "generalized principle of relativity." He expected that it could be implemented by imposing the mathematical requirement of an invariance, or rather "covariance" of the gravitational field equation under as general as possible coordinate transformations.

The breakthrough of mid-1912, marked by the recognition of the key role of the metric tensor and the formulation of a general equation of motion, was the result of a perfect match between a mental model of physical knowledge and a mental model of mathematical knowledge, mediated by a mathematical representation originally motivated by physical considerations. However, when Einstein began to search for a general gravitational field equation shortly afterwards, no such match was available. In particular, no mathematical representation lent itself to the expression of all the requirements listed above, let alone one that could be assimilated to a well-established mathematical framework. It was hence not even clear whether or not these requirements were at all compatible with each other since this question could only be settled on the basis of a mathematical representation embodying them. The integration of mathematical and physical knowledge associated with the formulation of a general gravitational field equation was therefore evidently not just a matter of finding an appropriate mental model, cutting across the borderlines of classical physics as was the case for the mental models related to the equivalence principle, or of combining two matching mental models as in the case of the curved spacetime model.

As it turned out, the search for a relativistic field equation of gravitation required instead a much more complex process of research, involving the systematic examination of candidate solutions and even the elaboration of a complete theory which was then discarded again, a process in the course of which some of the fundamental knowledge structures governing its heuristics and fueling its progress eventually had to be revised. It is this revolution of fundamental knowledge structures that makes Einstein's search for the gravitational field equation in the years between 1912 and 1915 an outstanding challenge for any attempt to understand the transition from classical to modern physics from the viewpoint of an historical epistemology. While other contributions to these volumes detail the structures of this revolution, we have focused here on the roots of Einstein's heuristics in the knowledge of classical and special relativistic physics. The principle aim of this contribution was to highlight some of the conditions under which general relativity could have emerged from a transformation of the knowledge of classical and special relativistic physics, and also to help understand the first steps of Einstein's pathway out of the disarray of classical physics.

JOHN STACHEL

THE FIRST TWO ACTS

PROLOGUE: THE DEVELOPMENT OF GENERAL RELATIVITY, A DRAMA IN THREE ACTS

In 1920, Einstein wrote a short list of "my most important scientific ideas".[1] The final three items on the list are:

1907 Basic idea for the general theory of relativity

1912 Recognition of the non-Euclidean nature of the metric and its physical determination by gravitation

1915 Field equations of gravitation. Explanation of the perihelion motion of Mercury.

Einstein's words provide the warrant for comparing the development of general relativity to a three-act drama:

Act I (1907) The formulation of the "basic idea," to which he soon referred as the equivalence principle.

Act II (1912) The mathematical representation of the gravitational field by a symmetric second rank tensor field, which enters into the line element of a four-dimensional spacetime; hence this tensor is usually referred to as the (pseudo-)metric of spacetime.[2]

Act III (1915) The formulation of the now-standard Einstein field equations for the metric field, and use of its spherically-symmetric solution to explain the anomalous precession of the perihelion of Mercury.

1 Einstein Archives, Hebrew University of Jerusalem, Control Index No. 11 196. (Hereafter, only the number of such items will be cited.) It appears from Einstein to Robert Lawson, 22 April 1920 (1–010), that it was written for the biographical note in (Einstein 1920a). This is the English translation of the fifth German edition of (Einstein 1920b). I thank Dr. Josef Illy of the Einstein Papers for locating Einstein's letter to Lawson. In (CPAE 8), it is incorrectly calendared under 1917 (see pp. 1005–1006).

2 Properly speaking, the term "metric" should be restricted to line elements with positive-definite signature; those with an indefinite signature are more properly termed "pseudo-metrics." But Einstein, and following him most physicists, referred to the four-dimensional tensor field with Minkowski signature as the metric tensor, and I shall follow that usage.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 1
Einstein's Zurich Notebook: *Introduction and Source*.

Act III certainly does not represent the end of general relativity, but a certain point of closure in its development, signaled by Einstein in his 1916 review paper (Einstein 1916a):

> "According to the general theory of relativity, gravitation plays an exceptional role as opposed to the other forces, in particular the electromagnetic..." (p. 779);

consequently, he concluded his exposition with a "Theory of the Gravitational Field" (pp. 801–822).

Up to this point, the story had been essentially an account of Einstein's struggles.[3] Now that the final form of the gravitational field equations had been achieved and one of its predictions validated, the theory became the property of the physics and astronomy communities. Its further development and interpretation became a subject of discussion among many participants, among whom Einstein's voice did not always carry the day.[4]

This book tells the story from the opening curtain of Act I in 1907 until the curtain goes down on Act III at then end of 1915. The great bulk of it is devoted to Act III, embracing the events between 1912 and 1915. In particular, it centers on the understanding of the Zurich Notebook, which opens Act III and has made a signal contribution to our understanding of subsequent events. As in most plays, the final act contains the *dénouement*; but the crucial events that lead up to it take place in the first two acts. It was his formulation of the equivalence principle in Act I, and constant adherence to it as the guiding thread in his search for a relativistic theory of gravitation that set Einstein apart from other physicists who were working on the problem of fitting gravitation within the framework of the (special) theory of relativity. And as usual, the high point of the drama comes in Act II, with Einstein's remarkable decision to represent gravitation, not by a scalar field, but by the ten components of a tensor field that also describes the chronogeometry of a non-flat four-dimensional spacetime.

It is at this point, with an expression for the line element in terms of the metric tensor field, that the Zurich Notebook opens. Clearly, it cannot be fully understood or evaluated without prior knowledge of what happened during the first two acts. Unfortunately, no equivalent of the Zurich Notebook has been found for this period from 1907–1912. So this chapter attempts to present what can be learned—or surmised—about what happened on the basis of Einstein's published papers and correspondence, as well as his later reminiscences.[5] In keeping with the documentary character of this book, rather than attempting to summarize them, I shall often cite Einstein's words *in extenso*.

---

3 David Hilbert played a significant role in the final moments of Act III, although not the one that is often attributed to him. See "Hilbert's Foundation of Physics: From a Theory of Everything to a Constituent of General Relativity" (in vol. 4 of this series).

4 For Einstein's side of this discussion during its first years, see (CPAE 7).

5 For another account, see (Pais 1982, Part IV, 177–296). For some critical comments, see (Stachel 1982); reprinted in (Stachel 2002, 551–554).

ACT I: THE EQUIVALENCE PRINCIPLE: "THE MOST FORTUNATE THOUGHT OF MY LIFE"

In 1920,[6] Einstein recalled how he first arrived at the ideas behind the equivalence principle:

> While I was occupied (in 1907) with a comprehensive survey of the special theory[7] for the "Yearbook for Radioactivity and Electronics," I also had to attempt to modify Newton's theory of gravitation in such a way that its laws fitted into the theory. Attempts along these lines showed the feasibility of this enterprise, but did not satisfy me, because they had to be based on physical hypotheses that were not well-founded. Then there came to me the most fortunate thought of my life in the following form:
>
> Like the electric field generated by electromagnetic induction, ... the gravitational field only has a relative existence. *Because, for an observer freely falling from the roof of a house, during his fall there exists*—at least in his immediate neighborhood—*no gravitation field*. Indeed, if the observer lets go of any objects, relative to him they remain in a state of rest or uniform motion, independently of their particular chemical or physical composition [note by AE: air resistance is naturally ignored in this argument]. The observer is thus justified in interpreting his state as being at rest.
>
> Through these considerations, the unusually extraordinary experimental law, that all bodies fall with equal acceleration in the same gravitational field, immediately obtains a deep physical significance. For if there were just one single thing that fell differently from the others in the gravitational field, then with its help the observer could recognize that he was falling in a gravitational field. If such a thing does not exist—which experiment has shown with great precision—then there is no objective basis for the observer to regard himself as falling in a gravitational field. Rather, he has the right to regard his state as one of rest and, with respect to a gravitational field, his neighborhood as field free. The experimental fact of the material-independence of the acceleration due to gravity is thus a powerful argument for the extension of the relativity postulate to coordinate systems in non-uniform relative motion with respect to each other .... The generalization of the relativity principle thus indicates a speculative path towards the investigation of the properties of the gravitational field (pp. 24–25).

Einstein alludes here to his initial attempts to set up a special-relativistic theory of gravitation, but gives no details. In 1933 he gave the fullest account of how he "arrived at the equivalence principle by a detour [*Umweg*]"[8] through such attempts.[9]

---

6 "Grundgedanken und Methoden der Relativitätstheorie, in ihrer Entwicklung dargestellt," in (CPAE 7, Doc. 31).

7 I shall follow the common but anachronistic practice of referring to "the special theory of relativity." During this period, Einstein initially called it "the principle of relativity" [*das Relativitätsprinzip*] and then, following the practice of others, "the theory of relativity" [*die Relativitätstheorie*]. For details, see the discussion in the Editorial Headnote, "Einstein on the Theory of Relativity," (CPAE 2, 254); reprinted in (Stachel 2002, 192).

8 "Erinnerungen-Souvenirs" (Einstein 1955, 145–153) was reprinted as "Autobiographische Skizze," in (Seelig 1955, 9–17). Citation from "Autobiographische Skizze," p. 14.

9 "Einiges über die Entstehung der allgemeinen Relativitätstheorie," the German text of a lecture given at the University of Glasgow, 20 June 1933. The German text was published in (Einstein 1934, 248–256). Cited from the paperback edition edited by Carl Seelig: (Seelig 1981, 134–138).

After mentioning his doubts after 1905 about the privileged dynamical role of inertial systems, and his early fascination by Mach's idea that the acceleration of a body is not absolute, but relative to the rest of the bodies in the universe, he turns to the events of 1907:

> I first came a step closer to the solution of the problem when I attempted to treat the law of gravitation within the framework of special relativity. Like most authors at the time, I attempted to establish a field law for gravitation, since the introduction of an unmediated action at a distance was no longer possible, at least in any sort of natural way, on account of the abolition of the concept of absolute simultaneity.
>
> The simplest thing naturally was to preserve the Laplacian scalar gravitational potential and to supplement Poisson's equation in the obvious way by a term involving time derivatives, so that the special theory of relativity was satisfactorily taken into account. The equation of motion of a particle also had to be modified to accord with the special theory. The way to do so was less uniquely prescribed, since the inertial mass of a body might well depend on its gravitational potential. This was even to be expected on the basis of the law of the inertia of energy.
>
> However, such investigations led to a result that made me highly suspicious. For according to classical mechanics, the vertical acceleration of a body in a vertical gravitational field is independent of the horizontal component of its velocity. This is connected with the fact that the vertical acceleration of a mechanical system, or rather of its center of mass, in such a gravitational field turns out to be independent of its internal kinetic energy. According to the theory I was pursuing, however, such an independence of the gravitational acceleration from the horizontal velocity, or from the internal energy of a system, did not occur.[10]
>
> This did not accord with an old fact of experience, that all bodies experience the same acceleration in a gravitational field. This law, which can also be formulated as the law of equality of inertial and gravitational mass, now appeared to me in its deep significance. I was most highly amazed by it and guessed that in it must lie the key to the deeper understanding of inertia and gravitation (pp. 135–136).

Turning from later reminiscences, let us see how Einstein presented his approach to gravitation in 1907:[11]

> Up to now we have only applied the principle of relativity, i.e., the presupposition that the laws of nature are independent of the state of motion of the reference system, to *acceleration-free* reference systems. Is it conceivable that the principle of relativity also holds for systems that are accelerated relative to each other?
>
> This is not the place for an exhaustive treatment of this question. Since, however, it is bound to occur to anyone who has followed the previous applications of the relativity principle, I shall not avoid taking a position on the question here.

---

10 As Einstein later realized, a special-relativistic theory of gravitation that does justice to the equivalence principle is possible, and indeed one was developed a little later by Gunnar Nordström. For an account of Nordström's theories, and Einstein's reaction to them, see (Norton 1992).

11 "Über das Relativitätsprinzip und die aus demselbem gezogenen Folgerungen," (Einstein 1907); "Berichtigungen," in (Einstein 1908).

> Consider two systems in motion Σ_1 and Σ_2. Let Σ_1 be accelerated in the direction of its X-axis, and let γ be the magnitude (constant in time) of this acceleration. Let Σ_2 be at rest, but in a homogeneous gravitational field that imparts an acceleration $-\gamma$ in the direction of the X-axis to all objects. As far as we know, the laws of physics with respect to Σ_1 do not differ from those with respect to Σ_2; this is due to the circumstance that all bodies in a gravitational field are equally accelerated. So we have no basis in the current state of our experience for the assumption that the systems Σ_1 and Σ_2 differ from each other in any respect; and therefore in what follows shall assume the complete physical equivalence of a gravitational field and the corresponding acceleration of a reference system.
>
> This assumption extends the principle of relativity to the case of uniformly-accelerated translational motion of the reference system. The heuristic value of this assumption lies in the circumstance that it allows the replacement of a homogeneous gravitational field by a uniformly accelerated reference system, which to a certain extent is amenable to theoretical treatment.[12]

Some further comments on this equivalence in his next paper on gravitation in 1911[13] are illuminating. He notes that in both systems, objects subject to no other forces fall with constant acceleration:

> For the accelerated system K' [corresponding to the 1907 Σ_1–JS], this follows directly from the Galileian principle [of inertia–JS]; for the system K at rest in a homogeneous gravitational field [corresponding to the 1907 Σ_2–JS], however, it follows from the experimental fact that in such a field all bodies are equally strongly uniformly accelerated. This experience of the equal falling of all bodies in a gravitational field is the most universal with which the observation of nature has provided us; in spite of that, this law has not found any place in the foundations of our physical picture of the world. ... From this standpoint one can as little speak of the *absolute acceleration* of a reference system, as one can of the *absolute velocity* of a system according to the usual [special–JS] theory of relativity. [note by AE: Naturally, one cannot replace an *arbitrary* gravitational field by a state of motion of the system without a gravitational field; just as little as one can transform all points of an arbitrarily moving medium to rest by a relativity transformation.] From this standpoint the equal falling of all bodies in a gravitational field is obvious.
>
> As long as we confine ourselves to purely mechanical processes within the realm of validity of Newtonian mechanics, we are certain of the equivalence of the systems K and K'. Our point of view will only have a deeper significance, however, if the systems K and K' are equivalent with respect to all physical processes, i.e., if the laws of nature with respect to K agree completely with those with respect to K'. By assuming this, we obtain a principle that, if it really is correct, possesses a great heuristic significance. For by means of theoretical consideration of processes that take place relative to a uniformly accelerated reference system, we obtain conclusions about the course of processes in a homogeneous gravitational field. (CPAE 3, 487–488)

With hindsight, one can see that Einstein's attempt to find the best way to implement mathematically the physical insights about gravitation incorporated in the equivalence principle was hampered significantly by the absence of the appropriate mathematical concepts. His insight, as he put is a few years later, that gravitation and inertia are "essentially the same" [*wesensgleich*],[14] cries out for implementation by

---

12 See (CPAE 7, 476). Also see p. 495 for a discussion of the meaning of uniform acceleration.
13 "Über den Einfluß der Schwerkraft auf die Ausbreitung des Lichtes," (Einstein 1911b).

their incorporation into a single inertio-gravitational field, represented mathematically by a non-flat affine connection on a four-dimensional manifold. But the concept of such a connection was only developed *after*, and largely in response to, the formulation of the general theory. So Einstein had to make do with what was available: Riemannian geometry and the tensor calculus as developed by the turn of the century, i.e., based on the concept of the metric tensor, without a geometrical interpretation of the covariant derivative. As I have suggested elsewhere, this absence is largely responsible for the almost three-year lapse between the end of Act I and the close of the play.[15]

ACT II: THE METRIC TENSOR: "JUST WHAT ARE COORDINATES ACTUALLY SUPPOSED TO MEAN IN PHYSICS?"

In 1949, Einstein himself raised the question of what was responsible for this long delay:

> This [recognition that the relativity principle had to be extended to non-linear transformations–JS] took place in 1908. Why were a further seven years required for setting up the general theory of relativity? The principal reason is that one does not free oneself so easily from the conception that an immediate physical significance must be attributed to the coordinates.[16]

Both the question and answer thus concern the entire period between 1907 (or 1908) and 1915. In 1933 Einstein made the answer more precise, and confined it to a shorter period of time:

> I soon saw that, according the point of view about non-linear transformations required by the equivalence principle, the simple physical interpretation of the coordinates had to be abandoned; i.e., one could no longer require that coordinate differences be interpreted as signifying the immediate results of measurements with ideal measuring rods and clocks. This recognition tormented me a great deal because for a long time I was not able to see just what *are* coordinates actually supposed to mean in physics? The resolution of this dilemma was reached around 1912. (Seelig 1981, 137)[17]

Einstein reference to 1912 is a clear allusion to his introduction of the metric tensor. But, as his reference to "a further seven years" after 1908 in the previous quotation suggests, the problem of the meaning of coordinates in general relativity was by no

14 In 1912 Einstein regarded "the equivalence of inertial and gravitational mass" as being reducible to the "essential likeness [*Wesensgleichheit*] of both of these elementary qualities of matter and energy"; and asserted that his theory of "the static gravitational field" allows him to regard it "as physically the same in essence [*wesensgleich*] as an acceleration of the reference system." See (Einstein 1912c, 1063).

15 The entire complex of problems raised in this paragraph is discussed at length in "The Story of Newstein or: Is Gravity just Another Pretty Force?" (in vol. 4 of this series).

16 From Albert Einstein's "Autobiographical Notes," which, although published first in 1949 (Einstein 1949, 2–94), were actually written in 1947. Cited here from (Einstein 1979, 63).

17 See (Seelig 1981, 1).

means completely resolved with the introduction of the metric tensor. Only with the resolution in 1915 of the "hole argument" [*Lochbetrachtung*] against general covariance that Einstein developed in 1913, did Einstein fully solve this problem; but discussion of the post-1912 aspects of the question will be found in later chapters.[18]

Now let me return to the problem of coordinates as Einstein saw it in 1907–1908. It is worth emphasizing that Einstein attributed his success in formulating the special theory in 1905 in no small measure to his insistence on physically defining coordinate systems that allow one to attach direct physical significance to coordinate differences:

> The theory to be developed—like every other electrodynamics—rests upon on the kinematics of rigid bodies, since the assertions of each such theory concern relations between rigid bodies (coordinate systems), clocks and electromagnetic processes. Taking this into account insufficiently is the root of the difficulties, with which the electrodynamics of moving bodies currently has to contend.[19]

Little wonder that Einstein was "tormented" by the problem of "just what coordinates are actually supposed to mean in physics" once they lose their direct physical significance!

This problem arose in the course of the application of the equivalence principle to linearly accelerated frames of reference and the attempt to apply it to uniformly rotating frames, both considered within the confines of Minkowski space.[20] Its resolution came out of Einstein's work on a theory of the static gravitational field, in particular on the equations of motion of a particle in this field; and his attempt to generalize this static theory to non-static fields.

Both problem areas, accelerated systems of reference in Minkowski space and static gravitational fields, ultimately led Einstein beyond the confines of Minkowski space to the consideration of non-flat Riemannian spacetimes. For convenience of exposition, I shall discuss these two strands of the story as if they were the subject of two separate scenes of Act Two, culminating in a third scene that ends the act. While it is broadly true that events in Scene One precede those in Scene Two, and certainly true that they all precede the events in Scene Three, to the extent that this division suggests a strict chronological separation between events in the First and Second Scenes, it does a certain violence to the actual course of events. However, it seems preferable to run this risk rather than attempt to jump back and forth between events in each of the intertwined strands of the story.[21]

---

18 For a historical discussion of Einstein's hole argument, see my 1980 Jena paper, published as (Stachel 1989); and reprinted in (Stachel 2002, 301–337).

19 "Zur Elektrodynamik bewegter Körper," (Einstein 1905); reprinted in (CPAE 2, 276–306), citation from p. 277. For further discussion of this paper see the Editorial Note "Einstein on the Theory of Relativity," in (CPAE 2, 253–274); reprinted in (Stachel 2002, 233–244)

20 For a discussion of the development of Einstein's concept of the equivalence principle, see (Norton 1985); reprinted in (Howard and Stachel 1989, 5–47).

21 Since contemporary documents are cited with dates, the chronological sequence can easily be reconstructed.

SCENE I: "TO INTERPRET ROTATION AS REST":

I shall start by again citing Einstein's 1949 comments on coordinates:

> The change [from the viewpoint that coordinates must have an immediate metrical significance] came about in more-or-less the following way.
>
> We start with an empty, field-free space as it appears with respect to an inertial system in accord with the special theory of relativity, as the simplest of all conceivable physical situations. Now if we imagine a non-inertial system introduced in such a way that the new system (described in three-dimensional language) is uniformly accelerated in a (suitably defined) direction with respect to the inertial system; then, with respect to this system, there exists a static parallel gravitational field. In this case, the reference system may be chosen as a rigid one, in which three-dimensional Euclidean metric relations hold. But that time [coordinate–JS], in which the field appears static, is *not* measured by *equally constituted* clocks at rest [in that system–JS]. From this special example, one already recognizes that, when one allows non-linear transformations of any sort, the immediate metrical significance of the coordinates is lost. One *must* introduce such transformations, however, if one wants to justify the equality of gravitational and inertial mass by the foundations of the theory, and if one wants to overcome Mach's paradox concerning inertial systems.[22]

Examination of Einstein's 1907 paper[23] shows that this account correctly reflects its contents. Einstein first demonstrates that—at least to first order in the acceleration—the spatial coordinates in a uniformly accelerating frame of reference retain their direct physical significance in terms of measuring rods; and thus, by the principle of equivalence, they still do so in the equivalent gravitational field. He then goes on to show that what he calls "the local time σ" [he uses both "*Ortszeit*" and "*Lokalzeit*" as names], which is essentially the proper time as measured by an ideal clock at a fixed point of the frame, differs from the "time τ," which he later called the "universal" [*universelle*] time,[24] which must be used to define simultaneity of distant events if one wants a time coordinate expressing the static nature of the gravitational field that is equivalent to the uniformly-accelerated one.

Thus, by the end of 1907, Einstein knew that differences between the "universal" time coordinates of events in a uniform gravitational field do not correspond to differences in the readings of ideal clocks in that field. It is true that he had shown that, at least to first order in the field strength, spatial coordinate differences still correspond to the results of measurements with rigid rods. But the fact that he felt compelled to demonstrate this for uniform gravitational fields suggests that he anticipated the pos-

22 "Autobiographical Notes," (Einstein 1979, 62 and 64); see note 16. An idea of what he meant by "Mach's paradox concerning inertial systems" may be gathered from the citations of Mach in Einstein's article, "Ernst Mach," (Einstein 1916b). See also (Einstein 1916a); reprinted in (CPAE 6, 284–339, Section 2), "Über die Gründe, welche eine Erweiterung des Relativitätspostulates naheliegen," pp. 286–288.

23 "Über das Relativitätsprinzip," (CPAE 2, Section 18, 476–480); for the full references, see note 11.

24 Einstein did not actually introduce this term until 1912, in his first paper on the static gravitational field, in which he contrasts the "local time" and the "universal time" (for the full reference, see note 36).

sibility that similar problems might arise for the spatial coordinates in more complicated gravitational fields.

Einstein did not publish anything on gravitation between 1908 and 1911, but he continued to think about the subject:

> Between 1909–1912 while I had to teach theoretical physics at the Zurich and Prague Universities I pondered ceaselessly on the problem.[25]

The earliest surviving indication that Einstein contemplated an extension of the relativity principle beyond linearly accelerated systems dates from 1909:

> The treatment of the uniformly rotating rigid body seems to me to be of great importance on account of an extension of the relativity principle to uniformly rotating systems along lines of thought analogous to those that I attempted to carry out for uniformly accelerated translation in the last section of my paper published in the *Zeitschrift für Radioaktivität*.[26]

What he had in mind is made more explicit in 1912 in a letter to his friend Michele Besso. After a rather full account of his new static theory (to be discussed below), he concludes: "You see that I am still far from being able to interpret [*auffassen*] rotation as rest. Every step is devilishly difficult..."[27]

As his reference to a "uniformly rotating rigid body" suggests, a solution to the problem of "interpreting rotation as rest" seemed to him to depend on developing a theory of rigid bodies in special relativity. In 1910 he wrote of this

> child of sorrow [*Schmerzenskind*], the rigid body. ... one should attempt to devise hypotheses about the behavior of rigid bodies that would permit a uniform rotation.[28]

Born had provided a definition of a relativistic rigid body in 1909, but he only discussed the case of linearly accelerated motion in any detail.[29] Further clarification soon came:

> The latest relativity-theoretical investigations of Born and Herglotz interest me very much. It really seems that in the theory of relativity there does not exist a "rigid" body with 6 degrees of freedom.[30]

This was disturbing, but brought new hope: If rigid *bodies* are incompatible with the special theory, rigid *motions* are not. In 1911, Laue summarized the situation concisely:

---

25 "Autobiographische Skizze," (Seelig 1955, 14).

26 Einstein to Arnold Sommerfeld, 29 September 1909, (CPAE 5, 210). Einstein incorrectly names the title of the journal in which his earlier paper was published (see Einstein 1907). Einstein had described the main theme of the last section of this paper in an earlier letter to Sommerfeld, Einstein to Arnold Sommerfeld, 5 January 1908, (CPAE 5, 86).

27 Einstein to Michele Besso, 26 March 1912,(CPAE 5, 435–438); citation from p. 436.

28 Einstein to Arnold Sommerfeld,19 January 1910, (CPAE 5, 228–230); citation from p. 229.

29 See (Born 1909a). It was his report on this work at the 1909 Salzburg meeting of the *Versammlung deutscher Naturforscher und Ärzte*, (Born 1909b), that provoked the above-cited letter of 1909 from Einstein to Sommerfeld. See also (Born 1910), discussed below.

30 Einstein to Jakob Laub, 16 March 1910, (CPAE 5, 231–233); citation from p. 232.

> The limiting concept of a body that is rigid under all circumstances, which is so useful everywhere in classical mechanics, in my opinion cannot be taken over [to the special theory–JS] on account of the impossibility of indefinitely large velocities for the propagation of elastic deformations. However this does not exclude a body moving at times like a rigid one; even according to classical mechanics, under certain circumstances a drop of fluid can move as if it were rigid. (Laue 1911, note at bottom of p. 107)

In short, the problem had been transformed from a dynamical one (what is a relativistic "rigid body" and how does it behave when accelerated?) to a kinematical one (given Born's relativistic definition, what types of "rigid motion" are possible?). Progress on the kinematical problem was much easier.[31] Indeed, in the paper cited by Einstein, Herglotz showed:

> that, as soon as one of the points of a [rigid–JS] body in Mr. Born's sense is fixed, it can only rotate uniformly about an axis passing through this point, like the usual rigid body. (Herglotz 1910, 403)

In the course of classifying all solutions of Born's rigidity condition, Herglotz gave the explicit form of the solution for rigid rotation about the z-axis (Herglotz 1910, 412). So Einstein could discuss the kinematics of such an ideal rigid rotation, and the gravitational field which is equivalent to the inertial forces in such a rotating frame, without having to solve the dynamical problem of what types of physical system could actually undergo such a motion.

But for Einstein, there remained a second, Machian type of question: What distribution of matter could *induce* the gravitational field in a frame at rest that is equivalent to the inertial forces in an accelerated frame? Einstein first considered this question for linear acceleration, so we shall discuss it before returning to the problem of rotation. In a 1912 paper on gravitational induction,[32] Einstein showed that, as a consequence of the inertia of energy and the equivalence principle, a spherical shell of matter K accelerated linearly relative to an unaccelerated frame exerts such an inductive accelerating (gravitational) effect on a particle P enclosed in the shell.[33] He also showed that:

---

31 Of course, a dynamical problem remained: how to create the circumstances that would lead a non-rigid body of a particular constitution to execute a particular rigid motion. But such special dynamical problems could be attacked *after* the general kinematical problem was solved.

32 "Gibt es eine Gravitationswirkung, die der elektrodynamischen Induktionswirkung analog ist?"(Einstein 1912a); reprinted in (CPAE 4, 175–179). Einstein published the article in this journal because it was part of a *Festschrift* for his friend, Heinrich Zangger, an expert in forensic medicine.

33 Presumably, this would be Einstein's answer to Laue's objection to the equivalence principle: "For the gravitational field in the system K [at rest, with a uniform gravitational field] there must be present a body that causes gravitation, not however for the accelerated system K'. So a search for it must immediately decide whether there is a real gravitational field or only an accelerated reference system," Max Laue to Albert Einstein, 27 December 1911, (CPAE 5, 384). This letter is discussed further below. Einstein evidently tried to answer Laue's objection in a footnote to his next paper, submitted two months later: "The masses that produce this field must be thought of as at infinity" (Einstein 1912b, 356). The paper on gravitational induction followed almost immediately.

> the presence of the massive shell K increases the inertial mass of the particle P within it. This makes likely the assumption that the entire inertia of a massive particle is an effect of the presence of all the other masses, based on a sort of interaction with the latter. This is completely the same standpoint that E. Mach had upheld in his acute investigations on the subject (*E. Mach, The Development of the Principles of Dynamics. Chapter Two. Newton's Views on Time, Space and Motion*).[34] How far this conception is justified will be seen when we are in the happy possession of a usable dynamics of gravitation (p. 177).

Presumably, Einstein already had in mind the application of this induction idea to rotational acceleration. In 1921, discussing the development of the general theory, Einstein wrote:[35]

> Can gravitation and inertia be identical [*wesensgleich*]? The posing of this question leads directly to the General Theory of Relativity. Is it not possible for me to regard the earth as free from rotation, if I conceive of the centrifugal force, which acts on all bodies at rest relative to the earth, as being a "real" field of gravitation (or part of such a field)? If this idea can be carried out, then we shall have proved in very truth the identity of gravitation and inertia. For the same effect [*Wirkung*] that is regarded as *inertia* from the point of view of the system not taking part in the rotation can be interpreted as *gravitation* when considered with respect to the system that shares the rotation.

I believe that the phrase "or part of such a field" makes clear what Einstein had in mind as his ultimate goal. The total gravitational field of the earth in a frame in which it is at rest (i.e., a co-rotating frame) consists of two parts: a gravito-static term, which would be present even if the earth were not in rotation (this is the Newtonian gravitational field), and a gravito-stationary term. The latter is usually interpreted as an inertial field, consisting of centrifugal and Coriolis terms, which would exist even if the earth were massless, i.e., in *any* rotating frame of reference. But, in accord with the principle of equivalence, these terms may be interpreted as a gravito-stationary field in a non-rotating frame of reference.

In summary: Because of his attraction to Mach's program from the beginning of his search for a theory of gravitation based on the equivalence principle, the aim of interpreting rotation as rest-plus-a-gravitational-field appears to have loomed large in Einstein's motivation. This motive led him to consider uniformly rotating systems of reference soon after his 1907 treatment of uniformly linearly accelerated systems. But only after the clarification of the question of rigid motions do we find any signs of progress on the rotation problem.

The study of uniformly rotating reference systems then led him to the conclusion that, in this case, the spatial coordinates cannot be given a direct physical meaning. He announced this result in February 1912, in an uncharacteristically tentative tone, in the course of a discussion of the spatial coordinates in a linearly accelerated frame of reference K:[36]

---

34 Exactly the same words about Mach's book occur in "Einstein's Scratch Notebook," reproduced with transcription in (CPAE 3, "Appendix A," 564–596; see p. 592).

35 "A Brief Outline of the Development of the Theory of Relativity, (Einstein 1921, 783). A German draft, "Kurze Skizze zur Entwicklung der Relativitätstheorie," has been used to correct the English text. Both appear in (CPAE 7).

> The spatial measurement of K is done with measuring rods that—when compared with each other at rest at the same place in K— possess the same length; the theorems of [Euclidean–JS] geometry are assumed to hold for lengths measured in this way, and thus also for the relations between the coordinates x, y, z and other lengths. That this stipulation is allowed is not obvious; rather it contains physical assumptions that eventually could prove incorrect. For example, it is highly probable that they do not hold in a uniformly rotating system, in which, on account of the Lorentz contraction, the ratio of the circumference to the diameter, using our definition of lengths, must be different from π.

There is evidence suggesting that he had this rotating disk argument before 1912, but it is indirect and suggestive rather than conclusive. Einstein's letter of 1909 to Sommerfeld, cited above,[37] was written just a few days after the Salzburg meeting of the Society of German Natural Scientists and Physicians [*Deutsche Naturforscher und Ärzte*], at which Einstein had spoken. As the editors of the Einstein Papers note:[38]

> At the Salzburg meeting Max Born had presented a paper on rigid body motion in special relativity ..., on which Sommerfeld had commented in the discussion following the paper. Einstein and Born had discussed the subject and had discovered that setting a rigid disk into rotation would give rise to a paradox: the rim becomes Lorentz-contracted, whereas the radius remains invariant (see Born 1910, p. 233).[39] The existence of this paradox was first pointed out in print by Paul Ehrenfest (1880–1933) in a paper that was received on the date of this letter.[40]

While the line of argument about setting a rigid disk into rotation (which has come to be called "Ehrenfest's Paradox") is not the same as that in Einstein's treatment of an already rigidly-rotating disk,[41] the basic idea in both arguments is the same: Relative to an inertial frame, measuring rods at rest in a uniformly rotating frame of reference *do not* contract if aligned in a radial direction, but *do* contract if aligned orthogonally to a radial direction.

So it is reasonable to suppose that Einstein, already alerted to the possibility that coordinate differences in an accelerating frame might not be directly interpretable in terms of physical measurements and having read Herglotz's 1910 paper, realized that this was indeed the case for the spatial coordinates in a rigidly rotating frame of reference.[42]

Indeed there is evidence that, by the end of 1911 at the latest, Einstein saw an analogy between the gravitational field that, according to the equivalence principle (conceiving rotation as rest), is equivalent to the inertial field in a uniformly rotating

frame of reference and the magnetostatic (or electro-stationary) field due to a stationary circular current distribution.[43] In the letter cited earlier,[44] Max Laue alludes to:

> your [i.e., Einstein's] question whether the gravitational field strength should be represented by a four-vector or a six-vector.

We shall return to this letter at some length below, but for the moment, consider the implications of Einstein's question. The most natural generalization of the Newtonian gravitational field strength would be a four-vector, since the force exerted by the Newtonian field depends only on the position and not the velocity of a mass in that field. On the other hand, the electric and magnetic field strengths together constitute a six-vector, and the force exerted on a charge in an electromagnetic field depends on the position (electric force) and velocity (magnetic force) of the charge. Around the turn of the century, H. A. Lorentz had suggested a gravitational theory modeled on electromagnetism, in which there were gravitational analogues of the electric and magnetic forces (Lorentz 1899–1900a).[45]

Thus, Einstein's question to Laue suggests that, by the end of 1911, he had reason to believe that the force exerted by the most general gravitational field might also be velocity dependent. In his 1911 paper, he had considered the gravitational analogue of a constant electrostatic field, and he was soon to consider the analogue of the general electrostatic field.[46] By 18 February 1912, Einstein was already communicating some of his results.[47]

There is also evidence that, by February 1912, Einstein was already considering the gravitational analogue of a magnetostatic field. Paul Ehrenfest visited Einstein in Prague during the last week of February, and Ehrenfest's diary entry for 24 February 1912 contains the following lines:

---

42 Curiously, neither he nor any other contemporary ever refers to a 1910 paper by Theodor Kaluza (of later five-dimensional Kaluza-Klein theory fame) solving the problem of the "proper geometry" [*Eigengeometrie*] of a Born rigidly-rotating body (Kaluza 1910). Kaluza was prevented by illness from presenting his work at the 1910 Königsberg meeting of the *Deutsche Naturforscher und Ärzte* which may help to explain its lack of impact on the rigid body discussion.

43 However, there is also an important difference between the two: The gravitational field equivalent to the inertial forces in an accelerated reference frame does not appear to correspond to any material sources, while the analogous electromagnetic fields are produced by a charged ring—rotating or not. As noted above, this was the purport of Max Laue's criticism of Einstein's treatment of the gravitational field equivalent to the inertial forces in a uniformly accelerated frame of reference (see note 33), to which Einstein hoped to provide a Machian answer.

44 Max Laue to Albert Einstein, 22 December 1911, (CPAE 5, 384–385); citation from p. 385.

45 English translation "Considerations on Gravitation," in (Lorentz 1899–1900b).

46 This was probably at least in part in response to Abraham's work on the problem of gravitation, which appeared early in 1912. Abraham's first two papers on the subject, dated "December 1911," were received 14 December and published in the issue of 1 January 1912 of *Physikalische Zeitschrift* (Abraham 1912a; Abraham 1912b). There is evidence that Einstein had corresponded with Abraham about his theory before publication (see below).

47 See Einstein to Hendrik Antoon Lorentz, (CPAE 5, 411–413); reference to gravitation on p. 413.

> Einstein told me about his gravitational work. [I omit some equations referring to the static case] Centrifuging of radiation.[48]

A subsequent letter from Ehrenfest makes clear the meaning of the final, rather cryptic phrase. He reports that a Russian colleague, Michael Frank, has "put me in a very uncomfortable situation" by asking Ehrenfest to translate into German a work concerning "the geometry of light rays in a uniformly rotating laboratory." After describing Frank's work, Ehrenfest adds:

> If one wanted to transform the acceleration field of uniform rotation into a corresponding force field at rest, as you do in your paper 'On the Influence of Gravitation ...' for uniform linear acceleration, then this substitute force-field would also have to give the proper Coriolis deflection for light rays.—That is the content of [Frank's] note. The thing is embarrassing [*peinlich*] for me since you had already communicated this argument to me. ... I told him that you had already told me about this (I remembered it naturally just at the moment when "Coriolis" was recognizable.)[49]

So "centrifuging of radiation" refers to "the geometry of light rays in a uniformly rotating laboratory," a problem on which Einstein had evidently worked before 24 February 1912 when he presented his results to Ehrenfest. Einstein's mention of "Coriolis" indicates that he had in mind a velocity-dependent gravitational force. It was presumably the publication of Frank's paper[50] that decided Einstein against publishing his own version of the results on light rays. He wrote Ehrenfest:

> Translate that work [of Frank-JS] in tranquility. I do not arrogate to myself any relativity-monopoly! Everything that is good is also welcome. You needn't send the proofs.[51]

So by February 1912, as seems probable on the basis of his own writings; and surely by April, on the basis of Ehrenfest's letter, Einstein was aware that the gravitational field equivalent to a rotating frame of reference would have to exert a force on a light ray that depends not only on its position but on (at least the direction of) its velocity—something that is incompatible with a scalar theory of gravitation. So, even while writing his first paper on the static gravitational field, he was aware that a scalar theory was not possible for more general gravitational fields. I shall return to this point below.

Ehrenfest continued to work on the kinematic aspects of the gravito-stationary problem. In a postcard, he writes that he has solved the "Problem: To determine the *most general* field of world-lines that is equivalent to a *stationary* gravitational field." He mentions two "special cases": "hyperbolic motion" (i.e., constant linear acceleration) and "uniform rotation."[52] Subsequent letters outline the proof his solution.[53] In

50 "Bemerkung betreffs der Lichtausbreitung in Kraftfeldern," (Frank 1912). The paper is dated 7 March 1912. Frank does not suggest that the force field equivalent to a force-free rotating frame of reference could be gravitational.

51 Einstein to Ehrenfest, 25 April 1912, (CPAE 5, 450–451); citation from p. 450.

reply to one of these letters, Einstein says that he does not understand Ehrenfest's result,[54] but adds some comments on the problem:

> A rotating ring does not generate a static field in this sense [the sense of Papers I and II, see note 70–JS], although it is a time-independent field. In such a field the reversibility of light paths does not hold.[55] My case corresponds to the electrostatic field in electromagnetic theory, while the more general static case would also include the analogue of the static magnetic field. I am not yet that far along. The equations I have found only relate to the static case of masses at rest.[56]

I have now given reasons for believing that, at the earliest by 1909 and the latest by the end of 1911, Einstein was aware of problems with the interpretation of both temporal and spatial coordinates in accelerating frame of reference in Minkowski space; and that, by February 1912 at the latest, he had every reason to expect that the full theory of gravitation would have to pass beyond the limits of a four-dimensional scalar theory, on the one hand; and, at least spatially, beyond the limits of Euclidean geometry. Now I shall turn to Einstein's investigation of static gravitational fields, which ultimately led to the resolution of these problems.

SCENE II: "THE SPEED OF LIGHT IS NO LONGER CONSTANT"

It may well have been Max Laue who directed Einstein's attention to the crucial importance of the gravitational potential, and the possibility of its replacement by the variable speed of light. The letter Laue sent Einstein at the end of 1911 was cited above, but I must now quote from it at greater length. (Unfortunately we do not have Einstein's letter, if there was one, to which this is a reply.)[57] Discussing Einstein's 1911 paper,[58] he writes:

---

52 Ehrenfest to Einstein, 14 May 1912, (CPAE 5, 460–461). In later chapters, these two "special cases" will become very familiar to the reader since they are the two test cases that Einstein uses again and again to evaluate candidate gravitational field equations.

53 Only Ehrenfest's drafts of his letters have been preserved: Ehrenfest to Einstein: after 16 May 1912, (CPAE 5, 461–464, see 462–463); 29 June 1912, (CPAE 5, 487–496). Einstein to Ehrenfest, 25 April 1912, (CPAE 5, 450–451, see 451); 27 April 1912, (CPAE 5, 455); before 20 June 1912, (CPAE 5, 484–486, see 485–486). (Only letters containing references to gravitation are cited.) Ehrenfest later published a paper on this subject: "On Einstein's Theory of the Stationary Gravitation Field," (Ehrenfest 1913a); original version, (Ehrenfest 1913b).

54 Einstein to Ehrenfest, before 20 June 1912, (CPAE 5, 484–486, see p. 485).

55 This assertion is analogous to the result discussed above that Frank had published, but with a subtle difference. Like Einstein, Frank had discussed Minkowski spacetime as seen from a uniformly rotating frame of reference and the field (he does not specify it as gravitational) equivalent to the inertial forces present in such a frame. Here, Einstein is discussing the gravitational field generated by a rotating material ring, which he must have realized would be non-Minkowskian since this is true even for the field of a non-rotating material ring.

56 Einstein to Ehrenfest, before 20 June 1912, (CPAE 5, 484–486, see p. 486).

57 Since Einstein does not raise the question of whether the gravitational field strength is a four-vector or a six vector in his 1911 paper, I assume that the phrase "Your question" in Laue's letter refers to either a previous letter or conversation.

> It seems extraordinarily characteristic to me that the gravitational potential thereby acquires a physical significance, which is completely lacking for the electrostatic potential. One could, in principle, immediately determine the former by measurement of the velocity of light.

This comment may well have been the cue that prompted Einstein's replacement of the gravitational potential by the variable speed of light in his gravito-static theory.

But, as indicated in the last section, the letter contains more significant clues to the direction in which Einstein was heading. Laue continues:

> Your question, whether the gravitational field strength should be represented by a four-vector or a six-vector, is thereby settled. Not it [the field strength–JS] but rather the potential accordingly seems to me to be the primary concept, the four-dimensional representation of which must be investigated.[59]

A little background is helpful in assessing the full significance of this comment of Laue's. After initially slighting the significance of Minkowski's four-dimensional reformulation of the special theory, Einstein had started to study it in earnest around 1910,[60] probably at least in part in response to Sommerfeld's exposition of a four-dimensional vector algebra and analysis (Sommerfeld 1910a; Sommerfeld 1910b),[61] and its incorporation and further development in Laue's textbook—the first on special relativity.[62]

A further motive for this study was Einstein's decision to include the four-dimensional approach in a major review article that he agreed to write in 1911, and started work on by 1912.[63] In this review he notes that an anti-symmetric second rank tensor "is, following Sommerfeld, usually designated as a six-vector" [*Sechservektor*],[64]

58 See (Einstein 1911b).

59 Max Laue to Albert Einstein, 27 December 1911, (CPAE 5, 384).

60 In 1908, Einstein and Laub thought it worthwhile to publish a paper rederiving Minkowski's four-dimensional results on electrodynamics (see Minkowski 1908) in three-dimensional form because that "work makes rather great demands mathematically on the reader," see (Einstein and Laub 1908). In a review talk on special relativity given in January 1911, Einstein included a brief discussion of "the highly interesting mathematical development that the theory has undergone, primarily due to Minkowski who unfortunately died so young," noting that it had led to "a very perspicacious representation of the theory, which essentially simplifies its application" see (Einstein 1911a). For a discussion of Minkowski's work and the varying forms of its assimilation by the physics and mathematics communities, see (Walter 1999).

61 He states that the formalism he presents "is (aside from imaginary coordinates) an immediate generalization of the customary three-dimensional vector methods", and provides "a complete substitute for the matrix calculus used by Minkowski" (Sommerfeld 1910a, 749).

62 Laue notes that he has "taken into account extensively the mathematical development of the theory that Sommerfeld has recently given" (Laue 1911, vi). Einstein commented: "His book on relativity theory is a little masterpiece," Einstein to Alfred Kleiner, 3 April 1912, (CPAE 5, 445–446).

63 This article, prepared for Erich Marx's *Handbuch der Radiologie*, was completed but has been published only recently: See "Manuscript on Relativity," (CPAE 4, 9–108). For its history, see the Editorial Note, "Einstein's Manuscript on the Special Theory of Relativity," (CPAE 4, 3–8).

64 See (CPAE 4, 72). Sommerfeld had given the names "four-vector" and "six-vector" to what Hermann Minkowski had called "spacetime vectors of type I and II," respectively (Minkowski 1908, 65–68).

and notes that the electromagnetic field strength, the components of which are the electric (see p. 9) and magnetic (see p. 10) field strengths, is a six-vector (see p. 81).

So it is reasonable to assume that Einstein had already mastered the four-dimensional formalism by the time that he raised the question of whether the gravitational field strength is a six-vector (as in the electromagnetic case) or a four-vector (as would be the case of it were the gradient of a scalar field). Laue's reply assumes knowledge of the fact that the electromagnetic six-vector is the curl of the electromagnetic potential four-vector;[65] which breaks up into the electric potential (a three-scalar) and the magnetic (three-)vector potential with respect to any inertial frame. If we look only at the electrostatic field strength, it can be written as the three-gradient of the electric potential. But, Laue points out, the electrostatic potential is of no physical significance (because of the possibility of what are now called gauge transformations of the electromagnetic potentials);[66] while Einstein's 1911 work showed that the gravitational potential has an immediate physical significance because of its influence on the speed of light. Therefore, Laue suggests, the important question is: What is the four-dimensional representation of the gravitational *potential*? The fact that, in the static case, it reduces to a single quantity that behaves as a scalar under three-dimensional spatial transformations is *not* decisive for answering this question. The same is true of the electrostatic potential; yet the latter is known to be the fourth (i.e., timelike) component of a four-vector.

Thus, Laue's comment could have served to draw Einstein's attention away from the representation of the gravitational field strength, and toward the question that, within a few months, was to occupy him: What is the four-dimensional representation of the gravitational potential in the non-static case?

Laue's comment, like all of his and Sommerfeld's work on the four-dimensional formalism, is situated within the context of the special theory of relativity. But, as we have seen, with Einstein's interpretation of the equivalence principle as implying an enlargement of the relativity group, Einstein had already moved beyond that context; and he soon moved into the context of non-flat spacetimes. Indeed, there is a comment by Einstein himself dating from mid-1912, on the question of the four-versus six-vector representation of the gravitational field strength, that suggests the need for this shift of context:

> If the gravitational field can be interpreted within our present [i.e., special–JS] theory of relativity [*sich ... im Sinne unserer heutigen Relativitätstheorie deuten läßt*], then this can only happen in two ways. One can consider [*auffassen*] the gravitational vector either as a four-vector or as a six-vector. [In either case] one arrives at results that contradict the ... consequences of the law of the gravitational mass of energy, [namely] ... that gravitation acts more strongly on a moving body than on the same body in case it is at rest. ... It must

65 See Laue's book, *Das Relativitätsprinzip*, (Laue 1911, 99–100), which defines the "four-potential vector" [*Viererpotential*] as the four-vector, the four-curl of which is the electromagnetic field six-vector; and notes that the four-potential vector is only determined up to the four-gradient of a scalar.

66 This was, of course, long before discussions of the physical significance of the electromagnetic potentials, based on the Aharonov-Bohm effect, took place.

> be a task of the immediate future to create a relativistic-theoretical schema in which the equivalence of gravitational and inertial mass finds expression.[67]

In a similar vein, he wrote to Wien that:

> the [special–JS] relativity theory imperatively demands a further development since the gravitational vector cannot be fitted into the relativity theory with constant c if one demands the *gravitational* mass of energy[68]

As it turned out, such a theory would not only pass beyond the bounds of the special theory; it would involve spacetimes with non-flat line elements, as we shall soon see.

To summarize: There are good reasons to suggest that, by the beginning of 1912, Einstein already realized that he would ultimately have to go beyond a scalar theory of gravitation. His strategy was to proceed in a step-by-step fashion towards a full dynamical theory. The first step in the program was to consider what I have called above the gravito-static case, the gravitational analogue of electrostatics; but he was already thinking about the next step, the gravito-stationary case, the gravitational analogue of magnetostatics. His ultimate goal was to develop a theory for time-dependent gravitational fields.

Let us look at the first step, gravito-statics. By March 1912 he was able to write Paul Ehrenfest:

> The investigations of gravitational statics (point mechanics electromagnetism gravito-statics) are complete and satisfy me very much. I really believe that I have found a part of the truth. Now I am considering the dynamical case, again also proceeding from the more special to the more general [case–JS].[69]

Einstein was referring to his two papers on the static gravitational field (hereafter cited as "Paper I" and "Paper II"), completed in February and March 1912 respectively.[70] These papers center on the gravitational potential, as Laue had suggested, but effect a crucial transformation of the problem in line with Laue's comment that the gravitational potential could "in principle be determined by measurement of the speed of light." In his 1911 paper, Einstein had already shown that, with a certain definition of the universal time:[71]

> in a static gravitational field a relation between c [the speed of light–JS] and the gravitational potential exists, or in other words, that the field is determined by c. (Einstein 1912b, 360)

In Papers I and II $c(x,y,z)$, the spatially variable but temporally constant and direction-independent speed of light, completely replaces the gravitational potential.

67 "Relativität und Gravitation. Erwiderung auf eine Bemerkung von M. Abraham," (Einstein 1912c). The paper was received on 4 July 1912. The citations are from pp. 1062–1063.

68 Einstein to Wilhelm Wien, 17 May 1912, (CPAE 5, 465).

69 Einstein to Paul Ehrenfest, 10 March 1912, (CPAE 5, 428).

70 Paper I:"Lichtgeschwindigkeit und Statik des Gravitationsfeldes," (Einstein 1912b); reprinted in (CPAE 4, 130–145); Paper II: "Zur Theorie des statischen Gravitationsfeldes," (Einstein 1912d); reprinted in (CPAE 4, 147–164). For a discussion of these papers, see the Editorial Note "Einstein on Gravitation and Relativity: The Static Field," (CPAE 4, 122–128).

Most of Paper I is concerned with establishing the gravitational field equation that c obeys, and the equations of motion of a (test) particle in the static gravitational field described by c. Much of Paper II is concerned with a revision of the field equation of Paper I (Section 4), and a crucial mathematical reformulation of the equations of motion (The "Supplement" to the Proofs).[72]

Einstein's introduction of a variable speed of light brought down much scorn upon him at the time,[73] but it was absolutely crucial in initiating the sequence of steps that lead to the culmination of Act II: Einstein's leap from a scalar to a tensorial gravitational potential, in which $c(x,y,z)$ becomes one of the ten components of the metric tensor used to construct the line element of a non-flat spacetime.

Paper I also contains another step in the process. Einstein shows that, if one uses a light clock, for example, to measure:

> the local time, which Abraham denotes by l, then this stands to the universal time $[t]$ in the relation $dl = c\ dt$. (Einstein 1912b, 366)

In retrospect (remembering that here c is non-constant), we recognize in this equation the relation between the differential element of the proper time dl between two events at the same place (i.e., $x,y,z = \text{const}$) in a static field, and the coordinate differential dt between the times of the two events, using the preferred static time coordinate t. This equation begins to answer the question of the relation between coordinates and physical measurements in a gravitational field that had been puzzling Einstein for almost five years.

But before expanding on this point, let me turn to a further step in the process, contained in Paper II. The equations of motion of a particle in a static gravitational field, developed in Paper I, were rewritten in Lagrangian form in a "Supplement to

---

71 "The time in the field [that is] defined by the stipulation that the speed of light c depends indeed upon the position but not on direction" as Einstein explained to Michele Besso, 26 March 1912, (CPAE 5, 435). This definition of the time is given in more detail in Paper I: "We think of the time in the [uniformly accelerated–JS] system K as measured by clocks of such a nature and such a fixed arrangement at the spatial points of K that the time intervals—measured with them—that a light ray takes to go from a point A to a point B of the system K does not depend on the moment of emission of the light ray at A [static condition]. Further it turns out that simultaneity can be defined without contradiction in such a way that, with respect to the settings of the clocks, the stipulation is satisfied that all light rays passing a point A of K have the same speed of propagation, independent of their direction" [isostropy condition] (Einstein 1912b, 357–358).

72 The revision of the gravitational field equation is discussed in some detail in "Pathways out of Classical Physics …" (in this volume). The remainder of Paper II is concerned with electromagnetism (Sections 1 and 2) and thermodynamics (Section 3) in a static gravitational field, topics I shall not consider.

73 Abraham, for example, exulted: "Einstein ... had already given up his postulate of constancy of the velocity of light at the turn of the year, which was so essential for his earlier theory; in a recent work he abandons the requirement of the invariance of the equations of motion under Lorentz transformations, thereby delivering the *coup de grace* to the theory of relativity. Those who, like the author, have repeatedly had to warn against the siren song of this theory, can only greet with satisfaction the fact that its originator has now convinced himself of its untenability" (Abraham 1912e).

the Proofs" of Part II. This step proved to be so significant that it soon led to the final resolution of the problem of the correct representation of the gravitational potentials.

> It is noteworthy that the equations of motion of a particle [*materielle Punkt*] in the gravitational field take a very simple form when they are given the form of Lagrange's equations. Namely, if one takes
>
> $$H = -m\sqrt{c^2 - q^2},$$
>
> then ... For a particle moving in a static gravitational field without the action of external forces, there holds accordingly
>
> $$\delta\left\{\int H\ dt\right\} = 0,$$
>
> or
>
> $$\delta\left\{\int\sqrt{c^2dt^2 - dx^2 - dy^2 - dz^2}\right\} = 0.$$
>
> Here too—as was proved by Planck for the usual [i.e., special] theory of relativity—it is seen that the equations of analytical mechanics possess a significance that extends far beyond Newtonian mechanics. Hamilton's equation as finally written down lets us anticipate [*ahnen*] the structure of the equations of motion of a particle in a dynamical gravitational field. (Einstein 1912d), 458)

Einstein's lecture notes on mechanics, which he had been teaching since 1909,[74] show his familiarity with the use of variational techniques to derive the Lagrangian equations of motion (CPAE 3, 91–95, 116–117). Even more important for present purposes, he stressed the coordinate-invariant nature of the resulting equations of motion:

> The Cartesian coordinates of the particle no longer enter into the [variational–JS] principle. It holds independently of whatever coordinates we use to determine the position of the particles of the system (p. 93).

Now we have in hand all the strands, the interweaving of which finally allowed Einstein to take the great leap forward to a metric theory of gravitation. But let me emphasize that, however much they may help us in retrospect to understand the process, there remains something almost uncanny in how Einstein made the choices that led him so far from the path trodden by other physicists in the search for a relativistic theory of gravitation. He was about to enter an entirely new land, in which the space-time structure becomes a dynamical field.

74 "Lecture Notes for Introductory Course on Mechanics at the University of Zurich, Winter Semester 1909–1910," (CPAE 3, 11–129). See also the Editorial Note, "Einstein's Lecture Notes," (CPAE 3, 3–10, especially Section II, 4–6). Einstein also taught mechanics in Prague during the winter semester of 1911; see "Appendix B: Einstein's Academic Courses," (CPAE 3, 598–600).

SCENE III: "TEN SPACETIME FUNCTIONS":

Just what did the variational reformulation of the equations of motion lead Einstein to "anticipate"? I propose to answer this question with the help of the first three sections of his following paper on the topic, the "*Entwurf*" paper, published early in 1913.[75] After introductory comments discussing the equivalence principle, Section 1 treats "The equations of motion of a particle in a static gravitational field." Except for one small but significant detail, it is just an expanded version of the "Supplement." The detail is notational: he writes ds as an abbreviation for $\sqrt{c^2dt^2 - dx^2 - dy^2 - dz^2}$ for both the case of constant c ("the usual theory of relativity") and the spatially variable but static $c(x,y,z)$.

The significance of this notation does not emerge until Section 2, which treats "Equations for the motion of a particle in an arbitrary gravitational field. Characterization of the latter":

> With the introduction of a spatial variability of the quantity c we have passed beyond the framework of the theory that is now designated as "the theory of relativity"; for the expression designated by ds no longer behaves as an invariant under linear orthogonal transformations of the coordinates. ...
>
> If we introduce a new spacetime system $K'(x', y', z', t')$ by means of an arbitrary substitution.
>
> $$\begin{aligned} x' &= x'(x, \mathrm{y}, z, t) \\ y' &= y'(x, y, z, \mathrm{t}) \\ z' &= z'(x, y, z, t) \\ t' &= t' = (x, y, z, t) \end{aligned}$$
>
> and if the gravitational field in the original system K is static, then under this substitution equation (1) goes over into an equation of the form
>
> $$\delta\left\{\int ds'\right\} = 0,$$
>
> where
>
> $$ds'^2 = g_{11}dx'^2 + g_{22}dy'^2 + \ldots + 2g_{12}dx'dy' + \ldots$$
>
> and the quantities $g_{\mu\nu}$ are functions of x', y', z', t' ...
>
> Thus we arrive at the interpretation that, in the general case, the gravitational field is characterized by ten spacetime functions ... . (Einstein and Grossmann 1913, 6)

75 "Entwurf einer verallgemeinerten Relativitätstheorie und einer Theorie der Gravitation I. Physikalischer Teil von Albert Einstein," (Einstein and Grossmann 1913); reprinted in (CPAE 4, 303–323). For a discussion of this paper, see the Editorial Note "Einstein on Gravitation and Relativity: The Collaboration with Marcel Grossmann," (CPAE 4, 294–301). See also the Editorial Note "Einstein's Research Notes on a Generalized Theory of Relativity,"(CPAE 4, 192–199, especially Section II, 193–195).

Einstein proceeds to derive the equations of motion from the generalized Hamiltonian function (which we would now call the Lagrangian):

$$H = -m\frac{ds}{dt} = -m\sqrt{g_{11}\dot{x}_1^2 + \dots + \dots + 2g_{12}\dot{x}_1\dot{x}_2 + \dots + \dots + 2g_{14}\dot{x}_4 + \dots + g_{44}}$$

[where $\dot{x}_1 = \frac{dx_1}{dt}$, etc. -JS].

He writes the three Lagrange equations for the three spatial coordinates x_i, derives from them expressions for the momentum of the particle and the force exerted on it by the gravitational field; and then derives the energy of the particle by performing the usual Legendre transformation on H. He closes this discussion by noting that:

> In the usual relativity theory only linear orthogonal substitutions are permitted. It will be shown that we are able to set up equations for the influence of the gravitational field on material processes that behave covariantly under arbitrary substitutions. (Einstein and Grossmann 1913, 7)

Up to this point, there is nothing in Einstein's results that depends on the interpretation of the $g_{\mu\nu}$ as anything more than a generalization of his 1912 results for the static gravitational field to their form in an arbitrary reference frame. (Remember that, for Einstein, a change of coordinates amounts to a change of spacetime reference frame.) In such a frame, the single static gravitational potential c is transformed into ten functions $g_{\mu\nu}$.

It is only in the next section of the paper, "Significance of the Fundamental Tensor $g_{\mu\nu}$ For the Measurement of Space and Time," that he proceeds to the geometrical interpretation of these functions in spacetime. After recalling that the time coordinate had already lost its immediate physical significance in a static gravitational field, he continued:

> In this connection, we remark that ds is to be understood as an invariant measure for the interval [*Abstand*] between two neighboring spacetime points. (Einstein and Grossmann 1913, 8)

Presumably, this is what his results in the "Supplement" suggested to him almost immediately: if the integrand is interpreted as the interval ds between neighboring points, then the variational principle can be interpreted as giving rise to the equation for a geodesic in the resulting non-flat space time. In a later reminiscence (Einstein 1955),[76] Einstein stated:

> The equivalence principle allows us ... to introduce non-linear coordinate transformations in such a [four-dimensional] space [with (pseudo)-Euclidean metric]; that is, non-Cartesian ("curvilinear") coordinates. The pseudo-Euclidean metric then takes the general form:
>
> $$ds^2 = \sum g_{ik}dx_i dx_k$$

76 Cited from those given in (Seelig 1955).

> summed over the indices i and k (from 1–4). These g_{ik} are then functions of the four coordinates, which according to the equivalence principle describe not only the metric but also the "gravitational field." ... This formulation so far applies only to the case of pseudo-Euclidean space. It indicates clearly, however, how to attain the transition to gravitational fields of a more general type. Here too the gravitational field is to be described by a type of metric, that is a symmetric tensor field g_{ik} ... The problem of gravitation was thereby reduced to a purely mathematical one. Do differential equations exist for the g_{ik} that are invariant under non-linear coordinate transformations? Such differential equations and *only* such could be considered as field equations for the gravitational field. The equation of motion of a particle was then given by the equation for a geodesic line.
>
> With this task in mind, I turned to my old student friend Marcel Großmann, who had in the meantime become Professor of Mathematics at the ETH (pp. 14–15).

Einstein here makes a rather precise claim about what he had accomplished before turning to Grossmann upon his move back to Zurich at the end of July 1912. Earlier, in 1923, he had made a similar claim, but with a significant addition—a reference to Gauss:

> I first had the decisive idea of the analogy between the mathematical problems connected with the theory and the Gaussian theory of surfaces in 1912 after my return to Zurich, initially without knowing Riemann's and Ricci's or Levi Civita's investigations.[77]

In the 1955 reminiscence, Einstein noted that Carl Friedrich Geiser's course on differential geometry at the ETH played an important role in his thinking; it was in that course that he learned about Gauss' theory of surfaces, based on analysis of the distance ds between neighboring points on a surface, expressed in terms of an arbitrary coordinate system on the surface, thereafter often called Gaussian coordinates.[78]

The spacetime interval ds Einstein introduced represents a generalization of what was often referred to in differential geometry as the "line element." The term "element" appears to go back to Monge, who speaks of the "elements" [*élémens*] of a curve in space. Coolidge comments: "An élémen is an infinitesimally short chord."[79] Gauss[80] makes the concept of what he calls a "line element" [he uses both "*Linienelement*" and "*Linearelement*"—see (Gauss 1881, 341–347)] connecting a pair of points on a two-dimensional surface central to his theory of surfaces, and

77 In the Preface to the Czech edition of his popular book on relativity. The German text is in (CPAE 6, 535, n. [4]).

78 In (Einstein 1955), Einstein described the lectures as "true masterpieces of pedagogical art, which later helped me very much when wrestling with general relativity" (pp. 10–11). In a letter of 24 April 1930 to Walter Leich, Einstein wrote: "Geiser was dry only in the large lectures, otherwise I owe him the most of all." For an outline of the contents of Geiser's course on "Infinitesimalgeometrie" given in the Winter Semester of 1897/1898 and the Summer Semester of 1898, based on Grossmann's lecture notes, see (CPAE 1, 365–366). Grossmann's notes are preserved in the ETH Bibliothek, Hs 421: 15 & 16.

79 See (Coolidge 1940), "Book III Differential Geometry," Chapters I, II and III, 318–387. The citations are from p. 322.

shows that it may be used to define the intrinsic properties of the surface, such as its curvature. Bianchi-Lukat (Bianchi 1910, 60–61)[81] defines ds as the "element of a curve" [*Bogenelement*], and comments:

> Since the expression for ds given by [$ds^2 = Edu^2 + 2Fdudv + Gdv^2$, the right hand side being the square of Gauss' expression for the line element] holds for any arbitrary curve on the surface, it is designated the *line element* of the surface. Gauss' ideas were generalized to n- dimensional manifolds by Riemann. (Riemann 1868)[82]

The basic ideas of Gauss' theory of surfaces are reproduced in Grossmann's notes on Geiser's course on differential geometry [*Infinitesimalgeometrie*].[83] Reich indicates some of the high points:

> Geiser treats the line element and its special form in different coordinate systems especially intensively,

indicating that he used the notation ds^2 for it.

> The curvature of surfaces and especially the Gaussian measure of curvature, which Geiser derives in Gauss' fashion and with Gauss' notation, is a particular theme of the semester. The result reads: 'if
>
> $$ds^2 = E\ dp^2 + 2F\ dp\ dq + G\ dq^2,$$
>
> then the measure of curvature depends solely on E, F, G and their derivatives.'... A further important point are geodesic lines. After a longish introduction, Geiser goes into the 'differential equation for geodesic lines,' ... It appears important to me that Geiser offers not only the geometrical aspect but also argues invariant-theoretically, as in the case of the metric, the measure of curvature and of geodesic lines. (Reich 1994, 164–165)

Geiser included a derivation of the equation for a geodesic on a surface by variation of the integral $\int ds$, where

$$ds^2 = \sqrt{E\ dp^2 + 2F\ dp\ dq + G\ dq^2},$$

along some curve $q = \psi(p)$ to find its minimum.[84] Comparison of this with Einstein's variational principle for the equations of motion of a particle in a static gravitational field could have suggested the analogy between Gauss' theory of surfaces and Einstein's theory of the static gravitational field.

80 "Disquisitiones generales circa superficies curvas," (Gauss 1828); reprinted in (Gauss 1881, 217–258). A valuable notice ["*Anzeige"*] by Gauss appeared in (Gauss 1827); reprinted in (Gauss 1881, 341–347). The basic idea of using the line element to investigate the properties of a surface had already been used in Gauss' 1822 Prize Essay, (Gauss 1825); reprinted in (Gauss 1881, 189–216). For discussions, see (Coolidge 1940, ch. III, sec. 1, 355–359) and (Stäckel 1918, Heft V, 25–142, sec. V, "Die allgemeine Lehre von den krummen Flächen," 104–138).

81 As we shall see below, this work was consulted by Marcel Grossmann.

82 This refers to the posthumous publication of Riemann's *Habilitationsschrift* of 1854.

83 These notes are described in (Reich 1994, 163–166).

84 Grossmann notes for 10 June 1898.

So much for the mathematical literature. In the physics literature, the equivalent proper time element $d\tau$ had been introduced by Minkowski for timelike worldlines.[85] But neither the concept of, nor the notation for, the line element ds or the proper time element $d\tau$ occurs in the works of Sommerfeld or Laue developing special-relativistic vector and tensor analysis (which, as we have seen Einstein studied) until after 1912.[86] Nor does it occur in Einstein's summary of vector and tensor analysis in his unpublished review of the special theory (discussed earlier).[87]

However, the concept and even the term, were beginning to appear in the physics literature in connection with the discussion of rigid bodies.[88] Herglotz seems to have introduced them (Herglotz 1910, 394). After pointing out that Minkowski had introduced the idea of representing the spatial and temporal coordinates "as the four coordinates of a point in a fourfold-extended manifold $R_4(x, y, z, t)$," he goes on:

> Similarly a measure relation [*Maßbestimmung*] is introduced in this R_4, according to which (the velocity of light being set equal to 1) the square of the distance of two infinitely neighboring points is:
>
> $$ds^2 = dx^2 + dy^2 + dz^2 - dt^2.$$
>
> Line elements of real length $(ds^2 > 0)$ are called spatial, however those of purely imaginary length $(ds^2 < 0)$ are called timelike.

Born's next paper on the definition of a rigid body (Born 1910, 233) speaks of "a four-dimensional space $x\ y\ z\ t$ ... in which a measure relation [*Maßbestimmung*] with the line element $dx^2 + dy^2 + dz^2 - c^2dt^2$ is introduced" (p. 233).

As noted above, Einstein refers to these papers in a 1910 letter, so we may assume that he was familiar with them.[89] And, it was in response to a criticism by Einstein that Abraham wrote:[90]

> On lines 16, 17 of my note "On the Theory of Gravitation," an oversight is to be corrected, of which I became aware through a friendly communication of Mr. A. Einstein. One should read "let us consider dx, dy, dz and $du = i\ dl = i\ cdt$ as components of a displacement ds in four-dimensional space." Thus,

---

85 See Section III, p. 108 of (Minkowski 1909a); it was soon reprinted as a separate booklet, (Minkowski 1909b); and then in Minkowski's *Gesammelte Abhandlungen*, vol. 2, (Minkowski 1911, 431–434).

86 Laue only introduces the proper time and uses it to define the four-velocity in the second edition of *Das Relativitätsprinzip* (Laue 1913, 57 and 69).

87 Einstein does define the four-velocity vector by the following equation:

$$G_\mu = \left\{ \frac{dx_\mu}{\sqrt{-\sum dx_\sigma^2}} \right\},$$

but without any explanation of the expression in the denominator, which does not occur anywhere else in the paper (CPAE 4, 84).

88 See (Maltese and Orlando 1995).

89 "The latest relativity-theoretical investigations of Born and of Herglotz interest me very much ..." Albert Einstein to Jakob Laub, 16 March 1910, (CPAE 5, 231–233; citation from 232).

90 "Berichtigung," (Abraham 1912c). This correction was submitted to issue no. 4, which had a closing date of 2 February 1912, but was published on 15 February 1912.

$$ds^2 = dx^2 + dy^2 + dz - c^2 dt^2$$

> is the square of the four-dimensional line element, in which the velocity of light c is determined by equation (6) [Abraham's relation between the gravitational potential and the speed of light–JS].[91]

Indeed, as noted above, in Paper I on the static field Einstein had written that, in using a light clock:

> we operate with a sort of local time, which Abraham designates with l. This stands in the relation
>
> $$dl = c\ dt$$
>
> to the universal time.

This is the earliest indication (the end of February 1912) that Einstein realized the need to use differentials of the two quantities in order to relate a coordinate time t to a physically measured time l (in this case, the proper time between two events at the same spatial point).

To summarize: on the basis of the mathematical and physical resources at his command, at some point in mid-1912, after generalizing the single gravitational potential c to the array of ten gravitational potentials g_{ik}, Einstein realized that they formed the coefficients of a quadratic form $\sum g_{ik} dx_i dx_k$, which could be regarded as the square of the invariant line element ($ds^2 = \sum g_{ik} dx_i dx_k$) of a four-dimensional spacetime manifold; and that the interval ds represents a physically measurable quantity—the proper time if the interval between two events were time-like, the proper length if it were space-like (of course it would vanish for null intervals).

I suggest that it was at this point that he turned to Grossman. Continuing the quotation from the 1955 reminiscence:

> I was made aware of these [works by Ricci and Levi-Civita—JS] by my friend Großmann in Zurich, when I put to him the problem to investigate generally covariant tensors, whose components depend only on the derivatives of the coefficients of the quadratic fundamental invariant.
>
> He at once caught fire, although as a mathematician he had a somewhat skeptical stance towards physics. ... He went through the literature and soon discovered that the indicated mathematical problem had already been solved, in particular by Riemann, Ricci and Levi-Civita. This entire development was connected to the Gaussian theory of curved surfaces, in which for the first time systematic use was made of generalized coordinates. (Seelig 1955, 15, 16)

91 Abraham reiterated this point in his next paper "Die Erhaltung der Energie und der Materie im Schwerkraftfelde," (Abraham 1912d): "As a result of the variability of c, the Lorentz group only holds in the infinitely small, so that dx, dy, dz and $du = i\ cdt$ represent the components of an infinitely small displacement in a four-dimensional space" (p. 312). Note that, in contrast to Einstein, Abraham's c may be a function of all four spacetime coordinates.

In short: While the analogy to Gaussian surface theory had occurred to Einstein *before* he consulted Grossmann, probably including the role of the line element; the connection between this theory and the later line of development from Riemann to Ricci and Levi-Civita only became clear to Einstein *after* consulting Grossmann.

Louis Kollross, another student friend of Einstein, who was also Professor of Mathematics at the ETH during this time, adds another name that belongs between those of Riemann and of Ricci and Levi-Civita:

> [Einstein] spoke to Großmann about his troubles and said to him one day: "Großmann, you must help me, otherwise I'll go crazy!" And Marcel Großmann succeeded in showing him that the mathematical instrument that he needed had been created precisely in Zurich in the year 1869 by Christoffel in the paper "On the Transformation of Homogeneous Differential Expressions of the Second Degree," published in volume 70 of "Crelle's Journal" for pure and applied mathematics.[92]

A look at Grossmann's Part II of their joint paper, confirms Kollros's recollection:

> The mathematical tool [*Hilfsmittel*] for the development of the vector analysis of a gravitational field that is characterized by the invariance of the line element
>
> $$ds^2 = \sum_{\mu\nu} g_{\mu\nu} dx_\mu dx_\nu$$
>
> goes back to the fundamental paper of Christoffel on the transformation of quadratic differential forms.[93]

So it was Marcel Grossmann, who introduced Einstein to the work of Ricci and Levi-Civita after Einstein's return to Zurich in early August 1912.[94] However, in his exposition Grossmann plays down the geometrical significance of vector and tensor analysis:

> In it I have purposely left geometrical methods [*Hilfsmittel*] aside, since in my opinion they contribute little to the visualization [*Veranschaulichung*] of the concepts constructed in vector analysis (p. 325).

This distinction between tensor analysis and geometrical methods is based on the distinction Ricci and Levi-Civita make between the "fundamental quadric or form" (p. 13),which they denote by ϕ, and the line element (they never use these words), denoted by ds^2, of an n-dimensional manifold, denoted by V_n (see, e.g., pp. 128, 153). They assert that: "The methods of the absolute differential calculus depend essentially on consideration of" the fundamental form (p. 133); but the geometrical interpretation of it "as the ds^2 of a surface" (p. 162) is merely one possibility.

93 "Entwurf einer verallgemeinerten Relativitätstheorie und einer Theorie der Gravitation II. Mathematischer Teil von Marcel Grossmann," (Einstein and Grossmann 1913, 23–38); reprinted in (CPAE 4, 324–339; citation from p. 324). The paper cited is (Christoffel 1869).

94 "Méthodes de calcul différentiel absolu et leurs applications," (Ricci and Levi-Civita 1901).This paper has been translated into English in (Hermann 1975).

Grossmann's exposition of tensor analysis is based on Chapter I, "Algorithm of the Absolute Differential Calculus" (pp. 128–144), which includes discussions of covariant differentiation and of the Riemann tensor that do not depend at all upon the geometrical interpretation of the fundamental form, but rather on the theory of algebraic and differential invariants of the fundamental form and other functions (see pp. 127 of the "Preface" and Section 1 of the first chapter, "Point transformations and systems of functions," pp. 128–130).[95] This is entirely in the spirit of Christoffel's exposition of the differential invariants of a quadratic differential form in n independent variables. Only in the last paragraph of his paper does he mention "a posthumous paper of Riemann" on "the square of the line element in a space of three dimensions" (Christoffel 1869, 70). And indeed, until Levi-Civita developed the concept of parallel displacement in a manifold with metric, geometrical methods did not contribute much to the interpretation of the covariant derivative and the Riemann tensor.[96] Only starting with Chapter II of Ricci and Levi-Civita, on "Intrinsic geometry as a calculational tool," are geometrical applications to n-dimensional manifolds introduced.

Bianchi-Lukat (Bianchi 1910), another source that Grossmann mentions,[97] also separates the invariant-theoretical treatment of "Binary Quadratic Forms" in Chapter II from the geometrical treatment of "Curvilinear Coordinates on Surfaces" in Chapter III, which includes the introduction of "The Line Element of Surfaces" in Section 33.

—But I have already begun to encroach on the opening scene of Act III. If, so far, Einstein's intuition led him almost without mis-step along the highway in the search for dynamical field equations governing the behavior of the metric tensor field, the last act will depict our hero's wanderings along many a curious by-way, before regaining the high road.

---

95 Only in Section 4 of this chapter, "Applications to vector analysis," is "the ds^2 of [Euclidean three-] space as the fundamental form" introduced (p. 135). The paper has a number of lapses: for example, the fundamental form is introduced on p. 130 without the name, and the notation ϕ for it is used on p. 132, before both are defined on p. 133. Most serious, the Christoffel symbols of the second kind are introduced and used to define the covariant derivative on p. 138, without ever being defined or related to the symbols of the first kind, which are defined and then used to define the covariant form of the Riemann tensor (called "the covariant system of Riemann) on p. 142.

PATHWAYS OUT OF CLASSICAL PHYSICS

Einstein's Double Strategy in his Search for the Gravitational Field Equation

CONTENTS

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 1
Einstein's Zurich Notebook: *Introduction and Source*.

1. INTRODUCTION

1.1 The Incomplete Revolution

The relativity revolution was far from complete when Einstein published his path-breaking paper on the electrodynamics of moving bodies in 1905. It started with his reinterpretation of Lorentz's theory of electromagnetism in what may be called a "Copernicus process" in analogy to the transition from the Ptolemaic to the Copernican world system or to the transition from preclassical to classical mechanics.[1] In such a transition the formalism of an old theory is largely preserved while its semantics change.[2] Einstein's special theory of relativity of 1905 had altered the semantics of such fundamental concepts like space and time, velocity, force, energy, and momentum, but it had not touched Newton's law of gravitation. Since, however, according to special relativity, physical interactions cannot propagate faster than light, Newton's well-established theory of gravitation, based on instantaneous action at a distance, was no longer acceptable after 1905. The relativity revolution was completed only when this conflict was resolved ten years later in November 1915 with Einstein's formulation of the general theory of relativity.

Neither the emergence of the special theory of relativity nor that of the general theory of relativity were isolated achievements. The virtual simultaneity of the beginning of the relativity revolution with Einstein's other breakthrough discoveries of 1905 indicate that his non-specialist outlook and, in particular, his youthful pursuit of atomistic ideas enabled him to activate the hidden potentials of highly specialized nineteenth-century physics that others, such as Henri Poincaré, had also exposed.[3] In 1907, Einstein first attempted to address the issue as to how to modify Newton's law of gravitation according to the new kinematic framework of special relativity, as did others, like Hermann Minkowski and Henri Poincaré.[4] But Einstein began to transcend the very special-relativistic framework in light of Galileo's insight that in a vacuum all bodies fall with the same acceleration. In 1912, to the amazement of colleagues like Max Abraham,[5] he abandoned the scalar gravitational potential of Newtonian physics in favor of a ten-component object—the metric tensor—the mathematics of which he subsequently began to explore with the help of his mathematician friend Marcel Grossmann. And he was able to formulate clear-cut criteria which a field equation for the metric tensor acting as a gravitational potential would have to satisfy. However, in the winter of 1912–1913, Einstein and Grossmann dis-

1 Cf. (Damerow et al. 2004, Renn 2004).
2 Such a change of semantics may be illustrated with the example of Lorentz's concept of local time. Originally merely a peripheral aspect of his theory, this auxiliary variable was reinterpreted by Einstein as the time actually measured by clocks in a moving reference system, thus assuming a central role in the new kinematics of special relativity. For an extensive treatment of the first phase of the relativity revolution compatible with this view, see, e.g., (Janssen 1995).
3 See (Renn 1993, 1997). For the parallelism between Einstein and Poincaré, see also (Galison 2003).

5 See (Cattani and De Maria 1989a) and "The Summit Almost Scaled ..." (in vol. 3 of this series).

carded generally-covariant field equations based on the Riemann tensor, an expression that included second-order derivatives of the metric tensor. Einstein even believed to have a proof that such field equations had to be ruled out, although in hindsight these were the only acceptable mathematical solution. In spite of the skepticism of many of his physics colleagues but supported by the critical sympathy of mathematicians like Tullio Levi-Civita and David Hilbert,[6] Einstein stood by his original agenda and in late 1915 returned to field equations based on the Riemann tensor, finally formulating the general theory of relativity, a theory which became the basis of all subsequent developments in physics and astronomy.

Einstein's Zurich Notebook represents a uniquely valuable and, as it turns out, surprisingly coherent,[7] record of his thinking in an intermediate phase of the emergence of general relativity. The entries begin in mid-1912 and end in early 1913. His aim during this period was to create a relativistic theory of gravitation that makes sense from a physical point of view and that, at the same time, corresponds to a consistent mathematical framework based on the metric tensor. Central to his thinking was the problem of interpreting the physical knowledge on gravitation in terms of a generalization of the mathematical representation associated with Minkowski's four-dimensional spacetime. The main challenge he faced was to construct a field equation, on the one hand, that can be reduced by an appropriate specialization to the familiar Newtonian law of gravitation, and, on the other hand, that satisfies the requirements resulting from his ambitious program to formulate a relativistic theory of gravitation.

There is perhaps no single episode that better illustrates the conceptual turn associated with the genesis of general relativity than the fact that, in the Zurich Notebook, Einstein first wrote down a mathematical expression close to the correct field equation and then discarded it, only to return to it more than three years later. Why did he discard in the winter of 1912–1913 what appears in hindsight to be essentially the correct gravitational field equation, and what made this field equation acceptable in late 1915?[8] Our analysis of the Zurich Notebook has made it possible not only to answer these questions but, more generally, to resolve what might be called the three epistemic paradoxes raised by the genesis of general relativity:

The paradox of missing knowledge. How was it possible to create a theory such as general relativity that was capable of accounting for a wide range of phenomena which were only later discovered in the context of several revolutions of observational astronomy? If neither the expansion of the universe, black holes, gravitational lenses, nor gravitational radiation were known when Einstein set up the gravitational field equation, how could he nevertheless establish such a firm foun-

---

7 See the "Commentary ..." (in vol. 2 of this series) and especially our reconstruction in section 6 of the present chapter.

8 For further discussion of these two questions, see also "Commentary ..." sec. 5, and "Untying the Knot ..." (both in vol. 2 of this series).

dation for modern cosmology? Which knowledge granted such stability to a theory that did not initially seem superior to its competitors, since no phenomena were known at the time which could not also be explained with traditional physics?

The paradox of deceitful heuristics. After a tortuous search in the course of which he even temporarily abandoned hope of ever solving his problem, how was Einstein able to formulate the criteria for a gravitational field equation years before he established the solution? How could he establish a heuristic framework that would quickly lead him to a correct mathematical expression, and then to the conclusion that it was unacceptable, only to bring him back to essentially the same expression three years later?

The paradox of discontinuous progress. How could general relativity with its non-classical consequences—such as the dependence of space and time on physical interactions—be the outcome of classical and special-relativistic physics although such features are incompatible with their conceptual frameworks?

Addressing the challenges which these paradoxes formulate requires taking into account all of the following dimensions that are crucial to a historical epistemology of scientific knowledge: the long-term character of knowledge development, the complex architecture of knowledge, and the intricate mechanisms of knowledge dynamics. In order to resolve these paradoxes and to adequately describe the reorganization of knowledge occurring between 1912 and 1915, we shall, in particular, make use of concepts from cognitive science, adapted to the description of the structures of shared knowledge resources such as those Einstein adopted from classical and special-relativistic physics. These concepts will be used to analyze the architecture of the knowledge relevant to Einstein's search for a gravitational field equation and to explain its restructuring as a result of the interaction with the mathematical representation of this knowledge.

We intend to show in the following that the history of Einstein's search for a gravitational field equation can, against the background of the Zurich Notebook, be written as that of a mutual adaptation of mathematical representation and physical meaning. The eventual success of this adaptation becomes intelligible only if it is conceived of as part of a long-term process of integrating intellectual resources relevant to Einstein's problem that were rooted in the shared knowledge of classical and special-relativistic physics.

Only by analyzing the complex architecture of these shared knowledge resources is it possible to understand in which sense classical and special-relativistic knowledge about gravitation and inertia, energy and momentum conservation, and the relation between different reference frames, was turned into a heuristic framework for Einstein's search. In the course of his work, elements of this heuristic framework crystallized into a double strategy that shaped his search in an essential way until he succeeded in formulating the definitive field equation of general relativity in November 1915.

The identification of the two components of this double strategy has not only allowed us to reconstruct Einstein's notes and calculations in the Zurich Notebook as traces of a surprisingly coherent research process, but also to analyze the dynamics of this process. It has become clear, in particular, how a combination of knowledge resources rooted in classical and special-relativistic physics could give rise to the theory of general relativity whose conceptual foundation is no longer compatible with the knowledge that formed the starting point of Einstein's search. In this way, the genesis of general relativity can be understood as resulting from a transformation of shared resources of knowledge, while Einstein's search for the gravitational field equation appears as an investigation of pathways out of classical physics.

In this introduction, we shall briefly recapitulate the essential elements of our story.[9] We begin with a review of the principal steps taken by Einstein towards a relativistic theory of gravitation between the years 1907 and 1912 before his research is documented in the Zurich Notebook.[10] Here our aim is to show that each of these steps highlighted knowledge resources that were relevant for addressing the challenge of constructing a relativistic theory of gravitation. The heuristics at work in the Zurich Notebook were the result of this prior research experience. We shall then offer a first description of the crucial role played by Einstein's double strategy for his heuristics and finally introduce the epistemological framework for our analysis of how exactly this strategy worked.

In the second section, we shall discuss what we will call Lorentz model, as the conceptual framework for Einstein's construction of a relativistic field theory of gravitation. In the third section, we shall examine the essential elements of his heuristics, showing in which sense these elements turned knowledge resources of classical and special-relativistic physics into key components of Einstein's search. In the fourth section, we shall analyze how this search process was structured by the way in which the Lorentz model functioned as a mental model in the sense of cognitive science. In the fifth section, we shall examine how the candidates for a gravitational field equation that Einstein considered in the course of his search fared in the light of the heuristic criteria he had established on the basis of his prior research experience. This discussion will help to understand why one and the same candidate fared differently depending on the depth to which Einstein had explored the implications of the mathematical representation. In the sixth section, we shall reconstruct Einstein's pathway, as documented in the Zurich Notebook, as a learning experience in which he passed from one candidate field equation to the other, building up strategic devices that would guide him until he reached his final result in 1915. In the seventh section, we

---

9 For Einstein's own account, see (Einstein 1933). The history of general relativity has been an intensive subject of research in the last decades, see, in particular, the contributions in (Stachel and Howard 1989–2006). Especially with respect to Einstein's own path, early contributions were (Hoffmann 1972, Lanczos 1972, Mehra 1974, Earman and Glymour 1978, Vizgin and Smorodinski 1979, Pais 1982, sec. IV., Stachel 1980, 1982), a groundbreaking paper was (Norton 1984). See also (Capria 2005, Howard and Norton 1992, Janssen 1999, 2005, Maltese 1991, Maltese and Orlando 1995, Miller 1992, Norton 1992a, 1992b, 1999, 2000, Renn 2005b, 2005c, Renn and Sauer 1996, 1999, 2003a, Sauer 2005b, Stachel 1987, 1989b, 1995, 2002, Vizgin 2001).

10 For detailed analyses of this part of the story, see "The First Two Acts" and "Classical Physics in Disarray …" (both in this volume).

shall turn to Einstein's elaboration of the so-called *Entwurf* theory, published in 1913 as the result of the research documented in the Zurich Notebook. It will be shown, in particular, how the work on this problematic theory created the preconditions for the conceptual changes of the final theory of general relativity. In the concluding eighth section, we shall review our reconstruction with a view to pinpointing the essential structures of this scientific revolution.

1.2 The Emergence of a Heuristic Framework

The incompatibility between Newton's theory of gravitation and the special theory of relativity of 1905 presented Einstein and his contemporaries with the task of constructing a relativistic theory of gravitation. Special relativity, for the purpose of our account, arose from the confrontation of classical mechanics and classical electrodynamics as two major knowledge blocks, i.e. from the confrontation of two highly elaborated, individually consistent, and empirically well-confirmed systems of knowledge whose simultaneous validity had nevertheless produced inconsistencies and contradictions. The newly established mathematical and conceptual framework of special relativity added to the physical knowledge available for dealing with the problem of a relativistic theory of gravitation. The knowledge blocks of classical mechanics and electrodynamics and of special relativity offered various points of departure for the continuation of the relativity revolution in coming to terms with the problem of gravitation.

The new spatio-temporal framework of special relativity suggested a plausible mathematical procedure for adapting the classical theory of gravitation to the requirements of a relativistic field theory. In classical physics, the Poisson equation determines the Newtonian gravitational potential by a given distribution of the masses that act as the sources of the gravitational field (which in turn can be derived from the gravitational potential).[11] This equation is not invariant with respect to the Lorentz transformations of special relativity. But the Poisson equation can easily be extended in a formal way to a relativistic field equation by adding a differential operator involving the time coordinate. The problem with this obvious generalization was that the resulting theory of gravitation no longer incorporates Galileo's principle according to which all bodies fall with the same acceleration. The most obvious way of bringing gravitation within the purview of the relativity revolution therefore came at the price of having to give up one of the fundamental insights of classical mechanics.

At this point, classical mechanics provided knowledge resources that were turned into an alternative heuristic starting point for the continuation of the relativity revolution. In 1907 Einstein formulated his principle of equivalence as a heuristic device

11 The Poisson equation, being an equation for the gravitational potential, should properly be called a potential equation. However, since the Einstein equations are commonly referred to as "field equations" rather than "potential equations," we will in the following loosely also refer to the Poisson equation as a "field equation."

that allowed him to incorporate Galileo's principle into a relativistic theory of gravitation.[12] The equivalence principle asserts that it is not possible to distinguish between a uniformly and rectilinearly accelerated reference frame without gravitational fields and an inertial system with a static and homogeneous gravitational field. Accordingly, the problem of a revision of the classical theory of gravitation became associated with that of a generalization of the relativity principle to accelerated motion, which henceforth constituted another heuristic guideline for Einstein's further research.[13]

Between 1907 and 1911 Einstein used the equivalence principle to derive several consequences of his yet to be formulated new gravitation theory.[14] By the spring of 1912, he made a first attempt at formulating a theory for a static but otherwise arbitrary gravitational field.[15] The gravitational field equation of this theory was a straightforward modification of the Poisson equation of classical physics. Since the Poisson equation embodies the classical knowledge of gravitation from Newtonian theory, it formed a crucial asset for Einstein's heuristics. The further elaboration of Einstein's theory of the static field met with great difficulties. He found that this theory was incompatible with the conservation of energy and momentum, another pillar of classical physics. This led to another key element of his heuristic framework, the requirement that the conservation laws must be fulfilled.

The various heuristic requirements serving as different starting points for the search for a relativistic theory of gravitation could lead into different directions, confronting it with different obstacles and different intermediate results, as well as leading perhaps to different solutions to the original problem. After finding a more or less satisfactory theory of the static field, Einstein further pursued the heuristics embodied in the equivalence principle and in the knowledge about field theory available in classical physics. This approach led him to consider uniformly rotating reference frames.[16] As with linearly accelerated motion, he sought to interpret the inertial forces occurring in such reference frames as generalized gravitational forces. This interpretation was made plausible by Mach's critical analysis of classical mechanics. But the conceptual and technical difficulties implied by the inclusion of rotating reference frames prevented, for the time being, the formulation of a gravitation theory that covered this more general case as well. In hindsight, it is clear that a response to the difficulties which Einstein encountered required the introduction of more sophisticated mathematical tools. The heuristics based on the equivalence principle led to

13 For a discussion of the problematic relation between the equivalence principle and the generalization of the relativity principle, see, for instance, secs. 1.1.1–1.1.2 of "Commentary" (in vol. 2 of this series) and (Janssen 2005, 61–74).

14 See (Einstein 1911).

15 See (Einstein 1912b) and, for historical discussion, (CPAE 4, 122).

16 The crucial role of rotating reference frames in recognizing the role of non-Euclidean geometry was first discussed in (Stachel 1980), see also (Maltese and Orlando 1995).

substantial but isolated physical insights, and not to the kind of coherent mathematical framework necessary for formulating a relativistic field theory of gravitation.

A different path had meanwhile been followed by Max Abraham, who exploited heuristic clues of the four-dimensional mathematical framework established by Minkowski for special relativity.[17] Abraham succeeded in developing a comprehensive theory of gravitation through an *ad-hoc* modification of this framework. Einstein soon discovered weaknesses in Abraham's theory. After a controversy with Abraham, he realized that a successful application of Minkowski's formalism to the problem of gravitation called for a mathematical generalization of this formalism. In late spring 1912 Einstein found the appropriate starting point for such a generalization of Minkowski's formalism. In the appendix to the last paper he published before the considerations documented in the Zurich Notebook, he formulated the equation of motion in a static gravitational field in a form that suggested that a generalization of his theory of gravitation would involve non-Euclidean geometry as had been formulated by Gauss for curved surfaces. As early as summer 1912 Einstein succeeded in formulating a generally-covariant equation of motion for a test particle in an arbitrary gravitational field. In this equation, the gravitational potential is represented by a four-dimensional metric tensor, which became the key object for Einstein's further research in the following years.

The search for a relativistic gravitational field equation, which occupied Einstein for the following three years, also involved a new role of the heuristic clues that had so far guided the research of Einstein and his contemporaries. Initially, these heuristic clues were more or less isolated hints. They gradually turned into elements of a more systematic research program, characterized by what we have called Einstein's "double strategy." This double strategy allowed him to attack the problem of finding a gravitational field equation by bringing to bear on this problem the entire range of knowledge resources embodied in the various heuristic elements sketched above.

1.3 The Double Strategy

The mathematical difficulty of finding a field equation for the ten-component metric tensor representing the gravitational potential showed Einstein that he needed much more sophisticated mathematical methods than those available to him at that point. A mathematical formalism providing what Einstein's generalized theory of relativity required had been developed in the second half of the 19th century by Gauss, Riemann, and Christoffel. In a paper published in 1901 by Ricci and Levi-Civita on the so-called absolute differential calculus, the work of these mathematicians had been extended to an elaborate mathematical apparatus.[18] However, among physicists, the absolute differential calculus remained largely unknown for a considerable time. Einstein was certainly not familiar with it until mid-1912.[19] Only after his move from

17 For a more detailed treatment, see "The Summit Almost Scaled ..." (in vol. 3 of this series).
18 See (Ricci and Levi Civita 1901).

Prague to Zurich did he gain access to these mathematical methods through his contact with Marcel Grossmann. In October 1912, he wrote to Arnold Sommerfeld:

> I am now working exclusively on the gravitation problem and believe that I can overcome all difficulties with the help of a mathematician friend of mine here. But one thing is certain: never before in my life have I troubled myself over anything so much, and I have gained enormous respect for mathematics, whose more subtle parts I considered until now, in my ignorance, as pure luxury! Compared with this problem, the original theory of relativity is child's play.[20]

The mathematical difficulty of finding a satisfactory relativistic field equation also gave a new role to the physical requirements that such an equation had to satisfy. These physical requirements had to be translated into mathematical conditions to be satisfied by candidate field equations. They were thus also brought into systematic relations with each other. This translation was by no means unambiguous, since Einstein was exploring an as yet largely unknown territory of knowledge. At the same time, the theory had to preserve the physical knowledge on gravitation already available, and its relation to other parts of physics, and it had to be formulated as a mathematically consistent theory built, according to Einstein's insight of 1912, around the four-dimensional metric tensor. This combination of relatively clear-cut conditions and the incompleteness of the information needed to turn the situation into a fully determined mathematical problem was characteristic of Einstein's situation when he began the search for a field equation as documented in the Zurich Notebook. The search strategy that gradually emerged enabled a mutual adaptation of mathematical representation and physical concepts, and provided a heuristic device that eventually turned out to be the adequate response to this situation.

What conditions to be imposed on a relativistic gravitational field equation for the metric tensor had emerged from Einstein's prior research experience? From the mathematical point of view, the task was to find a differential operator of second order for the metric tensor covariant with respect to the largest possible class of coordinate transformations. The requirement that the candidate differential operator has to be of second order follows from the analogy with the classical theory of gravitation: the Poisson equation for the Newtonian gravitational potential is a differential equation of second order. The requirement of the covariance of this differential operator under a broad class of coordinate transformations represented for Einstein the goal of a gen-

19 The works by Bianchi (1910) and Wright (1908) probably served as Einstein's mathematical reference books. For historical discussion, see (Reich 1994).

20 "Ich beschäftige mich jetzt ausschliesslich mit dem Gravitationsproblem und glaube nun mit Hilfe eines hiesigen befreundeten Mathematikers aller Schwierigkeiten Herr zu werden. Aber das eine ist sicher, dass ich mich im Leben noch nicht annähernd so geplag[t] habe, und dass ich grosse Hochachtung für die Mathematik eingeflösst bekommen habe, die ich bis jetzt in ihren subtileren Teilen in meiner Einfalt für puren Luxus ansah! Gegen dies Problem ist die ursprüngliche Relativitätstheorie eine Kinderei." Einstein to Arnold Sommerfeld, 29 October 1912, (CPAE 5, Doc. 421). Unless otherwise noted, all translations are based on the English companion volumes to the *Collected Papers of Albert Einstein*.

eralized relativistic theory in which, if possible, all reference frames would be equivalent.[21] A further requirement was that the classical field equation emerge as a special case of the relativistic field equations under appropriate restrictive conditions, such as for weak and static fields. The heuristic framework furthermore included general physical principles such as Galileo's principle and the laws of energy and momentum conservation applying to the energy and momentum of the gravitational field as well.

These requirements formed the relatively stable framing conditions shaping Einstein's search for the gravitational field equation from its beginning in summer 1912 to the formulation of the eventual solution in late 1915. His main problem was to ensure the compatibility of these different heuristic components by integrating them into a coherent gravitation theory represented by a consistent mathematical framework. It turned out that again and again, in the course of his investigations, only some of Einstein's heuristic goals could be fully realized while others had to be given up or at least modified. If not all of his goals could be satisfied, the appropriate balance between the different heuristic requirements for a gravitational field theory could not be decided *a priori*. Their relative weight could only be judged by their concrete embodiment in candidate gravitational field theories.

Physical properties or mathematical statements could each be looked upon either as principles of construction for the building blocks of the theory or as criteria by which the acceptability of such building blocks could be checked. It is this double perspective that provided the basis for the double strategy that emerged in the course of Einstein's search for the gravitational field equation, as documented in the Zurich Notebook. Earlier the choice between physically or mathematically motivated expressions had been a choice between entirely different approaches to the problem of gravitation. Einstein's 1912 theory of static gravitational field was, for instance, motivated by physical considerations based on the equivalence principle, while Abraham's theory started from mathematical considerations related to Minkowski's formalism. In the course of Einstein's work documented in the Zurich Notebook, the two approaches gradually grew closer and turned into complementary strategies of a more or less systematic research program. In this research program the two approaches were distinguished mainly by the sequence in which the building blocks of the theory come into play. Einstein's "physical strategy" took the Newtonian limiting case as its starting point, then turned to the problem of the conservation of energy and momentum and only then examined the degree to which the principle of relativity is satisfied. His "mathematical strategy," took the principle of relativity as its starting point and only then turned to the Newtonian limiting case and the conservation of energy and momentum. The reconstruction of Einstein's notes in the Zurich Notebook has made it evident that his search for the gravitational field equation is to a large extent determined by the exploration of the possibilities offered by these alternatives.

21 See (Norton 1999) for a discussion about Einstein's ambiguity regarding the difference between invariance and covariance during this period.

Einstein's oscillation between these two strategies is characteristic not only of his approach in the notebook but of his entire struggle with the problem of gravitation between 1912 and 1915, a struggle that brought him from his 1912 static theory, via the *Entwurf* theory of 1913, to the final theory of general relativity.[22]

This oscillation between the physical and the mathematical strategy suggests that his search for the gravitational field equation was not just a matter of resolving a well-defined mathematical problem, but involved an interaction between mathematical representation and physical concepts that affects the structures of the mathematical and physical knowledge. Why else did Einstein's first attempts along the mathematical strategy in the winter of 1912–1913 fail, while his pursuit of the physical strategy seemed to be essentially successful, at least until the demise of the *Entwurf* theory in late 1915?[23] As we will show in detail, the completion of the general theory of relativity required, in addition to the appropriation of the available mathematical knowledge, a revision of foundational concepts of physics, the extent of which Einstein could hardly have foreseen at the beginning of his search. He initially believed that classical physics would provide the appropriate context for the theory to be found and attempted to formulate a gravitational field equation by immediate generalization of familiar Newtonian concepts. It eventually turned out to be more successful to construct a field equation corresponding to Einstein's program of integrating gravitation and relativity than to relate it to the conceptual foundations of classical theory.

1.4 The Epistemological Framework of the Analysis

How was it possible for Einstein to formulate a theory involving conceptual novelties on the basis of knowledge that was still anchored in the older conceptual foundation of classical physics? Such a development can hardly be described in terms of formal logic. As Einstein's investigative pathway illustrates, scientific conclusions can result in a reconceptualization of the premises on which these conclusions were based. Even in cases involving major restructuring of knowledge, science never starts from scratch. In fact, not only scientific knowledge but also the knowledge of large domains of human experience transmitted over generations is not simply lost when new scientific theories replace the old ones. In the case at hand, the knowledge of classical physics had to be preserved and exploited in a conceptual revolution, the outcome of which was a relativistic theory of gravitation whose far-reaching physical implications were largely unknown when it was created. But they eventually changed our understanding of the universe. An adequate description of the cognitive dynamics of the genesis of general relativity therefore requires an account of the knowledge that

22 Very similar characteristics of a physical and mathematical double strategy have also been identified in Einstein's later work on unified field theory, see (van Dongen 2002, 2004) and (Sauer 2006) for further discussion. See also the discussion in (Norton 2000).

23 And, as is argued in "Untying the Knot …" (in vol. 2 of this series), beyond the demise of this theory as well.

makes it understandable. We have to understand, first, how past experiences can enter inferences about matters for which only insufficient information is available, and, second, how conclusions can be corrected without eventually having to start from scratch each time a premise is found to be wanting, with the possibility that the whole deductive structure changes in the process. Such an approach is offered by an historical epistemology that integrates the methodology of historical analysis with a theoretical framework informed by philosophical epistemology and cognitive science.

In order to adequately account for the features of Einstein's search for the gravitational field equation described above, we will in the following make use in particular of the concept of a "mental model" and the concept of a "frame."[24] A mental model for us is an internal knowledge representation structure serving to simulate or anticipate the behavior of objects or processes. It possesses "terminals" or "slots" that can be filled with empirically gained information, but also with default assumptions resulting from prior experience. The default assumptions can be replaced in light of new information, so that inferences based on the model can be corrected without abandoning the model as a whole. Information is assimilated to the slots of a mental model in the form of "frames." These are chunks of knowledge which themselves are equipped with terminals and which have a well-defined meaning anchored in a given body of shared knowledge.

Mental models can, as a rule, be externally represented by material models which also serve as the element of continuity in their transmission from one generation to the next. The basic features of the field-theoretical model of distant causation, which will play a central role in our analysis, may, for instance, be represented by the material model of a magnet setting a piece of iron into motion by affecting the state of its environment. In addition, it may be represented by symbolic representations making use of natural and formal language. The internal architecture of a system of knowledge is constituted by a network of mental models and frames that can be linked by operations in the sense of mental acts typically corresponding to handling external representations, be they material arrangements or symbolic expressions. A sequence of such operations constitutes a procedure which typically has a goal, for instance of creating an *ad hoc* knowledge representation structure, which is called a "real-time construction" in cognitive science. A real-time construction may be exemplified by the geometrical construction typically accompanying the Euclidean proof of a geometrical theorem or by a set of mathematical expressions corresponding to checking a candidate field equation according to one of Einstein's heuristic principles.

Two fundamentally important types of mental acts are "chunking" and "reflection." By chunking different knowledge representation structures are combined into a unity. This often leads to a linguistic representation of the resulting chunk by a technical term designating, for instance, a particular procedure. By reflection, the usage

24 For the concepts of frame and mental model, see (Minsky 1975, 1987; Damerow 1996; Gentner and Stevens 1983; and Davis 1984). For a view on the potential of cognitive science and cognitive psychology for the history of science to which the present work is much indebted, see (Damerow 1996).

of knowledge representation structures becomes the object of reasoning; it typically presupposes an external representation of these structures, for instance by a technical term. Reflection obviously plays a crucial role in accommodating a system of knowledge to new experiences by changing its architecture. An example is what we call a "Copernicus process" in which the internal network of a system of knowledge is essentially preserved while originally peripheral elements take on a central role in the deductive structure. The status of such elements as being either peripheral or central is prescribed by a "control structure." A control structure is constituted by any knowledge representation structure serving to control the operation and to order other such structures. In this sense, Einstein's heuristic principles as well as his double strategy may be considered examples of such control structures. These elements of the architecture of knowledge can partially be captured by traditional epistemological terminology. A concept, for instance, may be understood as the linguistic representation of a mental model, a frame, or a particular terminal of a frame, while a theory is just one example of many conceivable control structures. We shall also use of these traditional terms, specifying their meaning in the context of the epistemological framework we have introduced whenever appropriate.

We claim that the shared knowledge of classical and special-relativistic physics can be conceived of in terms of this richer epistemological framework, and that it then becomes understandable how this knowledge could serve as a resource for Einstein's search for the gravitational field equation. We will argue that essential relations between fundamental concepts such as that between field and source remain the same to a great extent even though the concrete applications of these concepts differ considerably from their applications to a classical or a relativistic field equation. This structural stability turned the concepts and principles of classical and special-relativistic physics into guiding principles when Einstein entered unknown terrain, for instance, when he encountered a new expression generated by the elaboration of a mathematical formalism. None of these expressions by themselves constituted a new theory of gravitation. Only by complementing them with additional information based on the experience accumulated in classical and special-relativistic physics, as well as in the relevant branches of mathematics did such expressions become candidates for a gravitational field equation embedded in a full-fledged theory of gravitation. In the language of mental models, such past experience provided the default assumptions necessary to fill the gaps in the emerging framework of a relativistic theory of gravitation. Because of their nature as default assumptions, they could be given up again in the light of novel information without making it necessary to abandon the underlying mental models, which thus continue to play their heuristic role.

In this way we hope to render understandable how a gradual process of knowledge accumulation could overcome the very conceptual foundations that had formed its starting point. The concepts of classical physics shaped Einstein's search at its beginning, and made the physical strategy the most natural approach to exploit his heuristic principles for finding the gravitational field equation. In the context of the physical strategy, the default assumptions of the relevant mental models were supplied by the knowledge of classical and special-relativistic physics. The mathematical strategy, on the other hand, drew on default assumptions based on prior mathematical knowledge and led to candidate field equations whose compatibility with established physical knowledge was problematic. The gradual accumulation of knowledge fostered by both of these approaches enriched the network constituted by the mental models and frames relevant to a relativistic theory of gravitation. Eventually, the reorganization of this network by a Copernicus process became feasible.

In the following, we shall discuss in detail the essential aspects and phases of this process, Einstein's heuristic framework, the gradual accumulation of knowledge in the course of his research, the successive replacement of one candidate gravitational field equation by another, the switches back and forth between the physical and the mathematical strategy, and finally the reinterpretation of the results acquired in this way as aspects of one and the same transformation leading from the system of knowledge of classical to that of general-relativistic physics.

2. THE MENTAL MODEL OF FIELD THEORY

2.1 The Poisson Equation of Classical Mechanics and the Field Equation of General Relativity

The revision of Newton's theory of gravitation confronted Einstein with two fundamental problems. He needed to find an equation of motion for bodies in a gravitational field (the analogue of Lorentz's equation of motion of a charged body in an electromagnetic field) and to find a field equation determining the gravitational field itself (the generalization of the Poisson equation and the analogue of Maxwell's equations relating the electromagnetic field to its sources). These two problems presented themselves in terms of basic concepts and structures of classical physics and the special theory of relativity. These concepts and structures also provided an essential part of the intellectual resources for solving these problems.

The most fundamental structures of knowledge relevant to Einstein's search for a new theory of gravitation were incorporated in the understanding of an equation of motion and of a field equation in classical physics and in the special theory of relativity. This understanding involves concepts such as force, energy, momentum, potential, field, source, and mass.[25] Above all, however, it involves the mental model of field theory which had emerged, in its most mature, successful, and widely accepted form, in Lorentz's electron theory of electrodynamics and hence may also be referred to as the Lorentz model.[26] This model actually comprises two mental models with more ancient roots in the history of physics; one for a field equation and one for the equation of motion. The Lorentz model of a field equation, which will be at the center

---

25 For Einstein's account of the emergence of fundamental concepts of physics, including that of field, see (Einstein and Infeld 1938).

26 See (Lorentz 1895), and for historical discussion (Whittaker 1951, ch. XIII, 1953, ch. II, Buchwald 1985, Janssen 1995, Darrigol 2000, Janssen and Stachel 2004).

of our analysis of Einstein's search for the gravitational field equation, has slots for the source, the potential, and a differential operator acting on the potential. Default settings for these slots are provided by the classical theory of gravitation which describes the relation between gravitational source and gravitational potential in terms of the Poisson equation. In the classical case, the source-slot and the potential-slot of the frame are filled by scalar functions that can be subsumed under what we might call the potential-frame and the mass-density-frame, respectively. The default setting for the differential-operator-slot is the Laplace operator.

Before we come back to a more detailed examination of the structure of the Lorentz model, we want to justify the introduction of this model by examining some of the basic concepts and knowledge structures relating the Poisson equation in classical mechanics to the Einstein field equation of general relativity. We claim that these common features played an important role in the historical development linking the two equations so that their description by an overarching structure makes historical sense.

The Poisson equation of classical gravitation theory describes how gravitating matter generates a gravitational potential. This potential can then be related to the gravitational field and to the force acting on material particles exposed to it. The Poisson equation is

$$\Delta\varphi = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right)\varphi = 4\pi\kappa\rho \tag{1}$$

where the gravitational potential is denoted by $\varphi = \varphi(x, y, z)$, which is a function of spatial coordinates x, y, z, where $\rho = \rho(x, y, z)$ denotes the density of gravitating matter, and where κ is a constant. Δ is a linear second-order differential operator, known as the Laplace operator.

The gravitational interaction between material bodies in classical physics can, of course, also be treated directly on the basis of Newton's law of gravitation. This law states that an attractive force between two point particles acts instantaneously along the direction defined by the two bodies and its strength varies inversely proportional to the squared distance between the particles. This action-at-a-distance force can also be calculated from a local potential function φ which is then determined by the Poisson equation introduced above.[27] While the Poisson equation thus appears only as an alternate description of the same physical content as Newton's law, this equation suggests, at the same time, a different physical interpretation of gravitation. According to this interpretation, gravitation—represented by the potential φ and produced by some matter distribution ρ which acts as its source—fills the entire space and exerts its influence on matter locally as a force. By virtue of this interpretation, the Poisson equation can be considered as a first hint at a gravitational field theory, in particular at a time when the field theoretic framework established by Maxwell's electrodynamics

27 Recall (see note 11) that we are loosely referring to the Poisson equation as a "field equation" even though it should properly be called a "potential equation."

suggested a field-theoretic revision of Newtonian gravitation. Nevertheless, the Newtonian gravitational potential lacks two essential features required by a genuine physical field theory. First, the gravitational field does not propagate with a limited speed, a field-theoretical feature that became mandatory after the advent of the theory of special relativity. It also does not describe some expected dynamical effects of gravitation such as dragging effects due to moving masses ("gravitational induction") or gravitational waves.

The Einstein equation stands at the end of a historical process in which the wish to conceive of the gravitational interaction in a truly field-theoretic manner played a significant heuristic role. The Poisson equation and the Einstein equation share a number of common features, in spite of the long and sometimes circuitous discovery process separating the two. In general relativity, the gravitational interaction is also determined by a second-order partial differential equation —the Einstein equation— which relates the gravitational potential to its source.

The Einstein field equation

$$G^{\mu\nu} = R^{\mu\nu} - \frac{1}{2} g^{\mu\nu} R = \bar{\kappa} T^{\mu\nu} \tag{2}$$

written in terms of the Ricci tensor $R^{\mu\nu}$ and the Riemann scalar R can also be written explicitly as (where summation over repeated indices is understood)

$$\begin{aligned} G^{\mu\nu} = \sum_{i\kappa} \Big(g^{\mu i} g^{\nu\kappa} - \frac{1}{2} g^{\mu\nu} g^{i\kappa} \Big) \\ \Bigg\{ \frac{1}{2} g^{lm} \Bigg(\frac{\partial^2 g_{im}}{\partial x^\kappa \partial x^l} + \frac{\partial^2 g_{\kappa m}}{\partial x^i \partial x^l} - \frac{\partial^2 g_{i\kappa}}{\partial x^m \partial x^l} - \frac{\partial^2 g_{lm}}{\partial x^i \partial x^\kappa} \Bigg) \\ + \frac{1}{2} \frac{\partial g^{lm}}{\partial x^l} \Bigg(\frac{\partial g_{im}}{\partial x^\kappa} + \frac{\partial g_{\kappa m}}{\partial x^i} - \frac{\partial g_{i\kappa}}{\partial x^m} \Bigg) - \frac{1}{2} \frac{\partial g^{lm}}{\partial x^\kappa} \frac{\partial g_{lm}}{\partial x^i} \\ - \frac{1}{4} g^{jm} g^{ln} \Bigg[\Bigg(\frac{\partial g_{ml}}{\partial x^i} + \frac{\partial g_{im}}{\partial x^l} - \frac{\partial g_{li}}{\partial x^m} \Bigg) \Bigg(\frac{\partial g_{jn}}{\partial x^\kappa} + \frac{\partial g_{\kappa n}}{\partial x^j} - \frac{\partial g_{\kappa j}}{\partial x^n} \Bigg) \\ - \Bigg(\frac{\partial g_{im}}{\partial x^\kappa} + \frac{\partial g_{\kappa m}}{\partial x^j} - \frac{\partial g_{i\kappa}}{\partial x^m} \Bigg) \frac{\partial g_{ln}}{\partial x^j} \Bigg] \Bigg\} = \bar{\kappa} T^{\mu\nu} \end{aligned} \tag{3}$$

where the gravitational potentials are denoted by $g_{\mu\nu}$ and $g^{\mu\nu}$, which are functions of the spacetime coordinates x_i, $(i) = 1, 2, 3, 4$, and where $\bar{\kappa} = -\frac{8\pi\kappa}{c^4}$ is a constant.

Like the left-hand side of the Poisson equation, the Einstein tensor $G^{\mu\nu}$ is a second-order differential operator applied to the gravitational potential, even though the operator in this case is much more complicated than the Laplace operator. $T^{\mu\nu}$ denotes the so-called stress-energy or energy-momentum tensor and corresponds to another element familiar from the Poisson equation, the role of matter as gravitating source. The mass density ρ which functions as the gravitating source in the Poisson equation reappears, for instance, in the following example of an energy-momentum tensor:

$$T^{\mu\nu} = \rho \frac{dx^{\mu}}{ds}\frac{dx^{\nu}}{ds}, \tag{4}$$

which describes a dust-like cloud of material particles acting as the source of the gravitational field where ρ stands for the mass-density of the swarm and dx^{μ}/ds denotes the special-relativistic four-velocity of the dust particles.

2.2 The Lorentz Model of a Field Equation

In our introduction of the Poisson equation as the point of departure in classical physics for a development eventually leading to the Einstein equations, we have emphasized their common features. One such basic feature is that both equations establish a relation between matter and gravitational potential; a second feature is that both equations relate the action of gravitation to its source by second-order partial differential equations. Such common features are more than distant mathematical similarities or analogies perceived only in hindsight. We claim that such similarities guided the historical development linking the two equations. These similarities, we believe, correspond to structural properties following from the basic mental model shaping the thinking process connected with this development. This interpretation is corroborated by the historical observation that the development from the Poisson to the Einstein equation went through a number of intermediate field equations of the same fundamental structure. We will show that they can all be interpreted as instantiations of the mental model of a field equation, which was modified, again and again, in response to inconsistencies by replacing a minimal number of specific features, while all other components retained their "default" settings. In spite of the inherently conservative structure of this development its outcome entailed fundamental changes in the conceptual structure of classical physics including the original mental model of a gravitational field equation itself.

We will write the basic structure of the mental model of a field equation implemented in the context of gravitational theory symbolically as:

OP(POT) = SOURCE. **(I)**

This equation is meant to symbolize a structure of shared physical knowledge according to which a source **SOURCE** generates a potential **POT**, related to each other by a differential equation with a second-order differential operator **OP** acting on the potential. We justify the introduction of our symbolic notation by the observation that the same knowledge structure can be found in such different cases as the Poisson equation, Einstein's intermediate equations for the gravitational potential, the Laplace equation for the electrostatic potential, and the four-dimensional potential formulation of Maxwell's equations. Correspondingly, **OP**, **POT**, and **SOURCE** can be instantiated in many different ways, such as the Laplace or the d'Alembert operators for **OP**, mass density or the energy-momentum tensor for **SOURCE**, Newton's gravitational potential or the metric tensor for **POT**. Notwithstanding the different contexts for each of those instantiations, we find an overarching conceptual structure relevant for each of them. It is the role of these overarching structures in guiding physical reasoning in a qualitative way that we wish to describe in terms of mental models and frames and that we wish to capture in our symbolic notation. We discuss the relevant instantiations for the frame of the field equation in somewhat greater detail.

Before the crucial phase of Einstein's search for a gravitational field equation in the years 1912 – 1915, the mental model of a field equation essentially covered two physical structures, that shaped Einstein's conceptual background in his search: the Poisson equation of classical mechanics and the potential equations of electrodynamics. In the latter, the structure even appears twice, once in electrostatics, in a simple form analogous to that in classical mechanics, and once in a more complex version extended to cover the dynamical aspects of the electromagnetic field as well. In electrostatics, the electrostatic potential φ_e is generated by an electric charge density ρ_e according to[28]

$$\Delta\varphi_e = -4\pi\rho_e. \tag{5}$$

The more extended version, which covers this equation as a special case under certain conditions, is the four-dimensional potential formulation of Maxwell's equations at the core of classical electrodynamics. The four-dimensional, special-relativistic formulation of electrodynamics was developed beginning in 1908 by Minkowski, Laue, and Sommerfeld[29] and was quickly established as a standard.[30] In this framework, the inhomogeneous Maxwell equations can also be written in a potential formulation:[31]

$$\Box\phi^{\mu} = \left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\phi^{\mu} = -\frac{4\pi}{c}j^{\mu} \tag{6}$$

---

28 The minus sign which does not appear in the Poisson equation of classical mechanics given in eq. (1) reflects the fact that the gravitational interaction is attractive whereas the electrostatic interaction of two charges of equal sign is repulsive.

29 See (Minkowski 1908, Laue 1911, and Sommerfeld 1910a; 1910b).

30 For historical studies, see (Reich 1994, Walter 1999).

31 See, e.g., (Laue 1911; 1913 § 19). The potential formulation of Maxwell's equation given in eq. (6) presupposes a gauge fixing of the form

$$\partial_{\mu}\varphi^{\mu} = \mathrm{div}\boldsymbol{A} + \frac{1}{c}\frac{\partial\varphi_e}{\partial t} = 0$$

(Lorentz gauge). Together with this gauge condition eq. (6) represents a fully equivalent representation of Maxwell's equations.

where $\Box$ is the d'Alembert operator, $\phi^{\mu} = (\varphi_e, \boldsymbol{A})$ the electromagnetic four-potential composed of a scalar electric potential φ_e, and a vector magnetic potential $\boldsymbol{A} = (A^x, A^y, A^z)$, and $j^{\mu} = (\rho_e c, \rho_e \boldsymbol{v})$ is the four-current, composed of the electric charge density ρ_e and the velocity vector $\boldsymbol{v} = (v^x, v^y, v^z)$ acting as a source of the potential.

As we shall discuss in more detail below,[32] the relation between electrostatics and electrodynamics provided Einstein and his contemporaries with a basis for an understanding of how Newton's theory of gravitation might be elaborated into a field theory satisfying the requirements of the relativity theory of 1905. Einstein explicitly compared the task of building a relativistic theory of gravitation to the task of developing the entire theory of electromagnetism knowing only Coulomb's law, and found it just as formidable.[33]

Concrete instantiations of the general structure (I) make it clear that there are profound differences between them that are not represented by the simple symbolic equation. A major difference between the gravitational or electrostatic Poisson equation (1) resp. (5) and the full electrodynamic wave equation (6) concerns, for instance, the behavior of the equations under coordinate transformations. The simple mathematical form of those two equations is valid only if specific systems of coordinates are used. The same equations rewritten for a different coordinate system would, in general, change their appearance, unless the new system of coordinates is related to the old one by a coordinate transformation of the appropriate covariance group. This group of admissible coordinate transformations is a mathematical feature of the equation, that is, of the differential operator as well as of the source-term appearing in the equation. It also expresses the validity of a relativity principle for the relevant physical theories, be they those of classical or special-relativistic physics. Coordinate systems can be associated with observers in different locations and in different states of motion, and covariance with regard to coordinate transformations can be associated with the independence of physical phenomena of the perspectives of these different observers.[34]

The Laplace operator, appearing in the electrostatic as well as in the gravitational Poisson equation, retains its form if Galilean coordinate transformations are used

32 See section on "correspondence principle," p. 148.

33 See (Einstein 1913). For more evidence that Einstein conceived the problem of gravitation in analogy with electrodynamics, consider e.g. the title of (Einstein 1912a): "Is there a Gravitational Effect Which Is Analogous to Electrodynamic Induction?" ("Gibt es eine Gravitationswirkung, die der elektrodynamischen Induktionswirkung analog ist?") or a number of references to the analogy with electrodynamics in Einstein's contemporary correspondence; see, e.g., Einstein to Paul Ehrenfest, before 20 June 1912: "A rotating ring does not generate a static field in this sense, even though it is a temporally invariant field. [...] My case corresponds to the electrostatic field in the theory of electricity, whereas the more general static case would also include the analogue of the static magnetic field. I haven't got as far as that yet." ("Ein sich drehender Ring erzeugt nicht ein statisches Feld in diesem Sinne, obwohl es ein zeitlich unveränderliches Feld ist. [...] Mein Fall entspricht in der Elektrizitätstheorie dem elektrostatischen Felde, wogegen der allgemeinere statische Fall noch das Analogon des statischen Magnetfeldes mit einschliessen würde. So weit bin ich noch nicht.") (CPAE 5, Doc. 409).

which relate the inertial reference frames of classical mechanics to each other; these inertial transformations express a symmetry of Newtonian spacetime. The d'Alembertian operator appearing in special relativistic electrodynamics, on the other hand, is invariant under the Lorentz transformations which relate inertial reference frames of special relativity to each other and express a symmetry of four-dimensional Minkowski spacetime.

This illustrates that there can still be profound differences between various instantiations of the structure (I). But whatever these differences may be, insofar as the relation between **OP**, **POT**, and **SOURCE** is cancelled, the corresponding frames enter the same network of relatively stable relations to other physical concepts such as field and force. The concept of a field, in particular, is related to the concept of potential appearing in this mental model by a structure according to which a field **FIELD** is derived from a potential **POT** by some differential operation **GRAD**. This relation can be written in symbolic notation as

$$\textbf{FIELD} = -\,\textbf{GRAD(POT)}. \qquad \textbf{(II)}$$

In classical mechanics the equation relating the gravitational potential φ to the gravitational field $\boldsymbol{g}$ is given by

$$\boldsymbol{g} = -\mathrm{grad}\varphi. \tag{7}$$

In electrostatics a similar equation holds for the electric field $\boldsymbol{E}$ derived from the electrostatic potential φ_e by

$$\boldsymbol{E} = -\mathrm{grad}\varphi_e. \tag{8}$$

In the case of electrodynamics the same structural relation reappears, albeit in a somewhat more complex form. The components of φ_e and $\boldsymbol{A}$ of the four-potential φ^μ are related to the electric field $\boldsymbol{E}$ and the magnetic field $\boldsymbol{B}$ by

$$\boldsymbol{E} = -\,\mathrm{grad}\varphi - \frac{d}{dt}\boldsymbol{A}, \tag{9}$$

and

$$\boldsymbol{B} = \mathrm{curl}\boldsymbol{A}. \tag{10}$$

These equations can be combined in a tensor equation for the electromagnetic field tensor $F_{\mu\nu}$

34 We add a note of caution here. From the point of view of modern coordinate-free descriptions of physical theories, the covariance of a particular equation under a specific group of coordinate transformations can be understood as expressing a symmetry property of the underlying spacetime manifold, if the coordinate systems related by the transformations are those associated with so-called geodesic observers. In this case, the geodesic observer field is also a Killing vector field of the manifold, see (O'Neill 1983, 358–362). See also the discussion in (Salmon et al. 1999, chap. 5) and (Norton 1992b). At the time, however, the validity of a physical principle of relativity was directly associated with the covariance of the corresponding equations under coordinate transformations, without considering the symmetry properties of a manifold independently from its coordinate representation.

$$F_{\mu\nu} = \frac{\partial\phi_\mu}{\partial x^\nu} - \frac{\partial\phi_\nu}{\partial x^\mu}, \tag{11}$$

which may be considered as another instantiation of (II).

The discussion of the foregoing examples should make it clear that any concrete meaning of our symbolic equations is context-dependent as is only fitting for relations between frames in the sense introduced above. Entities such as **OP**, **POT**, **SOURCE**, **FIELD**, **GRAD** but also operations such as multiplication can take on entirely different mathematical meanings in different contexts. These symbolic operators may inherit different default-settings from different frameworks of reasoning. There is no *a priori* guarantee that the resulting concrete expressions can still be subsumed under one overarching theory. If one looks, however, at the function of these frames as heuristic devices that guided Einstein's pathway out of classical physics, this obviously was precisely their strength.

In summary, the stability of the mental model of a field equation is a consequence of its embedding in a network of physical concepts covering a broad spectrum of physical knowledge. Specifically, the concepts of potential and mass have stable relations to such concepts as field, force, energy, momentum, and motion. Furthermore, all instantiations of the Lorentz model we have encountered in classical and special-relativistic physics include a second-order differential operator **OP** and can be characterized by symbolic relations between the associated physical concepts such as (II). For each instantiation, the mental model of a field equation acquires local stability also through the representation in terms of mathematical concepts that in themselves are interconnected in an elaborated network allowing for formal manipulations of the mathematical expressions using well-known formal rules.

The various slots in our symbolic equations can be filled with objects of very different mathematical character, **POT** and **SOURCE** may be instantiated by scalar or vectorial objects, which behave differently under coordinate transformations; the corresponding differential operator **OP** may be the Laplacian or the d'Alembertian operator. Physically, potential and mass enter the stable conceptual relation described above, but are at the same time connected with quite different physical concepts and hence quite different physical phenomena. Thus, the potential **POT** could be instantiated to the potential of gravitational, electrostatic, or electrodynamic interaction, and the source-term **SOURCE** could be gravitating mass-density, electric charge-density, or electric current.

The Einstein equation introduced in the beginning of this section emerged, as we shall see, in a process that started from the Poisson equation of classical mechanics and proceeded via intermediate field equations that are *all* structured by what we have called the Lorentz model of a field equation. It is therefore no accident that the Einstein equation also displays features of this model. We shall show that the Einstein equation came about only as the result of a complicated process of adaptations of the original mental model demanding a number of variations ("changes of default settings") that at each step had to fulfill different, and often conflicting requirements. A consistent solution for meeting those requirements was reached only with the final theory of general relativity. In this theory, however, the field equation has implications that, as we shall see, challenge the original mental model.

2.3 The Lorentz Model of an Equation of Motion

The field-theoretic model comprises not only a structure shaping the understanding of a field equation but also a scheme determining the meaning of an equation of motion. In classical physics a field equation must be complemented by an equation of motion. Their complementarity derives from the way in which interactions are split into cause and effect in the Lorentz model. In classical mechanics, the concept of force allows one to separate the generic features of the action of some agent, to be described in terms of a general force law, from its specific effect on a given physical object, to be described in terms of a change of its state of motion. A similar structure is characteristic of Maxwellian electrodynamics, especially in Lorentz's electron theory. The field equation describes how sources, represented in our symbolic equation by the **SOURCE**-frame, affect the state of the surrounding space, represented by the **POT**-frame or the **FIELD**-frame. The equation of motion describes the effect of the thus affected space on physical objects in it. From the perspective of classical mechanics, a field equation is therefore nothing but a specific way of prescribing a general force law. What is required is a bridge between the concept of field and that of force.

According to classical mechanics, the effect of a force is a deviation (to be observed within an inertial frame of reference) from a state of rest or a state of uniform rectilinear motion described in terms of an **ACCELERATION**-frame. The magnitude of the acceleration depends not only on the force (characterized in the following by a **FORCE**-frame) but also on the reactive properties of the physical object exposed to it; these properties will be summarily described by the inertial mass frame, $\mathbf{MASS_{IN}}$. In short, an equation of motion according to classical and special-relativistic physics, complies with a mental model of causation that may be called the "acceleration-implies-force model" and takes the form:

$$\mathbf{FORCE = MASS_{IN}\ x\ ACCELERATION.} \qquad \mathbf{(III)}$$

In classical mechanics this relation corresponds to Newton's

$$\boldsymbol{F} = m \cdot \boldsymbol{a}, \tag{12}$$

where m is the inertial mass of a material particle, a its acceleration in three-space and F a classical force. The special relativistic generalization of this relation is

$$F^{\mu} = m\frac{du^{\mu}}{ds}, \tag{13}$$

where m is the rest mass, u^{μ} the four-velocity and s the proper time. Here F^{μ} denotes the force as a four-vector.

The structure of the symbolic equation (III) also complies with that of a much more general and much older mental model of causation rooted in intuitive physics, the "force-implies-motion model," which thus serves as a "higher-order model" for the Newtonian relation (III):[35] According to this higher-order model of causation, the effect of an action (here **ACCELERATION**), depends on the strength of the action (here **FORCE**) as well as on the resistance to the action (here $\mathbf{MASS_{IN}}$).

How can the acceleration-implies-force model belonging to the core of Newtonian mechanics be integrated with the concept of field at the center of the field-theoretical model? In order to bridge the two models one needs a specification of the relation between **POT** or **FIELD**, describing the local state of the surrounding space, and **FORCE**, describing the role of this space as an agent determining the motion of matter. In classical field theory, this bridge relation is given by the notion that the field is tantamount to a local force. The force experienced by a particle in a field is proportional to the strength of the field at the point of the particle in space and time. It is also proportional to that quality of the particle that responds to the particular field, be it its gravitational mass, its electric charge, or its magnetic moment. We capture the relation between **FORCE** and **FIELD** by the symbolic relation

$$\mathbf{FORCE = CHARGE\ x\ FIELD} \qquad \mathbf{(IV)}$$

At this point, our symbolic relations allow us to describe a possible inference on the level of qualitative physical reasoning. We may use relation (II) between **FORCE** and **POT**, to derive a relation between **FIELD** and **POT**

$$\mathbf{FORCE = - CHARGE\ x\ GRAD(POT).} \qquad \mathbf{(V)}$$

From a different perspective, one may also look at the set of relations (II), (IV), and (V) as the expression for a conceptual network on the level of qualitative physical reasoning in which the frames **FORCE**, **FIELD**, **CHARGE** and **POT** are related to each other.

In electrostatics the **CHARGE**-frame is instantiated by the charge density ρ_e ,

$$\mathbf{CHARGE} \xrightarrow{\text{electrostatics}} \rho_e\,, \qquad \mathbf{(VI)}$$

and the force density acting on ρ_e and determined by an electric field $\boldsymbol{E}$ derived from the electrostatic potential φ_e is given by:

$$\boldsymbol{F}_e = \rho_e \boldsymbol{E} = -\rho_e \mathrm{grad}\varphi_e. \qquad (14)$$

In Newtonian gravitational theory the default setting of the **CHARGE** frame is the so-called "passive gravitational mass":

35 For the force-implies-motion model, see (Gentner and Stevens 1983; Renn 2000), and also "Classical Physics in Disarray …" (in this volume).

$$\textbf{CHARGE} \xrightarrow[\text{gravitation}]{\text{Newtonian}} m_p \text{ resp. } \rho_p . \qquad \textbf{(VII)}$$

Accordingly, the force density acting on a mass density ρ due to a gravitational field $\boldsymbol{g}$ that can be derived from a gravitational potential φ is given by:

$$\boldsymbol{F} = \rho \boldsymbol{g} = -\rho \operatorname{grad}\varphi . \qquad (15)$$

In the case of electrodynamics the same structural relation holds in terms of the electromagnetic field tensor $F^{\mu\nu}$ expressed in terms of a generalized electrodynamic potential in (11). The four-force density K^{μ} is given by

$$K^{\mu} = j_{\nu} F^{\mu\nu} . \qquad (16)$$

This equation again exhibits the structure **FORCE = CHARGE x FIELD**, even though the multiplication of our symbolic equation is realized in this case by a four-dimensional contraction.

The discussion of the bridge relation required to integrate the acceleration-implies-force model with the field concept makes the intrinsic complexity of the Lorentz model particularly evident. This complexity stands in striking contrast to certain elementary features of gravitational interactions. It is mainly due to the fact that the Lorentz model results from the integration of mental models referring to two kinds of physical substances, the model of an extended, space-filling physical medium traditionally labelled as "aether" and the model of matter constituted by particles. The relation between field and force given by (IV) mediates between these models and at the same time points to the conceptual intricacies resulting from their integration. For instance, what at first sight merely seems to be a problem of two bodies moving about their common center of gravity, say of the sun and a planet, appears, from the perspective of the Lorentz model as the consequence of a field generated by one body which is then felt by the other body as a force that in turn is the cause of its motion.

As a consequence of this construction, both the concept of force and the concept of mass take on connotations, which they did not possess independently in the more elementary models. In classical mechanics, for instance, the concept of force comprises actions at a distance, typically between particles. In the context of the field-theoretical model, it applies exclusively to local interactions, a rather artificial limitation from the point of view of Newtonian physics. Similarly, while the Newtonian concept of force entails a reciprocity of the interaction it describes, expressed in Newton's *actio = reactio*, such a reciprocity is less evident for an interaction that is conceived to relate a state of space, characterized by the **FIELD**-frame or the **POT**-frame, to changes of the state of motion of a physical object, characterized by the **ACCELERATION**-frame. As a matter of fact, theories such as Lorentz's electron theory violate this reciprocity and *actio = reactio* no longer holds for the interaction between ether and charged matter.

The conceptual intricacies implied by the Lorentz model for the concept of mass are even more serious. Mass may be conceived as a "source" causing changes of the state of space or of the "aether" according to (**I**). We thus have "active gravitational mass" in the case of gravitational interaction:

$$\textbf{SOURCE} \xrightarrow{\text{gravitation}} m_a \text{ resp. } \rho_a. \qquad \textbf{(VIII)}$$

Mass may also, according to (V) and (VII), be conceived as a passive property of a physical object exposed to the resulting field, determining the degree to which the field locally acts as a force (**CHARGE** or "passive gravitational mass" in the case of gravitation); it may finally be conceived, according to (III), as "inertial mass" $\mathbf{MASS_{IN}}$, i.e., as resistance to **ACCELERATION**. In classical electrostatics, these magnitudes are represented by electrical charge and inertial mass, respectively, and can vary independently from each other. In classical gravitation theory, gravitational and inertial mass happen to coincide empirically. In this case we are thus entitled to introduce a generic **MASS**-frame for which we have:

$$\mathbf{MASS = MASS_{IN}}, \qquad \textbf{(IX)}$$

which may hence be instantiated by inertial, or active gravitational, or passive gravitational mass.

The integration of different mental models within the field-theoretical model produces conceptual distinctions that may actually not be warranted by the available knowledge of the interactions it describes. The emergence of conceptual distinctions as an artefact of a theoretical framework was visible, in the case of the gravitational interaction, even from a less sophisticated perspective than that offered by the field-theoretical model. When the gravitational action is described not in terms of a field theory but simply using the Newtonian force law, the distinction between mass as a property of matter that *causes* gravitation and mass as a reactive property of matter that *resists* the acceleration caused by a gravitational force is rather artificial. Indeed, it has long been known that all bodies fall with the same acceleration in a gravitational field whatever their mass (Galileo's principle). Within the context of the field-theoretical model this insight suggests far-going consequences for the understanding of an equation of motion.

In fact, since in classical mechanics the **CHARGE**-frame and the **SOURCE**-frame instantiate to the passive and active gravitational mass resp. mass density according to (VII) and (VIII), we may identify these two frames with each other and with the general **MASS**-frame:

$$\textbf{SOURCE = CHARGE = MASS} \qquad \textbf{(X)}$$

Recalling the relations that the **FORCE**-frame enters with the **ACCELERATION**-frame and the **FIELD**-frame according to (III) and (IV), our symbolic equations entail

$$\textbf{ACCELERATION = FIELD.} \qquad \textbf{(XI)}$$

This symbolic equation translates Galileo's principle to the assertion that in a gravitational field theory the local acceleration actually represents the gravitational field. This makes it possible to interpret the effect of gravitation, namely **ACCELERATION**, directly as a representation of the local force, i.e. as a **FIELD**, independently of the properties of the object exposed to it. We emphasize that we introduced our symbolic notation in order to be able to represent this kind of inference which can be made largely on the level of qualitative physical reasoning independent of any concrete representation. It also expresses the fact that the identification of the **ACCELERATION**-frame and the **FIELD**-frame is a general relation between two frames that is not tied to the concrete conceptualization of the gravitational interaction. It may hence guide the physical reasoning also in situations where new ways of mathematical representation or else new conceptual relations within a gravitational theory are being explored.

Eq. (XI) no longer contains **FORCE**. This insight crucial for the development of general relativity. It suggests that it should be possible to set up a theory where field phenomena are equivalent to acceleration phenomena. This, of course, is exactly the idea at the core of Einstein's equivalence principle.[36] In such a theory Galileo's principle would find the conceptual justification it lacked in classical mechanics, where it appeared as a mere empirical coincidence.

The insight that in a gravitational field theory the acceleration is directly equivalent to the field, symbolically represented by eq. (XI), also suggests the formulation of an equation of motion in a gravitational field that does not make use of the intermediate concept of force. The idea of eliminating the concept of force was familiar from classical physics and had been elaborated in the context of the Lagrange formalism of analytical mechanics. In elementary situations of classical mechanics the Langrangian or Lagrange function at the center of this formalism is simply the difference between the kinetic and the potential energy of a physical system:

$$L = T - V. \tag{17}$$

The Lagrange formalism provides an alternative way of obtaining equations of motion. In this formalism the trajectory of a material body is selected from the set of all kinematically possible trajectories satisfying given constraints. The criterion for the selection is that the action, defined as the same integral of the Langrangian along a given trajectory is stationary, i.e., takes on either a maximum or a minimum value, for the actual trajectory. This criterion is known as Hamilton's principle. Saying that the action is stationary is the same as saying that its variation vanishes:

36 See the discussion below. Cf. in this context Einstein's use of the word "Beschleunigungsfeld" (acceleration field) in (Einstein 1912b): "the hypothesis that the "acceleration field" is a special case of the gravitational field [...]" ("die Hypothese, daß das 'Beschleunigungsfeld' ein Spezialfall des Gravitationsfeldes sei [...]" (p. 355).

$$\delta\left\{\int L dt\right\} = 0. \tag{18}$$

The situation is similar to the problem of finding the shortest path connecting two points on a curved surface. This problem can be solved by looking for an extremal value among the lengths of all possible paths connecting these points.

The Lagrange formalism yields the explicit equation of motion for a particle in the form of the so-called Euler-Lagrange equations, which follow from Hamilton's principle:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{x}_i}\right) - \frac{\partial L}{\partial x_i} = 0. \tag{19}$$

Under appropriate circumstances, these equations may be assimilated to the relation

$$\boldsymbol{F} = d\boldsymbol{p}/dt \tag{20}$$

between a force F and the change of momentum p familiar from classical mechanics. We capture the qualitative physical content of equations (19) and (20) by the symbolic equation

DIFF(MOMENTUM) – FORCE = 0, **(XII)**

introducing, at the same time, a **MOMENTUM**-frame and a **DIFF**-frame, the latter being in the present case instantiated by time-derivatives. The advantage of the Lagrange formalism compared to the explicit specification and use of forces becomes clear if one considers motion under geometrical constraints, such as the motion of a point particle on the surface of a sphere. Using the acceleration-implies-force model such geometrical constraints are realized by constraining forces which are defined only by their effect, i.e., if a body moving under geometric constraints departs from uniform rectilinear (inertial) motion this deviation is assumed to be caused by the constraining forces. The precise magnitude and direction of these forces are generally unknown and hence cannot be explicitly specified in order to obtain an equation of motion by instantiating the acceleration-implies-force model. The Lagrangian formalism uses the fact that these constraining forces do not perform work. They play no role in the interplay between kinetic and potential energy as captured by the Lagrange function if the latter is expressed solely in terms of those generalized coordinates that describe possible motions under the given constraints, without losing information about the physical situation.

The significance of the Lagrange formalism for Einstein's research on gravitation was twofold. For one, it represented a generalizable formalism that was applicable in cases where a force or a momentum was not easily identified. It therefore also applied in a geometrized theory by expressing the Lagrange function in terms of a geometry adapted to the physical situation at hand.[37] Describing motion in a gravitational field with the help of the Lagrange formalism, as we shall see, naturally suggests to conceive of gravitation as a consequence of geometry, rather than of force. And this conception of gravitation in turn suggests adopting the Lagrange formalism as the natural framework for formulating the equation of motion in a gravitational field.

3. THE ELEMENTS OF EINSTEIN'S HEURISTICS

In the course of the first period of Einstein's research on gravitation—between 1907 and 1912—specific components of the heuristics had crystallized as relatively stable structures which would guide his search for the gravitational field equation in the second period—documented in the Zurich Notebook. To some of them Einstein even attached labels, such as the "equivalence hypothesis,"[38] making their outstanding role for his heuristics evident, while other heuristic requirements were so obviously interwoven with canonical expectations from classical physics, such as the requirement of energy conservation, that they did not receive a special name. For ease of reference, we shall nevertheless introduce standard names.

Einstein's *equivalence principle*, which in the first period mainly served to find properties of special cases of gravitational fields, became in the second period a standard criterion for checking whether or not candidates for a general gravitational field equation incorporated his earlier insights about the intimate relation between gravitation and inertia. The *generalized relativity principle*, a closely related result of Einstein's research in the first period, was applied in the second period either as a starting point in the context of the mathematical strategy for choosing appropriate candidates for the gravitational field equation or as a validation criterion by which a candidate constructed in the context of the physical strategy was examined. The *conservation principle*, inherited from classical physics, played a crucial role in developing the theory of the static gravitational field and was similarly used in the second period both as a touch stone and as a building block. This was also the case for what we will call the *correspondence principle*. This principle represents the demand to incorporate in a new theory of gravitation the knowledge about Newtonian gravitation by requiring that the basic relations of the latter be recovered from the former in some approximation or as some special case. Its implementation as a component of Einstein's heuristics took clues from the relation between electrostatics and electrodynamics. Einstein thus expected that the generalized theory should be connected to the Newtonian theory via the intermediate case of the weak and static gravitational field.

---

37 Its significance for expressing the equation of motion in special relativity was realized by Max Planck (Planck 1906, 1907).

38 Although Einstein referred to the equivalence principle as a "hypothesis" in (Einstein 1907) and in (Einstein 1911), the terms "Aequivalenzhypothese" and "Aequivalenzprinzip" were used for the first time in (Einstein 1912b).

3.1 The Equivalence Principle and the Generalized Relativity Principle

According to Einstein's equivalence principle the effects of a homogeneous static gravitational field are equivalent to those in a uniformly and linearly accelerated reference frame. The equivalence principle, which establishes a connection between the gravitational field and inertial forces, is closely related to Galileo's principle that all bodies fall with the same acceleration in a gravitational field, independent of their constitution. While neither Galileo's principle nor the equivalence principle are part of the foundational structure of classical physics, they are part of the knowledge contained in it, as expressed by our symbolic equation (XI). Einstein established a meaningful connection between acceleration and the gravitational field by integrating two mental models of classical physics which originally belonged to different domains of knowledge, the mental model of a system with a homogeneous static gravitational field, familiar from everyday physics in local terrestrial laboratories, and the model of a system in uniformly accelerated motion (Einstein's famous elevator experiment), which was analyzable using standard tools of classical mechanics. The indistinguishability of motions in these two systems makes it possible to identify the terminals of these models and thus to establish an equivalence between gravitational and inertial forces as well as between an accelerated frame of reference and an inertial frame. These identifications turned out to have far-going consequences for the organization of physical knowledge. Such consequences can be spelled out if further elements of the knowledge of classical and special relativistic physics are taken into account and are combined, for instance, with simple mental models of ray optics leading to the conclusion that light is curved in a gravitational field.[39]

Einstein's "elevator model," admits an extension to a more general class of gravitational fields and accelerated motions. Such an extension was suggested, in particular, by the Machian idea to interpret the inertial forces occurring within a uniformly rotating system as due to the interaction with distant masses rather than due to "absolute space." Mach had compared an accelerated system—Newton's famous rotating bucket—with a system at rest in which an interaction with distant masses, the stars revolving around the bucket, accounts for the same physical phenomena as are produced by the inertial forces in the accelerated system. This thought experiment provided a blueprint for the elevator-thought-experiment, which is at the heart of Einstein's "principle of equivalence." In analogy to the "elevator model," a "bucket model" could thus be conceived as one in which the inertial forces occurring in a rotating reference frame are interpreted as the effects of a generalized gravitational field.

The elevator and the bucket models may both be considered as special cases of a general "gravito-inertial model" in which inertial forces resulting from arbitrarily accelerated motions are interpreted as coming from a "dynamic" gravitational field. This gravito-inertial model made it plausible to assume that inertial frames of reference play no privileged role in a theory that adequately describes such a generalized

39 See the discussion in "Classical Physics in Disarray …" (in this volume).

gravitational field. It also suggested that the generic properties of gravitational fields that can be thought of as resulting from accelerated motions are shared by arbitrary gravitational fields. It suggests, for instance, that the laws governing the motion of bodies are the same in both types of fields. More generally, the gravito-inertial model made it plausible that physical interactions taking place in a gravitational field are essentially equivalent to those taking place in a gravitation-free system that is described from the point of view of an accelerated observer. In hindsight, the equivalence principle—and the gravito-inertial model structuring the reasoning on which this principle is based—thus introduced four more or less distinct requirements into the search for a theory of general relativity:

– the theory should satisfy a "generalized principle of relativity" and eliminate as much as possible the privileged *a priori* structures which in the classical theory are associated with such notions as absolute space and inertial frames of reference;
– the theory should describe motion in a gravitational field as a "free fall" independent of the structure of the moving body;
– the theory should treat gravitation and inertia as aspects of one more general interaction; and
– the theory should describe non-gravitational physical interactions essentially in the same way as special relativity if an appropriate reference frame (local inertial frame) is chosen for that description.

These requirements are directly related to general relativity as we know it today. Historically, the impact of the equivalence principle on the search for a new theory of gravitation was much less straightforward than it may appear in hindsight. A number of conceptual and technical problems had to be resolved or at least disentangled before such a clear relation could emerge.[40] In particular, Einstein was convinced that the demand for a generalized relativity principle could be satisfied by requiring the equations of his theory to be generally covariant (Norton 1994, 1999). He lacked the modern notion of spacetime symmetries. Similarly, the description of motion in a gravitational field as "free fall" along a geodesic trajectory is closely related today to the understanding of the affine structure of spacetime. But Einstein did not have the concept of affine connection at his disposal and still saw the need to interpret the equation of motion in terms of a classical gravitational force.[41]

The equivalence principle and the generalized relativity principle did not give rise to requirements which the new theory had to satisfy as a set of fixed axioms; they acted in a more general and diffuse way as heuristic guiding principles which, in different contexts, had a variety of concrete implications not necessarily covered by their modern counterparts. The generalized principle of relativity, in particular, motivated Einstein to consider the absolute differential calculus as the appropriate lan-

guage for his new theory of gravitation but also to construct mathematical objects which are covariant merely under much more limited classes of coordinate transformations. The equivalence principle led him to identify qualitative consequences of general relativity such as light deflection even before the formulation of the definitive theory, albeit with numerically different results. It led Einstein to adopt the geodesic equation of motion as the law of motion appropriate for general gravitational fields but also to systematically check whether candidate field equations are covariant at least under transformations to linearly accelerated systems and to uniformly rotating systems.

In the context of Einstein's systematic search for the gravitational field equation documented in the Zurich Notebook the adoption of the generalized relativity principles amounted to a check of the covariance properties of a candidate field equation. But even the way in which this check was implemented—by the introduction of a generally-covariant differential operator along the mathematical strategy or by explicitly checking the behavior of a candidate under coordinate transformations along the physical strategy—depended on the specific perspective guiding the implementation. At the beginning of Einstein's search it was not at all clear whether he would eventually succeed in finding a generally-covariant field equation of gravitation incorporating the equivalence principle. From the outset it was unclear whether the ambitious aim of a generalized relativity principle and perhaps even the equivalence principle would be realizable or whether these postulates had to be restricted or modified in order to be able to satisfy other requirements to be imposed on such a field equation, such as the conservation principle.

3.2 The Conservation Principle

According to the conservation principle as it functioned in Einstein's heuristics, it should be possible to establish a balance of energy and momentum in a gravitational field, resulting in a conservation law if all contributions to the balance, including that of the gravitational field itself, are taken into account. This expectation was motivated by the experience of classical physics where such a balance of energy and momentum could indeed be obtained for all physical processes if only appropriate concepts of energy and momentum were identified for all relevant subdomains, such as mechanics, thermodynamics, and electrodynamics. This expectation had been both amplified and modified by the advent of special relativity, and in particular that of special relativistic continuum physics, which had shown that several distinct conservation laws of classical physics, such as those of mass, energy, and momentum actually had to be integrated into a single all-encompassing conservation law referring to a complex new entity, the stress-energy or energy-momentum tensor. Against this background, the conservation principle, understood as part of the heritage of classical and special-relativistic physics, introduced three more or less distinct requirements into the search for a theory of general relativity:

– the theory should take into account the close relation between mass and energy established by special relativity and consider not just mass but more generally mass and energy as embodied in the energy-momentum tensor (or some entity derived from it) as the source of the gravitational field;
– the theory should contain some generalization of the special-relativistic law for the conservation of energy and momentum; and, in particular,
– the gravitational field equation should be compatible with this generalized requirement of energy and momentum conservation.

From the perspective of today's understanding of general relativity, these requirements considerably restrict the choice of an acceptable gravitational field equation. But historically, just as with the generalized relativity principle, Einstein's heuristic expectations could not simply be turned into iron-clad axioms for the formulation of his new theory. Precisely because the requirements listed above were rooted in the knowledge of classical and special-relativistic physics, they were still embedded in a conceptual framework that was eventually overturned by general relativity. Furthermore, there were, at the outset of his search, still numerous possibilities for instantiating the general relations suggested by Einstein's classical expectations. It was, for instance, conceivable that not the energy-momentum tensor itself but its trace acts as the source of the gravitational field. For some time, Einstein assumed that he had to find a generally-covariant energy-momentum tensor of the gravitational field in analogy to the one for matter, while such a tensor does not exist according to the final theory. He also assumed that the conservation principle would play the role of an additional postulate of the theory, whereas it is implied by the correct gravitational field equations. Such conceptual novelties of general relativity could not have been anticipated on the basis of the knowledge of classical physics informing Einstein's heuristics. They were the eventual outcome of his heuristic schemes in the course of concrete and often futile attempts to identify a gravitational field equation compatible with criteria such as the conservation principle.

The effect on Einstein's search of the requirements here summarized under the label "conservation principle" depended on the specific questions he pursued and on the level of sophistication of the techniques at his disposal. At one point he erroneously convinced himself, for instance, that a gravitational theory based on a single scalar potential was incompatible with the conservation principle but then had to retract that argument in the light of a closer analysis of such a scalar theory.[42] The clear-cut function which the conservation principle eventually assumed as a compatibility requirement for an acceptable field equation in his search for such an equation documented in the Zurich Notebook was the result of his learning experience with the theory for static gravitational fields in 1912.[43] This experience demonstrated to Einstein the crucial significance of the conservation principle for his search. He became aware step by step of the full scope of the network of relations it implies. In the

42 See (Norton 1992a).
43 See "The First Two Acts" (in this volume) and the discussion below.

course of his research documented in the Zurich Notebook, involving the mathematically much more complex tensorial formalism, these relations combined to form a set of standard expectations for a field equation that had to be systematically checked for each candidate. Only towards the very end of this phase of his research did Einstein recognize the possibility of turning this network into a recipe for constructing a gravitational field equation satisfying the conservation principle—albeit as a requirement essentially still conceived within a classical framework.

3.3 The Correspondence Principle

The correspondence principle requires that the new relativistic theory of gravitation incorporate the empirically well-founded knowledge about gravitation contained in the classical Newtonian theory. Ideally, it should be possible to obtain the Newtonian theory as a limiting or special case from the new theory under appropriate conditions, such as low velocities and weak fields.[44] In contrast to the generalized relativity principle of which it was not clear at the outset to what extent it could be implemented in the new theory, the correspondence principle was a much less negotiable, if not absolutely necessary requirement for any acceptable theory of gravitation. It also seemed clear from the beginning how this principle would have to be implemented in concrete attempts to create a relativistic theory of gravitation. The classical theory offered a model for a gravitational field equation, the Poisson equation, even if this model does not take into account the relativistic demand of a finite speed of propagation of the gravitational action as would a field equation based on the d'Alembertian operator as in (6). But the Poisson equation did not only serve as a model for the structure of the new field equation. Einstein also expected it to emerge from a limiting process by which a relativistic field equation should touch base, via the intermediate case of a special-relativistic field equations based on the d'Alembertian operator, with the classical Newtonian theory. Einstein's theory of the static gravitational field provided another such base-line. Since it represents an intermediate situation between the full relativistic theory and the Newtonian case, he expected that the general theory would, under appropriate limiting conditions, first reproduce the results of the static special case and then, under further constraints, those of the Newtonian theory. A relativistic theory with this limiting behavior clearly would cover the full range of physical knowledge covered by the more specialized theories. Since the constraints imposed by the correspondence principle were embodied not just in abstract requirements but in well-developed theories, it follows that this heuristic principle could act not only as a compatibility condition for an acceptable gravitational field equation but also as a starting point for its construction.

---

44 For a discussion of the Newtonian limit of general relativity from a modern point of view, see (Kuenzle 1976, Ehlers 1981, 1986). For a discussion of the relation between Newtonian gravitation theory and general relativity from an axiomatic point of view as a case of reduction, see (Scheibe 1997, 1999, esp. ch. VIII).

As with the other criteria, there is a perspective from which the correspondence principle, together with a few other conditions, singles out general relativity as the only acceptable solution to Einstein's problem. But as we saw with the other heuristic principles, this hindsight-perspective tends to obscure rather than clarify the actual role of the correspondence principle in the creation of general relativity. This process involved conceptual innovations that could not have been anticipated on the basis of classical physics. From hindsight, we would rather have to say it could not even be anticipated *that* (let alone *how*) the definitive solution of his problem would yield the Newtonian theory since the classical limit of the final theory—which in some sense must exist for the reasons pointed out above—might not resemble the familiar Newtonian formulation of the classical knowledge about gravitation. Vice versa, the classical expectations concerning the relation between Newtonian and relativistic theory might impose restrictions on the choice of admissible candidates that could effectively rule out a satisfactory realization of Einstein's other heuristic requirements, in particular, of the generalized principle of relativity. The dilemma, in short, was that the correspondence principle represented, in view of its roots in the classical knowledge about gravitation, the most weighty of Einstein's heuristic principles but also the one most likely to be entangled with physical assumptions that would have to be given up if the new, relativistic theory of gravitation were to challenge those classical roots.

This dilemma could hardly be avoided. At the beginning of his search, Einstein sought to extrapolate the classical knowledge about gravitation into the new territory of a relativistic field theory. From his perspective, that territory, fortunately, was mapped out nicely by the implications of the Lorentz model. As we have seen, his model also determined the conceptualization of the relation between a generic field theory and the special case of a static field. In Maxwell's theory of the electromagnetic field that relation was well understood, so it could serve as a guide for exploring the analogous relation in the case of the relativistic gravitational field. The mental model of a field theory and the knowledge of classical physics it incorporates had governed Einstein's seemingly inductive procedure all along in examining special cases such as that of the static field.[45] It was clear to him from the outset that the static gravitational field corresponds to the electrostatic field while the field of a rotating reference frame corresponds to the magnetostatic field. The theory of electromagnetism also suggested that and how a many-component tensorial object representing the field in general turns into a much simpler object for the special case of a static field, which can be derived from a scalar potential. The fact that in classical physics both the electrostatic and the gravitational potential are represented by a scalar potential lent support to the assumption that a reduction to a scalar potential also takes place in a relativistic theory of gravitation, at least in the limit of weak static fields. Although this assumption eventually turned out to be wrong, it was backed by a long tradition in classical field theory to which no alternative was known and it initially prevented Einstein from accepting the Einstein tensor as a viable candidate for the left-hand side of the field equation.

Just as Einstein's other heuristic principles the correspondence principle did not act as an isolated axiom which in the end turned out to be either compatible or not with general relativity as we know it today. It was not an isolated statement at all but part of a network of arguments, affecting his heuristics in the context of a variety of considerations. The correspondence principle comprised, in particular, the demands that:

– the differential operator on the left-hand side of the gravitational field equation should, for weak fields, reduce to the d'Alembertian operator as in (6);
– the field equation, for weak static fields, should reduce to the Poisson equation for the scalar potential of classical physics;
– the same scalar potential should determine the behavior of a particle in a gravitational field, via the equation of motion.

The correspondence principle was also subject to modifications as Einstein's experience with attempts to implement this principle in concrete candidate field equations grew. The paradoxical fluid yet firm character of Einstein's qualitative reasoning on the level of his heuristic principles, which we have tried to grasp by describing it in terms of mental models and frames, allows it to first exclude and then support the correct field equations of general relativity. The correspondence principle thus left room for learning experiences as when Einstein found out that it was possible to meet the requirements of this principle with the help of additional constraints on the choice of the coordinate system.

While the technicalities of its implementation were subject to reconsideration and improvement, the basic structure of Einstein's understanding of the correspondence principle was stabilized by a wider context of arguments rooted in classical physics.

---

45 Compare the following equations from Einstein's correspondence: "I finished the investigations on the statics of gravitation (point mechanics electromagnetics gravitostatics) and am very satisfied with them. I really believe that I discovered a piece of truth. Now I ponder the dynamic case, going again from the more special to the more general." ("Die Untersuchungen über die Statik der Gravitation (Punktmechanik Elektromagnetik Gravitostatik) sind fertig und befriedigen mich sehr. Ich glaube wirklich, ein Stück Wahrheit gefunden zu haben. Nun denke ich über den dynamischen Fall nach, auch wieder vom spezielleren zum Allgemeineren übergehend.") Einstein to Ehrenfest, 10. March 1912, (CPAE 5, Doc. 369); "Lately I have been working like mad on the gravitation problem. Now I have gotten to the stage where I am finished with the statics. I do not know anything yet about the dynamic field, that will come only now. [...] You see that I am still far from being able to conceive of rotation as rest! Each step is devilishly difficult, and what I have derived so far is certainly still the simplest of all." ("In der letzten Zeit arbeitete ich rasend am Gravitationsproblem. Nun ist es soweit, dass ich mit der Statik fertig bin. Von dem dynamischen Feld weiss ich noch gar nichts, das soll erst jetzt folgen. [...] Du siehst, dass ich noch weit davon entfernt bin, die Drehung als Ruhe auffassen zu können! Jeder Schritt ist verteufelt schwierig, und das bis jetzt abgeleitete gewiss noch das einfachste.") Einstein to Michele Besso, 26. March 1912, (CPAE 5, Doc. 377); "My case corresponds to the electrostatic field in the theory of electricity, whereas the more general static case would also include the analog of the static magnetic field." ("Mein Fall entspricht in der Elektrizitätstheorie dem elektrostatischen Felde, wogegen der allgemeinere statische Fall noch das Analogon des statischen Magnetfeldes mit einschliessen würde.") Albert Einstein to Paul Ehrenfest, Prague, before 20 June 1912, (CPAE 5, Doc. 409).

Precisely because of this wider context, the modifications of Einstein's understanding in the course of his search for the field equation had the potential of challenging not only the technical aspects but also the conceptual framework of his heuristics.

3.4 Einstein's Heuristic Principles and his Double Strategy

Einstein's heuristic principles, as we have seen, did not constitute a set of axioms from which a theory of gravitation could be derived in a straightforward way. These principles yielded both too much and too little knowledge to find a new theory of gravitation—too little, because they were not sufficient to determine the new theory uniquely, too much, because they imposed requirements on the new theory that could not be maintained all at once. As we mentioned in the introduction, these principles initially even acted as competing approaches toward a relativistic theory of gravitation. In addition, their interpretation in concrete attempts to realize such a theory depended on the specific formalism applied and on the form other requirements took within that formalism. In the course of Einstein's work documented in the Zurich Notebook, these principles nonetheless developed together to become elements of a heuristic double strategy. Earlier research on the problem of a relativistic theory of gravitation, Einstein's own as well as that of others, had not only suggested the mathematical tools to be employed but had also circumscribed the requirements such a theory had to satisfy. As a consequence, the problem of identifying an acceptable gravitational field equation had become the task of constructing, as if in a theoretical laboratory, a more or less well-defined but never-tried device from a set of given building blocks.

Each of Einstein's heuristic principles against which constructions would have to be checked could be used either as a construction principle or as a criterion for their validity. The sequence in which the heuristic principles were used essentially determined their function. The approach we have labelled the "physical strategy" starts from the correspondence principle, i.e., from a candidate field equation which by inspection is seen to yield the Newtonian limit in the expected way. Such a candidate field equation is thus firmly rooted in classical physics. Typically, only mathematical knowledge familiar from the context of classical and special-relativistic physics was used in its construction. The compatibility of such a "physical candidate" with other criteria was, as a rule, less obvious and needed to be checked explicitly. If the primary goal was to stay as close to the familiar territory of classical physics as possible, the first thing to check was the conservation principle, which could turn out to be satisfied, give rise to modifications, or lead to the rejection of the candidate altogether. If the candidate survived this test, it was to be explored to what extent it complied with the generalized relativity principle, i.e., under how broad a class of coordinate transformations it would retain its mathematical form. For candidates that were not generally covariant, it had to be determined under which class of transformations the candidate was covariant and whether or not the restriction of this class was acceptable on physical grounds. In particular, it made sense to check whether at least the situations at the core of the equivalence principle, i.e., transformations to reference frames in uniform linear and rotational accelerated motion, were included in this class.

The approach we have labelled the "mathematical strategy" starts from the generalized relativity principle, i.e. from a candidate field equation which by inspection is seen to be covariant under a broad enough class of coordinate transformations. Since such a general principle of relativity was not part of classical physics, it was much less obvious than in the case of the correspondence principle what "by inspection" meant in this case. The expert mathematical knowledge of the time, however, provided him with a certain reservoir of suitable objects. Their relation to any meaningful physics was much less obvious than for a candidate of the physical strategy. It had to be checked explicitly whether such a "mathematical candidate" could be brought into agreement with the requirements of the correspondence principle. Failure to comply with the correspondence principle could lead to immediate rejection of the candidate, or generate additional conditions amounting to a restriction of the relativity principle. It could even trigger the discovery of a new way to obtain the Newtonian limit. It could also suggest how a given candidate was to be modified in order to pass the test. The situation was similar for the conservation principle, which represented another necessary condition for a physically meaningful theory. Since both the correspondence and the conservation principles could neither be circumvented nor substantially weakened, they tended, in turn, to impose restrictions on the generalized relativity principle or suggest modifications of the candidates.

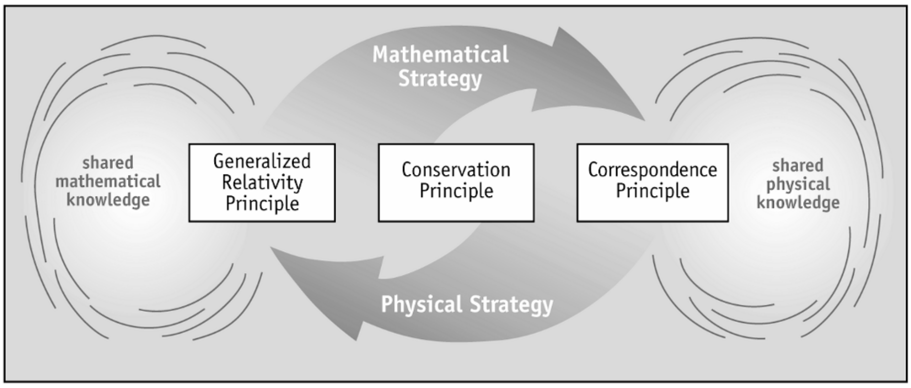

Figure 1: Einstein's double strategy arose from the different roles of the heuristic requirements of Generalized Relativity, Conservation, and Correspondence.

The two strategies are illustrated in Fig. 1 above. The physical and the mathematical strategy work with the same heuristic principles, draw on the same knowledge base of classical and special-relativistic physics, and essentially use the same mathematical representations. Why did they nevertheless produce, as we will see, different results in the course of Einstein's research? An answer is suggested by noting that the candidate solutions he examined are not determined directly by the two strategies but only through the concrete representations in which he attempted to embody his heuristic criteria. The two strategies did not act as an algorithm for producing solutions but rather as different channels for filling the Lorentz model with concrete mathematical and physical content. In other words, the two strategies constituted alternative ways for bringing to bear the available physical and mathematical knowledge on the problem of finding a gravitational field equation.

The notions of mental models and frames are helpful, we believe, for describing this process of knowledge assimilation. Because of its character as a mental model, the Lorentz model does not just represent an abstract scheme, but carries with it the experience of previous implementations. This prior experience includes the model's default settings enabling it to generate concrete candidate field equations even in the absence of sufficient knowledge about the properties of a relativistic gravitational field. The default settings make it possible to deal with the problem of insufficient knowledge by supplementing missing information drawn from prior experience. Moreover, since the experience of classical and special-relativistic physics entered the Lorentz model in the form of default settings, Einstein could give up prior assumptions in the course of his research without shattering his entire heuristic framework.

One and the same mental model may come with different sets of default settings, depending on prior experience, applications, knowledge resources, and higher-order models in which it is embedded. Default-settings depend on knowledge contexts. Classical field theory, the knowledge about Newtonian gravitation, the insights opened up by the elevator and the bucket models, the Machian interpretation of classical mechanics—all constitute different knowledge contexts relevant to the default assumptions of the Lorentz model when implemented in attempts to create a relativistic field theory of gravitation. The same is true for the mathematical resources of Gaussian surface theory, vector calculus, the theory of invariant forms, and the absolute differential calculus. Einstein's double strategy can be understood as a way of dealing with this problem of overabundant knowledge by consciously selecting alternate knowledge contexts dominating the default settings of the model. In this sense, the physical strategy, in particular, starts not just from the correspondence principle but from candidates embodying the classical knowledge about gravitation. The mathematical strategy likewise starts, not just from the generalized relativity principle but from candidates embodying the prior mathematical knowledge, in particular about generally-covariant, second-rank tensors of second order in the derivatives of the metric.

The selection of such different approaches dominating the default settings of the Lorentz model occurred initially, of course, in the hope that one or the other knowledge context would be more relevant or turn out to be more suitable to yield a full solution of the problem. Effectively, however, the alternation between different knowledge contexts led to a systematic exploration of resources that could not have been assimilated to the model all at once. The double strategy was not an astute plan for attacking the problem of finding field equations from two sides, the physical and the mathematical side. It emerged only gradually as a result of learning more about the implications of the field-theoretical model for gravitational field equations by varying its default settings. To understand Einstein's search for the gravitational field equation, it is therefore not enough to examine his heuristic principles as we have done in this chapter. We also have to reconstruct the default settings for the Lorentz model in different contexts of this search.

4. DEFAULT SETTINGS AND OPEN SLOTS IN THE LORENTZ MODEL FOR A GRAVITATIONAL FIELD EQUATION IN 1912

In this section we will introduce the principal entities figuring in Einstein's search for the gravitational field equation in the period documented by the Zurich Notebook. His research in this period focused on the problem of formulating a field equation for gravito-inertial phenomena, which had to satisfy all heuristic requirements, both those embodied in the mental model of a field equation and those that had emerged from his work between 1907 and 1912. The experience of these years had largely shaped the default assumptions that formed the starting point of Einstein's exploration of the mental model represented by the symbolic equation **OP(POT) = SOURCE**, cf. (I).

In particular, the metric tensor, which we will represent by the frame **METRIC**, was adopted as the representation of the gravitational potential and became the canonical instantiation of **POT** in the Lorentz model:

$$\mathbf{POT} =_{\mathbf{DEFT}} \mathbf{METRIC}, \tag{XIII}$$

where "$=_{\mathbf{DEFT}}$" is meant to express that the right-hand side of the equation represents the default-setting of the left-hand side. Similarly, we will refer to the energy-momentum tensor of matter and of the electromagnetic field, by the frame **ENEMO**, which became the new standard setting for **SOURCE**:

$$\mathbf{SOURCE} =_{\mathbf{DEFT}} \mathbf{ENEMO}. \tag{XIV}$$

These two key components of the gravitational field equation were generally-covariant tensors and thereby nurtured the expectation that the field equation itself would take the form of a generally-covariant tensorial equation, thus allowing Einstein to realize his ambition of creating a generalized relativity theory.

For the third component of the Lorentz model, the differential operator **OP**, the situation was more complicated. At the beginning of his search, Einstein was largely ignorant of the mathematical techniques necessary for constructing suitable candidates. The many requirements to be imposed on acceptable candidates prevented the selection of an obvious default assumption for the differential operator **OP** compatible with all these requirements.

We summarize the situation in the following figure which we will further elaborate in the following sections:

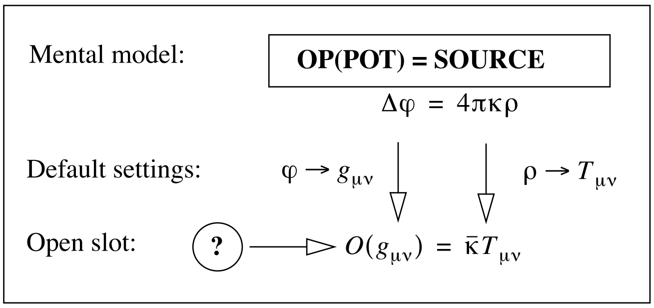

Figure 2: The Lorentz model evolved by changing the default settings for the ***POT****- and the* ***SOURCE****-slots, leaving the question of an appropriate instantiation of the* ***OP****-slot.*

4.1 The Metric as the Potential in the Gravitational Field Equation

In the middle of 1912 Einstein introduced the metric tensor as the new default setting for the **POT**- slot of the Lorentz model. This step affected both the field equation and the equation of motion. The grounds for this move had been prepared by his earlier attempts to set up a theory for the static gravitational field and his awareness that such a theory could only represent a special case within a wider framework suggested by the model. In these attempts Einstein had also learnt that Minkowski's spacetime framework for special relativity could be useful but had to be generalized for use within this larger context. This had been suggested, in particular, by Einstein's controversy with Abraham, pointing to the need for a generalization of the so-called "line element" used in the Minkowski framework, as well as by Einstein's insight into the geometrical consequences of applying special relativity to an accelerated system such as a rotating disk, pointing to the need for non-Euclidean geometry when describing gravitation.

An appropriate generalization of Minkowski's framework was found on the basis of the mathematical work of Gauss, Riemann, Christoffel, Ricci, and Levi-Civita. This led Einstein and Grossmann to the consideration of curvilinear coordinates and the introduction of a metric tensor $g_{\mu\nu}$ for a four-dimensional generalization of Gauss' theory of curved surfaces. Curvilinear coordinates are given by four functions x^{μ} with $\mu = 1, \ldots, 4$, mapping a point of spacetime to four numbers representing its coordinates similar to the use of coordinates in Gaussian surface theory. The generalized line element ds, giving the distance between two neighboring points in spacetime separated by coordinate differentials dx^{μ}, expresses a generalization of the Pythagorean theorem:

$$ds^2 = \sum_{\mu\nu} g_{\mu\nu} dx^{\mu} dx^{\nu}. \tag{21}$$

In the usual representation of Minkowski spacetime in Cartesian coordinates, this expression reduces to the four-dimensional form of the Pythagorean theorem in which the metric tensor $g_{\mu\nu}$ is given by the four-by-four matrix (c being the speed of light):

$$g_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2 \end{bmatrix}. \tag{22}$$

According to the gravito-inertial model inertial forces resulting from arbitrarily accelerated motions can be interpreted as being equivalent to effects of a "dynamic" gravitational field. In the generalized formalism, this model then suggests a natural default setting for the **POT** slot of the frame as well as a natural candidate for the equation of motion in a given gravitational field. The generalized principle of relativity finds a natural expression in terms of the admissibility of arbitrary (smooth) curvilinear coordinate systems representing accelerated reference frames. The inertial motion of a particle in such a reference frame can, on the basis of the gravito-inertial model, be interpreted as motion in a special kind of gravitational field. In the generalized Minkowski formalism such a motion can be described by a geodesic curve, in complete analogy to Gaussian surface theory where geodesic curves represent the natural generalization of straight lines in Euclidean geometry. Combining these two perspectives, it becomes plausible to assume that the motion of a particle under the influence of *any* gravitational field is represented by a geodesic line in a curved spacetime.

Mathematically, a geodesic line can be described as an extremal curve in spacetime determined by a given metric tensor:

$$\delta\left\{\int ds\right\} = 0. \tag{23}$$

From a physical perspective, this equation can be seen as Hamilton's principle (cf. eq. (18)) for the Lagrangian of a free particle of mass m:

$$L = -m\frac{ds}{dt}. \tag{24}$$

The Euler-Lagrange equations (cf. eq. (19)) then suggest to consider the metric tensor $g_{\mu\nu}$ as representing the gravitational potential, i.e. **POT =$_{\mathbf{DEFT}}$ METRIC**, as in eq. (XIII). The combination of the default setting (XIII) and the equation of motion (23) was compatible with the special case of Minkowski spacetime of special relativity where the metric tensor is given by eq. (22) and where the equation of motion of the form of eq. (23) had been developed well before Einstein had begun to work on the problem of gravitation. It was also supported by the special case a static gravitational field, as developed by Einstein in 1912, which could be integrated into the generalized Minkowski formalism in a special and seemingly natural way. Thus one could say that the **POT**-frame specializes to a $\mathbf{POT_{STAT}}$-frame in the context of Einstein's theory of static gravitation:

$$\mathbf{POT} \xrightarrow[\text{gravitation}]{\text{static}} \mathbf{POT_{STAT}} \ , \qquad \mathbf{(XV)}$$

and that the default setting for the $\mathbf{POT_{STAT}}$-frame was given by the following metric:

$$\mathbf{POT_{STAT}} =_{\mathbf{DEFT}} g_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2(x, y, z) \end{bmatrix}, \qquad (25)$$

Here $c(x, y, z)$ is the gravitational potential in Einstein's static theory. In the following we shall refer to this metric as the "canonical metric for a static field." It represents Einstein's default setting for representing a static gravitational field, This default setting mediated between a generic field and the Newtonian case, and was crucial to the heuristics of the correspondence principle.

4.2 The Source-Term in the Gravitational Field Equation

In classical and special-relativistic physics, the relation between force and acceleration (cf. eq. (III)) is not the only way to characterize the effect of a force on a physical system. The effect can also be described in terms of a change in the momentum and in the energy of the system. In classical physics, the force is equal to the rate of change in *time* of the momentum, which can be symbolically expressed as (cf. eq. (XII)):

FORCE = DIFF(MOMENTUM). (XVI)

But the force is also equal to the rate of change in *space* of the energy, which can be symbolically expressed as (cf. eq. (V)):

FORCE = – GRAD(ENERGY). (XVII)

These relations also express that whenever a system gains or loses momentum and energy this must be due to the action of an external force. Note that we have here again introduced new frames **GRAD** and **ENERGY**. As with the previous examples, one could discuss different instantiations of these frames in the context of, say, classical point mechanics, special-relativistic point mechanics, or Maxwellian electrodynamics. But from this point on, we will introduce and make use of our symbolic notation in a more roundabout and indirect way, relying on an intuitive understanding that we hope is conveyed by our choice of names for our symbolic notation (**ENERGY** for energy, **ENEMO** for energy-momentum, etc.). At crucial junctures, however, we will explicitly discuss the concrete instantiations of these frames in Einstein's research and thus provide a general argument for the impact of heuristic reasoning on a qualitative level for Einstein's concrete explorations of pathways out of classical physics.

In special relativity, the concepts of energy and momentum are integrated into a single new concept, the 10-component energy-momentum or stress-energy tensor, which we symbolically represent by the frame **ENEMO** so that the relation between force, energy, and momentum can now be written as:[46]

$$\textbf{FORCE} = -\,\textbf{DIV(ENEMO)}. \qquad \textbf{(XVIII)}$$

In his search for a relativistic gravitational field equation Einstein quickly realized that the source-term, i.e. the instantiation of **SOURCE** in the Lorentz model, had to be the energy-momentum tensor **ENEMO**. In our symbolic notation (cf. eq. (XIV)):

$$\textbf{SOURCE} =_{\textbf{DEFT}} \textbf{ENEMO}.$$

Two lines of arguments, a mathematical and a physical one, made this default setting almost inescapable. From a mathematical point of view—or alternatively, from the point of view of filling the slots of the Lorentz model—something more complex than the scalar mass density was required for **SOURCE** because the gravitational potential is represented by a tensorial object. The slots on both sides of the field equation have to be filled by analogous mathematical objects. While it was in principle conceivable to construct a scalar object out of the metric tensor, e.g. by forming its determinant, and hence to have a scalar field equation, it was more plausible to Einstein that the 10-components of the metric tensor enter into some many-component field equation, just as with the many-component object representing the electromagnetic field.[47]

From a physical point of view—or alternatively from the point of view of the default settings of the Lorentz model based on prior research experience—the energy-momentum tensor had turned out to be the appropriate generalization of the concept of mass in a four-dimensional spacetime setting, i.e.:

$$\textbf{MASS} =_{\textbf{DEFT}} \textbf{ENEMO}. \qquad \textbf{(XIX)}$$

The elaboration of four-dimensional relativistic electrodynamics and hydrodynamics had shown that the introduction of this tensor was necessary in order to adequately describe the energetic and inertial behavior of an extended physical system.[48] In view of Einstein's expectation that, in his relativistic theory of gravitation, energy and

---

46 For the sign compare (CPAE 4, Doc. 1, 92) and "Einstein's Zurich Notebook" 05R (in this volume). The significance of the sign becomes clear when considering the energy-momentum gained or lost by a physical system, for instance in the case of a system with electromagnetic interactions. The divergence of the energy-momentum tensor of the electromagnetic field at a point describes the increase of the energy-momentum of the field at that point, which corresponds to the flow of energy-momentum from the charges to the field. This in turn equals the negative flow of energy-momentum from the field to the charges, which is given by the negative of the Lorentz force.

47 For attempts to build a scalar theory, see John Norton's discussion of Nordström's theory and Einstein's objections in "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in vol. 3 of this series).

mass, as well as gravitational and inertial mass, would essentially be equivalent (cf. eq. (IX)), the energy-momentum tensor was the natural candidate for the right-hand side of the field equation. To sum up, the default setting for the source slot of the Lorentz model of a field equation, eq. (XIV), was inherited from the default setting for the mass slot, eq. (XIX), resulting from the special-relativistic generalization of the mass concept of classical physics.

In order to make the choice of the default setting for **SOURCE** acceptable from the broader point of view provided by eq. (XIX), it was necessary to check whether **ENEMO** also satisfies further properties of **MASS** in classical and special-relativistic physics. The field-theoretical model suggested using the same instantiation of **MASS** both in the field equation and in the equation of motion.

The structure of an equation of motion in a gravitational field involving the **ENEMO**-frame was suggested by the special-relativistic relation between force and energy-momentum represented by eq. (XVIII). Combining this equation with the relation between force and potential, eq. (V), and the appropriate default setting for **CHARGE**, (see eqs. (VII) and (IX) one obtains:

$$\mathbf{GRAD(POT)\ x\ ENEMO = DIV(ENEMO).} \qquad \mathbf{(XX)}$$

Initially, this structural relation provided merely a heuristic hint of what a general equation of motion involving the energy-momentum tensor would look like. To validate this hint, Einstein used a default-setting for the energy-momentum tensor which allowed him to establish a connection between the proper realm of the stress-energy-momentum tensor, i.e. continuum mechanics, and the mechanics of point particles, for which an equation of motion was well established (eq. (23)).[49] In this way, he built a bridge between the knowledge embodied in eq. (XX) and the knowledge that the trajectory of a particle in a gravitational field is a geodesic.

The instantiation **ENEMO** that Einstein used to build this bridge and which, in fact, became its default setting, was the energy-momentum tensor for a swarm of independent particles ("dust"). In our symbolic notation:

$$\mathbf{ENEMO =_{DEFT} DUST,} \qquad \mathbf{(XXI)}$$

where the energy-momentum tensor for **DUST** is mathematically represented by (cf. eq. (4)):

---

48 See the discussion in "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in vol. 3 of this series). At some point in 1913 Einstein even convinced himself that this consideration would altogether rule out a scalar theory of gravitation, which he believed to be incompatible with the conservation laws, but then had to acknowledge that his choice of a tensorial theory with the energy-momentum tensor as a source term was reasonable but not unavoidable. His own subsequent exploration of a relativistic scalar theory of gravitation made it clear, however, that such a theory was based on *a priori* assumptions about the geometry of spacetime, which Einstein was not willing to accept. Hence even this apparently far-fetched consideration, based on Mach's critique of Newton's concept of space, contributed to stabilizing Einstein's choice of the energy-momentum tensor as the default-setting for **SOURCE**.

49 "Einstein's Zurich Notebook" 05R, p. 43R (in this volume).

$$T^{\mu\nu} = \rho\frac{dx^{\mu}}{ds}\frac{dx^{\nu}}{ds}. \tag{26}$$

In the Lagrangian formalism for a point particle in a gravitational potential given by the metric tensor (cf. eq. (24)), Einstein obtained expressions for the momentum and energy of a particle. He then applied these expressions to the energy-momentum tensor for dust and interpreted the resulting terms. In this way he arrived at an equation corresponding to the structural relation eq. (XX):[50]

$$\frac{1}{2}\sqrt{-g}\frac{\partial g_{\mu\nu}}{\partial x^{\sigma}}T^{\mu\nu} = \frac{\partial}{\partial x^{\nu}}(\sqrt{-g}g_{\sigma\mu}T^{\mu\nu}). \tag{27}$$

Introducing mixed tensor densities $\mathfrak{T}_{\sigma}^{\nu} = \sqrt{-g}g_{\sigma\mu}T^{\mu\nu}$, we can write this equation more compactly:

$$\frac{1}{2}g^{\alpha\mu}\frac{\partial g_{\mu\nu}}{\partial x^{\sigma}}\mathfrak{T}_{\alpha}^{\nu} = \frac{\partial\mathfrak{T}_{\sigma}^{\nu}}{\partial x^{\nu}}. \tag{28}$$

The agreement between this concrete result for the default setting **DUST** with the general relation eq. (XX) supported the underlying physical heuristics and suggested that this equation holds for an arbitrary symmetric energy-momentum tensor.[51]

Equation (27) turned out to be very important for Einstein's further research. First, it supported the choice of the energy-momentum tensor as the source of a gravitational field equation and stabilized this instantiation of both **SOURCE** and **MASS**. Second, it provided Einstein with one of the fundamental components for the Lorentz

50 "Einstein's Zurich Notebook" 05R, (in this volume). In this form eq. (27) is valid only for a symmetric tensor $T^{\mu\nu}$. See also (CPAE 6, Doc. 9, 95).

51 The terms in eq. (27) are interpreted in (Einstein and Grossmann 1913) in the following way: "We ascribe to equation (10) [i.e. our (27)] a validity range that goes far beyond the special case of the flow of incoherent masses. The equation represents in general the energy balance between the gravitational field and a arbitrary material process; one has only to substitute for [$T^{\mu\nu}$] the stress-energy tensor corresponding to the material system under consideration. The first sum in the equation contains the space derivatives of the stresses or of the density of the energy flow, and the time derivatives of the momentum density or of the energy density; the second sum is an expression for the effects exerted by the gravitational field on the material process." ("Der Gleichung [(27)] schreiben wir einen Gültigkeitsbereich zu, der über den speziellen Fall der Strömung inkohärenter Massen weit hinausgeht. Die Gleichung stellt allgemein die Energiebilanz zwischen dem Gravitationsfelde und einem beliebigen materiellen Vorgang dar; nur ist für [$T^{\mu\nu}$] der dem jeweilen betrachteten materiellen System entsprechende Spannungs-Energietensor einzusetzen. Die erste Summe in der Gleichung enthält die örtlichen Ableitungen der Impuls- bzw. Energiedichte; die zweite Summe ist ein Ausdruck für die Wirkungen, welche vom Schwerefelde auf den materiellen Vorgang übertragen werden." p.11). Indeed, except for the original derivation of eq. (27) in (Einstein and Grossmann 1913), in all later publications up to 1916, this relation appears in a form where the two conceptually distinct terms of the left-hand side are set equal, rather than in the form of eq. (27) which asserts the vanishing of a generally-covariant object that only happens to be represented by the algebraic difference of two terms as in eq. (27).

model, a general equation of motion which describes how material processes are affected by the gravitational field. Third, this equation became, as we shall see, the starting point for the formulation of the requirement of energy-momentum conservation that had to be satisfied by any candidate for the left-hand side of the gravitational field equation. Fourth, its left-hand side suggested, in connection with the relation between **FIELD** and **POT** in eq.(II), an instantiation of **FIELD**:

$$\textbf{FIELD} = -\,\textbf{GRAD(POT)} =_{\textbf{DEFT}} -\frac{1}{2}g^{\alpha\mu}\frac{\partial g_{\mu\nu}}{\partial x^{\sigma}} \equiv \tilde{\Gamma}^{\alpha}_{\sigma\nu}. \qquad \textbf{(XXII)}$$

This choice was plausible but not without alternatives. Eq. (28) can also be written as:

$$-\Gamma^{\alpha}_{\sigma\nu}\mathfrak{T}^{\nu}_{\alpha} = \frac{\partial\mathfrak{T}^{\nu}_{\sigma}}{\partial x^{\nu}}, \qquad (29)$$

with $\Gamma^{\alpha}_{\sigma\nu}$ —in the following symbolically represented as **CHRIST**—defined as minus the so-called Christoffel symbols (of the second kind):

$$\Gamma^{\alpha}_{\sigma\nu} = -\left\{\begin{matrix}\alpha\\ \sigma\nu\end{matrix}\right\} = -\frac{1}{2}g^{\alpha\mu}\left(\frac{\partial g_{\mu\nu}}{\partial x_{\sigma}} + \frac{\partial g_{\mu\sigma}}{\partial x_{\nu}} - \frac{\partial g_{\sigma\nu}}{\partial x_{\mu}}\right). \qquad (30)$$

As a consequence, one obtains an alternative instantiation of **FIELD**:

$$\textbf{FIELD} =_{\textbf{DEFT}} -\,\textbf{CHRIST} =_{\textbf{DEFT}} \Gamma^{\alpha}_{\sigma\nu}. \qquad \textbf{(XXIII)}$$

The familiar form of the relation between field and potential in classical field theory made eq. (XXII) the natural first choice, and eq. (XXIII) only came into play when this first choice turned out to lead to difficulties.

Equation (27) had one final important implication. Written in the form:

$$\frac{\partial}{\partial x^{\nu}}(\sqrt{-g}g_{\sigma\mu}T^{\mu\nu}) - \frac{1}{2}\sqrt{-g}\frac{\partial g_{\mu\nu}}{\partial x^{\sigma}}T^{\mu\nu} = 0, \qquad (31)$$

its left-hand side could be conceived as a generic, generally-covariant differential operator known as “covariant divergence,” here symbolically represented as **DIV** $_{\textbf{COV}}$**(.)**, so that eq. (XX) can also be written as:[52]

$$\textbf{DIV}_{\textbf{COV}}\textbf{(ENEMO)} = \textbf{DIV(ENEMO)} - \textbf{GRAD(POT) x ENEMO} = \textbf{0}. \qquad \textbf{(XXIV)}$$

Although Einstein interpreted eq. (31) primarily from a physical point of view i.e. as a representation of the structure (XX), as we have seen, he knew, probably even before he became acquainted with the absolute differential calculus, that this equa-

52 Note that the embodiment eq. (31) of the symbolic eq. (XXIV) holds only for symmetric tensors.

tion involves a generic tensor operation which is generally covariant.[53] He had thus recognized the covariant divergence as a mathematical ingredient of his new theory that was meaningful in its own right and could in principle be used for other purposes. The formulation of eq. (31) is a prime example of how Einstein's physical strategy produced a result that turned out to be independent of the specifics of its derivation, such as the choice of **DUST** for **ENEMO**. Einstein even attempted to use the covariant divergence as a constituent of a candidate for the left-hand side of the gravitational field equation but failed because it vanishes when applied to the metric tensor.[54] The fact that the equation of motion expressed in terms of **ENEMO** turned out to be generally covariant must, in any case, have been an important confirmation of his program to establish a generally-relativistic theory of gravitation, suggesting that the other major constituent of the Lorentz model, the field equation, should also have this property.

4.3 The Differential Operator in the Gravitational Field Equation

For the differential operator acting as **OP** in eq. (I), Einstein did not have an immediately satisfactory candidate or even a heuristic shortcut for finding one. Substituting the metric tensor for the scalar gravitational potential quickly drove him out of any familiar mathematical terrain. He had to find a second-order differential operator acting on the metric tensor by relying either on attempts to directly construct such an operator or on the mathematical literature in order to find suitable starting points.

One of Einstein's earliest attempts[55] to construct a differential operator **OP** was to mimic the way in which the classical Laplace operator was formed, that is, by compounding the differential operations divergence and gradient familiar from three-dimensional vector calculus. In this way he obtained a first, natural instantiation for the differential operator on the left-hand side of the gravitational field equation:[56]

$$\mathbf{OP} =_{\mathbf{DEFT}} \mathbf{LAP} = \mathbf{DIV\ (GRAD)} \qquad \mathbf{(XXV)}$$

Applying **LAP** to the default setting for **POT**, we obtain what we will call the *core operator*:[57]

---

53 Einstein's remark "I have now found the most general equations." ("Ich habe nun die allgemeinsten Gleichungen gefunden.") in a letter to Ludwig Hopf, dated 16 August 1912 (CPAE 5, Doc. 416) in all probability refers to this insight, cf. the editorial note "Einstein on Gravitation and Relativity: The Collaboration with Marcel Grossmann" (CPAE 4, 294–301). The covariance of this equation was demonstrated in terms of the absolute differential calculus of Ricci and Levi-Civita by showing that it represents the covariant divergence of the (symmetric) contravariant stress-energy-tensor in Grossmann's "mathematical part" of (Einstein and Grossmann 1913, 32).

54 See p. 05R of "Einstein's Zurich Notebook" (in this volume).

55 The following discussion relies heavily on the analysis of Einstein's research notes contained in the Zurich Notebook. Since the actual historical path will be discussed in chapter 6, we will here only refer to the relevant pages of this notebook, without any further comments.

56 Cf. pp. 07R and 08L of "Einstein's Zurich Notebook" (in this volume).

57 Cf., e.g., p.07L of "Einstein's Zurich Notebook" (in this volume).

$$\mathbf{LAP(POT)} =_{\mathbf{DEFT}} \sum_{\alpha\beta} \frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial g^{\mu\nu}}{\partial x^{\beta}}\right). \qquad \mathbf{(XXVI)}$$

It has to be noted that this equation is only one of several possible instantiations of the frame **LAP**. Alternative instantiations typically involve additional factors of the determinant of the metric which typically affect the transformation behavior of the particular version of the core operator under consideration.

As a symbolic equation, the resulting tentative field equation reads:

$$\mathbf{LAP(POT) = ENEMO.} \qquad \mathbf{(XXVII)}$$

This instantiation of **OP** was supported by several arguments based, in particular, on the correspondence principle. The straightforward generalization of the Laplace operator was also plausible against the background of the field equation Einstein had developed for static gravitational fields. This field equation resulted from a simple instantiation of the Lorentz model obtained essentially by replacing the Newtonian potential in the classical Poisson equation by the variable speed of light, a move suggested by the equivalence principle:[58]

$$\Delta c = kc\rho. \qquad (32)$$

The constant k is related to the gravitational constant κ of the Poisson equation through $k = (4\pi\kappa/c^2)$.[59]

In the following, we discuss the implications of Einstein's heuristic framework for choosing and modifying the instantiations for the gravitational differential operator in his field equation: We examine the implications coming from the correspondence principle, the conservation principle, the generalized principle of relativity, and examine the Lagrangian formalism, respectively. This discussion is not meant as a substitute for a detailed account of Einstein's pathway, but as preparation for such an account by identifying the constraints under which it was pursued. These constraints

---

58 The explicit justification for this equation was follows. After noting that the variable velocity of light fulfills the Laplace equation for the matter-free case, Einstein continues: "It is easy to establish the presumably valid equation that corresponds to Poisson's equation. For it follows immediately from the meaning of c that c is determined only up to a constant factor that depends on the constitution of the clock with which one measures [the time] t at the origin of [the accelerated coordinate system] K. Hence the equation corresponding to Poisson's equation must be homogeneous in c. The simplest equation of this kind is the linear equation [eq. (32)] where k denotes the (universal) gravitational constant, and ρ the matter density." ("Es ist leicht diejenige vermutliche Gleichung aufzustellen, welche derjenigen von Poisson entspricht. Es folgt nämlich aus der Bedeutung von c unmittelbar, daß c nur bis auf einen konstanten Faktor bestimmt ist, der davon abhängt, mit einer wie beschaffenen Uhr man t im Anfangspunkte von K mißt. Die der Poissonschen Gleichung entsprechende muß also in c homogen sein. Die einfachste Gleichung dieser Art ist die lineare Gleichung [eq. (32)], wenn unter k die (universelle) Gravitationskonstante, unter ρ die Dichte der Materie verstanden wird.") (Einstein 1912b, 360)

59 The relation is obtained by identifying $c^2/2$ with the Newtonian potential φ and neglecting terms of order $(\partial_i c)^2$, cf. (Einstein 1912a, 362).

were rooted in the knowledge of classical physics, which provided the default settings for the frames with which Einstein operated. That these default settings often led to conflicting results necessitating their modification or replacement lies in the nature of Einstein's search, whose outcome could not be anticipated.

4.4 Implications of the Correspondence Principle

A gravitational field equation based on the core operator as given by eq. (XXVI) is in accordance with the correspondence principle, thus strengthening the role of this operator as an instantiation for the left-hand side of the field equation. For weak fields this differential operator reduces to the d'Alembertian operator, the default-setting for **OP** in the weak-field limit. The transition to this limiting case can be represented symbolically as:[60]

LIM(OP(.)) =$_{\mathbf{DEFT}}$ LIM(LAP(.)) =$_{\mathbf{DEFT}}$

$$\Box(\;) = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right). \qquad \textbf{(XXVIII)}$$

The weak-field equation thus takes on the canonical form:

$$\Box g_{\mu\nu} = \kappa T_{\mu\nu}. \qquad (33)$$

This equation can also be written as:

$$\Box h_{\mu\nu} = \kappa T_{\mu\nu}, \qquad (34)$$

where $h_{\mu\nu}$ is defined by

$$g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}, \qquad (35)$$

with $|h_{\mu\nu}| \ll 1$ denoting small deviations from the Minkowski metric:

$$\eta_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2 \end{bmatrix}. \qquad (36)$$

If the source is taken to first order as a pressureless, static cloud of dust of density ρ (compare eq. (4)), one can neglect all terms of the energy-momentum tensor on the right-hand side of eq. (33) except for the T_{44} - term, which can be identified with the

60 Cf. (Einstein and Grossmann 1913, 13). Note that in contrast to the *Entwurf* operator, the core operator reduces to the Laplacian for a static metric of the form (25) for *strong* static fields as well. Einstein never seems to have considered this case.

gravitating mass density appearing in the classical Poisson equation. The neglected terms in the energy-momentum tensor involve the velocity of the gravitating matter which, in the Newtonian case, will be small compared to the velocity of light. If one now considers the case of a *static* weak field, introducing **LIM$_{\mathbf{STAT}}$** and using the static metric of the canonical form (25) on the left-hand side of the weak-field equation, one has:

$$\mathbf{LIM_{STAT}(OP(POT)) =_{DEFT} LIM(LAP(POT_{STAT}))}. \qquad \mathbf{(XXIX)}$$

This expression reduces to the Laplace operator acting on a single component of the metric. Eq. (33) thus reduces to the familiar Poisson equation:

$$\Delta g_{44} = \kappa\rho \text{ or equivalently } \Delta h_{44} = \kappa\rho. \qquad (37)$$

The equation of motion in the Newtonian limit can be obtained from eq. (31) under similar assumptions, i.e., small velocities and a weak static field. The result is:

$$\frac{d^2 x_i}{dt^2} = -\frac{1}{2}\frac{\partial g_{44}}{\partial x_i} = -\frac{1}{2}\frac{\partial h_{44}}{\partial x_i} \qquad (i = 1, 2, 3). \qquad (38)$$

This equation shows that $g_{44}/2$ resp. $h_{44}/2$ plays the role of the Newtonian gravitational potential.

The assumption that the left-hand side of the field equation has the form of eq. (XXVIII) is not independent from the assumption that the metric tensor for weak static fields has the form (25). Under appropriate circumstances, a weak-field equation of this form gives rise to solutions precisely of this canonical form.[61] In other words, the most natural assumption for the form of a weak-field equation and the most natural assumption for the metric of a static field supported each other. A further argument supporting Einstein's understanding of the correspondence principle as implying a canonical metric of the form (25) was independent from the field equation but also related to the roots of this principle in the framework of classical physics.[62] This argument is based on Galileo's principle, that is, the requirement that all bodies fall with the same acceleration in a given gravitational field, and makes use of the basic relations between force, momentum, energy, and acceleration as understood in classical physics, with some additional ingredients from special relativity such as the equivalence of mass and energy. Einstein argued that particles with different energy, and hence different inertial mass, fall with different accelerations in a static gravitational field, *unless* such a field is represented by a metric tensor of the canonical form (25). As a criterion for the validity of Galileo's principle he used the requirement that the ratio of the force acting on a particle and its energy depend neither on the particle's mass nor on its velocity.

61 See (Norton 1984, 120–121).
62 The following argument is based on a reconstruction of p. 21R of "Einstein's Zurich Notebook" (in this volume).

4.5 Implications of the Conservation Principle

The fact that the core operator was firmly anchored in knowledge about the familiar cases of static and Newtonian gravitation made it the natural starting point for Einstein's "physical strategy." The core operator, however, had to pass a number of further checks, which could result in modifications. In particular, it remained to be seen how the operator could be brought into agreement with the conservation principle and the generalized relativity principle.

An acceptable field equation (I) had to be compatible with the equation of motion and the related structural insight into energy-momentum conservation represented by eq. (XX). This compatibility could be checked by replacing **ENEMO** in eq. (XX) by the left-hand side of the field equation, i.e. by **OP**:

$$\mathbf{GRAD(POT)\ x\ OP(POT) = DIV(OP(POT))}, \tag{XXX}$$

or, in the notation of eq. (XXIV):

$$\mathbf{DIV_{COV}(OP(POT)) = 0.} \tag{XXXI}$$

It was necessary to check whether this "conservation compatibility check" could be satisfied for a given candidate field equation if need be by imposing extra conditions, in addition to the field equation.

In the course of Einstein's research documented in the Zurich Notebook it became clear that the conservation compatibility check fails for a field equation based on the core operator:

$$\mathbf{GRAD(POT)\ x\ LAP(POT) \neq DIV(LAP(POT)).} \tag{XXXII}$$

This problem may not have surprised Einstein as it was already familiar to him from his theory of static gravitational fields. There he had also encountered the difficulty that the first choice of a field equation for the static field (eq. (32)) turned out to be incompatible with momentum conservation.[63] To demonstrate this conflict, Ein-

63 Cf. Einstein's second thoughts about the paper expressed in a letter to the editor of the *Annalen der Physik*, Wilhelm Wien: "I asked you this morning to return my manuscript, and now I am asking you to keep it after all. To be sure, not everything in the paper is tenable. But I think I should let the thing stand as it is, so that those interested in the problem can see how I arrived at the formulas." ("Heute Morgen bat ich Sie, mir mein Manuskript zurückzusenden und nun bitte ich Sie es doch zu behalten. Es ist zwar nicht alles haltbar, was in der Arbeit steht. Aber ich glaube die Sache doch so lassen zu sollen, damit diejenigen, welche sich für das Problem interessieren, sehen, wie ich zu den Formeln gekommen bin.") Einstein to Wien, 11 March 1912, (CPAE 5, Doc. 371). Since (Einstein 1912b), which contains eq. (32) was received by the *Annalen* on February 26, and (Einstein 1912c) where the problem with this equation is discussed, was received four weeks later, on March 23, the problem Einstein refers to in the letter to Wien is most probably the incompatibility with the conservation principle discussed in the following. To the published discussion of the potential equation for c in (Einstein 1912b) Einstein added a footnote reading: "A soon to be published paper will show that equation (5a) and (5b) cannot yet be exactly right. However, they will be provisionally used in the present paper." ("In einer in kurzem nachfolgender Arbeit wird gezeigt werden, daß die Gleichungen [$\Delta c = 0$] und [eq. (32)] noch nicht exakt richtig sein können. In dieser Arbeit sollen sie vorläufig benutzt werden.")

stein considered an assembly of masses fixed to a rigid, massless frame and showed that this assembly of masses would set itself in motion if the field equation were assumed to be (32). Following the logic underlying eq. (XXX), he substituted the left-hand side of the field equation for the mass density ρ in the expression for the force-density (compare eq. (V)):

$$\boldsymbol{F} = -\rho \operatorname{grad} c. \tag{39}$$

The integral of this expression over space (under the assumption that c is constant at infinity) should vanish on account of momentum conservation. However, the expression

$$\boldsymbol{F} = -\frac{1}{k}\frac{\Delta c}{c} \operatorname{grad} c, \tag{40}$$

resulting from this substitution cannot be transformed into a divergence expression, and momentum conservation is violated. The rigid massless frame would start to move, in contradiction with Newton's principle *actio = reactio*.

It is easily seen that the Poisson equation of classical mechanics and electrostatics does not present this problem. In a later paper Einstein himself explained how this can be shown in a way that suggests a generalization of the argument to the case of a relativistic gravitational field theory.[64] In electrostatics the ν th component of the momentum conferred to matter per unit volume and time (or the force density, compare (V)) is:

$$-\frac{\partial \varphi}{\partial x_\nu}\rho,$$

where φ represents the potential and ρ the density of the electrical charge. It can then be demonstrated that a field equation of the form (cf. eq. (5)):

$$\sum_\nu \frac{\partial^2 \varphi}{\partial x_\nu^2} = -\rho$$

satisfies the requirement of momentum conservation. This is done by showing that the rate of change of momentum:

$$-\frac{\partial \varphi}{\partial x_\nu} \cdot \rho = \frac{\partial \varphi}{\partial x_\nu}\sum_\mu \frac{\partial^2 \varphi}{\partial x_\mu^2}$$

can be transformed into a divergence expression, i.e., an expression with the property that the integral over a closed system vanishes so that the total momentum is conserved.

The challenge resulting from the problem with Einstein's first static theory was to find an expression for the force, the momentum transferred from the gravitational

64 See (Einstein and Grossmann 1913, part 1, §5).

field to material processes that can be written as a divergence. Let us try to capture the heuristic behind his reasoning in our symbolic notation. We conceive of the **FORCE**-frame as a divergence of some **FIELDMASS**-frame in an equation of the form:

FORCE = DIV(FIELDMASS), (XXXIII)

where **FIELDMASS** represents, in the three-dimensional case, the momentum (or, alternatively, the energy) and, in the four-dimensional case, the energy-momentum of the gravitational field. Such a force expression had to be extracted from a revised field equation in which the default setting **LAP** is replaced by a modified frame, let us call it **GRAV** for **OP**:

OP(POT) $=_{\mathbf{DEFT}}$ GRAV(POT) = LAP(POT) + CORR(POT). (XXXIV)

The correction term **CORR** introduced in the new choice for **OP** in eq. (XXXIV) had to be compatible, of course, with the correspondence principle and in particular with the default setting eq. (XXVIII) so that the condition

LIM(CORR(POT)) = 0 (XXXV)

follows. The correction term has to make sure that both eq. (XXX), the conservation compatibility check, and eq. (XXXIII), the equivalent divergence condition for the gravitational force, are satisfied:

FORCE =

– GRAD(POT) X GRAV = – DIV(GRAV) = DIV(FIELDMASS). (XXXVI)

In view of the definition of **GRAV** as a sum of **LAP** and **CORR** (see eq. (XXXIV)) one thus obtains the following symbolic equation:

LAP(POT) x GRAD(POT) =

– DIV(FIELDMASS) – CORR(POT)) x GRAD(POT). (XXXVII)

The crucial result is that this relation suggests a generic operational procedure for identifying the desired correction term, regardless of specific instantiations of the frames involved. From the force expression for Einstein's first field equation for static fields, eq. (40), it follows that the term which serves as the starting point for such a procedure, corresponding to **LAP(POT) x GRAD(POT)**, is:[65]

$$\frac{1}{c}\partial_i\partial_i c\partial_k c, \tag{41}$$

By repeated application of the Leibniz rule for the differentiation of products, one obtains an equation of the form (XXXVII):

65 In the following we assume summation over repeated (spatial) indices.

$$\frac{1}{c}\partial_i\partial_i c\partial_k c = \partial_i T_{ik} + \frac{1}{2c^2}\partial_i c\partial_i c\partial_k c \tag{42}$$

with

$$T_{ik} = \frac{1}{c}\partial_i c\partial_k c - \frac{\delta_{ik}}{2c}\partial_j c\partial_j c, \tag{43}$$

so that

$$\partial_i T_{ik} = \left(\frac{1}{c}\partial_i\partial_i c - \frac{1}{2c^2}\partial_i c\partial_i c\right)\partial_k c \tag{44}$$

is a divergence term and corresponds to **– DIV(FIELDMASS)**, while

$$\frac{1}{2c^2}\partial_i c\partial_i c\partial_k c \tag{45}$$

corresponds to **– CORR(POT)) x GRAD(POT)**. Eq. (45) therefore gives the correction term necessary to satisfy the conservation principle. In other words, this principle not only served to refute the first static field equation (32), it also provided Einstein with a procedure for constructing a modified field equation complying with this principle.

Einstein thus arrived at a new field equation (Einstein 1912b), the core of his so-called "second theory:"[66]

$$\frac{\Delta c}{c} - \frac{\mathrm{grad}^2 c}{2c^2} = k\sigma. \tag{46}$$

Since this revised equation no longer represents a direct analogue of the Poisson equation, Einstein faced the challenge to find a plausible physical interpretation of it. He had to reexamine both the equivalence principle and the role of energy and momentum conservation. A remarkable feature of eq. (46) is that the first derivative of the gravitational potential enters in a non-linear way so that the left-hand side of eq. (46) may be symbolically expressed with the help of eqs. (II) and (XXXIV) as:

$$\mathbf{GRAV} =_{\mathbf{DEFT}} \mathbf{DIV(FIELD)} + \mathbf{FIELD}^2 \tag{XXXVIII}$$

The second term had not been encountered before in working with the mental model of a gravitational field theory. It also threatened one of Einstein's key heuristic assumptions, the principle of equivalence, which could only be upheld for infinitesimally small fields.[67] This restriction made it all the more pressing to provide a plausible physical justification for the correction term. Einstein found such a justification in implications of both field theory and special relativity, i.e. in the fact that a field may

66 The theory advanced in this paper is commonly referred to as Einstein's second theory of static gravitation. Its main difference pertains to the amended field equation.

carry energy and that any kind of energy, being equivalent to mass, should act as a source of the gravitational field.[68]

The physical interpretation of the modified field equation (46) is brought out more clearly by rewriting it as:

$$\Delta c = k\left(c\sigma + \frac{1}{2ck}\mathrm{grad}^2 c\right). \tag{47}$$

This form of the equation suggests that the term

$$\frac{1}{2ck}\mathrm{grad}^2 c,$$

which appears on the right-hand side on the same footing as the material source, be interpreted as the energy density of the gravitational field acting as its own source.

This physical interpretation also supported the conclusion that the general field equation would be non-linear, a conclusion which, after this experience with the special case of the static field, became a standard expectation in Einstein's further search. In terms of our symbolic equations, the revised form of the generic field equation could either be expressed with the help of the **GRAV** and **CORR**-frames (see eq. (XXXIV)) or with the help of the **FIELDMASS**-frame, representing in the general, four-dimensional case the energy-momentum of the gravitational field, as:[69]

NORM(POT) = ENEMO + FIELDMASS. (XXXIX)

NORM(POT) thus represents a new setting of the differential operator slot **OP** allowing the field equation (I) to be written in the "normal" form of eq. (XXXIX); we thus define

OP =$_{\mathbf{DEFT}}$ NORM, (XL)

with a corresponding new setting for **SOURCE**:

---

67 "Thus, it seems that the only way to avoid a contradiction with the reaction principle is to replace equations (3) and (3a) with other equations homogeneous in c for which the reaction principle is satisfied when the force postulate (4) is applied. I hesitate to take this step because by doing so I am leaving the territory of the unconditional equivalence principle. It seems that the latter can be maintained for infinitely small fields only." ("Eine Beseitigung des genannten Widerspruches gegen das Reaktionsprinzip scheint also nur dadurch möglich zu sein, daß man die Gleichungen [$\Delta c = 0$] und [eq. (32)] durch andere in c homogene Gleichungen ersetzt, für welche das Reaktionsprinzip bei Anwendung des Kraftansatzes [39] erfüllt ist. Zu diesem Schritt entschließe ich mich deshalb schwer, weil ich mit ihm den Boden des unbedingten Äquivalenzprinzips verlasse. Es scheint, daß sich letzteres nur für unendlich kleine Felder aufrechterhalten läßt.") (Einstein 1912c, 455–456)

68 The discussion referred to in the following is introduced in (Einstein 1912c) by the phrase: "The term added in equation (3b) [$c\Delta c = \frac{1}{2}(\mathrm{grad}\ c)^2 = kc^2\sigma$] in order to satisfy the reaction principle wins our confidence thanks to the following argument." ("Das in Gleichung (3b) zur Befriedigung des Reaktionsprinzipes hinzugesetzte Glied gewinnt unser Vertrauen durch die folgenden Überlegungen."), p. 456–7.

69 For the following, see "Untying the Knot ..." (in vol. 2 of this series), sec. 3.

$$\mathbf{SOURCE} =_{\mathbf{DEFT}} \mathbf{ENEMO + FIELDMASS.} \qquad \mathbf{(XLI)}$$

This form of the field equation clearly brings out the parallelism between the energy-momentum of matter and the energy-momentum of the gravitational field. Eq. (XXXIX) is the symbolic expression of what eventually became Einstein's standard or normal expectation for the form of a field equation with the property that it is compatible with the conservation principle and with the requirement that gravitational energy and momentum enter the field equation on the same footing as the energy and momentum of matter. With this normal form the conservation principle takes on a particularly simple form. From the last equality in eq. (XXXVI) and the field equation it follows that:

$$\mathbf{DIV(ENEMO) + DIV(FIELDMASS) =}$$

$$\mathbf{DIV(ENEMO + FIELDMASS) = 0.} \qquad \mathbf{(XLII)}$$

This symbolic equation expresses the expectation that the conservation laws should hold for gravitation and matter taken together. Accordingly, the conservation compatibility check for **NORM(POT)** becomes

$$\mathbf{DIV(NORM) = 0,} \qquad \mathbf{(XLIII)}$$

(cf. eq. (XXXI))

It was natural to expect that **NORM** would take on the classical form of a divergence of the field, generated both by material processes and the energy-momentum of the gravitational field itself. The field operator might be brought into such a simple form, resembling the familiar structure from electromagnetic field theory by some appropriate mathematical manipulation, involving the source-term of the field equation as well. In other words, one would have the revised settings:

$$\mathbf{OP(POT)} =_{\mathbf{DEFT}} \mathbf{NORM(POT)}_{\mathbf{CLASS}} = \mathbf{DIV(FIELD),} \qquad \mathbf{(XLIV)}$$

with a corresponding setting for **SOURCE**:

$$\mathbf{SOURCE} =_{\mathbf{DEFT}} \mathbf{ENEMO + FIELDMASS.} \qquad \mathbf{(XLV)}$$

Note, however, that the requirement expressed by eq. (XLII) may not be compatible with the requirement expressed by eq. (XXXIX) if the particular form eq. (XLIV) for the left-hand side of the field equation is imposed.[70]

In summary, Einstein's experiences with implementing the conservation principle in his theory for static gravitational fields turned out to be of crucial significance for his further research, shaping the expectation for the differential operator in the generic gravitational field equation. Reflecting on these experiences, he could conclude, in particular, that

– the field equation would probably be non-linear and contain a term representing the gravitational field acting as its own source;

70 See the discussion in "Untying the Knot ..." (in vol. 2 of this series), secs. 3, §3.

– just as with the static field equation, the field equation might have to be found in two steps with a first step involving a linear second-order differential operator and a second step involving the non-linear, first-order correction terms;
– the correction term might be identified by trying to establish an energy-momentum balance, beginning with a linear, second-order differential operator as a first step.

4.6 Implications of the Generalized Relativity Principle

When starting from an instantiation of the left-hand side of the mental model of a gravitational field equation rooted in physical knowledge such as the core operator, the most challenging problem was to identify its transformation properties and to find out whether or not they allow the implementation of a generalized principle of relativity. Alternatively, one could start from an instantiation rooted in mathematical knowledge. While the physical strategy automatically takes care of the correspondence principle, the mathematical strategy automatically takes care of the generalized relativity principle. In the latter case the main challenge was the implementation of the correspondence and conservation principles, including a check of their mutual compatibility. In the course of his research, Einstein developed a strategy for addressing this challenge. This strategy involved replacing one immediately given default setting for **OP** by a more sophisticated one, better adapted to the purpose at hand. In this respect, the strategy resembles the strategy discussed above for adapting a setting suggested by the correspondence principle to the necessities implied by the conservation principle, i.e., for the transition from **LAP(POT)** to **GRAV(POT)**.

Instantiations for **OP** suggested by the mathematical strategy typically have well-defined transformation properties (e.g. are generally covariant). As his research proceeded Einstein familiarized himself with the relevant mathematical literature, in collaboration with his mathematician friend Marcel Grossmann.[71] While the mathematical horizon enlarged it came to include more and more sophisticated mathematical objects. At the beginning, the mathematical instrumentarium was limited to that of linear vector and tensor analysis in four dimensions as developed by Minkowski, Sommerfeld, and Laue.[72] After a number of unsuccessful attempts to employ these techniques in the construction of a suitable differential operator,[73] the core operator emerged as the most satisfactory candidate which could be obtained at this level of mathematical sophistication. The core operator, however, was covariant only under linear transformations and did thus not lead to a substantial generalization of the relativity principle.

71 For a discussion of Grossmann's role in the search for and reception of pertinent mathematical literature, see (Pais 1982, chap.12c; Norton 1992b, appendix; Reich 1994, chap. 5.3; CPAE 4, 294).
72 Cf. note 30.
73 Cf. pp. 39L–40L of "Einstein's Zurich Notebook" (in this volume).

Einstein subsequently became familiar with the so-called Beltrami invariants.[74] These mathematical objects, in particular the second Beltrami invariant, could be seen as a generalization of the ordinary Laplace operator and must have looked promising. They are generally covariant and thus provide a good starting point for pursuing the mathematical strategy. It was difficult, however, to see how the second Beltrami invariant, defined only for scalar functions, could be applied to a gravitational potential represented by the metric tensor. Einstein thus had two plausible but mutually incompatible default settings, the second Beltrami invariant for the differential operator, and the metric tensor for the gravitational potential. Einstein's dilemma at this point is illustrated in Fig. 3.

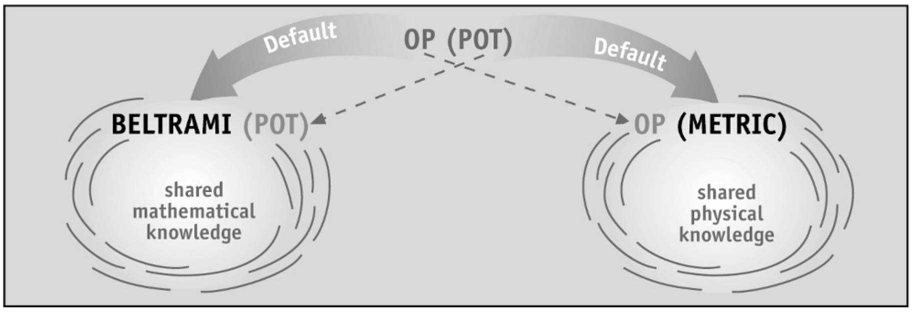

Figure 3: The incompatibility of instantiating the operator slot of Einstein's mental model of a gravitational field equation with the Beltrami invariant, and the potential slot with the metric produced posed a dilemma for Einstein.

The breakthrough for the mathematical strategy came when Einstein got acquainted with the Riemann tensor and its potential to produce suitable candidates for the differential operator in the gravitational field equation. The Riemann tensor represents a second-order differential operator on the metric and is generally covariant. Moreover, by a general theorem any generally-covariant differential operator, which consists of the metric components and its derivatives, and contains no higher than second-order derivatives and is linear in those, can be constructed from the Riemann tensor by tensor-algebraic operations.[75] It must have been clear to Einstein from the outset that the Riemann tensor itself could not play the role of an instantiation for **OP**. First, since the energy-momentum tensor appearing on the right-hand side of the field equation is a second-rank tensor with two indices, the differential operator on the left-hand side was required to have the same property. The Riemann tensor, however, is a fourth-rank tensor, with four indices. Second, a field equation with the Riemann tensor on the left-hand side would be much too restrictive. It would require that, outside the sources, the metric would be strictly Minkowskian so no

74 Cf. pp. 06L–07L of "Einstein's Zurich Notebook" (in this volume).
75 See (Einstein and Grossmann 1913, part II, §4). See also (Bianchi 1910).

non-trivial gravitational potential could exist, a conclusion, for instance, manifestly wrong for the field of a point mass.

A second-rank tensor serving as a natural candidate for **OP**, however, could be extracted from the Riemann tensor in various ways. Let us designate the frame of such a candidate by **RIEM**:

$$\mathbf{OP(POT)} =_{\mathbf{DEFT}} \mathbf{RIEM(POT).} \qquad \mathbf{(XLVI)}$$

As was pointed out above, such candidates come with assurances about their behavior under coordinate transformations (here designated as **TRAFO**). They inherit these transformation properties from their progenitor, the fourth-rank Riemann tensor. The default setting for this property is general covariance (here designated as **GCOVARIANT**):

$$\mathbf{TRAFO(RIEM)} =_{\mathbf{DEFT}} \mathbf{GCOVARIANT.} \qquad \mathbf{(XLVII)}$$

When relating the frame **RIEM** to the default settings **GRAV** or **NORM** for **OP** suggested by the correspondence and conservation principles (cf. eq. (XXXIV) and eq. (XL)), one typically finds a relation of the form:

$$\mathbf{RIEM(POT) = GRAV(POT) + DIST(POT),} \qquad \mathbf{(XLVIII)}$$

where **DIST(POT)** represents “disturbing” terms incompatible with the requirements of the correspondence and conservation principles. To obtain from **RIEM(POT)** a “reduced” candidate satisfying these principles one has to impose the revised default setting for the left-hand side of the gravitational field equation:

$$\mathbf{OP(POT)} =_{\mathbf{DEFT}} \mathbf{RIEM_{RED}(POT) = RIEM(POT) - DIST(POT),} \qquad \mathbf{(XLIX)}$$

which can be obtained from **RIEM** either by requiring that

$$\mathbf{DIST(POT) = 0.} \qquad \mathbf{(L)}$$

or by requiring that **DIST(POT)** behaves as a tensor under some group of coordinate transformations, in which case it can be subtracted leaving a reduced candidate invariant under this now restricted group of transformations:

$$\mathbf{TRAFO(RIEM_{RED}) \Rightarrow TRAFO(DIST),} \qquad \mathbf{(LI)}$$

Conditions such as (XLVII) can typically be derived from first-order conditions on the metric tensor, corresponding to a restriction of the admissible coordinate systems (here designated as **COORD(POT)**):

$$\mathbf{COORD(POT) = 0 \Rightarrow DIST(POT) = 0.} \qquad \mathbf{(LII)}$$

Such a coordinate restriction comes in turn with its own transformation behavior, but typically is at least covariant at least under linear transformations:

$$\mathbf{TRAFO(COORD)} =_{\mathbf{DEFT}} \mathbf{LINEAR.} \qquad \mathbf{(LIII)}$$

Coordinate systems selected in this way assumed for Einstein the role of privileged reference frames, similar to the distinguished role of inertial reference systems in classical physics. It is in these preferred coordinate systems that the physical laws are supposedly valid in their usual form. The condition **COORD(POT) = 0** represented for him a true limitation of the generalized relativity principle and is therefore referred to here as a "coordinate restriction."

From a modern perspective, the relation between a generally-covariant candidate for the left-hand side of the field equation and the condition expressed by eq. (LII) can be interpreted in an entirely different way: Since the Newtonian theory clearly does not hold in arbitrary coordinate systems, while generally-covariant field equations do, special coordinates have to be introduced to obtain the Newtonian limit. A *coordinate condition* in the modern sense, however, does not have the meaning of an overall restriction on the choice of admissible coordinates; it is only a tool adapted for this specific purpose. This tool in no way imposes a restriction on the covariance of the field equation, but is available precisely *because* of it. For the Einstein of the Zurich Notebook, however, it was more natural to think of eq. (LII) as a coordinate *restriction,* valid not only in the context of a special situation such as that of the Newtonian limit but necessary in general to ensure that the candidate gravitation tensor takes on the canonical form of eq. (XXXIV). The transformation properties of $\mathbf{RIEM_{RED}(POT)}$ are thus constrained by those of the coordinate restriction, a relation we can express as:

$$\mathbf{TRAFO(RIEM_{RED}) => TRAFO(COORD).} \qquad \mathbf{(LIV)}$$

An additional restriction of the generalized relativity principle typically follows from the conservation principle, given that its mathematical implementation (e.g., by eq. (XLIII)) does, in general, not lead to a generally-covariant equation:

$$\mathbf{TRAFO(DIV(NORM)) \neq GCOVARIANT.} \qquad \mathbf{(LV)}$$

Just as with the correspondence principle (cf. eq. (LII)), the condition **DIV(NORM) = 0** may be inferred from a simpler, possibly first-order condition representing the restriction to coordinate systems in which the conservation principle holds:

$$\mathbf{ENERG(POT) = 0 => DIV(NORM) = 0.} \qquad \mathbf{(LVI)}$$

For the transformation properties of the gravitational field equation we thus have similarly:

$$\mathbf{TRAFO(NORM) => TRAFO(ENERG),} \qquad \mathbf{(LVII)}$$

or, taken together with relation (LIV), replacing $\mathbf{RIEM_{RED}}$ and **NORM** by **GRAV**:

$$\mathbf{TRAFO(GRAV) => TRAFO(COORD) + TRAFO(ENERG).} \qquad \mathbf{(LVIII)}$$

This relation expresses that the transformation properties of the left-hand side of the gravitational field equation are restricted by the needs of the correspondence and the conservation principles taken together. In summary:

$$\mathbf{TRAFO(GRAV) <=>}$$

$$\mathbf{TRAFO(RIEM) + TRAFO(COORD) + TRAFO(ENERG).} \qquad \mathbf{(LIX)}$$

What this symbolic equation says is that the transformation properties of the field equation are known if those of the original default setting rooted in mathematical knowledge are given together with those of the coordinate restrictions imposed to satisfy the correspondence and the conservation principles.

The above considerations raise the more general problem of the compatibility between the mathematical implementations of the correspondence and conservation principles (the corresponding compatibility condition is designated here as **CC-COMP(GRAV)**). While this question could typically be dealt with at the level of the compatibility of the respective coordinate restrictions eq. (LII) and eq. (LVI), it was conceivable that the compatibility requirement gave rise to new conditions with implications not only for the transformation properties of the field equation but for other questions as well, including the question of whether the given default setting for **GRAV** was acceptable at all:

$$\mathbf{CC\text{–}COMP(GRAV) => (COORD = 0) + (ENERG = 0).} \tag{LX}$$

It was also conceivable that a conflict between a candidate for **GRAV** and the correspondence and conservation principles arose because the default setting for the metric of static gravitational fields eq. (25) was incompatible with one of the coordinate restrictions following from these principles:

$$\mathbf{COORD(POT_{STAT}) \neq 0,} \tag{LXI}$$

$$\mathbf{ENERG(POT_{STAT}) \neq 0.} \tag{LXII}$$

4.7 Implications of the Lagrange Formalism

At some point in his research, Einstein realized the significance of the Lagrange formalism not only for formulating the equation of motion but also for deriving the field equation.[76] Because of its earlier application in the context of classical electromagnetic field theory this formalism came with its own default-settings, which played an important role in Einstein's search for the gravitational field equation. Classical field theory suggested, in particular, to choose a Lagrangian quadratic in the field:

$$\mathbf{LAGRANGE =_{DEFT} FIELD^2.} \tag{LXIII}$$

The Lagrangian for the free Maxwell field for instance is of this form (cf. eq. (11)):

$$L = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu}. \tag{48}$$

The use of the Lagrange formalism had two immediate advantages for Einstein. First, when following the physical strategy, he could focus on a scalar object, the Lagrangian, to explore the transformation properties of his theory rather than on the

76 The first paper in which he made use of the Lagrangian formalism for this purpose is (Einstein and Grossmann 1914). This approach was fully developed in (Einstein 1914a).

more complex tensorial objects representing candidates for the left-hand side of the field equation:[77]

$$\textbf{TRAFO(GRAV)} \Leftrightarrow \textbf{TRAFO(LAGRANGE)}. \qquad \textbf{(LXIV)}$$

Second, when following the mathematical strategy, he could rely on an expression for **FIELDMASS** directly delivered by this formalism in terms of the Lagrangian to explore the validity of the conservation principle. The formalism produces a field equation which can easily be brought into a form corresponding to the default settings eq. (XLIV) and eq. (XLV):

$$\textbf{DIV(FIELD) = ENEMO + FIELDMASS}. \qquad \textbf{(LXV)}$$

It remains, of course, to be checked in each concrete case whether the resulting expression for **FIELDMASS** is compatible with the expectation for such an expression following from the conservation principle and, in particular, with eq. (XLII).[78]

The introduction of the Lagrange formalism had one further consequence for Einstein's search, which eventually turned out to be decisive for identifying the gravitational field equation of general relativity. Due to the default setting eq. (LXIII), the Lagrange formalism helped to highlight the importance of the **FIELD**-frame, pointing to the alternative between eq. (XXII) and eq. (XXIII), one leading to the non-covariant *Entwurf* theory, the other to an essentially generally-covariant theory which quickly opened up the pathway toward the field equation of general relativity.

5. TESTING THE CANDIDATES: EINSTEIN'S CHECK LIST FOR GRAVITATION TENSORS

The reservoir of candidates for the left-hand side of the field equation **OP** available to Einstein was determined by the mathematical knowledge available to him. Roughly three levels of knowledge can be distinguished, each coming with its own set of candidates as shown in Fig. 4 below. Not all candidates played the same prominent role in Einstein's research. The four most important ones were the *Entwurf* operator, the Ricci tensor, the Einstein tensor, and the November tensor (Einstein 1915a).

Einstein examined these four differential operators twice in the course of two exploratory phases of his work. He first confronted them with his heuristic requirements in the period documented by the Zurich Notebook dating from the winter 1912–1913, and then once more in the fall of 1915, as documented by publications and correspondence. He came to different conclusions in these two stages of his work. Before we discuss in detail in which way his research experience led him to

---

77 Einstein's point of view was, however, criticized by the mathematician Tullio Levi-Civita, who contested that the Euler-Lagrange equations have the same covariance group as the Lagrangian in the case of the *Entwurf* theory. See, e.g., Tullio Levi-Civita to Einstein, 28 March 1915 (CPAE 8, Doc. 67).

78 For the detailed mathematical considerations, see "Untying the Knot ..." (in vol. 2 of this series), secs. 3.1 and 3.2.

these different views, we shall systematically examine how the various candidates fare when confronted with his heuristic requirements and give an overview of the results of his checks. In this way, we shall be able to establish the potential of these candidates independently of their actual role in the dramatic history of Einstein's search for the field equation. As a consequence, the twists and turns of this search will become understandable as reactions to the epistemic constraints and potentials inherent in the knowledge resources available to Einstein. These constraints are largely embodied in the mental models and frames guiding his research, as well as in their default settings and the instantiations of their open slots. But the conflicting implications of these default settings and instantiations were only revealed in the course of Einstein's elaboration of his theory on the level of concrete mathematical

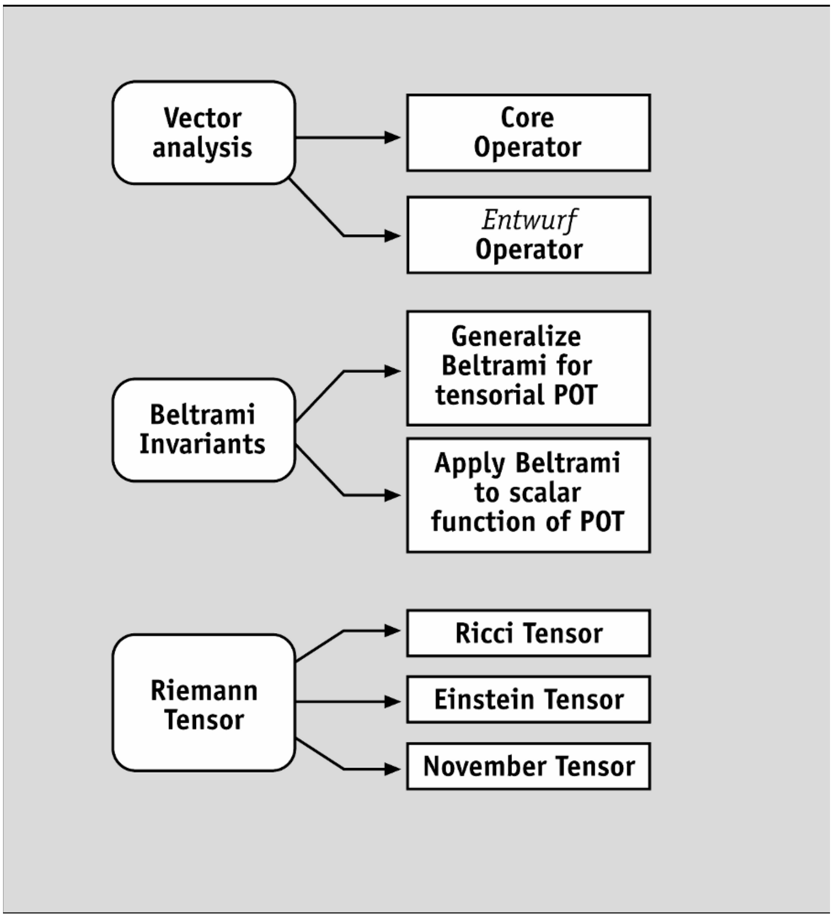

Figure 4: A list of Einstein's most important candidates for differential operators to fill the operator slot of his mental model of a gravitational field equation.

representation. As a matter of fact, the fate of a candidate not only depended on the structural constraints of his heuristics but also on the *order* in which these structures were implemented, on the *exploration depth* with which they were treated, and on the *perspective* under which Einstein examined the answers to his questions. As we shall show in more detail in the next section, in all three of these *performative dimensions* of his evaluation of candidates, the situation of the winter of 1912–1913 was very different from that of October and November 1915 when he once more examined these candidates.

5.1 The Entwurf Operator and the Correspondence Principle in the Winter of 1912–1913

The *Entwurf* operator, first written down in the Zurich Notebook and then published by Einstein and Grossmann in the spring of 1913, gives rise to the field equations:

$$\mathbf{ENTWURF} =_{\mathbf{DEFT}} \frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\sqrt{-g}\frac{\partial g^{\mu\nu}}{\partial x^{\beta}}\right) - g^{\alpha\beta}g_{\tau\rho}\frac{\partial g^{\mu\tau}}{\partial x^{\alpha}}\frac{\partial g^{\nu\rho}}{\partial x^{\beta}} = \kappa(T^{\mu\nu} + t^{\mu\nu}) \quad (49)$$

with the following expression for the gravitational energy-momentum:

$$\mathbf{FIELDMASS} =_{\mathbf{DEFT}} -\kappa t^{\mu\nu} = \frac{1}{2}g^{\mu\alpha}g^{\nu\beta}\frac{\partial g^{\tau\rho}}{\partial x^{\beta}}\frac{\partial g_{\tau\rho}}{\partial x^{\alpha}} - \frac{1}{4}g^{\mu\nu}g^{\alpha\beta}\frac{\partial g^{\tau\rho}}{\partial x^{\alpha}}\frac{\partial g_{\tau\rho}}{\partial x^{\beta}}. \quad (50)$$

The *Entwurf* field equations satisfy the correspondence principle just as the core operator does since the correction terms which distinguish the two vanish in the limiting procedure for obtaining the Newtonian theory. One has, in particular, (cf. eq. (XXIX)):

$$\mathbf{LIM_{STAT}(ENTWURF) = LIM(LAP(POT_{STAT}))}. \quad \mathbf{(LXVI)}$$

5.2 The Entwurf Operator and the Conservation Principle in the Winter of 1912–1913

By their very construction, the *Entwurf* field equations satisfy the conservation principle since the correction terms distinguishing them from the core operator are generated in such a way that an identity of type (XXXVII) holds. Evidently, the field equations (49) are of the form (XXXIX), while an equation of the form (XLII) expresses the conservation principle:

$$\frac{\partial}{\partial x^{\nu}}(\boldsymbol{T}^{\mu\nu} + \boldsymbol{t}^{\mu\nu}) = 0. \quad (51)$$

5.3 The Entwurf Operator and the Generalized Relativity Principle in the Winter of 1912–1913

The principal challenge for the *Entwurf* theory was the question of the transformation properties of the *Entwurf* field equations and hence of the extent to which the theory satisfies the generalized relativity principle. The *Entwurf* operator had *not* been obtained from a generally-covariant object along the mathematical strategy, (cf. eq. (XLIX)). By construction, the *Entwurf* operator is covariant only under linear transformations (cf. eq. (LIII)):

$$\textbf{TRAFO(ENTWURF)} =_{\textbf{DEFT}} \textbf{LINEAR.} \qquad \textbf{(LXVII)}$$

In different stages of Einstein's work during the reign of the *Entwurf* theory, i.e., between the winter of 1912–1913 and the fall of 1915, he took different positions on the question of whether or not the theory admits a wider class of coordinate transformations. These positions ranged from the acceptance that the *Entwurf* theory is covariant only under linear transformations to the belief that it fully complies with the demands of a generalized relativity principle. Einstein at first believed that the issue of the transformation properties of the *Entwurf* equations was wide open and could be settled only by an extensive mathematical investigation. In the summer of 1913, however, he came to the conclusion that a mere inspection of the form of eq. (51) was sufficient to resolve the problem in favor of the claim that the *Entwurf* theory could *only* be covariant under linear transformations.[79] He thus accepted that the conservation principle requires a severe limitation of the generalized relativity principle.

5.4 The Entwurf Operator and the Correspondence Principle in the Fall of 1915

In the course of his elaboration of the *Entwurf* theory, Einstein succeeded in deriving the field equations from a Lagrange formalism with the default setting for the field given by eq. (XXII). The field then enters the Lagrangian in the form of eq. (LXIII). After an initial attempt to select this default setting for the field with the help of a consistency argument involving the conservation principle (see below), he returned to the correspondence principle as the main argument for choosing, among several options to specify the field variable, the default setting eq. (XXII), giving rise to the familiar *Entwurf* field equation.

5.5 The Entwurf Operator and the Conservation Principle in the Fall of 1915

In the course of his elaboration of the *Entwurf* theory, Einstein succeeded in bringing its field equation into the canonical form described by eqs. (XLIV), (XLV) with the condition (XLIII), a form that was expected on the basis of classical field theory:

79 Cf. Einstein to H.A. Lorentz, 16 August 1913, (CPAE 5, Doc. 470, Norton 1984, 126).

$$\textbf{ENTWURF} =_{\textbf{DEFT}} \frac{\partial}{\partial x^\alpha}(\sqrt{-g}g^{\alpha\beta}\tilde{\Gamma}^\lambda_{\mu\beta}) = \kappa(T^\lambda_\mu + t^\lambda_\mu), \tag{52}$$

with

$$\textbf{FIELDMASS} =_{\textbf{DEFT}} \kappa t^\lambda_\mu = \sqrt{-g}\Big(g^{\lambda\rho}\tilde{\Gamma}^\alpha_{\tau\mu}\tilde{\Gamma}^\tau_{\alpha\rho} - \frac{1}{2}\delta^\lambda_\mu g^{\rho\tau}\tilde{\Gamma}^\alpha_{\beta\rho}\tilde{\Gamma}^\beta_{\alpha\tau}\Big). \tag{53}$$

Here $\tilde{\Gamma}^\alpha_{\sigma\nu}$ represents the default setting for the field as given by eq. (XXII). In 1914 Einstein erroneously believed that a compatibility requirement resulting from the conservation principle and the generalized relativity principle (cf. eq. (87) below) would uniquely fix the *Entwurf* Lagrangian. However, this requirement merely corresponds to demanding the compatibility between **FIELDMASS** in the sense of eq. (XLV) and **FIELDMASS** in the sense of eq. (XLII) and does not substantially restrict the choice of possible gravitation tensors.[80]

5.6 The Entwurf Operator and the Generalized Relativity Principle in the Fall of 1915

Einstein quickly discovered that his argument based on the form of eq. (51) was fallacious since the energy-momentum expression of the gravitational field does not represent a generally-covariant tensor.[81] But he soon found another, seemingly powerful argument in order to justify the *Entwurf* theory's lack of general covariance, the so-called hole argument.[82] To identify the covariance group of the *Entwurf* field equations compatible with this argument, Einstein again made use of eq. (51) but now in a different way which corresponds to the conservation compatibility check as represented by eq. (XLIII), i.e. he combined energy-momentum conservation with the gravitational field equation in order to derive a condition for the class of admissible coordinate systems. By exploring the transformation properties of the Lagrangian (cf. eq. (LXIV), Einstein and Grossmann (1914) claimed to have shown that this condition is both necessary and sufficient (cf. eqs. (LV) and (XLIV)):

$$\textbf{TRAFO(NORM}_{\textbf{CLASS}}\textbf{)} \Leftrightarrow \textbf{TRAFO(DIV(NORM}_{\textbf{CLASS}}\textbf{))} \tag{LXVIII}$$

with

$$\textbf{DIV(NORM}_{\textbf{CLASS}}\textbf{)} =_{\textbf{DEFT}} B_\mu = \frac{\partial^2}{\partial x^\nu \partial x^\alpha}(\sqrt{-g}g^{\alpha\beta}\tilde{\Gamma}^\nu_{\sigma\beta}) = 0. \tag{54}$$

These four third-order differential equations for the metric tensor complement the ten gravitational field equations and embody the conditions enforcing the restriction of general covariance characteristic of the theory. They were understood by Einstein and

80 See "Untying the Knot ..." (in vol. 2 of this series), sec. 3.

81 Cf. the footnote in (Einstein and Grossmann 1914, 218).

82 For historical discussion, see (Earman and Norton 1987, Stachel 1989b) and "What Did Einstein Know ..." (in vol.2 of this series) as well as further references cited therein.

Grossmann as determining the coordinate systems "adapted" to the *Entwurf* theory.[83] It was difficult to see exactly which transformations to accelerated coordinate systems are admitted by these conditions.

5.7 The Ricci Tensor and the Correspondence Principle in the Winter of 1912–1913

The generally-covariant Ricci tensor, first taken into consideration by Einstein in the Zurich Notebook (see p. 22R), can be expressed in terms of the Christoffel symbols (cf. eqs. (30) and (XLVI)) as:

$$\mathbf{RIEM} =_{\mathbf{DEFT}} \mathbf{RICCI} =_{\mathbf{DEFT}} R_{\mu\nu} = \frac{\partial\Gamma^{\alpha}_{\mu\nu}}{\partial x^{\alpha}} - \frac{\partial\Gamma^{\alpha}_{\mu\alpha}}{\partial x^{\nu}} + \Gamma^{\beta}_{\nu\beta}\Gamma^{\alpha}_{\mu\alpha} - \Gamma^{\beta}_{\mu\nu}\Gamma^{\alpha}_{\beta\alpha}. \tag{55}$$

The validity of the correspondence principle could be examined by bringing **RICCI** into the form (cf. eqs. (XXXIV) and (XLIX))

$$\mathbf{RIEM} =_{\mathbf{DEFT}} \mathbf{RICCI}_{\mathbf{RED}} = \mathbf{LAP(POT)} + \mathbf{CORR(POT)}, \tag{LXIX}$$

and by checking whether (cf. eq. (L))

$$\mathbf{DIST(POT) = 0.}$$

In the Zurich Notebook Einstein identified the relevant terms as:

$$\mathbf{DIST(POT)} =_{\mathbf{DEFT}} \frac{\partial^2 g_{\alpha\alpha}}{\partial x_{\mu}\partial x_{\nu}} - \frac{\partial^2 g_{\mu\alpha}}{\partial x_{\alpha}\partial x_{\nu}} - \frac{\partial^2 g_{\nu\alpha}}{\partial x_{\alpha}\partial x_{\mu}}. \tag{56}$$

The vanishing of these disturbing terms can be achieved by imposing a set of four *first-order* partial differential equations for the metric tensor which is given by (cf. eq. (LII)):

$$\mathbf{COORD(POT)} =_{\mathbf{DEFT}} \mathbf{COORD}_{\mathbf{HARM}}\mathbf{(POT)} =_{\mathbf{DEFT}} g^{\lambda\kappa}\Gamma^{\mu}_{\lambda\kappa} = 0. \tag{57}$$

---

83 This expression is chosen to resolve the ambiguity of German expressions which may be translated by "condition" as well as by "restriction." Cf. the formulations in (Einstein and Grossmann 1914): "understood [...], that an acceptable theory of gravitation implies necessarily a specialization of the coordinate system." ("eingesehen [...], daß eine brauchbare Gravitationstheorie notwendig einer Spezialisierung des Koordinatensystems bedarf [...]", p. 218); "restriction" ("Einschränkung", p. 218, note); "true condition" ("wirkliche Bedingung", p. 219); "conditions [...], by which we restricted the coordinate systems" ("Bedingungen [...], durch die wir die Koordinatensysteme eingeschränkt haben.", p. 225). In a letter to Michele Besso, ca. 10 March 1914, (CPAE 5, Doc. 514), Einstein comments on eq. (54): "These are 4 third-order equations for the [...] or [...], which can be conceived as the conditions for the special choice of the reference system." ("Dies sind vier Gleichungen dritter Ordnung für die $g_{\mu\nu}$ [...], welche man als die Bedingungen für die spezielle Wahl des Bezugssystems auffassen kann.")

These equations, representing the "harmonic" coordinate restriction, were interpreted by Einstein as singling out a particular class of coordinate systems that were then called "isothermal" and are now referred to as "harmonic" coordinates.

The reduced Ricci tensor $\mathbf{RICCI_{RED}}$ suffered from yet another problem related to Einstein's understanding of the correspondence principle. It consists in a conflict between the harmonic coordinate restriction and the canonical metric for a static gravitational field $\mathbf{POT_{STAT}}$ (cf. eq. (25)):

$$\mathbf{COORD_{HARM}(POT_{STAT}) \neq 0.} \qquad \mathbf{(LXX)}$$

However, as far as the available evidence from the Zurich Notebook and other contemporary sources show, this argument played no role in evaluating the reduced Ricci tensor.[84]

5.8 The Ricci Tensor and the Conservation Principle in the Winter of 1912–1913

As far as the conservation principle is concerned, the exploration depth reached in the Zurich Notebook was characterized by the fact that Einstein examined only the weak-field equation following from a gravitational field equation based on the Ricci tensor. He considered, in other words, an equation of the type of eq. (33). For such a weak-field equation in which the source is given by pressureless dust (cf. eq. (4)), Einstein succeeded in representing the force exerted by the gravitational field as a divergence expression in the sense of eq. (XXXVI)):

$$\mathbf{-\,GRAD(POT)\ X\ LIM(RICCI) = DIV(LIM(FIELDMASS)),} \qquad \mathbf{(LXXI)}$$

which in his notation reads:[85]

$$\sum_{\kappa i m} \gamma_{\kappa\kappa} \frac{\partial^2 g_{im}}{\partial x_\kappa^2} \frac{\partial g_{im}}{\partial x_\sigma} = \sum_{\kappa i m} \gamma_{\kappa\kappa} \left[\frac{\partial}{\partial x_\kappa} \left(\frac{\partial g_{im}}{\partial x_\kappa} \frac{\partial g_{im}}{\partial x_\sigma} \right) - \frac{1}{2} \frac{\partial}{\partial x_\sigma} \left(\frac{\partial^2 g_{im}{}^2}{\partial x_\kappa} \right) \right]. \qquad (58)$$

The conservation compatibility check similarly takes on a simpler form if considered for the weak field case. In first-order approximation the covariant derivative in eq. (XXXI) can be replaced by an ordinary derivative and **OP(POT)** by **LAP(POT)** with its default setting according to eq. (XXVIII) so that this condition can be written, in Einstein's notation, as:

$$\mathbf{LIM(DIV_{COV}(OP)) = DIV(LIM(LAP)= 0.} \qquad \mathbf{(LXXII)}$$

Interchanging the two differential operations,

84 See "Untying the Knot ..." (in vol. 2 of this series), fn. 12 for further discussion.

85 See p. 19R of "Einstein's Zurich Notebook" and sec. 5.4.2 of the "Commentary" (in vol. 2 of this series), fn. 10 for further discussion. Einstein's notation, which is somewhat sloppy, is explained in detail in the commentary; note that he used an imaginary time coordinate and that the terms $g_{\mu\nu}$ here stand for the small deviations $h_{\mu\nu}$ from the covariant Minkowski metric.

DIV(LIM(LAP(POT)) = LIM(LAP(DIV(POT))), (LXXIII)

which, in Einstein's notation amounts to:

$$\frac{\partial}{\partial x_m}(\Box g_{im}) = \Box\left(\frac{\partial g_{im}}{\partial x_m}\right) = 0, \tag{59}$$

it becomes clear that the conservation compatibility check is satisfied at the weak-field level if an appropriate set of first-order conditions hold in the sense of eq. (LVI):

LIM(ENERG) =$_{\mathbf{DEFT}}$ DIV(POT) = 0 => DIV(LIM(LAP)) = 0. (LXXIV)

More specifically, the conservation compatibility check works out in the weak field limit if the condition:

$$\textbf{LIM(ENERG)} =_{\textbf{DEFT}} \textbf{COORD}_{\textbf{HERTZ}} = \textbf{DIV(POT)} =_{\textbf{DEFT}} \frac{\partial g_{im}}{\partial x_m} = 0 \tag{60}$$

is fulfilled. This condition was mentioned by Einstein in a letter to Paul Hertz from 22 August 1915[86] and will therefore be called the "Hertz condition" or the "Hertz restriction" depending on the context. In the case at hand, it is appropriately referred to as the "Hertz restriction" since it represents a restriction of the admissible coordinates required by the conservation principle.

As it turned out, the combination of the two coordinate restrictions eq. (57) and eq. (60), resulting from the correspondence and the conservation principle, and the weak-field field equation imposed a restriction which Einstein considered to be unacceptable. According to this condition, the trace of the source term has to vanish, which can be expressed in terms of eq. (LX) as:

TRACE(SOURCE) = 0 => CC-COMP(LIM(LAP)). (LXXV)

This condition was indeed incompatible with the default setting for the source term of the gravitational field equation, pressureless dust (cf. eq. (XXI)). Combining restrictions eq. (57) and eq. (60) furthermore implies that the trace of the potential must be constant which is obviously in conflict with the default setting for the metric of a static field eq. (25).[87]

5.9 The Ricci Tensor and the Generalized Relativity Principle in the Winter of 1912–1913

Given the compatibility problem just described, the transformation properties of the reduced Ricci tensor remained unexplored.

86 For a detailed discussion of this letter, see (Howard and Norton 1993).
87 See "Commentary ..." (in vol. 2 of this series), sec. 5.4.3 for detailed discussion.

5.10 The Ricci Tensor and the Correspondence Principle in the Fall of 1915

When Einstein returned to the Ricci tensor in November 1915 both the perspective and the exploration depth of his investigation had changed. He then considered the Ricci tensor in coordinate systems with:

$$\sqrt{-g} = 1 \tag{61}$$

in which it takes on the simpler form:

$$\textbf{RICCI} =_{\textbf{DEFT}} \frac{\partial \Gamma^{\alpha}_{\mu\nu}}{\partial x^{\alpha}} + \Gamma^{\beta}_{\mu\alpha}\Gamma^{\alpha}_{\nu\beta}. \tag{62}$$

Within this framework, the Ricci tensor could be brought into the appropriate weak-field form eq. (XXXIV) by assuming the Hertz condition:

$$\textbf{COORD}_{\textbf{HERTZ}} = \textbf{DIV(POT)} =_{\textbf{DEFT}} \frac{\partial g_{im}}{\partial x_m} = 0. \tag{63}$$

In November 1915, Einstein was aware of the fact that it was sufficient for satisfying the correspondence principle to use such an equation (cf. eq. (LII)) in the modern sense of a coordinate *condition* that simply makes use of the freedom within a generally-covariant framework to pick appropriate coordinate frames—without imposing an overall restriction. In this sense, Einstein's understanding of the correspondence principle had been substantially enhanced by a greater exploration depth of his formalism.[88]

In contrast to eq. (LXX) we now have:

$$\textbf{COORD}_{\textbf{HERTZ}}(\textbf{POT}_{\textbf{STAT}}) = \textbf{0}, \tag{LXXVI}$$

so that the conflict between the coordinate condition and the canonical metric for a static field is apparently removed. This is, in any case, what Einstein at first must have believed when he published, in November 1915, a gravitational field equation based on the Ricci tensor. What he seems to have overlooked, however, was the fact that his canonical metric given by eq. (25) was incompatible with the condition eq. (61) on which his entire framework, including the coordinate condition eq. (63), crucially depended. In other words, the available evidence suggests that Einstein had first published his theory based on the Ricci tensor although it actually violates the correspondence principle as he then conceived it.

He only realized the challenge represented by the choice of the Ricci tensor for his understanding of the correspondence principle when he examined the implication of this choice for the explanation of Mercury's perihelion motion, an examination that gave him a nearly perfect match with the observational data.[89] Einstein at first

88 See "Untying the Knot ..." (in vol. 2 of this series), secs. 1.5 and 6 for detailed discussion.

interpreted this agreement as evidence in favor of his hypothesis of an electromagnetic theory of matter which had made the proposal of a field equation with the Ricci tensor as its left-hand side acceptable to him (see below).

5.11 The Ricci Tensor and the Conservation Principle in the Fall of 1915

By the fall of 1915, the exploration depth of Einstein's investigation had been increased, in particular, by the development of a technique allowing him to derive a gravitational energy-momentum expression **FIELDMASS** for the full field equation from the Lagrange formalism, if the coordinate condition eq. (61) is assumed and the default setting for the field is given by eq. (XXIII). He was thus able to bring a field equation based on the Ricci tensor into a form corresponding to eq. (XXXIX) with the conservation equation (XLII):

$$\textbf{NORM(POT)} =_{\textbf{DEFT}} (g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma} = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}), \tag{64}$$

with

$$\textbf{FIELDMASS} =_{\textbf{DEFT}} \kappa t^{\lambda}_{\sigma} = \frac{1}{2}\delta^{\lambda}_{\sigma}g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} - g^{\mu\nu}\Gamma^{\alpha}_{\mu\sigma}(\Gamma_{\alpha\nu},)^{\lambda} \tag{65}$$

and

$$\textbf{DIV(ENEMO + FIELDMASS)} =_{\textbf{DEFT}} (T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda} = 0. \tag{66}$$

Einstein, however, did not manage to comply with the requirement expressed by the default setting eq. (XLIV). Bringing the left-hand side of the field equation into the form of eq. (XLIV) would result in a formulation in which the right-hand side no longer satisfies the default setting eq. (XLI) for **SOURCE**:

$$\textbf{NORM(POT)}_{\textbf{CLASS}} = \textbf{DIV(FIELD)} =_{\textbf{DEFT}} (g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} = -\kappa\left(T^{\lambda}_{\mu} + t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}t\right) \tag{67}$$

with

$$\textbf{SOURCE} =_{\textbf{DEFT}} \textbf{ENEMO + FIELDMASS} \neq_{\textbf{DEFT}} -\kappa\left(T^{\lambda}_{\mu} + t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}t\right). \tag{68}$$

Equation (66) could be used to perform the conservation compatibility check in a straightforward manner. Einstein succeeded in showing that this check turned out successful if the trace of the energy-momentum tensor vanishes (cf. eq. (LXXV))—without imposing any further conditions on the admissible coordinate systems:

TRACE(SOURCE) = 0 => DIV(ENEMO + FIELDMASS) = 0. (LXXVII)

The odd assumption of a vanishing trace, violating the default assumption eq. (XXI), was now acceptable to Einstein since both the exploration depth of his investi-

89 See (Einstein 1915b) and for historical discussion, (Earman and Janssen 1993).

gation and his perspective had changed. He now reexamined the Ricci tensor from the perspective of an electromagnetic theory of matter in which this condition was fulfilled from the outset, given that the trace of the electromagnetic energy-momentum tensor vanishes.[90]

5.12 The Ricci Tensor and the Generalized Relativity Principle in the Fall of 1915

The field equations based on the Ricci tensor as formulated by Einstein in the fall of 1915 represents, according to his heuristic criteria, a complete implementation of the generalized principle of relativity. The conservation compatibility check for these field equations had given Einstein, as we have seen, merely a condition on the trace of the energy-momentum tensor which does not imply any restriction on the choice of coordinate systems. As a consequence, there no longer was any conflict between the conservation and the correspondence principles as he had encountered it in the winter of 1912–1913. It was thus possible to impose either the harmonic coordinate condition eq. (57) or the combination of eqs. (61) and (63) in order to reduce the Ricci tensor to the canonical weak field form eq. (LXIX) from which the Newtonian limit could be obtained—at least if the objection resulting from eq. (LXX) could be solved or circumvented.

5.13 The Einstein Tensor and the Correspondence Principle in the Winter of 1912–1913

The generally-covariant Einstein tensor, first taken into consideration, albeit only in the weak-field approximation, in the Zurich Notebook, can be expressed in terms of the Ricci tensor $R_{\mu\nu}$ and its trace R (cf. eq. (55)) as:

$$\textbf{RIEM} =_{\textbf{DEFT}} \textbf{Einstein} =_{\textbf{DEFT}} E_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R. \tag{69}$$

A field equation based on the Einstein tensor may also be written by shifting the trace term to the right-hand side by a simple mathematical argument. The equation then reads

$$R_{\mu\nu} = -\kappa\left(T_{\mu\nu} - \frac{1}{2} g_{\mu\nu} T\right), \tag{70}$$

where T is the trace of the energy-momentum tensor $T_{\mu\nu}$. Here the Ricci tensor again appears on the left-hand side as the differential operator acting on the metric tensor.

---

90 See (Einstein 1915d) where the consequence is called "introducing an admittedly bold additional hypothesis on the structure of matter." ("Einführung einer allerdings kühnen zusätzlichen Hypothese über die Struktur der Materie", p. 799).

The exploration level of the first examination of the Einstein tensor in the winter of 1912–1913 was, just as that of Einstein's analysis of the Ricci tensor, characterized by a focus on the weak-field equations and the assumption that the correspondence principle could only be satisfied by a coordinate restriction. Given that the Einstein tensor results from a modification of the Ricci tensor according to eq. (69), it was natural to presuppose the harmonic coordinate restriction **COORD$_{\mathbf{HARM}}$(POT) = 0** (cf. eq. (57)). As a matter of fact, in the winter of 1912–1913 the Einstein tensor was obtained directly by an ad hoc modification of the weak-field form of the gravitational field equation eq. (33), resulting in:[91]

$$\Box\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right) = T_{i\kappa} \tag{71}$$

with the trace term:

$$U = \sum g_{\kappa\kappa}, \tag{72}$$

or alternatively as:

$$\Box g_{ij} = T_{ij}-\frac{1}{2}\delta_{ij}\left(\sum T_{\kappa\kappa}\right). \tag{73}$$

It surely would have been possible for Einstein to carry out the corresponding modification on the level of the original Ricci tensor, turning it into what we now call the Einstein tensor, by the subtraction of a trace term.

On closer inspection, however, the harmonic coordinate restriction does not achieve the desired reduction of the field equation to the required standard form in the sense of eq. (LII). Indeed, if the left-hand side is brought into the canonical form eq. (XXVIII) so that eq. (73) is obtained, the right-hand side does obviously not represent the default setting for **SOURCE** as given by eq. (XIV):

$$\mathbf{SOURCE} \neq_{\mathbf{DEFT}} T_{ij}-\frac{1}{2}\delta_{ij}\left(\sum T_{\kappa\kappa}\right). \tag{LXXVIII}$$

Instead an additional trace term appears which in general is not constant. If one examines, in particular, a static mass distribution as the default setting for **SOURCE** so that the 44 component is the only non-vanishing term of the energy-momentum tensor, it follows from the weak-field equation (73) that *all* diagonal components of the metric tensor will be variable so that one has in general:

$$g_{ii} \neq \text{const for } i = 1, \ldots, 4. \tag{74}$$

As a consequence, the weak-field equation (73) no longer admits the canonical metric **POT$_{\mathbf{STAT}}$** defined by eq. (25) as a solution. At that point in time, Einstein saw no way to avoid this default setting for the potential, and he rejected the Einstein tensor—lin-

91 See "Commentary" (in vol. 2 of this series), sec. 5.4.3.

earized and reduced by the harmonic coordinate restriction—as a candidate for the left-hand side of the gravitational field equation.[92]

5.14 The Einstein Tensor and the Conservation Principle in the Winter of 1912–1913

At the weak-field level, the results of Einstein's check of the conservation principle turned out to be promising. In spite of the additional trace term it was possible to write the gravitational force density in the required form of a divergence of the gravitational energy-momentum density, which in Einstein's notation reads (cf. eqs. (XXXVI) and (LXXI)):

$$\sum_{i\kappa\nu}\frac{\partial}{\partial x_\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\frac{\partial g_{i\kappa}}{\partial x_\sigma}\right)-\frac{1}{2}\sum_{i\kappa\nu}\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\right)^2\right)$$
$$-\frac{1}{2}\sum_\nu\frac{\partial}{\partial x_\nu}\left(\frac{\partial U}{\partial x_\nu}\frac{\partial U}{\partial x_\sigma}\right)+\frac{1}{4}\sum\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial U}{\partial x_\nu}\right)^2\right). \tag{75}$$

At the level of the weak-field equation it was also immediately clear that the conservation compatibility check is no longer in conflict with the correspondence principle, in contrast to what he had found before for the Ricci tensor. In analogy with eq. (59) one now obtains:

$$\frac{\partial}{\partial x_\kappa}\left(\Box\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right)\right) = \Box\left(\frac{\partial}{\partial x_\kappa}\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right)\right) = 0, \tag{76}$$

which, in symbolic notation, corresponds to (cf. eqs. (LXXII), (LXXIV)):

$$\textbf{DIV(LIM(EINSTEIN)) = LIM(LAP(COORD}_{\textbf{HARM}}\textbf{)) = 0.} \tag{LXXIX}$$

In other words, the conservation compatibility check is, in the weak-field limit, satisfied *because* of the harmonic coordinate restriction eq. (57) required by the correspondence principle—without imposing any restriction on the trace of the energy-momentum tensor.

5.15 The Einstein Tensor and the Generalized Relativity Principle in the Winter of 1912–1913

Whether or not the generalized relativity principle was satisfied would, according to Einstein's understanding in the winter of 1912–1913, depend on whether the coordinate restrictions necessary to fulfill his other heuristic criteria would leave him enough covariance. In view of the clash between the Einstein tensor and the corre-

92 See "Commentary" (in vol. 2 of this series), sec. 5.4.6.

spondence principle (see eq. (LXXVIII)), this issue remained unexplored at this point in time.

5.16 The Einstein Tensor and the Correspondence Principle in the Fall of 1915

When Einstein returned to the Einstein tensor in November 1915 he focused on coordinate systems with:

$$\sqrt{-g} = 1 . \tag{77}$$

The field equations based on the Einstein tensor then take on the form (cf. eqs (70) and (62)):

$$\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} = -\kappa\left(T_{\mu\nu} - \frac{1}{2}g_{\mu\nu}T\right). \tag{78}$$

In view of eqs. (69) and (70), one could use, just as in the case of the Ricci tensor, the harmonic condition eq. (57)[93] to bring the left-hand side of the field equation into the required form. This condition was now understood as a coordinate condition in the modern sense. Proceeding in this way, one reduces the Einstein field equation for weak fields to an equation of the form (73). The usual transition to the Newtonian theory could now proceed by taking the energy-momentum tensor of dustlike matter as the source and neglecting all terms except the T_{44}-term, which can be identified with the gravitating mass density ρ appearing in the classical Poisson equation (cf. eq. (37)).

What remained to be shown was that the canonical metric for a static field was compatible with the non-standard form of the right-hand side of the weak-field equations (73). Even in 1915 this conflict remained, in a sense, unresolved. The additional trace term on the right-hand side made it impossible to accept the canonical metric for static fields as a solution of the weak field equations since the 11 ... 33 components of the source term had to be retained in the transition to the Newtonian case (cf. eq. (74)). Therefore the correction term in the Einstein tensor made the transition to the Newtonian case *a fortiori* impossible following the procedure suggested by the correspondence principle. All this had been known to Einstein in 1912[94] and remained, of course, true also in 1915, when he took up the Einstein tensor a second time (Einstein 1915d).

But now Einstein was able to circumvent this problem. Even though the field equation failed to satisfy the correspondence principle as hitherto understood, this did not affect the equation of motion. In the weak-field limit of the equation of motion, the non-standard character of the weak-field Einstein equation plays no role. For weak static gravitational fields and for velocities negligible in comparison with that of light, the general equation of motion (31) reduces, as we have seen, to eq. (38).

93 For a comment on the role of the Hertz condition in this context, see Albert Einstein to Karl Schwarzschild, Berlin, 19 February 1916, (CPAE 8, Doc. 194).

94 Cf. pp. 20L–21R of "Einstein's Zurich Notebook" (in this volume).

This equation now implies that, under the conditions assumed, a gravitational field equation based on the Einstein tensor is actually compatible with the experimental data on gravitation that are adequately described by Newton's theory if $g_{44}/2$ is, as usual, identified with the Newtonian potential, while the other components of the metric tensor play no role at this level of the weak-field limit of the Einstein equation.

5.17 The Einstein Tensor and the Conservation Principle in the Fall of 1915

When Einstein returned to the Einstein tensor in late 1915, the greater exploration depth of his investigation made it possible to establish an energy-momentum expression for the gravitational field of the required form. Also the question of the conservation compatibility check could now be addressed in a straightforward manner. He succeeded in bringing the field equation into a form corresponding to eq. (XXXIX) with a conservation equation of the form of eq. (XLII):

$$\textbf{NORM(POT)} =_{\textbf{DEFT}} (g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa(t+T) = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}). \tag{79}$$

The satisfaction of the conservation compatibility check (cf. eq. (XLIII)) now no longer imposes any additional conditions interfering with the field equation as was the case for the tensor where this check implied that the trace of both sides of the field equation has to vanish.

In the field equation based on the Einstein tensor, the trace terms of the energy-momentum of matter and of the gravitational field enter, in contrast to what happens for the Ricci tensor (cf. eq. (67)), in complete parallel to each other. As a matter of fact, the introduction of these trace terms corresponds to changing the default setting eq. (XLI) for **SOURCE** into:

$$\textbf{SOURCE} =_{\textbf{DEFT}}$$

$$\textbf{(ENEMO – 1/2 TRACE(ENEMO)) +}$$

$$\textbf{(FIELDMASS – 1/2 TRACE(FIELDMASS)).} \tag{LXXX}$$

With this new instantiation for the source term, Einstein now also managed to comply with the expectation for the left-hand side of the field equation expressed by the default setting eq. (XLIV):

$$\textbf{NORM(POT)}_{\textbf{CLASS}} = \textbf{DIV(FIELD)} =_{\textbf{DEFT}} (g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} \tag{80}$$

with

$$\textbf{SOURCE} =_{\textbf{DEFT}} -\kappa\left(\left(T^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}T\right) + \left(t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}t\right)\right). \tag{81}$$

Note, however, that with this redefinition of the source-term the field equation no longer corresponds with the canonical expectation for its right-hand side expressed by the default setting eq. (XLII) suggested by the conservation principle. Even for a field equation based on the Einstein tensor it is simply impossible to satisfy all expectations raised by the experience of classical field theory!

5.18 The Einstein Tensor and the Generalized Relativity Principle in the Fall of 1915

Since neither the correspondence nor the conservation principle imposed any further restrictions, field equations based on the Einstein tensor fully implement the generalized relativity principle.

5.19 The November Tensor and the Correspondence Principle in the Winter of 1912–1913

The November tensor, first considered in the Zurich Notebook, can be obtained from the Ricci tensor (cf. eqs. (55) and (62)) by restricting the covariance group to unimodular transformations and then splitting off a term:

$$\mathbf{RIEM} =_{\mathbf{DEFT}} \mathbf{NOVEMBER} =_{\mathbf{DEFT}} N_{\mu\nu} = \frac{\partial\Gamma^{\alpha}_{\mu\nu}}{\partial x^{\alpha}} + \Gamma^{\beta}_{\mu\alpha}\Gamma^{\alpha}_{\nu\beta}. \tag{82}$$

The exploration level of the November tensor in the winter of 1912–1913 was, in general, characterized by a limitation to the weak-field equation and the expectation that the implementation of the correspondence and conservation principles requires a coordinate restriction. The correspondence principle, in particular, can be satisfied if the Hertz restriction eq. (60) is imposed, bringing **NOVEMBER** into the form (cf. eqs. (XXXIV) and (XLIX)):

$$\mathbf{RIEM} =_{\mathbf{DEFT}} \mathbf{NOVEMBER_{RED}} = \mathbf{LAP(POT) + CORR(POT)}, \qquad \mathbf{(LXXXI)}$$

so that also the weak-field equation takes on the canonical form of eq. (33) which can be solved by the canonical metric for a static field given by eq. (25). One now also has (cf. eqs. (LXX) and (LXXVI)):

$$\mathbf{COORD_{HERTZ}(POT_{STAT}) = 0.} \qquad \mathbf{(LXXXII)}$$

5.20 The November Tensor and the Conservation Principle in the Winter of 1912–1913

The weak-field equation for the November tensor has the same form as that obtained from a field equation based on the Ricci tensor since (cf. eq. (XXVIII)):

$$\mathbf{LIM(RICCI) = LIM(NOVEMBER) = LIM(LAP).} \qquad \mathbf{(LXXXIII)}$$

It is clear therefore that the conservation principle holds, at least in the weak-field limit. It is possible to form a divergence expression such as that given by eq. (LXXI) and to satisfy the conservation compatibility check as represented by eq. (LXXII) if the Hertz restriction eq. (60) is imposed. But contrary to the case of the Ricci tensor, the coordinate restrictions required by the correspondence and the conservation principles, respectively, now coincide (cf. eq. (LX)):

$$\mathbf{LIM(ENERG) = COORD_{HERTZ} = 0.} \qquad \mathbf{(LXXXIV)}$$

5.21 The November Tensor and the Generalized Relativity Principle in the Winter of 1912–1913

The check of the generalized relativity principle was eased by the fact that the transformation behavior of the reduced November tensor (cf. eq. (XXXIV)) could be inferred from the transformation properties of the restriction distinguishing it from the original November tensor, the Hertz restriction. Indeed, if the Hertz restriction remains covariant under a given unimodular coordinate transformation so must the reduced November tensor (cf. eq. (LIX)). In the winter of 1912–1913, Einstein examined this transformation behavior for the two cases central to the heuristics governed by the equivalence principle, the case of uniform acceleration ("the elevator") and the case of rotation ("the bucket"). To simplify matters, he considered the case of infinitesimal transformations and found that, while the Hertz restriction is satisfied by infinitesimal rotations, it is not by infinitesimal transformations to a uniformly accelerated system.[95] At least as far as the exploration level of his calculations (limited to the weak-field case) allowed, Einstein could conclude that the reduced November tensor clashes with the equivalence principle, even in the case of infinitesimal transformations. He may well have found that transformations to finite rotations are incompatible with the Hertz restriction as well.

5.22 The November Tensor and the Correspondence Principle in the Fall of 1915

When Einstein returned to the November tensor in 1915, he could make use of the results he had established earlier, in particular with regard to the correspondence principle and how to satisfy that principle by imposing the Hertz restriction (cf. eq. (LXXXI)). His reexamination was, on the other hand, characterized by an increased exploration depth, which allowed him to treat this restriction as a coordinate condition in the modern sense. As we shall see, the conservation principle again leads to a coordinate restriction following from **DIV(NORM) = 0** (cf. eq. (XLIII)) which made it necessary to recheck the compatibility of this condition with the correspondence principle. As it turned out, the conservation compatibility check only gives rise to a weak scalar condition in this case, which in the weak-field limit, can easily be satisfied if the Hertz condition is fulfilled (cf. eq. (LVI)):

95 See "Commentary" (in vol. 2 of this series), sec. 5.5.3 and secs. 4.5.2–4.5.3.

$$\mathbf{LIM(ENERG(POT))} =_{\mathbf{DEFT}} \mathbf{COORD_{HERTZ} = 0 \Rightarrow}$$

$$\mathbf{LIM(DIV(NORM)) = 0.} \qquad \mathbf{(LXXXV)}$$

Under these circumstances, the Hertz condition can thus be considered as a strengthening of the restriction **DIV(NORM) = 0** following from the conservation principle. But as this sharpening turned out to be necessary only for the purpose of implementing the correspondence principle by choosing a class of coordinate systems suitable for this purpose, the Hertz condition could now indeed be interpreted, for the first time, as a *coordinate condition* in the modern sense.

5.23 The November Tensor and the Conservation Principle in the Fall of 1915

In the fall of 1915, Einstein succeeded in deriving a gravitational energy-momentum expression **FIELDMASS** for the full field equation based on the November tensor from a Lagrange formalism in which the default setting for the field is given by eq. (XXIII). He brought the field equation into a form corresponding to eq. (XXXIX), thus obtaining eqs. (64), (65), and (66), familiar from our discussion of the Ricci tensor.

What remained was the check of compatibility with the conservation principle and the question of which coordinate transformations it allowed. This question could now be addressed not just on the weak-field level—where the transformation properties of the Hertz restriction had led to a disappointing answer—but on the level of the full field equation. Einstein succeeded in expressing the conservation compatibility check in terms of an equation of the form of eq. (XLIII) which now, however, has the remarkable property that it represents not four equations but rather follows from a single scalar condition (cf. eq. (LVI)):[96]

$$\mathbf{ENERG(POT)} =_{\mathbf{DEFT}} \mathbf{DIV(SCALAR(POT)) = 0 \Rightarrow DIV(NORM) = 0,(LXXXVI)}$$

where:

$$\mathbf{SCALAR(POT)} =_{\mathbf{DEFT}} \sum_{\alpha\beta} \frac{\partial^2 g^{\alpha\beta}}{\partial x^\alpha \partial x^\beta} - \sum_{\sigma\tau\alpha\beta} g^{\sigma\tau} \Gamma^\alpha_{\sigma\beta} \Gamma^\beta_{\tau\alpha} = 0. \qquad (83)$$

This condition clearly is much less restrictive than the Hertz restriction. As mentioned above, the Hertz restriction could therefore be reinterpreted as a coordinate condition, obtained by strengthening the weak-field version of this scalar condition.

5.24 The November Tensor and the Generalized Relativity Principle in the Fall of 1915

The November tensor was obtained from the generally-covariant Ricci tensor by imposing a restriction to unimodular coordinate transformations. The conservation compatibility check (cf. eq. (83)) gave rise to a further restriction of the choice of

96 See "Untying the Knot ..." (in vol. 2 of this series), sec. 6, eqs. (75)–(78), for detailed discussion.

admissible coordinate systems, the "November restriction," as it might be called. Combining the trace of the full field equation with eq. (83), the following scalar equation results:[97]

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = -\kappa T. \tag{84}$$

This additional coordinate restriction requires, in particular, that the coordinate system cannot be chosen in such a way that $\sqrt{-g} = 1$ since this would imply the physically implausible consequence that the trace of the energy-momentum tensor vanish.[98]

Since the November restriction was much weaker than the Hertz restriction, it offered a way to overcome the latter's fatal implications for the equivalence principle. In particular, transformations of a given coordinate system to a rotating system or a system whose origin moves in any given way were now allowed so that the generalized principle of relativity is amply, but not fully satisfied. Indeed if a given coordinate system, for instance the usual representation of Minkowski space in Cartesian coordinates, satisfies this coordinate restriction, any other system resulting from the given one by a unimodular transformation must also fulfill this restriction, which is covariant under unimodular transformations.

6. CHANGING HORSES: EINSTEIN'S CHOICE OF GRAVITATION TENSORS FROM 1912–1913

The checklist for candidates for the left-hand side of the field equations that we used in the preceding section was based on the heuristic criteria that Einstein had essentially established by the end of 1912. The decision as to which candidate fares best given these heuristic criteria depends on the state of elaboration of the various mathematical and physical consequences associated with that candidate. The relative arbitrariness of elaborating the consequences of a physical theory along various conceivable pathways, which from the outset can never be overlooked in their totality, therefore entails an element of historical contingency. As the comparison between the *Entwurf* theory, maintained by Einstein essentially for three years, and his final theory of general relativity shows, this contingency may take the form of different physical theories with different empirical consequences, which, at the time, were open to debate.

---

97 See (Einstein 1915a, p.785). Cf. "Untying the Knot ..." (in vol. 2 of this series), sec. 6, eqs. (79)–(82).

98 "In writing the previous paper, I was not yet aware that the hypothesis $\sum T^{\mu}_{\mu} = 0$ is, in principle, admissible." ("Bei Niederschrift der früheren Mitteilung [Einstein 1915a] war mir die prinzipielle Zulässigkeit der Hypothese $\sum T^{\mu}_{\mu} = 0$ noch nicht zu Bewußtsein gekommen.") (Einstein 1915b, 800).

Furthermore, even if the more developed state of elaboration reached by Einstein by the fall of 1915 is taken into account, it is as we have seen in the previous section the November tensor rather than the Einstein tensor which fits Einstein's original heuristic criteria best. The November tensor had passed all tests of Einstein's checklist with only a minor adjustment of the generalized relativity principle while the Einstein tensor had failed the test of the correspondence principle as originally conceived by Einstein. This was all the worse for the Einstein tensor since the generalized relativity principle was an ambitious and idiosyncratic goal which was not shared by many of Einstein's contemporaries, while the correspondence principle had all the support of classical physics and special relativity. That it was the Einstein tensor that in the end won the race can only be understood by taking into account another aspect of the historical process, which we have so far neglected, changes in the heuristic criteria themselves as well as in their relative importance. We therefore need to take a closer look at the actual development of Einstein's thinking.

Why exactly did he turn from one candidate to the other? How did his judgement of candidates evolve? What made him come back eventually to previously discarded candidates after spending almost three years working out a more or less satisfactory relativistic theory of gravitation based on one of them? These questions are the focus of this and the next chapter dealing with what one might describe as Einstein's discovery process or better, as his "investigative pathway."[99] As we have argued, the eventual success of Einstein's research was based on applying shared knowledge resources to the problem of gravitation. The actual mechanism of these applications has so far been considered only from a single perspective, that of assimilating physical and mathematical resources to the basic model of a field equation. In the following, we shall argue that focusing on the exploitation of these resources not only allows us to understand the basic pattern of Einstein's search, the alternation between physical and mathematical strategy. It also allows us to reconstruct, to a surprising extent, the actual course of his search, if we take into account an additional cognitive process as well. While the assimilation of physical and mathematical knowledge to the Lorentz model of a gravitational field equation is basically a top-down process that is guided by the relatively stable high-level cognitive structures at the core of Einstein's heuristic criteria, a reflection on the experiences resulting from such an assimilation, including its failures, could trigger a corresponding bottom-up process of accommodating these high-level structures, including the very mental model itself, to the outcome of these experiences. These two complementary processes were mediated by the external representation of the mental model in terms of mathematical language. The combination of these processes produced conclusions that evolved with the elaboration of the formalism and with the accumulation of Einstein's experience. In order to substantiate this schematic account, we shall, in the following, review his pathways, first in the period documented by the Zurich Notebook and then—in the next chapter—in the period between 1913 and 1915. Relying heavily on the joint

99 See (Renn, Damerow and Rieger 2001; Holmes, Renn and Rheinberger 2003).

work presented in this volume,[100] we shall interpret these pathways as being governed by an interplay between assimilation and accommodation, mediated by the mathematical formalism.

6.1 The Tinkering Phase in the Zurich Notebook

The earliest notes on gravitation in the Zurich Notebook represent a stage of Einstein's search for the field equation in which he had few sophisticated mathematical tools at hand that would allow him to construct candidates fitting the framework provided by the Lorentz model. Even his knowledge of the metric tensor and its properties was still rudimentary. Only gradually did he find ways of exploiting his knowledge of vector analysis for his search. Eventually he familiarized himself with the scalar Beltrami invariants as another instrument that allowed him to investigate the few building blocks at his disposal, that is, the metric as a representation of the gravitational potential, the four-dimensional Minkowski formalism, and his theory of the static gravitational field. In spite of the lack of mathematical sophistication characterizing this early tinkering phase, not to mention the failure to produce promising candidate field equations, it is in this period that Einstein acquired essential insights shaping his research in subsequent phases of work.

These insights consisted, first of all, in a number of concrete results that later turned out to be useful, such as the identification of the core operator (cf. eq. (XXVI)), the establishment of a repertoire of techniques for dealing with coordinate transformations, results on the transformation properties of the Hertz restriction, and, most importantly, the successful implementation of the Lorentz model of an equation of motion in a generally relativistic framework (cf. eq. (XX)). The most far-reaching insights of this period were, however, of a different nature. They consisted in more general ideas resulting from a reflection on the experiences in the tinkering phase, ideas that were largely independent from the concrete mathematical material to which they were applied. Here we encounter a second function of reflection in this context, beyond that of modifying one or the other of Einstein's heuristic principles: reflection could also result in higher-level structures operating on a strategic level, that is, guiding the implementation of these heuristic principles. The most important example is certainly the idea to first impose a coordinate restriction on an object of broad covariance in order to satisfy the correspondence principle and then to explore the transformation properties of this coordinate restriction in order to check the extent to which the generalized principle of relativity is satisfied as well (cf. eq. (LIV)). Even the alternation between more physically and more mathematically motivated approaches emerged as a distinct pattern in this period, again with far-reaching implications for Einstein's subsequent research. The reflection on the experiences of this tinkering phase thus led to what one might describe as a "chunking" of Einstein's

---

100 See, in particular, "Commentary" for this section and "Untying the Knot ..." for the next section (both in vol. 2 of this series).

heuristic principles in terms of procedures that interconnected them in such a way as to ease their implementation as a whole.[101] Such procedures could involve the subsequent translation of these principles into well-defined mathematical requirements on a gravitational field theory (e.g., the choice of a generally-covariant candidate, followed by the stipulation of a coordinate restriction) or they could consist in alternating between physical and mathematical default settings.

6.2 Assimilating Knowledge about the Static Gravitational Field to a Metric Formalism (39L–39R)

When Einstein began systematically to explore a metric theory of gravitation, he was confronted with the problem that the knowledge resources available to him for constructing such a theory presented themselves as more or less isolated building blocks that could not easily be fitted together. On the page of the Zurich Notebook which documents the point of departure of his exploration (p. 39L), he therefore started his investigation simply by listing three such building blocks, the line element in terms of the metric tensor representing the gravitational potential, the four-dimensional Minkowski formalism, and his theory of the static gravitational field. How could they be brought into relation to each other?

The principal challenge was to assimilate the knowledge about the special case of a scalar, static gravitational potential to a tensorial formalism. If such an assimilation were successful, the mental model of a field equation for a tensorial gravitational potential would acquire a physically meaningful instantiation. Einstein's first consideration of the problem of gravitation that is recorded in the Zurich Notebook is precisely such an attempt to assimilate the static case to a metric formalism, concentrating on two of the slots of the Lorentz model for a field equation, that for the differential operator and that for the gravitational potential. For reasons that we have discussed earlier, the default setting for the latter slot was given by the canonical metric for a static field (cf. eq. (25)). Brought into proper mathematical form, Einstein's scalar field equation for the static gravitational field could therefore be conceived as a second-order partial differential equation for the one variable component of this special metric tensor, expressed in a special coordinate frame in which the metric takes on its canonical form. Exploiting mathematical knowledge about the behavior of a tensorial field equation under coordinate transformations, one should then be able to generalize this equation for one component to a field equation for the full metric tensor.

By transforming the equation for the static field into a more general coordinate system, Einstein made an observation that suggested a new pathway to him. He found that, under linear coordinate transformations, the metric tensor behaves exactly the same way as the second-order partial derivatives of a scalar function. This observation opened up a new possibility for drawing on hitherto unexploited mathematical

101 For the concept of "chunking" in cognitive science, see (Minski 1987).

resources and thus for identifying a suitable differential operator acting on the metric tensor.

6.3 Assimilating Knowledge about Scalar Differential Invariants to a Metric Formalism (40L–41L)

Einstein's key problem was that the default settings for two of the slots of the mental model for a gravitational field equation, suggested by his earlier experiences with implementations of this model, could not be matched to each other (see Fig. 3, p. 173). While the default setting for the gravitational potential was represented by the canonical metric, the default setting for the differential operator was, at this point, an object like the Laplace operator, applicable only to scalar functions and covariant only under linear transformations. Was there a way of bridging this gap between a scalar differential operator and a tensorial potential? Einstein's insight into the analogy between the transformational properties of the metric tensor and those of the second-order partial derivatives of a scalar function offered such a bridge, allowing him to bring to bear on this problem mathematical knowledge about scalar differential operators. It suggested the possibility of building some higher-order differential operator acting on a scalar function, which could then be translated into a differential operator acting on the metric tensor. All that was needed for such a translation was the replacement of a second-order partial derivative term by the corresponding components of the metric tensor; the remaining partial derivatives could then be considered as a differential operator acting on the metric.

What could be gained by such a roundabout procedure? If the scalar differential operators involved are just linearly covariant, like the Laplace operator, relatively little. If, however, scalar differential invariants are taken as the building blocks of such a construction, it could lead to the formulation of a generally-covariant differential operator for the metric tensor. There is some indication in the Zurich Notebook that this may have been Einstein's hope. In any case, he systematically checked whether various higher-order scalar differential operators would yield, after translation, a suitable candidate for the left-hand side of the gravitational field equations. But apparently he was unable to single out a candidate promising to fulfill his other heuristic criteria as well, and did not pursue this investigation for the time being. As is clear from later pages of the notebook, however, Einstein did not consider the potential of scalar differential invariants for his project to be exhausted. The purpose of a somewhat obscure calculation on the immediately following pages (pp. 40R-41L), dealing with linear transformations of an algebraic quadratic form, might well have been to learn more about such invariants and their properties.

6.4 Implementing the Lorentz Model of the Equation of Motion (05R)

At some later point, Einstein made a new beginning in his research on a theory of gravitation. He now turned to the other element of the field-theoretical model, the equation of motion. He probably had realized by this time that the equation of motion for a point particle in a gravitational field corresponds to the equation for a geodesic curve in a four-dimensional curved spacetime (cf. eq. (23)).[102] But he probably also had realized that an equation of motion in this sense was not quite the match of the gravitational field equation for which he was looking. The default-setting for the source-slot of the Lorentz model for the field equation was not a point particle but the energy-momentum tensor (cf. eq. (XIV)). The mental model of a field equation together with special relativistic continuum theory now suggested what such an equation should look like in terms of the energy-momentum tensor (cf. eq. (XX)).[103] Such an equation would provide, at the same time, an expression for energy-momentum balance in the presence of a gravitational field.

When Einstein studied the equation of motion problem, he was confronted with the challenge of how to link his general expectations concerning the structure of such an equation with his concrete knowledge about the motion of point particles in a gravitational field. To bridge this gap he made use, as we have discussed before, of a particular model of matter, which allowed him to link point mechanics and continuum mechanics, i.e. the model of "dust" (cf. eq. (XXI)). At a mathematical level, the bridge was built with the help of the Lagrangian formalism (cf. eq. (19)). The dust model allowed Einstein to generalize the equation of motion derived within the Lagrange formalism into a relation between components of the energy-momentum tensor. This relation suggested, in turn, what the full tensorial equation of motion in gravitational field should look like, if it was supplemented by both mathematical and physical default-assumptions provided by the corresponding special relativistic equation.[104] As discussed above, eq. (XX) expresses the energy-momentum balance in a gravitational field, i.e. the generalization of the special relativistic relation between force, energy, and momentum (cf. eq. (XVIII)). Einstein also realized that, from a mathematical point of view, it corresponds to the covariant divergence of the energy-momentum tensor (cf. eq. (XXIV)). This remarkable convergence of physical and mathematical perspectives must have confirmed the expectation that his result also applies to other kinds of sources and turned Einstein's equation into the default-setting for the equation of motion in the Lorentz model and for the energy-momentum balance in a gravitational field.

---

102 He reproduced the proof that the trajectory of a force-free motion constrained to a two-dimensional surface is a geodesic on a page of the notebook immediately following the consideration of quadratic invariants mentioned in the previous subsection (see p. 41R).

103 Einstein emphasized the central role of the energy-momentum tensors and the importance of special-relativistic continuum mechanics in an article he wrote in 1912 but never published, see (CPAE 4, Doc. 1, 63).

104 See the discussion in (Norton 2000, Appendix C).

6.5 A Mathematical Toy Model as a New Starting Point (6L–7L)

The mismatch between the instantiations for two of the slots of the mental model of a field equation, that for the differential operator and that for the gravitational potential, left Einstein with two principal options as to how to proceed. He could continue trying to build an appropriate differential operator applicable to the metric tensor or he could tentatively explore substitutions of the default-setting for the gravitational potential, thus creating "toy-models" in the sense of obviously unrealistic instantiations of the model. Even if that meant temporarily suspending the insight that the gravitational potential is represented by the metric tensor, it might still be possible to gain knowledge from exploring such toy-models that could be helpful in constructing a more realistic candidate field equation.

When Einstein became familiar with the generally-covariant Beltrami invariants as a generalization of scalar differential operators, they must have appealed to him as a promising starting point for his search for a relativistic gravitational field equation. A field equation based on those invariants would automatically satisfy the heuristic requirement of the generalized principle of relativity. A first attempt to construct a differential operator for the metric out of operators acting on a scalar function had, as we have seen, turned out to be too speculative. It was hence worth trying to explore a generalization of the scalar Poisson equation in a generally-covariant setting by using—instead of the Laplace operator—the second Beltrami invariant applied to a scalar function. While such a generally-covariant scalar field equation was only a toy model, it confronted Einstein with a serious problem, viz. that of reconciling a mathematically satisfactory candidate with the physical knowledge of his theory of static gravitational fields, (see Fig. 3, p. 173). In a sense, a scalar field equation formulated in terms of the second Beltrami invariant represents the counterpart of the scalar field equation of Einstein's static theory: while the latter constitutes an initial, physically plausible instantiation for the field-theoretical model, the former represents an equally plausible initial instantiation rooted in mathematical knowledge. In both cases, the resulting field equations were merely starting points for further investigations that had to make contact with knowledge not yet embodied in these first default-settings.

It therefore comes as no surprise that Einstein tried to find out under which conditions a generally-covariant scalar field equation formulated in terms of the second Beltrami invariant reduces to the ordinary Poisson equation. Such a reduction must be possible if the candidate (or rather toy) field equation is to comply with the correspondence principle. It turned out that the implementation of this heuristic principle in this concrete case requires an additional constraint on the choice of the coordinates, supplementing the field equation. Essentially by inspection, Einstein could identify the harmonic coordinate restriction (cf. eq. (57)) as a condition that would make sure that the Beltrami field equation reduces to the ordinary Poisson equation for weak gravitational fields. In other words, the exploration of a toy field equation taught Einstein that a candidate field equation obtained from a mathematical default-setting may require an additional coordinate restriction to be viable from a physical point of view as well; it also familiarized him with a specific example of such restriction, which later turned out to be useful when studying the Ricci tensor.

How could the toy field equation be turned into a real candidate field equation? If the Beltrami field equation is considered as a mathematically reasonable structure to which physical knowledge should now be assimilated, such as the insight that the gravitational potential is actually represented by the metric tensor, it made sense to try to bring this knowledge into an appropriate mathematical form. If unimodular coordinate transformations are assumed, the determinant of the metric transforms as a scalar and can be used to fill the potential-slot of a scalar field equation. The next question was whether the resulting field equation, for the special case of a static field, could be related to the familiar static field equation. Einstein tried to extend this approach by taking into account different versions of a Beltrami-type field equation but failed to integrate the mathematical and the physical knowledge in this way.

6.6 A Physical Toy Model as a New Starting Point (7L–8R)

Einstein's first exploration of the Beltrami invariant had not answered the question as to how to get from a mathematically plausible scalar differential equation to a tensorial field equation that is both mathematically and physically plausible. Reflecting on this gap, Einstein may well have considered the possibility of dividing this transition into two steps. The first would be to construct a tensorial field equation that, even if its mathematical properties were unclear at the outset, made good sense physically. The second step would take him, relying on mathematical tools, from such a physically-plausible toy field equation to the final equation.

In any case, instead of taking a simplified instantiation for the potential-slot of Lorentz model for a field equation to explore a mathematical toy model, Einstein now chose a simplified instantiation for the differential operator slot, while keeping the realistic setting for the potential slot, i.e. the metric tensor. His experience with vector calculus and its use in physics allowed him to write down a straightforward translation of the ordinary Laplacian operator into a differential operator acting on the metric tensor, the core operator. Einstein's experience with the Beltrami invariants must have made it clear that the core operator could hardly represent a generally-covariant object. From the way in which it was constructed, however, it was equally clear that a field equation based on the core operator satisfies the correspondence principle. For this reason, the core operator (cf. eq. (XXVI)) became the default-setting for all of Einstein's subsequent attempts to implement this principle.

This candidate now had to be checked against the other heuristic requirements and, in particular, its behavior under coordinate transformations needed to be explored. This could be done in two distinct ways: either by directly checking the transformational behavior of the core operator, or by considering it—in the sense indicated above—an intermediate step towards the final field equation. Einstein began with the first option. To get beyond linear transformations, however, he used a special kind of coordinate transformations, which explicitly depend on the metric tensor, and which he later called "non-autonomous transformations".[105] The behavior of the core operator under such transformations is determined by differential equations for the transformation matrices involving the metric tensor and its derivatives. Einstein succeeded in writing down, at least for infinitesimal transformations, the essential term in such a differential equation. But probably in view of the complexity that this condition would take on for finite transformations and, more generally, in view of the unfamiliar character of these non-autonomous transformations, he abandoned this approach and turned instead to the more familiar territory of ordinary coordinate transformations.

In that case the only way to go beyond linear transformations was to generalize the core operator. Einstein developed an ingenious method for doing so. First of all, he considered the two differential operators constituting the core operator separately, the divergence and the gradient (or exterior derivative, cf. eq. (XXV)). He then took the familiar form of these operators applied to some second-rank tensor in Minkowski spacetime with (pseudo-)Cartesian coordinates as his starting point. Einstein now made the assumption that these operators actually transform as tensors under arbitrary coordinate transformations. Under this assumption, a coordinate transformation carrying these operators from their special form in Cartesian coordinates to arbitrary coordinates should reveal their generic form. The idea was similar to that of obtaining a generalization of the line element of Minkowski spacetime to that of a generic curved spacetime by passing from pseudo-Cartesian to arbitrary coordinates in Minkowski spacetime. In both cases one simply had to assume that an equation obtained for the Minkowski metric in arbitrary coordinates is actually valid for the metric of a generic spacetime. Although Einstein did not see his calculations through to the end, he essentially succeeded in finding covariant generalizations of the constituents of the core operator. Eventually he must have realized, however, that this success amounted to no more than a Pyrrhic victory since these generally-covariant differential operators give zero when applied to the metric tensor. In other words, a generalized core operator built from these covariant differential operators is not suitable as a candidate for the left-hand side of the gravitational field equation. Eventually, this failure forced Einstein to take the peculiar non-autonomous coordinate transformations of his first approach much more seriously than he had probably intended when he first encountered them.

6.7 Identifying the Core Operator as the Target of the Mathematical Strategy (8R–9R)

In his next attempt Einstein, reflecting on his earlier failures and insights, combined his prior experiences to develop a procedure for constructing candidate field equations that he would repeatedly use in the notebook (cf. eq. (XLVIII)). The genesis of

---

105 See Einstein to H. A. Lorentz, 14 August 1913, (CPAE 5, Doc. 467). For discussion, see "Commentary ..." (in vol. 2 of this series), sec. 4.3.

this procedure as the result of an oscillation between a more mathematically and a more physically motivated attempt illustrates Einstein's learning experience in the course of his search, which therefore cannot be seen simply as the successive elimination of unsatisfactory alternative candidates.

The attempt to conceive of the physically plausible core operator as the representation of a more general covariant object in specific coordinates had failed because of the degeneracy of the corresponding differential operations when applied to the metric. It made therefore sense to return to the earlier direct exploration of the transformation properties of the core operator. This pathway had not definitively failed yet but turned out to be too rough. Considered from a higher level of reflection, the core operator could not just serve as a physically plausible starting point but also as the possible target of a strategy starting from a mathematically well-defined object. At this point, the only such mathematically well-defined objects that Einstein had at his disposal were the Beltrami invariants. It therefore was natural to deal with them once again, but now not with the theory of the static gravitational field but with the core operator as the more promising physically meaningful target. This approach came with a new challenge, the task to extract a tensorial object, the core operator, from a scalar invariant. This challenge turned out to be manageable.

In short, the idea was to once more start from a mathematically motivated instantiation, the second Beltrami invariant, trying to exploit its familiar mathematical properties in order to determine the transformational behavior of the physically plausible core operator. The necessary bridges between tensorial and scalar objects were readily at hand. From his earlier experience, Einstein knew that he could use the determinant of the metric tensor in the second Beltrami invariant if he considered only unimodular transformations. Now he realized that he could, in turn, try to extract a tensor from a scalar by conceiving the latter as a contraction between two tensors, in this case of the metric tensor and the core operator.

The concrete implementation of this approach confronted Einstein with a number of problems, minor and major. There was, first of all, the need for a restriction to unimodular coordinate transformations. More importantly, when trying to extract the core operator from the second Beltrami invariant applied to the determinant of the metric tensor, he encountered an additional first-order term that required further consideration. Einstein's understanding of the conservation principle, and in particular his experience with his second theory of the static gravitational field, must have immediately suggested to him that this first-order term might be related to an expression for gravitational energy-momentum (cf. eq. (XXXIV)).

In the end, however, Einstein did not succeed in establishing a convincing bridge between core operator and Beltrami invariants. As a consequence, he failed to clarify the transformational properties of the core operator or of a suitably amended candidate gravitation tensor constructed from it. At this point, he took up once more the direct exploration of the transformational properties of the core operator earlier abandoned because of the intricacy of the non-autonomous transformations involved in it. This resort to an earlier approach was, however, no return to square one. Einstein could benefit from the insights he had made in the meantime, in particular from the breaking down of the original problem into simpler ones that the introduction of the Beltrami invariants had made possible. The new first-order term posed a problem analogous to the one Einstein had first encountered when comparing a mathematical toy model based on the second Beltrami invariant with the ordinary Laplace operator and thus suggested the remedy of introducing a coordinate restriction as an additional hypothesis under which a mathematically acceptable expression reduces to a physically plausible one. One could limit then the direct exploration of transformational properties to the remainder term distinguishing the second Beltrami invariant from the contraction of the core operator with the metric tensor. This task was simpler than the original one given the structure of the remainder term. If the class of non-autonomous transformations leaving this term invariant could be determined, one would thereby have found the class of transformations leaving the principal term, i.e., the contraction of the core operator with the metric, invariant as well (cf. eq. (LI)). In this way, a bridge would have been built between the transformational behavior of the mathematically well-defined second Beltrami invariant and that of the physically plausible core operator. In spite of this simplification with respect to Einstein's original attempt to determine the transformational behavior of the core operator, even this reduced task still turned out to be too cumbersome to carry out.

Although this entire episode was fraught with frustrations of reasonable hope, it gave Einstein strategic insights well beyond the concrete mathematical material at hand. There was, first of all, the recognition of the canonical form for the left-hand side of a gravitational field equation, which would have to consist of a core operator plus first-order correction terms somehow related to gravitational energy-momentum (cf. eq. (XXXIV)). Second, the experiences of this episode brought the mathematical strategy into a form that was to dominate much of the subsequent work documented in the notebook. The general idea now was to start from an object with well-defined mathematical properties, in particular with a broad enough covariance group to meet the demands of the generalized principle of relativity (cf. eq. (XLVI)). The next step was to extract from it a candidate gravitation tensor with well-defined physical behavior, more specifically the core operator possibly with correction terms not invalidating the correspondence principle (cf. eq. (XLVIII)). The extent to which the generalized principle of relativity was actually fulfilled could be determined by checking the transformational behavior of the term distinguishing the candidate gravitation tensor from the mathematical starting point (cf. eq. (LI)). This term could be eliminated by imposing the appropriate coordinate restriction (cf. eqs. (L), (LII)). It is remarkable that this strategy, crucial to Einstein's exploration of the Riemann tensor, was in place before he had even seen a single realistic candidate gravitation tensor.

6.8 Subjecting the Core Operator to a Piecemeal Approach (10L–12R, 41L–R)

While in the last episode Einstein had developed an overall strategy for solving his problem and failed, he now took a more piecemeal approach. He focused on a mathematically much simpler object to avoid the complexity of the non-autonomous transformations he had considered so far. On the whole, this phase of his work was characterized by the attempt to break down his main problem, the identification of appropriate field equations, into smaller, more manageable pieces in the hope of identifying reliable building blocks that could then be used to put the puzzle together.

This line of pursuit was largely shaped by the options and constraints that had emerged in the course of Einstein's preceding experience. In particular, while he had just established a paradigm for what was to become his mathematical strategy, for the time being this strategy was powerless for want of mathematical objects other than the Beltrami invariants that could serve as input. The core operator, on the other hand, inspired confidence as a solid achievement that would be a physically meaningful starting point were it not for the difficulties of determining its transformation properties. Yet in view of the absence of other mathematical resources, the use of non-autonomous transformations may have seemed unavoidable. And if hope was to remain of connecting possible results to the Beltrami invariants, the only advanced mathematical objects at Einstein's disposal, the transformations should be unimodular as well.

It is against this backdrop that the emergence of the main idea guiding Einstein's work in this episode becomes understandable. This work may have sprung from the idea to consider simpler mathematical objects that would make a direct approach to the examination of their transformation properties feasible. In any case, at some point it must have become clear to Einstein that the full problem, the determination of the transformation properties of the core operator, could actually be broken down into the study of such simpler objects, if possible vectors or even scalars (cf. eq. (XXV)). The preceding experience with the attempt to extract the core operator from the scalar Beltrami invariant may have triggered this idea. It therefore made sense to carefully check the covariance of these simpler objects in particular under the transformations relevant to the implementation of the elevator and the bucket models, i.e. transformations in Minkowski spacetime to uniformly accelerated or to rotating systems.

The realization of the idea just described brought Einstein to study the transformation properties of the Hertz restriction (cf. eq. (60)). If this restriction was imposed, the core operator reduces to a simpler object whose transformation properties can then be determined separately. But in spite of the greater simplicity of these objects, it turned out to be necessary to introduce a further simplification and to limit the analysis to infinitesimal transformations. With these presuppositions in place, Einstein was able to obtain some specific results even if these were not all that encouraging. In particular, when attempting to implement the elevator model and satisfy the equivalence principle, he found that compatibility with the covariance properties of the Hertz restriction required a modification of the transformation to a uniformly accelerated system, which turned out to be unacceptable for physical reasons. In short, Einstein found it difficult to establish a match between the transformational properties of the objects under study and his physical expectations. How much of the room opened up by his main idea, that of splitting the core operator into two simpler pieces, did he actually investigate in the course of his calculations? It is clear from his notes that he was aware of variants of this operator and hence of alternative splits (involving e.g. the harmonic restriction instead of the Hertz restriction), but he left this option unexplored.

In the end, Einstein once again assembled a number of isolated results that later became useful. In addition, he gained strategic insights governing the subsequent course of his research. As far as his specific results are concerned, he established, for instance, that the Hertz restriction is covariant under infinitesimal non-autonomous transformations to a rotating system in Minkowski spacetime but, as mentioned above, not under a transformation to a uniformly accelerated system. He also found that the core operator is covariant under antisymmetric non-autonomous transformations in Minkowski spacetime, without however being able to associate physical meaning with this result. In the course of his work, he gradually shifted the emphasis of his quest from the transformation properties of the constituents of the core operator to a careful reexamination of the physically relevant transformations themselves. He thereby again accumulated some useful findings such as the derivation of the metric for Minkowski spacetime in rotating coordinates from the Lagrangian formalism. Eventually he made a fresh start, taking unimodular transformations as a starting point for implementing the generalized principle of relativity. He once more tried to match them with transformations to a uniformly accelerating system, again without success. He then abandoned this attempt to incorporate the equivalence principle, alongside with his entire endeavor to deal with the covariance properties of the core operator on the basis of his piecemeal strategy. What remained, apart from specific achievements, was the experience that non-autonomous transformations could be handled after all, at least when applied to sufficiently simple objects. But this was an insight that Einstein would be able to put to good use only much later, when he explored the transformation properties of the finished *Entwurf* theory, in particular in its Lagrangian formulation (cf. eqs. (LXIII), (LXIV)). Of more immediate impact was his realization, fostered by the disappointments produced even by his piecemeal strategy, that it might be prudent to put the pursuit of an audacious interpretation of the generalized principle of relativity on hold, turning instead to the physical requirements embodied in the conservation principle.

6.9 Using the Core Operator as the Starting Point for the Physical Strategy (13L–13R)

Einstein's next move was to look at his problem from a different angle, bracketing the intricate problems raised by the generalized principle of relativity and making sure that what he had achieved so far was at least sound in other respects. And even after the disappointing yield of his piecemeal approach, the identification of the core operator as a candidate compatible with the correspondence principle remained such a sound result. Einstein now tried to address the seemingly intractable aspects of the exploration of the core operator by reducing the ambitious goals imposed by the generalized principle of relativity. For this purpose, he set up a more manageable framework for dealing with the other central, but as yet unexamined aspect of the validity of the core operator as a candidate gravitation tensor, its compatibility with the conservation principle.

His previous research had already suggested that perhaps the core operator needed to be supplemented by additional first-order terms representing the energy-momentum of the gravitational field in the gravitational field equation. But at that point the problem of energy-momentum conservation had occurred only as a marginal aspect of the relativity problem at the center of Einstein's attention. The impasse of his work on this problem provided a natural occasion to return to the issue.

Einstein created a manageable framework by restricting all considerations to unimodular, linear transformations. The requirement of linearity would secure the tensorial character of the core operator, while the requirement of unimodularity kept the door open for establishing contact with the Beltrami invariants later. By setting up a systematic framework for generating vectors and tensors involving the metric Einstein could hope, first of all, to reduce the ambiguities of his approach and second, to gain solid ground for examining the relation between core operator and conservation principle without the interference of the relativity problem. Such an examination might, in particular, help to find the correction terms that he had earlier tried to obtain from the first Beltrami invariant.

Einstein constructed a framework for generating tensorial objects involving the metric with well-defined transformation properties, beginning with the Hertz expression (cf. eq. (60)). He set up a survey of the first-order objects and then stopped, either because these were the objects in which he was mainly interested with a view to the correction terms needed for the core operator or because even this limited overview dashed any hopes he might have had for a reduction of the space of possible candidates. Whatever the case may be, it was at this point that he once more took up the core operator directly, checking its compatibility with energy-momentum conservation. As it turned out, his network of results had become dense enough to allow for such a check which, even if it failed, would probably still provide hints about what was still needed to enforce compatibility. Einstein combined the left-hand side of a field equation based on the core operator with the expression for the energy-momentum balance he had established earlier (cf. eq. (XXX)). He thus produced an expression corresponding to (cf. eq. (XXXII)):

GRAD(POT) X LAP – DIV(LAP) **(LXXXVII)**

which *a priori* could be expected to be of third differential order. But if one now assumes that a field equation of the form (cf. eq. (XXXIX)):

LAP = ENEMO + FIELDMASS **(LXXXVIII)**

holds, then compatibility with the conservation principle requires that the above expression reduces to the second-order expression (cf. eqs. (XXXI), (XXIV)):

GRAD(POT) x FIELDMASS – DIV(FIELDMASS) **(LXXXIX)**

with an appropriate explicit form of **FIELDMASS**. Einstein found indeed that imposing the Hertz condition implies that no third-order terms appear. But, unfortunately, he failed to arrange the terms in the resulting expression in a way that would have allowed him the extraction of an explicit form of **FIELDMASS**.

In summary, Einstein succeeded neither in identifying the conditions under which the core operator is compatible with the conservation principle nor in finding the correction terms that could possibly help establishing such compatibility. Even for such a simple object as the core operator the differential equation resulting from his compatibility check appeared to be too complicated. His calculations and the reflections stimulated by them had nonetheless laid the groundwork for the global approach we have called his "physical strategy," all elements of which were now assembled. The core operator provided him with the starting point for this approach and the calculations just considered constituted the conservation compatibility check for this candidate (cf. eq. (XXXI)). The restriction to linear transformations made it possible to postpone a check of the extent to which the generalized relativity principle was satisfied. What was still lacking was a procedure for guessing or generating suitable correction terms to be added to the core operator to turn it into a viable candidate. Einstein had arrived at a dead end, but not with empty hands. Not only had he accumulated a reservoir of insights and tools that would be useful for his further search, but he had developed two overall strategies, each capable of guiding this search. For the time being, however, both strategies were doomed to be abeyant as long as certain elements that could trigger their application were missing. But as soon as an appropriate incentive was provided, either of them could be activated. For the physical strategy to become productive, all that was needed was a way to generate plausible correction terms to the core operator. For the mathematical strategy to become productive, all that was required were tensors with second-order derivatives of the metric and a well-defined transformational behavior. As it turned out, the latter option was realized first.

6.10 The Systematic Search Phase in the Zurich Notebook

The raw material needed to set the mathematical strategy in motion was evidently delivered by Marcel Grossmann whose name appears next to the first occurrence of the Riemann tensor in the notebook. With this entry, the first phase of Einstein's research was over and a phase of systematic searching for suitable gravitational field equations began. The Riemann tensor represented something like a raw diamond for Einstein to which he could now apply the various extraction schemes that he had elaborated earlier as well additional stratagems he developed in the course of his search. Among these schemes was the contraction of the fourth-rank Riemann tensor to yield a second-rank candidate gravitation tensor, the extraction of such a candidate from a scalar object, the stipulation of coordinate restrictions, and the possibility of modifying candidate field equations by adding or subtracting terms. The products to which these extraction processes gave rise had an impact on Einstein's search procedure going well beyond their immediate evaluation as being either refinements or debris, as is particularly evident from the identification and subsequent rejection of the Einstein tensor.

Einstein's procedure was guided throughout by the Lorentz model, which suggested that candidates for the left-hand side of the field equations have the form of a core operator plus correction terms (cf. eq. (XXXIV)). His prior experience with extracting such candidates from the second Beltrami invariant furthermore gave him guidance on how to handle those terms not fitting his expectations, i.e., how to eliminate them with the help of a coordinate restriction. Since he started from objects with well-defined transformation properties, the main heuristic criteria to be checked were the correspondence and conservation principles. From the point of view of the mathematical strategy, both criteria posed similar challenges and thus seemed to call for similar responses, viz. coordinate restrictions to be imposed in addition to the field equations. This parallel strengthened Einstein's expectation that the stipulation of these heuristic principles required a restriction of the covariance of the object used as the starting point of the mathematical strategy. On the weak-field level, the two restrictions, one resulting from the correspondence, the other from the conservation principle could easily be compared with each other; their compatibility or rather the lack thereof was an important driving force in the search for field equations (cf. eq. (LX)).

The severe restriction on the generalized relativity principle that seemed to be the almost unavoidable consequence of Einstein's procedure made it all the more urgent to check whether or not at least the most essential requirements associated with this principle were satisfied and, in particular, whether the important special case of rotation was included. Not surprisingly, Einstein more than once reexamined this special case during his search.

The difficulties Einstein encountered in the course of his attempts to enforce his heuristic criteria within the formalism he was weaving around the Riemann tensor naturally provoked a reflection on the validity, the physical meaning, and the mathematical implementation of these criteria. After all, they may just have been prejudiced. Does the conservation principle really require the covariant divergence of the stress-energy tensor to vanish (cf. eq. (XXIV))? Does the correspondence principle really demand a static gravitational field to be represented by a spatially flat metric (cf. eq. (25))? Can the generalized relativity principle perhaps be satisfied for rotation by metric tensors other than the one obtained from a coordinate transformation of the standard Minkowski metric? Such questioning of his original heuristic criteria and the default settings suggested by them would eventually pave the way for the breakthrough of 1915. But in the winter of 1912–1913, the answers that Einstein found to these questions confirmed his original conceptions and solidified them by extending the network of inferences in which they were embedded. Ironically, it was precisely the lack of a candidate field equation complying with his heuristic criteria and worthy of further elaboration that also prevented, for the time being, the construction of an even wider network of inferences that would allow these criteria to be overcome.

While Einstein's search would eventually turn up just such a candidate, the *Entwurf* field equation, this candidate was no longer the result of an extraction from the Riemann tensor.

What was overturned in the course of the research documented by the notebook was not Einstein's reliance on his heuristic criteria but the way in which he tried to meet them following his mathematical strategy. Even when he managed to find a candidate for which the coordinate restrictions implied by the correspondence and conservation principles, respectively, could be matched, at least on the weak-field level, the ensuing restriction of the generalized relativity principle and the question of how to satisfy the conservation principle for the full equation made the entire attempt look futile. The appeal of the generalized principle of relativity thus gradually faded away, and the conservation principle gradually emerged as the major stumbling block of the mathematical strategy and, at the same time, as the key stone for a new approach corresponding to a successful implementation of the physical strategy.

Einstein's checks of the conservation principle in the context of the mathematical strategy were limited to weak-field equations. Accordingly, all of his results concerning candidate gravitation tensors—positive as well as negative—were provisional only. For the time being, the limited exploration level of the conservation principle could not be overcome in the context of the mathematical strategy. First, Einstein had no systematic mathematical technique at his disposal for implementing this principle beyond the weak-field level. He would acquire such a technique only much later when developing a variational formalism for the *Entwurf* theory in 1914. Second, the ad-hoc strategies he used to implement the conservation principle beyond the weak-field level necessitated substantial modifications of the candidate field equations serving as the starting point of the mathematical strategy, modifications that made the transformation properties of the proposed field equations intractable despite their origin in the generally-covariant Riemann tensor.

Einstein's experiences with extracting candidate gravitation tensors from the Riemann tensor thus displayed a remarkable parallelism to his prior experiences with the Beltrami invariants. In both cases, the advantages gained by starting from an invariant or generally-covariant object had to be gradually given up in favor of satisfying the other heuristic requirements rooted in the knowledge of classical physics until finally nothing was left of the covariance properties that recommended these objects in the first place. But it was not only this twofold experience of failure that ultimately triggered a switch from the mathematical to the physical strategy. It was precisely the main weakness of Einstein's attempts to come to terms with the conservation principle, i.e., the limitation to the weak-field level, that indicated a way out of the impasse. If the implementation of the conservation principle at the weak-field level could not be the final word, it made sense to take energy-momentum conservation for the weak-field equations as a starting point for identifying those additional terms that were needed to turn the core operator into a viable candidate complying with this heuristic requirement, irrespective of the generalized principle of relativity. Einstein thus found a way of solving the problem that had blocked the pursuit of the physical strategy before, viz. the lack of a procedure for generating plausible correction terms to the core operator. His difficulties with the mathematical strategy suggested a procedure, whose first elements were found before they turned into a systematic mechanism. Once more the essential pattern governing the next step of Einstein's research, the derivation of the *Entwurf* field equations, had been prepared by reflecting on the blocked pathways encountered in the previous episode.

The failure of Einstein's pursuit of the mathematical strategy in the Zurich Notebook resulted in the derivation of the *Entwurf* field equations along the physical strategy. The establishment of these field equations, compatible with both the correspondence and the conservation principles, ended, for the time being, his systematic search for gravitational field equations. What remained from his efforts in the winter of 1912–1913, however, was more than yet another and, as it eventually turned out, unsatisfactory candidate that would eventually be discarded. There was the November tensor, which did not immediately fall victim to any knock-out argument derived from Einstein's heuristic checklist, and which was dropped, not in favor of a better candidate, but in favor of a seemingly better strategy. There were the Ricci tensor and the linearized Einstein tensor, which had been explored only at the weak-field level. From this perspective, their later revival is not surprising. But apart from candidates that he would consider again in late 1915, Einstein's search for field equations in the winter of 1912–1913 also left its mark at the strategic level, both in his subsequent attempts to consolidate the *Entwurf* theory and in his renewed search for field equations at the end of 1915. In fact, even when he focused exclusively on the *Entwurf* theory, he never abandoned the expectation, grounded in the experience documented by the Zurich Notebook, that it should be possible to arrive at the same field equations using either the physical or the mathematical strategy. It was this persistence, perhaps more than the potential of any not yet fully explored candidate, that prevented Einstein from ceasing his quest before he had reached his goal of a generally-relativistic theory of gravitation in late 1915.

6.11 Fitting the Riemann Tensor to the Lorentz Model (14L–18R)

When Marcel Grossmann introduced Einstein to the Riemann tensor, this new mathematical resource fell on ground that was well-prepared by Einstein's previous investigations. The expectations with which he approached the new object, however, sent him in a direction very different to where our modern expectations would take us, viz. the derivation of the Einstein field equation from the Riemann tensor. For Einstein, the Lorentz model essentially prescribed the steps to take to evaluate the new candidate. His prior attempts to implement this model had led him, in particular, to expect a field equation with a left-hand side of the form (XXXIV), i.e., a left-hand side of the form 'core operator plus correction terms,' which is incompatible with what we now take to be the correct field equations.

The central role of the Riemann tensor within the absolute differential calculus as the wellspring of all other "differential tensors" and "differential invariants"—a role of which Grossmann was certainly aware (Einstein and Grossmann 1913, 35)—and its unexplored status in Einstein's investigations must initially have nourished high hopes for the project of extracting from it a suitable left-hand side of the field equations. Einstein may even have expected that the direct pathway from the Riemann tensor to an object fitting the Lorentz model would produce the desired result, without any of the moves and tricks that had been necessary in the earlier attempts based on more pedestrian mathematics. If needed, however, by now such auxiliary schemes were available to Einstein should difficulties arise. In any case, the fourth-rank Riemann tensor had to be turned into a second-rank tensor that could serve as the left-hand side of gravitational field equations whose right-hand side was the second-rank stress-energy tensor (cf. eq. (XIV)). This was a straightforward mathematical operation, which Einstein carried out as soon as he had been handed the Riemann tensor. Unfortunately, the result of this operation, the second-rank Ricci tensor (cf. eq. (55)) did not fit to instantiate the open operator slot of the Lorentz model for the field equation but contained additional, unwanted second-order terms invalidating the correspondence principle (cf. eq. (56)). Einstein's first attempt to assimilate the Riemann tensor to his mental model thus resulted in the condition that these disturbing terms would have to vanish. The appearance of such an additional condition is reminiscent of similar hindrances he had encountered exploring the Beltrami invariants.

Now that the direct approach had failed, Einstein was forced to exploit the tricks and tools he had assembled before. The most obvious way to connect his new predicament with his earlier experiences was the construction of a scalar object from the Riemann tensor, the Ricci curvature scalar. This scalar object could be subjected to exactly the same procedure as the scalar Beltrami invariant. Einstein thus attempted to extract a tensorial object from it in analogy to his earlier treatment of the second Beltrami invariant, i.e., by conceiving the scalar as the contraction of this new, contravariant tensorial object and the covariant metric tensor. Also in analogy with his earlier work on the Beltrami invariants, he set the determinant of the metric equal to unity to simplify his calculations, thereby imposing a restriction to unimodular coordinate transformations.

The hope was that the new second-rank tensor extracted in this way from the curvature scalar would represent a suitable candidate for the left-hand side of the field equations, meeting the requirements of the Lorentz model. Unfortunately, the considerable calculational effort required to pursue this option failed to produce more acceptable results than the direct approach. Einstein even briefly considered introducing an additional condition on the metric tensor—a weaker form of the Hertz restriction—but apparently gave up this idea because it did not seem to promise an easy way out either. He then tried to make some progress by comparing the two unsatisfactory candidates he had extracted from the Riemann tensor in both their contravariant and covariant forms. This procedure also followed the example set by his experiments with the Beltrami invariants and may similarly have been driven by a concern for uniqueness and the hope to learn from combining different pathways. While the procedure was given up without reaching a definite conclusion, it gave an insight that quickly proved to be important. Using techniques familiar from his Beltrami experiments, Einstein found that the constancy of the determinant of the metric could be used to replace one of three disturbing second-order terms occurring in the Ricci tensor by a first-order expression.

At the same time, it must have been clear to him that disturbing second-order terms of some sort were there to stay, and, consequently, that at least some aspects of what might initially have appeared to be mere stop gaps were there to remain as well. Precisely because of the original promise of the Riemann tensor, it was clear that the problem could no longer be the lack of mathematical resources and that no amount of calculational sophistication would suffice to turn the Riemann tensor into an acceptable candidate gravitation tensor without introducing further hypotheses, in all likelihood with serious physical repercussions. The need for further hypotheses was also suggested by the fact that the conservation principle had not played any role in the analysis of the Riemann tensor so far. It was to be expected that this heuristic requirement would exact its price as soon as the physical consequences of a gravitation theory based on the Riemann tensor were pursued any further.

6.12 Establishing a Contradiction between the Correspondence and the Conservation Principles (19L–19R)

When Einstein had tried to match the second Beltrami invariant to the correspondence principle, he had hit upon the harmonic coordinate restriction as a suitable auxiliary hypothesis. Trying to match the Ricci tensor to the correspondence principle, he found that the same hypothesis could be used to eliminate *all* disturbing second-order terms. This first-order condition on the metric tensor was suggested by the condition following from the restriction to unimodular coordinates. This immediately gave it a similar status, i.e., that of a global coordinate restriction. Against the background of his earlier experience with the Beltrami invariants, the introduction of such an auxiliary hypothesis was clearly an application of what we have called the mathematical strategy. The natural next step would thus have been to explore the transformational properties of this additional restriction (cf. eq. (LIV)).

However, Einstein's earlier experience had also involved wrestling with the conservation principle. He had come to realize that this principle might entail further restrictions, affecting the covariance properties of the theory. Knowing that exploring the transformational properties of such extra conditions could become quite involved, he first tackled the issue of conservation. It made sense to collect all necessary restrictions first, and establish the transformational properties of overall restriction later (cf. eq. (LIX)). To explore the emerging network of conditions, Einstein simplified his framework, focusing on a first-order, weak-field approximation. He thereby effectively introduced another toy model, now with the goal to explore the entanglement of correspondence and conservation principles.

In weak-field approximation, the harmonic coordinate restriction coming from the correspondence principle could easily be related to the restriction coming from the requirement of compatibility between field equation and energy-momentum conservation. It was immediately clear that the field equations in first-order approximation satisfy the divergence condition (LXXI). The conservation compatibility check (LXXIV) gave rise to an additional restriction which could also be brought into a first-order form, for comparison with the harmonic restriction. The combination of the resulting Hertz restriction with the harmonic restriction implies that the trace of the metric tensor must be constant. This implication was inacceptable to Einstein on physical grounds. It was incompatible not only with the default-setting for the metric tensor of a weak static gravitational field (25) but also, via the field equations (cf. eq. (LXXV)) with the default-setting for the stress-energy of matter as given by eq. (XXI). In view of this discrepancy between the mathematical consequences of his heuristic principles and his physical expectations, it is not surprising that Einstein at this point reexamined the legitimacy of the conservation compatibility check which had evidently triggered this conflict. A crucial implication with physical significance was the vanishing of the covariant divergence of the energy-momentum tensor (cf. eq. (XXIV)). Within his weak-field approximation, Einstein therefore rederived this relation from first principles, i.e., from the continuity equation and the equation of motion. In this way, he not only extended his network of arguments to include the latter results but, more importantly, he firmly established the existence of a contradiction within this network, with no simple escape by adjusting his heuristic principles.

In summary, Einstein's exploration of the Ricci tensor as a candidate for the left-hand side of the gravitational field equations had ended in an impasse. At the same time, this exploration had helped him to further extend his strategic resources. They now included, in particular, the consideration of a weak-field equation. Furthermore, the mathematical strategy was amplified by adding as a routine a compatibility check of the restrictions resulting from the correspondence and the conservation principles, respectively. As a result, the notion of coordinate restrictions as a virtually unavoidable consequence of combining a generalized relativity principle with other physical requirements was solidified. Perhaps the most important result of Einstein's exploration of the Ricci tensor was, however, the establishment of a sharp contradiction in the argumentative framework. The identification of this contradiction offered a range of fairly clear options of how to avoid it. Among the alternative pathways to explore was the option of changing the physical default settings entering his argument, in particular those for the metric tensor of a static field and for the stress-energy or energy-momentum tensor. Another option was to reconsider the implementation of the correspondence principle with the help of the harmonic coordinate restriction, e.g., by extracting a new candidate from the Riemann tensor with the help of a different coordinate restriction. Probing a different implementation of the correspondence principle probably looked like the more sensible option given that Einstein's reconsideration of the conservation principle had strongly confirmed *its* implications. In the course of his research, Einstein eventually pursued all of these options. The option he chose to explore first came courtesy of the new toy model he had introduced, the weak-field equation. Why should it not be possible to tinker with the field equations themselves, within the weak-field framework, in order to find out whether there really was no way to satisfy all requirements on the table, including the harmonic coordinate restriction?

6.13 Matching the Riemann Tensor and the Correspondence Principle: the Failure of the Linearized Einstein Tensor (20L–21R)

The preceding considerations had shown Einstein that the contradiction between the coordinate restrictions implied by the correspondence and conservation principles, respectively, had to be taken seriously enough to entertain even a modification of the form of the field equations. His starting point had been a weak-field equation obtained from the Ricci tensor by imposing the harmonic coordinate restriction to satisfy the correspondence principle. The most obvious conflict was that between the implication of the conservation principle that the trace of the stress-energy tensor of matter must vanish, on the one hand, and the default-setting for this tensor (XXI), on the other hand. Einstein's earlier experience with the adjustment of his original theory of the static gravitational field to the requirements of the conservation principle helped to make a modification of the field equation acceptable as a possible way out of this dilemma. In addition, the weak-field equations made the exploration of possible modifications easier by making it possible to study the interplay between the various constraints in a mathematically simplified form. While the overall logic of this exploration was dominated by the mathematical strategy, the challenges it produced for the various physical default-settings of Einstein's search for the gravitational field made it necessary to reflect on his heuristic presuppositions as well and to go back once more to the physical principles guiding his search such as the equivalence principle and even to the more secure part of his theory in the making, the equation of motion.

Since neither the conservation principle nor the default-setting for the stress-energy tensor of matter could be given up easily, the conflict between them first turned Einstein's attention to the source slot of the field equation, or rather on its default-setting, the energy-momentum tensor of matter according to eq. (XIV). If this default setting could be changed, the default setting **DUST** (XXI) for the stress-energy might well be retained without leading to a conflict with the conservation principle. By replacing the default-setting eq. (XIV) with a traceless quantity, Einstein was indeed able to avoid the conclusion that the trace of the stress-energy tensor has to vanish if the trace of the field equation vanishes, as it would have to as a result of combining harmonic and Hertz restrictions, as we have seen.

This remarkable achievement did not provide an entirely satisfactory solution to the compatibility problem of the correspondence and conservation principles. Einstein had resolved the conflict between the combined coordinate restrictions following from these principles and the default-setting for the energy-momentum tensor (XXI), the discrepancy between the combined coordinate restrictions and the default-setting for the metric tensor of a weak static gravitational field (25) still existed. The preceding experience had taught Einstein how modifying the field equation could help in dealing with disturbing coordinate restrictions. If that method had worked to get rid of the unwanted trace condition, why not try to use it again to get rid of the Hertz restriction altogether rather than to make it compatible with the harmonic coordinate restriction?

Once again, an unsuccessful line of thought had thus paved the way for an important strategic insight, which, in this case, gave Einstein the harmonically reduced and linearized Einstein tensor as a candidate for the left-hand side of the field equations. Instead of giving up and replacing the default-setting for the right-hand side of the field equations, changing the way in which the source-term enters the equation, he modified the way in which the gravitational potential enters the left-hand side of the equations, i.e. the default-setting for the weak-field version of **LAP** (XXVIII), the d'Alembert operator. In a sense, this may have appeared to Einstein as the more conservative approach because it interfered less with the canonical form of the field equation. More specifically, Einstein changed the left-hand side of the field equations by adding a trace term in such a way that the object on which **LAP** operates becomes equal to the left-hand side of the harmonic coordinate restriction if the divergence of this left-hand side is taken (cf. eq. (LXXIX)). In this way, the vanishing divergence of the energy-momentum tensor, which is required by the conservation principle and which originally resulted in the Herz restriction, is now implied by the harmonic coordinate restriction alone—without imposing an additional constraint (cf. eq. (76)).

Now that the correspondence principle and the conservation compatibility check in its weak-field form had been taken care of, the next step was to make sure that the conservation principle was satisfied in all of its facets. For the modified field equations, Einstein needed to check, in particular, whether the gravitational force could be represented as the divergence of a gravitational stress-energy expression. The weak-field equations passed this test without any problem, in spite of the additional trace term they involve (cf. eq. (75)). It was less obvious how this success could be extended to the full version of the equations. A half-hearted attempt to solve this problem was, apparently, enough for Einstein to see that this extension represented a major challenge and that it might even bring back additional coordinate restrictions.

After this preliminary exploration of the conservation issue beyond the weak-field case, Einstein returned to the correspondence principle and discovered that another conflict between the modified field equations and the default-settings of his search was still unresolved. The canonical metric for a static field (25) is no longer a solution of the modified field equations. Since the weak-field equation with the added trace term had otherwise fared fairly well in comparison to earlier candidates, it made sense to carefully reexamine the legitimacy of the one obstacle that remained, the default-setting for the weak static gravitational field. He tested its justification by physical knowledge in the same way in which he had earlier checked the legitimacy of the Hertz restriction when it proved to be an obstacle. He turned to the more solid ground provided by the equation of motion. Since the entire theory of the static field had, in a sense, originated from the equation of motion with the help of the equivalence principle, a check of the default assumption about the static gravitational field with the help of this principle was the most natural option to pursue. From this perspective, the crucial question was whether the default-setting for the weak static gravitational field was actually inescapable given the equivalence principle. What does Galileo's principle of equal acceleration in a gravitation field, on which the equivalence principle hinges, imply about the form of a metric tensor for a weak static gravitational field?

All Einstein had to do to address this question was to formulate Galileo's principle in terms of his metric formalism. The conceptual framework within which his question was formulated suggested to do so by trying to identify the elements of Newton's equation (cf. eq. (III)) within this formalism, in particular the force term and the mass (or energy) term. His earlier work on the equation of motion and his experience with the Lagrange formalism gave him the tools for writing down the required quantities. Since their interpretation was governed by the conceptual framework of Newtonian physics, Einstein could draw the conclusion that, if the force was to vary as the energy, so as to ensure the validity of Galileo's principle, the metric for a static field must take on its canonical form. As a consequence of this inference, based on combining physical with mathematical elements, in a way that in hindsight can be recognized as problematic, the default-setting for the weak static gravitational field became even more firmly rooted in Einstein's heuristic framework, making its clash with the linearized Einstein tensor so much the worse for the latter.

In summary, Einstein's attempt to match the Riemann tensor first with the correspondence principle and then with the conservation principle by setting up a field equation for which only the harmonic coordinate restriction was needed as a supplementary condition had left him in the end without a viable candidate to pursue. The promising candidate he had found in the process had to be rejected because it seemed to be irreconcilable with the equivalence principle. Thus, in this dramatic episode of the search for gravitational field equations, the Einstein tensor of general relativity was, albeit only in a weak-field approximation and for harmonic coordinates, identified and discarded. Clearly, the criteria that led to its rejection had to be changed before it could be accepted. In particular, the default-setting for the metric of a weak static field had to be given up, in spite of its support by the canonical form of the weak-field equation and the—in hindsight—spurious argument based on the equivalence principle. The rejection of the equations in the winter of 1912–1913 was a matter of heuristic criteria that were still rooted in classical physics and that were incompatible with general relativity as we know it today. It was also a matter of a network of arguments that were still too loosely woven to produce a contradiction between any candidate field equation and these classical criteria, that could seriously challenge the latter rather than leading only to the rejection of the former.

Again, the failure to establish an acceptable candidate field equation in this preceding episode strengthened Einstein's vision and generated new strategic insights. The mathematical strategy was now fully operative, from the extraction of a candidate from the Riemann tensor, via the introduction of a weak-field approximation, to the matching of the coordinate restrictions following from the correspondence and the conservation principle, respectively. Among the new insights may have been an appreciation of the difficulty in passing from a weak-field to a full-fledged implementation of the conservation principle. But before this problem could even be addressed another candidate equation was needed. The options for avoiding the original conflict between the coordinate restrictions resulting from the correspondence and the conservation principle, respectively, suggested a different implementation of the correspondence principle. The pathway toward such a different implementation and thus to a new candidate was, in a sense, suggested by the original conflict itself. So far, Einstein had tried to get rid of the Hertz restriction in order to follow the path indicated by the harmonic restriction. Since this path looked like a dead end, it made sense to abandon the harmonic restriction, retaining the Hertz restriction instead.

6.14 Matching the Riemann Tensor and the Conservation Principle: the Failure of the November Tensor (22L–25R)

The Ricci tensor and the Einstein tensor do not exhaust the potential represented by the Riemann tensor and the mathematical strategy for producing candidates for the gravitational field equations. As mentioned above, the direction in which to proceed was indicated by the as yet unresolved conflict between the correspondence and the conservation principles, which was embodied in the clash between two coordinate restrictions, the harmonic restriction and the Hertz restriction, respectively. Since the constraints imposed by the conservation principle appeared to be unavoidable, and since Einstein's earlier attempt to suppress the need for the Hertz condition had failed, he now explored the possibility of realizing the correspondence principle in a new way, without the help of the harmonic restriction.

It was once again Marcel Grossmann who prepared the ground for pursuing this other possibility. At the price of a restriction to unimodular transformations, the Ricci tensor could be split into two parts, each part individually transforming as a tensor under unimodular transformations. One of those two parts was a promising new candidate for the left-hand side of the field equations, the "November tensor" (cf. eq. (82)).

The November tensor has a surprisingly elegant form: the divergence of a Christoffel symbol plus a quadratic expression in the Christoffel symbols. If the Christoffel symbols were taken to represent the gravitational field (cf. eq. (XXIII)), the candidate would have the canonical form of eq. (XXXVIII). Such an interpretation, however, was in conflict with Einstein's heuristics at this stage, which demanded the implementation of the correspondence principle first by imposing an appropriate coordinate restriction; furthermore the default setting for the gravitational fields was given by eq. (XXII). At this point, Einstein only looked for an interpretation of a candidate in terms of field components once he had found the *reduced* field equations, i.e., once he had imposed a coordinate restriction to meet the demands of the correspondence principle (cf. eq. (LXXXI)).

As he had done before, Einstein expanded the Christoffel symbols in terms of derivatives of the metric to identify the disturbing second-order terms preventing the implementation of the correspondence principle. These disturbing second-order terms, it turned out, could be eliminated with the help of the Hertz restriction so that the harmonic restriction was no longer needed. Since the Hertz restriction also guarantees the vanishing of the divergence of the linearized stress-energy tensor, the conflict between correspondence and conservation principle was thus resolved, at least at the weak-field level.

Now that this major conflict was settled, new problems arose, among them the question of the transformations allowed by the reduced field equations and the question of the implementation of the conservation principle for the full field equations. Einstein first addressed the issue of covariance which, given the known transformational behavior of the November tensor and following a strategy first established in the context of the Beltrami invariants (cf. eq. (LIX)), could be addressed by exploring the transformation properties of the Hertz restriction. Einstein could also build on an earlier analysis of the Hertz restriction which seemed to indicate that transformations in Minkowski space to a linearly accelerated frame presented a problem, but that transformations to rotating frames did not.

A complete clarification of the transformation properties of the Hertz restriction could be obtained by a larger effort dealing with non-autonomous transformations. Before undertaking such an effort, Einstein preferred, it seems, to turn once more to the conservation issue. How could he extend his results concerning the conservation principle from the weak-field level to the full field equations? He must have been aware of the crucial role of the first-order correction terms to the core operator. Considering the reduced November tensor, i.e. the terms left of the November tensor after imposing the Hertz restriction, Einstein was confronted with a number of such first-order terms, destroying the simple structure which the new candidate displayed when written in terms of the Christoffel symbols. Einstein tried to reintroduce the Christoffel symbols. While this allowed him to group certain terms more effectively, the resulting expression became even more opaque, mixing as it did first-order derivatives of the metric and Christoffel symbols. It was difficult to see, on the basis of this expression, how the conservation principle for the full field equation could be satisfied.

At this point Einstein had an idea that may seem ingenious but whose grounds were prepared by the contrast between the simple and elegant original structure of the November tensor expressed in terms of the Christoffel symbols and its confusing complexity when written in terms of derivatives of the metric. What was needed was a preservation of the original structure in terms of what, in Einstein's understanding, would be the true representation of the gravitational field, viz. the first-order derivatives of the metric (cf. eq. (XXII)). The resulting candidate gravitation tensor would then be of the canonical form (XXXVIII) and, in all likelihood, comply with both the correspondence and the conservation principle. The idea was to impose a new coordinate restriction that would effectively allow Einstein to replace the Christoffel symbols by first-order derivatives of the metric. This was somewhat more difficult than the above sketch would suggest, as it required in particular the introduction of an indirectly defined coordinate restriction amounting to the stipulation that an object we have designated as the "theta expression" behaves as a tensor. It nevertheless proved to be fairly successful. Not only did Einstein manage to obtain a "theta-reduced November tensor" of the desired canonical form but, along the way he also found out that he no longer needed the Hertz restriction as an additional condition to recover the Newtonian theory.

The next challenge was to determine the covariance properties of this theta-reduced November tensor implied by the somewhat strange new coordinate restriction. Einstein first derived a general condition for the infinitesimal non-autonomous transformations leaving the theta expression invariant, which, however, was just as formidable as the conditions of this kind that he had encountered earlier. He then turned to a special case and tried to identify the class of transformations in Minkowski space that preserve the theta condition. In doing so, he found a puzzling result: among the metric tensors satisfying the theta coordinate restriction was a metric corresponding to Minkowski space in rotating coordinates but with interchanged covariant and contravariant components, an object we shall call the "theta rotation metric," or simply the "theta metric." This curious result continued to concern Einstein almost until the end of the research period covered by the Zurich Notebook.

What did this strange finding actually mean? Was rotation covered by the theta restriction or was it not? To answer this question, Einstein had to find a physical interpretation of the curious theta rotation metric, exploring whether or not it was possible to connect it to the dynamics of rotation. He did so in various ways. First he rederived the equations of motion with the help of the Lagrange formalism in order to identify Coriolis and centrifugal forces. He abandoned this approach because it became too involved. Then he switched covariant and contravariant components in the theta condition, since this reformulated condition would obviously admit the ordinary rotation metric as a solution. Finally, in yet another attempt to come to terms with the physical interpretation of the theta condition, Einstein took recourse to the law of energy-momentum conservation, reformulating it in terms of the covariant rather than the contravariant stress-energy tensor and trying to extract from the reformulated law and from the theta metric the correct expression for the centrifugal force. Due to an error, Einstein at first convinced himself that this was actually possible but then appears to have developed doubts.

While the physical meaning of the theta rotation metric remained obscure, its exploration, nonetheless, had two consequences for Einstein's subsequent work: First, it proved increasingly difficult to reach a comprehensive implementation of the generalized relativity principle, and rotation increasingly became something of a litmus test, the one case of accelerated motion that Einstein expected his theory to cover to comply with his original heuristic mission. Second, checking the theta metric with respect to the dynamics of rotation may well have directed Einstein's attention once again to the significance of the force expression as a clue to viable field equations.

Let us try to reconstruct such a clue by means of our symbolic expressions. It was indeed possible to derive a force expression from the linearized field equation, expressing it as the divergence of the gravitational stress-energy density (cf. eqs. (XXXIII), (XXVIII)):

$$\textbf{LIM(FORCE) = DIV(FIELDMASS).} \tag{XC}$$

If such an expression offers a physically meaningful starting point, for instance because it vanishes for rotation, it might serve as a criterion for picking a suitable gravitation tensor instead of just serving as an indirect consistency check by way of a particular solution such as the theta metric. In that case, the force expression could perhaps be reinterpreted as representing an exact quantity even though it was obtained in linear approximation. The force expression could thus become, in a way similar to the transition from Einstein's first to his second theory of the static gravitational field, the starting point for extracting a suitably corrected full gravitation tensor from it (cf. eq. (XXXVI)):

$$\textbf{FORCE = GRAV x FIELD} \tag{XCI}$$

A gravitation tensor **GRAV** constructed in this way would automatically satisfy the conservation principle and looked promising with respect to the generalized relativity principle, at least as far as rotation was concerned. After all, it fulfilled a necessary condition for being compatible with the relativity of rotation, the vanishing of the corresponding force expression in the case of rotation.

If Einstein were in fact trying to implement such ideas, he ran into a number of difficulties, caused in part by calculational errors. First of all, Einstein did at first not systematically construct a candidate gravitation tensor **GRAV** but seems to have merely guessed it. Second, the gravitation tensor he extracted from the force equation does not vanish for rotation as he had hoped, but then he found that this extraction itself involved errors whose elimination might well yield the desired result after all. Third, he must have realized that by postulating a physically meaningful force expression as his new starting point he effectively abandoned the link with the November tensor with its well-defined transformation properties. It therefore made sense to interpret the candidate field equation extracted from the force expression not as the definitive result of a physical strategy but rather as the new preliminary target, itself subject to further corrections, of the mathematical strategy starting from the November tensor. In this way, the advantage of well-defined transformational properties might be combined with that of a physically meaningful force expression ensuring the satisfaction of the conservation principle and perhaps even covering the generalized relativity principle for the case of rotation.

In a sense, Einstein may have reached once again reached the constellation he had reached earlier when establishing the core operator as the physically meaningful target (modulo correction terms) of a mathematical strategy taking the second Beltrami invariant as its starting point. Now the place of the Beltrami invariant was taken by the November tensor and that of the core operator by a candidate gravitational field equation that received its physical meaning not just from the correspondence principle but from the conservation principle as well. In the end, however, Einstein once again was unable to build a convincing bridge between his mathematical starting point and his physically meaningful target.

Unable to build a bridge between the two, Einstein put the November tensor to one side for the time being and explored the field equation suggested by his force expression. However, at this bifurcation point of his research, he does not seem to have had, perhaps for the first time, any promising idea about how to proceed. Neither his overall heuristics nor his remarkable ability to draw strategic lessons from failure suggested a plausible next step. The entries in the notebook at this point do not seem to follow any coherent and well-defined strategy. As noted above, the field equation suggested by the force expression vanishing for rotation does itself not vanish for the rotation metric. Does it perhaps vanish for the curious theta rotation metric obtained by interchanging covariant and contravariant components? This question may sound absurd but was nevertheless pursued by Einstein. He even convinced himself—arbitrarily adjusting a coefficient—that his candidate field equation does indeed vanish for the theta metric, a conclusion that is in fact erroneous. This specious result encouraged him to resort to an earlier trick: if the candidate field equation vanishes for the theta metric, a new candidate field equation could be constructed by interchanging contravariant and covariant components that would vanish for the ordinary rotation metric. The new candidate resulting from this crude operation was mathematically ill-defined. Nevertheless, Einstein explored it. It covered, or so he may have believed, the case of rotation, was compatible with the correspondence principle, and looked promising as far as the conservation principle was concerned.

This last issue called for a closer examination and brought Einstein back to the starting point of this phase of his search, the expression for the force density. The new candidate would be compatible with the conservation principle if it gave rise to a force density that can be represented as the divergence of a stress-energy expression for the gravitational field. Now that he had found an apparently viable candidate complying with the rotation criterion by merely formal manipulations, it made sense to repeat the procedure that originally brought him to the expression for the force density and that had been the point of departure of this whole line of reasoning. Following this procedure, Einstein began to write down the force density for the linearized version of the new candidate field equation, which he then tried to make exact. If everything worked out as expected, his procedure should correspond to the transition from eq. (XC) to eq. (XCI) so that he should be able to reconstruct his full candidate in this way, that is, essentially from inserting the right candidate for **LAP** into the expression for the force expression **LIM(FORCE)** and then generating the correction terms yielding **GRAV**.

Unfortunately, things did not work out in the end. Einstein managed to extract terms from **LIM(FORCE)** that had the required form of a divergence or that could be put on the left-hand side of the field equation as correction terms, but he also encountered a term that could not be treated in either of these two ways. But he got close as only one disturbing term remained. Remarkably, the terms that were put on the left-hand side of the field equation not only induced correction terms of the form **CORR(POT) x FIELD** but also a term of the form **LAP(POT) x FIELD**. This suggested that Einstein's expansion of **LIM(FORCE)** might actually produce an identity if only the right expression for **LAP(POT)** was taken as the starting point. Eventually, Einstein nonetheless abandoned the entire calculation, probably not only because he failed to establish the compatibility of his candidate with the conservation principle but also because he may have realized at some point that this candidate did not make good sense mathematically in the first place.

In summary, Einstein had extracted yet another candidate from the Riemann tensor in addition to the Ricci, the harmonically reduced Ricci, and the harmonically reduced Einstein tensors: the November tensor. In the end, this candidate was judged to be just as unsatisfactory as its predecessors. Its original appeal gradually waned because of the problems Einstein ran into when he tried to turn the November tensor into a viable candidate by adding appropriate coordinate restrictions. The discouraging result was that it hardly made any difference whether a candidate resulted from reducing a covariant object by additional coordinate restrictions or whether it was merely constructed *ad hoc*. Either way, the main challenges, the compatibility with rotation and the satisfaction of the conservation principle, had to be addressed directly, by explicit construction. As a consequence, Einstein's mathematical strategy lost its appeal and gave way to another tinkering phase.

In this tinkering phase Einstein focused on the expression for the gravitational force which had the advantage of having a clear physical interpretation. Such an expression had already played a key role in the transition from his first to his second theory of the static gravitational field. If the force can be written as a divergence, the conservation principle is satisfied automatically. And if the expression for the force happened to vanish for rotation, there was at least a chance of meeting some of the demands of the generalized relativity principle as well. Einstein's problem was that he had yet to find a way of systematically extracting a candidate gravitation tensor from such a force expression. His attempts to construct or guess candidate gravitation tensors along this line tended to destroy the promise of his initial ansatz. Given a candidate consisting of some version of the core operator plus correction terms suggested by a force expression, it still had to be checked against the conservation principle. This in turn meant forming a force expression from the linearized field equation which then was to be rewritten as a divergence, possibly with the help of introducing new correction terms to the original ansatz. Having tried this procedure once if not twice without being able to reproduce his original ansatz, Einstein noticed that he could actually begin simply with the core operator and *use the conservation principle as a means for producing correction terms* to it. The realization of this possibility was the birth of the *Entwurf* strategy and, as far as the research documented in the Zurich Notebook is concerned, the end of the mathematical strategy.

6.15 Matching Correspondence and Conservation Principles: The Emergence of the Entwurf Equations (25R–26R)

As the November tensor gradually dropped out of sight, the mathematical strategy launched with the introduction of the Riemann tensor into Einstein's research fell victim to the attrition associated with the efforts to realize Einstein's physically motivated heuristics when starting from a generally-covariant object. His principal instrument for implementing the correspondence and the conservation principles was to impose coordinate restrictions, which, first of all, had to be brought into agreement with one another and then tended to consume the original benefit provided by a generally-covariant starting point. Meanwhile, he had developed more concise ideas about what a viable candidate satisfying both the correspondence and the conservation principles should look like. In the course of his research he had even encountered candidates that seemed close to satisfying these heuristic criteria. Einstein, however, never succeeded in building a bridge between a mathematically viable starting point such as the November tensor and a candidate that looked promising from a physical point of view. While the November tensor, in particular, was never quite refuted, it just became more and more uninteresting.

On a heuristic level, Einstein's difficulties in implementing simultaneously the correspondence and the conservation principles counteracted the potential advantage of starting from a candidate satisfying the generalized relativity principle. Even when the battle was won at the weak-field level, the mathematical strategy failed to provide any hint for winning it at the level of the full equations. Instead, such a hint came from mere formal manipulations of the force expression that had already guided Einstein's pathway from his first to his second theory of the static field. Against the background of his prior experience with a physical strategy and the inadequacy of the mathematical strategy to cope with the conservation principle, this hint prepared the ground for the derivation of the *Entwurf* field equation.

The gist of this derivation consists in starting from the force expression for the core operator which is then transformed into a divergence expression plus terms which are identified as correction terms (cf. eq. (XXXVII)). The resulting identity then yields both the correction terms and the gravitational stress-energy expression whose divergence corresponds to the force expression for the definitive gravitation tensor. The gravitation tensor produced in this fashion even happened to involve the gravitational stress-energy expression in such a way that the field equation could be written in the canonical form of eq. (XXXIX), with the energy-momentum of the gravitational field entering the field equations on the same footing as the energy-momentum tensor of matter (cf. eqs. (49) and (50)). This strategy was the result of Einstein's reflection on his earlier attempts to generalize the representation of the force as a divergence expression from the weak-field to the general case. Rather than guessing the right correction terms, he had now found a systematic construction procedure, which seemed to uniquely identify a candidate gravitation tensor compatible with both the correspondence and the conservation principle.

The match between these two heuristic principles was achieved at the expense of the generalized principle of relativity. All that could be known in that respect about a candidate gravitation tensor produced in this way was its covariance under linear transformations (cf. eq. (LXVII)). Einstein was ready to accept this consequence. He had already turned his attention to a simplified approach encompassing only linear transformations once before so that he could get a better handle on the conservation principle. This was when his earlier attempts to determine the covariance properties of the core operator with or without the help of the Beltrami invariants had run into similar difficulties as his efforts involving to the Riemann tensor. While, at that point, the restriction to linear transformations was merely a presupposition for formulating the conservation problem, Einstein may now have felt that this was the price to pay for its solution.

In the course of Einstein's pursuit of the mathematical strategy, the conservation principle had emerged as the major challenge for his search for the gravitational field equation. This challenge triggered the switch to a physical strategy, judiciously incorporating results found while pursuing the mathematical strategy, from the form of the field equation to the role of coordinate restrictions. With the establishment of the *Entwurf* field equations with the help of this physical strategy Einstein had succeeded, for the first time in the course of his research documented by the notebook, to satisfy the conservation principle without restriction to the weak-field level. The major challenge for Einstein's research now was the generalized principle of relativity. How far could the covariance properties of the *Entwurf* field equation be extended or was their covariance really restricted to linear transformations only? Why were the physically satisfying *Entwurf* field equations not generally-covariant to begin with? These were the questions delineating Einstein's research program for the further exploration of the *Entwurf* equation. Its compliance with the heuristic principles rooted in classical physics, the correspondence and the conservation principle, made it possible to consider these questions not as incentives for continuing the search for gravitational field equations but as remaining puzzles within an established conceptual framework, that of the *Entwurf* theory. For the time being, Einstein's search for the gravitational field equations was over—even if this meant turning his back on a reservoir of possible further candidates.

7. PROGRESS IN A LOOP: EINSTEIN'S GENERAL RELATIVITY AS A TRIUMPH OF THE "*ENTWURF*" THEORY IN THE PERIOD FROM 1913 TO 1915

7.1 Consolidation, Elaboration, and Reflection

This chapter focuses on what has traditionally been seen as the most uneventful period of Einstein's search for a generalized theory of relativity, the time between spring of 1913 and fall of 1915, in which he clung to the erroneous *Entwurf* theory, which he published together with Marcel Grossmann before the end of June 1913. According to the dramatic narratives of the emergence of general relativity, this period was one of stagnation, it was the calm interval between two major thunderstorms, Einstein's tragic struggle with and eventual rejection of generally-covariant field equations in the winter of 1912–1913 in favor of a theory with only limited covariance properties and the sudden revelation of errors in the *Entwurf* theory, which led immediately to its demise and then to a triumphant, if gradual, return to generally-covariant field equations in the fall of 1915. The assumption of a "pitfall" in 1912–1913 and of a "breakthrough" in late 1915 constitutes the traditional explanation for the most peculiar feature of the genesis of general relativity, Einstein's double discovery of generally-covariant gravitational field equations, first formulated in 1912 and then rediscovered in 1915. How else, if not by the introduction and later elimination of errors, can this closed loop be explained?[106]

From the perspective of an historical epistemology, the supposed period of stagnation between 1913 and 1915 can be considered a period in which new knowledge was assimilated to a conceptual structure still rooted in classical physics. As a result of this assimilation of knowledge, this conceptual structure became richer, both in terms of an ever more extended network of conclusions that it made possible, and in terms of new opportunities for ambiguities and internal conflicts within this network. It was this gradual process of enrichment that eventually created the preconditions for a reflection on the accumulated knowledge which, in turn, induced a reorganization of the original knowledge structure. The enrichment of a given conceptual structure by the assimilation of new knowledge and the subsequent reflective reorganization of the enriched structure are the two fundamental cognitive processes which explain the apparent paradox that the preconditions for the formulation of general relativity matured under the guidance of a theory that is actually incompatible with it.

As we will argue in the following, the results achieved on the basis of the *Entwurf* theory should not be understood as so many steps in the wrong direction, whereupon it appears that their only function was to make the deviation from the truth evident, but rather as instruments, first for accumulating knowledge and then for rearranging it in a new order. Both these processes are essential to the development of scientific knowledge. The second half of this chapter covers Einstein's papers of November 1915, with the intention to demonstrate the role in these papers of insights and techniques developed in the period before.

When elaborating the *Entwurf* Theory, Einstein still pursued the same heuristics that had shaped his search for a gravitational field equation in the winter of 1912–1913 as documented by the Zurich Notebook, although the heuristics were now governed by the perspective of consolidation rather than by that of exploration of alternatives. In particular, the unresolved tensions between Einstein's heuristic principles guided his attempts to consolidate the *Entwurf* theory. These attempts were characterized by two complementary approaches. Following a defensive approach, he attempted to justify the restricted covariance of the *Entwurf* field equations by arguments based on the knowledge of classical physics. Following a bold approach, he attempted to look for a generalization of the relativity principle even in the framework of the *Entwurf* theory. The outcome of these efforts was, as we shall see, that he eventually succeeded in both, the defensive and the bold approach.

In the first phase of the consolidation period of the *Entwurf* theory, lasting roughly from spring to summer 1913, Einstein formulated two problematic argu-

106 This section relies heavily on (Renn 2005c) and "Untying the Knot ..." (in vol. 2 of this series).

ments, an argument based on the consideration of energy-momentum conservation and the notorious hole argument, both justifying the restricted covariance properties of the theory. Although these arguments later turned out to be erroneous, they were nevertheless significant in bringing out decisive conceptual peculiarities of general relativity that distinguished it from classical theories, including the *Entwurf* theory. The further development, refutation or clarification of these arguments revealed the non-locality of energy-momentum conservation, as expressed by the nonexistence of a local energy-momentum tensor for the gravitational field, the impossibility of ascribing physical significance to single spacetime points independent of the metric, and the fundamental connection between conservation laws and symmetries of spacetime structure later explicated in the Noether theorems.

In the second phase of the consolidation of the *Entwurf* theory, roughly lasting from fall 1913 to the end of 1914, Einstein elaborated this theory, which he originally found along the physical strategy, from the point of view of the complementary mathematical strategy. Guided by this heuristic strategy, Einstein found a new derivation of the *Entwurf* field equations, which he completed by the fall of 1914. The second phase of the consolidation period of the *Entwurf* theory had, like the first phase, a paradoxical character. On the one hand, Einstein's findings stabilized the *Entwurf* theory, on the other hand they provided instruments for overcoming the objections that had earlier prevented him from accepting candidate gravitational field equations found along the lines of the mathematical strategy. In particular, the variational techniques explored in the context of the new derivation of the *Entwurf* theory made it possible for Einstein to solve one of the crucial problems associated with the candidates for a gravitational field equation that he had discarded in the winter of 1912–1913, the establishment of energy-momentum conservation. That he did not immediately draw this consequence was partly a matter of perspective since, from the point of view governing the consolidation period, there was no reason for reexamining the earlier candidates.

Having discovered flaws in the *Entwurf* theory and its derivation along a modified mathematical strategy, Einstein eventually abandoned the consolidation phase and subsequently returned to a new exploratory phase, searching once more for the correct gravitational field equation. In hindsight, he gave three reasons for his rejection of the *Entwurf* theory: It could not explain the perihelion shift of Mercury; it did not allow the interpretation of a rotating system as being equivalent to the state of rest, and hence did not satisfy his Machian expectations, and finally, the derivation of its field equations along a mathematical strategy involved an unjustified assumption. For a short time, the theory survived *all* of these problems. Even the last problem, the discovery of a flaw in the derivation of the field equations, did not lead to a refutation of the Entwurf theory but only to a successful attempt of repairing it on a technical level. But the discovery of this problem had nevertheless fargoing consequences on the level of Einstein's reflection on the results he had achieved. By its very nature this discovery had a double effect:

– It showed that the adaptation of the mathematical strategy to the *Entwurf* theory failed and forced Einstein to return to the arguments at the core of the physical strategy as the only possible justification of the *Entwurf* theory.
– It showed that the mathematical strategy adapted to the *Entwurf* theory did not single out this theory but rather opened up the possibility of examining other candidate field equations. And he *needed* new equations because of the problem of rotation.

Together with the other short-comings found earlier, the discovery of the error in the derivation of the field equations, after a period of reflection, caused Einstein to drop his attempts to consolidate the *Entwurf* theory and eventually brought him back to an exploratory phase.

The second part of this chapter deals with the short period of three weeks before Einstein presented the definitive field equations of general relativity to the Prussian Academy on 25 November 1915. This period began when Einstein started to check whether the *Entwurf* field equations are necessarily the only solution to his problem and thus returned to his 1912–1913 attempts to search for a solution by examining candidate field equations familiar from his pursuit of the mathematical strategy, the November tensor, the Ricci tensor, and the Einstein tensor. By focusing on the impact of Einstein's achievements under the reign of the *Entwurf* theory, it is possible to answer the question of why in 1915 he could accept field equations that he had rejected in 1912–1913. In a note Einstein submitted to the Prussian Academy on 4 November 1915, he proposed a new gravitation theory based on the November tensor, considered earlier in the Zurich Notebook. In contrast to the situation in 1912–1913, he was now able to demonstrate that the new theory complies with the conservation principle. Just as he had done in the *Entwurf* theory, Einstein continued to interpret the conservation principle as implying a restriction of the admissible coordinate systems which now, however, turned out to be much less restrictive than the condition he had earlier found on the basis of his examination of the weak field equation (cf. eq. (LXXXVI)). He thus reached a decoupling of the coordinate restrictions implied by the conservation and the correspondence principles, respectively. Reflecting on this decoupling, Einstein was now able, for the first time, to conceive the choice of coordinates required for implementing the correspondence principle as a coordinate condition in the modern sense.

In an addendum to the note published on 4 November, Einstein reinterpreted another already familiar candidate in a new context, the Ricci tensor. This new context was provided by a speculative electromagnetic theory of matter, probably stimulated by the contemporary work of David Hilbert on such a theory. Due to this new context, Einstein shifted the restriction on the choice of coordinates, which he had found for the theory based on the November tensor, to a restriction of the choice of a particular kind of matter acting as the source of gravitational fields. Einstein thus arrived at a generally-covariant theory based on the Ricci tensor, which he considered as being merely a reinterpretation of the theory based on the November tensor so that he could take over essential results such as those concerning energy-momentum conservation.

He thus partly resolved—on the basis of the *Entwurf* theory—and partly circumvented—on the basis of an electromagnetic theory of matter—the objections he had earlier encountered against such a theory when he first considered it in 1912–1913.

In a paper submitted on 18 November 1915 Einstein calculated the perihelion shift of Mercury, claiming to provide support for the hypothesis of an electromagnetic nature of matter on which his new theory of gravitation was based. In a sense, the Mercury problem now offered a theoretical laboratory for the Ricci Tensor. Einstein's paper is largely based on techniques he had developed jointly with Besso in 1913 in the context of the *Entwurf* theory. It also includes the crucial insight that the determination of the Newtonian limit for a gravitational field equation involves, in general, more complex considerations than originally envisioned along the physical strategy, and that were used earlier to object to the harmonically reduced Ricci tensor in the Zurich Notebook. This insight into the complex nature of the correspondence principle had already been attained in 1913 as well, in the context of the *Entwurf* theory (at least by Besso) but was then of no relevance as Einstein and Besso did their original calculations in the consolidation phase of this theory.

Einstein's more sophisticated understanding of the Newtonian limit had, in the context of the renewed exploratory phase at the end of 1915, decisive consequences: It made it possible for him, in his final paper of that period, to base a theory of gravitation on the Einstein tensor, whose harmonically reduced and linearized form had been rejected in 1912 because of its apparent incompatibility with the correspondence principle. Also the status of energy-momentum conservation changed in the new theory. The insight into its different status was a consequence and not a presupposition of the establishment of the definitive version of general relativity, which on Einstein's part was established entirely in the conceptual framework of the *Entwurf* theory. The *Entwurf* theory and general relativity were initially not separated by a conceptual gulf, but merely by technical insights on the one hand, and a change of perspective on the other. Remarkably, these were both the result of the same process, the elaboration of the *Entwurf* theory during the supposed period of stagnation. Since the technical achievements attained in this period could still have been, in principle, assimilated to the theory that had given rise to them, taken by themselves they would have induced only a linear progress, thus yielding an increasingly sophisticated and increasingly complex *Entwurf* theory. It thus becomes clear that in light of the new technical achievements of the consolidation phase of the *Entwurf* theory, Einstein's reflection on his earlier knowledge, including previously discarded candidate gravitation tensors, was the crucial process that made the establishment of general relativity the result of progress in a loop.

7.2 The First Phase of the Consolidation Period of the Entwurf Theory: The Defensive and the Bold Approach

With the formulation of the *Entwurf* field theory and its publication by Einstein and Grossmann in the spring of 1913, the search for the field equations, as documented by the Zurich Notebook, had manifestly come to an end. Einstein no longer examined different candidates by comparing them with his heuristic expectations. Instead, he used his growing mastery of the mathematical representation to develop the one most promising candidate he had found. He thus entered the consolidation period of the *Entwurf* theory. A consolidation of the *Entwurf* theory was necessary in view of the main problem left open by the *Entwurf* paper of 1913, the determination of the covariance properties of the field equations and thus of the extent to which the new theory realized the generalized principle of relativity. The covariance was more restricted than that of the candidate gravitation tensors derived from the generally-covariant Riemann tensor that had formed the points of departure of Einstein's mathematical strategy. It therefore made sense to address this problem by trying to explain and justify the restricted covariance of the *Entwurf* equations and to explore these covariance properties in the hope of generalizing the relativity principle as much as possible.

Einstein's probing of these two approaches came to a first conclusion in August 1913. All his bold efforts up to that point to identify by explicit calculations non-linear transformations under which the *Entwurf* field equations might be covariant had failed, including an attempt to show that the metric for Minkowski spacetime in rotating coordinates is a solution of these equations. At the same time, his defensive efforts had led to a first result. Not surprisingly, this result was based on the conservation principle which had earlier motivated a restriction of the generalized principle of relativity on several occasions in the Zurich Notebook. An interpretation of the expression for energy-momentum conservation in the *Entwurf* theory, following the model of classical and special-relativistic physics, was now taken by Einstein to indicate that the *Entwurf* theory is covariant only under linear transformations. Both results, the failure of his attempts to identify non-linear transformations and the conservation argument, as we shall call it, thus pointed in the same direction and encouraged Einstein to look for further arguments along the defensive.

By the end of August 1913, he found, quite possibly in discussion with Michele Besso,[107] another argument against general covariance, the so-called "hole argument," which is based on the assumption, again motivated by classical and special-relativistic physics, that points in spacetime can be identified by means of coordinate systems, independently from any physical processes. In a formulation by Besso, the argument merely seeks to express the non-uniqueness of the metric tensor in terms of two distinct sets of functions which solve the same set of differential equations with given boundary values. Einstein elaborated this argument to a construction of two distinct solutions for the metric tensor considered within one and the same coordinate system. This more sophisticated version of the hole argument makes use of the idea, in modern parlance, to drag values of the metric tensor from one spacetime point to the other and later raised the important question of which aspects of a generally-covariant theory are physically meaningful.

---

107 See "What Did Einstein Know ..." (in vol. 2 of this series).

By means of the hole argument, Einstein convinced himself that generally-covariant gravitational field equations, together with boundary values, do not determine uniquely the metric tensor representing the gravitational field. Having thus identified an apparently fundamental reason for rejecting general covariance, he interpreted his earlier argument from the conservation principle as providing the necessary specialization of the reference frames to be used within the theory. With these results, the *Entwurf* theory had come to a certain closure, ending the first phase of its consolidation period.

7.3 The Failure of the Generalized Principle of Relativity: A Conflict Between Formalism and Physical Intuition

Einstein's decision to settle for the non-generally-covariant field equations of the 1913 *Entwurf* paper was the consequence of his failure to find generally-covariant equations and not of a conviction or an insight that such equations could not exist. In the spring of 1913, he could not be sure that he had just failed to find generally-covariant equations that would fulfill his hopes for fully implementing the generalized principle of relativity. In the notebook, he had considered several candidates for generally or at least unimodularly covariant field equations and found them defective. But the fact that these candidates failed for *different* reasons must have made it difficult for Einstein to accept that generally-covariant field equations did not exist since these different reasons did not include a clear hint as to why a full implementation of the generalized relativity principle could not exist. Either the conflict with the realization of the Newtonian limit as required by the correspondence principle, or with the demonstration of energy-momentum conservation as required by the conservation principle, or both, led to the rejection of a promising candidate, but these conflicts by themselves did not provide any counter-argument against the possibility of the generalized principle of relativity. The failure to find generally-covariant field equations was, after all, merely a technical result, incompatible with the physical intuition incorporated in the generalized principle of relativity.[108] The conflict between formalism and physical understanding motivated Einstein's further elaboration of the *Entwurf* theory.

If Einstein, at the time of the notebook or of the publication of the *Entwurf* paper, had seen any reason to modify or restrict this principle, he might have done so explicitly in order to justify his failure to achieve its full implementation. In a letter to Ehrenfest from May 1913, in which he announced the forthcoming publication of the *Entwurf* paper, he asserts his firm belief in a generalized principle of relativity, but points out that he had been unable to realize this principle on the level of the theory's formalism:

---

108 For discussion of the problematic relation between the physical intuition incorporated in the generalized principle of relativity and general covariance, see (Janssen 2005).

> I slowly convinced myself that *privileged coordinate systems do not exist at all*. However, I succeeded only partly in arriving at this position also from a formal point of view.[109]

In the *Entwurf* paper itself, Einstein refers to the conflicts between the generalized relativity principle and his other heuristic principles in order to justify the new theory's lack of general covariance (Einstein and Grossmann 1913, 11). He emphasized, in particular, the difficulties he had found in realizing the correspondence principle, suggesting a second-order field equation, as a justification for his failure to achieve a generally-covariant field equation. He also admitted that his introduction of the *Entwurf* field equations was merely based on plausible assumptions and not on a strict derivation from postulates such as a generalized principle of relativity.

The failure to find generally-covariant field equations was most evident from an intrinsic asymmetry of the *Entwurf* theory, between the non-generally-covariant field equation and the generally-covariant equation for material processes in a gravitational field, i.e., the equation for energy-momentum conservation. This asymmetry is also emphasized in the *Entwurf* paper itself. Einstein attempted to interpret it as a clue for justifying the failure to establish a generally-covariant field equation, pointing at the different ways in which the metric tensor enters into the equation for energy-momentum conservation, on the one hand, and the field equation, on the other:

> This exceptional position of the gravitational equations in this respect, as compared with all of the other systems, has to do, in my opinion, with the fact that only the former can contain second derivatives of the components of the fundamental tensor.[110]

In a sense, he simply turned the description of the problem into its solution at this point. Einstein's problem remained that this assertion was merely speculative and, in the final account, based on nothing but his failure to find appropriate, generally-covariant, second-order gravitational field equations.

7.4 The Failure of Einstein's Search for Non-Linear Transformations

While in the spring of 1913 Einstein made his first attempts at justifying the lack of general covariance of the *Entwurf* field equation, he tried, at the same time, to overcome this problem. In fact, it could not be excluded that, even though all derivations in the *Entwurf* theory merely involve the assumption of linear covariance, the field equations would turn out to be covariant under a wider class of transformations. In the *Entwurf* paper, this question is singled out as the most important one left to be resolved (Einstein and Grossmann 1913, 18).

---

109 "Die Überzeugung, zu der ich mich langsam durchgerungen habe, ist die, *dass es bevorzugte Koordinatensysteme überhaupt nicht gibt*. Doch ist es mir nur te[i]lweise gelungen, auch formal bis zu diesem Standpunkt vorzudringen." Einstein to Paul Ehrenfest, 28 May 1913, (CPAE 5, Doc. 441).

110 "Die diesbezügliche Ausnahmestellung der Gravitationsgleichungen gegenüber allen anderen Systemen hängt nach meiner Meinung damit zusammen, daß nur erstere zweite Ableitungen der Komponenten des Fundamentaltensors enthalten dürften." (Einstein and Grossmann 1913, 18)

There are indications that Einstein attempted to find out by calculation whether the *Entwurf* field equation transforms also under a wider class of transformations. From his Zurich Notebook, he was familiar with techniques for exploring the transformational behavior of field equations. But the *Entwurf* field operator confronted him with a case that was far more complex than any other candidate in the notebook for which he had attempted to determine the transformational behavior by directly subjecting it to coordinate transformations.

One indication for Einstein's explorative attempts and their failure comes from a couple of pages of the so-called Einstein-Besso manuscript, pages that were probably written around June 1913 and that deal specifically with the problem of rotation.[111] Another indication comes from a letter Einstein wrote on 14 August 1913 to Hendrik A. Lorentz. This letter marks the preliminary end of Einstein's search for non-linear transformations of the *Entwurf* field equation and provides a succinct resume of the situation of the *Entwurf* theory just on the verge of the renouncement of the bold approach. The letter begins with the confession that the lack of general covariance represents a profound dilemma for the new theory of gravitation:

> And now to gravitation. I am delighted that you so warmly espouse our investigation. But, unfortunately, there are still such major snags in the thing that my confidence in the admissibility of the theory is still shaky. So far the "Entwurf" is satisfactory insofar as it concerns the effect of the gravitational field on other physical processes. For the absolute differential calculus permits the setting up of equations here that are covariant with respect to arbitrary substitutions. The gravitational field ($g_{\mu\nu}$) seems to be the skeleton, so to speak, on which everything hangs. *But, unfortunately, the gravitation equations themselves do not possess the property of general covariance*. Only their covariance with respect to *linear* transformations is certain. But all of our confidence in the theory rests on the conviction that an acceleration of the reference system is equivalent to a gravitational field. Hence, if not all of the equation systems of the theory, and thus also equations (18), permit other than linear transformations, then the theory refutes its own starting point; then it has no foundation whatsoever.[112]

The letter to Lorentz continues with a description of Einstein's unsuccessful attempts to find non-linear transformations under which the *Entwurf* field equation remains covariant, discussing two types of transformations, autonomous and non-autonomous ones.[113] In the Zurich Notebook, he had attempted on several occasions to find the transformational properties of a physically plausible candidate by deriving differential equations for the transformation coefficients involving the metric tensor. But he had never found a simple solution to the problem posed in this way. In view of the many reasons in favor of the *Entwurf* theory, he must have applied this technique to it with even greater persistence. Einstein's letter to Lorentz shows, however, that these efforts remained as unsuccessful as they had been in the Zurich Notebook. He was, in fact, ready to give up the bold approach to solve the most fundamental problem of the *Entwurf* theory and turn to the defensive approach, searching for more substantial

111 See (CPAE 4, Doc 14 [pp. 41–42]) and the discussion in (Janssen 1999).

arguments to justify the lack of covariance of the field equations than those adduced in the *Entwurf* paper.

7.5 Einstein's Reinterpretation of the Conservation Principle

For the candidates which Einstein had encountered pursuing the mathematical strategy, the conservation principle typically implied a restriction of the generalized principle of relativity. Given this experience, it must have been plausible for him to examine whether an explanation for the restricted covariance of the *Entwurf* field theory could perhaps also be found in the context of energy-momentum conservation. Only a day after Einstein sent the letter to Lorentz quoted above, on 15 August 1913, he indeed found a way to justify the limited covariance of the *Entwurf* theory on the basis of the conservation principle. A crucial heuristic ingredient of his argument was the parallelism between gravitational energy and other forms of energy, represented in the *Entwurf* theory by eq. (51). In another letter to Lorentz, written on 16 August 1913, Einstein wrote:

> Furthermore, yesterday I found out to my greatest delight that the doubts regarding the gravitation theory, which I expressed in my last letter as well as in the paper, are not appropriate. The solution of the matter seems to me to be as follows: The expression for the energy principle for matter & gravitational field taken together is an equation of the form (19), i.e., of the form $\sum \frac{\partial F_{\mu\nu}}{\partial x_\nu} = 0$; starting out from this assumption, I set up

---

112 "Nun zur Gravitation. Ich bin beglückt darüber, dass Sie mit solcher Wärme sich unserer Untersuchung annehmen. Aber leider hat die Sache doch noch so grosse Haken, dass mein Vertrauen in die Zulässigkeit der Theorie noch ein schwankendes ist. Befriedigend ist der Entwurf bis jetzt, soweit es sich um die Einwirkung des Gravitationsfeldes auf andere physikalisch[e] Vorgänge handelt. Denn der absolute Differenzialkalkül erlaubt hier die Aufstellung von Gleichungen, die beliebigen Substitutionen gegenüber kovariant sind. Das Gravitationsfeld ($g_{\mu\nu}$) erscheint sozusagen als das Gerippe an dem alles hängt. *Aber die Gravitationsgleichungen selbst haben die Eigenschaft der allgemeinen Kovarianz leider nicht*. Nur deren Kovarianz *linearen* Transformationen gegenüber ist gesichert. Nun beruht aber das ganze Vertrauen auf die Theorie auf der Überzeugung, dass Beschleunigung des Bezugssystems einem Schwerefeld äquivalent sei. Wenn also nicht alle Gleichungssysteme der Theorie, also auch Gleichungen (18) [i.e. the gravitational field equations] ausser den linearen noch andere Transformationen zulassen, so widerlegt die Theorie ihren eigenen Ausgangspunkt; sie steht dann in der Luft." Einstein to Hendrik A. Lorentz, 14 August 1913, (CPAE 5, Doc. 467). In view of the later development, in which the question of whether the manifold with its coordinate systems or the metric tensor is the "skeleton" on which all physical processes depend acquired a certain significance, it is remarkable that in the above formulation Einstein singled out the metric tensor as the crucial object. As we will see below when discussing the hole argument, in defending the lack of general covariance of his field equations Einstein for a while assumed that the points of the manifold identified by certain sets of coordinates actually have a reality and physical significance by themselves, that is, also independently from the metric tensor.

113 This fact also suggests that Einstein at this point did not assume that the *Entwurf* field equations remain covariant under rotations.

> equations (18). But a consideration of the general differential operators of the absolute differential calculus shows that an equation so constructed is never absolutely covariant. Thus, by postulating the existence of such an equation, we tacitly specialized the choice of the reference system. We restricted ourselves to the use of such reference systems with respect to which the law of momentum and energy conservation holds in this form. It turns out that if one privileges such reference systems, then only more general linear transformations remain as the only ones that are justified.[114]

With this insight, the conservation principle was no longer merely a technical impediment to the full implication of the generalized relativity principle but provided the concrete physical reason for the restriction to specific, well-defined transformations. Accordingly Einstein continued in his letter to Lorentz:

> Thus, in a word; *By postulating the conservation law, one arrives at a highly determined choice of the reference system and the admissible substitutions*. Only now, after this ugly dark spot seems to have been eliminated, does the theory give me pleasure.[115]

Einstein's argument presupposes, however, that the objects appearing in his equation for energy-momentum conservation eq. (51) behave themselves as tensors. This is true for the stress-energy tensor of matter, but not for the stress-energy expression for the gravitational field, as Einstein came to realize a few months later.[116] But if this quantity fails to behave as a tensor, the transformational properties of eq. (51) cannot be read off by inspection as Einstein claimed to be able to do in his letter to Lorentz.

Einstein immediately incorporated the argument for linear covariance found on 15 August 1913 and exposed to Lorentz a day later into his manuscript for a lecture he was invited to hold on 23 September 1913 in Vienna.[117] In § 6 of this lecture, enti-

---

114 "Ferner fand ich gestern zu meiner grossen Freude, dass die gegenüber der Gravitationstheorie in meinem letzten Briefe, sowie in der Arbeit geäusserten Bedenken nicht angezeigt sind. Die Sache scheint sich mir folgendermassen zu lösen. Ausdruck des Energieprinzips für Materie & Gravitationsfeld zusammen ist eine Gleichung von der Form (19) d.h. von der Form $\sum \frac{\partial F_{\mu\nu}}{\partial x_\nu} = 0$; von dieser Voraussetzung ausgehend stellte ich die Gleichungen (18) [i.e. the field equations] auf. Nun zeigt aber eine Betrachtung der allgemeinen Differenzialoperatoren des absoluten Differenzialkalküls, dass eine so gebaute Gleichung niemals absolut kovariant ist. Indem wir also die Existenz einer solchen Gleichung postulierten, spezialisierten wir stillschweigend die Wahl des Bezugssystems. Wir beschränkten uns auf den Gebrauch solcher Bezugssysteme, inbezug auf welche der Erhaltungssatz des Impulses und der Energie in dieser Form gilt. Es zeigt si[ch], dass bei der Bevorzugung solcher Bezugssysteme nur mehr allgemeine lineare Transformationen als allein berechtigt übrig bleiben." Einstein to Hendrik A. Lorentz, 16 August 1913, (CPAE 5, Doc. 470).

115 "Also kurz gesagt: *Durch die Postulierung des Erhaltungssatzes gelangt man zu einer in hohem Masse bestimmten Wahl des Bezugssystems und der zuzulassenden Substitutionen*. Erst jetzt macht mir die Theorie Vergnügen, nachdem dieser hässliche dunkle Fleck beseitigt zu sein scheint."

116 Einstein found the fallacy of this argument in the period between ca. 20 January 1914 and ca. 10 March 1914, see Einstein to Heinrich Zangger, ca. 20 January 1914, (CPAE 5, Doc. 507) and Einstein to Paul Ehrenfest, before 10 March 1914, (CPAE 5, Doc. 512), as well as Einstein to Heinrich Zangger, ca. 10 March 1914, (CPAE 5, Doc. 513). The last two letters mention, for the first time after a long period of intermission (to which the first letter to Zangger evidently still belongs), progress in the work on the gravitation problem related to the covariance properties of the *Entwurf* equation.

tled “Bemerkungen über die mathematische Methode,” Einstein summarized some of the mathematical properties of the *Entwurf* theory. In the previous paragraph he had dealt with equations describing the effect of the gravitational field on other physical processes, and in particular with energy-momentum conservation, in the next he was going to develop the gravitational field equation. Towards the end of § 6, he took the occasion to comment on the remarkable asymmetry between the transformational behavior of these two types of equations (Einstein 1913, 1257). He explained that the arguments in favor of a generalized principle of relativity, on the one hand, and his argument in favor of its restriction, on the other, are located on different levels, one on the general level of the spacetime structure, the other on the level of concrete physical requirements. Whereas the first level remains the relevant one for all equations dealing with the effects of the gravitational field on other physical processes, the second level becomes relevant only for the gravitational field equation itself. The introduction of a specialization of the reference system only “after the fact” may well have motivated him to continue his search for an explanation that makes the restriction of the generalized relativity principle understandable also on the level of the spacetime structure. Furthermore, the asymmetry between the transformational behavior of the gravitational field equations and that of all other equations of physics hinted at an explanation that is related to the mathematical nature of the field equations. As we shall now see, Einstein eventually found such an explanation in the hole argument.

7.6 The Construction of the Hole Argument[118]

The use of the conservation principle to justify the limited covariance of the *Entwurf* field equation was a relief but contributed, in effect, little to *understanding* the restriction of the generalized principle of relativity. In a first attempt to come to terms with this unsatisfactory situation, Einstein reformulated the Machian heuristics that had originally suggested the introduction of this principle. This attempt is visible already in his earliest statements concerning the conservation argument described above, but is most clearly expressed in a letter Einstein wrote to Ernst Mach in the second half of December 1913:

> It seems to me absurd to ascribe physical properties to “space.” The totality of masses produces the $g_{\mu\nu}$ field (gravitational field), which in turn governs the course of all processes, including the propagation of light rays and the behavior of measuring rods and clocks. First of all, everything that happens is referred to four completely arbitrary space-time variables. If the principles of momentum and energy conservation are to be satisfied, these variables must then be specialized in such a way that only (completely) linear substitutions shall lead from one justified reference system to another. The reference sys-

---

117 Einstein completed the manuscript for this lecture about a month earlier, see (CPAE 4, note 17) and “What Did Einstein Know ...” note 19 (in vol. 2 of this series).

118 See also “What Did Einstein Know ...” (in vol. 2 of this series) and further references cited there.

> tem is, so to speak, tailored to the existing world with the help of the energy principle, and loses its nebulous aprioristic existence.[119]

In this reformulated argument against absolute space, the role of the cosmic masses and their relations in constituting space is now taken over by the conservation principle which is claimed to provide the physical justification of preferred reference frames. But Einstein's revised Machian heuristics nevertheless failed to completely ban the plausibility of a generalization of the relativity principle. This is evident from the efforts by Einstein and his friend Michele Besso to find a deeper connection between the limited transformation properties of the *Entwurf* field equation and the structure of spacetime.

These efforts are documented, in particular, by a manuscript in the hand of Michele Besso.[120] In a group of pages, the first of which carries the dateline 28 August 1913, Besso listed a number of problems which he had probably encountered while working jointly with Einstein on the problem of Mercury's perihelion shift in the context of the *Entwurf* theory.[121] These problems were evidently not intended as a program for the further development of the *Entwurf* theory but rather constituted the results of reflections on what had been achieved so far. In a note found in the part of the manuscript belonging to a later period, Besso modestly characterized himself as being merely an "*orrechiante*," that is, as an amateur who had the privilege of listening to a great master. But some of Besso's observations turned out to be most consequential, introducing a possibly naive but fresh perspective. It seems in fact that he went together with Einstein through his list of problems, some of them directly formulated as questions, and that they discussed them one by one; at some later point Besso then entered Einstein's responses.[122] Three of Besso's problems are relevant for the present discussion, the first concerning the issue of rotation, the second regarding the logical status of the restriction implied by the conservation principle, and the third concerning what later was to become the hole argument, Einstein's central argument to defend the restricted covariance of the *Entwurf* theory.

---

119 "Für mich ist es absurd, dem "Raum" physikalische Eigenschaften zuzuschreiben. Die Gesamtheit der Massen erzeugt ein $g_{\mu\nu}$-Feld (Gravitationsfeld), das seinerseits den Ablauf aller Vorgänge, auch die Ausbreitung der Lichtstrahlen und das Verhalten der Massstäbe und Uhren regiert. Das Geschehen wird zunächst auf vier *ganz willkürliche* raum-zeitliche Variable bezogen. Diese müssen dann, wenn den Erhaltungssätzen des Impulses und der Energie Genüge geleistet werden soll, derart spezialisiert werden, dass nur (ganz) *lineare* Substitutionen von einem berechtigten Bezugssystem zu einem anderen führen. Das Bezugssystem ist der bestehenden Welt mit Hilfe des Energiesatzes sozusagen angemessen und verliert seine nebulose apriorische Existenz." Einstein to Ernst Mach, second half of December 1913, (CPAE 5, Doc. 495).

120 For more detailed discussion of both the contents and the dating of this document, see "What Did Einstein Know ..." (in vol. 2 of this series).

121 For a facsimile reproduction of these pages, see (Renn 2005a, 126–130).

122 This pattern is made evident also by the arrangement of problems and answers on these pages, the answers being often written in a slightly different hand than the questions and squeezed in between the lines or at the margin.

In his notes on the first problem, Besso summarized the failure of Einstein's hopes to fully implement his Machian heuristics within the *Entwurf* theory. Besso noted that it was impossible to conceive of rotation as equivalent to a state of rest in a gravitational field that is a solution of the *Entwurf* field equations.[123] This represented a challenge either for the *Entwurf* theory or the generalized principle of relativity. In the consolidation period of the *Entwurf* theory the decision was made in favor of the theory. That was bound to change only in the context of Einstein's renewed exploratory phase in the fall of 1915. In his notes Besso studied the question of whether the failure of the *Entwurf* theory to interpret rotation as a state of rest can possibly be explained by a failure of the conservation principle in a rotating system. If that were so, he would have succeeded in establishing the desired physical connection between the problem of implementing the generalized relativity principle and the restriction of the admissible coordinate systems required by the conservation principle. The remainder of the text, probably going back to Einstein's intervention, shows that this attempt of explaining the problem with rotation in terms of the conservation principle does not work.

In a second passage, Besso posed a more general question concerning the role of energy-momentum conservation for the selection of admissible coordinate systems:

> Is every system that satisfies the conservation laws a justified system?[124]

If the conservation principle is really the explanation for the restriction on the choice of coordinate systems, it should not only be a necessary but also a sufficient condition for this choice. Besso therefore wondered whether *any* coordinate system satisfying the constraints imposed by the conservation laws is compatible also with the covariance of the field equations. Since there is no note which may be traced back to a reaction by Einstein on this issue, it seems that he did, at first, not seriously consider Besso's suggestion. In fact, given Einstein's belief at that point that the conservation equation (51) is covariant under linear transformations only, the question may have held little interest for him since it offered no promise of generalizing the covariance properties of the *Entwurf* field equations beyond linearity. Eventually, however, when Einstein turned to the exploration of a mathematical strategy for the *Entwurf* theory, he did realize, as we shall see, the significance of Besso's question.

After writing down his second question, Besso sketched an idea of how the failure of realizing general covariance on the level of the gravitational field equation might be explained, namely as a problem of the uniqueness of its solutions. The text of his third problem reads:

> The requirement of [general] covariance of the gravitational equations under arbitrary transformations cannot be imposed: if all matter [is given] were contained in one part of space and for this part of space a coordinate system [is given], then outside of it the coordinate system could still [essentially] except for boundary conditions be chosen arbi-

123 See "What Did Einstein Know ..." sec. 3 (in vol. 2 of this series).

124 "Ist jedes System, welches den Erhaltungssätzen genügt, ein berechtigtes System?"

> trarily, [through which the g arbitrarily] so that a unique determinability of the g ’s cannot be obtained.
>
> It is, however, not necessary that the g themselves are determined uniquely, only the observable phenomena in the gravitation space, e.g., the motion of a material point, must be.[125]

In this passage Besso imagines a central mass to be surrounded by empty space and wonders whether the solution for the metric tensor is, in this case, determined uniquely for the empty region. His mental model appears to be the inverse of Einstein’s famous hole argument where matter may be anywhere outside an empty hole for which the problem of the ambiguity of solutions then supposedly arises. In Besso’s argument the ambiguity of solutions is conceived as being due to the arbitrary choice of the coordinate system in the empty region, giving rise to arbitrary coordinate expressions for the metric tensor (which have to satisfy, however, the boundary conditions). Apart from the inversion of hole and matter, Besso’s “proto-hole argument” thus corresponds to the primitive version of the hole argument that was traditionally ascribed to Einstein, charging him with the naivety of being unaware that different coordinate representations of the metric tensor do not correspond to different solutions of the field equations. It is therefore remarkable that even Besso immediately realized the flaw of this naive version since he added, in the second paragraph of the above text, that only observable phenomena, such as the motion of a particle, should be determined uniquely.

How did Besso’s idea emerge and how was it transformed into the hole-argument familiar from Einstein’s later publications? As to the first question, it seems plausible that Besso related, in the context of his reflections on the *Entwurf* theory, the problem of the restriction of general covariance to other problems that had arisen for this theory, in particular in the course of his joint research with Einstein. One such problem was rotation, as we have just seen. Another problem was the perihelion shift of Mercury, the central subject of a paper Besso planned to write.

In 1913 Besso had in fact encountered the problem of uniqueness when he worked on the perihelion problem in the context of the *Entwurf* theory. In fact, a note in the Einstein-Besso manuscript explicitly refers to the question of uniqueness in connection with the ansatz used for solving the *Entwurf* field equation by an approximation procedure. For the first step of that iterative procedure Einstein and Besso had used a metric with only one variable component, the same spatially flat metric (25)

125 “Die Anforderung der [allgemeinen] Covarianz der Gravitationsgleichungen für beliebige Transformationen kann nicht aufgestellt werden: wenn in einem Teile des Raumes alle Materie [gegeben ist] enthalten wäre und für diesen Teil ein Coordinatensystem, so könnte doch ausserhalb desselben das Coordinatensystem noch, [im wesentlichen] abgesehen von den Grenzbedingungen, beliebig gewählt werden, [wodurch die g beliebig eine] so dass eine eindeutige Bestimmbarkeit der g s nicht eintreten könne.
Es ist nun allerdings nicht nötig, dass die g selbst eindeutig bestimmt sind, sondern nur die im Gravitationsraum beobachtbaren Erscheinungen, z.B. die Bewegung des materiellen Punktes, müssen es sein.”

that is also crucial for obtaining the Newtonian limit of the *Entwurf* theory. Besso then wondered whether that choice of a metric was sufficiently general for recovering all possible solutions of the field equation:

> Is the static gravitational field in § 1 $g_{\mu\nu} = 1$, 1 to 3 $g_{44} = f(x, y, z)$ a particular solution? Or is it the general solution expressed in particular coordinates?[126]

It may have been this question arising in the context of the perihelion calculation that suggested to Besso that covariant field equations suffer, in general, from a problem of uniqueness. In fact, the physical model of Besso's proto-hole argument is strikingly similar to that of the perihelion problem, a central mass surrounded by empty space. And when Besso reminded himself that it was not the expression for the metric tensor that mattered but physically observable phenomena, he chose the motion of a material particle, such as that of Mercury around the sun, as an example.

How did Einstein react to Besso's consideration of the proto-hole argument and how did the definitive version of the hole argument emerge? Einstein's reaction is, it seems, preserved in a text written below Besso's note quoted earlier. It starts, just as Einstein's earlier remark concerning rotation and energy conservation, with a characteristic "Of no use" ("Nützt nichts"):

> Of no use, since with [the] a solution a motion is also fully given. If in coordinate system 1, there is a solution K_1, then this same construct is also a solution in 2, K_2; K_2, however, also a solution in 1.[127]

Remarkably, Einstein did not simply agree with Besso's conclusion that the ambiguity of the coordinate representation of the metric tensor was of no physical consequence. He apparently found Besso's idea to justify the lack of general covariance of the *Entwurf* field equations on the basis of a uniqueness argument intriguing and effectively reinterpreted it as an argument about the nature of space and time, and, in particular, about the role of coordinate systems in identifying points in space and time. In fact, a solution of the field equation in a particular coordinate system, expressed in terms of functions representing the components of the metric tensor, can be transformed to another coordinate system, producing a different set of functions representing the same solution. But if, as Einstein's argument suggests, this set of functions "this same construct" ("dieses selbe Gebilde") can somehow be related to the original coordinate system, it there represents a different metric which, however, solves the same field equation, provided that the right-hand side of these equations remains unchanged by the coordinate transformation, which is the case for an empty region where the stress-energy tensor of matter vanishes. To avoid the issue of additional boundary conditions, it turned out to be convenient for Einstein to reverse the

126 "Ist das stat Schwerefeld des § 1 $g_{\mu\nu} = 1$, 1 bis 3, $g_{44} = f(x, y, z)$ ein spezielles? oder ist es das allgemeine, auf spec. Coordinaten zurückgeführtes" (CPAE 4, Doc. 14, [p. 16]).

127 "Nützt nichts, denn durch eine Lösung ist auch eine Bewegung voll gegeben. Ist im Koordinatensystem 1 eine Lösung K_1, so ist dieses selbe Gebilde auch eine Lösung in 2, K_2; K_2 aber eine Lösung in 1." For a facsimile of this passage, see Fig. 2 on p. 300 of "What Did Einstein Know ..." (in vol. 2 of this series) and (Renn 2005a, 128).

physical model proposed by Besso and consider, instead of a void with a lump of mass, matter with a hole in it—the well-known configuration of the hole argument.[128]

Einstein's interpretation of a solution initially given in one coordinate system as referring to another coordinate system implicitly presupposes that coordinate systems have their own physical reality and allow to identify points in spacetime. The crucial but hidden point of this reinterpretation of Besso's proto-hole argument is therefore a reification of coordinate systems, which are conceived as part of the physical set-up constituting a solution and not only as a mathematical device for describing it. Only the later refutation of the hole argument made it eventually clear that it is not "motions" in the sense used here which constitute physically real events but rather spacetime coincidences for which a coordinate-independent description can be given.[129]

Our reconstruction suggests that the hole argument was, in spite of its philosophical appeal, not rooted in a metaphysical prejudice concerning the nature of space and time or the role of coordinate systems, preventing Einstein from accepting generally-covariant field equations. On the contrary, it was the necessity of justifying a non-generally-covariant field equation that led to the construction of this argument, triggering a peculiar interpretation of the physical significance of coordinate systems, an interpretation moreover that largely remained implicit in the initial formulation of the argument. The hole argument was just the kind of argument Einstein had been after in his earlier attempts to justify the failure of general covariance: a mathematical argument related to the structure of space and time. It was this peculiar perspective, shaped by the context of the consolidation period of the *Entwurf* theory, that probably led him to take Besso's naive point seriously and search for a physically significant interpretation of a mathematically trivial property, the coordinate dependence of expressions for the metric tensor. It is hardly surprising that to formulate such an interpretation, Einstein relied on the conceptual resources of classical physics, implicitly defining what a motion is in terms of the relation between a particle and a coordinate system. As a result, he found a way of relating the formalism of absolute differential calculus to a physical interpretation of coordinate systems that allowed him to justify the restricted covariance of the *Entwurf* field equations. In short, the necessity of interpreting a complex mathematical formalism under a peculiar perspective was crucial for the emergence of the hole argument. Only when Einstein eventually succeeded in formulating physically acceptable, generally-covariant field equations did he abandon this argument and revise the physical interpretation of coordinate systems as well as of space and time associated with it.[130] The deep conceptual insight into the crucial role of spacetime coincidences was thus no presuppo-

sition of general relativity but merely a consequence of its establishment—effectively implying a refutation of the hole argument.

With the advent of the hole argument, the conservation principle lost its role as the primary physical reason for the restriction of general covariance of the *Entwurf* field equations; the restriction to linear transformations now merely appeared as a concrete result in harmony with a more general insight. Einstein reinterpreted his first argument defending the restricted covariance of the *Entwurf* field equation accordingly as a specific physical complement to what he saw as a general "logical" principle.[131] That he considered the hole argument not merely as an addition but as the solution of a puzzle left unresolved by the earlier physical argument is confirmed by a letter he wrote in the beginning of November 1913 to Ehrenfest:

> The gravitation affair has been clarified to my *complete satisfaction* (namely the circumstance that the equations of the gr. field are covariant only with respect to *linear* transformations. For it can be proved that *generally covariant* equations that determine the field *completely* from the matter tensor cannot exist at all. Can there be anything more beautiful than this, that the necessary specialization follows from the conservation laws?[132]

7.7 The Second Phase of the Consolidation Period of the Entwurf Theory: A Mathematical Strategy for the Entwurf Theory

The insights Einstein had acquired pursuing the mathematical strategy in the Zurich Notebook continued to set standards for his further elaboration of the *Entwurf* theory developed along the lines of the physical strategy. In particular, the procedure at the core of the mathematical strategy by which non-generally-covariant field equations could be extracted from a generally-covariant object remained plausible. Even if generally-covariant field equations were excluded for a satisfactory relativistic theory of gravitation, the physical and the mathematical strategies should converge because only in this way was it possible to fully clarify and stabilize the relation between the physical and the mathematical knowledge expressed in the theory. Even if Einstein had good reasons for restricting the generalized principle of relativity, it still made sense for him to search for a derivation of the field equations of the *Entwurf* theory along the mathematical strategy, albeit now with the aim of confirming what had

---

131 In a later paper he formulated with regard to these two arguments: "But there are two weighty arguments that justify this step [i.e. the restriction of general covariance], one of them of logical, the other one of empirical provenance" ("Es gibt aber zwei gewichtige Argumente, welche diesen Schritt rechtfertigen, von denen das eine logischen, das andere empirischen Ursprungs ist", CPAE 4, Doc. 25, [178]).

132 "Die Gravitationsaffäre hat sich zu meiner *vollen Befriedigung* aufgeklärt (der Umstand nämlich, dass die Gleichungen des Gr. Feldes nur *linearen* Transformationen gegenüber kovariant sind. Es lässt sich nämlich beweisen, dass *allgemein kovariante* Gleichungen, die das Feld aus dem materiellen Tensor *vollständig* bestimmen, überhaupt nicht existieren können. Was kann es schöneres geben, als dies, dass jene nötige Spezialisierung aus den Erhaltungssätzen fliesst?" Einstein to Paul Ehrenfest, before 7 November 1913, (CPAE 5, Doc. 481).

already been found through the physical strategy. This approach is characteristic for what we call the "second phase" of the consolidation of the *Entwurf* theory.

It was probably in pursuing a mathematical strategy for the *Entwurf* theory that, in early 1914, Einstein discovered a flaw in his conservation argument for linear covariance. It turned out that the quantity representing the stress-energy of the gravitational field is not a tensor. Einstein thus realized that, while the conservation principle still requires a restriction on the admissible coordinate systems, this restriction was not as stringent as it had seemed before. The issue of the covariance properties of the *Entwurf* theory was therefore reopened since the hole argument only excluded general covariance but did not by itself prescribe a specific covariance group. It remained to be clarified, in particular, in which sense the transformational properties of the *Entwurf* field equation were restricted by the conservation principle, which now appeared as implying a "weak" restriction only taking full advantage perhaps of the leeway left by the hole argument.

A suggestion by the Zurich mathematician Paul Bernays made it possible for Einstein and Grossmann to return in early 1914 to the "bold" approach, once again exploring the transformational properties of the *Entwurf* field equation by direct calculation. Bernays suggested to derive the *Entwurf* field equation from a variational principle in order to be able to focus attention on a single scalar quantity, the Lagrangian, rather than on the complex tensorial objects constituting the field equation itself. Einstein and Grossmann succeeded indeed in finding a Lagrangian from which the *Entwurf* field equations could be derived. They found that this Lagrangian is invariant under transformations between coordinate systems specified solely by the requirement of energy-momentum conservation. The necessary restriction of covariance following from the conservation principle thus turned out to be also a sufficient one, just as Michele Besso had envisaged. This result seemed to be in perfect agreement also with the hole argument since the four additional equations resulting from the conservation principle were apparently just enough to remove the ambiguity in the metric field on which this argument turns.

With these results, attained by March 1914, the "defensive" and the "bold" approaches had converged and, once again, a sense of closure in the development of the *Entwurf* theory was reached, this time on a higher level than half a year earlier and more durable: it would last until October 1915. Einstein was convinced that he had obtained an optimal realization of the generalized relativity principle and that he had understood the profound reasons for the impossibility of general covariance. He even came to believe that the restriction of covariance imposed by the conservation principle in fact does not imply a restriction of the possible solutions to the field equation but merely a restriction of the possible coordinate systems in which these solutions can be expressed. Consequently, Einstein also became convinced that the *Entwurf* theory fully realized the equivalence principle and other heuristic ideas, such as a description of Minkowski spacetime in a rotating frame of reference as a special case of the gravitational field, in spite of the difficulties at the level of explicit calculations.[133]

The success of this exploration of the *Entwurf* theory along the lines of the mathematical strategy encouraged Einstein to undertake a new derivation of its field equations; he completed this derivation by the fall of 1914. By February 1914, he had abandoned his earlier conviction that the *Entwurf* field equation had no relation to the absolute differential calculus essential to the mathematical strategy. When Einstein took up the project of deriving the *Entwurf* field equation along the mathematical strategy, however, he did not start from the generally-covariant objects suggested by the original mathematical strategy as he had done in the Zurich Notebook. He rather generalized the variational derivation, developed together with Grossmann, into a mathematical formalism applicable not only to the *Entwurf* field equations but to other candidate field equations. He then searched for a mathematical reason to justify choosing the Lagrangian corresponding to the *Entwurf* equation and erroneously convinced himself that he had actually found such reasons.

7.8 A Prelude: The First Reawakening of the Mathematical Strategy

Einstein's failure to reach general covariance had been a target of criticism by his colleagues.[134] In January 1914 he wrote a paper in reply to such criticism (Einstein 1914b). Apart from presenting his arguments in favor of a restricted covariance of the *Entwurf* field equations such as the hole argument, he had to admit that the relation of this field equations to the generally-covariant objects of the absolute differential calculus was still an open problem. As a consequence, the relation between physical and mathematical strategies, which should have been just two different pathways to the same result, also remained unclear.

Defending the restricted covariance of the *Entwurf* theory, Einstein had to acknowledge that there are profound reasons why generally-covariant equations should exist which correspond to the *Entwurf* field equation (Einstein 1914b, 177–178). He argued that there must be, in modern terms, a coordinate-free representation of any meaningful mathematical relation between physical magnitudes. Ideally, the *Entwurf* equation should be derived from such a representation by a suitable specialization of the coordinate system. This would correspond to its derivation along the lines of the mathematical strategy. But as if to excuse himself for the failure to realize such a derivation, Einstein claimed that the hole argument and the argument from energy momentum conservation suggested that it would not be worthwhile to search for the generally-covariant counterpart of the *Entwurf* equation.[135]

In spite of this excuse Einstein embarked, at about the same time, on precisely such a search, albeit for another gravitation theory with restricted covariance properties serving as a toy model. On 19 February 1914 he submitted a joint paper with

Adriaan Fokker on a generally-covariant reformulation of Nordström's special relativistic theory of gravitation (Einstein and Fokker 1914). They demonstrated that the field equation of this theory, in its original version only Lorentz covariant, can in fact be obtained from a generally-covariant equation. Just as in the mathematical strategy employed in the Zurich Notebook, a generally-covariant expression derived from the Riemann tensor served as the starting point of their approach, from which a suitable left-hand side of the gravitational field equation was then obtained by imposing additional conditions on the metric tensor. In the case of the Nordström theory, the additional condition amounted to the requirement of the constancy of the speed of light. This additional condition in turn led to a restriction on the admissible coordinate systems, in this case to those systems which are adapted to the principle of the constancy of the velocity of light (Einstein and Fokker 1914, 326).

As a consequence of the successful reformulation of Nordström's theory in generally-covariant terms, it was only natural to search for an analogous reformulation also of the *Entwurf* theory, in spite of the skepticism which Einstein had expressed in his earlier paper. That such a search made sense was precisely the conclusion which Einstein and Fokker drew at the end of their joint paper:

> Finally, the role that the Riemann-Christoffel differential tensor plays in the present investigation suggests that this tensor may also open the way for a derivation of the Einstein-Grossmann gravitation equations that is independent of physical assumptions. The proof of the existence or nonexistence of such a connection would represent an important theoretical advance.[136]

In a footnote to the above passage, they added:

> The argument in support of the nonexistence of such a connection, presented in §4, p. 36 of "Entwurfs einer verallgemeinerten Relativitätstheorie" ["Outline of a Generalized Theory of Relativity"], did not withstand closer scrutiny.[137]

On the cited page of the *Entwurf* paper, Einstein and Grossmann had simply claimed that, in the case of field equations with restricted covariance, it was understandable that no relation to generally-covariant tensors could be established (Einstein and Grossmann 1913, 36). But in view of Einstein's realization that a connection with a generally-covariant formulation must exist for any physically meaningful theory, the failure to discover such a connection could no longer be defended in this simple way.

In their paper, Einstein and Fokker used a terminology for the relation between generally-covariant equations and field equations with restricted covariance that

136 "Endlich legt die Rolle, welche bei der vorliegenden Untersuchung der Riemann-Christoffelsche Differentialtensor spielt, den Gedanken nahe, daß er auch für eine von physikalischen Annahmen unabhängige Ableitung der Einstein-Großmannschen Gravitationsgleichungen einen Weg öffnen würde. Der Beweis der Existenz oder Nichtexistenz eines derartigen Zusammenhanges würde einen wichtigen theoretischen Fortschritt bedeuten." (Einstein and Fokker 1914, 328).

137 "Die in §4, p. 36, des "Entwurfs einer verallgemeinerten Relativitätstheorie" angegebene Begründung für die Nichtexistenz eines derartigen Zusammenhanges hält einer genaueren Überlegung nicht stand."

would soon become standard in the further analysis of the covariance properties of the *Entwurf* theory. They spoke, in particular, of "preferred" ("*bevorzugt*") coordinate systems, "adapted" ("*angepasste*") to a certain physical situation.[138] Nordström's theory and the terminology developed for its treatment helped to further pursue the questions which had to be answered for a derivation of the *Entwurf* theory along the lines of the mathematical strategy to succeed: What were the "preferred" coordinate systems of the *Entwurf* theory? And what was the physical condition to which these coordinate systems are "adapted"? Although Einstein must have believed that he had answers to these questions, given his argument in favor of a restriction to linear transformations from energy-momentum conservation, it remained open how these answers could assist him in relating the *Entwurf* theory to its unknown generally-covariant counterpart. It was the experience gathered with Nordström's theory that eventually helped him to make progress in this regard—by challenging the answers that had seemingly settled the fate of the generalized relativity principle in the *Entwurf* theory.

7.9 A First Consequence of the Return to the Mathematical Strategy

In early March Einstein wrote to his friends about a breakthrough in his work on the *Entwurf* theory.[139] By this time he had not only recognized the fallacy of his argument for restricted covariance from energy-momentum conservation but had also investigated, jointly with Marcel Grossmann, the covariance properties of the theory in a new way. This new analysis, contained in a joint paper published on 29 May 1914 (Einstein and Grossmann 1914), was based on the use of variational techniques which allowed them to pursue the bold approach of exploring covariance properties by direct calculation.

Einstein's breakthrough was prepared by his reflection on the relation between non-covariant and covariant formulations of a theory, substantiated by his analysis of Nordström's theory. In light of these considerations, the *Entwurf* theory appears as a specialization of a generally-covariant theory to coordinate systems which are adapted to a certain physical condition. In the case of the *Entwurf* theory, this physical condition was the validity of energy-momentum conservation in the sense of eq. (51).

If generally-covariant field equations are expressed in coordinates adapted to this condition, they should take on the form of the *Entwurf* field equation eq. (52).

In analogy to the treatment of the Nordström theory, eq. (51) should be considered as a condition on the metric tensor $g_{\mu\nu}$, providing the necessary coordinate restriction. But in Einstein's original version of the argument for restricted covariance from energy-momentum conservation, this equation does not so much *provide* a con-

138 See (Einstein and Fokker 1914, 326).

139 See Einstein to Paul Ehrenfest, before 10 March 1914, (CPAE 5, Doc. 512) and Einstein to Heinrich Zangger, ca. 10 March 1914, (CPAE 5, Doc. 513).

dition on the metric tensor, but actually *presupposes* one. In fact, the argument that eq. (51) is only covariant under linear transformations only works, as Einstein was aware, if it is assumed that $\boldsymbol{t}^{\mu\nu}$ has the same transformational behavior as $\boldsymbol{T}^{\mu\nu}$, i.e. if it is a generally-covariant object. However, $\boldsymbol{t}^{\mu\nu}$ is a coordinate-dependent expression.[140] While the assumption that it is generally covariant may have at first appeared plausible to Einstein in the light of his conviction that gravitational and other forms of energy should behave in the same way as sources of the gravitational field, this assumption becomes much less plausible once eq. (51) is seen as imposing a coordinate restriction on generally-covariant equations. That perspective requires in fact a much closer examination of its ingredients, since it is now the content rather than the form of the equation that matters. Apart from checking more closely the character of $\boldsymbol{t}^{\mu\nu}$, Einstein's earlier experience with what we have called the conservation compatibility check in the sense of eq. (XLIII) suggested expressing $\boldsymbol{T}^{\mu\nu} + \boldsymbol{t}^{\mu\nu}$ in this equation by means of the field equations so that eq. (51) becomes a condition merely in terms of the metric tensor and its derivatives. One thus obtains eq. (54) as a condition for the class of admissible coordinate systems.

This equation played a central role in Einstein's new approach to the problem of the covariance properties of the *Entwurf* field equation. It first appeared in Einstein's and Grossmann's 1914 paper[141] and expresses in fact a physically motivated coordinate restriction in a sense that was quite familiar to him from his experiences along the mathematical strategy in the Zurich Notebook. In distinction from the original mathematical strategy, however, the generally-covariant equation from which the *Entwurf* field equation should be derivable by means of this coordinate restriction was unknown. But finding this generally-covariant equation may have been precisely Einstein's point in formulating eq. (54). In summary, a reconsideration from the perspective of the mathematical strategy of the argument for restricted covariance based on energy-momentum conservation could have led Einstein both to see the fallacy of his original argument and to cast it into a new form.

This reconstruction is supported by the timing of the transformation of the original argument for a linear covariance of the *Entwurf* equations into an argument about a coordinate restriction in the sense of the Zurich Notebook. In the manuscript of a popular exposition on his theory,[142] which Einstein completed by the end of January 1914,[143] he still included the argument in its original form. When he submitted the paper for publication by March, 21, 1914, that is, before he left Zurich, the passage arguing for the linear covariance of the *Entwurf* field equation was cancelled. By the beginning of March, Einstein had already achieved a breakthrough along the varia-

---

140 There are a number of arguments by which Einstein could have seen his fallacy: 1) There are no generally-covariant tensors involving only the metric and its first order derivatives. 2) In a suitably chosen coordinate system, the stress-energy complex of the gravitational field $t_{\mu\nu}$ can be made to vanish.

141 See (Einstein and Grossmann 1914, 218).

142 The published version is (Einstein 1914c). For references to and transcriptions of the manuscript version, see the annotations in (CPAE 4, 621–622).

tional approach, as we know from his correspondence. The paper by Einstein and Fokker on Nordström's theory, on the other hand, in which, as we have also seen, the application of the mathematically strategy to the *Entwurf* theory is formulated as a program, was submitted on 19 February 1914. In other words, Einstein must have reformulated his argument based on the conservation principle at some point between the end of January and the beginning of March 1914, at the time or shortly after he was working on the application of the mathematical strategy to Nordström's theory.

With the discovery of the fallacy in the original argument, the question of the covariance properties of the *Entwurf* field equation was open again. While it was obvious that eq. (54) imposes a necessary condition on the coordinates systems "adapted" to this theory, it remained to be clarified whether this condition is also a sufficient one and how it related the *Entwurf* field equation to its generally-covariant counterpart. Einstein had thus arrived at a point where it made sense for him to take up the second point raised in Besso's notes:

> Is *every* system *that satisfies the conservation laws* a *justified* system?[144]

In the context of Einstein's reconsideration of the *Entwurf* field equation from the perspective of the mathematical strategy, the relation between conservation laws and "justified" coordinate systems must have assumed a new significance. Exploring whether or not this field equation actually retained its form under transformations between the "preferred" coordinate systems characterized by eq. (54) now became a pressing task. Unfortunately, the absolute differential calculus offered little help in addressing this task.

7.10 A New Turn for the Mathematical Strategy: Variational Calculus

When Einstein took up the mathematical strategy once again and adapted it to the *Entwurf* theory, he faced difficulties achieving concrete results along this strategy, and must have searched out mathematical advice. It is unclear at exactly which point Grossmann re-entered the story. Perhaps he was already instrumental in recognizing the fallacy of Einstein's original argument for restricted covariance from energy-momentum conservation. Perhaps he entered the picture only when Einstein needed help in exploring the consequences of the new coordinate restriction eq. (54). But Grossmann was, it seems, as little successful as Einstein in establishing relations between the *Entwurf* theory and absolute differential calculus. At some point they both turned to another Zurich mathematician colleague, Paul Bernays, for help.[145] Bernays advised Einstein and Grossmann to bring the field equation of the *Entwurf* theory into the form of a variational principle.[146]

The reformulation of the *Entwurf* theory in terms of a variational principle did not, however, provide any clue concerning the relation of this theory to absolute dif-

144 "Ist *jedes* System, *welches den Erhaltungssätzen genügt*, ein *berechtigtes* System?" For a facsimile of this passage, see Fig. 2 on p. 300 of "What Did Einstein Know ..." (vol. 2 of this series).

ferential calculus. The latter would have suggested, as it later did to Hilbert, to take the Ricci scalar as a starting point for such a reformulation. But, by analyzing the relation of this scalar to the B_μ of their coordinate restriction, Einstein and Grossmann convinced themselves that the B_μ do not form a generally-covariant vector and that the *Entwurf* field equation has nothing to do with the invariant Ricci scalar.[147] Nevertheless, a variational reformulation of the *Entwurf* had, for Einstein and Grossmann, one chief advantage: instead of having to study the covariance properties of a complex tensorial field equation, they could instead explore the invariance group of a single scalar object, the action integral (cf. eq. (LXIV)). Much later Einstein still considered the simplification due to the introduction of the more familiar scalar quantities the main advantage of the variational calculus.[148]

In early 1914, the suggestion to make use of the variational calculus brought Einstein and Grossmann back to the initial bold approach of exploring by direct calculation the covariance properties of the *Entwurf* field equation. In pursuing this approach they could rely on their experience from the Zurich Notebook where they had attempted to study the covariance properties of objects found along the physical strategy or of coordinate restrictions by means of infinitesimal transformations.

However, one crucial presupposition of the new approach had to be established first, the expression for the action integral from which the *Entwurf* field equation could be derived by means of the variational formalism. In their 1914 paper Einstein and Grossmann only give the end result, without mentioning what had motivated them to introduce a particular Langrangian, other than its successful employment in deriving the field equations.[149] Probably they found the Lagrangian of the *Entwurf* theory by starting from an expression quadratic in the fields in analogy to classical and special-relativistic physics according to the default setting eq. (LXIII). With Einstein's default setting for the components of the gravitational field, the Lagrangian required for deriving the *Entwurf* field equation was found to be:

$$L = g^{\mu\nu} g_{\beta\mu,\alpha} g_{\alpha\nu,\beta} = g^{\mu\nu} \tilde{\Gamma}^{\alpha}_{\beta\mu} \tilde{\Gamma}^{\beta}_{\alpha\nu}. \tag{85}$$

145 Bernays later became known for his work in mathematical logic and set theory, was in Zurich from 1912 to 1919 after completing a mathematical doctoral thesis on the analytic theory of binary quadratic forms under the supervision of the mathematician E. Landau. Before coming to Zurich, Bernays had spent two years in Göttingen studying mathematics and physics chiefly with Hilbert, Landau, Weyl, Klein, Voigt and Born. Bernays was at the time concerned with an extension of the special theory of relativity.

146 In their paper, Einstein and Grossmann acknowledge the stimulation received from Bernays in a footnote (Einstein and Grossmann 1914, 218).

147 See (Einstein and Grossmann 1914, 225).

148 Einstein to Lorentz, 19 January 1916 and Einstein to T. De Donder, 23 July 1916 (CPAE 8, Docs. 184 and 240).

149 See (Einstein and Grossmann 1914, 219).

The *Entwurf* theory was thus solidified by connecting its field equation in yet another way with the established knowledge of classical and relativistic physics, in this case about the canonical form of a Lagrangian.

The identification of both the Langrangian for the *Entwurf* field equation and of a physically motivated coordinate restriction now gave Einstein and Grossmann a clear definition of their next goal, the establishment of a relation between the coordinate restriction and the transformational properties of this Lagrangian. Does the coordinate restriction eq. (54) resulting from the conservation principle indeed constitute not only a necessary but also a sufficient condition for the covariance of the *Entwurf* Lagrangian? In that case, by establishing a connection between conservation and covariance, Einstein would have achieved a result effectively preparing the later Noether theorem.[150] The close connection between conservation and covariance, first suggested by the ill-fated argument for a restriction of the *Entwurf* theory to linear transformations, became a heuristic guiding principle for Einstein's further exploration and a criterion that he expected a satisfactory theory to fulfill.

The means to answer his question concerning the covariance properties of the *Entwurf* Lagrangian was provided by the infinitesimal coordinate transformations explored earlier in the Zurich Notebook. With their help, Einstein and Grossmann succeeded in establishing a connection between the transformational properties of the action integral for the *Entwurf* Lagrangian and the physically motivated coordinate restriction eq. (54). Their bold approach had finally given them what they had failed to achieve with the help of the absolute differential calculus—a link between the physical and the mathematical strategies.

7.11 Looking Back on a Breakthrough: The General Relativity of the Entwurf *Theory*

With their proof of the covariance properties of the *Entwurf* field equations, Einstein and Grossmann had finally closed the crucial gap in their 1913 publication. But in Einstein's view, they had achieved much more. In the time between the completion of this proof by early March 1914 and the discovery of a problem with transformations to rotating frames of reference in September 1915, he was convinced that he had finally reached not only a generalization of the relativity principle but a truly general theory of relativity. In early March he wrote to Paul Ehrenfest that the proof of the existence of "most general transformations" leaving the field equations covariant demonstrated the validity of the principle of equivalence as well:

> The work on gravitation progresses, but at the cost of extraordinary efforts; gravitation is coy and unyielding! The equivalence principle is valid after all in the sense that there exist highly general transformations that transform the gravitational equations into themselves. What has been found is simple, but the search is hell![151]

In a similar vein he expressed himself in a contemporary letter to Heinrich Zangger:

---

150 See "Untying the Knot ..." (in this volume).

> I was toiling again on the gravitation theory to the point of exhaustion, but this time with unheard-of success. That is to say that I succeeded in proving that the gravit. equations hold for arbitrarily moving reference systems, and thus that the hypothesis of the equivalence of acceleration and the gravitational field is absolutely correct, in the widest sense. Now the harmony of the mutual relationships in the theory is such that I no longer have the slightest doubt about its correctness.[152]

In these passages Einstein left it somewhat open what he meant by qualifying the covariance he had reached as "most general" or "in the widest sense." In another contemporary passage he showed himself convinced that the transformation to a rotating coordinate system was comprised by this covariance:

> By means of a *simple* calculation I have been able to prove *that the gravitation equations hold for every reference system that is adapted to this condition*. From this it follows that there exist acceleration transformations of the most varied kind that transform the equations to themselves (e.g., also rotation), so that the equivalence hypothesis is preserved in its original form, even to an unexpectedly large extent.[153]

The "simple calculation" to which Einstein refers must be the demonstration of the covariance properties of the *Entwurf* equation published jointly with Grossmann, since he emphasizes the crucial element of this demonstration, the condition for adapted coordinate systems. He obviously perceived the more specific properties of the field equation, such as its covariance under rotation, as being merely a trivial consequence of this proof. Einstein thus believed he had achieved a full implementation of the generalized principle of relativity.

Yet, the exact relation of the *Entwurf* field equation to the absolute differential calculus had not been clarified. It seems, however, that Einstein did not bother too much about this problem. When he learned that Grossmann had finally succeeded in establishing such a relation, Einstein viewed this result as a nice complement to what they had already achieved earlier but not more. In late March or early April 1914 he wrote to Ehrenfest:

---

151 "Die Gravitation macht Fortschritte, aber unter ausserordentlichen Anstrengungen; sie ist spröde! Das Aequivalenzprinzip gilt nun doch in dem Sinne, dass es höchst allgemeine Transformationen gibt, die die Gravitationsgleichungen in sich überführen. Das Gefundene ist einf[a]ch, aber das Suchen ganz verflucht." Einstein to Paul Ehrenfest, before 10 March 1914, (CPAE 5, Doc. 512).

152 "Ich habe mich wieder bis zur Erschöpfung geplagt mit der Gravitationstheorie, aber diesmal mit unerhörtem Erfolge. Es ist nämlich der Beweis gelungen, dass die Gravit. Gleichungen für beliebig bewegte Bezugssysteme gelten, dass also die Hypothese von der Aequivalenz der Beschleunigung und des Gravitationsfeldes durchaus richtig ist, im weitesten Sinne. Nun ist die Harmonie der gegenseitigen Beziehungen in der Theorie eine derartige, dass ich an der Richtigkeit nicht mehr im Geringsten zweifle." Einstein to Heinrich Zangger, 10 March 1914, (CPAE 5, Doc. 513).

153 "Ich habe beweisen können durch eine *einfache* Rechnung, *dass die Gleichungen der Gravitation für jedes Bezugssystem gelten, welches dieser Bedingung angepasst ist*. Hieraus geht hervor, dass es Beschleunigungstransformationen mannigfaltigster Art gibt, welche die Gleichungen in sich selbst transformieren (z.B. auch Rotation), sodass die Aequivalenzhypothese in ihrer ursprünglichen Form gewahrt ist. sogar in ungeahnt weitgehendem Masse." Einstein to Michele Besso, ca. 10 March 1914, (CPAE 5, Doc. 514), Einstein's emphasis. The "einfache Rechnung" probably refers to the covariance proof. For an alternative interpretation, see (Janssen 1999, n. 125).

> Grossmann wrote me that now he also is succeeding in deriving the gravitation equations from the general theory of covariants. This would be a nice addition to our examination.[154]

The more Einstein thought about the proof of the covariance properties of the *Entwurf* field equation he had jointly developed with Grossmann, the more he became convinced that what he had reached was general covariance. This is apparent from his ever more optimistic assessments of their result. In June 1914 Einstein wrote to Wien:

> In Zurich I had found the proof for covariance in the gravitation equations. Now the theory of relat[ivity] really is extended to arbitrarily moving systems.[155]

In July Einstein wrote to Planck, also claiming that he had now his theory covered every possible manifold and that the restriction was only one of the coordinate system:

> Then also a brief reply to a comment you made recently at the Academy in the welcoming speech. There is an essential difference between the reference system restriction introduced by classical mechanics for the theory of relativity and that which I apply in the theory of gravitation. For the latter can always be adopted no matter how the $g_{\mu\nu}$'s may be selected. To the contrary, the specialization introduced by the principle of the constancy of the velocity of light presupposes differential correlations between the $g_{\mu\nu}$'s, that is, correlations that ought to be very difficult to interpret physically. Satisfaction of these correlations cannot be forced by the appropriate choice of a reference system for any given manifold.[156]

According to the explanation given to Planck, Einstein considered the principal distinction between the specialization of the reference system in classical mechanics and in the special theory of relativity, on the one hand, and that which he had introduced in his new gravitation theory, on the other hand, to be the fact that in the latter case the specialization of the reference system refers only to the choice of the coordinate system in an otherwise arbitrarily given manifold. Einstein made this point particu-

---

154 "Grossmann schreibt mir, dass es ihm nun auch gelingt, die Gravitationsgleichungen aus der allgemeinen Kovariantentheorie abzuleiten. Es wäre dies eine hübsche Ergänzung zu unserer Untersuchung." Einstein to Paul Ehrenfest, 10 April 1914, (CPAE 8, Doc. 2).

155 "In Zürich fand ich noch den Nachweis der Kovarianz der Gravitationsgleichungen. Nun ist die Relat[ivitäts]theorie wirklich auf beliebig bewegte Systeme ausgedehnt." Einstein to Wilhelm Wien, 15 June 1914, (CPAE 8, Doc. 14).

156 "Sodann noch eine kurze Beantwortung einer Bemerkung, die Sie neulich in der Akademie in der Begrüssungsrede geäussert haben. Es gibt einen prinzipiellen Unterschied zwischen derjenigen Spezialisierung des Bezugssystems, welche die klassische Mechanik bezw. die Relativitätstheorie einführt und zwischen derjenigen, welche ich in der Gravitationstheorie anwende. Die letztere kann man nämlich stets einführen, wie auch die $g_{\mu\nu}$ gewählt werden mögen. Diese durch das Prinzip der Konstanz der Lichtgeschwindigkeit eingeführte Spezialisierung dagegen setzt Differenzialbeziehungen zwischen den $g_{\mu\nu}$ voraus, und zwar Beziehungen, deren physikalische Interpretation sehr schwierig sein dürfte. Das Erfülltsein dieser Beziehungen kann nicht für jede gegebene Mannigfaltigkeit durch passende Wahl des Bezugssystems erzwungen werden." Einstein to Max Planck, 7 July 1914, (CPAE 8, Doc. 18).

larly clear in a letter he wrote to Lorentz a few months later. In this letter Einstein explained in what sense the restriction to adapted coordinate systems in his understanding was compatible with the claim that the theory would be a "general" theory of relativity. He referred to an analogous situation in the Gaussian theory of surfaces:

> Although I prefer certain reference systems, the fundamental difference to the Galilean preference is, however, that my coordinate selection makes no physical assumptions about the world; let this be illustrated by a geometric comparison. I have a plane of unknown description which I want to subject to geometric analysis. If I require that a coordinate system (p, q) on the plane be selected in such a way that
>
> $$ds^2 = dp^2 + dq^2,$$
>
> I therefore assume that then the surface can be unfolded on to a [Euclidean] plane. Were I only to demand, however, that the coordinates be chosen in such a way that
>
> $$ds^2 = A(p, q)dp^2 + B(p, q)dq^2$$
>
> i.e., that the coordinates be orthogonal, then I am assuming nothing about the nature of the surface; this can be obtained on any surface.[157]

The analogy with Gaussian surface theory suggests a geometrical interpretation of the coordinate restriction introduced in Einstein's theory of gravitation. A letter Einstein wrote in 1915 to Paul Hertz shows that he had searched in vain for such an interpretation and that for elucidating the meaning of this coordinate restriction, he had little more to offer than the comparisons he mentioned in the letter to Lorentz.

> He who has wandered aimlessly for so long in the chaos of possibilities understands your trials very well. You do not have the faintest idea what I had to go through as a mathematical ignoramus before coming into this harbor. Incidentally, your idea is very natural and would by all means be worth following up, if it could be carried through at all, which, based upon my experiences gathered during my wayward wanderings, I doubt very much.
>
> Given an arbitrary manifold of 4 dimensions (given $g_{\mu\nu}(x_\sigma)$). How can one distinguish a coordinate system or a group of such? This appears not to be possible in any way simpler than the one chosen by me. I have groped around and tried all sorts of possibilities, e.g., required: The system must be chosen such that the equations
>
> $$\sum_\nu \frac{\partial g^{\mu\nu}}{\partial x_\nu} = 0 \qquad (\mu = 1-4)$$

157 "Ich bevorzuge zwar auch gewisse Bezugssysteme, aber der fundamentale Unterschied gegenüber der Galileischen Bevorzugung besteht darin, dass meine Koordinatenwahl nichts über die Welt voraussetzt; dies sei durch einen geometrischen Vergleich erläutert. Es liegt mir eine Fläche unbekannter Art vor, auf der ich geometrische Untersuchungen machen will. Verlange ich, es solle auf der Fläche ein Koordinatensystem (p, q) so gewählt werden, dass $ds^2 = dp^2 + dq^2$, [s]o setze ich damit voraus, dass die Fläche auf eine Ebene abwickelbar sei. Verlange ich aber nur, dass die Koordinaten so gewählt seien, dass $ds^2 = A(p, q)dp^2 + B(p, q)dq^2$ ist, d.h. dass die Koordinaten orthogonal seien, so setze ich damit über die Natur der Fläche nichts voraus; man kann dies auf jeder Fläche erzielen." Einstein to H.A. Lorentz, 23 January 1915, (CPAE 8, Doc. 47).

> are satisfied throughout.
> At least it seemed definite to me *a priori* that a transformation group exceeding the Lorentz group must exist, because those observations summed up in the words "relativity principle" and "equivalency principle" point to it.
> The coordinate limitation that was finally introduced deserves particular trust because it establishes a link between it and the postulate of the event's complete determination.
> A theoretical differential geometric interpretation of preferred systems would be of great value. The weakest point of the theory as it stands today consists precisely in this, that the group of justified transformations are by no means closely assessable. There is not even any *exact* proof that arbitrary motions can be transformed to motionlessness.[158]

The letter shows that Einstein saw all coordinate restrictions he had examined to function essentially on the same level, that is, to be generally imposed as conditions supplementary to the field equations; this is made clear by his formulation that he assumed what we have called the "Hertz restriction" eq. (60) to be satisfied "everywhere." He evidently treated the Hertz restriction on the same level as the condition eq. (54) for adapted coordinate systems, despite their different form. Both conditions were motivated, as we have seen, by the conservation principle. But, as Einstein points out in his letter, the condition for adapted systems could also be justified on a deeper level; the causality considerations were related to the hole argument, and therefore inspired more confidence. The letter to Hertz furthermore confirms that Einstein was convinced that this condition just implies a particular choice of the coordinate system without restricting the range of possible manifolds. He implicitly claimed that, in the *Entwurf* theory, all motions can be transferred to rest, although he admitted that he had been unable to demonstrate this "exactly."

---

158 "Wer selber im Chaos der Möglichkeiten sich so viel herumgetrieben hat, begreift Ihre Schicksale sehr gut. Sie haben ja keine blasse Ahnung, was ich als mathematischer Ignorant habe durchmachen müssen, bis ich in diesen Hafen eingelaufen bin. Übrigens ist Ihre Idee sehr natürlich und wäre auf jeden Fall ernster Verfolgung wert, wenn sie sich überhaupt durchführen liesse, was ich auf Grund meiner im Herumirren allmählich angesammelten Erfahrung sehr bezweifle.
Gegeben eine beliebige Mannigfaltigkeit von 4 Dimensionen ($g_{\mu\nu}(x_\sigma)$ gegeben). Wie kann man ein Koordinatensystem bezw. eine Gruppe von solchen auszeichnen? Es scheint dies auf einfacher als die von mir gewählte Art nicht möglich zu sein. Ich habe herum getastet und alles Mögliche versucht, z.B. verlangt: Das System soll so gewählt werden, dass überall die Gleichungen [eq.] erfüllt seien.
Immerhin schien es mir a priori sicher, dass eine über die Lorentz-gruppe hinausgehende Transformationsgruppe vorhanden sein müsse, da jene Erfahrungen, die mit den Worten Relativitätsprinzip, Aequivalenzprinzip zusammengefasst werden, darauf hinweisen.
Die schliesslich eingeführte Koordinatenbeschränkung verdient deshalb besonderes Vertrauen, weil sie sich mit dem Postulat der vollständigen Bedingtheit des Geschehens in Zusammenhang bringen lässt.
Eine flächentheoretische Interpretation der bevorzugten Systeme wäre von sehr grossem Werte. Der schwächste Punkt der Theorie bei ihrem heutigen Stande besteht nämlich gerade darin, dass man die Gruppe der berechtigten Transformationen durchaus nicht scharf übersieht. *Exakt* ist nicht einmal der Beweis geliefert, dass beliebige Bewegungen auf Ruhe transformiert werden können." Einstein to Paul Hertz, 22 August 1915, (CPAE 8, Doc. 111). For an extensive discussion of this letter, see (Howard and Norton, 1993).

In spite of such reservations, Einstein was nevertheless convinced that he had reached all his major original heuristic goals within the *Entwurf* theory. What remained were only some minor problems, such as the establishment of the connection of the methods used by Einstein and Grossmann to the absolute differential calculus, and a clarification of some other mathematical aspects of the theory. Einstein also had the impression that the crucial proof of the covariance properties of the *Entwurf* field equation still required improvement. This was the task he set himself in mid-1914 in the context of composing a major review article, finished by the end of October and providing a full exposition of the finally complete theory which now was called, for the first time, the "general theory of relativity" (Einstein 1914a).

7.12 The Revised Covariance Proof and the Definitive Formulation of the Hole Argument[159]

When at the end of 1914 Einstein looked back on his first review article on general relativity, entitled "The Formal Foundations of General Relativity" and submitted on 29 October 1914, the revision of the covariance proof appeared to him as the central achievement, as is suggested in a letter he wrote in December to Paul Ehrenfest:

> In recent months I reworked extremely carefully the basis of the general theory of rel. The covariance proof of last spring was not yet completely right. Otherwise, I have also been able to penetrate a few things more clearly. Now I am entirely satisfied with that matter. You will soon receive the paper; read it, you will find it very enjoyable.[160]

The proof of the covariance properties of the *Entwurf* field equation as originally conceived by Einstein and Grossmann was based on the idea that an infinitesimal, adapted coordinate transformation leaves the variation of the action integral invariant. The variation of the manifold giving rise to the variation of this integral had to be performed in two steps, an "adapted" variation, making it possible to vary the coordinate system along with the manifold so that it remains adapted to it, and a variation of the manifold that merely corresponds to the introduction of a new coordinate system, a "coordinate variation." The problem with the original proof was that the first of these two variations was not clearly defined. In fact, Einstein and Grossmann had obvious difficulties in arguing for the possibility of an appropriate variation of the adapted coordinate system "following" that of the manifold. This variation of the coordinate system was introduced rather as an afterthought to the variation of the manifold, an afterthought which left open exactly how the variation of the manifold is restricted by the condition that it must be possible to vary the adapted coordinate system along

---

159 See (Cattani and De Maria 1989b).

160 "In den letzten Monaten habe ich die Grundlage der allgemeinen Rel Theorie nochmals höchst sorgfältig bearbeitet. Der Kovarianzbeweis vom letzten Frühjahr war noch nicht ganz in Ordnung. Auch sonst habe ich manches klarer durchdringen können. Nun bin ich aber völlig zufrieden mit der Angelegenheit. Du erhälst bald die Arbeit, lies sie, Du wirst grosse Freude daran finden." Einstein to Paul Ehrenfest, December 1914 (CPAE 8, Doc. 39).

with it. The origin of Einstein's difficulties was his concept of a manifold being closely tied to its representation by the metric tensor and hence lacked the clear-cut distinction from the representation of a manifold in terms of coordinates.[161]

At the outset of his new approach, Einstein distinguished more clearly a variation of the manifold and a variation of the coordinate system. It was probably for the purposes of such a cleaner separation of the different kinds of variations that he treated coordinate systems—as suggested by the hole argument and in contrast to the modern understanding—as being essentially given independently from the manifold for whose description they serve. Einstein believed that in this way he could refer to two different manifolds, or rather one manifold before and, after the variation, to one and the same coordinate system.[162] The ensuing challenge to refer changes of the values of the metric tensor due to a coordinate transformation to one and the same coordinate system, given independently from the manifold, may well have induced him to formulate more clearly than he had done before the artifice of transposing values of the metric tensor characteristic of the hole argument.

Einstein's treatment of the hole argument in his 1914 review paper is in fact the first published version of this argument that makes plain how values of the metric tensor given at one point of the manifold are to be referred to another point, a notion implicit in its original formulation in late August 1913 but obscured in the subsequent published presentations. It is also the first version that introduces a distinct notation for the metric tensor and its representation in a particular coordinate system.[163] The mature and more elaborate formulation of the hole argument was hence closely associated with the reworking of the covariance proof. Revisiting, together with Marcel Grossmann, the covariance properties of the *Entwurf* field equation, Einstein arrived at a formulation of this argument that now pointed to philosophical questions concerning the mathematical representation of the physical properties of space and time.

7.13 A Shaky Mathematical Derivation and a Spin-off with Consequences

In the introduction to his 1914 review paper Einstein mentioned the peculiar combination of physical and mathematical arguments that led him to the *Entwurf* theory and announced a purely mathematical derivation:

> In recent years I have worked, in part together with my friend Grossmann, on a generalization of the theory of relativity. During these investigations, a kaleidoscopic mixture of postulates from physics and mathematics has been introduced and used as heuristical tools; as a consequence it is not easy to see through and characterize the theory from a formal mathematical point of view, that is, only based upon these papers. The primary

---

161 See (Norton 1992b).

162 See (Einstein 1914a, 1071–1073). Einstein conceived a variation of the metric tensor generated by a coordinate transformation, referring its result to the same original coordinate system. His transformation can thus not be an ordinary coordinate transformation, but must be the kind of transport of values of the metric tensor from one coordinate system to the other as it is essential to the hole argument.

163 See (Einstein 1914a, 1067).

> objective of the present paper is to close this gap. In particular, it has been possible to obtain the equations of the gravitational field in a purely covariance-theoretical manner ... .[164]

The basis for this derivation was provided by the variational formalism. In their paper of early 1914, Einstein and Grossmann had, as we have seen, solved the problem of identifying an appropriate Lagrangian from which the *Entwurf* equations were derived. Since their Lagrangian now represented the natural starting point for building up the entire edifice of Einstein's theory, the question arose whether this Lagrangian could be justified by reasons other than that of generating the desired field equation. In order to answer this question, Einstein generalized the formalism jointly developed with Grossmann to apply to an arbitrary Lagrangian. While this generalization was rather straightforward, it was a more challenging task to pinpoint the assumptions by which the resulting formalism could be specialized again so as to determine the Lagrangian appropriate for the *Entwurf* field equation. Einstein's approach was effectively guided by the mathematical strategy presupposing a generic mathematical object, which is then specialized in light of concrete physical requirements. In the generalized formalism of his 1914 review paper, such physical requirements had to be formulated as mathematical criteria serving to select the *Entwurf* Lagrangian.

It was a combination of two criteria that helped Einstein to achieve this goal, one derived from the conservation principle, the other from the generalized principle of relativity. He formulated both criteria in terms of differential conditions for the Lagrangian and concluded, erroneously as it later turned out, that the requirement of their compatibility singles out a particular candidate. In the *Entwurf* theory, the implementation of the conservation principle imposed, as we have seen, a coordinate restriction $B_\mu = 0$ (cf. eq. (54)). This condition played, as we have also seen, the double role of ensuring the satisfaction of the conservation principle and of determining the covariance properties of the field equation. The exact same equation $B_\mu = 0$ also played a role in Einstein's interpretation of the generalized theory, but here only in the context of analyzing its covariance properties. The formulation of the conservation principle within the generalized framework yielded a slightly different equation, now comprising two terms instead of one:

$$\sum_\nu \frac{\partial S_\mu^\nu}{\partial x_\nu} - B_\mu = 0. \tag{86}$$

164 "In den letzten Jahren habe ich, zum Teil zusammen mit meinem Freunde Grossmann, eine Verallgemeinerung der Relativitätstheorie ausgearbeitet. Als heuristische Hilfsmittel sind bei jenen Untersuchungen in bunter Mischung physikalische und mathematische Forderungen verwendet, so daß es nicht leicht ist, an Hand jener Arbeiten die Theorie vom formal mathematischen Standpunkte aus zu übersehen und zu charakterisieren. Diese Lücke habe ich durch die vorliegende Arbeit in erster Linie ausfüllen wollen. Es gelang insbesondere, die Gleichungen des Gravitationsfeldes auf einem rein kovarianten-theoretischem Wege zu gewinnen ... ." (Einstein 1914a, 1030)

The existence of two similar but not identical conditions could be turned into a compatibility argument identifying the *Entwurf* theory as a special case of the generalized formalism. He thus demanded:

$$S_\mu^\nu \equiv 0, \tag{87}$$

and claimed that this condition, together with the additional requirement that the Lagrangian be a homogeneous function of second degree in the gravitational fields, determines uniquely the *Entwurf* Lagrangian. Einstein's additional "mathematical" requirement has, as is the case for his other constraints, also physical aspects, here the analogy with the Lagrangian for a free electromagnetic field (cf. the default setting eq. (LXIII)). In his paper Einstein did not explicitly prove his claim. It may well have been his long-held conviction that the conservation principle determines uniquely the *Entwurf* field equation, that simply correlated with his belief that the *Entwurf* theory can be uniquely characterized with the help of eq. (87).

It turned out later that Einstein's reasoning was flawed. A more careful analysis of his formalism later showed him that eq. (87) did not actually impose a strong additional selective criterion, but could be easily fulfilled by simply requiring that the Lagrangian be an invariant under linear transformations, a criterion that does not help to single out the *Entwurf* theory. Einstein had imposed this requirement implicitly in the context of his analysis of the covariance properties and had effectively suppressed the condition involving S_μ^ν in this context, thus coming up with what appeared to be two different sets of conditions, one derived from the generalized principle of relativity, the other from the conservation principle. A deeper exploration of his formalism, first achieved about a year later, eventually offered him the insight that the analysis of the covariance and the conservation aspects actually implied the same set of conditions, an important step towards what later became Noether's theorem. This step was prepared by Einstein's seemingly successful attempt to derive the *Entwurf* theory along a mathematical strategy in which, alongside the conservation principle, covariance considerations had assumed the role of the correspondence principle in restricting the admissible candidate Lagrangians. More than anything else, it was the supposed achievement of being able to renounce the correspondence principle as part of Einstein's derivation that gave it the appearance of being largely independent of specific physical knowledge about gravitation (Einstein 1914a, 1076).

Nevertheless, what Einstein had achieved was satisfactory also from a physical point of view. In the course of his mathematical elaboration of the *Entwurf* theory, he had brought its field equation into a form satisfying all structural requirements following from the conservation principle. In particular, he succeeded in identifying, even for a generic Lagrangian, an expression for the stress-energy tensor of the gravitational field, i.e. for **FIELDMASS**. Furthermore, he was able to write the field equation in a form corresponding to eqs. (XLIV) and (XLV), thus demonstrating the structural analogy with classical field theory as well as the parallelism between the stress-energy tensor of matter and of the gravitational field as sources of the field. In this way, Einstein had built up a mathematical framework lending itself to direct physical interpretation:

> The system of equations (81) allows for a simple physical interpretation in spite of its complicated form. The left-hand side represents a kind of divergence of the gravitational field. As the right-hand side shows, this is caused by the components of the total energy tensor. A very important aspect of this is the result that the energy tensor of the gravitational field itself acts field-generatingly, just as does the energy tensor of matter.[165]

7.14 From Consolidation to Exploration

7.14.1 Living with the Less than Perfect

If considered in hindsight of general relativity, the *Entwurf* theory has considerable flaws: it does not comply with the only astronomical test available before 1919[166] for a relativistic gravitation theory, the anomalous perihelion advance of Mercury by ca. 43” per century, which is inexplicable in terms of Kepler’s laws; it does not include the Minkowski metric in rotating coordinates as a solution and hence disappointed Einstein’s Machian expectations; and the mathematical derivation from general principles was based on an error. Einstein’s discovery of these flaws in the *Entwurf* theory may appear to constitute a step-by-step refutation, clearing the way for a new approach. However, uncovering these flaws did not immediately shatter the *Entwurf* theory. As was shown above, the *Entwurf* theory had emerged as a theory firmly grounded in the knowledge of classical physics, incorporating, in particular, both the correspondence and the conservation principles. At the same time, the theory allowed for a limited extension of the generalized relativity principle to at least general linear transformations, this limitation being, however, justified by both physical and mathematical arguments. Whatever Einstein achieved in the second phase beyond this state—in terms of an astronomical confirmation of the theory, of a further generalization of the relativity principle, or in terms of its mathematical elaboration—was not necessary to support the theory. The successes and failures beyond the core established in the consolidation period concerned the more ambitious part of Einstein’s heuristics, in particular the extension of the generalized principle of relativity, which from the beginning was a less stringent criterion for the validity of his new gravitation theory than its relation to the knowledge of classical physics.

In this section, we shall briefly assess the impact of the discovery of flaws in the *Entwurf* theory on Einstein’s attitude with respect to his theory. It demonstrates his

165 “Das Gleichungssystem (81) [cf. eq. (52)] läßt trotz seiner Kompliziertheit eine einfache physikalische Interpretation zu. Die linke Seite drückt eine Art Divergenz des Gravitationsfeldes aus. Diese wird—wie die rechte Seite zeigt—bedingt durch die Komponenten des totalen Energietensors. Sehr wichtig ist dabei das Ergebnis, daß der Energietensor des Gravitationsfeldes selbst in gleicher Weise felderregend wirksam ist wie der Energietensor der Materie.” (Einstein 1914b, 1077)

166 For a discussion of the status of the other two classical tests, gravitational light bending and gravitational redshift, by 1919, see the introduction to (CPAE 9).

ability to live with the less than perfect or, more specifically, his resistance to abandoning an elaborate edifice because of damage it suffered on one of its floors.

7.14.2 The Mercury Problem

In temporal order, Einstein's discovery of the failure of the *Entwurf* theory to yield the correct perihelion shift of Mercury came first; it was made as early as the summer of 1913. The extensive research notes by Einstein and Besso, which document their joint effort to calculate Mercury's perihelion motion, show that this endeavor was actually part of a broader program that included not only the *Entwurf* theory, but also Nordström's gravitation theory, and not only the perihelion shift of Mercury, but also other possible checks of a non-Newtonian gravitation theory, such as its compatibility with the effects anticipated on the basis of Einstein's Machian heuristics. This broader perspective may have shaped Einstein's reaction to finding that the *Entwurf* theory could not account for the astronomically observed value of the perihelion shift. First of all, this anomaly could not be explained by other contemporary gravitation theories; second, there might have been a purely astronomical explanation for it; and third, there was a range of other possible checks of the *Entwurf* theory, such as the deflection of light in a gravitational field and gravitational redshift. In view of this situation, the negative finding on Mercury's perihelion shift was not a result of immediate significance for the validity of the *Entwurf* theory. It had required some effort to perform the perihelion calculation, but from the beginning it must have been at best a hope that a relativistic gravitation theory could actually account for this effect. Einstein himself did not publish his negative result. He encouraged Besso to complete a paper offering a comparative evaluation of contemporary gravitation theories both on empirical and epistemological grounds.[167] In his contemporary letters, he appeared more convinced of or worried by, as the case might be, the theory's internal consistency or lack thereof.

The failure of the perihelion calculation was not mentioned in Einstein's publications and hardly ever in his contemporary correspondence. It only played a role in Einstein's later justifications of his abandonment of the *Entwurf* theory. If his and Besso's extensive manuscript notes had not survived, one would not have known how much effort they had invested into this calculation. And yet, this calculation had a profound impact on the genesis of general relativity, which is discussed more extensively below, by affecting the speed with which Einstein could calculate the perihelion shift on the basis of his later generally-covariant theory.[168] This was possible because the formalism he had developed for the *Entwurf* theory turned out to be more generally applicable and hardly required any modification when used in the context of another gravitation theory. But the perihelion calculation also had more subtle effects which, as we shall see, later turned out to be beneficial to Einstein's renewed

---

167 Einstein to Michele Besso, after 1 January 1914 (CPAE 5, Doc. 499).
168 For detailed historical discussion, see (Earman and Janssen 1993).

exploration of generally-covariant candidate field theories. It led, in particular, to an improved understanding of the Newtonian limit.

7.14.3 The Rotation Problem

The method developed by Einstein and Besso for calculating the perihelion advance was based on an iterative procedure for finding approximate solutions of the field equation. It also turned out to be applicable to the investigation of another question of great heuristic significance for Einstein's attempt to generalize the relativity principle.[169] As we have discussed earlier, this attempt was guided, from the beginning, by the idea of conceiving rotation as being equivalent to a state of rest, interpreting the inertial forces arising in a rotating frame of reference as a special gravitational field. If the *Entwurf* theory were actually compatible with this heuristics, the Minkowski metric in rotating coordinates should be a solution of its field equations.

The inertial forces arising in a rotating frame, centrifugal and Coriolis forces, are of a different order in the angular velocity, the centrifugal force depending on its square, the Coriolis forces depending linearly on this velocity. Einstein and Besso's approximation scheme could thus be used to check whether one can obtain from a first-order approximation of a Minkowski metric in rotating coordinates, containing only the components relevant for the Coriolis forces, the correct second order term relevant for the centrifugal forces. The result of this calculation could then be compared with that of the direct transformation of the Minkowski metric in rotating coordinates.

In a scratch notebook Einstein first wrote down the one component relevant for the centrifugal force and then two components relevant for the Coriolis force. Underneath he wrote:

> Is the first equation [concerning the centrifugal force] a consequence of the other two [concerning the Coriolis force] on the basis of the theory?[170]

In a page of the bundle of manuscripts used jointly by Einstein and Besso for their calculations on the perihelion shift, Einstein actually performed this check (CPAE 4, Doc. 14, [41–42]). Although the approximation scheme applied to the *Entwurf* theory does not yield the correct value for the 4–4 component of a Minkowski metric in rotating coordinates, he at first came to the erroneous conclusion that it actually does, and ended his calculation with the remark "stimmt" (CPAE 4, Doc. 14, [41]).

There is, however, as early as 1913 evidence that this was not Einstein's last word. In the draft for his paper on contemporary gravitation theories, Besso listed the failure of the *Entwurf* theory to yield the correct combination of centrifugal and Coriolis forces, in other words, its failure to include the Minkowski metric in rotating coordi-

---

169 For a discussion of this procedure, see the editorial note on the Einstein-Besso manuscript in (CPAE 4, 346–349), as well as (Earman and Janssen 1993, 142–143).

170 "Ist die erste Gleichung Folge der beiden letzten auf Grund der Theorie?" (CPAE 3, Appendix A, [66]).

nates as a solution, as problems to be thought about and to be discussed with Einstein. From these notes it seems that at some point by the end of August 1913, Besso was aware of this problem. Einstein's contemporary correspondence suggests that he as well had realized by mid-August that the positive result mentioned above was actually based on an error.[171]

The problem resurfaced only when Einstein had convinced himself, after the discovery of a flaw in his original conservation argument (cf. subsection "Einstein's Reinterpretation of the Conservation Principle," p. 235, that there actually exists a large variety of transformation to accelerated reference systems under which the *Entwurf* theory was covariant. On 20 March 1914, Michele Besso wrote to Einstein, after the latter had reported his progress in analyzing the covariance properties of the *Entwurf* field equations:

> Does the result obtained also give a clue, perhaps, for a more complete treatment of the rotation problem, so that one can get the correct value of the centrifugal force? Unfortunately, my brain, at least the way it has been trained, is much too feeble for me to answer this question myself, or even to guess from what side it could be attacked. For reasons already discussed, it seems to me that it (?) is of importance for the astronomical problem as well (for until now it at least seemed that a system in which no Coriolis forces flit about could still be a seat of centrifugal forces, or the reverse).[172]

The passage clearly confirms that Besso was aware by spring 1914—and also assumed Einstein to be aware—that the "incomplete treatment" of the problem of rotation (probably referring to the use of an approximation procedure) did not yield the correct result for the Coriolis force. Besso also claimed that the solution to this problem might be relevant for the calculation of the perihelion shift of Mercury (possibly the "astronomical problem" to which he alluded). Einstein did not, however, at this point check the compatibility of his general insights into the covariance properties of the *Entwurf* field equations with concrete calculations on the level of his approximation scheme.

It was only in September 1915 that Einstein rediscovered, to his surprise, the result that the iterative solution of the *Entwurf* field equations does not yield the correct Minkowski metric in rotating coordinates. This is known from a letter he wrote

---

171 See, e.g., Einstein to H. A. Lorentz, 14 August 1913, (CPAE 5, Doc. 467). Einstein did not allude to anything like having established the Minkowski metric in rotating coordinates as a solution of the *Entwurf* equations (at least in second-order approximation) in his letters to Lorentz nor in those he wrote to other colleagues and friends, who would have been interested in the issue, such as Ernst Mach, Erwin Freundlich, Heinrich Zangger, Paul Ehrenfest, and Michele Besso. See also the extended discussion in "What Did Einstein Know ..." (in vol. 2 of this series).

172 "Gibt das erreichte Resultat vielleicht auch einen Wink für eine vollständigere Behandlung des Drehungsproblems, so dass man den richtigen Wert der Centrifugalkraft bekommen kann? Leider ist mein Kopf, wenigstens so wie er einmal erzogen ist, viel zu schwach, um mir die Frage selbst zu beantworten, oder auch nur zu ahnen, wo man sie angreifen könnte. Aus schon besprochenen Gründen scheint sie (?) mir auch für das astronomische Problem von Bedeutung (weil es früher wenigstens so aussah, ein System in welchem keine Corioliskräfte huschen, doch Sitz von Centrifugalkräften sein könnte, oder umgekehrt)." Michele Besso to Einstein, 20 March 1914, (CPAE 5, Doc. 516, 606).

on 30 September 1915 to Erwin Freundlich, in which he now also connected this finding with the perihelion problem, just as Besso had done in the letter quoted above. Evidently Einstein was quite concerned by his finding:

> I am writing you now about a scientific matter that electrifies me enormously. For I have come upon a logical contradiction of a quantitative nature in the theory of gravitation, which proves to me that there must be a calculational error somewhere within my framework. [...]
>
> Either the equations are already numerically incorrect (numerical coefficients), or I am applying the equations in a principally incorrect way. I do not believe that I myself am in the position to find the error, because my mind follows the same old rut too much in this matter. Rather, I must depend on a fellow human being with unspoiled brain matter to find the error. If you have time, do not fail to study the topic.[173]

The letter leaves open in which context Einstein redid the earlier calculation. It is plausible to assume that it was once more Besso who stimulated the reconsideration of this problem. In fact, Besso and Einstein probably discussed the Mercury as well as the rotation problem during the latter's stay in Switzerland in September 1915.[174] The letter to Freundlich was sent only a week after Einstein's return to Berlin.[175] It was probably written as a reaction to a request for political support and represented one of the first occasions for Einstein to present the revived rotation problem to a colleague who must have been interested in it because of its implication for the understanding of the Mercury problem.[176]

Evidently, this time Einstein found the rotation problem much more alarming than he did in the summer of 1913. In his letter to Freundlich he still did not substantially question the *Entwurf* field equation but merely took into consideration that he applied

---

173 "Ich schreibe Ihnen jetzt in einer wissenschaftlichen Angelegenheit, die mich ungeheuer elektrisiert. Ich bin nämlich in der Gravitationstheorie auf einen logischen Widerspruch quantitativer Art gestossen, der mir beweist, dass in meinem Gebäude irgendwo eine rechnerische Unrichtigkeit stecken muss. [...] Entweder sind die Gleichungen schon numerisch unrichtig (Zahlenkoeffizienten) oder ich wende die Gleichungen prinzipiell falsch an. Ich glaube nicht, dass ich selbst imstande bin, den Fehler zu finden, da mein Geist in dieser Sache zu ausgefahrene Gleise hat. Ich muss mich vielmehr darauf verlassen, dass ein Nebenmensch mit unverdorbener Gehirnmasse den Fehler findet. Versäumen Sie nicht, wenn Sie Zeit haben, sich mit dem Gegenstande zu beschäftigen." Einstein to Erwin Freundlich, 30 September 1915 (CPAE 8, Doc. 123), extensively discussed in (Janssen 1999), here just a summary,

174 He wrote to Elsa Einstein from Lucerne: "In Zurich I was together with Besso very often; my stay in Zurich was very much improved by it, but thus I neglected my duties to others." ("In Zürich war ich sehr viel mit Besso zusammen, mein Aufenthalt wurde dadurch sehr verschönert, doch vernachlässigte ich so meine Pflicht gegen andere.") Einstein to Elsa Einstein, 11 September 1915, (CPAE 8, Doc. 116).

175 See Calender (CPAE 8, 998).

176 Einstein had written to Freundlich in March of the same year on the perihelion problem, see Einstein to Erwin Freundlich, 19 March 1915 (CPAE 8, Doc. 63). He had written a letter to Lorentz a day after his return from Switzerland, Einstein to H. A. Lorentz, 23 September 1915, (ibid., Doc. 122), in which he did not mention this problem, probably because he was ashamed.

it incorrectly—probably a reference to the unclear status of the approximation procedure—or that some numerical coefficients were wrong.

That the discovery of this flaw, taken by itself, did not amount to a refutation of the *Entwurf* theory is made evident also by Einstein's immediate reaction to the rotation problem. Apparently encouraged by his general results on the covariance properties of the *Entwurf* theory, which, as we have seen, amounted for him to the claim that there was no physical restriction of the generalized relativity principle but only on the choice of admissible coordinates, he attempted to show that the *Entwurf* field equation could be solved by a rotating system in a different set of coordinates; but this attempt failed as well.[177] Shortly afterwards, he developed a new derivation of the *Entwurf* field equation, to which we will turn below, effectively confirming its immunity with regard to the rotation problem. It was only after his return to the November tensor, that he listed the problem of rotation as one of the three flaws which undermined his trust in the *Entwurf* theory.

Einstein's diverse reactions over the course of time to the same problem of the *Entwurf* theory are correlated with his changing perspectives during the elaboration of this theory. When he first believed that his rotation calculation worked, it seemed like progress on the bold approach, without providing him with a general insight into the covariance properties of the *Entwurf* theory. When it turned out that it does not actually work, this negative result became irrelevant because Einstein successfully developed his defensive approach with the supposed consequence that the *Entwurf* field equation is covariant only under linear transformations. When Einstein then, in the second phase of the consolidation period of the *Entwurf* theory, achieved more general insights into its covariance properties, these insights seemed to make a check on the level of concrete calculations superfluous. Eventually, Einstein took it for granted that rotation did not present a problem for the *Entwurf* theory. Only when he reviewed the problem in September 1915, possibly at Besso's prompting, he finally connected his general considerations with his concrete calculations—and rediscovered the problem. This result now questioned not only his earlier conviction concerning rotation, but also more generally the significance of his insights into the theory's covariance properties. Still, the discovery of this failure implied little more than a return to the status of the *Entwurf* theory at the end of the first phase of the consolidation period, its covariance being guaranteed only for general linear transformations.

7.14.4 The Failure of the Covariance Proof

We now turn to the last flaw that Einstein discovered, probably in early October, some weeks before he gave up the *Entwurf* theory. This flaw concerns Einstein's attempt to derive the *Entwurf* field equation along the mathematical strategy. As our earlier discussion of this endeavor has made clear, one of its problems was the neces-

177 See the calculations on the back of the draft of letter Einstein wrote to Otto Naumann after 1 October 1915, (CPAE 8, Doc. 124).

sity to adapt general tools, such as variational calculus, to the requirement of restricted covariance. This aspect had been at the center of Einstein's discussion in early 1915 with the Italian mathematician Tullio Levi-Civita, which apparently was triggered by a letter from Max Abraham.

Abraham may well have been one of the first to discover a problem with Einstein's derivation of the *Entwurf* field equation from a Lagrangian function. On 23 February 1915 he wrote to Levi-Civita:

> Really I did not understand on which hypotheses his new demonstration is based. Among all possible invariants that could be used to construct the [Lagrangian] function *H* he chooses very arbitrarily the one that yields his field equations.[178]

Abraham thus succinctly summarized the crucial weakness of Einstein's proof.

But Levi-Civita's exchange with Einstein did not touch upon this crucial problem. Levi-Civita focused instead on a specific technical problem in Einstein's derivation; his proof of the claim that the candidate for the left-hand side of the field equations is a tensor.[179] He produced a counter-example which Einstein, however, declared irrelevant by pointing to the fact that Levi-Civita's example does not satisfy the condition of being covariant under the linear transformations that he had explicitly stipulated.[180] As we shall see, he only later would realize the questionable role of this condition in his proof. Levi-Civita, in any case, did not insist on this aspect. Einstein had more difficulties in responding to other problems in his proof to which Levi-Civita drew his attention. In spite of his attempts to rebut the latter's criticism, Einstein eventually had to admit that his derivation was incomplete, without, however, losing faith in it actually fulfilling its purpose in yielding the *Entwurf* field equations.[181] On the contrary, as Einstein wrote to Levi-Civita during their controversy:

> I must even admit that, through the in-depth considerations to which your interesting letters have led me, I have become only more firmly convinced that the proof of the tensor character of $\mathfrak{E}_{\mu\nu}/\sqrt{-g}$ is correct in principle.[182]

Further objections by Levi-Civita did not shatter this conviction. Nevertheless Einstein and Levi-Civita agreed upon a shortcoming of Einstein's proof; eventually when Levi-Civita proposed an alternative gravitation theory involving a scalar gravitational potential, Einstein lost interest in the exchange and broke it off.[183]

Einstein's discovery of the crucial flaw in his proof was not stimulated by Levi-Civita's criticism but by a reconsideration of this proof in light of a paper by Lorentz about six months later. When Einstein returned from Switzerland on 22 September

182 "Ich muss sogar gestehen, dass ich durch die tieferen Überlegungen, zu denen mich Ihre interessanten Briefe brachte, noch fester in der Überzeugung wurde, dass der Beweis vom Tensorcharakter von $\mathfrak{E}_{\mu\nu}/\sqrt{-g}$ im Prinzip richtig ist." Einstein to Tullio Levi-Civita, 8 April 1915 (CPAE 8, Doc. 71)

183 See Einstein to Tullio Levi-Civita, 5 May 1915, (CPAE 8, Doc. 80).

1915, he found Lorentz's recently published paper on Hamilton's principle in the theory of gravitation, including a treatment of electromagnetic fields. In a letter to Lorentz dated the following day Einstein wrote:

> Your article delighted me. I have also found a proof for the validity of the [relativistic] energy-momentum conservation principle for the electromagnet. field taking gravitation into consideration, as well as a simplified covariant theoretical representation of the vacuum equations, in which the "dual" six tensor [*Sechservektor*] concept proves unessential. At the moment I am occupied with studying your paper.[184]

Lorentz's paper on generally-covariant Maxwell theory introduced a generic Hamiltonian principle without deriving Einstein's specific choice from it.[185] In a first reaction to this paper, Einstein attempted to convince Lorentz that the theory of invariants actually leads to such a specific choice. Although the letter in which Einstein expressed this conviction is not preserved, this much can be concluded from a subsequent letter in which Einstein revoked his claim:

> Subsequent reflections on the last letter I sent you have revealed that I made erroneous assertions in that letter. In actual fact the invariant theory method does not yield more than Hamilton's principle when determining your function $Q(= H\sqrt{-g})$.[186]

Evidently, it was the thorough comparison with Lorentz's approach that directed Einstein's attention to a flaw in his derivation of the *Entwurf* field equations.

On reexamining his 1914 derivation, Einstein found that the condition of linearity, which had apparently entered his argument as an unproblematic default setting, was less innocent than it first appeared to him:

> The reason why I did not notice this last year is that on p. 1069 of my article I had frivolously introduced the condition that H was invariant against linear transformation.[187]

As we discussed earlier, it was by introducing this condition that Einstein had found the condition $B_\mu = 0$ for the choice of an adapted coordinate system, while he had derived the condition $\sum_\nu \partial S_\mu^\nu / \partial x_\nu - B_\mu = 0$ as a consequence of energy-momentum conservation—without taking into account the linear covariance of the Lagrangian.

---

184 "Über Ihre Abhandlung habe ich mich sehr gefreut. Ich habe auch einen Beweis für die Gültigkeit des Impuls Energ[ie]satzes des elektromagnet. Feldes mit Berücksichtigung der Gravitation gefunden sowie eine kovariantentheoretisch vereinfachte Darstellung der Vakuumgleichungen, indem sich der Begriff des "dualen" Sechservektors als entbehrlich erweist. Ich bin gerade mit dem Studium Ihrer Arbeit beschäftigt." Einstein to H. A. Lorentz, 23 September 1915, (CPAE 8, Doc. 122).

185 See (Lorentz 1915).

186 "Nachträgliche Überlegungen zu dem letzten Briefe, den ich an Sie richtete, haben gezeigt, dass ich in diesem Briefe Unrichtiges behauptete. Thatsächlich liefert die invariantentheoretische Methode nicht mehr als das Hamilton'sche Prinzip wenn es sich um die Bestimmung der Ihrer Funktion $Q(= H\sqrt{-g})$ handelt." Einstein to H. A. Lorentz, 12 October 1915, (CPAE 8, Doc. 129).

187 "Dass ich dies letztes Jahr nicht merkte liegt daran, dass ich auf Seite 1069 meiner Abhandlung leichtsinnig die Voraussetzung einführte, H sei eine Invariante bezüglich *linearer* Transformationen." (CPAE 8, Doc. 129)

The basic error which Einstein discovered thus consisted in requiring the compatibility of two conditions derived under different assumptions, once with linearity and once without. An acceptable derivation of the *Entwurf* field equation from the Lagrangian formalism had therefore to be based on additional assumptions. In his letter to Lorentz, Einstein reintroduced the correspondence principle in order to justify the selection of the *Entwurf* Lagrangian among the lengthy list of candidates given in his 1914 paper:

> That $Q/\sqrt{-g}$ had been set by me as equal to the fourth expression given there can be justified by the fact that only with this choice does the theory contain Newton's in approximation. That I believed it possible to support this selection on the equation S^{λ}_{μ} was based on error.[188]

Einstein's derivation along a mathematical strategy was thus reduced, in its substance, to that of the original 1913 *Entwurf* paper. He had come back to his starting point—but with one important difference: In spite of the failure of his hope to achieve a derivation essentially from covariant theory only, he had effectively found a derivation in which mathematical principles came first and were supplemented by the physical requirements of energy-momentum conservation and Newtonian limit embodied in the default settings of his field equation. In other words, Einstein had established a derivation which follows precisely the pattern of his attempted derivations along the mathematical strategy in the Zurich Notebook. But instead of taking a generally-covariant object suggested by absolute differential calculus as a starting point, Einstein's point of departure was now the variational calculus he had developed himself.

From Einstein's correspondence it becomes clear that he did not yet consider the state of affairs just described as a reason for abandoning the *Entwurf* theory. There is no trace of this in his letter to Lorentz. Also in a letter written to Zangger a few days later,[189] Einstein treated gravitation as one among several topics, clearly considering his current work on it as business as usual:

> It has unfortunately become clear to me now that the "new stars" have nothing to do with the "lens effect," moreover that, taking into account the stellar densities existing in the sky, the latter must be such an incredibly rare phenomenon that it would probably be futile to expect one of the like.[190]

---

188 "Dass $Q/\sqrt{-g}$ von mir gleich dem vierten der dort angegebenen Ausdrücke gesetzt werde, lässt sich dadurch rechtfertigen, dass die Theorie nur bei dieser Wahl die Newton'sche als Näherung enthält. Dass ich glaube, diese Auswahl auf die Gleichung S^{λ}_{μ} stützen zu können, beruhte auf einem Irrtum." (CPAE 8, Doc. 129)

189 The letter was dated by the editors of (CPAE 8) as 15 October 1915, but since it is explicitly dated only as "Friday" and other indications leave a window between 30 September and 21 October, it may well have been written on 8 October, i.e. before the letter to Lorentz.

190 "Seit ich hier bin, habe ich sehr fest auf meiner Bude gearbeitet. Es ist mir nun leider klar geworden, dass die "neuen Sterne" nichts mit der "Linsenwirkung" zu thun haben, das ferner letztere mit Rücksicht auf die am Himmel vorhandenen Sterndichten ein so ungeheuer seltenes Phänomen sein muss, dass man wohl vergeblich ein solches erwarten würde. Ich schrieb eine ergänzende Arbeit zu meiner letztjährigen Untersuchung über die allgemeine Relativität. Gegenwärtig arbeite ich etwas in Wärmetheorie." Einstein to Heinrich Zangger, 15 October 1915, (CPAE 8, Doc. 130).

Einstein evidently considered what he believed to be the impossibility of relating the observation of nova stars to the gravitational lensing effect he had predicted in 1912[191] to be more important than the problem he had discovered in the mathematical proof of the *Entwurf* theory. Even the paper that he mentions as being supplementary to his 1914 review is probably not a reference to a planned revocation of his proof[192] but to a paper mentioned in his earlier letter to Lorentz on generally-covariant electrodynamics, which was eventually published in 1916 (Einstein 1916b). Thus, also the third flaw which Einstein discovered in the *Entwurf* theory did not immediately lead to its refutation.[193] It nevertheless must have had a subversive effect on his belief in this theory as will be discussed in the next section.

In summary, we have seen that the endeavor to develop a mathematical strategy for deriving the *Entwurf* field equation had to face tensions between the non-covariance of the theory and the properties of a mathematical apparatus naturally tuned to generally-covariant objects. These tensions implied the necessity to repeatedly rework the mathematical analysis of the covariance properties of the theory and the derivation of the field equation based on it; they became particularly evident in the criticism by Abraham and Levi Civita. The latter's critique, however, never questioned the goal of Einstein's derivation, to show the supposed uniqueness of the *Entwurf* field equation. Einstein's exposition of his theory to the Göttingen mathematicians and physicists in a series of six Wolfskehl lectures, delivered in late June and early July 1915 at the invitation of David Hilbert,[194] may also have induced a renewed reflection on the justification of the *Entwurf* theory along the mathematical strategy.

The problematic character of Einstein's derivation of the *Entwurf* field equation from a Lagrangian formalism may have emerged, as we have also seen, in the context of applying the formalism to a different context, that of a generally-covariant Maxwell theory. It was here that the formalism developed specifically for the *Entwurf* theory first proved its greater generality. Against this background Einstein's discovery of a flaw in his derivation could have had a double effect: It pointed out the familiar physical arguments for deriving the *Entwurf* theory, and it suggested taking up once more the mathematical strategy of trying out the newly empowered techniques on different candidates. Initially Einstein chose the first option, but his rederivation of the *Entwurf* theory from a variational formalism plus one extra physical condition may

191 See (Renn and Sauer 2003b).

192 As conjectured in (Janssen 1999, note 51).

193 We leave aside here the question of a possible, direct or indirect, influence by David Hilbert, who had also found a flaw in Einstein's reasoning around this time. It is, however, unclear whether and if so when and what Einstein may have learned about Hilbert's work prior to 7 November 1915 when their extant correspondence on this issue begins. See (Corry 2004, ch. 7) and further references cited therein for a discussion of the interaction between Einstein and Hilbert in this period. See also the discussion below in sec. 7.18.1

194 Fragments of an auditor's notes taken during one of the lectures are published in (CPAE 6, Appendix B). For further historical discussion of Einstein's Göttingen visit in June and July 1915, see (Corry 2004, pp. 320–329).

have made it clear to him how much more general this formalism was, particularly since the conservation principle no longer presented a major obstacle.

7.15 Einstein's November Revolution: the Restoration of an Old Candidate

7.15.1 Looking Back in Anger and Hope

With his publication of 11 November 1915, submitted on the 4th of November, Einstein made his definite rejection of the *Entwurf* theory public:

> My efforts in recent years were directed toward basing a general theory of relativity, also for nonuniform motion, upon the supposition of relativity. I believed indeed to have found the only law of gravitation that complies with a reasonably formulated solution in a paper that appeared last year in the *Sitzungsberichte*.
> Renewed criticism showed to me that this truth is absolutely impossible to show in the manner suggested. That this seemed to be the case was based upon a misjudgment.[195]

Among the three major flaws he had meanwhile found in the *Entwurf* theory, the Mercury failure, the rotation failure, and the breakdown of its mathematical derivation, the latter was publicly the most visible, documented as it was by Einstein's lengthy 1914 review paper. It was, in any case, the only failure explicitly mentioned in his first 1915 article:

> The postulate of relativity—*as far as I demanded it there*—is always satisfied if the Hamiltonian principle is chosen as a basis. But in reality, it provides no tool to establish the Hamiltonian function H of the gravitational field.[196]

As we have seen, none of the problems of the *Entwurf* theory, taken by themselves or together, resulted in an immediate rejection of this theory. Therefore it is not self-evident that Einstein, in view of these problems, finally decided to give up the *Entwurf* theory, as he pointed out in the 1915 paper:

> For these reasons I lost trust in the field equations I had derived, and instead looked for a way to limit the possibilities in a natural manner.[197]

---

195 "In den letzten Jahren war ich bemüht, auf die Voraussetzung der Relativität auch nicht gleichförmiger Bewegungen eine allgemeine Relativitätstheorie zu gründen. Ich glaubte in der Tat, das einzige Gravitationsgesetz gefunden zu haben, das dem sinngemäß gefaßten, allgemeinen Relativitätspostulate entspricht, und suchte die Notwendigkeit gerade dieser Lösung in einer im vorigen Jahre in diesen Sitzungsberichten erschienenen Arbeit darzutun.
Eine erneute Kritik zeigte mir, daß sich jene Notwendigkeit auf dem dort eingeschlagenen Wege absolut nicht erweisen läßt; daß dies doch der Fall zu sein schien, beruhte auf Irrtum." (Einstein 1915c, 778)

196 "Das Postulat der Relativität, *soweit ich es dort gefordert habe*, ist stets erfüllt, wenn man das Hamiltonsche Prinzip zugrunde legt; es liefert aber in Wahrheit keine Handhabe für eine Ermittelung der Hamiltonschen Funktion H des Gravitationsfeldes." (Einstein 1915c, 778)

197 "Aus diesen Gründen verlor ich das Vertrauen zu den von mir aufgestellten Feldgleichungen vollständig und suchte nach einem Wege, der die Möglichkeiten in einer natürlichen Weise einschränkte." (Einstein 1915c, 778)

This step cannot be exclusively accounted for, we believe, on the basis of the failures of that theory but only becomes plausible in view of the unexploited resources that he still had at his disposal from his earlier work in the Zurich Notebook. This is also suggested by the sentences following immediately in the paper:

> In this pursuit I arrived at the demand of general covariance, a demand from which I parted, though with a heavy heart, three years ago when I worked together with my friend Grossmann. As a matter of fact, we were then quite close to that solution of the problem, which will be given in the following.[198]

In fact, after abandoning the *Entwurf* theory Einstein returned to one of the mathematical objects he had encountered along the mathematical strategy three years ago in the Zurich Notebook, the November tensor (cf. eq. (82)). As the above passage suggests, he did not insist on the specific requirement of general covariance, but merely required a "more general covariance of the field equations." It was thus, above all, a return to the mathematical strategy applied to the absolute differential calculus that marked the turning point of 11 November 1915, rather than a radical break with his earlier experiences concerning the restriction of covariance if it turned out to be necessary. Indeed, Einstein now emphatically embraced the absolute differential calculus:

> Nobody who really grasped it can escape from its charm, because it signifies a real triumph of the general differential calculus as founded by Gauss, Riemann, Christoffel, Ricci, and Levi-Civita.[199]

In the context of our account, the crucial questions for understanding Einstein's shift in late 1915 are:

1. What eventually convinced him to give up the *Entwurf* theory and return to the mathematical strategy applied to the absolute differential calculus?
2. How could *any* of the tensors explored and discarded in the course of Einstein's work on the Zurich Notebook now again represent a resource for a renewed exploration?
3. What made the November tensor particularly suitable for such a renewed exploration? And, finally:
4. How exactly did Einstein find his way back to the November tensor?

The answer to the first question follows from our analysis of the third flaw Einstein discovered in the *Entwurf* theory, the erroneous derivation. His last derivation of the *Entwurf* field equation had effectively reinstalled the mathematical strategy in its

198 "So gelangte ich zu der Forderung einer allgemeineren Kovarianz der Feldgleichungen zurück, von der ich vor drei Jahren, als ich zusammen mit meinem Freunde Grossmann arbeitete, nur mit schwerem Herzen abgegangen war. In der Tat waren wir damals der im nachfolgenden gegebenen Lösung des Problems bereits ganz nahe gekommen." (Einstein 1915c, 778)

199 "Dem Zauber dieser Theorie wird sich kaum jemand entziehen können, der sie wirklich erfaßt hat; sie bedeutet einen wahren Triumph der durch Gauss, Riemann, Christoffel, Ricci und Levi-Civiter begründeten Methode des allgemeinen Differentialkalküls." (Einstein 1915c, 779)

original sense, starting from a generally-covariant object which is then checked and, if necessary, modified according to physical criteria. However, both the starting point and the check list of criteria now looked somewhat different from how they did in 1912–1913. If Einstein's starting point had then been a second-rank tensor representing a candidate for the left-hand side of the field equation, it was now a scalar representing the Lagrangian of the theory. And if the conservation principle was then a criterion that had to be laboriously checked for each single candidate, it was now automatically fulfilled for any candidate fitting into the general framework. The correspondence principle therefore remained the crucial criterion for choosing the right candidate. If Einstein at any point after his letter to Lorentz of 12 October 1915 decided to actually check his claim that the *Entwurf* theory was determined uniquely by this criterion, his search would have been governed by the renewed mathematical strategy. In a word, checking the *Entwurf* theory and pursuing the mathematical strategy simply coincided in the end.

To answer the second question of why, in general, tensors earlier discarded could now be considered worthy of further examination, we must turn once again to the Zurich Notebook. Einstein's examination in the notebook of candidate gravitation tensors extracted from the Riemann tensor was restricted to the weak-field form of the field equation. In the notebook, Einstein mastered energy-momentum conservation only for weak fields—with the exception of the *Entwurf* operator at the end of the notebook. Therefore, all candidates extracted from the Riemann tensor were left only partially explored in the notebook when Einstein decided to move on to the next candidate. This unexplored potential of the candidates encountered along the mathematical strategy was one of the essential reasons why he considered it worthwhile to reexamine them in 1915. Another crucial reason for such progress in a loop—or by reflection—was the fact that Einstein's renewed mathematical strategy now drew on more resources, in particular, the variational calculus as applied for the *Entwurf* theory.

In answering the third question of what made the November tensor particularly suitable for a renewed exploration, we again must look at the Zurich Notebook. There Einstein, with Grossmann's help, had derived the November tensor from the Ricci tensor under the stipulation of unimodular coordinate transformations. Contrary to the Ricci tensor, the November tensor satisfies Einstein's physically motivated criteria because it could be reduced to a form suitable for obtaining the Newtonian limit by assuming a coordinate restriction (the Hertz restriction) that was the same as the restriction required by energy-momentum conservation in the weak field limit (cf. eq. (LXXXIV)). Contrary to the Einstein tensor, the harmonization of these two restrictions for the November tensor did not require a change in the view of how the Newtonian limit was to be achieved. Clearly, the November tensor offered a natural starting point for a renewal of the mathematical strategy, since in its case the check of the weak field equation with regard to the conservation and correspondence principles produced a positive outcome—shadowed only by the restricted covariance properties of the candidate that resulted from the November tensor by imposing the required coordinate restriction. The questions that remained were whether or not this result could be extended to the full field equation as well, and which restrictions of covariance were implied for the full equation by the conservation principle. These questions could now be addressed with the help of an improved mathematical apparatus.

The answer to the fourth question, concerning the actual path that Einstein took in rediscovering the November tensor in the fall of 1915 is suggested by several comments pointing to the crucial role of the default setting for the gravitational field eq. (XXII) which, in hindsight, played the role of a "fateful prejudice" with its substitution by the default setting eq. (XXIII) being the "key to the solution."[200] The path leading from the *Entwurf* field equation to a field equation based on the November tensor can be reconstructed with fair confidence in view of the default setting for the Lagrangian in terms of the field eq. (LXIII). It was, as we have discussed, this default setting, rooted in classical field theory, which had also made the *Entwurf* Lagrangian look particularly promising.

It must have been tempting for Einstein to look for other Lagrangians that could be interpreted in this way as involving a "square" of the gravitational fields, experimenting with the definition of the gravitational field. In fact, the internal logic of the mathematical representation exerted a pressure on Einstein's interpretation, since in that representation the connection coefficients, i.e. the Christoffel symbols, have a central importance in, e.g. the concept of a covariant derivative, the geodesic equations, or the definition of the Riemann and Ricci tensors. This role of the connection coefficients was at odds with the significance that Einstein attached to the coordinate derivatives of the metric. Thus, when Einstein took the mathematical tradition more seriously again, the mathematical knowledge that was accumulated in the representation, forced him to reconsider his physical prejudices. And it was indeed not far fetched to reinterpret the Christoffel symbol as representing the field, a choice that almost immediately leads to the Lagrangian of the November theory. Einstein's earlier experience, documented in the Zurich Notebook, might have helped find this path from the *Entwurf* to the November theory because at that time he had already explored the relation between gravitation tensors expressed by Christoffel symbols and their expression in terms of the derivatives of the metric, e.g. in the context of studying the so-called "theta-restriction."[201]

In summary, in the fall of 1915 Einstein succeeded in combining insights from his earlier mathematical strategy and canonical mathematical knowledge with the achievements of the physically motivated *Entwurf* theory. He had probably omitted the November tensor from the Zurich Notebook because he lacked the mathematical means to build a full-scale theory around it, in particular, with regard to the implementation of the conservation principle. His unsuccessful attempt at deriving the *Entwurf* theory from a mathematical strategy had laid just those means in his hands. The failure of the mathematical derivation of the *Entwurf* theory left Einstein with a formalism that initially seemed tailor-made for this very purpose, but then turned out to

200 See "Untying the Knot ..." (in vol. 2 of this series).
201 See the "Commentary …" (in vol. 2 of this series).

be much more generally applicable. An attempt to rederive the *Entwurf* field equation within this formalism turned almost automatically into a renewal of his search along the mathematical strategy. Einstein's physical expectations, not only of the correspondence and the conservation principles, but also of the role of the gravitational field in the Lagrangian and in the equation of motion, must have quickly led him to identify the November tensor as the most appropriate candidate, which not only was probably the easiest to handle given Einstein's propensity for unimodular coordinates but for which the implications of the mathematical and the physical strategies seemed to coincide.

7.15.2 Removing an Old Stumbling Block and Encountering a New One: The Conservation Principle in 1915

The demonstration of energy-momentum conservation for a theory based on the November tensor and the representation of the gravitational field by the Christoffel symbols were, for Einstein, the hallmark of the turnaround in November 1915. His contemporary comments and later recollections not only confirm that his earlier rejection of candidates derived from the Riemann tensor was just as much associated with the difficulty in demonstrating the validity of the conservation principle as with difficulties related to the correspondence principle.[202] They also confirm that it was his revision of the understanding of the components of the gravitational field that was a crucial turning point associated with his return to the mathematical strategy in November 1915.[203]

The decisive progress from Einstein's earlier exploration of a theory based on the November tensor was made possible by the Lagrangian formalism that allowed him to demonstrate that the theory complies with the conservation principle. He thus succeeded in removing an old stumbling block that had earlier forced him to abandon the November tensor, as well as expressions based on it, in the Zurich Notebook. However, the problem of establishing the compatibility between conservation and relativity principles, which had also been a problem with the November tensor in 1912–1913, continued to challenge him even in 1915 when it presented new insights as well as a new obstacle.

The most consequential new insight was related to the fact that the coordinate restriction resulting from the conservation principle turned out to have a remarkably simple structure, being reduced to the requirement that a certain scalar function is constant (cf. eq. (83)). Instead of the usual four equations, Einstein merely obtained a single condition from the requirement of energy-momentum conservation. In spite of this simplification, his physical interpretation of this condition did not change; he still saw it as defining adapted coordinates and admissible transformations (Einstein 1915c, 785).

---

202 Einstein to Michele Besso, 10 December 1915, (CPAE 8, Doc. 162) quoted in the introduction.
203 For extensive discussion, see "Untying the Knot …" (in vol. 2 of this series).

Due to the technical novelties of the November theory, Einstein's perspective on the role of coordinate restrictions changed. Now the requirements arising from the conservation principle and those related to the correspondence principle began to play different roles. The first kind of requirements only led to a minimal but still global constraint on the choice of coordinate systems, the second kind of requirements essentially fixes the coordinate system—but now only in the context of a specific physical situation without global implications. In his paper, Einstein for the first time introduced coordinate conditions in this modern sense albeit without any further explanation. He simply made use of the opportunity that the formalism of the November theory had opened up for him.

Considering his earlier failures, the November theory implemented Einstein's heuristic requirements without requiring much of an adjustment of these requirements. What had changed was, as we have seen, the default setting for the representation of the gravitational field. Furthermore, the way in which the conservation principle had earlier fully determined adapted coordinate systems was, as we have also seen, now changed into a weak constraint that could be harmonized with the requirements of the correspondence principle, thus giving rise to the idea of coordinate conditions in the modern sense. On the other hand, what had not changed was the view of the conservation principle as imposing additional conditions on the choice of coordinates. Finally, the way in which the Newtonian limit is attained in the November theory, that is, via a weak field equation of the form of eq. (33), also remained, by default, the same. That Einstein, at the time, did not regard the November theory as a first step towards a more complete theory—as it must appear to a modern reader. This is evident by a letter he wrote to his son on the day he submitted his first November paper, the 4th of November 1915:

> In the last few days I completed one of the finest papers of my life; when you are older I'll tell you about it.[204]

The formalism of the November theory generated one, apparently minor novelty that could *not* easily be assimilated to Einstein's expectations and that therefore called for a physical interpretation. This new stumbling block was the scalar condition for the choice of adapted coordinates eq. (84). In view of its derivation from the conservation principle, it could not have been surprising to Einstein that this condition determines the choice of adapted coordinates by the properties of the stress-energy tensor of matter.[205] But this general argument does little to make the precise way of this determination plausible, let alone make it understandable that coordinate systems for which $\sqrt{-g} = 1$ are to be excluded, as is implied by Einstein's condition. This was a point where the new formalism of the November theory confronted him with the challenge

204 "Dieser Tage habe ich eine der schönsten Arbeiten meines Lebens fertig gestellt; wenn Du einmal grösser bist, erzähle ich Dir davon." Einstein to Hans Albert Einstein, 4 November 1915, (CPAE 8, Doc. 134).

205 The very existence of an additional coordinate restriction must have been a puzzle in view of Einstein's earlier insights into the relation between covariance and conservation.

to find an adequate physical interpretation. Einstein did not hesitate to take up this challenge and, less than a week after the submission of his first November paper, submitted a short addendum dedicated to the physical interpretation of this condition.

7.16 A Familiar Candidate in a New Context: Einstein's Return to the Ricci Tensor

Einstein's addendum to his first November paper was submitted on 11 November and published on 18 November 1915 (Einstein 1915d). It does not contain a single novel formula with respect to the earlier paper but merely constitutes a reinterpretation of what had been achieved. Yet, it introduced a new, now generally-covariant field equation, replacing that of the November theory, which was covariant only for unimodular transformations. The new field equation is instead based on the Ricci tensor, a candidate that Einstein had also considered earlier while working on the Zurich Notebook (cf. eq. (55)). How did he reinterpret his earlier results?

The point of departure for this reinterpretation was the scalar condition for the choice of adapted coordinates eq. (84). This equation, together with the requirement of unimodularity, were the only obstacles, it appeared, that separated Einstein from the realization of general covariance. Furthermore, there was no general physical interpretation for these two requirements: Why should coordinate transformations be unimodular and why should it nevertheless be impossible to select a coordinate system so that $\sqrt{-g} = 1$? These must have been questions motivating Einstein's further search, beyond what he had achieved in his first November paper. In the new approach presented in the addendum, these two questions were answered in the context of an issue that at first glance appears to be unrelated to gravitation theory; the question of the fundamental constitution of matter.

In the introductory part of his addendum, Einstein discussed a contradiction arising in an electromagnetic theory of matter. He argued that the inclusion of gravitation in the energy-momentum balance could resolve, at least in principle, the following contradiction: The hypothesis that all matter is of electromagnetic origin, and Maxwell's equations imply that the trace of the energy-momentum tensor vanishes:[206]

$$\sum T^{\mu}_{\mu el} = 0. \tag{88}$$

It is also clear that for the default setting of the source-term, i.e. pressureless dust (cf. eq. (4)), the trace of the energy-momentum tensor does not vanish. The conflict between this implication and eq. (88) seems to indicate that matter if conceived of as pressureless dust cannot be constructed on an electromagnetic basis.

However, it is possible to conceive the energy-momentum tensor as being composed of two parts, as is suggested by the parallelism of the energy-momentum of

206 Cf. (Laue 1911, § 13).

matter and of the gravitational field on right-hand side of the field equation (cf. eq. (XLI)):

$$\sum_{\mu} T^{\mu}_{\mu} = \sum_{\mu} (T^{\mu}_{\mu el} + t^{\mu}_{\mu grav}) = \sum_{\mu} (0 + t^{\mu}_{\mu grav}), \tag{89}$$

where $T^{\mu}_{\mu el}$ is due to the electromagnetic origin of matter and $t^{\mu}_{\mu grav}$ to gravitational fields, which are now assumed to play a role in the constitution of matter as well. It follows that the non-vanishing trace of the energy-momentum tensor for matter no longer necessarily contradicts with eq. (88) since it seems possible that the vanishing of $T^{\mu}_{\mu el}$ is compensated by $t^{\mu}_{\mu grav}$. In other words, the additional assumption that gravitational fields play a role in the constitution of matter might be considered as hinting at the solution of a puzzle in a purely electromagnetic theory of matter (Einstein 1915d, 800).[207]

The discussion of an electromagnetic theory of matter in the introductory part of Einstein's addendum raises the obvious question of its function in his theory of gravitation. In his introductory paragraph he stakes the following claim:

> In a recent investigation I have shown how Riemann's theory of covariants in multidimensional manifolds can be utilized as a basis for a theory of the gravitational field. I now want to show here that an even more concise and logical structure of the theory can be achieved by introducing an admittedly bold additional hypothesis on the structure of matter.[208]

The hypothesis of an electromagnetic constitution of matter on the basis of "a theory more complete than Maxwell's theory" allowed Einstein to invalidate an important implication regarding the source term of the gravitational field equation—its non-vanishing trace. In his first November paper, this default assumption had forced him to introduce the coordinate condition that excluded coordinate systems with $\sqrt{-g} = 1$. Even earlier, in the Zurich Notebook, he had discarded the Ricci tensor as a candidate for the left-hand side of a gravitational field equation (if only on the level of linear approximation) because this candidate implies the vanishing of the trace of the stress-energy tensor in contrast to the default properties of Einstein's standard model of matter (cf. eq. (LXXV)). The hypothesis of an electromagnetic origin of

207 Apart from the fact that Einstein does not elaborate on the question as to how matter might be conceived of on the basis of "einer gegenueber Maxwells Theorie vervollstaendigten Elektrodynamik" (p. 800), Einstein's suggestion suffers, however, from a rather conspicuous difficulty: Since t^{μ}_{ν} is no tensor but a coordinate-dependent expression, it can in fact not replace the stress-energy tensor of matter. In particular, the claim that the coordinate-dependent expression t^{μ}_{μ} is positive remains unproven in Einstein's paper and can be refuted in a rather simple way by considering a coordinate system in which this quantity vanishes as well. See (Earman and Glymour 1978, 298).

208 "In einer neulich erschienenen Untersuchung habe ich gezeigt, wie auf Riemanns Kovariantentheorie mehrdimensionaler Mannigfaltigkeiten eine Theorie des Gravitationsfeldes gegründet werden kann. Hier soll nun dargetan werden, daß durch Einführung einer allerdings kühnen zusätzlichen Hypothese über die Struktur der Materie ein noch strafferer logischer Aufbau der Theorie erzielt werden kann." (Einstein 1915d, 799)

matter made it possible to resolve both these problems at the same time. In fact, under the condition $\sqrt{-g} = 1$, admissible under this hypothesis, the November tensor coincides with the generally-covariant Ricci tensor. Together with the generalized principle of relativity, this mathematical feature led Einstein to choose the Ricci tensor rather than the November tensor as the more appropriate candidate for the left-hand side of a gravitational field equation. With the introduction of the generally-covariant Ricci tensor, the other problem of the November theory—its restriction to unimodular coordinate systems—disappeared.

All aspects of the new Ricci theory are simply straightforward consequences of the November field equation plus the condition $\sqrt{-g} = 1$ which can now be conceived of as a coordinate condition in the sense that its stipulation does not affect the physical validity of the equations. In particular, Einstein did not present a new derivation of the new field equation from a Hamiltonian variation principle, now to be formulated for the Ricci tensor. He did not write down the free field Lagrangian that would produce the Ricci tensor in the field equation. Instead, Einstein still used the technique of reducing his gravitational field equation, using the condition $\sqrt{-g} = 1$, to the November field equation in his conclusive 1915 paper, and even in the 1916 review paper on general relativity. Similarly, in his addendum, he neither provided an independent discussion of energy-momentum conservation nor of the Newtonian limit, but just assumed that everything would carry over unchanged from the November theory. In his paper, he explicitly claimed that the physically relevant relations remain unchanged by the transition from the November to the Ricci theory:

> Based upon this system one can—by retroactive choice of coordinates—return to those laws which I established in my recent paper, and without any actual change in these laws, ...[209]

He emphasized that the only difference was the increased freedom in choosing a coordinate system:

> The only difference in content between the field equations derived from general covariance and those of the recent paper is that the value of $\sqrt{-g} = 1$ could not be prescribed in the latter.[210]

Even more radically, Einstein claimed in his letter to Hilbert of 12 November that his latest modification implied that Riemann's tensor would now directly produce the gravitational equations but would not change the equations of the theory.[211] In short, his new generally-covariant field equation based on the Ricci tensor represented for

209 "Von diesem System aus kann man durch nachträgliche Koordinatenwahl leicht zu dem System von Gesetzmäßigkeiten zurückgelangen, welches ich in meiner letzten Mitteilung aufgestellt habe, und zwar ohne an den Gesetzen tatsächlich etwas zu ändern." (Einstein 1915d, 801)

210 "Der Unterschied zwischen dem Inhalte unserer aus den allgemein kovarianten gewonnenen Feldgleichungen und dem Inhalte der Feldgleichungen unserer letzten Mitteilung liegt nur darin, daß in der letzten Mitteilung der Wert für $\sqrt{-g} = 1$ nicht vorgeschrieben werden konnte." (Einstein 1915d, 801)

211 Einstein to David Hilbert, 12 November 1915, (CPAE 8, Doc. 139).

Einstein largely a reinterpretation of his earlier results from the November theory.[212] Only the condition $\sqrt{-g} = 1$ had changed its status from being an excluded special case to a key relation for translating results from the older theory into the new one. What had also changed was the physical interpretation of the theory, in particular with regard to its implications for physics outside of gravitation theory.

Concerning Einstein's new gravitation theory, the only significant property of his new model of matter that replaces his standard instantiation of the slot for the source term of pressureless dust is the vanishing of the trace of the stress-energy tensor. All other aspects of such a theory of matter were irrelevant. As we have seen, he had merely two tenuous arguments to support his audacious new approach. According to the first argument, the inclusion of gravitation in an electromagnetic theory of matter could help to avoid the conflict between the vanishing of the trace of the stress-energy tensor for electromagnetic fields and its non-vanishing for matter. This argument was, however, only an unelaborated idea and quite problematic. According to the second argument, an electromagnetic theory of matter was rendered plausible by the greater consistency of the theory of gravitation that it made possible.

Since all essential equations, according to Einstein's assertion, remain the same in the Ricci and November theories, the question of which theory was to be given preference was thus a matter of choice between the following two options:

1. to rely on a standard model of matter and to accept the physically unmotivated restriction of the theory to unimodular transformations and an inexplicable exclusion of certain coordinate systems (November theory);
2. to achieve a generally-covariant theory without special requirements on coordinate systems and with a logically simple structure, but to accept the introduction of non-trivial consequences for a highly problematic fundamental theory of matter (Ricci theory).

Einstein's preference for the second option was affected by the context in which he formulated his new approach, in particular, by the contemporary discussion about an electrodynamic worldview and the parallel work of David Hilbert, which constituted serious competition for Einstein.[213] The context of this discussion lent some credibility to the introduction of speculative assumptions about a fundamental theory of matter.

---

212 In his paper, Einstein did not address the conflict between the Ricci tensor and the correspondence principle, cf. (Stachel 1989; Norton 1984). This conflict was somewhat hidden by the fact that the physical consequences of the Ricci theory were elaborated in terms of the November theory in which the Newtonian limit can be attained via the Hertz condition which is not in conflict with Einstein's default assumption about the static metric. The conflict here arises from to the condition $\sqrt{-g} = 1$, mediating between the two theories and implying, together with the Hertz condition, the harmonic condition. It seems that Einstein was, either at that time or when working on the Zurich Notebook, not aware of this conflict.

7.17 The Mercury Problem as a Theoretical Laboratory for the Ricci Tensor

7.17.1 Einstein's Motivation

Only seven days after his last note, on 18 November 1915, Einstein presented an application of his newly found field equation, his "Explanation of the Perihelion Motion of Mercury from the General Theory of Relativity" (*Erklärung der Perihelbewegung des Merkur aus der allgemeinen Relativitätstheorie*) to the Academy. It was the only one of his November papers which he submitted as a manuscript to the assembly of the Academy accompanied by oral comment, as is documented by the protocols.[214] He saw the excellent agreement between his calculated value of the perihelion shift of Mercury (43") and astronomical observations (45" +/– 5") as a breakthrough for his new theory. Einstein may also have commented publicly on his note because he hoped that his achievement would attract the attention of the astronomers attending his presentation to the Academy, such as Karl Schwarzschild.[215]

Einstein achieved his result in only seven days, a very short time for an involved calculation. David Hilbert showed himself impressed by Einstein's rapid success:

> Many thanks for your postcard and cordial congratulations on conquering perihelion motion. If I could calculate as rapidly as you, in my equations the electron would correspondingly have to capitulate, and simultaneously the hydrogen atom would have to produce its note of apology about why it does not radiate.[216]

Einstein must have been eager to quickly find convincing physical consequences for his new theory for three main reasons:[217]

1. he had produced several candidate theories among which no definite decision had yet been possible; the *Entwurf* theory, the November theory, and the Ricci theory,
2. he was in close competition with Hilbert who had just sent him a manuscript about his own gravitational field theory and had to make an effort in order to secure his priority, and
3. he may have been looking for further confirmation for his bold hypothesis of a combined electromagnetic and gravitational origin of matter, a hypothesis which so far had been based mainly on reasons of internal consistency or on general philosophical arguments.

All three motivations for Einstein's concern with the perihelion problem are well documented by his contemporary correspondence with Hilbert.[218] Einstein consid-

216 "Vielen Dank fuer Ihre Karte und herzliche Gratulation zu der Ueberwältigung der Perihelbewegung. Wenn ich so rasch rechnen könnte wie Sie, muesste bei meinen Gleichg entsprechend das Elektron kapituliren und zugleich das Wasserstoffatom seinen Entschuldigungszettel aufzeigen, warum es nicht strahlt." David Hilbert to Einstein, 19 November 1915, (CPAE 8, 149).

217 See also the discussion in (Earman and Janssen 1993), on which the following relies.

218 See Einstein to David Hilbert, 12 November 1915, Einstein to David Hilbert, 18 November 1915, and David Hilbert to Einstein, 19 November 1915, (CPAE 8, Docs. 139, 148, 149).

ered the Mercury calculation as a piece of evidence in favor of an electromagnetic theory of matter is also confirmed by the abstract of his paper in the Academy proceedings:

> It is shown that the general theory of relativity explains qualitatively and quantitatively the perihelion motion of Mercury, which was discovered by Leverrier. The hypothesis of the vanishing of the stress-energy tensor of matter is thus confirmed. Furthermore, it is shown that the examination of the bending of light rays in the gravitational field makes it also possible to verify this important hypothesis.[219]

7.17.2 The Advantages of a Second Attempt

What enabled Einstein to check this physical consequence of the anomalous perihelion advance of Mercury on the basis of the new field equation so rapidly was his earlier attempt in 1913, undertaken jointly with Michele Besso, to calculate the perihelion shift for the *Entwurf* theory.[220] This earlier attempt had given him a quantitative result that is too small (18") if compared to the empirical value. But this attempt had given Einstein the tools that could now be applied without any essential modification to the new field equation based on the Ricci tensor. The additional resource which the earlier work had laid in Einstein's hands not only allowed him to achieve quick success by applying his new theory to a challenging problem. Even more remarkably, this application also had a profound repercussion on the applied theory itself. The employment of the Mercury calculation scheme in the context of the Ricci theory effectively changed the heuristic criteria of Einstein's search for the field equation and resulted in a more sophisticated understanding of the correspondence principle.

This far-reaching consequence emerged only after Einstein's theory was explored in greater depth with his new calculation of the Mercury problem. His first two November papers were short and contain hardly any discussion of the physical consequences of the postulated field equations. The addendum of November 11 refers entirely to the considerations, including the Newtonian limit, that are presented in the main paper of November 4. The study of the Mercury problem hence constitutes the first elaboration of the Ricci theory, giving it a justification beyond the field equation and its immediate consequences. This holds even if one takes into account Einstein's earlier consideration of this theory in the Zurich Notebook. But now, in mid-November 1915, a fully fledged calculation scheme permitted the determination of approximate solutions to the gravitational field equation. This calculation scheme was inherited form the earlier calculation of the Mercury problem in the context of the

219 "Es wird gezeigt, daß die allgemeine Relativitätstheorie die von Leverrier entdeckte Perihelbewegung des Merkurs qualitativ und quantitativ erklärt. Dadurch wird die Hypothese vom Verschwinden des Skalars des Energietensors der "Materie" bestätigt. Ferner wird gezeigt, daß die Untersuchung der Lichtstrahlenkrümmung durch das Gravitationsfeld ebenfalls eine Möglichkeit der Prüfung dieser wichtigen Hypothese bietet." (Einstein 1915e)

220 See (CPAE 4, Doc. 14; Earman and Janssen 1993).

Entwurf theory; it had been developed after Einstein's struggle with various candidate field equations in the Zurich Notebook at a time when he believed in the validity of the *Entwurf* theory. This scheme had therefore not yet been applied to different candidate field equations and had thus not have had effect on the balance between Einstein's heuristic criteria. The lasting impact of the Mercury problem on the development of the field equations of general relativity in 1915 was to provide the judgement about candidate field equations with knowledge about the formalism of a gravitational field theory that was essentially independent of the field equations and that had been acquired as early as 1913. The accumulation of this knowledge triggered a process of reflection which guided Einstein to the definite field equation of general relativity.

Einstein's calculation of Mercury's perihelion shift was based on finding an approximate solution to the gravitational field equation by an iterative procedure. To find the solution of first order, Einstein and Besso, in 1913, turned directly to the first-order field equation with which Einstein was familiar from his consideration of the Newtonian limit (cf. eq. (33)), (CPAE 4, 360). The solution to this equation was hence given in terms of the canonical metric for a static field (25) which Einstein used to obtain the Newtonian limit. To obtain the second approximation, Einstein and Besso wrote down the general form of a spherically symmetric metric in Cartesian coordinates in terms of three unknown functions so as to immediately satisfy one of the constraints of the problem with an appropriate ansatz (CPAE 4, 364). These functions were then determined by the iterative procedure, starting from the first approximation.

In his 1915 paper, Einstein no longer proceeded in two separate steps but immediately started from the generic ansatz for a spherically symmetric metric (Einstein 1915b, 833). In 1915, this approach was not only natural but also necessary. It was natural because the procedure Einstein and Besso had constructed in 1913 worked just as well for the first as for the second approximation so that there was really no reason for proceeding in two steps as they had done when first developing their method for calculating the Mercury problem. In 1915 it was necessary to begin right away with the second step since the first step of 1913 no longer worked for the field equation of the Ricci theory. While Einstein's default assumption about the metric for a static field presented no manifest problem in the November theory, as it was compatible with the Hertz condition that served to obtain its Newtonian limit, this default assumption was no longer acceptable in the Ricci theory due to the additional condition $\sqrt{-g} = 1$. The conflict between this condition and Einstein's earlier understanding of the Newtonian limit is also addressed in a letter Einstein wrote to Schwarzschild in early 1916, probably referring to a problem analogous to the conflict represented by eq. (LXXV):

> My comment in this regard in the paper of November 4 no longer applies according to the new determination of $\sqrt{-g} = 1$, as I was already aware. [At this point he added in footnote: The choice of coordinate system according to the condition $\sum \partial g^{\mu\nu}/\partial x_\nu = 0$ is not consistent with $\sqrt{-g} = 1$.] Since then, I have handled Newton's case differently, of course, according to the final theory.[221]

In the context of the Ricci theory, Einstein's generic ansatz for a spherically symmetric metric pointed almost without any further calculation to the existence of non-trivial values for $g_{11}...g_{33}$ in contrast to his default assumption about the metric for static gravitational fields. Einstein considered the difference to his earlier assumption about such a metric a remarkable consequence of the application of his methods for solving the perihelion problem to the new field equation. This is evident from his contemporary correspondence. After the completion of the final version of general relativity, he repeatedly mentioned this fact in letters to Michele Besso. In a letter from 10 December, he remarked:

> You will be surprised by the appearance of the $g_{11}...\dot{g}_{33}$.[222]

A little more than a week later, Einstein returned to this point, again emphasizing the remarkable nature of the deviation from what he expected to be the metric for weak static fields. He was now able to point out how the conflict between this deviation and the Newtonian limit could be avoided:

> Most gratifying is the agreement with perihelion motion and the general covariance; strangest, however, is the circumstance that Newton's theory of the field is incorrect already in the 1st order eq. (appearance of the $g_{11}...g_{33}$). It is just the circumstance that the $g_{11}...g_{33}$ do not appear in first-order approximations of the motion eqs. which determines the simplicity of Newton's theory.[223]

The scheme for calculating a spherically symmetric static metric did not in itself lead to a way in which the deviation from Einstein's standard metric could be reconciled with the correspondence principle. However, it was clear that gravitational fields cannot be observed directly but only via the motion of bodies within these fields—a point stressed in Besso's 1913 memo[224]—so that the equation of motion, at second glance, suggested a natural way out of this dilemma. This second glance showed that in first-order approximation only the g_{44}-component of the metric tensor determines the motion of a material point and that, accordingly, non-trivial values for $g_{11}...g_{33}$

---

221 "Meine diesbezügliche Bemerkung in der Arbeit von 4. November gilt gemäss der neuen Festsetzung $\sqrt{-g} = 1$ nicht mehr, wie mir schon bekannt war. [At this point he added in footnote: Die Wahl des Koordinatensystems gemäß der Bedingung $\sum \partial g^{\mu\nu}/\partial x_\nu = 0$ ist nicht vereinbar mit $\sqrt{-g} = 1$.] Seitdem habe ich ja den Newton'schen Fall nach der endgültigen Theorie ja anders behandelt." Einstein to Karl Schwarzschild, 19 February 1916 (CPAE 8, Doc. 194). For a discussion of the role of coordinate conditions in general relativity, see also Einstein's paper on gravitational waves (Einstein 1916c).

222 "Du wirst über das Auftreten der $g_{11}...g_{33}$ überrascht sein." Einstein to Michele Besso, 10 December 1915, (CPAE 8, Doc. 162).

223 "Das Erfreulichste ist das Stimmen der Perihelbewegung und die allgemeine Kovarianz, das Merkwürdigste aber der Umstand, dass Newtons Theorie des Feldes schon in Gl. 1. Ordnung unrichtig ist (auftreten der $g_{11}...g_{33}$). Nur der Umstand, dass die $g_{11}...g_{33}$ nicht in den ersten Näherungen der Bewegungsgleichungen des Punktes auftreten, bedingt die Einfachheit von Newtons Theorie." Einstein to Michele Besso, 21 December 1915, (CPAE 8, Doc. 168).

224 For a facsimile of the relevant passage, see Fig. 2 on p. 300 of "What Did Einstein Know..." (in vol. 2 of this series) and (Renn 2005a, 128).

do not affect the first-order equation of motion and hence the Newtonian limit of Einstein's theory.

In a third letter to his friend Besso, Einstein once more returned to this point, now in order to explain that the new way of obtaining the Newtonian limit is closely related to the perihelion shift of Mercury and hence to the excellent agreement between theory and experiment.

> The great magnification of the effect against our calculation stems from that, according to the new theory, the $g_{11} \dots g_{33}$'s also appear in the first order and hence contribute to the perihelion motion.[225]

This close connection between the empirical success of the theory and the deviation from the correspondence principle, as originally conceived by Einstein, stabilized the modified understanding of this principle and freed it from the aura of a dubious technical trick.

7.17.3 A New Problem Meets an Old Solution

Einstein repeatedly stressed the fact that only g_{44} matters for the equation of motion, a circumstance that must have seemed a strange but lucky coincidence to him. This solution to the dilemma created by the occurrence of non-trivial diagonal components in the first-order static metric was in itself as little new in 1915 as the dilemma itself. We have seen that in 1912–1913 the harmonically reduced and linearized Einstein tensor had been discarded because it led to a metric for weak static fields with non-trivial diagonal components (cf. eq. (74)). Furthermore, the very ansatz for a spherically symmetric static metric used to treat the Mercury problem pointed to the possibility of such non-trivial components. When Einstein first developed this ansatz in 1913, he did not give this possibility serious consideration because he was convinced of the validity of the *Entwurf* equation which does not give rise to such components.

It is remarkable is that, even though the dilemma of a non-spatially flat static metric was in mid-1913 no longer (and not yet) a real one for Einstein, it was nevertheless at that time already considered and resolved by Besso, and probably also by Einstein. This is documented by a page in the Einstein-Besso manuscript, written by Michele Besso on the back of a letter to Einstein. The page can be dated to June 1913 when both worked together in Zurich (CPAE 4, 392). It is one of a couple of pages on which Besso recapitulated the procedure he and Einstein had applied in order to determine the perihelion shift of Mercury. The purpose of this recapitulation was evidently not only Besso's wish to understand more thoroughly a method that in essence had probably been developed by Einstein, but also his intention to apply this method to more complex cases such as the field of a rotating sun or the inclusion of the sun's pressure in the calculation. Given the reflective character of Besso's notes, we also

225 "Die starke Vergrösserung des Effektes gegenüber unserer Rechnung führt daher, dass gemäss der neuen Theorie auch die $g_{11} \dots g_{33}$). in Grössen erster Ordnung auftreten und so zur Perihelbewegung beitragen." Einstein to Michele Besso, 3 January 1916, (CPAE 8, Doc. 178).

find, along with the recapitulation of essentials, general remarks concerning the nature and plausibility of assumptions which Einstein and Besso had made in the course of their application of the method. It is among such remarks that one finds the brief reflection on the assumption of the spatially flat static metric quoted above, which shows that the assumption of this form of the metric was not an unquestioned prejudice.[226] Besso also considered the more general possibility of a weak-field metric in which components other than the 4–4 one deviated from the Minkowski metric. He came to the same conclusion as Einstein in his perihelion paper of November 1915, namely that, to first order, only the g_{44}-component is relevant for the equation of motion:

> The values so derived and inserted in the equations for the motion of the material point lead to the result that in the latter, [as far as] deviations of the magnitudes g from the relativity scheme [i.e. the Minkowski metric] [are concerned], only the elements g_{44} have any influence.[227]

This observation from June 1913 shows that the possibility of attaining the Newtonian limit also for spatially non-flat static metrics was not new. What was new was the necessity to bring this knowledge to bear on a field equation which seemed to forclude any other way of satisfying the correspondence principle. The novelty on 18 November 1915 was thus the combination of two chunks of knowledge that had been available independently for years, i.e., to base field equations on the Ricci tensor and to attain the Newtonian limit also for spatially non-flat static metrics.[228] In the following, we shall see that this combination triggered a new development that would very soon lead Einstein beyond the Ricci tensor.

7.18 Completing the Circle: Einstein's Return to the Einstein Tensor

7.18.1 Finding the Capstone of General Relativity by Double-Checking a New Theory of Matter

Einstein's completion of general relativity in November 1915 was essentially a solitary phase during which he had little correspondence and no collaboration on this subject, except for the mathematician David Hilbert, with whom Einstein's corresponded on the progress of their respective efforts. Hilbert had a long-standing interest in physics and was especially interested in foundational issues within his program of an axiomatization of the natural sciences.[229] When Gustav Mie published a special

226 See (CPAE 4, Doc. 14 [p. 16]). The mention of § 1 is probably a reference to (Einstein and Grossmann 1913).

227 "Die so ermittelten Werte in die Gleichg[ung]en für die Beweg[ung] des Materiellen Punktes eingesetzt, ergeben dass in denselben Abweichngen der Grössen g vom Relativitätsschema nur die Glieder g_{44} von Einfluss sind." (CPAE 4, Doc. 14 [p. 16])

228 For Einstein's continued concern with the problem of the appearance of other components of the metric tensor than g_{44}, see Albert Einstein to Erwin Freundlich, 19 March 1915, (CPAE 8, Doc. 63).

229 See (Corry 2004).

relativistic, electromagnetic theory of matter in 1912, he was particularly intrigued by it, and after Einstein's visit to Göttingen, at Hilbert's invitation, in the summer of 1915, Hilbert engaged in an attempt to find a synthesis between Mie's theory and Einstein's approach to gravitation. In November 1915, he was close to finishing his work and became Einstein's competitor for priority of the field equation of general relativity. The two scientists exchanged criticism and preliminary results, directly and possibly also indirectly via others, so that the question arises of the extent to which their results can be considered independent achievements. A set of proofs of Hilbert's "First Communication on the Foundations of Physics" (Hilbert 1915) rules out the possibility that Einstein took the last and crucial step in completing general relativity from the work of David Hilbert. Since this issue is discussed elsewhere in detail,[230] we limit ourselves here to the analysis of how Einstein completed this last step along the pathways of his own prior research.

Einstein considered the calculation of the perihelion shift of Mercury as the success of a generally-covariant theory of gravitation based on the Ricci tensor, but also as confirming the possibility of a new theory of matter. This is clear from the abstract of his paper quoted above and also from a letter he wrote to his friend Besso:

> In these last months I had great success in my work. *Generally covariant* gravitation equations. *Perihelion motions explained quantitatively.* The role of gravitation in the structure of matter. You will be astonished. I worked horrendously intensely; it is strange that it is sustainable.[231]

But the agreement between theoretical and empirical values for the perihelion shift of Mercury supported the new theory of matter only through the condition $\sqrt{-g} = 1$. The precarious role of this condition for further considerations by Einstein is made evident by a footnote appended to the perihelion paper:

> In a forthcoming communication it will be shown that this hypothesis is unnecessary. It is because such a choice of reference frame is possible that the determinant $|g_{\mu\nu}|$ takes on the value –1. The following investigation is independent of this choice.[232]

Einstein reexamined the connection between this determinant condition and his new theory of matter, which found its essential expression in the vanishing of the trace of the stress-energy tensor of matter. The requirement of the vanishing trace resulted

For a facsimile reproduction of both the proofs and the published version of (Hilbert 1915), see (Renn 2005, 146–173). In this series, the relation between Einstein's and Hilbert's work is further discussed in the section "Including Gravitation in a Unified Theory of Physics" (vol. 4 of this series).

231 "Ich habe mit grossem Erfolg gearbeitet in diesen Monaten. *Allgemein kovariante* Gravitationsgleichungen. *Perihelbewegungen quantitativ erklärt*. Rolle der Gravitation im Bau der Materie. Du wirst staunen. Gearbeitet habe ich schauderhaft angestrengt; sonderbar, dass man es aushält." Einstein to Michele Besso, 17 November 1915, (CPAE 8, Doc. 147).

232 "In einer bald folgenden Mitteilung wird gezeigt werden, daß jene Hypothese entbehrlich ist. Wesentlich ist nur, daß eine solche Wahl des Bezugssystems möglich ist, daß die Determinante $|g_{\mu\nu}|$ den Wert –1 annimmt. Die nachfolgende Untersuchung ist hiervon unabhängig." (Einstein 1915b, 831)

from the comparison of two equations Einstein had derived in his paper of 4 November 1915, one with the help of the energy-momentum balance, the other directly from the field equation. With the help of the trace t of the energy-momentum expression of the gravitational field, these equations can be rewritten as:[233]

$$\sum_{\alpha\beta} \frac{\partial^2 g^{\alpha\beta}}{\partial x_\alpha \partial x_\beta} - \kappa t = 0, \text{ and} \tag{90}$$

$$\sum_{\alpha\beta} \frac{\partial^2 g^{\alpha\beta}}{\partial x_\alpha \partial x_\beta} - \kappa t + \frac{\partial}{\partial x^\alpha}\left(g^{\alpha\beta} \frac{\partial}{\partial x^\beta} \log \sqrt{-g}\right) = \kappa t. \tag{91}$$

Comparing these two requirements Einstein had derived the scalar coordinate restriction of his first November paper, eq. (84). Both the empirical success of his perihelion calculation and the support for his new theory of matter were hinging on this condition. But there was another way of bringing the trace of the full field equation into agreement with eq. (83). Possibly feeling uneasy about the far-reaching consequences that this delicate compatibility argument had to support, Einstein reexamined his earlier reasoning.

From this perspective, the system of equations (90) and (91) provided a representation in which to explore the optimal way of putting together the pieces of his puzzle. This exploration led to yet another modification of the field equation. A reflection on how conditions (90) and (91) had been derived from the November field equation may have sufficed for the identification of an appropriate modification of this field equation by adding a multiple of the trace of the stress-energy tensor of matter to its right-hand side so as to yield instead:[234]

$$\sum_{\alpha\beta} \frac{\partial^2 g^{\alpha\beta}}{\partial x_\alpha \partial x_\beta} - \kappa(t + T) = 0, \text{ and} \tag{92}$$

$$\sum_{\alpha\beta} \frac{\partial^2 g^{\alpha\beta}}{\partial x_\alpha \partial x_\beta} - \kappa(t + T) + \frac{\partial}{\partial x^\alpha}\left(g^{\alpha\beta} \frac{\partial}{\partial x^\beta} \log \sqrt{-g}\right) = 0. \tag{93}$$

This set of equations no longer gives rise to problematic additional conditions.

The compatibility of Einstein's two conditions could thus be achieved without requiring $\sqrt{-g} = 1$ to imply that the trace of the stress-energy tensor must vanish, i.e. without eq. (61). This was the final step by which Einstein arrived at the definitive field equations of general relativity, which were presented in his paper of 25 November 1915 (cf. eqs. (69), (70)).

The modified source term in the new field equation violated the default assumption eq. (XLI) about the right-hand side of Einstein's mental model of a gravitational field equation. But Einstein could accept this violation since the energy-momentum

233 Cf. (Einstein 1915a, eqs. 9 and 10).
234 See "Untying the Knot …" (in vol. 2 of this series), sec. 7, eqs. 85–91.

tensor of matter and the energy-momentum expression of the gravitational field now entered the right-hand side of the field equation in a completely analogous way, (cf. eq. (68) to eq. (81)). It may also have played a role that the step from the Ricci to the Einstein tensor was, after all, not unfamiliar given his earlier experience in the Zurich Notebook. In his paper, Einstein lapidarily noted:

> I now quite recently found that one can get away without this hypothesis about the energy tensor of matter merely by inserting it into the field equations in a slightly different way than is done in my earlier papers.[235]

What had earlier prevented Einstein from accepting the (harmonically reduced and linearized) Ricci and Einstein tensors—his understanding of the correspondence principle—had meanwhile been transformed in the context of the perihelion calculation. The success of his solution to the Mercury problem included a solution to the problem of the Newtonian limit, and this solution now effectively replaced the correspondence principle as a criterion for an acceptable field equation.

In summary, the final phase of Einstein's work in November 1915 was not so much a phase in which new results challenged old prejudices, but rather one of reflection on the knowledge that was already available to him and in which different options were weighed against each other. One of the results of this process of reflection was that there was no support for a new theory of matter as Einstein had believed, possibly following Hilbert, in his addendum of 11 November. In the conclusion of his last November paper Einstein explicitly revoked his earlier claim:

> With this, we have finally completed the general theory of relativity as a logical structure. The postulate of relativity in its most general formulation (which makes spacetime coordinates into physically meaningless parameters) leads with compelling necessity to a very specific theory of gravitation that also explains the movement of the perihelion of Mercury. However, the postulate of general relativity cannot reveal to us anything new and different about the essence of the various processes in nature than what the special theory of relativity taught us already. The opinions I recently voiced here in this regard have been in error. Every physical theory that complies with the special theory of relativity can, by means of the absolute differential calculus, be integrated into the system of general relativity theory—without the latter providing any criteria about the admissibility of such physical theory.[236]

---

235 "Neuerdings finde ich nun, daß man ohne Hypothese über den Energietensor der Materie auskommen kann, wenn man den Energietensor der Materie in etwas anderer Weise in die Feldgleichungen einsetzt, als dies in meinen beiden früheren Mitteilungen geschehen ist." (Einstein 1915a, 844)

236 "Damit, ist endlich die allgemeine Relativitätstheorie als logisches Gebäude abgeschlossen. Das Relativitätspostulat in seiner allgemeinsten Fassung, welches die Raumzeitkoordinaten zu physikalisch bedeutungslosen Parametern macht, führt mit zwingender Notwendigkeit zu einer ganz bestimmten Theorie der Gravitation, welche die Perihelbewegung des Merkur erklärt. Dagegen vermag das allgemeine Relativitätspostulat uns nichts über das Wesen der übrigen Naturvorgänge zu offenbaren, was nicht schon die spezielle Relativitätstheorie gelehrt hätte. Meine in dieser Hinsicht neulich an dieser Stelle geäußerte Meinung war irrtümlich. Jede der speziellen Relativitätstheorie gemäße physikalische Theorie kann vermittels des absoluten Differentialkalküls in das System der allgemeinen Relativitätstheorie eingereiht werden, ohne daß letztere irgendein Kriterium für die Zulässigkeit jener Theorie lieferte." (Einstein 1915a, 847)

7.18.2 Reorganizing the Structure of General Relativity

The further history of general relativity shows that this theory could not yet be considered "logically complete," as Einstein formulated in the last paragraph of his conclusive paper. Even if one disregards later developments such as his modification of the field equations with a cosmological term, fundamental issues such as the status of energy-momentum conservation as an independent postulate of the theory still remained to be clarified. Without this clarification, the theory was initially unconvincing even to those physicists, such as Ehrenfest and Lorentz, who supported Einstein and closely followed his work.

Ehrenfest argued that one can eliminate the stress-energy tensor of matter from the two postulates of the theory, the conservation equation and the field equation, and thus arrive at a new differential equation, which the metric tensor has to satisfy in addition to the field equations. He therefore doubted, apparently following Einstein's earlier line of argumentation, that the new field equation was actually generally covariant. On 1 January 1916 Einstein wrote to Lorentz:

> I am conducting a discussion with Ehrenfest at present essentially on whether the theory really does fulfill the general covariance requirement. He also indicated to me that you had encountered problems or objections to it as well; you would do me a great favor if you were to inform me of them briefly. I have broken in my hobbyhorse so thoroughly that with a short hint I certainly also would notice where the crux of the problem lies.[237]

It was in the exchange with Ehrenfest that Einstein arrived at the conclusion that energy-momentum conservation was not an independent postulate but a consequence of the field equation.[238] The substantial clarification of the conservation principle that Einstein achieved in this debate became a starting point for a rearrangement of the foundational elements of his theory. The first step was taken in a lengthy letter that Einstein wrote to Ehrenfest.[239] In this letter he presented a derivation of the field equation from scratch and showed how energy-momentum conservation can be derived from it. Einstein proceeded in four steps:

1. He first derived the Lagrangian form of the field equation.
2. He next turned to the conservation principle. However, he did not yet derive the conservation of energy and momentum from the field equation. Rather, he assumed an equation that includes an unspecified function that has the form of energy-momentum conservation of matter, as he had postulated it in the earlier

237 "Mit Ehrenfest stehe ich in einer Diskussion im Wesentlichen darüber, ob die Theorie die Forderung der allgemeinen Kovarianz wirklich erfülle. Er deutete mir auch an, dass Sie Schwierigkeiten bezw. Einwendungen gefunden hätten; Sie würden mir große Freude machen, wenn Sie mir dieselben kurz mitteilten. Mein Steckenpferd habe ich so gründlich eingeritten, dass ich gewiss auch nach kurzer Andeutung merke, wo das Wesen der Schwierigkeit liegt." Einstein to H. A. Lorentz, 1 January 1916 (CPAE 8, Doc. 177).

238 Einstein to Paul Ehrenfest, 29 December 1915, Einstein to Paul Ehrenfest, 3 January 1916, Einstein to Paul Ehrenfest, 24 January 1916 (CPAE 8, Docs. 174, 179,185).

239 Einstein to Paul Ehrenfest, 24 January 1916 or later (CPAE 8, Doc. 185).

versions of his theory, and then derived from this equation another equation that has the form of energy-momentum conservation for matter *and* gravitation.

3. In the next step, Einstein wrote the gravitational field equation in terms of mixed tensor densities. He had apparently two reasons for doing so, the first being the possibility of an immediate physical interpretation of the equation in this form. The second reason was the preparation of the fourth and final step of his argument in which the conservation principle is demonstrated.
4. In his last step, Einstein derived energy-momentum conservation with the help of an indirect proof. He showed that one obtains a contradiction with the field equation in the mixed form if one does not assume that the unspecified function in the hypothetical equation for energy-momentum conservation (step 2) vanishes.

Einstein considered this line of argument as a new achievement clarifying the foundations of the theory, as becomes evident from the final passage of his letter:

> You will certainly not encounter any more problems now. Show this thing to Lorentz as well, who also does not yet perceive the need for the structure on the right-hand side of the field equations. I would appreciate it if you would then give these pages back to me, because nowhere else do I have these things so nicely in one place.[240]

Einstein made this new derivation the basis for his exposition in the 1916 review paper (Einstein 1916a), submitted on 20 March 1916.[241]

In the 1916 review, however, Einstein introduced a further rearrangement of the foundational elements of his theory. His main new results were a transformation of the indirect proof of the letter to Ehrenfest into a direct proof of energy-momentum conservation and the establishment of a connection between this derivation and a mathematical theorem by Hilbert, which was later generalized by Emmy Noether. The latter result is particularly important as it amounted, in effect, to a recognition of the contracted Bianchi identities and their role as integrability conditions for the sources of the field equation of general relativity.

In his review Einstein proceeded in six steps. We will briefly review these steps and show how a new deductive structure of general relativity emerged from Einstein's reflection on his discovery process and from the insights obtained in the controversy with Ehrenfest:

1. Einstein first introduced the field equations for the source-free case. In this step he transformed his own pathway from the Ricci to the Einstein tensor into a strategy for justifying the foundations of his theory. He introduced the Ricci equation as the appropriate gravitational field equation for empty space conceiving it as a weakening of an equation based on the Riemann tensor (Einstein 1916a, 803).

240 "Du wirst nun wohl keine Schwierigkeit mehr finden. Zeige die Sache auch Lorentz, der die Notwendigkeit der Struktur der rechten Seite der Feldgleichungen auch noch nicht empfindet. Es wäre mir lieb, wenn Du mir diese Blätter dann wieder zurückgäbest, weil ich die Sachen sonst nirgends so hübsch beisammen habe." (CPAE 8, Doc. 185)

241 For historical discussions of this paper, see (Janssen 2005, Sauer 2005).

2. He then developed the Lagrangian formalism and derived an equation for energy-momentum conservation of the gravitational field alone using the pseudo-tensor for the stress-energy of the gravitational field.
3. Einstein next reformulated the field equation in “mixed” form, including the trace term of the pseudo-tensor that suggested the new default setting eq. (81). The peculiar way in which the matter tensor has to be introduced as the source term of the Einstein field equation was thus prepared.
4. Einstein then supplemented the source-free field equation with this matter term, which was introduced in analogy to the pseudo-tensor for the stress-energy of the gravitational field, and thus arrived at the complete Einstein field equation. With respect to the paper of 25 November 1915, the context for Einstein’s justification of his new field equations had changed: Equations corresponding to eq. (92) and eq. (93) no longer appear in the 1916 review paper since energy-momentum conservation is not introduced as an independent postulate. As a consequence, these equations were no longer available as a justification for the new field equation. Instead, Einstein introduced the requirement that the energy of matter and the energy of gravitation enter the field equation on the same footing as the primary motivation for postulating the particular form of the Einstein field equation (Einstein 1916a, 808). He made it additionally clear that the main justification for his postulated field equation were the deductive consequences following from it.
5. Again in analogy to the source-free case, Einstein next showed that an energy-momentum equation holds for matter and the gravitational field. Previously, the equivalents of this equation in the earlier versions of the theory, going back to and including the *Entwurf* theory, were derived from the field equation, together with the independent postulate of energy-momentum conservation. Einstein had now succeeded in deriving this equation from the field equation alone.
6. In his final step, Einstein shows how his usual equation for the energy-momentum conservation of matter in the presence of a gravitational field, which was represented by the vanishing covariant divergence of the stress-energy tensor of matter, actually follows from his field equation. In other words, what had been a heuristic principle useful for selecting appropriate field equations now became a consequence of the field equation that was useful for selecting an appropriate stress-energy tensor of matter suitable to act as a source of the field equation (Einstein 1916a, 809–810).

In the last step of his deductive construction, Einstein also established a bridge to Hilbert’s contemporary work integrating one of its mathematical corner stones into his own newly established framework of general relativity. As we have just seen, within this framework the stress-energy tensor of matter is no longer conceived as an independent ingredient of the theory with properties that affect its physical interpretation (such as the selection of preferred coordinates) but this tensor has itself to satisfy certain constraints imposed by the theory. In a short remark, Einstein characterized this partly dependent and partly independent status of the material process in his theory of gravitation:

> Thus the field equations of gravitation contain four conditions which govern the course of material phenomena. They give the equations of material phenomena completely, if the latter is capable of being characterized by four differential equations independent of one another.[242]

At this point Einstein appended a footnote in which he referred to Hilbert.[243] Einstein provides here a reinterpretation of the mathematical claim central to Hilbert's theory, which constitutes the core of what later became Noether's theorem.[244] In fact on the page referred to by Einstein we find the following passage:

> ... then in this invariant system of *n* differential equations for the n quantities there are always four that are a consequence of the remaining $n-4$ in this sense, that among the *n* differential equations and their total derivatives there are always four linear and linearly independent combinations that are satisfied identically.[245]

By referring this general theorem to the relation between his gravitational field equation and the four differential equations corresponding to the vanishing of the covariant divergence of the stress-energy tensor, Einstein gave a physical interpretation of this theorem that was quite different from Hilbert's. Combining his own results with those of Hilbert, he was able to understand that energy-momentum conservation follows from the field equations. He had thus finally realized the structural role which the four differential equations, expressing energy-momentum conservation and mathematically corresponding to the contracted Bianchi identities, play for the conservation principle in the general theory of relativity as we understand it today.

8. THE TRANSITION FROM CLASSICAL PHYSICS TO GENERAL RELATIVITY AS A SCIENTIFIC REVOLUTION

In the preceding sections, we have reconstructed the complex process by which Einstein's heuristics led to the formulation of the general theory of relativity. We have shown that a key role was played by the interaction between the heuristics guiding the search for the new theory and the concrete representations of intermediate results in terms of physically interpreted mathematical formalisms. These representations opened up new possibilities for further development and often required adjustments

---

242 "Die Feldgleichungen der Gravitation enthalten also gleichzeitig vier Bedingungen, welchen der materielle Vorgang zu genügen hat. Sie liefern die Gleichungen des materiellen Vorganges vollständig, wenn letzterer durch vier voneinander unabhängige Differentialgleichungen charakterisierbar ist." (Einstein 1916a, 810)

243 Cf. (Hilbert 1915, 3). Einstein's page number actually refers to an offprint of Hilbert's paper, not to the published version. Offprints were available to Hilbert already by mid-February 1916, the published paper itself appeared on 31 March 1916, see (Sauer 1999, note 74).

244 See (Sauer 1999). For the roots of this theorem in Einstein's own work, see sec. 3 of "Untying the Knot ..." (in vol. 2 of this series).

245 "... so sind in diesem invarianten System von *n* Differentialgleichungen für die *n* Größen stets vier eine Folge der n – 4 übrigen – in dem Sinne, daß zwischen den *n* Differentialgleichungen und ihren totalen Ableitungen stets vier lineare, von einander unabhängige Kombinationen identisch erfüllt sind." (Hilbert 1915, 3). See vol. 4 of this series.)

of physical concepts and heuristic principles. Einstein's heuristics, together with such concrete intermediate results, was evidently capable of generating enough of those arguments on which the justification of general relativity as an essential part of modern physics, is still based today.

This heuristics itself and some of Einstein's conceptual starting points in classical physics underwent changes that justify the designation of this process as a scientific revolution. In this final section, we shall first review the beginning and the end of the development of Einstein's heuristics in order to highlight the conceptual innovations brought about by this development with respect to classical physics. We shall then summarize our answers to the three epistemic paradoxes raised by this scientific revolution. These answers make use of the key elements for an understanding of a scientific revolution that is suggested by historical epistemology: the long-term character of knowledge development, the architecture of knowledge, and the mechanisms of knowledge dynamics.

8.1 The Lorentz Model Remodelled

Our analysis has shown that for Einstein's search, the Lorentz model was structurally the most significant heuristic element inherited from classical physics. At each stage of its development, the structure of this mental model and its default settings determined the way in which the specific problems of finding the field equations could be addressed. As long as it remained unquestioned, the model thus opened (or closed) the viable paths of further exploration and determined the possibilities of conceptual unfolding. In classical physics, the two basic structures of the Lorentz model, the field equation and equation of motion, are related to each other as independent components of which the first determines the creation of a global field by a local source, while the second determines the effect of the global field on a local probe. Within the classical framework, source and probe are essentially independent entities entering into this model.

In general relativity, this basic structure has changed. First, the source can no longer be independently prescribed from the field. The distribution of matter and energy acting as a source of the gravitational field can only be described in a given geometry of spacetime, which in turn is only another aspect of the gravitational field determined by the field equation. Second, the equation of motion is no longer an independent aspect of the problem, linked to the description of the gravitational field by an overarching force concept, but is constrained and in special cases even completely determined by the field equation.[246] These features of general relativity, which mark its conceptual distinction from classical physics were not yet evident in 1915 when Einstein formulated his field equations. In other words, the corresponding conceptual innovation was not the presupposition but the result of his research. Thus Einstein's heuristics, which was structured by the Lorentz model, led to the develop-

246 For historical discussion of this point, see (Havas 1989, Kennefick 2005).

ment of a theory whose cognitive content can no longer be adequately captured by this mental model.

The discovery of general relativity would, however, have been impossible if the Lorentz model had not at least been adequate for capturing just those partial aspects of the final theory that made its discovery possible. As we have seen in the previous sections, it was even possible to construct and interpret the definitive field equation of general relativity according to this model. Furthermore, the kind of solutions that Einstein had in mind when he searched for the field equation obscured the new relation between matter distribution and geometry mentioned above. The solutions that he seriously considered were given either by Minkowski spacetime (a vacuum solution) described in various coordinate systems, or weak field solutions that could be obtained from it by an iterative procedure. The problem of having to first specify the geometry and then the distribution of matter and energy in order to solve the field equation turns into an approximation procedure. The further elaboration of the consequences of Einstein's field equation revealed the changes with respect to the Lorentz model. That a revision of this mental model was implied by the field equation of general relativity was clear to Einstein as soon as he noticed that the field equation of the new theory would have to be non-linear. As early as 1912, he interpreted this technical feature as representing the conceptual conclusion that the gravitational field possessing energy must also act as its own source. However, at that time, this modification of the model did not appear to be a radical break, since a modification of only a default setting of the mental model ("linearity of the field equation") was sufficient to account for the insight that gravitation can act as its own source.

8.2 The Ill-Conserved Conservation Principle

In classical physics, the conservation of energy and momentum is a consequence of the fundamental laws governing gravitational and electrodynamic interaction. In special relativity, the conservation principle has found an elegant formulation as a tensorial equation that unifies the conservation of momentum and energy. In both classical and special-relativistic physics, momentum and energy are conceived as localizable physical quantities whose conservation can be described by a partial differential equation which describes a local balance between the various contributions to the energy and momentum of a physical system. Einstein's consideration of a particular example (the behavior of a pressureless dust of particles in a gravitational field) formed the basis, as we have seen, for a tentative generalization of the equation expressing the conservation principle in special relativity, which now also included the effect of gravitation, interpreted as the effect of an external force. Two distinct perspectives on this equation exist, one from classical physics and special relativity, the other from general relativity. The possibility of having these two perspectives on the same mathematical expression turned out to be crucial for the emergence of general relativity.

From the point of view of classical physics and of special relativity, Einstein's postulated equation represented a twofold constraint for the gravitational field equation to be found: the resulting field theory of gravitation had to be compatible with this equation, even at the price of restricting its range of applicability, and, furthermore, the field equation should allow this equation to be rewritten as a local, frame-independent balance between the energy-momentum of matter and that of gravitation.

Further elaboration of the consequences of this equation, however, made this latter request questionable. In the course of his search, Einstein was forced to realize that the expression for energy-momentum conservation which he had postulated turned out to be incompatible with the assumption of a frame-independent stress-energy tensor of gravitation. If this postulate is accepted, then energy and momentum of a gravitational field cannot, in contrast to classical physics, be localizable physical quantities. In this way, a feature of general relativity that is incompatible with classical physics was suggested by a framework still anchored in its fundamental concepts. Einstein's insight into the character of the expression representing the stress-energy of the gravitational field might have given him good reason to abandon this entire approach since its results conflicted with his well-founded expectation that the gravitational field has localizable energetic properties just like all the other known physical fields. Why did he hold on to this equation in spite of its, from the point of view of classical physics, problematic implications? His reasons were in any case not an anticipation of those of the later theory of general relativity.

The equation expressing the energy-momentum balance in a gravitational field that Einstein had postulated at the beginning of his search, and from which the problematic conceptual consequences summarized above can be inferred is obtained in general relativity as an integrability condition of the field equation. Technically speaking, it is a condition to be imposed on an admissible energy momentum tensor, representing the right-hand side of the field equation, required in order to be compatible with a mathematical identity—the contracted Bianchi identity—valid for the left-hand side of the field equation. The Bianchi identity ensures that the gravitational field equation determines the dynamics of the geometry of spacetime without determining also the coordinate system. It reduces the 10 components of the field equation for the 10 components of the metric tensor to only 6 component-equations, thus leaving open the choice of four arbitrary functions corresponding to the choice of a coordinate system. The Bianchi identity together with the gravitational field equation then also determines the evolution of energy and momentum in space and time by way of the equation which Einstein interpreted as the expression for the conservation of energy and momentum in the presence of a gravitational field.

Clearly this argument could not have played a role for Einstein when he was still searching for the correct field equation. He was not even familiar with the Bianchi identity at the time when he concluded his search with the publication of the field equation of general relativity in 1915. Instead he only had two comparatively weak arguments to hold on to this equation even when he recognized that it did not lead him to an invariant local expression for the energy-momentum of the gravitational field. The first argument was that, for the special case of a dust-like cloud of particles, it was possible to obtain this equation from the equation of motion of a single point-particle in a gravitational field described by the metric tensor. The second argument was related to the mathematical form of energy-momentum conservation. The corresponding equation has the form of a generally-covariant divergence equation which is not only the precise analogon for the corresponding special relativistic equation but which also reduces to the latter in the absence of a gravitational field. These two arguments reinforced each other and are in turn supported by other aspects of Einstein's heuristics, in particular by the generalized relativity principle and all those aspects which underlay his understanding of motion in a gravitational field and the requirement of a close correspondence between special relativistic insights and their generalizations in the new theory to be constructed.

But in whatever way Einstein could support his understanding of energy-momentum conservation by drawing on special cases and analogies, it was, from the point of view of the deductive structure of the later theory, support for the wrong side of his argumentative construction, in so far as it stabilized the role of energy-momentum conservation as an independent first principle rooted in the conviction of the fundamental status of energy and momentum conservation for any physical theory. This understanding motivated its use both as a compatibility requirement and as an additional constraint on trial field equations. From the perspective of general relativity, Einstein had thus developed an improper argumentative structure around a proper equation, whereas from his own perspective at the time, he had attained a partial insight into the deductive structure of the theory which he attempted to construct. Only after his achievement of 1915 he was able to reverse this deductive structure and obtain the vanishing of the covariant divergence of the energy-momentum tensor as a consequence of the gravitational field equation in the sense explained above. As was the case for the development of the mental model in Einstein's research, the structural and conceptual insights associated with understanding the role of energy-momentum conservation in general relativity were thus the result and not the presupposition of finding the correct equations.

8.3 The Lack of Correspondence between the Correspondence Principle as seen from Classical Physics and from General Relativity

The way in which the classical theory of gravitation is contained in the theory of general relativity could, of course, not be anticipated on the basis of classical physics before that theory was actually formulated. Nevertheless, the same heuristics which led to the introduction of the principal building block of the new theory, the metric tensor, also determined, to a large extent, Einstein's understanding of the relation between the theory of gravitation which he was looking for and Newton's theory. All in all, he developed, as we have seen, in the course of his research three different arguments in favor of the representation of static gravitational fields by a spatially flat metric tensor in which, for an appropriate coordinate representation, only one component is variable and a function of the three space coordinates; this function then, so Einstein's conclusion, corresponded, under certain limiting conditions, to the Newtonian gravitational potential in his new theory, whatever the precise field equation would be.

The first argument was directly related to the introduction of the metric tensor as representing a gravito-inertial field, a step that was, as we have seen, motivated by the equivalence principle. Einstein conceived Newtonian gravitation and inertia as special cases of a more general interaction. For the case of uniform acceleration he was able to directly identify inertial effects with a scalar Newtonian gravitational field and he expected that he would be able to do the same for more general cases by generalizing the notion of the gravitational field. A model for that generalization was delivered by electrodynamics. In spite of the obvious differences between gravitation theory and electrodynamics, the analogy between them was in fact the only available one and hence determined Einstein's view of the general pattern according to which a theory of the static field should be contained as a special case in a general field theory. According to this pattern, the general potential was represented by a many-component object such as a vector or a tensor which, in the special case of a static field, reduces to a single-component object. In the case of gravitation it should naturally be possible to identify this single-component object with Newton's gravitational potential. This expectation was reinforced by the fact that Einstein had developed, even before introducing a metric formalism, a theory of static gravitational fields in which these are represented by a single function. When he began to employ a metric formalism, it was hence natural to describe static fields by a metric with one variable component and to identify this component with the gravitational potential of his theory of static fields.

Einstein's "classical" understanding of the transition from his general theory to Newton's theory was stabilized by further arguments developed in the course of his research. The second argument was based on the role of special relativity as an intermediate step in this transition. In order to describe the gravitational effects known from classical physics as aspects of a more general gravitational field it is necessary to specify also the conditions under which such an identification is possible. These physical circumstances require, in particular, the general field to be weak and static. These conditions are, however, not sufficient for restricting the realm of gravitational effects to that covered by Newton's theory. The case in which the masses involved perform motions of high velocities requires a treatment by the special theory of relativity. According to this line of reasoning, weak fields, and in particular weak static fields, should hence play the role of an intermediate case in the transition to Newtonian gravitation, an intermediate case to which the special theory of relativity should be applicable. It should hence be possible to formulate a special relativistic gravitational field equation which holds under these circumstances. As it turned out, the solutions of such a weak-field equation, as suggested by the appropriate default-settings of the Lorentz model for this case, exactly correspond to Einstein's classical expectations.

Nevertheless, these expectations were, as we have seen, challenged in the course of Einstein's research which pointed on several occasions towards a representation of static fields by a metric tensor whose form does not correspond to the one which he expected. He therefore felt, at some point, the necessity of developing yet another argument in favor of this expectation. His third argument, which we have also discussed above, was completely independent of a particular gravitational field equation. In essence it consisted in a problematic attempt to deriving the form of the metric tensor for static gravitational fields from the postulate underlying the equivalence principle that all bodies—no matter what their energy content—fall with the same acceleration in a gravitational field.

The assertion that the metric for static fields is of the canonical form expected by Einstein does not belong to the realm of classical physics. It rather appears to be a specific technical assumption which entered his preliminary gravitational theories as an inconspicuous and perhaps precisely for this reason fateful prejudice delaying his progress towards the correct field equation. However, the preceding synopsis of the reasoning by which this assumption was actually anchored in Einstein's thinking shows that, once the metric tensor was introduced as a representation of gravitational fields, the association of static fields with a metric tensor of the canonical form was a necessary consequence of Einstein's understanding of classical physics applied to this representation.

This entire network of reasoning, and in particular, the procedure for attaining the Newtonian limit which forms its core, is not compatible with the final theory of general relativity. According to this theory, static fields are, in general, not represented by a metric tensor of the canonical form. A consistent treatment of the problem of the Newtonian limit in general relativity is an intricate problem[247] and indeed requires a mathematical formalism which did not even exist when Einstein first formulated the theory in 1915; it was only introduced much later by Cartan and others (Cartan 1923, 1924). It is only in this formalism, by using the concept of an affine connection, that it is possible to formulate both general relativity and Newton's theory of gravitation in a way that makes them mathematically comparable.[248] In fact, whereas in general relativity, the geometry of spacetime is described by a metric structure, in Newtonian theory of gravitation, the four-dimensional metric structure is degenerate and only an affine structure can be introduced for spacetime. But since a metric determines also an affine structure, both theories can, with the help of this mathematical concept, actually be expressed in the same mathematical terms. Vice versa, the fact that the spacetime of general relativity carries not only an affine but also a metric structure represents a conceptual leap with respect to Newtonian physics that cannot be bridged by considering the special theory of relativity, which also comprises a metric structure of spacetime, as an intermediate case. It is simply impossible to describe Newtonian gravitational fields by a non-degenerate four-dimensional metric tensor.

---

247 See note 44 above.

248 See "The Story of Newstein …" (in vol. 4 of this series).

This conceptual leap between general relativity and Newtonian physics, together with the strong arguments which Einstein had in favor of his classical conception of the correspondence principle, raise the question as to how he could have ever overcome the crucial hurdle of dealing with the Newtonian limit of his new theory. The surprising solution is that it was in fact not the removal of this major stumbling block which freed his way, but rather its circumvention for the specific problems in the focus of his attention at the time, in particular for the treatment of the motion of a point mass in a gravitational field. By showing that, although the spatial curvature is present even under Newtonian conditions, it remains unobservable if only slowly moving particles are considered, Einstein found a technical loop-hole through which he could escape from his dense network of reasons supporting the canonical form of the metric.

8.4 The Ambiguity of the Equivalence Principle

We have identified the beginning and end points of the development of those aspects of Einstein's heuristics which were obviously rooted in classical physics. We have concluded that this classical heuristics was just sufficient to allow for the formulation of the key equations of general relativity, whose exploration then, however, led to conceptual insights with which the original expectations were no longer compatible. We now turn to those elements of Einstein's heuristics which were peculiar to his specific research strategy, the equivalence principle and the generalized relativity principle. No such principles belonged to the accepted core of classical physics at the time when he took up his research.

If one separates, however, the mathematical development from that of the physical theories, then Einstein's introduction of the principle of equivalence appears to be much less of an idiosyncrasy than it may seem at first sight. To make this clear, consider the reformulation of the classical Newtonian theory of gravitation as a spacetime theory with a non-trivial geometry. This geometry can be described in terms of an affine connection determining the notion of parallel transport of vectors and hence also the geodesic lines in that spacetime. It is a fundamental statement of this reformulation of Newton's theory that the geodesic lines represent the motions of freely falling particles according to the law of gravitation. Remarkably, the equality of gravitational and inertial mass has become, in this modern formulation, an in-built feature rather than a contingent fact as in the traditional formulation. In the formulation of the law of motion as being given by the geodesic lines, the notion of mass appears not at all, while only the notion of gravitational mass enters the field equation of the theory which determines the geometry of spacetime.

From the point of view of this mathematically advanced formulation, Einstein's adoption of the principle of equivalence can hence be recognized as expressing a fundamental feature of Newton's theory of gravitation, shaped, however, by the particular mathematical formulation of the classical theory which formed his starting point and which suggested a sharp conceptual and technical distinction between gravitational and inertial forces. This conclusion indeed frees Einstein's adherence to the principle of equivalence from its idiosyncratic appearance. One might even conjecture that, had the development of the appropriate mathematical tools come a little earlier, others as well might have found it attractive to employ them for a new formalization of the classical knowledge on gravitation, thus arriving at the considerations outlined above even before the advent of general relativity. But it now emerges, on the other hand, even more as a riddle how a principle expressing the knowledge of classical mechanics could have served as a crucial heuristic guidance for overcoming this theory in favor of a theory incompatible with it.

The key to resolving this riddle comes from considering the fact that Einstein used the principle of equivalence not in order to reorganize the knowledge of classical mechanics but the knowledge embodied in both, classical mechanics and the special theory of relativity. His theory of the static gravitational field as well as his early attempts to generalize that theory were nothing but a reinterpretation of the special theory of relativity with the help of the introduction of accelerated frames of reference. His systematic consideration of such accelerated frames induced him to make use of generalized Gaussian coordinates in order to describe the coordinate systems adapted to these frames. It was then a short step for him to consider the metric tensor, coming with the introduction of such coordinates, also as the representation of gravitational effects when these could not be generated by acceleration. In other words, with the introduction of the metric tensor Einstein had found an object that was capable of representing gravitational and inertial effects on the same footing, just as is the affine connection within the modern reformulation of Newton's theory.

It was, however, not a mere coincidence governed by the availability of mathematical methods that Einstein directly attempted to implement the principle of equivalence in a theory that was to generalize special relativity rather than concentrating on a reformulation of classical mechanics. He was aiming from the beginning at a new theory of gravitation which was to comprise both the knowledge on gravitation and inertia represented by classical mechanics and the knowledge on the structure of space and time embodied by special relativity. Effectively, the principle of equivalence acted, according to this reconstruction, as a demand for integrating the knowledge on gravitation and inertia from classical mechanics, which in a modern formulation can be expressed by means of an affine connection, with the knowledge on the metric structure of spacetime from special relativity. It thus acted as a particular instance of Einstein's general strategy to exploit the entire range of classical and special-relativistic physics for constructing his new theory of gravitation. The analysis given here does, however, not square with Einstein's own interpretation of the principle of equivalence as guiding the development of classical and special-relativistic physics with its privileged systems of reference towards a theory of gravitation which would have to encompass also a generalized principle of relativity.

8.5 The Relativity Principle Relativized

Einstein's view that it made sense to search for a generalization of the relativity principle of classical mechanics and special relativity was, as we have seen, based on his acceptance of a philosophical critique of classical mechanics raised by Mach and others. According to this critique, the justification of the privileged role of inertial frames of reference by the notion of absolute space was problematic, while the inertial forces experienced in accelerated frames of reference require an explanation in terms of the interaction between physical masses. Such an explanation would then eliminate any need for absolute space as a causal agent in the analysis of motion. The generalized relativity principle would go, so at least was Einstein's expectation, a long way, and might actually go all the way, towards an implementation of Mach's critique of classical mechanics in the new theory of gravitation.

The implementation of Mach's critique of classical mechanics by way of the generalized relativity principle in Einstein's new theory of gravitation was, however, rather indirect. Rather than explaining inertial properties directly by a physical interaction of masses, they were described by a gravito-inertial field represented by the metric tensor in a way that in fact depends on the frame of reference. But the gravito-inertial field itself would be determined only by the distribution of masses in the universe via a generally-covariant field equation. It follows that the question of whether or not this approach would lead to an exhaustive explanation of inertial properties by the relative distribution of masses depends on the precise nature of the field equation and its solutions. While Einstein was initially convinced that his theory would fully do justice to the Machian roots of the generalized relativity principle, he felt eventually forced to introduce what he called Mach's principle as a separate and additional criterion to be satisfied by the field equation and its solutions. With the establishment of the General Theory of Relativity in 1915, Einstein succeeded in formulating a theory which implemented the generalized relativity principle in its utmost form, the theory being generally covariant; whether it also satisfied Mach's principle, demanding a complete determination of the gravito-inertial field by the distribution of matter in the universe, remained, on the other hand, a much debated issue for a long time to come.[249]

On closer inspection, however, even Einstein's realization of the generalized relativity principle by his formulation of a generally-covariant theory of gravitation represented a questionable success of this heuristic principle. In fact, not only the general theory of relativity of 1915, but also several other theories of gravitation and in particular also the classical Newtonian theory can be given a generally-covariant formulation. The demand for general covariance has to be considered as nothing but a minimal requirement to be imposed on any sensible physical theory, namely to make assertions about physical processes which do not depend on the specific coordinates used for describing them. But Einstein's generalized relativity principle—together with its broader Machian understanding—effectively corresponded, as we have seen,

249 For extensive discussion, see "The Third Way to General Relativity …" (in vol. 3 of this series).

to further requirements beyond the demand for a generally-covariant formulation of the theory of gravitation. It also comprised the demand for treating inertia and gravitation as aspects of a more general interaction as well as the demand for the absence of any prior geometry of spacetime. The latter requirement excludes, for instance, Nordström's theory as being not compatible with Einstein's heuristics since it assumes the geometry of spacetime a priori to be Minkowskian, up to a conformal factor representing the gravitational potential.

Nevertheless, Einstein's own interpretation of this heuristics can hardly be vindicated by the modern understanding of general relativity. First, the demand for treating inertia and gravitation as aspects of a more general interaction can, as we have seen in our discussion of the equivalence principle, already be fulfilled by classical mechanics in an appropriate reformulation. Second, the general covariance of Einstein's theory does not embody a generalization of the relativity principle from classical mechanics and the special theory of relativity, since, in the modern understanding, relativity principles are represented by the symmetry properties of a theory and not by their behavior under coordinate transformations. Third, "Mach's principle" in the sense of Einstein's demand that the metric structure of space be completely determined by the material masses makes little sense according to the modern understanding of general relativity, since the very notion of material bodies acting as a "source" of the gravitational field that can be prescribed independently from the field has turned out to be problematic.

8.6 The Long-Term Development of Knowledge

In the preceding discussion we have emphasized the differences between Einstein's heuristics and the conceptual consequences of the theory whose development was guided by this heuristics. These differences were the result of a process covering two eras stretching from the beginning of the relativity revolution in 1905 to the present: The first era comprised the elaboration of the foundational equations of the new theory guided by the original heuristics, a process that was essentially complete with Einstein's formulation of general relativity in 1915 and that also included, as we have seen, adjustments of the original heuristics. The second era consists in the exploration of the conceptual consequences of the new theory on the basis of an interpretation of the results achieved in the first era as well as in the course of its further elaboration, a process that has still not come to a hold today. In view of the often striking differences between the modern interpretation of general relativity and Einstein's original motivations for searching for such a theory, it represents a remarkable challenge for the historical reconstruction to explain how these original motivations could have led him to such a definitive formulation of the new theory of gravitation. In the beginning we have formulated this challenge in terms of the three epistemic paradoxes of the emergence of general relativity, the paradox of missing knowledge, the paradox of deceitful heuristics, and the paradox of discontinuous progress.

As our reconstruction has shown, an adequate response to the missing-knowledge paradox can only be found when the long-term development of scientific knowledge is taken into account. This development led, after all, to the emergence of a theory whose understanding of how gravity affects motion in terms of spacetime structure is closer to Aristotle's concept of natural motion than to Newton's explanation in terms of an anthropomorphic force. The knowledge on which the astonishing stability of general relativity is founded was, as we have seen, accumulated long before its creation by centuries of physics, astronomy, and mathematics. Our modern acceptance of general relativity is not only based on experiments or observations related to some of its special predictions but also on the fact that it incorporates the entire Newtonian knowledge on gravitation, including its relation to other physical interactions, that has been accumulated over a long period of time in classical physics and in the special theory of relativity. This knowledge embraces, among other aspects, Newton's law of gravitation including its implications for the conservation of energy and momentum, the relation between gravitation and inertia, the understanding that no physical action can propagate with a speed greater than that of light, which was first achieved by the field theoretic tradition of classical physics and then finally established with the formulation of special relativity, and, more generally, the local properties of space and time, also formulated in special relativity.

After special relativity had elevated the causality requirements implicit in field theory to a universal status, gravitation, traditionally a subject at the core of mechanics, had effectively turned into a borderline problem between mechanics and field theory. As was the case for other borderline problems, its successful solution depended on the shared knowledge resources taken into account. In the case of the creation of special relativity, Einstein's success depended on his combining the heritage of mechanics, embodied in the relativity principle, with the heritage of electrodynamics, embodied in the principle of the constancy of the speed of light. In the case of a relativistic theory of the gravitational field, the combination of the heritage of mechanics represented by the Newtonian theory of the static gravitational field with what was known about dynamic fields from electrodynamics was, however, insufficient to create a new and satisfactory theory—as Einstein's competitors experienced to their chagrin. There was, in particular, no clue to the properties of dynamical gravitational fields so that the challenge to build a relativistic field theory of gravitation was comparable to the development of the entire theory of electromagnetism knowing only Coulomb's law.

It was at this point that Einstein's broad perspective, including the philosophical critique of classical mechanics by Mach, allowed him to muster additional resources from classical physics. Einstein exploited the Machian interpretation of the inertial forces in an accelerated reference frame as being due to the interaction of moving masses in order to fill the above-described gap in a field theory of gravitation. By conceiving the inertial forces in accelerated reference frames, such as Newton's rotating bucket, as embodying dynamical gravitational fields he managed in fact to anticipate essential properties of the relativistic theory of gravitation he was about to construct, in particular the necessity to generalize the spatio-temporal framework of special relativity, which led to the notion of a curved spacetime.

8.7 The Architecture of Knowledge

The answer to the second paradox of how Einstein could have formulated the criteria for a gravitational field equation years before finding the solution comes, as we have seen, from considering the architecture of the shared knowledge resources available to him. These resources were in fact part of a system of knowledge with active components capable of providing heuristic guidance to his research.

The characteristics of Einstein's search have become comprehensible by realizing that it was guided by a qualitative knowledge representation structure inherited from classical physics: the mental model of a field theory as embodied in an exemplary way by Lorentz's electron theory. Einstein's preliminary research on a relativistic theory of gravitation in the years between 1907 and 1912 had established default-settings for two of its terminals; the field-slot (filled by assuming that the gravitational potential is represented by the metric tensor), and the source-slot (filled by the stress-energy tensor of matter as suggested by relativistic continuum mechanics). In the context of his research the differential operator describing how the source generates the field represented an open slot for which Einstein was unable to identify a satisfactory instantiation.

As we have discussed, Einstein's difficulty did not result from the fact that too little was known but rather from the fact that too much knowledge had to be taken into account to formulate a field equation that responded to the understanding of gravitation as a borderline problem of mechanics and field theory. On the one hand, a physically plausible instantiation for the differential operator was suggested by knowledge of the Newtonian static gravitational field as well as of the relation between static and dynamic fields in electrodynamic field theory. Constructed in this way, the new theory would automatically be compatible with Newton's theory, thus fulfilling the correspondence principle. On the other hand, a mathematically plausible way to obtain an instantiation of the differential operator was offered by the knowledge about dynamic fields incorporated in Einstein's equivalence principle, which suggested taking generally-covariant objects such as the Riemann tensor as the starting point. Constructed in this way, the new theory would automatically fulfill the generalized relativity principle. The equivalence principle and the generalized relativity principle had helped, in addition, to reveal just those elements of the traditional knowledge on whose integration the new theory could be based. In the modern formulation, they posed the problem of the compatibility between chronogeometry and gravito-inertial structure. Within the knowledge system of classical physics, the Lorentz model was, furthermore, embedded in a network of relations to other frames and mental models; this network served as a control structure for any acceptable implementation of the model. In particular, the new theory had to satisfy the conservation principle, generalizing similar principles from classical and special-relativistic physics.

In short, Einstein's heuristics was overdetermined by the knowledge available to him, explaining why it was so powerful and yet so fortuitous at the same time. The compatibility of the various requirements it imposed could not be established *a priori* but had to be checked by elaborating a mathematical representation of the Lorentz model, starting from one or the other default setting and shaping it according to the remaining heuristic criteria. Einstein's oscillation between a physical strategy starting from an implementation of the correspondence principle, and a mathematical strategy starting from an implementation of the generalized relativity principle could thus be interpreted as realizing alternative and ultimately converging pathways with which to integrate the knowledge of classical physics.

8.8 Knowledge Dynamics

The third paradox, of discontinuous progress, could only be resolved by taking into account that the development of knowledge does not only consist of enriching a given architecture but also comprises processes of reflection by which this architecture is being transformed. Einstein's learning experience was, in fact, characterized by a bottom-up process that accommodated the higher-order structures at the core of his heuristic principles to the outcome of the experiences he made implementing these principles. The interplay between assimilation and accommodation mediated by the mathematical representation has turned out to be the crucial process determining the knowledge dynamics leading to the creation of general relativity as a non-classical theory. Against this background four stages of Einstein's search for the gravitational field equation could be distinguished.

The *tinkering phase* of fall 1912 is documented in the early pages of Einstein's Zurich Notebook. It is characterized by his unfamiliarity with the mathematical operations suitable for constructing a field equation for the metric tensor. Nevertheless, reflecting on his first attempts to formulate a field equation that satisfied his heuristic principles, Einstein built up higher-order structures operating on a strategic level that would later guide his systematic implementation of these principles, in particular, the physical and the mathematical strategy.

The *systematic searching phase* from late 1912 to early 1913 is also extensively documented by the Zurich Notebook. In this phase Einstein systematically examined candidates according to his heuristic principles alternating between physical and mathematical strategies. Meanwhile, the relative weight of the heuristic principles kept changing with the conservation principle emerging as the principal challenge. Paradoxically, the main result of the pursuit of the mathematical strategy was the derivation of an erroneous theory—the *Entwurf* theory—along the physical strategy.

The *consolidation phase* is documented by Einstein's publications and correspondence between 1913 and mid-1915. During this phase he elaborated the *Entwurf* theory, essentially following his earlier heuristics but now under the perspective of consolidation rather than exploration. Paradoxically, however, the main result of the consolidation period was the creation of the presuppositions for a renewed exploration of candidate field equations. Adapting the mathematical strategy to legitimize the *Entwurf* theory, Einstein found that the resulting mathematical formalism did not single out this theory but reopened the perspective of examining other candidates, removing, in particular, the difficulty of implementing the conservation principle. Because of the extended network of results meanwhile assembled, this reexamination could now take the form of a reflective reorganization of Einstein's earlier achievements.

The *reflection phase*, decisive in resolving the paradox of discontinuous progress, is documented by the dramatic series of four communications Einstein submitted to the Prussian Academy in November 1915. The essence of Einstein's return in the first of these communications to a field equation related to the Riemann tensor consists in reinterpreting results achieved in the context of the *Entwurf* theory. As a consequence, also Einstein's original heuristic principles received a revised physical interpretation. The crucial step of the transition from the *Entwurf* theory, still rooted in classical physics, to the non-classical theory of general relativity was, however, the shift in the physical interpretation of the representation he had unfolded in the preceding years.[250] This transition was a Copernicus process resembling Einstein's reinterpretation of Lorentz's auxiliary variable for local time as the time measured in a moving reference frame. But in passing from the *Entwurf* theory to general relativity, however, Einstein was, in a sense, his "own Lorentz"—hence the more isolated character of the second phase of the relativity revolution. In the case of the transition to general relativity, it was, in particular, the Christoffel symbol, initially only an auxiliary quantity, that assumed a new physical meaning, now representing the gravitational field.

The synthesis represented by general relativity was not without alternatives at the time of its establishment—nor is it today. Some of these alternatives were even distinguished by consequences which could be tested empirically. The observational consequences which distinguish general relativity from its main competitor at the time, Newton's and Nordström's theory of gravitation, were, however, by no means momentous and could have easily gone unnoticed for a long time, or might have remained irrelevant for a decision between alternative theories of gravitation had Einstein's research not drawn attention to them. The contemporary discussion about these alternatives and their elaboration document a process of equilibration between individual perspectives and shared knowledge resources.[251] Even the most ingenious phase of the relativity revolution—the phase of reflection—was, from the point of view of historical epistemology, not the privilege of an outstanding individual, but just one aspect of the transformation of a system of knowledge.

ACKNOWLEDGEMENTS

First drafts of this chapter resulted from a collaboration in the context of the Arbeitsstelle Albert Einstein, funded in the years 1990–1995 by the Berlin Senate, see (Castagnetti et al. 1994). First and above all, we wish to thank Peter Damerow for his inspiration and support. It is through him that we learned about the potential use of concepts from cognitive science for the history of science. We are also grateful to our colleagues John Norton, John Stachel, and especially to Michel Janssen for many discussions and all their unrelenting criticism. The final version owes much to recent joint work with Michel Janssen (see "Untying the Knot ..." and "Commentary ..." (in this volume)), who also co-edited the text. We also wish to thank Diana Buchwald for her support and understanding. Last not least, we wish to express our sincere gratitude to Lindy Divarci for her reliable help with copy-editing this paper.

EINSTEIN’S ZURICH NOTEBOOK

Descriptive Note

The document known as the Zurich Notebook is a blue bound notebook, 17.5 x 21.5 cm, containing 45 sheets of squared white paper (not counting two sheets that were torn out, probably by Einstein). Three sheets were left blank. The document thus consists of 84 pages. Two typed notes are taped to the front cover (reproduced on p. 316), probably by Einstein's secretary, Helen Dukas. One says: "Notes for lecture on Relativity probably Zurich." The other describes the back cover (reproduced on p. 317): "s. back of this notebook "Relativitaet" in aE's hand." The first and the last page are glued to the insides of the covers.

The number assigned to the Zurich Notebook in the Einstein Archive is "3–006." This numbering is also reflected in the numbering of the images of the online facsimile reproduction of the document (Einstein Archives Online at http://www.alberteinstein.info). In copies of the Einstein Archive, pairs of facing pages have been numbered "1" through "43." The labels "L" and "R" are used to distinguish pages on the left in such pairs from pages on the right. Einstein used the notebook from both ends. This is reflected in the numbering of the pages. Pages 1L through 31L are numbered from the back of the notebook, pages 32L through 43L are numbered from the front. Between the two parts (i.e., between 31L and 43L) three sheets were left blank. Both between pages 29L and 29R and between pages 38L and 38R a sheet was torn out. Since the part starting from the front contains the earliest notes on gravity in the notebook, we present that part (32L–43L) before the part starting from the back (1L–31L). Although we are concerned only with the material on gravity in these volumes, we present a facsimile reproduction and a transcription of all entries in the notebook. The notebook touches on the following topics:

- Electrodynamics (32L–38L)
- Quantum theory (38L–38R)
- Gravity (39L–43L)
  - · First exploration of a metric theory (39L–41R)
  - · Auxiliary calculations (41L–43L)
- Quantum theory (1L–5L)
- Gravity (5R–29L)
  - · Energy-momentum conservation (5R)
  - · Beltrami invariants and core operator (6L–13R)
  - · Riemann tensor, Ricci tensor, and November tensor (14L–25R)
  - · *Entwurf* theory (26L–29L)
- Thermodynamics

The 57 pages of the notebook dealing with gravity (39L–43L, 5R–29L) were presented in transcription as Doc. 10 in Vol. 4 of *The Collected Papers of Albert Einstein* (CPAE 4). The editors numbered these pages 1 through 58. Page 43L contains material written from the top and material written from the bottom. The former is presented as p. 9 of Doc. 10 in CPAE 4, the latter as p. 58. We likewise present 43L twice, as 43La, with the facsimile the way it appears in the notebook and with a transcription only of the material written from the top, and as 43Lb, with the facsimile upside down and a transcription only of the material written from the bottom.

The authors and editors thank the Albert Einstein Archives at the Hebrew University of Jerusalem and the Einstein Papers Project at the California Institute of Technology for generous permission to reproduce Einstein's Zurich Notebook.

The conversion table below should make it easy to compare our presentation and discussion of the notes on gravity in the notebook to the annotated transcription of this material in CPAE 4.

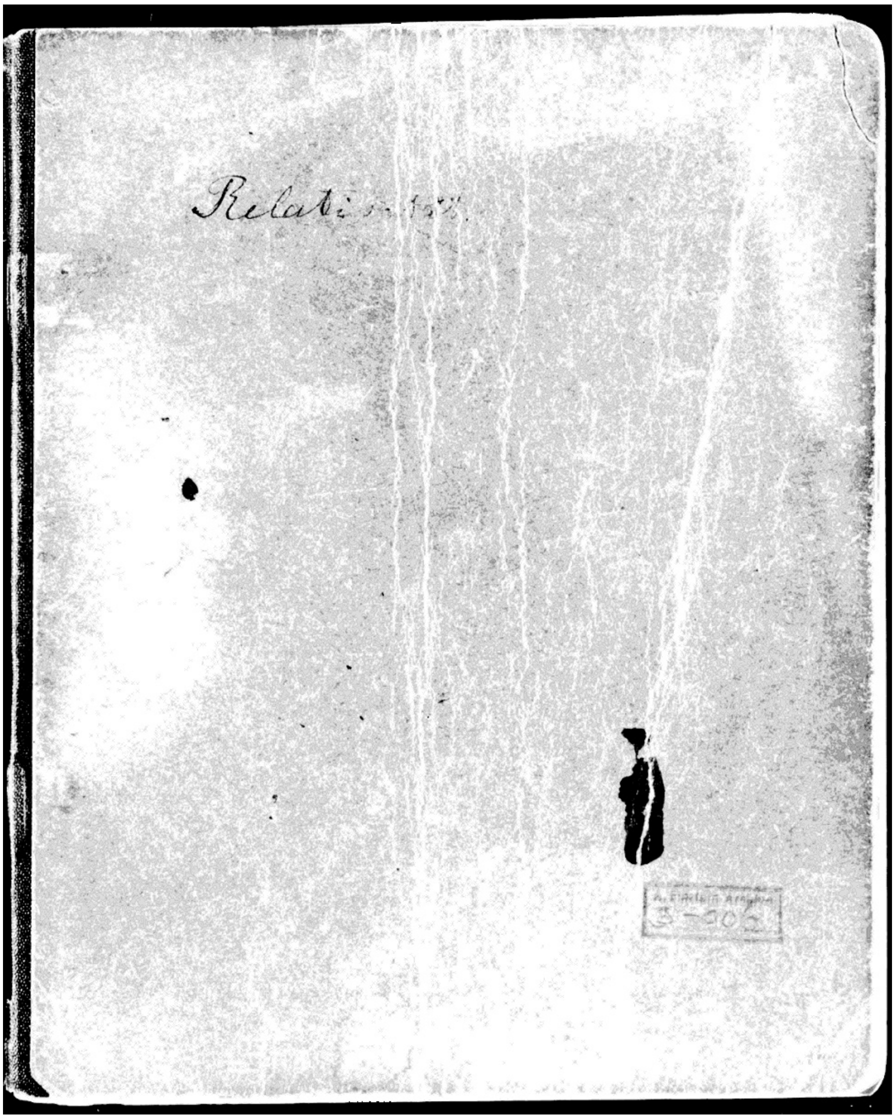
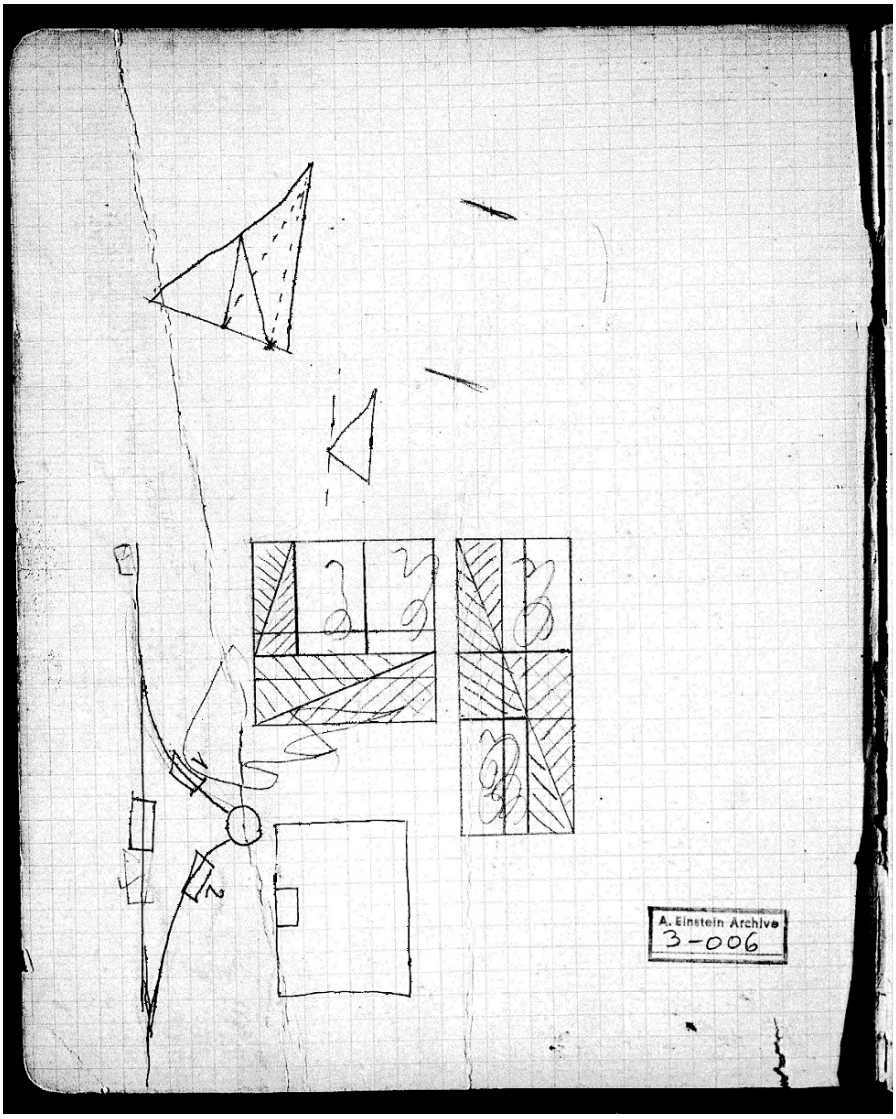
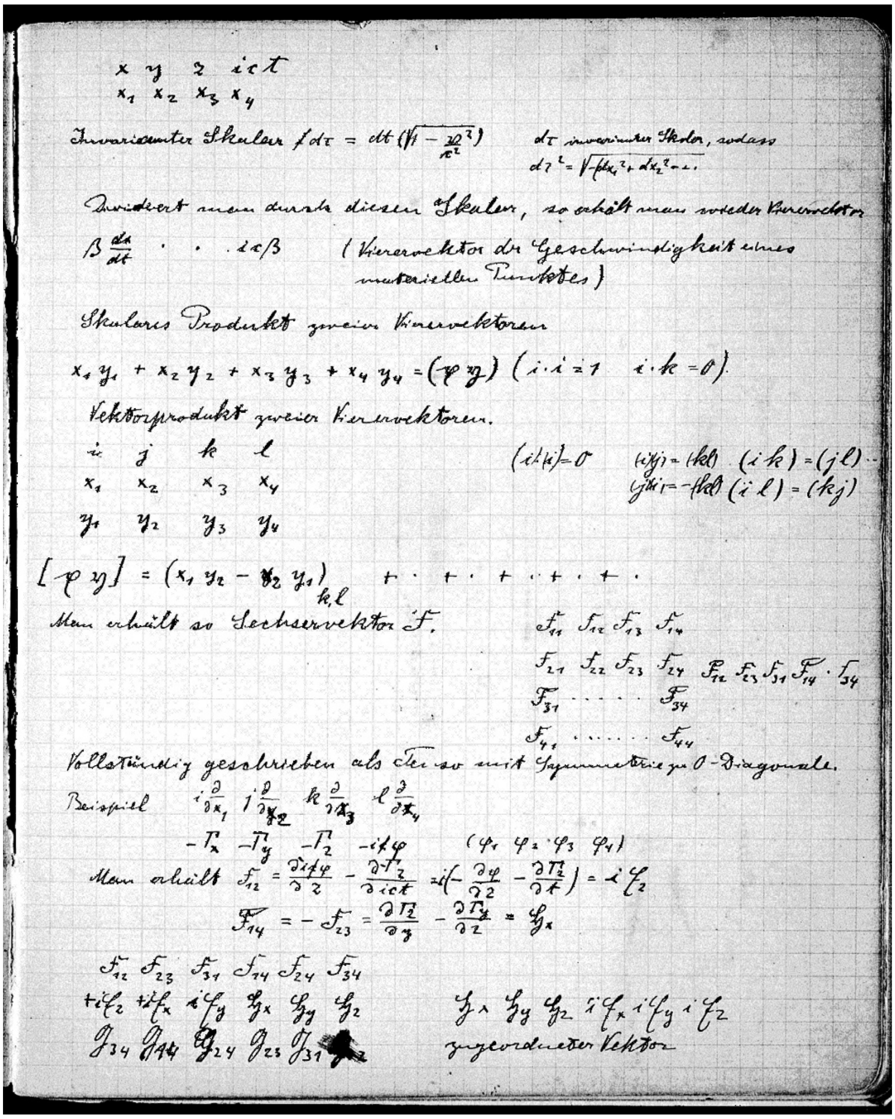
Notes for lecture on Relativity
probably Zuerich
13-0061
s. back of this notebook
"Relativitaet" in E's hand.



[p. 32 L]



[p. 32 R]



$x \quad y \quad z \quad ict$
$x_1 \quad x_2 \quad x_3 \quad x_4$

Invarianter Skalar $f d\tau = dt\left(\sqrt{1-\frac{v^2}{c^2}}\right)$ $d\tau$ invarianter Skalar, sodass $d\tau^2 = \sqrt{-(dx_1^2 + dx_2^2 \ldots}$

Dividiert man durch diesen Skalar, so erhält man wieder Vierervektor

$\beta \frac{dx}{dt} \quad \cdot \quad \cdot \quad . ic\beta$ (Vierervektor der Geschwindigkeit eines materiellen Punktes)

Skalares Produkt zweier Vierervektoren

$x_1 y_1 + x_2 y_2 + x_3 y_3 + x_4 y_4 = (\varphi y) \quad (i \cdot i = 1 \quad i \cdot k = 0)$.

Vektorprodukt zweier Vierervektoren.

$i \quad j \quad k \quad l$ $\qquad (i i) = 0 \quad (i j) = (k l) \quad (i k) = (j l) \cdot$
$x_1 \quad x_2 \quad x_3 \quad x_4$ $\qquad (j i) = -(k l) \quad (i l) = (k j)$
$y_1 \quad y_2 \quad y_3 \quad y_4$

$[\varphi y] = (x_1 y_2 - \cancel{x_2} y_1)_{k,l} \quad + \cdot \ + \cdot \ + \cdot + \cdot + \cdot$

Man erhält so Sechservektor $\mathfrak{F}$.

$\mathfrak{F}_{11} \ \mathfrak{F}_{12} \ \mathfrak{F}_{13} \ \mathfrak{F}_{14}$
$\mathfrak{F}_{21} \ \mathfrak{F}_{22} \ \mathfrak{F}_{23} \ \mathfrak{F}_{24} \quad \mathfrak{F}_{12} \ \mathfrak{F}_{23} \ \mathfrak{F}_{31} \ \mathfrak{F}_{14} \cdot \mathfrak{F}_{34}$
$\mathfrak{F}_{31} \ \cdots \ \mathfrak{F}_{34}$
$\mathfrak{F}_{41} \ \cdots\cdots \ \mathfrak{F}_{44}$

Vollständig geschrieben als Tensor mit Symmetrie zu 0-Diagonale.

Beispiel $\quad i\frac{\partial}{\partial x_1} \quad j\frac{\partial}{\partial x_2} \quad k\frac{\partial}{\partial x_3} \quad l\frac{\partial}{\partial x_4}$

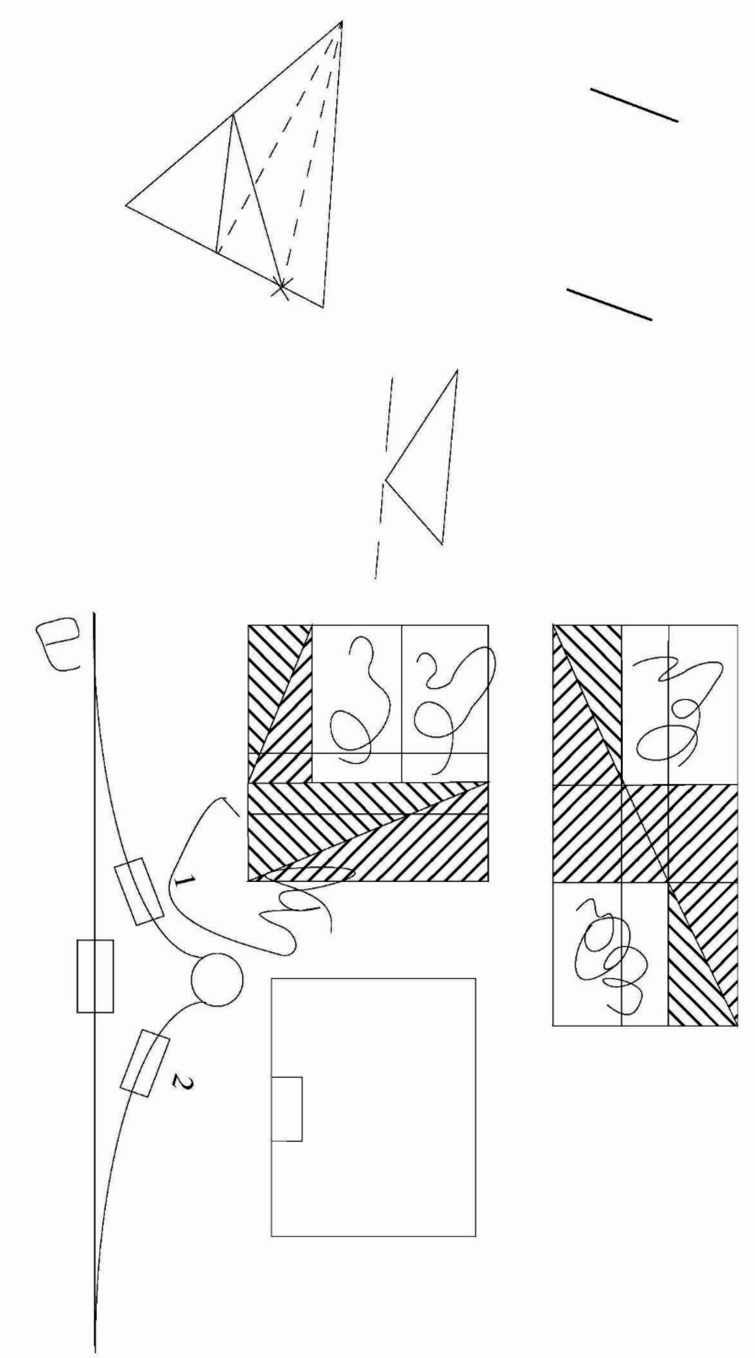
$-\Gamma_x \quad -\Gamma_y \quad -\Gamma_z \quad -i\varphi \qquad (\varphi_1 \ \varphi_2 \ \varphi_3 \ \varphi_4)$

Man erhält $\mathfrak{F}_{12} = \frac{\partial i\varphi}{\partial z} - \frac{\partial \Gamma_z}{\partial ict} = i\left(-\frac{\partial \varphi}{\partial z} - \frac{\partial \Gamma_z}{\partial t}\right) = i\mathfrak{E}_z$

$\mathfrak{F}_{14} = -\mathfrak{F}_{23} = \frac{\partial \Gamma_z}{\partial y} - \frac{\partial \Gamma_y}{\partial z} = \mathfrak{H}_x$

$\mathfrak{F}_{12} \ \mathfrak{F}_{23} \ \mathfrak{F}_{31} \ \mathfrak{F}_{14} \ \mathfrak{F}_{24} \ \mathfrak{F}_{34}$
$+i\mathfrak{E}_z \ +i\mathfrak{E}_x \ i\mathfrak{E}_y \ \mathfrak{H}_x \ \mathfrak{H}_y \ \mathfrak{H}_z$ $\qquad \mathfrak{H}_x \ \mathfrak{H}_y \ \mathfrak{H}_z \ i\mathfrak{E}_x \ i\mathfrak{E}_y \ i\mathfrak{E}_z$
$\mathfrak{G}_{34} \ \mathfrak{G}_{14} \ \mathfrak{G}_{24} \ \mathfrak{G}_{23} \ \mathfrak{G}_{31}$ $\qquad$ zugeordneter Vektor

[p. 32 L]



[p. 32 R]

$$\begin{array}{cccc} x & y & z & ict \\ x_1 & x_2 & x_3 & x_4 \end{array}$$

Invarianter Skalar $\cancel{i}d\tau = dt\left(\sqrt{1-\frac{v^2}{c^2}}\right)$ $d\tau$ invarianter Skalar, sodass

$$d\tau^2 = \sqrt{-(dx_1^2 + dx_2^2 + + \cdot}$$

Dividiert man durch diesen Skalar, so erhält man wieder Vierervektor

$\beta\frac{dx}{dt} \cdot \cdot \cdot \; ic\beta$ (Vierervektor der Geschwindigkeit eines materiellen Punktes)

Skalares Produkt zweier Vierervektoren

$$x_1y_1 + x_2y_2 + x_3y_3 + x_4y_4 = (xy) \qquad (i \cdot i = 1 \qquad i \cdot k = 0).$$

Vektorprodukt zweier Vierervektoren.

$$\begin{array}{cccc} i & j & k & l \\ x_1 & x_2 & x_3 & x_4 \\ y_1 & y_2 & y_3 & y_4 \end{array}$$

$$(i)\cdot(i) = 0 \quad (i)(j) = (kl) \quad (ik) = (jl)\cdots$$
$$(j)(i) = -(kl) \quad (il) = (kj)$$

$$(xy) = (x_1y_2 - y_2y_1)_{k,l} \quad + \cdot + \cdot + \cdot + \cdot + \cdot$$

Man erhält so Sechservektor *F*.

$$\begin{array}{llll} F_{11} & F_{12} & F_{13} & F_{14} \\ F_{21} & F_{22} & F_{23} & F_{24} \\ F_{31} & \ldots\ldots & & F_{34} \\ F_{41} & \ldots\ldots & & F_{44} \end{array} \qquad F_{12}F_{23}F_{31}F_{14} \cdot F_{34}$$

Vollständig geschrieben als Tenso[r] mit Symmetrie zu 0-Diagonale.

Beispiel $i\frac{\partial}{\partial x_1} \quad j\frac{\partial}{\partial x_2} \quad k\frac{\partial}{\partial x_3} \quad l\frac{\partial}{\partial x_4}$

$$-\Gamma_x \quad -\Gamma_y \quad -\Gamma_z \quad -i\cancel{c}\varphi \qquad (\varphi_1 \;\; \varphi_2 \;\; \varphi_3 \;\; \varphi_4)$$

Man erhält $F_{12} = \frac{\partial i\cancel{c}\varphi}{\partial z} - \frac{\partial -\Gamma_z}{\partial ict} = i\left(-\frac{\partial\varphi}{\partial z} - \frac{\partial\Gamma_z}{\partial t}\right) = iE_z$

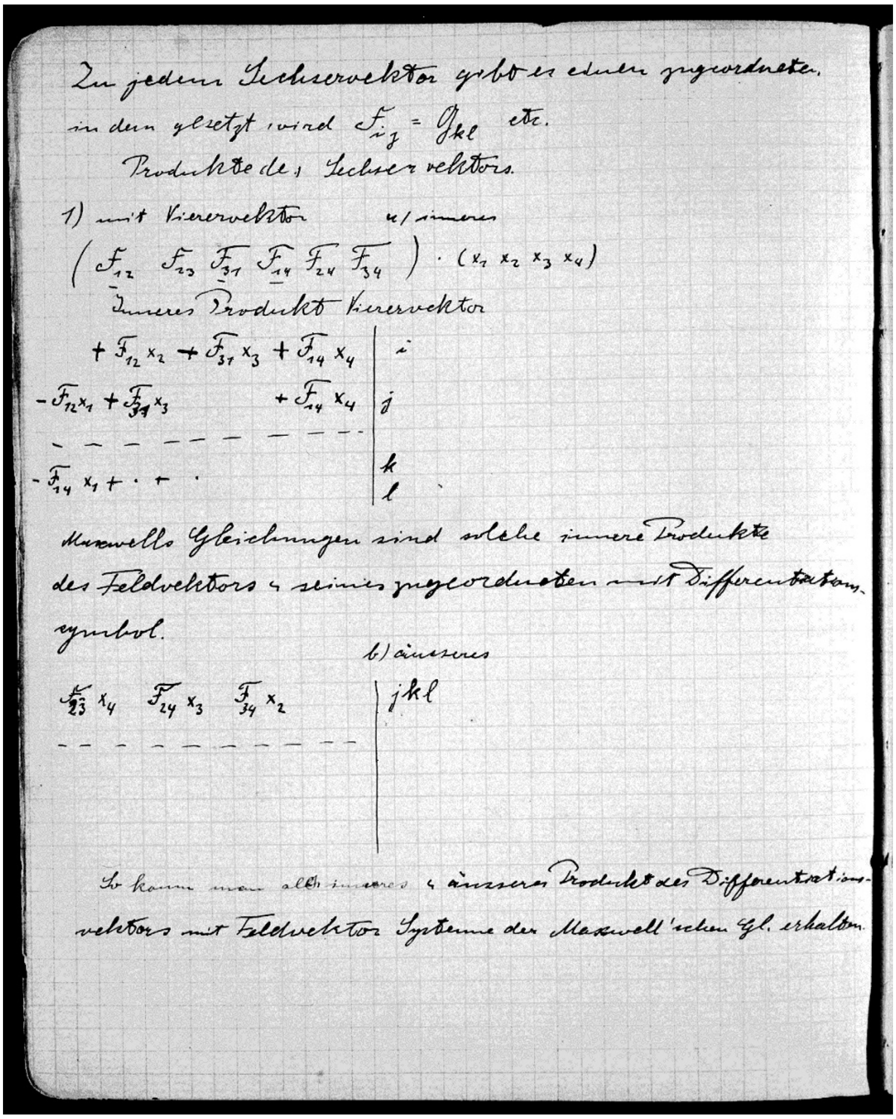
$$F_{14} = -\mathrm{F}_{23} = \frac{\partial\Gamma_z}{\partial y} - \frac{\partial\Gamma_y}{\partial z} = H_x$$

$$\begin{array}{cccccc} F_{12} & F_{23} & F_{31} & F_{14} & F_{24} & F_{34} \\ +iE_z & +iE_x & iE_y & H_x & H_y & H_z \\ G_{34} & G_{14} & G_{24} & G_{23} & G_{31} & G_{12} \end{array}$$

$H_x \; H_y \; H_z \; iE_x \; iE_y \; iE_z$

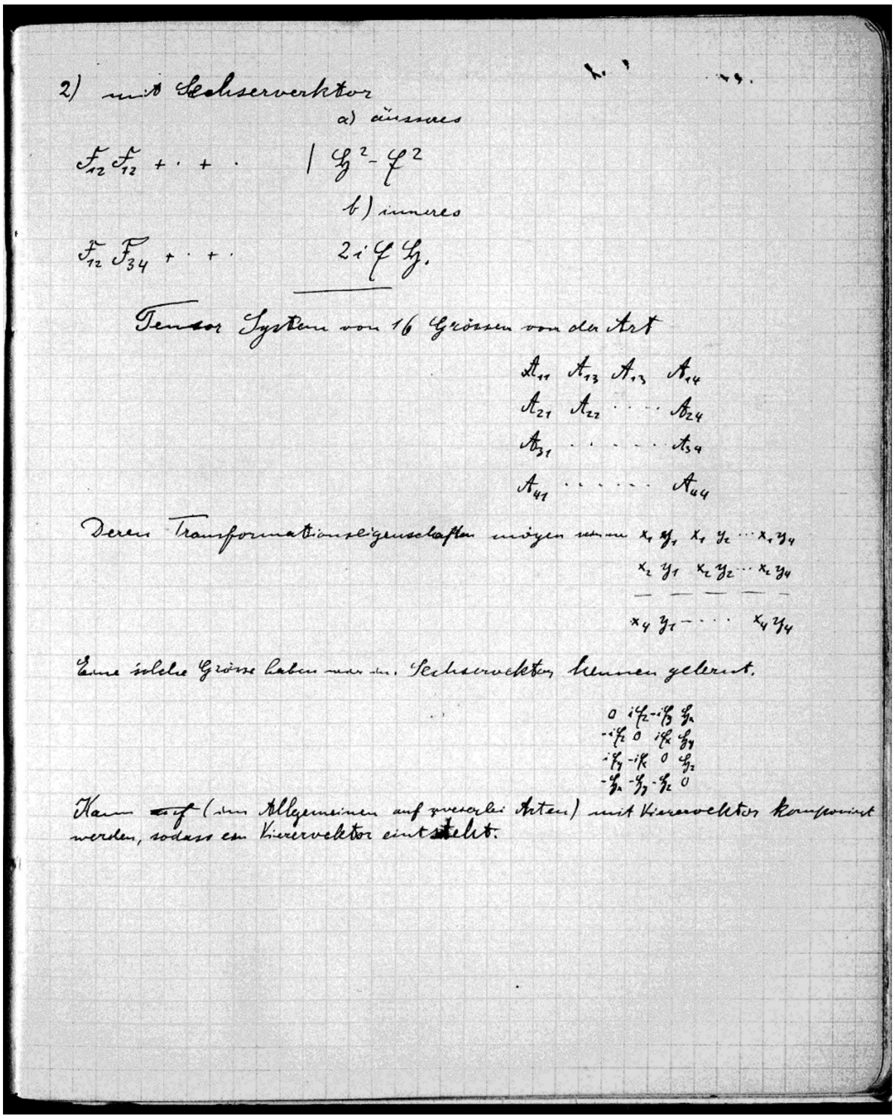
zugeordneter Vektor

[p. 33 L]



Zu jedem Sechservektor gibt es einen zugeordneten.
in dem gesetzt wird $\mathfrak{F}_{ij} = \mathfrak{G}_{kl}$ etc.
Produkte des Sechservektors.
1) mit Vierervektor
a) inneres
$\left(\mathfrak{F}_{12}\ \mathfrak{F}_{23}\ \mathfrak{F}_{31}\ \mathfrak{F}_{14}\ \mathfrak{F}_{24}\ \mathfrak{F}_{34}\right) \cdot (x_1\ x_2\ x_3\ x_4)$
Inneres Produkt Vierervektor
$+\mathfrak{F}_{12}x_2 + \mathfrak{F}_{31}x_3 + \mathfrak{F}_{14}x_4$ | i
$-\mathfrak{F}_{12}x_1 + \mathfrak{F}_{31}x_3 + \mathfrak{F}_{14}x_4$ | j
$- - - - - -$ | k
$-\mathfrak{F}_{14}x_1 + \cdot + \cdot$ | l
Maxwells Gleichungen sind solche innere Produkte
des Feldvektors u. seines zugeordneten mit Differentiations-
symbol.
b) äusseres
$\mathfrak{F}_{23}x_4\ \ \mathfrak{F}_{24}x_3\ \ \mathfrak{F}_{34}x_2$ | jkl
So kann man als inneres u. äusseres Produkt des Differentiations-
vektors mit Feldvektor Systeme der Maxwell'schen Gl. erhalten.

[p. 33R]



2) mit Sechservektor

α) äusseres

$\mathfrak{F}_{12}\mathfrak{F}_{12} + \cdot + \cdot \quad | \quad \mathfrak{H}^2 - \mathfrak{E}^2$

b) inneres

$\mathfrak{F}_{12}\mathfrak{F}_{34} + \cdot + \cdot \qquad 2i\mathfrak{E}\mathfrak{H}.$

Tensor System von 16 Grössen von der Art

$$\begin{matrix} A_{11} & A_{12} & A_{13} & A_{14} \\ A_{21} & A_{22} & \cdots & A_{24} \\ A_{31} & \cdots & \cdots & A_{34} \\ A_{41} & \cdots & \cdots & A_{44} \end{matrix}$$

Deren Transformationseigenschaften mögen wie

$$\begin{matrix} x_1 y_1 & x_1 y_2 & \cdots & x_1 y_4 \\ x_2 y_1 & x_2 y_2 & \cdots & x_2 y_4 \\ - & - & - & - \\ x_4 y_1 & \cdots & & x_4 y_4 \end{matrix}$$

Eine solche Grösse haben wir im Sechservektor kennen gelernt.

$$\begin{matrix} 0 & i\mathfrak{H}_z & -i\mathfrak{H}_y & \mathfrak{E}_x \\ -i\mathfrak{H}_z & 0 & i\mathfrak{H}_x & \mathfrak{E}_y \\ i\mathfrak{H}_y & -i\mathfrak{H}_x & 0 & \mathfrak{E}_z \\ -\mathfrak{E}_x & -\mathfrak{E}_y & -\mathfrak{E}_z & 0 \end{matrix}$$

Kann ~~auf~~ (im Allgemeinen auf zweierlei Arten) mit Vierervektor kombiniert werden, sodass ein Vierervektor entsteht.

[p. 33 L]

Zu jedem Sechservektor gibt es einen zugeordneten.
in dem gesetzt wird $F_{ij} = G_{kl}$ etc.

Produkte des Sechservektors.

1) mit Vierervektor a) inneres

$$(F_{\underline{12}}\ F_{23}\ F_{\underline{31}}\ F_{\underline{14}}\ F_{24}\ F_{34}) \cdot (x_1 x_2 x_3 x_4)$$

Inneres Produkt Vierervektor

$$\begin{array}{r|l}
+F_{12}x_2 + F_{31}x_3 + F_{14}x_4 & i \\
-F_{12}x_1 + F_{31}x_3 \qquad + F_{14}x_4 & j \\
------------- & \\
-F_{14}x_1 + \ \cdot\ + \ \cdot \qquad\qquad & k \\
 & l
\end{array}$$

Maxwells Gleichungen sind solche innere Produkte
des Feldvektors u seines zugeordeneten mit Differentiations-
symbol.

b) äusseres

$$\begin{array}{l|l}
F_{23}x_4 \quad F_{24}x_3 \quad F_{34}x_2 & jkl \\
------------- & \\
 &
\end{array}$$

So kann man al<l>s inneres u äusseres Produkt des Differentiations-
vektors mit Feldvektor Systeme der Maxwell'schen Gl. erhalten.

[p. 33 R]

2) mit Sechservektor

a) äusseres

$F_{12}F_{12} + \cdot + \cdot \quad \Big| \quad H^2 - E^2$

b) inneres

$F_{12}F_{34} + \cdot + \cdot \quad 2iEH.$

Tensor System von 16 Grössen von der Art

$$\begin{matrix} A_{11} & A_{13} & A_{13} & A_{14} \\ A_{11} & A_{22} & \cdots & A_{24} \\ A_{31} & \cdots & \cdots & A_{34} \\ A_{41} & \cdots & \cdots & A_{44} \end{matrix}$$

Deren Transformationseigenschaften mögen sein w

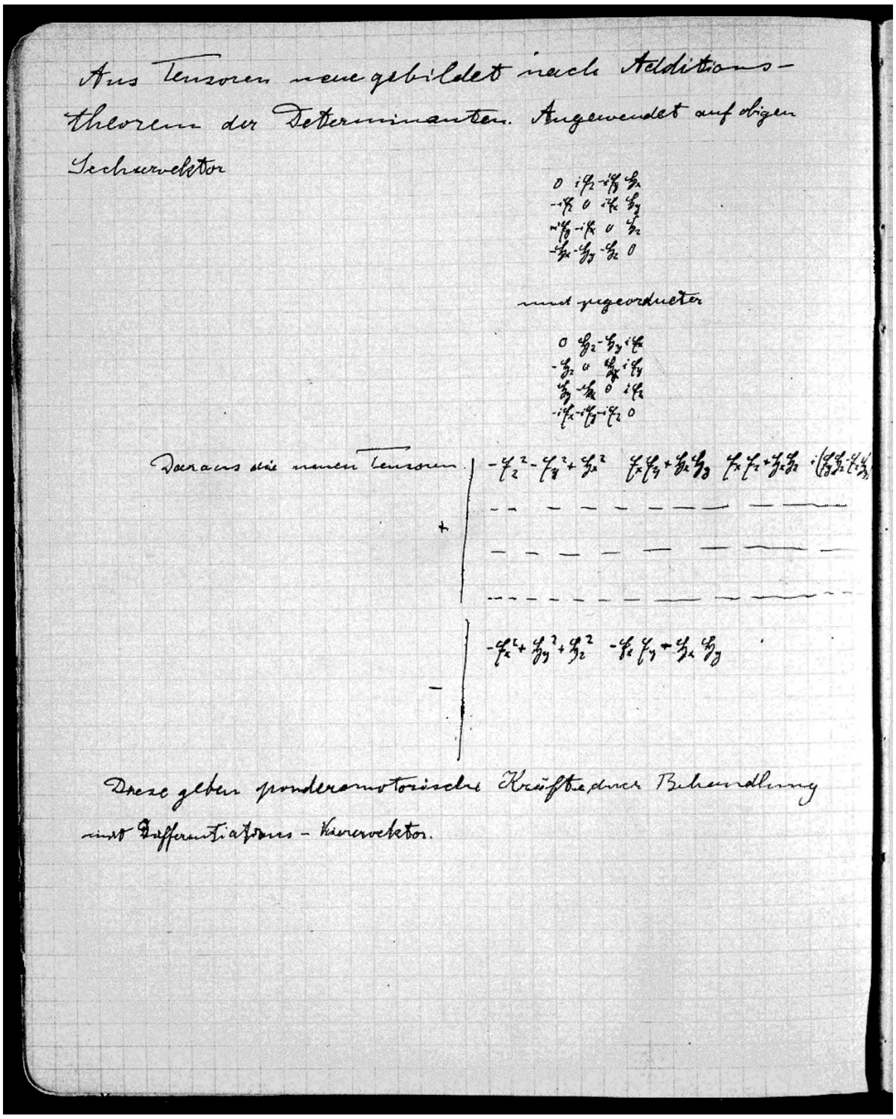
$$\begin{matrix} x_1y_1 & x_1y_2 & \cdots & x_1y_4 \\ x_2y_1 & x_2y_2 & \cdots & x_2y_4 \\ - & - & - & - \\ x_4y_1 & \cdots & \cdots & x_4y_4 \end{matrix}$$

Eine solche Grösse haben wir im Sechservektor kennen gelernt.

$$\begin{matrix} 0 & iE_z & -iE_y & H_x \\ -iE_z & 0 & iE_x & H_y \\ iE_y & -iE_x & 0 & H_z \\ -H_x & -H_y & -H_z & 0 \end{matrix}$$

Kann ~~auf~~ (im Allgemeinen auf zweierlei Arten) mit Vierervektor komponiert werden, sodass ein Vierervektor eintsteht.

[p. 34 L]



Aus Tensoren neue gebildet nach Additionstheorem der Determinanten. Angewendet auf obigen Sechservektor

$$\begin{matrix} 0 & i\mathfrak{E}_z & -i\mathfrak{E}_y & \mathfrak{H}_x \\ -i\mathfrak{E}_z & 0 & i\mathfrak{E}_x & \mathfrak{H}_y \\ i\mathfrak{E}_y & -i\mathfrak{E}_x & 0 & \mathfrak{H}_z \\ -\mathfrak{H}_x & -\mathfrak{H}_y & -\mathfrak{H}_z & 0 \end{matrix}$$

und zugeordneten

$$\begin{matrix} 0 & \mathfrak{H}_z & -\mathfrak{H}_y & i\mathfrak{E}_x \\ -\mathfrak{H}_z & 0 & \mathfrak{H}_x & i\mathfrak{E}_y \\ \mathfrak{H}_y & -\mathfrak{H}_x & 0 & i\mathfrak{E}_z \\ -i\mathfrak{E}_x & -i\mathfrak{E}_y & -i\mathfrak{E}_z & 0 \end{matrix}$$

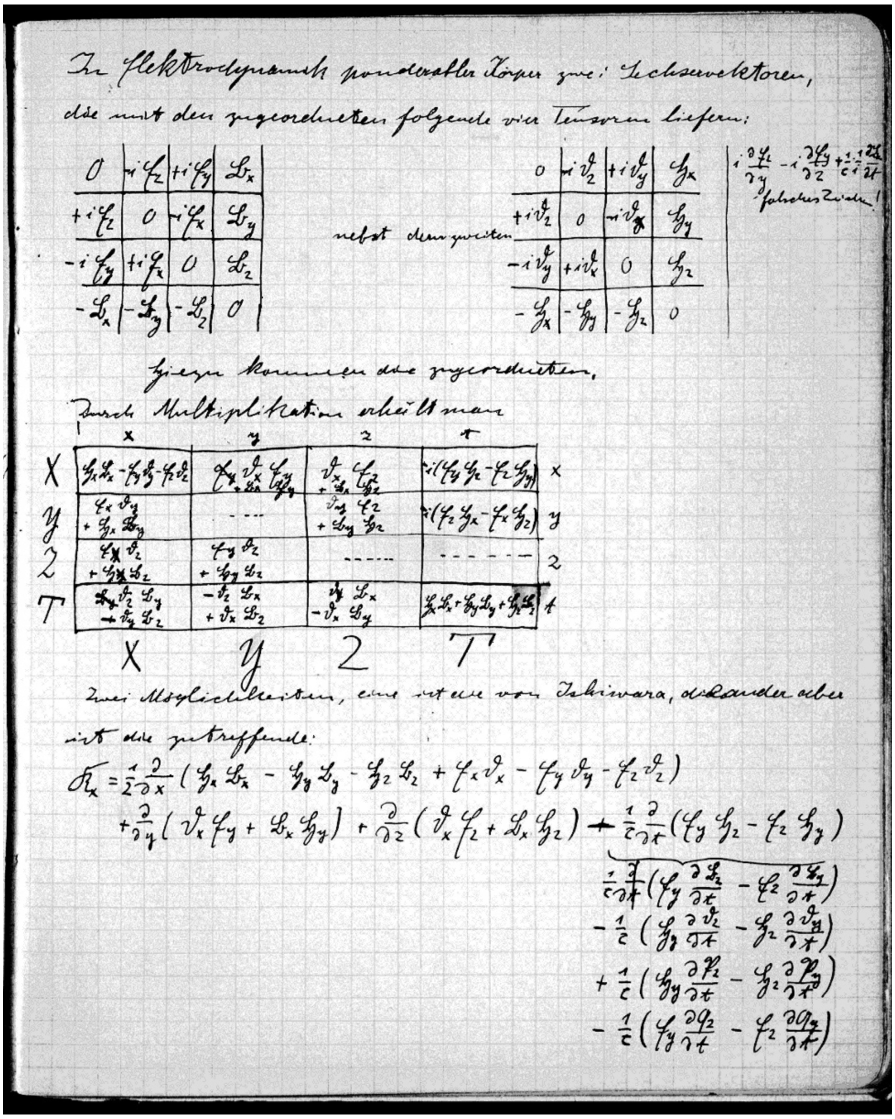
Daraus die neuen Tensoren

$$+\left|\begin{matrix} -\mathfrak{E}_z^2-\mathfrak{E}_y^2+\mathfrak{H}_x^2 & \mathfrak{E}_x\mathfrak{E}_y+\mathfrak{H}_x\mathfrak{H}_y & \mathfrak{E}_x\mathfrak{E}_z+\mathfrak{H}_x\mathfrak{H}_z & i(\mathfrak{E}_y\mathfrak{H}_z-\mathfrak{E}_z\mathfrak{H}_y) \\ - & - & - & - \\ - & - & - & - \\ - & - & - & - \end{matrix}\right.$$

$$-\left|\begin{matrix} -\mathfrak{E}_x^2+\mathfrak{H}_y^2+\mathfrak{H}_z^2 & -\mathfrak{E}_x\mathfrak{E}_y-\mathfrak{H}_x\mathfrak{H}_y & \cdot \end{matrix}\right.$$

Diese geben ponderomotorische Kräfte durch Behandlung mit Differentiations-Vierervektor.

[p. 34 R]



In Elektrodynamik ponderabler Körper zwei Sechservektoren, die mit den zugeordneten folgende vier Tensoren liefern:

$$\begin{array}{cccc} 0 & -i\mathfrak{E}_z & +i\mathfrak{E}_y & \mathfrak{B}_x \\ +i\mathfrak{E}_z & 0 & -i\mathfrak{E}_x & \mathfrak{B}_y \\ -i\mathfrak{E}_y & +i\mathfrak{E}_x & 0 & \mathfrak{B}_z \\ -\mathfrak{B}_x & -\mathfrak{B}_y & -\mathfrak{B}_z & 0 \end{array} \qquad \text{nebst dem zweiten} \qquad \begin{array}{cccc} 0 & -i\mathfrak{D}_z & +i\mathfrak{D}_y & \mathfrak{H}_x \\ +i\mathfrak{D}_z & 0 & -i\mathfrak{D}_x & \mathfrak{H}_y \\ -i\mathfrak{D}_y & +i\mathfrak{D}_x & 0 & \mathfrak{H}_z \\ -\mathfrak{H}_x & -\mathfrak{H}_y & -\mathfrak{H}_z & 0 \end{array}$$

$i\frac{\partial \mathfrak{E}_z}{\partial y} - i\frac{\partial \mathfrak{E}_y}{\partial z} + \frac{1}{c}\frac{\partial \mathfrak{B}_x}{\partial t}$ falsches Zeichen!

Hiezu kommen die zugeordneten.

Durch Multiplikation erhält man

	x	y	z	t	
X	$\mathfrak{H}_x\mathfrak{B}_x - \mathfrak{E}_y\mathfrak{D}_y - \mathfrak{E}_z\mathfrak{D}_z$	$\mathfrak{D}_x\mathfrak{E}_y + \mathfrak{B}_x\mathfrak{H}_y$	$\mathfrak{D}_x\mathfrak{E}_z + \mathfrak{B}_x\mathfrak{H}_z$	$i(\mathfrak{E}_y\mathfrak{H}_z - \mathfrak{E}_z\mathfrak{H}_y)$	x
Y	$\mathfrak{E}_x\mathfrak{D}_y + \mathfrak{H}_x\mathfrak{B}_y$	----	$\mathfrak{D}_y\mathfrak{E}_z + \mathfrak{B}_y\mathfrak{H}_z$	$i(\mathfrak{E}_z\mathfrak{H}_x - \mathfrak{E}_x\mathfrak{H}_z)$	y
Z	$\mathfrak{E}_x\mathfrak{D}_z + \mathfrak{H}_x\mathfrak{B}_z$	$\mathfrak{E}_y\mathfrak{D}_z + \mathfrak{H}_y\mathfrak{B}_z$	------	------	z
T	$\mathfrak{D}_z\mathfrak{B}_y - \mathfrak{D}_y\mathfrak{B}_z$	$-\mathfrak{D}_z\mathfrak{B}_x + \mathfrak{D}_x\mathfrak{B}_z$	$\mathfrak{D}_y\mathfrak{B}_x - \mathfrak{D}_x\mathfrak{B}_y$	$\mathfrak{H}_x\mathfrak{B}_x + \mathfrak{H}_y\mathfrak{B}_y + \mathfrak{H}_z\mathfrak{B}_z$	t
	X	Y	Z	T	

Zwei Möglichkeiten, eine ist die von Ishiwara, die andere aber ist die zutreffende:

$$\mathfrak{K}_x = \frac{1}{2}\frac{\partial}{\partial x}(\mathfrak{H}_x\mathfrak{B}_x - \mathfrak{H}_y\mathfrak{B}_y - \mathfrak{H}_z\mathfrak{B}_z + \mathfrak{E}_x\mathfrak{D}_x - \mathfrak{E}_y\mathfrak{D}_y - \mathfrak{E}_z\mathfrak{D}_z)$$

$$+\frac{\partial}{\partial y}(\mathfrak{D}_x\mathfrak{E}_y + \mathfrak{B}_x\mathfrak{H}_y) + \frac{\partial}{\partial z}(\mathfrak{D}_x\mathfrak{E}_z + \mathfrak{B}_x\mathfrak{H}_z) + \underbrace{\frac{1}{c}\frac{\partial}{\partial t}(\mathfrak{E}_y\mathfrak{H}_z - \mathfrak{E}_z\mathfrak{H}_y)}$$

$$\frac{1}{c}\frac{\partial}{\partial t}\left(\mathfrak{E}_y\frac{\partial \mathfrak{B}_z}{\partial t} - \mathfrak{E}_z\frac{\partial \mathfrak{B}_y}{\partial t}\right)$$

$$-\frac{1}{c}\left(\mathfrak{H}_y\frac{\partial \mathfrak{D}_z}{\partial t} - \mathfrak{H}_z\frac{\partial \mathfrak{D}_y}{\partial t}\right)$$

$$+\frac{1}{c}\left(\mathfrak{H}_y\frac{\partial \mathfrak{P}_z}{\partial t} - \mathfrak{H}_z\frac{\partial \mathfrak{P}_y}{\partial t}\right)$$

$$-\frac{1}{c}\left(\mathfrak{E}_y\frac{\partial \mathfrak{Q}_z}{\partial t} - \mathfrak{E}_z\frac{\partial \mathfrak{Q}_y}{\partial t}\right)$$

[p. 34 L]

Aus Tensoren neue gebildet nach Additionstheorem der Determinaten.
Angewendet auf obigen Sechservektor

$$\begin{array}{cccc} 0 & iE_z & -iE_y & H_x \\ -iE_z & 0 & iE_x & H_y \\ +iE_y & -iE_x & 0 & H_z \\ -H_x & -H_y & -H_z & 0 \end{array}$$

und zugeordneter

$$\begin{array}{cccc} 0 & H_z & -H_y & iE_x \\ -H_z & 0 & H_x & iE_y \\ H_y & -H_x & 0 & iE_z \\ -iE_x & -i\mathrm{E}_y & -iE_z & 0 \end{array}$$

Daraus die neuen Tensoren.

$$+\left|\begin{array}{cccc} -E_z^2 - E_y^2 + H_x^2 & E_xE_y + H_xH_y & E_xE_z + H_xH_z & i(E_yH_z - E_zH_y) \\ - - - & - - - & - - - & - - - \\ - - - & - - - & - - - & - - - \\ - - - & - - - & - - - & - - - \end{array}\right.$$

$$-\left|\begin{array}{cccc} -E_x^2 + H_y^2 + H_z^2 & -E_xE_y + H_xH_y & \cdot & \cdot \\ & & & \\ & & & \end{array}\right.$$

Diese geben ponderomotorsche Kräfte, durch Behandlung mit Differentiations-Vierervektor.

[p. 34 R]

In Elektrodynamik ponderabler Körper zwei Sechservektoren, die mit den zugeordneten folgende vier Tensoren liefern:

$$\begin{array}{c|c|c|c|}
0 & -iE_z & +iE_y & B_x \\ \hline
+iE_z & 0 & -iE_x & B_y \\ \hline
-iE_y & +iE_x & 0 & B_z \\ \hline
-B_x & -B_y & -B_z & 0
\end{array}
\quad \text{nebst dem zweiten} \quad
\begin{array}{c|c|c|c|}
0 & -iD_z & +iD_y & H_x \\ \hline
+iD_z & 0 & -iD_x & H_y \\ \hline
-iD_y & +iD_x & 0 & H_z \\ \hline
-H_x & -H_y & -H_z & 0
\end{array}$$

$$i\frac{\partial E_z}{\partial y} - \frac{\partial E_y}{\partial z} + \frac{1}{c}\cdot\frac{1}{i}\frac{\partial B_x}{\partial t}$$

falsches Zeichen!

Hie[r]zu kommen die zugeordneten.

Durch Multiplikation erhält man

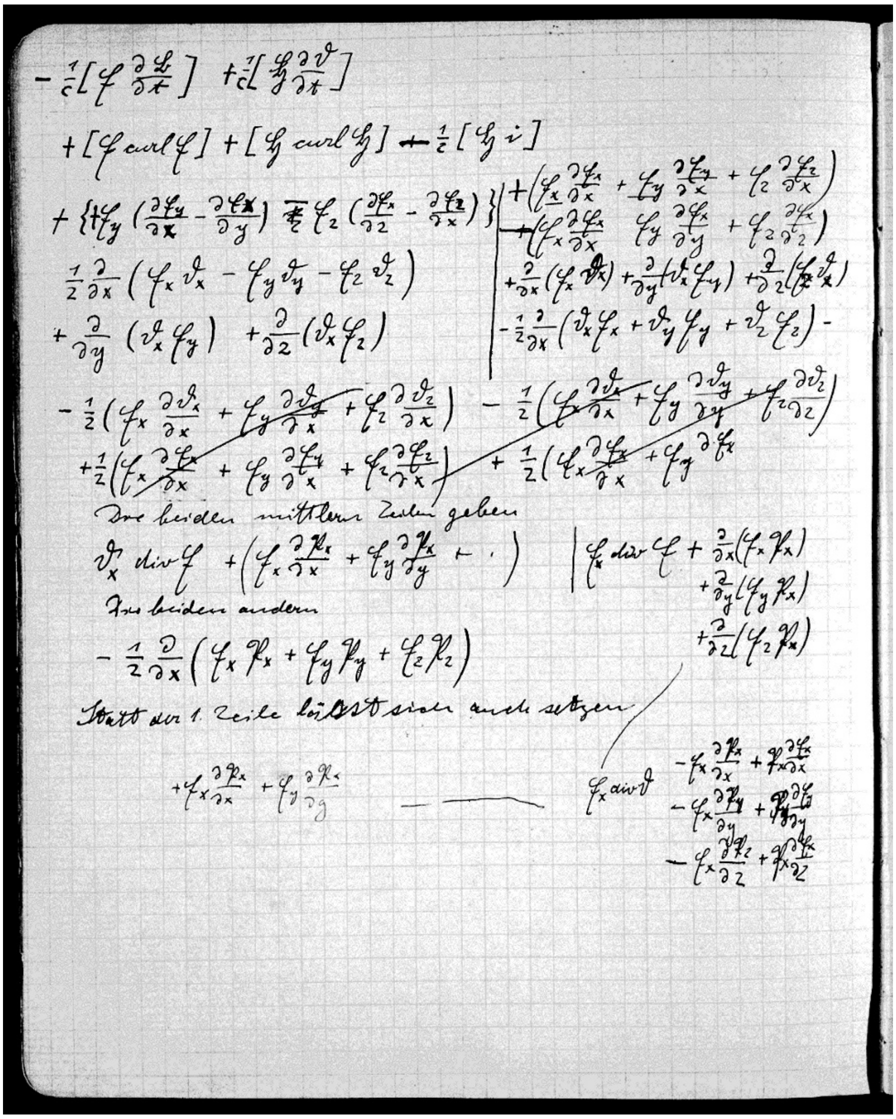
	x	y	z	t	
X	$H_xB_x - E_yD_y - E_zD_z$	$\cancel{E_y}D_xE_y$ $+B_xH_y$	D_xE_z $+B_xH_z$	$-i(E_yH_z - E_zH_y)$	x
Y	E_xD_y $+H_xB_y$	$- - - -$	D_yE_z $+B_yH_z$	$-i(E_zH_x - E_xH_z)$	y
Z	E_xD_z $+H_xB_z$	E_yD_z $+H_yB_z$	$- - - -$	$- - - - - - - - -$	z
T	$\cancel{B_y}D_zB_y$ $\cancel{+}-D_yB_z$	$-D_zB_x$ $+D_xB_z$	D_yB_x $-D_xB_y$	$H_xB_x + H_yB_y + H_zB_z$	t
	X	Y	Z	T	

Zwei Möglichkeiten, eine ist die von Ishiwara, die andere aber ist die zutreffende:

$$K_x = \frac{1}{2}\frac{\partial}{\partial x}(H_xB_x - H_yB_y - H_zB_z + E_xD_x - E_yD_y - E_zD_z)$$

$$+\frac{\partial}{\partial y}(D_xE_y + B_xH_y) + \frac{\partial}{\partial z}(D_xE_z + B_xH_z)\langle + \rangle \underbrace{-\frac{1}{c}\frac{\partial}{\partial t}(E_yH_z - E_zH_y)}_{\begin{array}{l}
\frac{1}{c}\cancel{\frac{\partial}{\partial t}}\left(E_y\frac{\partial B_z}{\partial t} - E_z\frac{\partial B_y}{\partial t}\right) \\
-\frac{1}{c}\left(H_y\frac{\partial D_z}{\partial t} - H_z\frac{\partial D_y}{\partial t}\right) \\
+\frac{1}{c}\left(H_y\frac{\partial P_z}{\partial t} - H_z\frac{\partial P_y}{\partial t}\right) \\
-\frac{1}{c}\left(E_y\frac{\partial Q_z}{\partial t} - E_z\frac{\partial Q_y}{\partial t}\right)
\end{array}}$$

[p. 35 L]



$$-\frac{1}{c}\left[\mathfrak{E}\frac{\partial \mathfrak{L}}{\partial t}\right] + \frac{1}{c}\left[\mathfrak{H}\frac{\partial \vartheta}{\partial t}\right]$$

$$+[\mathfrak{E}\,\mathrm{curl}\,\mathfrak{E}] + [\mathfrak{H}\,\mathrm{curl}\,\mathfrak{H}] \cancel{+} \frac{1}{c}[\mathfrak{H}\,i]$$

$$+\left\{\mathfrak{E}_y\left(\frac{\partial \mathfrak{E}_y}{\partial x}-\frac{\partial \mathfrak{E}_x}{\partial y}\right) - \mathfrak{E}_z\left(\frac{\partial \mathfrak{E}_x}{\partial z}-\frac{\partial \mathfrak{E}_z}{\partial x}\right)\right\}$$

$$\frac{1}{2}\frac{\partial}{\partial x}\left(\mathfrak{E}_x\vartheta_x - \mathfrak{E}_y\vartheta_y - \mathfrak{E}_z\vartheta_z\right)$$

$$+\frac{\partial}{\partial y}(\vartheta_x\mathfrak{E}_y) + \frac{\partial}{\partial z}(\vartheta_x\mathfrak{E}_z)$$

$$+\left(\mathfrak{E}_x\frac{\partial \mathfrak{E}_x}{\partial x} + \mathfrak{E}_y\frac{\partial \mathfrak{E}_y}{\partial x} + \mathfrak{E}_z\frac{\partial \mathfrak{E}_z}{\partial x}\right)$$

$$-\left(\mathfrak{E}_x\frac{\partial \mathfrak{E}_x}{\partial x} + \mathfrak{E}_y\frac{\partial \mathfrak{E}_x}{\partial y} + \mathfrak{E}_z\frac{\partial \mathfrak{E}_x}{\partial z}\right)$$

$$+\frac{\partial}{\partial x}(\mathfrak{E}_x\vartheta_x) + \frac{\partial}{\partial y}(\vartheta_x\mathfrak{E}_y) + \frac{\partial}{\partial z}(\mathfrak{E}_z\vartheta_x)$$

$$-\frac{1}{2}\frac{\partial}{\partial x}\left(\vartheta_x\mathfrak{E}_x + \vartheta_y\mathfrak{E}_y + \vartheta_z\mathfrak{E}_z\right) -$$

$$-\frac{1}{2}\left(\mathfrak{E}_x\frac{\partial \vartheta_x}{\partial x} + \mathfrak{E}_y\frac{\partial \vartheta_y}{\partial x} + \mathfrak{E}_z\frac{\partial \vartheta_z}{\partial x}\right) - \frac{1}{2}\left(\mathfrak{E}_x\frac{\partial \vartheta_x}{\partial x} + \mathfrak{E}_y\frac{\partial \vartheta_y}{\partial y} + \mathfrak{E}_z\frac{\partial \vartheta_z}{\partial z}\right)$$

$$+\frac{1}{2}\left(\mathfrak{E}_x\frac{\partial \mathfrak{E}_x}{\partial x} + \mathfrak{E}_y\frac{\partial \mathfrak{E}_y}{\partial x} + \mathfrak{E}_z\frac{\partial \mathfrak{E}_z}{\partial x}\right) + \frac{1}{2}\left(\mathfrak{E}_x\frac{\partial \mathfrak{E}_x}{\partial x} + \mathfrak{E}_y\frac{\partial \mathfrak{E}_x}{}\right.$$

Die beiden mittleren Zeilen geben

$$\vartheta_x\,\mathrm{div}\,\mathfrak{E} + \left(\mathfrak{E}_x\frac{\partial \mathfrak{K}_x}{\partial x} + \mathfrak{E}_y\frac{\partial \mathfrak{K}_x}{\partial y} + \cdot\right) \quad \Big|\ \mathfrak{E}_x\,\mathrm{div}\,\mathfrak{E} + \frac{\partial}{\partial x}(\mathfrak{E}_x\mathfrak{K}_x) + \frac{\partial}{\partial y}(\mathfrak{E}_y\mathfrak{K}_x) + \frac{\partial}{\partial z}(\mathfrak{E}_z\mathfrak{K}_x)$$

Die beiden andern

$$-\frac{1}{2}\frac{\partial}{\partial x}\left(\mathfrak{E}_x\mathfrak{K}_x + \mathfrak{E}_y\mathfrak{K}_y + \mathfrak{E}_z\mathfrak{K}_z\right)$$

Statt der 1. Zeile lässt sich auch setzen

A COMMENTARY ON THE NOTES ON GRAVITY IN THE ZURICH NOTEBOOK

TABLE OF CONTENTS

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 2
Einstein's Zurich Notebook: Commentary and Essays.

1. INTRODUCTION

The Zurich Notebook provides what appears to be a virtually complete record of Einstein's search for gravitational field equations in the winter of 1912–1913. He had just started to explore a new theory of gravitation in which the ten components of the metric tensor take over the role of the gravitational potential in Newton's theory.[1] The notes documenting Einstein's search for field equations for this theory take up the better part of the notebook. They start on pp. 39L–41R and continue on pp. 5R–29L and pp. 42L–43L. Our text is a detailed running commentary on these notes.[2] It provides line-by-line reconstructions of all calculations and discusses the purpose behind them.[3] The commentary is self-contained and can in principle be read independently of the notebook. It is designed, however, to be used in conjunction with the facsimile

1 For discussion of how Einstein arrived at this theory, see "The First Two Acts" (in vol. 1 of this series). In terms of this metaphor, the search for field equations comprises the third act. It starts with the Zurich Notebook and ends with the four communications to Berlin Academy of November 1915 in which Einstein completed general relativity as we know it today with the formulation of the generally-covariant Einstein field equations (Einstein 1915a, b, c, d).

2 The commentary does not cover pp. 27L–29L, which deal with the behavior of matter in a given metric field.

3 We follow the notation used in the notebook and clearly indicate whenever we use elements of modern notation (such as the Kronecker delta or a more compact notation for derivatives) in our reconstructions of Einstein's calculations. Einstein's notation should be easy to follow for readers familiar with the basics of the standard modern notation of general relativity. The one exception is Einstein's idiosyncratic convention before (Einstein 1914b) of writing all indices downstairs and distinguishing between covariant and contravariant components (e.g., the components $g_{\mu\nu}$ and $g^{\mu\nu}$ of the metric) by using Latin letters for one ($g_{\mu\nu}$) and Greek letters for the other ($\gamma_{\mu\nu}$). In the notebook, to make matters worse, Einstein sometimes used Latin for contravariant and Greek for covariant components. The contravariant stress-energy tensor, e.g., is denoted by $T_{\mu\nu}$ in the notebook while its covariant counterpart is denoted by $\Theta_{\mu\nu}$ (see, e.g., p. 5R and equation (64)), which is just the reverse of the notation used in (Einstein and Grossmann 1913) and subsequent publications. The summation convention (repeated indices are summed over) was only introduced in (Einstein 1916a, 788). In the notebook, however, Einstein occasionally omitted summation signs, thus implicitly using it. When providing intermediate steps for calculations in the notebook we shall frequently and tacitly use the summation convention.

and the transcription of the notebook presented in vol. 1 of this series. The reader seeking guidance in reading a particular passage of the notebook can go directly to the section of the commentary in which that passage is analyzed. To help the reader find the relevant section, both the table of contents and the running heads of the text match (sub) (sub-)sections of the commentary to pages of the notebook. When looking up the annotation for a specific passage of the notebook, the reader is advised to consult the introduction to the (sub-)(sub-)section of the commentary dealing with that passage first.

After covering the earliest research on gravity documented by the notebook (pp. 39L–41R) in sec. 2 and the derivation of the law for the energy-momentum balance between matter and gravitational field (p. 5R) in sec. 3, the commentary continues with its two longest sections, sec. 4 covering pp. 6L–13R and 41L–R and sec. 5 covering pp. 14L–25R and 42L–43L. These two sections have extensive introductions, providing an overview of the material cross-referenced both with the page numbers of the notebook and the numbers of the (sub-)subsections of the commentary where the material is covered in detail. Sec. 4 covers a stage in Einstein's research during which, through trial and error, he found a body of results, strategies, and techniques that he drew on for the more systematic search for field equations during the next stage. Sec. 5 follows the fate of a series of candidate field equations as Einstein checked them against a list of criteria they would have to satisfy. All these candidates are extracted from the Riemann tensor, which makes its first appearance on p. 14L, the first of the pages covered by sec. 5.

In the course of his investigations, Einstein already came across some of the field equations published in November 1915. One of the central tasks of the commentary is to analyze why these candidate field equations were rejected three years earlier. In the notebook Einstein eventually gave up trying to extract field equations from the Riemann tensor. Drawing on results and techniques found during the earlier stage instead, he developed a way of generating field equations guaranteed to meet what he deemed to be the most important of the requirements to be satisfied by such equations. In this way he found the field equations of severely limited covariance published in the spring of 1913 in a paper co-authored with Marcel Grossmann (Einstein and Grossmann 1913). The theory and the field equations presented in this paper are known, after the title of the paper, as the "*Entwurf*" ("outline") theory and the "*Entwurf*" (field) equations. The derivation of the *Entwurf* field equations on pp. 26L–R of the notebook is covered in sec. 6, the short section that concludes the commentary.

To get an overview of the contents of the gravitational part of the Zurich Notebook, the reader is advised to read the balance of this section as well as secs. 4.1 and 5.1–5.2, the introductions to the two main sections of the commentary.

1.1 *The Four Heuristic Requirements*

For our analysis of the notebook it is important to distinguish two strategies employed by Einstein in his search for suitable gravitational field equations and four requirements serving as guideposts and touchstones in this search. In sec. 1.2 we introduce the two strategies; in this section we introduce the four heuristic requirements, which, for ease of reference, we have labeled relativity, equivalence, correspondence, and conservation.[4]

1.1.1 *The Relativity Principle*

Throughout the period in which Einstein formulated general relativity as we know it today (i.e., the years 1912–1915), he was under the impression that the principle of relativity for uniform motion of special relativity can be generalized to arbitrary motion by extending the manifest Lorentz invariance of special relativity in the formulation of Minkowski (1908), Sommerfeld (1910a, b), Laue (1911b) and others to general covariance.[5] Only in the fall of 1916 did Einstein come to realize that general covariance does not automatically lead to relativity of arbitrary motion.[6] Kretschmann (1917) was the first to give a precise formulation of the difference between general covariance and general relativity.[7] Given his conflation of the two at the time, Einstein tried to implement the relativity principle in the notebook by constructing field equations of the broadest possible covariance. He was thus drawn to generally-covariant objects such as the Beltrami invariants (p. 6L) and the Riemann tensor (p. 14L). He found these in the mathematical literature with the help of Marcel Grossmann. Einstein would sacrifice some covariance to meet the other requirements the field equations had to satisfy. Contrary to what we know today, he assumed that both energy-momentum conservation and the recovery of Newtonian theory for weak static fields put constraints on the class of admissible coordinate transformations. Initially, his hope was that this class would still include transformations to frames of reference in arbitrary states of motion. In the course of the research documented in the notebook it became clear to him that this is not the case. By the end of the notebook (pp. 26–R), Einstein had settled for invariance under general linear transformations, hoping to extend the principle of relativity to non-uniform motion in a different way, suggested by the equivalence principle.

1.1.2 *The Equivalence Principle*

Einstein's fundamental insight in developing general relativity was that there is an intimate connection between acceleration and gravity. As Einstein put it in 1918, the two are "of the exact same nature" ("wesensgleich," Einstein 1918, 176). They are two

---

5 For an analysis of Einstein's conflation of the status of Lorentz invariance in special relativity and the status of general covariance in general relativity, see (Norton 1992, 1999).

6 This became clear to Einstein in discussions with Willem de Sitter. For further discussion, see the headnote, "The Einstein-De Sitter-Weyl-Klein Debate," in (CPAE 8, 351–357).

7 For discussion of Kretschmann's paper and Einstein's brief response to it in (Einstein 1918), see, e.g., (Norton 1993, sec. 5).

sides of the same coin, which explains Galileo's principle that all bodies fall alike in a given gravitational field, or, in Newtonian terms, that inertial mass is equal to gravitational mass. Einstein first explored the connection between acceleration and gravity in (Einstein 1907) and started calling it the equivalence principle in (Einstein 1912a). Einstein wanted to use this principle to extend the relativity of uniform motion to non-uniform motion and develop a new theory of gravity at the same time.[8]

The general-relativity principle that Einstein formulated on the basis of the equivalence principle is of a somewhat peculiar nature. It is best illustrated with a couple of paradigmatic examples. Two observers in the vicinity of some massive body, one in free fall, one resisting the pull of gravity, can both claim to be at rest as long as they agree to disagree about whether or not there is a gravitational field present in their region of spacetime. The observer in free fall can legitimately claim that there is *no* gravitational field, that he is at rest, and that the other observer is accelerating upward. The observer resisting the pull of gravity is equally justified in claiming that there *is* a gravitational field, that she is at rest, and that the other observer is accelerating downward. They can make similar claims when they are both in some flat region of spacetime, one hovering freely, the other firing up the engines of her spacecraft. The first observer can claim that there is no gravitational field, that he is at rest, and that the other observer is accelerating upwards. The second observer can claim that a gravitational field came into existence the moment she turned on her engines, that she is at rest in this field, and that the other observer is accelerating downward in it. In neither of these two cases—close to some massive body or in some flat region of spacetime—are the situations of these two observers physically equivalent to one another. The equivalence, in fact, is between the observer in free fall in the first case and the one hovering in outer space in the second and between the observer resisting the pull of gravity in the first case and the one in the accelerating rocket in the second. In both cases it is not the motion of the two observers with respect to one another that is relative—in the sense of being determined only with reference to the observer making the call—but the presence or absence of a gravitational field.[9]

Einstein implemented the equivalence principle by letting the metric field $g_{\mu\nu}$ represent both the gravitational field and the inertial structure of spacetime. For the equivalence principle to go through it is crucial that in all cases such as the ones considered above the metric field is a solution of the same field equations in the coordinate systems of both observers. This is automatically true if the field equations are generally covariant. But general covariance, while sufficient, is not necessary to meet this requirement. Whenever general covariance proved unattainable in the notebook (and similarly during the subsequent reign of the *Entwurf* theory with its field equations of severely restricted covariance), Einstein tried to meet the requirement in a different way, involving what he first called "non-autonomous" ("unselbständige") transformations[10] and later "justified" ("berechtigte") transformations between "adapted"

8 For discussion of Einstein's equivalence principle, see (Norton 1985).
9 For further discussion, see (Janssen 2005, 63–66).

("angepaßte") coordinates.[11] In the case of ordinary, autonomous, transformations, the new coordinates are simply functions of the old ones. If the field equations are invariant under some autonomous transformation, any solution in the old coordinates is guaranteed to turn into a solution in the new ones under that transformation. In the case of non-autonomous transformations, the new coordinates are functions of the old coordinates and the metric field (expressed in terms of the old coordinates).[12] If the field equations are invariant under a non-autonomous transformation for some metric field that is a solution of the field equations in the old coordinates, only that particular solution is guaranteed to turn into a solution in the new coordinates. This suffices for the implementation of the equivalence principle. Given the difficulty of finding field equations invariant under a broad enough class of autonomous transformations, it need not surprise us that non-autonomous transformations play a prominent role in the notebook. Einstein was especially interested in non-autonomous transformations to uniformly rotating and uniformly accelerating frames of reference in flat spacetime, in which case the metric in the old coordinates is simply the standard diagonal Minkowski metric.

1.1.3 *The Correspondence Principle*

An obvious constraint on Einstein's new gravitational theory was that Newton's theory be recovered under the appropriate circumstances. We call this the correspondence principle. In the case of weak static fields, the 44-component of the metric (where x_4 is the time coordinate multiplied by the velocity of light) is proportional to the gravitational potential in Newtonian theory. The correspondence principle thus requires that, in the case of weak static fields, the component of the field equations that determines g_{44} reduce to the Poisson equation for the Newtonian potential. Einstein expected g_{44} to be the only variable component of the metric in this case so that the spatial part of the metric would remain flat. This would allow him to connect his new theory both to Newtonian theory and to his own earlier theory for static fields in which the gravitational potential is represented by a variable speed of light (Einstein 1912a, b).

It turns out that the correspondence principle does not require the metric for weak static fields to be spatially flat. Other components of the metric besides g_{44} can be variable without losing compatibility with Newtonian theory. This is because, regardless of the values of the other components, g_{44} is the only component to enter into the equations of motion for matter moving in the gravitational field in the relevant weak-field slow-motion approximation. Einstein only came to realize this in the course of his calculation of the perihelion motion of Mercury in November 1915 (Einstein 1915c).[13] Throughout the notebook he assumed that only g_{44} can be variable for weak

10 Einstein to H. A. Lorentz, 14 August 1913 (CPAE 5, Doc. 467). The relevant passage is quoted in footnote 94.

11 (Einstein and Grossmann 1914, 221; Einstein 1914b, 1070)

12 For more detailed discussion of non-autonomous transformations, see the introduction to sec. 4.3.

static fields. At one point he contemplated relaxing this requirement but quickly convinced himself that this is not allowed.[14]

Despite this additional constraint on the form of the metric for weak static fields, Einstein found various field equations that satisfy the correspondence principle. On the face of it, it looks as if Einstein applied coordinate conditions to various field equations of broad covariance to establish that they reduce to the Poisson equation in the appropriate limit.[15] On closer examination, it turns out that Einstein actually used what we shall call coordinate *restrictions*. He took expressions of broad covariance and truncated them by imposing additional conditions on the metric to obtain candidate field equations that reduce to the Poisson equation in the case of weak static fields. Einstein did not see such truncated equations as representing candidate field equations of broader covariance in a limited class of coordinate systems for the purpose of comparing them with Newtonian theory, as we would nowadays, but as candidates for the fundamental field equations of the theory. The status of the conditions on the metric with which Einstein did the truncating is therefore very different from that of modern coordinate conditions. This is why we introduced the special term coordinate restrictions.[16]

Coordinate restrictions played an important role in Einstein's attempts to find non-autonomous coordinate transformations under which candidate field equations would be invariant. If such candidates had been extracted from expressions of broad covariance with the help of some coordinate restriction, their covariance was determined by the covariance of that coordinate restriction. The expressions involved in coordinate restrictions are much simpler than the field equations themselves and the covariance properties of the former are therefore much more tractable than those of the latter. Many pages of the notebook are thus given over to the investigation of the covariance properties of various coordinate restrictions.[17] Einstein routinely checked whether the coordinate restrictions he imposed allow non-autonomous transformations to uniformly rotating and uniformly accelerating frames of reference in Minkowski spacetime.

The correspondence principle led Einstein to expect the left-hand side of the field equations to have the form of a sum of what we shall call a core operator, a term with second-order derivatives of the metric that for weak static fields reduces to the Laplacian acting on the metric, and various correction terms quadratic in first-order derivatives of the metric that vanish in a weak-field approximation. He either extracted

14 See p. 21R discussed in secs. 5.4.4 and 5.4.6.

15 See in particular pp. 19L and 22R discussed in sec. 5.4.1 and sec. 5.5.2, respectively. When considered in isolation, these two pages strongly suggest that Einstein applied coordinate conditions in the modern sense in the notebook, a conclusion that was indeed drawn in (Norton 1984).

16 For a particularly illuminating example of a coordinate restriction, see pp. 23L–R discussed in sec. 5.5.4.

17 See, e.g., pp. 10L–11L (covered in secs. 4.5.1–4.5.3), p. 22L (covered in 5.5.3), and pp. 23R, 42L–R (covered in secs. 5.5.5–5.5.6).

equations of this form from equations of broad covariance with the help of coordinate restrictions or he determined what terms had to be added to the core operator on the basis of considerations of energy-momentum conservation.

1.1.4 *The Conservation Principle*

Einstein's 1912 theory for static gravitational fields had taught him to pay close attention to what we shall call the conservation principle, the compatibility between the field equations and energy-momentum conservation. The field equations proposed in (Einstein 1912a) had turned out to be incompatible with energy-momentum conservation and Einstein had been forced to add a term to them in (Einstein 1912b).[18] The extra term, it turned out, gave the energy density of the gravitational field and entered the field equations on the same footing as the energy density of the field's material sources. This, as Einstein realized, had to be the case given the equivalence of energy and inertial mass expressed in $E = mc^2$, the equality of inertial and gravitational mass asserted by the equivalence principle, and the equality of active and passive gravitational mass. The field equations of the new metric theory would thus have to satisfy a similar requirement. Einstein accordingly sought to interpret the correction terms to the core operator mentioned above as the energy-momentum density of the gravitational field, occurring on a par with the stress-energy tensor of matter.[19]

That the stress-energy tensor of matter should replace the mass of Newtonian theory as the source of the gravitational field Einstein had learned from the development of special-relativistic mechanics.[20] The early years of special relativity had brought a transition from Galilean-invariant particle mechanics based on Newton's second law to Lorentz-invariant continuum mechanics based on energy-momentum conservation, expressed by the vanishing of the four-divergence of the total stress-energy tensor of closed systems, $\partial_\nu T^{\mu\nu}_{\mathrm{tot}} = 0$ (∂_ν shorthand for $\partial / \partial x_\nu$). The conservation principle requires that the gravitational field equations be compatible with this law in a weak-field approximation in which the energy-momentum of the gravitational field itself can be neglected. The weak-field field equations have the form $\Box g^{\mu\nu} = -\kappa T^{\mu\nu}$

18 See footnote 119 for more details.

19 Following the terminology in (Einstein and Grossmann 1913, e.g., p. 11 and p. 16), we shall use the term stress-energy tensor' throughout the commentary rather than the more common 'energy-momentum tensor' or the more cumbersome 'stress-energy-momentum (SEM) tensor'. In the notebook Einstein referred both to the "tensor of momentum and energy" ("Tensor der Bewegungsgröße u. Energie," p. 5R) and to the "stress-energy tensor" [*Sp[annungs]-Energie-Tensor*] p. 20R).

20 In his 1912 manuscript on special relativity, Einstein called the extension of the central role of the stress-energy tensor in electrodynamics to all of physics "the most important recent advance in relativity theory" ("den wichtigsten neueren Fortschritt der Relativitätstheorie." CPAE 4, Doc. 1, p. [63]). He gave credit to Minkowski, Abraham, Planck, and Laue for this development. The symmetry of the stress-energy tensor in its two indices encodes such physical knowledge as the inertia of energy and the conservation of angular momentum (Laue 1911a). This means that the differential operator acting on the metric set equal to the stress-energy tensor in the field equations must have that same symmetry. This requirement is indeed imposed, though not emphasized, in the notebook (cf. footnotes 219 and 220).

($\Box$ is the d'Alembertian, $\eta^{\mu\nu}\partial_\mu\partial_\nu$, with $\eta^{\mu\nu} \equiv \mathrm{diag}(-1, -1, -1, 1)$ the standard diagonal Minkowski metric). Einstein imposed the coordinate restriction $\partial_\nu g^{\mu\nu} = 0$ in which case these field equations imply energy-momentum conservation in the weak-field approximation.[21] This coordinate restriction, which Einstein used both to satisfy the conservation principle and to satisfy the correspondence principle, occurs so frequently in the notebook that we have given it a special name. We call it the Hertz restriction.[22]

When the energy-momentum coming from the gravitational field cannot be neglected, the situation gets more complicated. On p. 5R Einstein derived an equation giving the exact energy-momentum balance between matter and gravitational field. In modern terms, this equation states that the covariant divergence of the stress-energy tensor of matter vanishes. It is the sum of two terms, the ordinary divergence of the stress-energy tensor of matter and an expression, once again containing this tensor, that can be interpreted as the gravitational force. The field equations set some second-order differential operator acting on the metric equal to the stress-energy tensor of matter. One of the most important tests to which Einstein submitted candidate field equations was to use them to eliminate the stress-energy tensor from the expression for the gravitational force in the energy-momentum balance and check whether the resulting expression can be written as the divergence of an expression that could be interpreted as the energy-momentum density of the gravitational field itself.[23] Given the form of the stress-energy tensor of the electromagnetic field and of the stress tensor of the gravitational field in his static theory, Einstein expected and required this quantity to be quadratic in first-order derivatives of the metric. That way gravitational energy-momentum could indeed be neglected in the weak-field approximation. With the help of this quantity, Einstein could now rewrite the energy-momentum balance between matter and gravitational field as an ordinary divergence of the total energy-momentum density—of matter and of the gravitational field. The balance equation thus turns into a genuine conservation law. That a covariant divergence can be rewritten as an ordinary divergence in this manner immediately makes it clear that gravitational energy-momentum density cannot be represented by a generally-covariant tensor. It is what we now call a pseudo-tensor. Throughout the notebook, however, Einstein tacitly assumed that its transformation properties are the same as those of any other stress-energy tensor. He only recognized in early 1914 that this is not true.[24] Einstein eventually turned this test of the conservation principle into a powerful method for generating field equations. It was this method that gave him the *Entwurf* field equations.[25]

---

21 See p. 19R discussed in sec. 5.4.2.

22 Named after Paul Hertz, the recipient of an important letter in which Einstein discussed this restriction (Einstein to Paul Hertz, 22 August 1915 [CPAE 8, Doc. 111]).

23 See, e.g., p. 19R.

24 See (Einstein and Grossmann 1914). For discussion, see (Norton 1984, sec. 5), "Pathways out of Classical Physics …" (in vol. 1 of this series), and "What Did Einstein Know …" sec. 2 (in this volume).

In summary, the conservation principle resulted in (at least) four related but distinct requirements that candidate field equations have to satisfy. First, the energy-momentum density of the gravitational field has to enter into the field equations in the same way as the energy-momentum density of matter. Secondly, the field equations should guarantee that the four-divergence of the stress-energy tensor of matter vanishes in the weak-field approximation. Thirdly, the field equations should allow the gravitational force density in the energy-momentum balance between matter and gravitational field to be written as the divergence of some gravitational stress-energy pseudo-tensor. Finally, this pseudo-tensor should be an expression quadratic in first-order derivatives of the metric. Given this rich harvest of requirements, the conservation principle was probably the most fruitful of the four heuristic principles that guided Einstein in his search for suitable field equations.

1.2 *The Two Strategies*

Einstein attacked the problem of finding suitable field equations for the metric field from two directions, clearing the hurdles he had himself erected with his four heuristic requirements— relativity, equivalence, correspondence, and conservation—in a different order. In what we call the 'mathematical strategy,' Einstein tackled relativity and equivalence first and then moved on to correspondence and conservation. In what we call the 'physical strategy' it is just the other way around. There he started with correspondence and conservation and then turned to relativity and equivalence.[26] The identification of these two complementary strategies not only turned out to be key to our reconstruction of many of Einstein's arguments and calculations in the notebook, it also greatly enhanced our understanding of his work on general relativity during the subsequent period of 1913–1915.[27] In this section we briefly characterize these two strategies.

The mathematical strategy was to use one of the generally-covariant quantities that can be found in the mathematical literature, such as the Beltrami invariants or the Riemann tensor, to construct a second-order differential operator acting on the metric (or its determinant) that is then set equal to the stress-energy tensor of matter (or its trace). If this can be done without compromising the general covariance of the initial quantity too much, such field equations will automatically meet the relativity and equivalence requirements. The problem that Einstein ran into was that the correspondence and conservation requirements, if they could be met at all, called for severe coordinate restrictions. Still, as explained in sec. 1.1.3, knowing that candidate field equations can be extracted from equations of broad covariance with the help of a coordinate restriction makes their covariance properties much more tractable. Their covariance is fully

---

25 See p. 13R, p. 24R, and p. 26L-R, discussed in secs. 4.6.2, 5.6.1, and 6, respectively.

26 For more detailed discussion of these two strategies, see (Renn and Sauer 1999) and "Pathways out of Classical Physics ..." (in vol. 1 of this series).

27 See "Untying the Knot ..." (in this volume).

determined by the covariance of the coordinate restriction. Unfortunately, Einstein found again and again that the coordinate restrictions he needed to satisfy the correspondence and conservation requirements ruled out the kind of transformations to accelerating frames of reference needed to meet the relativity and equivalence requirements.

The physical strategy was to model the field equations for the metric field on the Poisson equation of Newtonian gravitational theory and Maxwell's equations for the electromagnetic field.[28] As explained in secs. 1.1.3 and 1.1.4, the correspondence and conservation requirements suggest that the field equations have a core operator, which for weak static fields reduces to the Laplacian acting on the metric, and a term representing gravitational energy-momentum density on the left-hand side and the stress-energy tensor of matter on the right-hand side. The conservation principle can be used to determine the exact form of the gravitational stress-energy pseudo-tensor. The physical strategy thus amounts to constructing candidate field equations guaranteed to meet the correspondence and conservation requirements. The problem is that their construction sheds little light on their covariance properties. Only their covariance under general linear transformations is assured. It thus remains completely unclear whether they satisfy the relativity and equivalence requirements. The best Einstein could do on this score was to check whether they allowed the Minkowski metric in various accelerated frames of reference so that they would at least be invariant under some non-autonomous non-linear transformations corresponding to acceleration.

In the first half of the notes (pp. 39L–41R, 5R–13R), we see Einstein vacillate between the mathematical and the physical strategy. On p. 6L, for instance, the Beltrami invariants are introduced and used as input for the mathematical strategy. Two pages later, Einstein switched to the core operator and the physical strategy. On the following pages Einstein combined his two strategies trying in vain to connect field equations based on the core operator to the Beltrami invariants in an attempt to clarify their transformation properties. On p. 13R he made further progress along the lines of the physical strategy by introducing considerations of energy-momentum conservation. Then, on p. 14L, the Riemann tensor makes its first appearance in the notebook, and Einstein abruptly switched from the physical to the mathematical strategy. What follows is a concerted effort, taking up most of the second half of the notes (pp. 14L–23R, 42L–43L), to extract field equations from the Riemann tensor. Eventually (p. 24R–26R), Einstein went back to the physical strategy, continuing the line of reasoning begun on p. 13R. He briefly combined the two strategies again, trying to find (on p. 25L) a coordinate restriction with which to extract field equations found along the lines of the physical strategy (on p. 24R) from the Riemann tensor. He then decided to go exclusively with the physical strategy, which led him to the *Entwurf* field equations on pp. 26L–R.

39L–41L

2. FIRST EXPLORATION OF A METRIC THEORY OF GRAVITATION (39L–41L)

2.1 *Introduction*

Einstein's attempt to construct a new dynamical theory of gravitation starts from three basic elements: (1) the representation of the gravitational field by the ten components of the metric tensor; (2) the four-dimensional spacetime formalism of special relativity; and (3) his scalar theory of the static gravitational field. For Einstein, all three components were recent additions to his stock of knowledge.

In Prague, in the spring of 1912, he brought his attempts to formulate a theory of gravitation for the special case of a static field to a satisfactory conclusion. Only after returning from Prague to Zurich in the summer of 1912 did he recognize the relevance of Gauss' theory of surfaces to the gravitation problem. Gauss' theory represents the metrical geometry of surfaces of variable curvature by a line element, the square root of a quadratic differential form invariant under arbitrary coordinate transformations. Einstein had become familiar with the four-dimensional formalism for special relativity developed by Minkowski, Sommerfeld, and Laue, and he realized that a four-dimensional extension of Gauss' theory could provide a mathematical framework suitable for a new, dynamical theory of gravitation.

The three components, out of which he hoped to build the new theory, each posed distinct but interrelated problems. Gauss' theory for two-dimensional surfaces had to be extended to a four-dimensional space with indefinite signature. The flat Minkowski spacetime formalism had to be extended to a vector and tensor analysis valid for arbitrary coordinate systems in a non-flat spacetime. Einstein's static gravitational theory was formulated in terms of a single (three)-scalar gravitational potential. The single partial differential equation governing this potential had to be generalized to a system of partial differential equations for the ten-component tensorial gravitational potential.

On pp. 39L–41L of the notebook, Einstein explored a few simple ways of combining these three components to find the gravitational field equations for a static field in special coordinates. No clear candidates emerged from Einstein's first foray into the problem. This may have signaled to him that a higher level of mathematical sophistication was called for. Even at the elementary level of these early calculations, however, one can see an alternation between physically and mathematically motivated approaches foreshadowing the two basic strategies that we distinguished in sec. 1.2.

39L

2.2 *The Three Building-Blocks: Gauss, Minkowski, Einstein (39L)*

This page includes three groups of formulas, separated from each other by two horizontal lines. Each of these groups can be associated with one of the elements mentioned above. Einstein started by writing down the square of the four-dimensional line element

$$ds^2 = \Sigma G_{\lambda\mu} dx_\lambda dx_\mu \,. \tag{1}$$

His use of a capital letter "G" indicates that this is the earliest occurrence of the metric tensor in the notebook. After p. 40R, Einstein switched to the common lower-case g.

He then derived the transformational behavior of the metric tensor under four-dimensional coordinate transformations from the condition that the line element be invariant under such transformations. The transformations between the unprimed and primed coordinates are expressed by a matrix of coefficients and its inverse[29]

$$\begin{array}{c|c|c|c|c} & x'_1 & x'_2 & x'_3 & x'_4 \\ \hline x_1 & \alpha_{11} & \alpha_{21} & \alpha_{31} & \alpha_{41} \\ \hline x_2 & \alpha_{12} & & & \\ \hline x_3 & \alpha_{13} & & & \\ \hline x_4 & \alpha_{14} & & & \end{array} \qquad \begin{array}{ccccc} & x_1 & x_2 & x_3 & x_4 \\ x'_1 & \beta_{11} & & & \\ x'_2 & \beta_{12} & & & \\ x'_3 & \beta_{13} & & & \\ x'_4 & \beta_{14} & & & \end{array} \tag{2}$$

From the invariance of the square of the line element under such a transformation,

$$\begin{aligned} \sum\sum G_{\lambda\mu} dx_\lambda dx_\mu &= \sum\sum G'_{\rho\sigma} dx'_\rho dx'_\sigma \\ &= \sum_\rho \sum_\sigma \sum_\eta \sum_\zeta G'_{\rho\sigma} \alpha_{\rho\eta} \alpha_{\sigma\zeta} dx_\eta dx_\zeta , \end{aligned} \tag{3}$$

Einstein read off the transformation laws for the components of the metric

$$G_{\lambda\mu} = \sum_\rho \sum_\sigma G'_{\rho\sigma} \alpha_{\rho\lambda} \alpha_{\sigma\mu} \,, \tag{4}$$

and "analogously" ("analog")

$$G'_{\lambda\mu} = \sum_\rho \sum_\sigma G_{\rho\sigma} \beta_{\rho\lambda} \beta_{\sigma\mu} \,. \tag{5}$$

Next to these results, Einstein noted explicitly the equations for the coordinate transformation

$$x'_r = \sum_s \alpha_{rs} x_s \,. \tag{6}$$

So apparently Einstein was considering linear transformations at this point.[30] For the corresponding first-order partial derivative operators, he wrote

29 As is indicated by a line through the first column, the transformation is given by $x'_1 = \alpha_{11}x_1 + \alpha_{12}x_2 + \alpha_{13}x_3 + \alpha_{14}x_4$, etc. A similar matrix is found in (Laue 1911b, 57) and in Einstein's 1912 manuscript on special relativity (CPAE 4, Doc. 1, secs. 15 and 16).

30 In the transformation matrix at the top of the page he may have had non-linear transformations in mind with non-constant α's: In the top row of that matrix Einstein seems to have written dx instead of simply x for the first three entries, and it may have been only later that he restricted himself to linear transformations.

$$\frac{\partial}{\partial x_s} = \sum_r \alpha_{rs} \frac{\partial}{\partial x'_r}. \tag{7}$$

In the middle of the page, below the first horizontal line, Einstein considered a "special case for the $G_{\lambda\mu}$" ("Spezialfall für die $G_{\lambda\mu}$"), namely the case of a coordinate system in which the metric is diagonal

$$\begin{array}{cccc} G_{11} & G_{12} & G_{13} & G_{14} \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & c^2 \end{array} \cdot \tag{8}$$

The spatial metric is flat and expressed in Cartesian coordinates, and the 44-component of the metric is identified with the square of the speed of light.[31] If c^2 is a constant, this metric represents the Minkowski spacetime of special relativity in quasi-Cartesian coordinates. If c^2 is a function of the spatial coordinates, $c^2 = c^2(x_1, x_2, x_3)$, it represents the metrical generalization of Einstein's static theory.

At the bottom of the page, under the second horizontal line, Einstein turned to this theory of the static gravitational field. The gravitational field equation of his static theory,[32]

$$c\Delta c - \frac{1}{2}\mathrm{grad}^2 c = kc^2\sigma, \tag{9}$$

is a partial differential equation for the velocity of light, which serves as the single gravitational potential of this theory. In a four-dimensional metric theory, the field equations will be partial differential equations for all ten components of the metric tensor, resulting from the action of some differential operator acting on it. Einstein assumed that, in the special case of a static field and with an appropriate choice of coordinates, the metric tensor would reduce to the form given in equation (8) with $c = c(x_1, x_2, x_3)$.[33] In this case, the gravitational field equations would be expected to reduce to equation (9). The problem was to reverse this reduction and find the differential operator that enters into field equations for the metric tensor.

The first step in his attempt to find this operator was to rewrite the left-hand side of equation (9) in terms of the components of the metric tensor in equation (8), i.e., to

31 A striking feature of this expression is the signature of the metric, which is in contrast to the appearance of the metric for this special case on pp. 6R and 21R, where Einstein wrote $\mathrm{diag}(-1, -1, -1, c^2)$. One possible explanation for this is that Einstein implicitly used an imaginary time coordinate at this point, which he had explicitly introduced on p. 32R in the context of his treatment of electrodynamics in moving media.

32 (Einstein 1912b, 456, equation (3b)).

33 Einstein later made this expectation explicit (Einstein and Grossmann 1913, Sec. 2).

rewrite the equation in terms of c^2 instead of c. Einstein began with the left-hand side of equation (9)

$$c\Delta c - \frac{1}{2}\mathrm{grad}^2 c \,. \tag{10}$$

He then wrote down the first- and second-order partial derivatives of c^2 with respect to x

$$c^2 \qquad 2c\frac{\partial c}{\partial x} \qquad 2\left(\frac{\partial c}{\partial x}\right)^2 + 2c\frac{\partial^2 c}{\partial x^2} \,. \tag{11}$$

Since the y- and z-derivatives behave similarly, Einstein could now read off the Laplacian of c^2,

$$\Delta(c^2) = 2\mathrm{grad}^2 c + 2c\Delta c \,, \tag{12}$$

as well as the gradient of c^2,

$$\mathrm{grad}(c^2) = 2c\,\mathrm{grad}\,c \,, \tag{13}$$

in terms of c and its derivatives.

At this point, Einstein probably realized that various factors of 2 on the right-hand sides of equations (11)–(13) cancel if one looks at $c^2/2$ instead of c^2. In any case, he defined a function

$$\gamma = \frac{c^2}{2} \tag{14}$$

such that

$$\Delta\gamma = \mathrm{grad}^2 c + c\Delta c \,, \tag{15}$$

and

$$\mathrm{grad}\,\gamma = c\,\mathrm{grad}\,c \,. \tag{16}$$

This equation allowed Einstein to express $\mathrm{grad}^2 c$ in terms of γ:

$$\frac{\mathrm{grad}^2\gamma}{2\gamma} = \mathrm{grad}^2 c \,. \tag{17}$$

Using equations (15) and (17), he finally wrote the expression (10) in terms of γ:

$$\Delta\gamma - \frac{3}{4}\frac{\mathrm{grad}^2\gamma}{\gamma} \,. \tag{18}$$

Einstein presumably expected that this expression could be recovered from the tensorial field equations. He may have hoped that it would emerge as the 44-component of the left-hand side of these field equation, but he could, of course, not be certain that tensorial equations would yield the familiar static theory in this way.[34]

34 Alternatives are conceivable but less likely. For example, expression (18) might be the trace of the left-hand side of the unknown gravitational field equations.

39R

2.3 *Finding a Metric Formulation of the Static Field Equation (39R)*

At the top of p. 39R, Einstein wrote down the vacuum field equations of his 1912 static theory in terms of the variable γ introduced on the facing page:

$$\gamma\Delta\gamma - \frac{3}{4}\mathrm{grad}^2\gamma = 0 . \tag{19}$$

Next to this equation, he started to write the word "Umfo[rmen]" (to re-express), then deleted it in favour of "Transformieren" (to transform). Presumably, the point of such transformations was to generalize this field equation for one component of the static field in a special coordinate system to field equations for all components of the field—static or non-static—in more general coordinates.

However, instead of dealing with the field equations, Einstein turned to a simpler but related problem. In the Cartesian coordinates used so far, the static character of the spatially flat metric in equation (8) can be expressed as[35]

$$\frac{\partial G_{44}}{\partial x_4} = 0 , \tag{20}$$

the vanishing of the time derivative of the 44-component. Einstein now tried to find a covariant formulation of the condition that this metric be static. To this end, he began to transform condition (20) to primed coordinates. Using equation (7), he first expressed the derivative with respect to x_4 in terms of primed coordinates:

$$\frac{\partial}{\partial x_4} = \alpha_{14}\frac{\partial}{\partial x'_1} + \alpha_{24}\frac{\partial}{\partial x'_2} + \cdot + \cdot \tag{21}$$

Using equation (4), he then did the same for the 44-component of the metric

$$G_{44} = \sum_{\rho}\sum_{\sigma} G'_{\rho\sigma}\alpha_{\rho 4}\alpha_{\sigma 4} . \tag{22}$$

He now used the inverse transformation for $G'_{\rho\sigma}$ on the right-hand side:

$$\begin{aligned} G'_{\lambda\mu} &= k + \sum\sum G_{\rho\sigma}\beta_{\rho\lambda}\beta_{\sigma\mu} \\ &= k + G_{44} \underbrace{\sum\sum \beta_{4\lambda}\beta_{4\mu}}_{B_{\lambda\mu}} . \end{aligned} \tag{23}$$

The inclusion of the term k in the first line appears to be an error, perhaps anticipating the need for such a term on the next line, which absorbs all terms in the summation except those containing G_{44}.[36] If k is a constant, as the notation suggests, then Einstein seems to be considering the special case of linear transformations (in which case only G_{44} is non-constant). It is evident from equation (23) that, under arbitrary linear transformations, all components of $G'_{\lambda\mu}$ can be non-constant. This expression, how-

35 Originally, this equation was written as $\partial G_{44}/\partial t = 0$.

36 In the second line, Einstein presumably forgot to take out the summation signs.

ever, does not indicate how the $G'_{\lambda\mu}$ depend on the primed coordinates, which would require expressing G_{44} as a function of the primed coordinates. Perhaps looking for such an expression, Einstein began rewriting an expression for G_{44} but quickly gave up, possibly because such a substitution would just result in the composition of a transformation and its inverse. Finally, he deleted the entire calculation and started afresh in the top right corner of the page. (This part is ruled off by a horizontal and a vertical line.)

So Einstein had failed to find a covariant reformulation of the physically-motivated condition (20) through direct transformation. He now turned his attention to the mathematically more promising relation

$$\mathrm{Div}\,\Gamma = 0\,, \tag{24}$$

which reduces to equation (20) in the case of the spatially flat static metric (8). That Einstein did indeed find this equation promising is indicated by the word "probable" ("wahrscheinlich") that he wrote above it. The differential operator "Div" is analogous to the quasi-Cartesian coordinate divergence of a tensor, an operation well known in Minkowski's four-dimensional spacetime formalism.[37] Einstein was familiar with the use of this operation in four-dimensional electrodynamics. The symbol "Γ" denotes the metric tensor ("Tensor der G").

Einstein now asked "Is this invariant?" ("Ist dies invariant?") and wrote out equation (24) explicitly:

$$\sum_{\mu}\frac{\partial G_{\lambda\mu}}{\partial x_{\mu}} = 0,\ \lambda = 1234\,. \tag{25}$$

Using the transformation equations (4) and (7), he transformed this equation to primed coordinates:

$$\sum_{\tau}\alpha_{\tau\mu}\frac{\partial}{\partial x'_{\tau}}\left\{\sum_{\rho}\sum_{\sigma}G'_{\rho\sigma}\alpha_{\rho\lambda}\alpha_{\sigma\mu}\right\} = 0\,. \tag{26}$$

Equation (26) shows that the condition does indeed transform as a vector (i.e., is "invariant") under linear transformations (i.e., for constant α's). This concludes the investigation of the condition that the metric be static.

At this point, Einstein presumably returned to the field equations. This is suggested by his derivation on the bottom half of p 39R of the transformation equations for second-order derivatives. To simplify matters, he suppressed two spatial coordinates: "Everything only dependent on x_1 and x_2 (time)." ("Alles nur von x_1 und x_2 (Zeit) abhängig"). From the actual calculations at the bottom of p. 39R, it is clear that Ein-

37 The notation "Div" for a four-dimensional generalization of the ordinary three-dimensional divergence was introduced by (Sommerfeld 1910b, 650). It is also used in (Laue 1911b, 70). The four-divergence is implicitly used in the derivation of Maxwell's equations on p. 33L. Note that the ordinary divergence is written with a lower case "*d*" on p. 5R.

stein focused on linear transformations with symmetric transformation matrices (i.e., $a_{12} = a_{21}$).[38] The end result of his calculation is

$$\left(\frac{\partial^2}{\partial x_1^2}\right) = \alpha_{11}^2 \frac{\partial^2}{\partial x'^2_1} + 2\alpha_{11}\alpha_{21}\frac{\partial^2}{\partial x'_1 \partial x'_2} + \alpha_{22}^2 \frac{\partial^2}{\partial x'^2_2} \tag{27}$$

(the last term on the right does not appear in the notebook). This equation shows that, under (symmetric) linear transformations, the set of second-order partial derivatives of a scalar function transforms like the components of the metric tensor, an insight that Einstein put to good use on the next page.

40L–R 2.4 *Searching for a Generalization of the Laplacian in the Metric Formalism (40L–R)*

At the bottom of p. 39R, Einstein had found that second-order partial derivatives of a scalar function have the same transformation behavior under linear transformations as the metric tensor. This insight probably prompted the calculations on pp. 40L–R, which are an attempt to find candidates for the differential operator acting on the metric tensor in the field equations on the basis of expressions involving well-known differential operators acting on a scalar field. Given some striking similarities between expressions found on p. 40L and a list of differential invariants in (Wright 1908), Einstein (or Grossmann) probably consulted this book while working on the calculations on this page.[39] Since the field equations have to be of second order and the components of the metric tensor are equivalent—as far as their transformation properties are concerned[40]—to second-order derivatives of a scalar, Einstein had to consider expressions containing fourth-order derivatives of the scalar function. In the course of his calculations, he further imposed the condition that all four coordinates enter on the same footing into the differential operator acting on the scalar function. The attempt was abandoned after the first few lines on p. 40R.

40L After a few false starts, Einstein listed a number of expressions with the Laplacian and the gradient operator acting on a scalar function φ. First, he wrote down three expressions with “second-order” (“2. Ordnung”) derivatives:

$$\Delta\varphi,\ \ \varphi\Delta\varphi,\ \ \mathrm{grad}^2\varphi\,. \tag{28}$$

---

38 In the 1+1 dimensional spacetime considered by Einstein, all Lorentz transformations are boosts. These are all represented by symmetric matrices. Presumably, this is the physical rationale behind Einstein’s focus on such matrices.

39 Einstein was familiar with this book, as can be inferred from Einstein to Felix Klein, 21 April 1917: “Grossmann (I believe) had the little book by Weight [sic] when we were working together on relativity four years ago” (“Das Büchlei[n] von Weight [sic] hatte Grossmann (glaube ich), als wir vor 4 Jahren zusammen über Relativität arbeiteten.” CPAE 8, Doc. 328). For historical discussion of (Wright 1908), see (Reich 1994, 105–107).

40 The equivalence can only refer to the behavior under coordinate transformations since a direct identification of the metric tensor with the second partial derivatives of a scalar function would result in severe, unacceptable restrictions on the metric.

Then he wrote down a number of expressions with "fourth-order" ("4. Ordnung") derivatives

$$\Delta\Delta\varphi,\ \Delta(\varphi\Delta\varphi),\ \Delta(\mathrm{grad}^2\varphi),\ \varphi(\Delta\Delta\varphi),\ \mathrm{grad}^2\Delta\varphi\,. \tag{29}$$

The list shows some resemblance to a list on pp. 56–57 of (Wright 1908).[41] On the next line, the first of these expressions, $\Delta\Delta\varphi$, is expanded, with the help of the definition of the Laplacian in Cartesian coordinates in two dimensions, $\Delta \equiv \partial^2/\partial x^2 + \partial^2/\partial y^2$. He then expanded the second term of the list, $\Delta(\varphi\Delta\varphi)$, as[42]

$$\underline{\Delta\varphi\cdot\Delta\varphi} + \varphi\Delta\Delta\varphi + \underbrace{\left(\frac{\partial\varphi}{\partial x}\frac{\partial}{\partial x}\Delta\varphi + \cdot + \cdot\right)}_{\mathrm{grad}\varphi\,\mathrm{grad}\Delta\varphi}. \tag{30}$$

The terms $\Delta\Delta\varphi$ and $\Delta\varphi\Delta\varphi$ only contain second-order derivatives of the scalar function φ and can therefore be translated into expressions with (differential operators acting on) components of the metric. The underlining of these two terms in the notebook thus confirms our interpretation of the rationale for these calculations.

Einstein then wrote "the first two steps" ("Die ersten 2 Schritte"), drew a horizontal line, wrote "2 dimensions" ("2 Dimensionen"), and then crossed out the calculations he had made so far and tried again.

Einstein's next comment makes his strategy explicit: "system of the G equivalent to system $\partial^2\varphi/\partial x_\mu\partial x_\nu$" ("System der G äquivalent dem System $\partial^2\varphi/\partial x_\mu\partial x_\nu$"). In other words, he now spelled out the equivalence of second-order derivatives of a scalar function and components of the metric tensor as far as their behavior under linear coordinate transformations is concerned. Einstein's next step was to impose an additional constraint on candidate field equations constructed from the kind of expressions he had been examining above: "The equation should be such that in every term one has the same number of differentiations with respect to every x" ("Gleichung soll so sein, dass in jedem Glied nach allen x gleich oft diff[erenziert] wird.").

Einstein now had three constraints that any acceptable expression had to satisfy. First, for every factor φ there should be two partial-derivative operators $\partial/\partial x_\mu$ to enable the translation to components of the metric tensor. Second, there should be two additional partial-derivative operators to yield second-order field equations. Third, for each of the four coordinates the expression should contain an equal number of operators $\partial/\partial x_\mu$.

He first considered an expression linear in φ:

41 In Wright's book the list is formed from combinations of the two Beltrami invariants (Wright 1908, 56–57). At this point in the notebook, the operator Δ does not seem to be related to the Beltrami invariants. Einstein nevertheless may have hoped that Wright's book would give him some guidance in finding a differential invariant that he could use to construct the left-hand side of the gravitational field equations. The Beltrami invariants explicitly appear on later pages of the notebook (for the first time on p. 7L; for discussion see sec. 4.2).

42 There is a factor of 2 missing in the third term.

$$\frac{\partial^8\varphi}{\partial x_1^2\partial x_2^2\partial x_3^2\partial x_4^2}. \tag{31}$$

Einstein rejected this possibility, writing: "linear impossible, of 8th order in φ" ("Linear unmöglich von 8. Ordnung in φ"). The problem with this expression is that it leads to sixth-order field equations. For instance, using the derivatives with respect to x_4 for the translation to components of the metric tensor, one arrives at the expression

$$\frac{\partial^6 g_{44}}{\partial x_1^2\partial x_2^2\partial x_3^2}. \tag{32}$$

The next possibility he considered was an expression quadratic in φ:

$$\frac{\partial^2\varphi}{\partial x_1^2}\frac{\partial^6\varphi}{\partial x_2^2\partial x_3^2\partial x_4^2}. \tag{33}$$

This term, as Einstein noted, would correspond to an expression with fourth-order derivatives of the metric: "will necessarily be of fourth order" ("wird notwendig 4. Ordnung").

To obtain an expression satisfying all three constraints, one needs an expression cubic in φ. Einstein thus wrote: "third degree in φ will be of second order, as it has to be" ("dritten Grades in φ wird 2. Ordnung, wie es sein muss") and then wrote down an example of such an expression:

$$\frac{\partial^2\varphi}{\partial x_1^2}\frac{\partial^2\varphi}{\partial x_2^2}\frac{\partial^4\varphi}{\partial x_3^2\partial x_4^2}. \tag{34}$$

40R The equivalence under linear coordinate transformations of the metric tensor and the partial derivatives of a scalar function is further explored at the top of p. 40R. There Einstein tried a different way of achieving symmetry between the four space-time coordinates. He changed what we identified above as the third constraint. Rather than looking at the expression corresponding to the field equations, he now exclusively concentrated on the second-order derivatives of φ representing components of the metric in this context. Taking as his starting point the product of two such second-order derivatives (corresponding to $g_{12}g_{34}$ [43]), he ensured that all four coordinates occur on equal footing by adding terms obtained through permutation of the indices. Einstein initially wrote down the cyclic permutations $g_{23}g_{41}$ and $g_{34}g_{12}$. However, $g_{34}g_{12} = g_{12}g_{34}$, so he crossed out this first attempt and tried again. He now wrote down the terms $g_{13}g_{24}$ and $g_{14}g_{23}$, the only non-redundant terms given the symmetries $g_{ik} = g_{ki}$ and $g_{mn}g_{ik} = g_{ik}g_{mn}$. He then translated these three terms into partial differential operators acting on φ:

43 Here, on top of p. 40R Einstein used the lower case g for the first time, a practice he continued throughout the rest of the notebook.

$$\frac{\partial^2\varphi}{\partial x_1\partial x_2}\frac{\partial^2\varphi}{\partial x_3\partial x_4}+\frac{\partial^2\varphi}{\partial x_1\partial x_3}\frac{\partial^2\varphi}{\partial x_2\partial x_4}+\frac{\partial^2\varphi}{\partial x_1\partial x_4}\frac{\partial^2\varphi}{\partial x_2\partial x_3}\,. \tag{35}$$

This expression is fully symmetric under permutation of the indices. By having a second-order derivative operator symmetric in all four coordinates (such as the d'Alembertian) acting on this expression, one can now construct field equations that meet all three constraints, the two original ones and the modified version of the third one. However, Einstein did not pursue this line of inquiry any further.

2.5 *Transforming the Ellipsoid Equation as a Model for Transforming the Line Element (40R–41L)* 40R–41L

Einstein's first exploration of a metric theory of gravitation ends at the horizontal line drawn on p. 40R with the calculations discussed above. The remaining pages of this part, pp. 40R–43L, do not seem to be a direct continuation of these investigations.

On the bottom half of p. 40R and the top half of p. 41L, Einstein considered transformations of equations describing three-dimensional ellipsoids. Only these calculations, which bear on Einstein's exploration of the transformation properties of the metric tensor, will be discussed here. On the bottom half of p. 41L and the top half of p. 41R, Einstein examined some properties of infinitesimal unimodular transformations. These calculations will be discussed in sec. 4.5.7 along with very similar calculations at the bottom of p. 12R. The bottom half of p. 41R, dealing with constrained motion along a two-dimensional surface, will be discussed in the sec. 4.5.8. Finally, most, if not all, of the material on pp. 42L–43L is related to Einstein's considerations on pp. 23L–R and will be discussed in secs. 5.5.6–5.5.10.

On the bottom half of p. 40R, Einstein transformed the equation for a three-dimensional ellipsoid to its principal-axis form. On the top half of p. 41L, he then tried to determine the class of linear transformations that would leave this description of the ellipsoid invariant. The calculation on p. 40R is analogous to finding coordinate transformations that take the line element in arbitrary coordinates to its standard Minkowski form. This geometrical analogy can also be found in (Einstein and Grossmann 1913, sec. 3): "the real cone $ds^2 = 0$ appears brought to its principal axes" ("der reelle Kegel $ds^2 = 0$ erscheint auf seine Hauptachsen bezogen"). The calculation on p. 41L is analogous to finding the class of linear transformations leaving the Minkowski line element in its standard diagonal form invariant.[44]

The calculation starts from the defining equation for an ellipsoid in Cartesian coordinates x, y, and z: 40R

$$\alpha_{11}x^2+2\alpha_{12}xy+\ldots..\alpha_{33}z^2 = 1\,. \tag{36}$$

44 These calculations may have been motivated by the following remark in (Wright 1908, 18): "The problem of the equivalence of two quadratic differential forms is reduced to that of the equivalence of two sets of algebraic forms, where one set is obtained from the other by a linear transformation."

For this equation to describe an ellipsoid, the left-hand side must be a positive definite quadratic form. Immediately below this expression, Einstein wrote the equation for the same ellipsoid in rotated primed coordinates such that the coordinate axes are aligned with the principal axes of the ellipsoid,

$$\frac{x'^2}{A^2} + \frac{y'^2}{B^2} + \frac{z'^2}{C^2} = 1 , \tag{37}$$

where A, B, and C are the lengths of the three semi-principal axes of the ellipsoid.

Next he wrote down the matrix of coefficients of the orthogonal coordinate transformation corresponding to this rotation:[45]

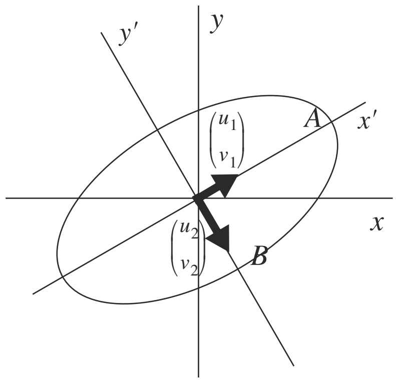
$$\begin{array}{c|c|c|c} & x' & y' & z' \\ \hline x & \alpha_1 & \alpha_2 & \alpha_3 \\ \hline y & \beta_1 & \beta_2 & \beta_3 \\ \hline z & \gamma_1 & \gamma_2 & \gamma_3 \end{array} . \tag{38}$$

Under the three columns of this matrix, Einstein wrote $1/A$, $1/B$, and $1/C$, respectively, indicating that he wanted to rescale the coefficients by these factors. He denoted the rescaled coefficients by $u_1 = \alpha_1/A$, $v_1 = \beta_1/A$, etc. The matrix of the rescaled coefficients is written below the transformation matrix,

$$\begin{array}{ccc} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{array} \tag{39}$$

For the remainder of these calculations, Einstein used the geometrical meaning of these quantities. To understand Einstein's reasoning, it is helpful to examine the two-dimensional case.

45 Similar transformation schemes appear on p. 39L and on the following p. 41L. More explicitly, the transformation reads $x' = \alpha_1 x + \beta_1 y + \gamma_1 z$, etc.



Consider the diagram on the left. In the primed coordinate system, the equation for the ellipse is:

$$\frac{x'^2}{A^2} + \frac{y'^2}{B^2} = 1\,, \tag{40}$$

which can be rewritten as

$$(\mathbf{u}_1 \cdot \mathbf{x})^2 + (\mathbf{u}_2 \cdot \mathbf{x})^2 = 1\,. \tag{41}$$

In the primed coordinate system, the vectors $\mathbf{x}$, $\mathbf{u}_1$ and $\mathbf{u}_2$ have components (x', y'), $(1/A, 0)$ and $(0, -1/B)$, respectively.

Einstein wrote down the three-dimensional analogue of equation (41) in the unprimed coordinates:[46]

$$(u_1 x + v_1 y + w_1 z)^2 + (u_2 x + v_2 y + w_2 z)^2 + (u_3 x + v_3 y + w_3 z)^2 = 1\,. \tag{42}$$

Expanding the binomials and comparing the resulting coefficients with those of equation (36), one finds[47]

$$\begin{aligned} u_1^2 + u_2^2 + u_3^2 &= \alpha_{11} & \quad v_1 w_1 + v_2 w_2 + v_3 w_3 &= \alpha_{23} \\ v_1^2 + v_2^2 + v_3^2 &= \alpha_{22} & \quad w_1 u_1 + w_2 u_2 + w_3 u_3 &= \alpha_{31} \\ w_1^2 + w_2^2 + w_3^2 &= \alpha_{33} & \quad u_1 v_1 + u_2 v_2 + u_3 v_3 &= \alpha_{12}. \end{aligned} \tag{43}$$

The vectors (u_1, v_1, w_1), (u_2, v_2, w_2), and (u_3, v_3, w_3) are in the direction of the semi-axes of the ellipsoid (cf. the figure above). It follows that these three vectors are orthogonal and that their norms are the reciprocal of the lengths of the ellipsoid's semi-axes. The orthogonality of the three vectors is expressed by:

$$\begin{aligned} u_1 u_2 + v_1 v_2 + w_1 w_2 &= 0, \\ u_1 u_3 + v_1 v_3 + w_1 w_3 &= 0, \\ u_2 u_3 + v_2 v_3 + w_2 w_3 &= 0. \end{aligned} \tag{44}$$

Their norms are given by:

46 The third term is only indicated by a dot in the notebook.

47 The equations for α_{33}, α_{31}, and α_{12} are indicated by dashes in the notebook, and instead of α_{23} Einstein erroneously wrote α_{12}.

$$
\begin{aligned}
u_1^2 + v_1^2 + w_1^2 &= \frac{1}{A^2}, \\
u_2^2 + v_2^2 + w_2^2 &= \frac{1}{B^2}, \\
u_3^2 + v_3^2 + w_3^2 &= \frac{1}{C^2}.
\end{aligned}
\tag{45}
$$

Equations (44) and (45) are the ones written down at the bottom of p. 40R.[48]

41L On the next page, Einstein recapitulated, remarking that “the u, v, w determine orientation and size of the ellipsoid” (“Die u, v, w bestimmen Lage und Grösse des Ellipsoids.”). Equation (42) for the ellipsoid can be written $\sum(u_i x + v_i y + w_i z)^2 = 1$, the left-hand side of which can be interpreted as the sum of the squared scalar products of (u_1, v_1, w_1), (u_2, v_2, w_2), and (u_3, v_3, w_3) with the radius vector x, y, z.

On p. 40R, Einstein had been concerned with the transformation to principal axes for the ellipsoid. On p. 41L, he investigated “arbitrary linear transformations of x, y, z to x', y', z' for an invariant ellipsoid function” (“Beliebige lineare Transformationen der x, y, z in x', y', z' bei invarianter Ellipsoidfunktion.”). In other words, he asked which linear transformation leave the principal-axes form of the equation for the ellipsoid invariant. He thus wrote down the equation for the ellipsoid in two different coordinate systems:[49]

$$\sum(u_i x + v_i y + w_i z)^2 = \sum(u'_i x' + v'_i y' + w'_i z')^2 \ . \tag{46}$$

Einstein next wrote down transformation matrices for the linear transformations between the three spatial coordinates that parallel those introduced earlier for the four spacetime coordinates:

$$
\begin{array}{c|ccc}
 & x' & y' & z' \\
x & \beta_{11} & \beta_{21} & \beta_{31} \\
y & \beta_{12} & \beta_{22} & \beta_{32} \\
z & \beta_{13} & \beta_{23} & \beta_{33},
\end{array}
\tag{47}
$$

and:[50]

48 The last two lines of equations (44) and (45) are only indicated by dashes in the notebook.

49 In writing this expression, Einstein seems to have added the summation signs as an afterthought: additional terms on the right-hand side were deleted in favor of the summation sign, and the summation index “i” in that equation is an “l” in the notebook.

50 Note that the notation here is the reverse of the notation introduced on p. 39L (cf. equation (2)).

$$
\begin{array}{c|ccc}
 & x & y & z \\
x' & \alpha_{11} & \alpha_{21} & \alpha_{31} \\
y' & \alpha_{12} & \alpha_{22} & \alpha_{32} \\
z' & \alpha_{13} & \alpha_{23} & \alpha_{33}.
\end{array}
\tag{48}
$$

From equation (46), it follows that the transformation matrix for the vectors (u_1, v_1, w_1), (u_2, v_2, w_2), and (u_3, v_3, w_3) is the transposed of the matrix in equation (47), i.e., in Einstein's notation:

$$
\begin{array}{c|ccc}
 & u'_1 & v'_1 & w'_1 \\
u_1 & \beta_{11} & \beta_{12} & \beta_{13} \\
v_1 & \beta_{21} & \beta_{22} & \beta_{23} \\
w_1 & \beta_{31} & \beta_{32} & \beta_{33}.
\end{array}
\tag{49}
$$

Using these transformation equations, one can write:

$$
\begin{aligned}
u'^2_1 &= (u_1\beta_{11} + v_1\beta_{21} + w_1\beta_{31})^2, \\
u'^2_2 &= (u_2\beta_{11} + v_2\beta_{21} + w_2\beta_{31})^2, \\
u'^2_3 &= (u_3\beta_{11} + v_3\beta_{21} + w_3\beta_{31})^2.
\end{aligned}
\tag{50}
$$

The sum of these three expressions may be more conveniently expressed as:

$$
u'^2_1 + u'^2_2 + u'^2_3 = \sum_{i=1}^{3} (u_i\beta_{11} + v_i\beta_{21} + w_i\beta_{31})^2 \tag{51}
$$

In the notebook this equation is written as[51]

$$
u'^2_1 + u'^2_2 + u'^2_3 = \sum (u_1\beta_{11} + v_1\beta_{21} + w_1\beta_{31})^2 . \tag{52}
$$

Similarly, he found:

$$
v'^2_1 + v'^2_2 + v'^2_3 = \sum (u_1\beta_{12} + v_1\beta_{22} + w_1\beta_{32})^2 . \tag{53}
$$

The third equation, for $w'^2_1 + w'^2_2 + w'^2_3$, is indicated by a dashed line. At this point, the calculation breaks off.

The remaining pages of the part starting from the back of the notebook contain material that was added later and will be covered later. The calculations on the bottom half of p. 41L and on p. 41R will be discussed in section 4; the calculations on p. 42L–43L in section 5.

---

51 In other words, Einstein neglected to change u_1, v_1, w_1 to u_i, v_i, w_i on the right-hand side.

3. ENERGY-MOMENTUM BALANCE BETWEEN MATTER AND GRAVITATIONAL FIELD (5R)

We now turn to the notes on gravitation that start from the back of the notebook,
5R beginning with p. 5R. The calculations on these pages are not a direct continuation of those on pp. 39L–41R examined in sec. 2. A clear indication that p. 5R ff. are later is that the calculations on these pages are much more sophisticated mathematically than those on pp. 39L–41R.

On p. 5R, Einstein derived the equation for the energy-momentum balance for pressureless dust in the presence of a gravitational field,[52] an argument that later appeared in (Einstein and Grossmann 1913, secs. 2 and 4). It starts with the derivation of the equations of motion of a point particle in a metric field from an action principle, where the action integral is just the proper length of the particle's worldline. Expressions for the particle's momentum and the gravitational force acting on the particle are read off from the resulting Euler-Lagrange equations. Einstein generalized these results to expressions for the momentum density and the force density in the case of pressureless dust, or, as it is described in (Einstein and Grossmann 1913, 9), "continuously distributed incoherent masses" ("kontinuierlich verteilter inkohärenter Massen"). He identified the expression for momentum density as part of the stress-energy tensor for pressureless dust. Inserting this stress-energy tensor and a similar expression for the density of the force acting on the pressureless dust into the equations of motion that he started from, Einstein arrived at a plausible candidate for the law of energy-momentum conservation in the presence of a gravitational field, or, more accurately, an equation for the energy-momentum balance between matter and gravitational field.[53] What made the candidate all the more promising were its transformation properties. In fact, the equation is generally covariant. As was shown explicitly by Grossmann in his part of (Einstein and Grossmann 1913*;* part II, sec. 4), it expresses the vanishing of the covariant four-divergence of the stress-energy tensor. On p. 5R, Einstein made a similar claim, namely that the result of the expression found at the bottom of the page is always a vector. He performed a calculation for a special case that at least made this claim plausible. The equation thus looked like a promising generalization of the vanishing of the ordinary four-divergence of the stress-energy tensor, which Laue (1911a, b) had made the fundamental equation of relativistic mechanics. Like Laue, Einstein presumably wanted to generalize it from the special case of pressureless dust to arbitrary physical systems.[54]

Einstein's analysis on p. 5R thus provides an excellent example of how physical and mathematical considerations complement each other in the course of Einstein's

---

52 Essentially the same calculation can be found on p. 20R. For discussion see sec. 5.4.4. P. 5R is also discussed in (Norton 2000, appendices A through C).

53 On p. 43LB, Einstein performed a calculation that is the "inverse" of that on p. 5R. Rather than deriving the law of energy-momentum balance from the equations of motion of a point particle, he derived the equations of motion from the law of energy-momentum balance. This calculation will be discussed in sec. 5.5.10.

development of the general theory of relativity. First, Einstein derived an equation for the energy-momentum balance between matter and gravitational field on the basis of physical arguments centering on the special case of pressureless dust. Then, he confirmed its generalizability to arbitrary physical systems on the basis of mathematical arguments.

We shall now examine Einstein's calculations on p. 5R in detail. He started by writing down the line element,

$$g_{11}dx^2 + \ldots + g_{44}dt^2 = ds^2 . \tag{54}$$

Next to it, he noted that this expression is "always positive for a point" ("immer positiv für Punkt"), i.e., the worldline of a material particle is time-like.[55]

As he had first done in a note added in proof to the paper presenting his second static theory (Einstein 1912b, 458), Einstein used this line element to define the Lagrangian—or "Hamiltonian function" ("Hamiltonsche Funktion") as he called it (Einstein and Grossmann 1913, 7)—for a point particle moving in a given metric field:[56]

$$\frac{ds}{dt} = H . \tag{55}$$

He then wrote down the corresponding Euler-Lagrange equations, the "equations of motion" ("Bewegungsgleichungen"):

$$\frac{d}{dt}\left(\frac{\partial H}{\partial \dot{x}}\right) - \frac{\partial H}{\partial x} = 0 . \tag{56}$$

The equation initially had a plus rather than a minus sign on the left-hand side. This sign error is carried through all the way to the end of the calculation. Einstein only corrected it after he discovered that it led to an unacceptable end result (see the discussion following equation (75)). The equation,

---

54 Einstein made this generalization explicit in his paper with Grossmann: "We ascribe to equation (10) a range of validity that goes far beyond the special case of the flow of incoherent masses. The equation represents in general the energy balance between the gravitational field and an arbitrary material process" ("Der Gleichung (10) schreiben wir einen Gültigkeitsbereich zu, der über den speziellen Fall der Strömung inkohärenter Massen weit hinausgeht. Die Gleichung stellt allgemein die Energiebilanz zwischen dem Gravitationsfelde und einem beliebigen materiellen Vorgang dar …;" Einstein and Grossmann 1913, p. 11). Statements almost verbatim the same as this one can be found in the printed text of Einstein's lecture on the problem of gravitation in Vienna in September 1913 (Einstein 1913, 1253 and 1257).

55 From this we can infer that at this point, Einstein's sign convention is such that the Minkowski metric in its standard diagonal form is $\mathrm{diag}(-1, -1, -1, c^2)$. This same convention was used in the *Nachtrag* to (Einstein 1912b) and in (Einstein and Grossmann 1913). On p. [39L], however, the Minkowski metric in its standard diagonal form was given as $\mathrm{diag}(1, 1, 1, -c^2)$ (if we switch from an imaginary to a real time coordinate).

56 Given the sign convention on this page (see the preceding footnote), H should be $-H$ (cf. Einstein and Grossmann 1913, 7; Einstein 1912b, 458).

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{x}}\right) = -\frac{\partial \Phi}{\partial x}\,, \tag{57}$$

written to the right of equation (56), was presumably added at that point and helped Einstein correct his sign error. It is easy to see how equation (57) could play that role. When the Lagrangian can be written as $H = L - \Phi$, where Φ is a potential energy term and L (which stands for "lebendige Kraft") is the kinetic energy term, equation (56) is equivalent to equation (57). The latter equation is readily recognized as a generalization of Newton's second law. This then confirmed that the left-hand side of equation (56) must indeed have a minus sign.

Underneath equation (56), Einstein wrote down the partial derivative of H with respect to $\dot{x}$:[57]

$$\frac{\partial H}{\partial \dot{x}} = \frac{g_{11}\dot{x} + g_{12}\dot{y} + . + g_{14}}{ds/dt}\,. \tag{58}$$

This is the x-component of the momentum of a particle of unit mass. He then generalized this result to an expression for the x-component of the momentum density of pressureless dust:[58]

$$\rho_0\sqrt{G}\left(g_{11}\frac{dx}{ds}\frac{dt}{ds} + g_{12}\frac{dy}{ds}\frac{dt}{ds} + \cdot + \cdot\right) \tag{59}$$

The derivation of this expression is not given in the notebook, but can easily be reconstructed (see Einstein and Grossmann 1913, secs. 2 and 4). Using equation (58) for the x-component of momentum J_x and dividing it by the volume V in the same coordinate system, one arrives at an expression for the x-component of momentum density

$$\frac{J_x}{V} = \frac{1}{V}\frac{\partial H}{\partial \dot{x}} = \frac{1}{V}\frac{g_{11}\dot{x} + g_{12}\dot{y} + g_{13}\dot{z} + g_{14}}{ds/dt}\,. \tag{60}$$

To obtain equation (59), the coordinate volume V has to be replaced by the proper volume V_0. The relation between the two is given by (Einstein and Grossmann 1913, 10):[59]

$$V = V_0\frac{ds}{dt}\frac{1}{\sqrt{G}}\,, \tag{61}$$

where G is minus the determinant of the metric tensor. Substituting this expression for V on the right-hand side of equation (60), one arrives at equation (59) for what, as

---

57 $\frac{\partial H}{\partial \dot{x}} = \frac{\partial}{\partial \dot{x}}\left(\sqrt{\frac{ds^2}{dt^2}}\right) = \frac{1}{2}\frac{dt}{ds}\frac{\partial}{\partial \dot{x}}\left(g_{\mu\nu}\frac{dx_\mu}{dt}\frac{dx_\nu}{dt}\right) = \frac{dt}{ds}g_{1\nu}\dot{x}^\nu$.

58 Given the sign convention on this page (see footnote 55), G stands for minus the determinant of the metric.

59 This relation can also be found on p. 20R (see equation (524)) and at the bottom of p. 27L.

Einstein wrote under it, "is the momentum per unit volume" ("ist Bewegungsgrösse pro Volumeinheit"):

$$
\begin{aligned}
\frac{J_x}{V} &= \frac{1}{V_0}\sqrt{G}\frac{dt}{ds}\frac{dt}{ds}(g_{11}\dot{x} + g_{12}\dot{y} + g_{13}\dot{z} + g_{14}) \\
&= \frac{1}{V_0}\sqrt{G}\left(g_{11}\frac{dx}{dt}\frac{dt}{ds}\frac{dt}{ds} + g_{12}\frac{dy}{dt}\frac{dt}{ds}\frac{dt}{ds} + . + g_{14}\frac{dt}{ds}\frac{dt}{ds}\right) \\
&= \rho_0\sqrt{G}\left(g_{11}\frac{dx}{ds}\frac{dt}{ds} + g_{12}\frac{dy}{ds}\frac{dt}{ds} + \cdot + \cdot\right),
\end{aligned}
\tag{62}
$$

where $\rho_0 = 1/V_0$ is the proper density of a unit mass of dust. The energy density E/V of the dust can be found through a similar argument:[60]

$$
\frac{E}{V} = \rho_0\sqrt{G}\sum g_{4\nu}\frac{dx_\nu}{ds}\frac{dx_4}{ds}. \tag{63}
$$

Equation (62) for the x-component of momentum density, similar expressions for its y- and z-components, and equation (63) for the energy density, all divided by $\sqrt{G}$, give four components of the contravariant stress-energy tensor for pressureless dust, which is written down immediately below equation (59):[61]

$$
T^b_{ik} = \rho_0\frac{dx_i}{ds}\frac{dx_k}{ds}. \tag{64}
$$

Einstein called this quantity the "tensor of the motion of masses" ("Tensor der Bewegung der Massen").[62] Contracting this tensor with the metric and multiplying by $\sqrt{G}$, one recovers the momentum and energy densities (cf. equations (62)–(63))

$$
\frac{J_x}{V} = \sqrt{G}\sum g_{1i}T^b_{i4}, \quad \frac{E}{V} = \sqrt{G}\sum g_{4i}T^b_{i4}. \tag{65}
$$

Einstein thus introduced what he called the "tensor of momentum and energy" ("Tensor der Bewegungsgröße u[nd] Energie.").

$$
T_{mn} = \left|\sum\sqrt{G}g_{m\nu}T^b_{\nu n}\right|. \tag{66}
$$

In fact, this is not a tensor but a (mixed) tensor density.

---

60 Cf. footnote 57:

$$
\frac{E}{V} = \left(\frac{1}{V_0}\sqrt{G}\frac{dt}{ds}\right)\frac{\partial H}{\partial\dot{x}_4} = \left(\frac{1}{V_0}\sqrt{G}\frac{dt}{ds}\right)\left(\frac{dt}{ds}g_{4\nu}\dot{x}^\nu\right) = \rho_0\sqrt{G}\sum g_{4\nu}\frac{dx_\nu}{dt}\frac{dt}{ds}\frac{dt}{ds} = \rho_0\sqrt{G}\sum g_{4\nu}\frac{dx_\nu}{ds}\frac{dx_4}{ds}.
$$

61 Note that the indices are written "downstairs" even though they refer to contravariant components. Einstein's convention here and elsewhere in the notebook is just the opposite of the one adopted in (Einstein and Grossmann 1913), where all contravariant quantities are indicated by Greek and all covariant ones by Latin characters.

62 The superscript 'b' stands for "Bewegung" ("motion").

With the help of equation (64), Einstein could begin to rewrite the Euler-Lagrange equations (56) in terms of a stress-energy tensor, which would allow him to generalize the equation from the special case of pressureless dust to any physical system described by a stress-energy tensor. The second term of equation (56) represents the gravitational force on a particle. Einstein generalized this term to an expression for the "negative ponderomotive force per volume unit" ("Negative Ponderomotorische Kraft pro Volumeinheit")[63] on pressureless dust:[64]

$$\frac{1}{2}\sqrt{G}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T^b_{\mu\nu}\,. \tag{67}$$

As with equation (59), the derivation of this expression is not given in the notebook, but can easily be reconstructed (see Einstein and Grossmann 1913, secs. 2 and 4). Defining the x-component of the gravitational force $\mathfrak{K}$ as $\partial H/\partial x$ and using the definition of the Lagrangian H, one can write:

$$\frac{\mathfrak{K}_1}{V} = \frac{1}{V}\frac{\partial H}{\partial x_1} = \frac{1}{V}\frac{\partial}{\partial x_1}\left(\frac{ds}{dt}\right). \tag{68}$$

Using the definition of the line element, one can rewrite this as:

$$\frac{\mathfrak{K}_1}{V} = \frac{1}{V}\frac{\frac{\partial}{\partial x_1}\sqrt{g_{\mu\nu}dx_\mu dx_\nu}}{dt} = \frac{1}{V}\frac{1}{2}\frac{\sum\limits_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_1}dx_\mu dx_\nu}{ds dt} = \frac{1}{V}\frac{1}{2}\frac{\sum\limits_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_1}\frac{dx_\mu}{dt}\frac{dx_\nu}{dt}}{ds/dt} \tag{69}$$

With the help of equation (61), the coordinate volume V can be replaced by the proper volume V_0:

$$\frac{\mathfrak{K}_1}{V} = \frac{1}{V_0}\sqrt{G}\frac{1}{2}\frac{dt}{ds}\frac{dt}{ds}\sum_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_1}\frac{dx_\mu}{dt}\frac{dx_\nu}{dt} = \frac{1}{2}\rho_0\sqrt{G}\sum_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_1}\frac{dx_\mu}{ds}\frac{dx_\nu}{ds}\,. \tag{70}$$

Inserting $T^b_{\mu\nu}$, the stress-energy tensor for pressureless dust, for $\rho_0(dx_\mu/ds)(dx_\nu/ds)$, one arrives at the $m = 1$-component of Einstein's equation (67). As he had done before (see equation (66)), Einstein assumed that this result, derived for the special case of the stress-energy tensor of pressureless dust, will hold for the stress-energy tensor of any matter.

On the next line Einstein wrote down the tensorial generalization of the Euler-Lagrange equations (56), using equations (66) and (67) and replacing d/dt by $\partial/\partial x_n$:[65,66]

$$\sum_{\nu n}\frac{\partial}{\partial x_n}(\sqrt{G}g_{m\nu}T_{\nu n}) - \frac{1}{2}\sqrt{G}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} = 0\,. \tag{71}$$

---

63 The word "Negative" was later added.

64 In the expression below, G was corrected from D (which presumably stands for "Determinante"), the subscript m was corrected from some illegible character, and a factor ρ_0 was deleted.

At this point he dropped the index 'b' since he expected the equation to hold for all matter, not just for pressureless dust.

Einstein now tried to gain some insight into the transformational behavior of this equation by rewriting its left-hand side as the action of a generalized derivative on an arbitrary tensor. First, he introduced the (contravariant) tensor density corresponding to the (contravariant) stress-energy tensor $T_{\mu\nu}$ in equation (71). He wrote: "If we set" ("Setzen wir")[67]

$$\sqrt{G}T_{\mu\nu} = \Theta_{\mu\nu}, \tag{72}$$

then equation (71) can be rewritten as:

$$\sum_{\nu n}\frac{\partial}{\partial x_n}(g_{m\nu}\Theta_{\nu n}) - \frac{1}{2}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}\Theta_{\mu\nu} = 0. \tag{73}$$

To write the left-hand side as a differential operator acting on a tensor, Θ should appear with the same indices in both terms. Therefore Einstein relabeled the summation indices in the first term in order to conform with the occurrence of $\Theta_{\mu\nu}$ in the second term, made the assumption that $\Theta_{\mu\nu}$ is symmetric, and rewrote the equation as:[68]

$$\sum_{\mu\nu}\frac{\partial}{\partial x_\mu}(g_{m\nu}\Theta_{\mu\nu}) - \frac{1}{2}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}\Theta_{\mu\nu} = 0. \tag{74}$$

To the right of this equation, he wrote: "In general associated vector" ("Im Allgemeinen zugeordneter Vektor"), and below it "Valid for every symmetric tensor, e.g., $\sqrt{G}\gamma_{\mu\nu}$" ("Gilt für jeden symm[etrischen] Tensor z. B. $\sqrt{G}\gamma_{\mu\nu}$").[69] "Associated" ("zugeordnet") means "covariant" in this context, as is clear from its usage on pp. 6L–R. The notation $\gamma_{\mu\nu}$ for the contravariant components of the metric (see Einstein and Grossmann 1913, 12, note 4) occurs here for the first time in the notebook. Einstein's

65 The expression in parentheses is underlined once, and $T_{\mu\nu}$ in the second term is underlined twice. The equation also contains a number of corrections. The minus sign was corrected from a plus sign. This error stems from the sign error in equation (56). In the first term, the index n was corrected from m and the factor $\sqrt{G}$ was inserted later. In the second term, the factor $1/2$ was deleted once and rewritten. This correction is related to a correction in equation (75) below. Moreover, G was corrected from D (as in equation (67)). Note that $T_{\mu\nu}$ in equation (71) stands for the contravariant stress-energy tensor, whereas in equation (66) it stands for the corresponding mixed tensor density.

66 The same equation appears in slightly different versions and in slightly different notation at various other places in the notebook (see pp. 24L, 26L, 28L, and 43LB) and in (Einstein and Grossmann 1913, p. 10, equation (10)).

67 The notation in the notebook (see also pp. 20R, 24L, 24R, 26L, and 43LB) is different from the notation used in (Einstein and Grossmann 1913), where the contravariant stress-energy tensor is denoted by $\Theta_{\mu\nu}$ and the covariant form by $T_{\mu\nu}$.

68 The equation originally had a plus rather than a minus sign, an error it inherited from equation (56). The factor $1/2$ was deleted once and rewritten. This correction is related to a correction in equation (75) below. The index ν in $g_{\mu\nu}$ is corrected from μ. Both characters Θ are corrected from T's.

69 The word "symm[etric]" is interlineated. Recall that Einstein had to assume symmetry in going from equation (73) to equation (74).

claim is that the quantity on the left-hand side of equation (74) is a vector as long as $\Theta_{\mu\nu}$ is a symmetric tensor. This claim is correct. The expression is just the covariant divergence of a symmetric tensor, as is shown in (Einstein and Grossmann 1913). The result appears in Grossmann's part, which suggests that Einstein may have learnt it from him.

Einstein checked his claim for the specific example $\sqrt{G}\gamma_{\mu\nu}$ mentioned above. Insertion of this tensor density into equation (74) produces:[70]

$$\sum_{\mu\nu}\frac{\partial}{\partial x_\mu}(\sqrt{G}g_{m\nu}\gamma_{\mu\nu})-\frac{1}{2}\sum_{\mu\nu}\left(\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_m}\gamma_{\mu\nu}\right) = 0\,, \tag{75}$$

Since $\sum g_{m\nu}\gamma_{\mu\nu} = \delta_{m\mu}$, with $\delta_{m\mu}$ the Kronecker delta, the first term is equal to

$$\frac{\partial\sqrt{G}}{\partial x_m}\,, \tag{76}$$

which Einstein wrote underneath the first term of equation (75). Since[71]

$$\sum_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_m}\gamma_{\mu\nu} = \frac{1}{G}\frac{\partial G}{\partial x_m}\,, \tag{77}$$

the expression in parentheses in the second term is equal to

$$\frac{1}{\sqrt{G}}\frac{\partial G}{\partial x_m}\,, \tag{78}$$

which Einstein wrote underneath the second term of equation (75).[72]

Inserting expressions (76) and (78) into equation (75), one sees that the latter is indeed satisfied.

It is at this point that Einstein recognized two errors that had found their way into his calculations. First, equation (75) inherited the erroneous minus sign from the Euler-Lagrange equations (56) that formed the starting point of this whole calculation. Second, Einstein omitted a factor $1/2$ when he went from equation (74) to equation (75). Einstein probably only caught these errors when the result of his calculations did not meet this expectation, i.e., when he saw that equation (75) with a plus rather than a minus and without the factor $1/2$ does not hold. Einstein probably corrected the sign error first, tracing it all the way back to the Euler-Lagrange equations (56). Equation (57) next to these equations was probably added in this context. As to the omitted factor $1/2$, Einstein originally seems to have been under the impression that expression (76) is equal to expression (78) without the factor $1/2$ multiplying the latter in equation (75). It is probably for this reason that he deleted this

70 The equation originally had a plus rather than a minus sign, an error it inherited from equation (56). Einstein initially omitted the factor of $1/2$. The factor $\sqrt{G}$ was inserted later.

71 See p. 6L for a derivation of this relation.

72 The index m is corrected from μ.

factor in equations (74) and (71), respectively, only to put them back in once he realized that this factor was needed in equation (75) after all.

After making these corrections, Einstein wrote at the bottom of the page: "correct" ("stimmt"). Einstein's trial calculation supported the claim that his physically motivated expression for energy-momentum balance between matter and gravitational field does indeed lead to a differential operator that acts on a symmetric tensor to produce a vector.[73]

4. EXPLORATION OF THE BELTRAMI INVARIANTS AND THE CORE OPERATOR (6L–13R, 41L–R)

4.1 *Introduction* (6L–13R, 41L–R)

Einstein returned to the question of finding field equations for the metric field on p. 6L. He had meanwhile become more sophisticated mathematically. For example, at this point he knew about the Beltrami invariants and carefully distinguished between covariant and contravariant tensors. However, there were still large gaps in his knowledge. He still did not know about the Riemann tensor or covariant differentiation, which severely handicapped his search for satisfactory field equations. Most of the calculations on pp. 6L–13L are investigations of the covariance properties of various expressions that might either be part of the field equations or play a role in their construction. These calculations did not lead to any promising candidates for the left-hand side of the field equations, but they led to several clusters of important results, ideas, and techniques that Einstein was able to put to good use once he learned about the Riemann tensor (see p. 14L). 6L

First of all, one can begin to discern the double strategy discussed in sec. 1.2. On p. 6L Einstein started with two generally-covariant operators acting on a scalar function, known as the Beltrami invariants. The second Beltrami invariant is a generally-covariant generalization of the Laplacian of a scalar function and as such provided a natural point of departure in Einstein's search for gravitational field equations. The basic challenge was to get from an operator acting on a scalar function to an operator acting on the metric tensor. Einstein did not immediately see how to achieve this goal. On p. 7L, he therefore temporarily abandoned his mathematically-oriented approach for a physically-oriented one. He wrote down a version of what we call the "core operator," an expression constructed out of the metric tensor and its coordinate derivatives in such a way that for weak fields it reduces to the d'Alembertian acting on the metric. The problem with this core operator is that its transformation properties are unclear. Einstein addressed this problem by trying to relate the physically well-understood core operator to the mathematically well-understood Beltrami invariants. 7L

73 On p. 8R, Einstein found that the generally-covariant generalization of the exterior derivative operator acting on the metric also vanishes (see the discussion following equation (182)).

Two key components of Einstein's mathematical strategy first emerge in the course of the calculations documented on these pages. The first is the idea is to start from expressions with a well-defined covariance group (either generally covariant or covariant under unimodular coordinate transformations) and then to extract candidates for the left-hand side of the field equations by imposing additional conditions, such as the condition that the correspondence principle be satisfied (i.e., that the field equations reduce to the Poisson equation of Newtonian theory for weak static fields).

The other key component is the use of what Einstein would later call "non-autonomous transformations" ("unselbständige Transformationen").[74] To investigate the covariance properties of various expressions constructed out of the metric tensor and its derivatives, he wrote out the transformation law for such an expression under general coordinate transformations and identified those terms that would have to vanish if the expression were to transform as a tensor. The vanishing of these terms gives conditions on the transformation matrices that depend explicitly on the components of the
7L-R, metric (see pp. 7L-R, 9R, 10L). Because of this dependence, such transformations are
9R, 10L called "non-autonomous." Initially, Einstein investigated the behavior of his candidate field equations under such non-autonomous coordinate transformations. Eventually he realized that the complexity of the relevant calculations could be reduced considerably by combining the notion of non-autonomous transformations with the basic idea of the mathematical strategy, namely to extract candidate field equations from expressions with well-known covariance properties by imposing additional conditions. The covariance properties of field equations constructed in this fashion are determined by the covariance properties of these additional conditions, which typically will be much simpler than the field equations themselves. Einstein could thus focus on determining the class of non-autonomous transformations under which these simpler additional conditions transform tensorially.[75]

An important example of such an additional condition is what we shall call the "Hertz restriction," in which the so-called "Hertz expression," $\sum \partial\gamma_{\mu\nu}/\partial x_\nu$, is set
10L–11L equal to zero.[76] On pp. 10L–11L, Einstein investigated whether the class of non-autonomous transformations under which the Hertz expression transforms as a tensor includes the transformations from quasi-Cartesian coordinates to rotating and linearly accelerating frames in the special case of Minkowski spacetime. These transformations were crucially important to Einstein's attempts to extend the relativity principle from uniform to non-uniform motion and to establish the equivalence of rotation and acceleration in Minkowski spacetime to corresponding gravitational fields.

Later in the notebook, Einstein applied the same strategy to candidate field equations constructed out of the Riemann tensor. As before, the covariance properties of the additional condition(s) determine the covariance properties of the candidate field

74 See Einstein to H. A. Lorentz, 14 August 1913 (CPAE 5, Doc. 467). See sec. 4.3 for further discussion.

75 See p. 9R and the discussion in footnote 134 for the first example of this type of argument.

76 Named after Paul Hertz (see footnote 22). The Hertz restriction reappears in the course of Einstein's exploration of the Riemann tensor on p. 22R (see sec. 5.5.2).

equations. Einstein regarded such conditions as essential parts of the theory, restricting the class of admissible coordinate systems. We therefore refer to these conditions as "coordinate restrictions." They should be distinguished from "coordinate conditions." Mathematically, one and the same equation can express a coordinate restriction or a coordinate condition, but the two have a very different status. Coordinate conditions may always be imposed on generally-covariant equations to choose a suitable class of coordinate systems for some particular purpose. Consequently, different coordinate conditions may be used for different purposes, just as different gauge conditions can be used for different purposes. In contrast, coordinate restrictions are an integral part of the theory, imposing a limitation on the allowed class of coordinate systems in which the theory is expected to hold. With coordinate restrictions, one does not have the freedom to pick different conditions for different purposes.

On p. 9L, building on the energy-momentum balance equation derived on p. 5R, 9L
Einstein arrived at two important insights related to energy-momentum conservation. First, drawing on his experience with the 1912 static theory, he realized that for the field equations to be compatible with energy-momentum conservation their left-hand side should be the sum of a core operator and a quantity representing the stress-energy of the gravitational field. Secondly, he found a way to construct a candidate for this stress-energy tensor out of the first Beltrami invariant.

Einstein's main concern in this part of the notebook, however, was not how to satisfy the conservation principle but how to satisfy simultaneously his other three heuristic requirements, the correspondence principle, the relativity principle, and the equivalence principle.[77] By the time he made the entries at the bottom of p. 12R, Einstein had established a number of results related to the latter three principles. He had
(*i*) introduced the core operator (p. 7L); (*ii*) found its relation to the second Beltrami 7L–12R,
invariant with the determinant of the metric playing the role of the scalar function in 41L–R
the latter's definition (pp. 8R–9R); (*iii*) investigated unimodular transformations since the determinant of the metric transforms as a scalar under this restricted class of transformations only; (*iv*) recognized the importance of the Hertz restriction in getting from the second Beltrami invariant first to the core operator and then to weak field equations with the d'Alembertian acting on the metric (p. 10L); (*v*) derived conditions for the classes of non-autonomous transformations under which the weak field equations and the Hertz expression transform as a tensor and a vector, respectively (pp. 10L–11R); and (*vi*) developed a strategy for checking whether such non-autonomous transformations include the important special cases of the transformation to rotating and accelerating frames in Minkowski spacetime (pp. 11L, 12L–R, 41L–R). However, serious difficulties on all these counts remained.

On pp. 13L–R, Einstein therefore bracketed the question of the covariance proper- 13L–R
ties of his candidate field equations and turned to the compatibility with energy-momentum conservation instead, provisionally requiring only covariance under autonomous unimodular linear transformations. On p. 13R he returned to the physical

---

77 See sec. 1.1 for discussion of these requirements.

strategy trying to find the left-hand side of the field equations by starting from the weak field equations and imposing energy-momentum conservation. An ingenious simpler version of this strategy was used on pp. 26L–R to derive the *Entwurf* field equations. On p. 13R Einstein did not yet see how to generate field equations in this way. Given this impasse and the difficulties he had run into in his investigation of the covariance properties on pp. 6L–12R, one can well imagine Einstein turning to his mathematician friend Marcel Grossmann for fresh ideas.[78] On the next page, p. 14L, the Riemann curvature tensor makes its first appearance in the notebook with Grossmann's name written next to it. Einstein only returned to the physical strategy emerging on p. 13R after a series of failed attempts to extract field equations from the Riemann tensor (see pp. 14L–25R, 42L–43L covered in sec. 5).

6L–7L

4.2 *Experimenting with the Beltrami Invariants (6L–7L)*

Beltrami's two differential invariants (more precisely "differential parameters") are generally-covariant scalars constructed out of the metric, its first- and second-order derivatives, and some arbitrary, at least twice-differentiable scalar function φ.[79] The first Beltrami invariant can be defined as

$$\Delta_1\varphi = \gamma_{\mu\nu}\frac{\partial\varphi}{\partial x_\mu}\frac{\partial\varphi}{\partial x_\nu}, \tag{79}$$

the second as[80]

$$\Delta_2\varphi = \frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\sqrt{G}\frac{\partial\varphi}{\partial x_\nu}\right). \tag{80}$$

6L

At the top of p. 6L, Einstein wrote down the contraction of the contravariant metric with the gradient of some scalar function φ

$$\sum\gamma_{\mu\nu}\frac{\partial\varphi}{\partial x_\nu}. \tag{81}$$

---

78 As is related in (Kollros 1956, 278), Einstein allegedly turned to Grossmann at one point and said: "Grossmann, you have to got to help me, otherwise I am going mad" ("Grossmann, Du mußt mir helfen, sonst werd' ich verrückt!").

79 See (Bianchi 1910, secs. 22–24) or (Wright 1908, sec. 53).

80 Equations (79) and (80) are equivalent to (Bianchi 1910, sec. 23, eq. (8), and sec. 24, eq. (19)), respectively. The second Beltrami invariant is alluded to in the 1914 review article on the *Entwurf* theory. In sec. 8 of this paper, Einstein points out that the covariant divergence of the contravariant vector $g^{\mu\nu}\partial\varphi/\partial x_\nu$ is equal to "the well-known generalization of the Laplacian $\Delta\varphi$, $\Phi = \sum_{\mu\nu}\frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\mu}\left(\sqrt{g}g^{\mu\nu}\frac{\partial\varphi}{\partial x_\nu}\right)$" ("die bekannte Verallgemeinerung des Laplaceschen $\Delta\varphi$ …;" Einstein 1914b, 1051–1052; see also Einstein 1916, 797). This generalization is nothing but the second Beltrami invariant. Following (Weyl 1918), Einstein also used the second Beltrami invariant, again without identifying it by name, in lectures in 1919 (see CPAE 7, Doc. 19, [p. 22], and Doc. 20, [p. 1]).

Next to this expression he wrote: “vector” (“Vektor”).[81]

Einstein now applied a differential operator to this vector. In this way, he obtained the second Beltrami invariant

$$\frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\sqrt{G}\frac{\partial\varphi}{\partial x_\nu}\right). \tag{82}$$

Next to this expression, he wrote: “scalar” (“Skalar”).

Einstein then investigated a condition, under which expression (82) would reduce to the ordinary Laplacian acting on a scalar. He called this condition a “plausible hypothesis” (“Naheliegende Hypothese”):

$$\sum\frac{\partial}{\partial x_\nu}(\sqrt{G}\gamma_{\mu\nu}) = 0. \tag{83}$$

This condition determines so-called “isothermal coordinates,”[82] or, as they are now called, harmonic coordinates. The corresponding harmonic coordinate restriction came to play an important role later in the notebook in Einstein’s analysis of the Ricci tensor (see pp. 19L–20L and the discussion following equation (471) in sec. 5.4.1).

In the last four lines of p. 6L, Einstein rewrote equation (83) to eliminate the derivative of the determinant G, leaving only derivatives of components of the metric:

$$\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\mu} + \gamma_{\mu\nu}\frac{1}{2\sqrt{G}}\frac{\partial G}{\partial x_\mu} = 0. \tag{84}$$

Dividing by $\sqrt{G}$, he arrived at:

$$\sum\left(\frac{\partial\gamma_{\mu\nu}}{\partial x_\mu} + \frac{1}{2}\gamma_{\mu\nu}\frac{1}{G}\frac{\partial G}{\partial x_\mu}\right) = 0. \tag{85}$$

He then rewrote the second term using that the components of the contravariant metric are defined as

$$\gamma_{\mu\nu} = \frac{\Gamma_{\mu\nu}}{G} \tag{86}$$

where $\Gamma_{\mu\nu}$ is the minor of the $\mu\nu$-component of the covariant metric. Einstein thus rewrote the second term of equation (85) as:

$$\frac{1}{G}\frac{\partial G}{\partial x_\mu} = \sum_{\rho\sigma}\frac{\partial g_{\rho\sigma}}{\partial x_\mu}\frac{\Gamma_{\rho\sigma}}{G} = \sum_{\rho\sigma}\frac{\partial g_{\rho\sigma}}{\partial x_\mu}\gamma_{\rho\sigma}. \tag{87}$$

---

81 He initially wrote and then deleted “associated vector” (“zugeordneter Vekt”). “Associated” stands for “covariant” in this context. Expression (81) is a contravariant vector. Cf. the use of the term “*zugeordnet*” on p. 5R (see the discussion following equation (74) in sec. 3) and on p. 6R (see the remarks following equation (88)).

82 See, e.g., (Bianchi 1910, sec. 36-37) or (Wright 1908, sec. 57).

Here the calculation breaks off. A possible explanation is that Einstein wanted to check whether the spatially flat static metric, which reappears on the next page, satisfies the "plausible hypothesis" (83). The first term of equation (85) clearly vanishes for this metric, but the second term does not.

6R On p. 6R Einstein made a fresh start, denoting the gradient of the scalar function introduced at the top of p. 6L by:

$$\alpha_\nu = \frac{\partial\varphi}{\partial x_\nu}. \tag{88}$$

This is a covariant vector as is indicated by the label "associated vector" ("zugeordneter Vektor") written next to it. Recall that on the facing page 6L, Einstein started to write and then deleted this same label next to expression (81), the contravariant form of this vector.

Writing the contravariant form as $a_\nu = \gamma_{\nu\mu}\alpha_\mu$, Einstein wrote down the second Beltrami invariant (cf. equation (82)) as:

$$\sum \frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\nu}(\sqrt{G}\,a_\nu). \tag{89}$$

Einstein now replaced all covariant elements in this expression by their contravariant counterparts and vice versa. To this end, he defined $\xi_\mu = \Sigma g_{\mu\nu}x_\nu$ (with inverse $x_\nu = \Sigma\gamma_{\mu\nu}\xi_\mu$).[83] He thus arrived at:

$$\sum \frac{1}{\sqrt{\Gamma}}\frac{\partial}{\partial \xi_\nu}(\sqrt{\Gamma}\,\alpha_\nu), \tag{90}$$

where Γ is the determinant of the contravariant metric and

$$\frac{\partial}{\partial\xi_\nu} = \sum \gamma_{\nu\sigma}\frac{\partial}{\partial x_\sigma}. \tag{91}$$

If Einstein thought that in going from the second Beltrami invariant (89) to the expression (90) he had constructed another scalar invariant, he was wrong. But he proceeded to rewrite expression (90) in terms of $\partial/\partial x_\nu$ and G in order to compare it with the second Beltrami invariant:

$$\sum \sqrt{G}\gamma_{\nu\sigma}\frac{\partial}{\partial x_\sigma}\left(\frac{1}{\sqrt{G}}\frac{\partial\varphi}{\partial x_\nu}\right). \tag{92}$$

Next to this expression, he noted that it is a "scalar" ("Skalar"). It is not.

On the next line, Einstein expanded expression (92) to:

---

83 Note that in these definitions, Einstein used finite coordinates x_ν instead of infinitesimals dx_ν, as he had done on p. 39L (cf. equations (6) and (7)). It seems doubtful whether, at this time, Einstein realized that only coordinate differentials are proper vectors, and that these formal definitions have no invariant significance for finite coordinates.

$$\sum_{\nu\sigma} \gamma_{\nu\sigma} \frac{\partial^2 \varphi}{\partial x_\nu \partial x_\sigma} + \gamma_{\nu\sigma} \frac{\partial \varphi}{\partial x_\nu} \frac{1}{2G} \frac{\partial G}{\partial x_\sigma} \quad , \tag{93}$$

losing a minus sign in the differentiation of $1/\sqrt{G}$. The plus sign should thus be a minus sign.

To compare this expression with the second Beltrami invariant, he expanded expression (82) on p. 6L for the latter to

$$\sum_{\nu\sigma} \gamma_{\nu\sigma} \frac{\partial^2 \varphi}{\partial x_\nu \partial x_\sigma} + \gamma_{\nu\sigma} \frac{\partial \varphi}{\partial x_\nu} \frac{1}{2G} \frac{\partial G}{\partial x_\sigma} + \frac{\partial \varphi}{\partial x_\nu} \frac{\partial \gamma_{\sigma\nu}}{\partial x_\sigma} \quad . \tag{94}$$

In the notebook there is actually a line connecting expression (82) on p. 6L to expression (94) on p. 6R.

Comparing the expressions (93) and (94), Einstein noted: "Should there only be *one* such scalar, it has to be the case that

$$\sum_{\sigma} \frac{\partial \gamma_{\sigma\nu}}{\partial x_\sigma} = 0 \text{''} \tag{95}$$

("Soll es nur *einen* derartigen Skalar geben so muss $\sum_{\sigma} \partial \gamma_{\sigma\nu} / \partial x_\sigma = 0$"). Recall, however, that expression (90) is *not* a scalar and that there is a sign error in the subsequent expression (93) for this alleged scalar. Einstein did not discover these errors until the top of p. 7L. On p. 6R, he was under the impression that the second Beltrami invariant and expression (92), which he took to be a scalar, were identical once condition (95), which we shall call the "Hertz restriction,"[84] was imposed. Adding this condition, he now proceeded as if he had two expressions—the second Beltrami invariant (89) and quantity constructed out of it in expression (92)—for one and the same scalar invariant.

To turn this scalar invariant into a candidate for the left-hand side of the field equations, Einstein substituted $\sqrt{G}$ for the scalar φ in expression (92). The resulting field equations will be invariant under unimodular transformations since $\sqrt{G}$ transforms as a scalar under such transformations. In a separate box to the right of equations (92)–(94), Einstein wrote down how G and Γ transform under a coordinate transformation with determinant P:[85]

$$\begin{aligned} G' &= P^2 G, \\ \Gamma' &= \frac{1}{P^2} \Gamma. \end{aligned} \tag{96}$$

If $P = 1$, i.e., for unimodular transformations, G and Γ are indeed scalars. At the bottom of p. 6L, Einstein had just gone through the derivation of another result for G:

84 The reason for naming it after Paul Hertz is explained in footnote 22.
85 This follows from the multiplication theorem for determinants.

$$\frac{1}{2\sqrt{G}}\frac{\partial\sqrt{G}}{\partial x_\nu} = \gamma_{\rho\sigma}\frac{\partial g_{\rho\sigma}}{\partial x_\nu}. \tag{97}$$

Inserting $\sqrt{G}$ for φ in expression (92) and using equation (97), Einstein arrived at the following candidate field equations:

$$\sum_{\mu\nu\rho\sigma}\gamma_{\mu\nu}\frac{\partial}{\partial x_\mu}\left(\gamma_{\rho\sigma}\frac{\partial g_{\rho\sigma}}{\partial x_\nu}\right) = 0 \tag{98}$$

"or" ("oder"), equivalently,[86]

$$\sum_{\mu\nu\rho\sigma}\gamma_{\mu\nu}\frac{\partial}{\partial x_\mu}\left(g_{\rho\sigma}\frac{\partial \gamma_{\rho\sigma}}{\partial x_\nu}\right) = 0\,. \tag{99}$$

Note that Einstein omitted a factor $\sqrt{G}/2$ in the expressions on the left-hand sides of both these equations. These expressions, however, retain the transformation behavior under unimodular transformations of the supposedly-invariant expression (92) from which Einstein constructed them. Since $\sqrt{G}$ is a scalar under unimodular transformation, a scalar divided by $\sqrt{G}$ remains a scalar.

Einstein now turned to "special cases $\mu = \nu$ and $\rho = \sigma$" ("Spezialfälle $\mu = \nu$ $\rho = \sigma$") of diagonal metric tensors. He quickly focused on one such case, namely the spatially flat static metric first introduced on p. 39L. He accordingly corrected "special cases" ("Spezialfälle") to "special case" ("Spezialfall") and wrote down the diagonal components of the static metric:[87]

$$\begin{aligned} &g_{11} = g_{22} = g_{33} = -1 \quad g_{44} = c^2 \\ &\gamma_{11} = \gamma_{22} = \gamma_{33} = +1 \;\; \gamma_{44} = -\frac{1}{c^2}, \end{aligned} \tag{100}$$

as well as its determinant $G = -c^2$, which he could read off from the matrix $\mathrm{diag}(-1, -1, -1, c^2)$ written directly above this expression.

Einstein now inserted the static metric into equations (98) and (99) for the index combinations $\rho = \sigma = 4$ and $\mu = \nu = 1, 2, 3$, the only combinations giving a non-vanishing contribution. He found

$$\sum_\nu\frac{\partial}{\partial x_\nu}\left(+\frac{1}{c^2}\frac{\partial c^2}{\partial x_\nu}\right) = 0\,, \tag{101}$$

and

86 Note that $0 = \frac{\partial}{\partial x_\nu}(g_{\rho\sigma}\gamma_{\rho\sigma}) = \gamma_{\rho\sigma}\frac{\partial g_{\rho\sigma}}{\partial x_\nu} + g_{\rho\sigma}\frac{\partial \gamma_{\rho\sigma}}{\partial x_\nu}$.

87 In the notebook, the "-1" seems to be corrected from "0." The contravariant components have the wrong sign. Einstein originally wrote them down correctly, but then changed the signs.

$$\sum \frac{\partial}{\partial x_\nu}\left(c^2 \frac{\partial}{\partial x_\nu}\frac{1}{c^2}\right) = 0\,, \tag{102}$$

"respectively" ("b[e]z[iehungs]w[eise]").[88]

Both equations are equivalent to[89]

$$\frac{\partial^2 \log c}{\partial x_\nu^2} = 0\,. \tag{103}$$

This equation has the form of the four-dimensional generalization of the Poisson equation and therefore looks promising as a component of candidate field equations.

Next to equation (103) wrote: "In this way not distinguishable" ("So nicht unterscheidbar."). Presumably, this refers to Einstein's query in the middle of the page concerning the relation between expression (94) for the second Beltrami invariant and expression (93) for what Einstein took to be an alternative scalar invariant. Since the spatially flat static metric satisfies condition (95), which reduces the former expression to the latter, it is clear this special case cannot be used to distinguish the two.

At the top of p. 7L, Einstein returned to the more general considerations above the horizontal line on p. 6R, where he had written down expression (93) for what he thought was an alternative scalar invariant. In fact, it is not a scalar and contains a sign error. Einstein had compared this expression to expression (94) for the second Beltrami invariant and had noticed that the former reduces to the latter if the Hertz condition (95) is imposed. 7L

Einstein began his considerations on p. 7L by writing down an expression that can be obtained from the second Beltrami invariant (82) on p. 6L by imposing the Hertz condition (95):[90]

$$\frac{\gamma_{\mu\nu}}{\sqrt{G}}\frac{\partial}{\partial x_\mu}\left(\sqrt{G}\frac{\partial\varphi}{\partial x_\nu}\right) \tag{104}$$

and wrote next to it that this is a "scalar" ("Skalar"). In the next two lines, Einstein tried to construct a vector out of the scalar quantities he had formed on the preceding two pages.

---

88 Inserting the components (100) of the static metric (with or without correcting the sign error noted in the preceding note) into the left-hand sides of equations (98) and (99), one finds the left-hand sides of equations (101) and (102) with the opposite sign. Probably, Einstein wrote down equation (101) using $\gamma_{11} = \gamma_{22} = \gamma_{33} = -1$ and $\gamma_{44} = 1/c^2$, then adjusted the result once he changed the sign of $\gamma_{\mu\nu}$.

89 For equations (101) and (102), one finds $\frac{\partial}{\partial x_\nu}\left(\frac{1}{c^2}\frac{\partial c^2}{\partial x_\nu}\right) = \frac{\partial}{\partial x_\nu}\left(\frac{2}{c}\frac{\partial c}{\partial x_\nu}\right) = 2\frac{\partial^2 \log c}{\partial x_\nu^2} = 0$ and $\frac{\partial}{\partial x_\nu}\left(c^2\frac{\partial}{\partial x_\nu}\frac{1}{c^2}\right) = \frac{\partial}{\partial x_\nu}\left(-\frac{2}{c}\frac{\partial c}{\partial x_\nu}\right) = -2\frac{\partial^2 \log c}{\partial x_\nu^2} = 0$, respectively.

90 The labeling of the indices suggests that this expression was obtained directly from expression (82) on p. 6L.

On the assumption that Einstein meanwhile caught the sign error in expression (93), one can readily understand these two lines: "If one forms [the second Beltrami invariant] $\Delta_2\varphi$ in two ways, it follows that

$$\sum_\nu \frac{1}{G}\frac{\partial}{\partial x_\nu}(\gamma_{\mu\nu}G) \tag{105}$$

[is] a vector" ("Bildet man $\Delta_2\varphi$ auf zwei Arten, so folgt $\sum_\nu \frac{1}{G}\frac{\partial}{\partial x_\nu}(\gamma_{\mu\nu}G)$ ein Vektor"). The conclusion was subsequently deleted.

If the error in expression (93) is corrected, then the difference between expressions (93) and (94) becomes:

$$\frac{\partial\varphi}{\partial x_\nu}\left(\gamma_{\nu\sigma}\frac{1}{G}\frac{\partial G}{\partial x_\sigma} + \frac{\partial\gamma_{\sigma\nu}}{\partial x_\sigma}\right) = \frac{\partial\varphi}{\partial x_\nu}\left(\frac{1}{G}\frac{\partial}{\partial x_\sigma}(\gamma_{\nu\sigma}G)\right). \tag{106}$$

Except for the labeling of its indices, the term in parentheses on the right-hand side is exactly equal to Einstein's expression (105) above. This explains why Einstein initially expected expression (105) to be a vector. Since expression (105) contracted with the covariant vector $\partial\varphi/\partial x_i$ (for arbitrary φ) is the difference between (what Einstein took to be) two scalars, the contraction must also be a scalar and expression (105) itself must be a contravariant vector. However, Einstein presumably recognized that expression (105) is in fact not a vector. The expression is equal to

$$\frac{1}{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\nu} + \frac{1}{G}\frac{\partial G}{\partial x_\nu}. \tag{107}$$

The second term is a vector. For the entire expression to be a vector, the first term would have to be a vector as well. This, however, is not the case, as Einstein presumably knew. One can thus understand why he eventually deleted the claim that expression (105) is a vector. This immediately told Einstein that the starting point of this entire line of reasoning, the assumption that expression (90) is a scalar, had to be mistaken.

The reconstruction given above leaves one question unanswered: how did Einstein discover the sign error in expression (93)? There is a plausible answer to this question. Suppose Einstein went through the same argument that we just described before he corrected this sign error. He would then have arrived at the conclusion that

$$\frac{\partial\varphi}{\partial x_\nu}\frac{\partial\gamma_{\nu\sigma}}{\partial x_\sigma} \tag{108}$$

is a scalar and that

$$\frac{\partial\gamma_{\nu\sigma}}{\partial x_\sigma} \tag{109}$$

therefore has to be a vector. Einstein already knew this to be false (see p. 39R). This then might well have alerted him to the sign error in expression (93). He may then have repeated the construction of a vector out of the difference between his two scalars (82) and (92), using the corrected version of the former.[91]

4.3 *Investigating the Core Operator (7L–8R)* 7L–8R

On pp. 6L–6R Einstein had tried to construct field equations for the metric tensor using as his starting point a familiar object from differential geometry, the generally-covariant second Beltrami invariant. The calculations documented on these pages had not produced any promising results. On pp. 7L–8R, he tried a different approach inspired by physical rather than mathematical considerations. He generalized the Laplace operator acting on the scalar potential of Newtonian gravitational theory to an operator acting on the tensorial potential $\gamma_{\mu\nu}$. We shall call this object the "core operator." It is a combination of two simpler operators, explicitly called "divergence" ("Divergenz" [p 7R]) and "exterior derivative" ("Erweiterung" [p. 8L]) in the notebook.[92] Einstein first examined the covariance properties of the core operator as a whole (pp. 7L-R). He then switched to generalizing the two constituent operators. The aim of both investigations was to see whether the core operator would provide him with a basis for extending the relativity principle from uniform to non-uniform motion.

One can discern two strategies with which Einstein tried to achieve his aim. The first strategy was to find a special type of non-linear coordinate transformations under which the core operator transforms as a tensor. The second strategy was to generalize the core operator to a differential operator that transforms as a tensor under ordinary non-linear transformations.

We introduce some special notation to facilitate a concise discussion of these two strategies. Consider an object, $\mathbf{O}(\partial, g)$ —constructed out of the metric, $g_{\mu\nu}$, and the derivative operator, $\partial / \partial x_\alpha$ —that transforms as a tensor under arbitrary *linear* transformations, $T_{\text{linear}} : x \rightarrow x'$. The transformation law for $\mathbf{O}$ under the inverse transformation, T_{linear}^{-1}, can schematically be written as:

$$\mathbf{O}(\partial, g) = T_{\text{linear}}^{-1} \mathbf{O}(\partial', g') . \tag{110}$$

If one now expresses ∂' and g' on the right-hand side in terms of ∂ and g with the help of T_{linear}, one, of course, just reproduces $\mathbf{O}$ in unprimed coordinates:

$$T_{\text{linear}}^{-1} \mathbf{O}(T_{\text{linear}}(\partial), T_{\text{linear}}(g)) = \mathbf{O}(\partial, g) . \tag{111}$$

---

91 It remains unclear exactly what Einstein took the relation between expressions (82) and (92) to be. His comment on p. 6R ("Should there only be one such scalar, it has to be the case that …") suggests that he thought of them as two different quantities that coincide only if an additional condition is imposed. However, his comment on p. 7L ("If one forms $\Delta_2\varphi$ in two ways …") suggests that he thought of them as different expressions of the same quantity. In that case, however, expression (90) should vanish, whereas Einstein only says that it is a vector.

92 Cf. (Einstein and Grossmann 1913, Part I, sec. 5).

Einstein's strategy for dealing with arbitrary *non-linear* transformations, T: $x \rightarrow x'$, involves two steps analogous to the two steps above. In general, $\mathbf{O}$ will *not* transform as a tensor under T. The first step is to introduce the object, $\tilde{\mathbf{O}}(\partial, g)$, that one obtains when applying the inverse transformation T^{-1} to $\mathbf{O}(\partial', g')$ *as if* $\mathbf{O}$ *does transform as a tensor under* T, more specifically, as if $\mathbf{O}$ transforms under T the same way it transforms under T_{linear}:

$$\tilde{\mathbf{O}}(\partial, g) \equiv \tilde{T}^{-1}\mathbf{O}(\partial', g') \ . \tag{112}$$

The tilde on $\tilde{T}^{-1}$ merely indicates this special use of the transformation rules. The second step is to express ∂' and g' in terms of ∂ and g with the help of T. Since in general $\mathbf{O}$ does not transform as a tensor under T, this operation will in general not just reproduce $\mathbf{O}$. In addition to $\mathbf{O}$, it will produce a (sum of) term(s), $\mathbf{C}$, constructed out of ∂, g, and the transformation matrices p and π for T and T^{-1}:[93]

$$\tilde{T}^{-1}\mathbf{O}(T(\partial), T(g)) = \mathbf{O}(\partial, g) + \mathbf{C}(\partial, g, p, \pi) \tag{113}$$

This two-step procedure is common to both strategies distinguished above. The two strategies differ in the way they make use of equation (113).

In the first strategy, Einstein uses equations such as equation (113) to read off the condition on the transformation matrices p and π for T that needs to be satisfied for $\mathbf{O}$ to transform as a tensor under T. This will be the case if $\tilde{\mathbf{O}}(\partial, g) = \mathbf{O}(\partial, g)$, i.e., in view of equations (112)–(113), if

$$\mathbf{C}(\partial, g, p, \pi) = 0 \, . \tag{114}$$

This condition gives a set of differential equations involving the transformation matrices, the components of the metric, and derivatives of both. Inserting a specific metric into equation (114) and solving the resulting equation for the transformation matrices, $p(g)$ and $\pi(g)$, one arrives at a special type of coordinate transformations. In the case of ordinary coordinate transformations, the transformation matrices are functions only of the coordinates. In the case of these special coordinate transformations, however, they depend both on the coordinates and on the metric. Following a suggestion by Paul Ehrenfest, Einstein later introduced the term "non-autonomous transformations" ("unselbständige Transformationen") for such transformations.[94] The transformation rule for such non-autonomous transformations can be written as

$$\mathbf{O}(\partial', g') = T(g)\mathbf{O}(\partial, g) , \tag{115}$$

where the matrices p and π for the transformation $T(g)$ must satisfy a condition for non-autonomous transformations of the form of equation (114).

In the case of the second strategy, Einstein looked upon the right-hand side of equation (113) as a generally-covariant expression that in the special case of a diagonal Minkowski metric reduces to the object $\mathbf{O}$ he started from. One can then set $g'_{\mu\nu} = \mathrm{diag}(-1, -1, -1, 1)$ in the transformation laws $g_{\mu\nu} = p_{\alpha\mu}p_{\beta\nu}g'_{\alpha\beta}$ and $\gamma_{\mu\nu} = \pi_{\alpha\mu}\pi_{\beta\nu}\gamma'_{\alpha\beta}$ and express the transformation matrices p and π in terms of $g_{\mu\nu}$

93 For the definition of these transformation matrices, see equations (119)–(122) below.

and its derivatives. Substituting the resulting expressions $p(g)$ and $\pi(g)$ into $\mathbf{C}$ in equation (113), one arrives at a new expression $\mathbf{D}$ that depends only on the metric and its derivatives:

$$\mathbf{D}(\partial, g) \equiv \mathbf{C}(\partial, g, p(g), \pi(g)) . \tag{116}$$

One can now define the generalization $\mathbf{O}_{\text{gen}}$ of the original object $\mathbf{O}$:

$$\mathbf{O}_{\text{gen}}(\partial, g) \equiv \mathbf{O}(\partial, g) + \mathbf{D}(\partial, g) . \tag{117}$$

$\mathbf{O}_{\text{gen}}$ reduces to $\mathbf{O}$ in the special case of the Minkowski metric in pseudo-Cartesian coordinates. The construction of $\mathbf{O}_{\text{gen}}$ only guarantees that $\mathbf{O}_{\text{gen}}$ transforms as a tensor under arbitrary transformations in Minkowski spacetime. Einstein, however, expected and made an attempt to prove (at the top of p. 8L), that $\mathbf{O}_{\text{gen}}$ would transform as a tensor under arbitrary transformations for any metric field.

Einstein applied the first of the two strategies described above to find non-autonomous transformation under which the core operator as a whole transforms as a tensor. He then applied the second strategy to generalize the two constituent operators of the core operator and thereby the core operator itself to expressions that transform as tensors under arbitrary transformations. He did not see these calculations through to the end. He came to realize that the generalized operators produced by this strategy degenerate when applied to the metric tensor. Einstein thereupon abandoned this second strategy altogether. The first strategy and the concept of non-autonomous transformations, however, continue to play an important role in the notebook.

4.3.1 *Covariance of the Core Operator under Non-autonomous Transformations (7L–R)*

Underneath the horizontal line on p. 7L, Einstein wrote down the core operator: 7L

---

94 See Einstein to H. A. Lorentz, 14 August 1913 (CPAE 5, Doc. 467): "One can consider two fundamentally different possibilities. 1) Transformations which are independent of the existing $g_{\mu\nu}$-field, which Ehrenfest designated as 'autonomous transformations;' according to my knowledge group theory has only dealt with this kind of transformations. 2) Transformations whose [matrices] would have to be determined by differential equations for the $g_{\mu\nu}$-field considered as given, which hence have to be adapted to the existing $g_{\mu\nu}$-field. Such transformations have—as far as I know—not yet been systematically studied. ('non-autonomous transformations')" ("Zwei Möglichkeiten prinzipiell verschiedener Art kommen da in Betracht. 1) Transformationen, welche von dem vorhandenen $g_{\mu\nu}$-Feld unabhängig sind, welche Ehrenfest als 'selbständige Transformationen' bezeichnete; nur mit solchen hat sich meines Wissens bisher die Gruppentheorie beschäftigt. 2) Transformationen, deren [...] erst durch Differentialgleichungen zu dem als gegebenen zu betrachtenden $g_{\mu\nu}$-Feld zu bestimmen wären, die also dem vorhandenen $g_{\mu\nu}$-Feld angepasst werden müssen. Solche Transformationen sind—soviel ich weiss—noch nicht systematisch untersucht worden. (‚unselbständige Transformationen')"). For further discussion of non-autonomous transformations—or, as Einstein later called them "justified" ("berechtigte") transformations between "adapted" ("angepaßte") coordinates" (Einstein and Grossmann 1914, 221; Einstein 1914b, 1070)—see "Untying the Knot ..." sec. 3.3 (in this volume). For a modern discussion of such transformations, see (Bergmann and Komar 1972).

$$\sum \frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}\right). \tag{118}$$

For weak static fields represented by a metric tensor of the form $\mathrm{diag}(-1, -1, -1, c^2(x, y, z))$ the 44-component of this operator reduces to minus the Laplacian acting on c^2, the square of the gravitational potential of Einstein's 1912 theory.

On pp. 7L–8R, Einstein studied the transformation properties of the core operator using transformation matrices $p_{\mu\nu}$ and $\pi_{\mu\nu}$, which are defined as follows. Under a transformation from coordinates x_μ to x'_μ, a contravariant vector a_μ transforms as

$$a'_\mu = \sum p_{\mu\nu} a_\nu \quad \text{with } p_{\mu\nu} \equiv \frac{\partial x'_\mu}{\partial x_\nu}, \tag{119}$$

while a covariant vector transforms as[95]

$$\alpha'_\mu = \sum \pi_{\mu\nu} \alpha_\nu \quad \text{with } \pi_{\mu\nu} \equiv \frac{\partial x_\nu}{\partial x'_\mu}. \tag{120}$$

The inverse transformation of a contravariant vector is given by:

$$a_\mu = \sum \pi_{\nu\mu} a'_\nu \text{ with } \pi_{\nu\mu} = \frac{\partial x_\mu}{\partial x'_\nu}; \tag{121}$$

the inverse transformation of a covariant vector by:

$$\alpha_\mu = \sum p_{\nu\mu} \alpha'_\nu \text{ with } p_{\nu\mu} \equiv \frac{\partial x'_\nu}{\partial x_\mu}. \tag{122}$$

It follows that

$$\sum p_{\mu\alpha}\pi_{\nu\alpha} = \delta_{\mu\nu} \tag{123}$$

and that

$$\sum p_{\alpha\mu}\pi_{\alpha\nu} = \delta_{\mu\nu}, \tag{124}$$

where we availed ourselves of the Kronecker delta, which Einstein does not use in the notebook.

Einstein considered the transformation of the core operator from x'_μ to x_μ. Substituting $\gamma'_{\mu\nu} = p_{\mu\alpha} p_{\nu\beta} \gamma_{\alpha\beta}$ and $\partial/\partial x'_\mu = \pi_{\mu\alpha}(\partial/\partial x_\alpha)$ into[96]

---

95 Notice that the definitions of $p_{\mu\nu}$ and $\pi_{\mu\nu}$ differ from the definitions of these quantities in (Einstein and Grossmann 1913, 24), where they are defined as $p_{\mu\nu} \equiv \partial x_\mu / \partial x'_\nu$ and $\pi_{\mu\nu} \equiv \partial x'_\nu / \partial x_\mu$. In other words, the roles of p and π are interchanged as are the indices μ and ν. This is related to the fact that in the Zurich Notebook contravariant quantities (with some exceptions such as the contravariant components $\gamma_{\mu\nu}$ of the metric) are generally denoted by Latin letters and covariant quantities by Greek ones, whereas in (Einstein and Grossmann 1913) this is just the other way around.

96 Expression (125) is a concrete example of $\mathbf{O}(\partial', g')$ introduced in equation (112).

$$\sum_{\mu\nu} \frac{\partial}{\partial x'_\mu}\left(\gamma'_{\mu\nu}\frac{\partial \gamma'_{i\kappa}}{\partial x'_\nu}\right), \tag{125}$$

one arrives at the equation written directly under expression (118) for the core operator in the notebook:[97]

$$\sum_{\alpha\beta\mu\nu\rho\sigma} \pi_{\mu\alpha}\frac{\partial}{\partial x_\alpha}\left(p_{\mu\rho}p_{\nu\sigma}\gamma_{\rho\sigma}\pi_{\nu\beta}\frac{\partial}{\partial x_\beta}(p_{il}p_{\kappa m}\gamma_{lm})\right). \tag{126}$$

The contraction of $p_{\nu\sigma}$ and $\pi_{\nu\beta}$ gives $\delta_{\beta\sigma}$. Einstein also set

$$\pi_{\mu\alpha}\frac{\partial}{\partial x_\alpha}(p_{\mu\rho}\ldots) = \frac{\partial}{\partial x_\rho}(\ldots), \tag{127}$$

tacitly making the erroneous assumption that $\pi_{\mu\alpha}\partial p_{\mu\rho}/\partial x_\alpha = 0$, possibly on the basis of the following incorrect application of the chain rule:[98]

$$\pi_{\mu\alpha}\frac{\partial p_{\mu\rho}}{\partial x_\alpha} = \frac{\partial x_\alpha}{\partial x'_\mu}\,\frac{\partial^2 x'_\mu}{\partial x_\alpha \partial x_\rho} = \frac{\partial^2 x'_\mu}{\partial x'_\mu \partial x_\rho} = 0. \tag{128}$$

With these simplifications, Einstein arrived at the following expression for the core operator in x'_μ-coordinates in terms of quantities in x_μ-coordinates:[99]

$$\sum_{\mu\nu} \frac{\partial}{\partial x'_\mu}\left(\gamma'_{\mu\nu}\frac{\partial \gamma'_{i\kappa}}{\partial x'_\nu}\right) = \sum \frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}\gamma_{lm})\right). \tag{129}$$

To further investigate the covariance properties of the core operator, Einstein adopted the two-step procedure described in the introduction of sec. 4.3. The first step is to write down the law according to which the core operator would transform if it transformed as a tensor under the transformation from x'^μ to x^μ. Adopting Einstein's notation

$$(\gamma)_{\alpha\beta} \equiv \sum \frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial \gamma_{\alpha\beta}}{\partial x_\nu}\right) \tag{130}$$

for the core operator, one can write this tensorial transformation law as[100]

$$(\gamma)_{\alpha\beta} = \sum \pi_{i\alpha}\pi_{\kappa\beta}(\gamma)'_{i\kappa}. \tag{131}$$

The second step of the procedure is to rewrite $(\gamma)'_{i\kappa}$, the core operator in the primed coordinate system, in terms of quantities in the unprimed coordinate system. Inserting

---

97 There is also a summation over m and l.

98 This error was committed repeatedly by Einstein. See, e.g., pp. 7R, 8L. It was eventually discovered on p. 10L (see sec. 4.5.1 below).

99 The notebook has $\partial/\partial\rho$ and $\partial/\partial\sigma$ instead of $\partial/\partial x_\rho$ and $\partial/\partial x_\sigma$.

100 Equations (131) and (132) form a concrete example of a combination of equations (112) and (113): $\tilde{\mathbf{O}}(\partial, g) \equiv \tilde{T}^{-1}\mathbf{O}(\partial', g') = \tilde{T}^{-1}\mathbf{O}(T(\partial), T(g))$.

(the erroneous) expression (129) for $(\gamma)'_{i\kappa}$ found earlier, one arrives at the equation given in the notebook at this point:

$$(\gamma)_{\alpha\beta} = \sum \pi_{i\alpha}\pi_{\kappa\beta}\frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}\gamma_{lm})\right). \tag{132}$$

If $(\gamma)_{\alpha\beta}$ transforms as a tensor under the transformation from x^μ to x'^μ and vice versa, the right-hand side of this equation should be equal to the core operator

$$\sum \frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\right). \tag{133}$$

This is trivially true for linear transformations.[101] Einstein wanted to find more general transformations for which the right-hand side of equation (132) reduces to expression (133). For such transformations the sum of all terms on the right-hand side of equation (132) that involve derivatives of the components of the transformation matrix $p_{\mu\nu}$ should vanish. Einstein set out to collect such terms.

First, he considered the differential operator $\partial/\partial x_\sigma$ in front of the innermost set of parentheses on the right-hand side of equation (132). He rewrote this part of the equation as:

$$p_{il}p_{\kappa m}\frac{\partial \gamma_{lm}}{\partial x_\sigma} + \gamma_{lm}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}). \tag{134}$$

Then he turned to the differential operator $\partial/\partial x_\rho$ in front of the outermost set of parentheses on the right-hand side of equation (132). First, using equation (134), he wrote down the term that comes from having $\partial/\partial x_\rho$ act on $\gamma_{\rho\sigma}$:

$$\frac{\partial \gamma_{\rho\sigma}}{\partial x_\rho}\left(p_{il}p_{\kappa m}\frac{\partial \gamma_{lm}}{\partial x_\sigma} + \gamma_{lm}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m})\right). \tag{135}$$

Finally, he wrote down the four terms that result from applying $\partial/\partial x_\rho$ to expression (134) and contracting it with $\gamma_{\rho\sigma}$:

$$\begin{aligned}\gamma_{\rho\sigma}p_{il}p_{\kappa m}\frac{\partial^2 \gamma_{lm}}{\partial x_\rho \partial x_\sigma} + \gamma_{\rho\sigma}\frac{\partial \gamma_{lm}}{\partial x_\sigma}\frac{\partial}{\partial x_\rho}(p_{il}p_{\kappa m}) + \gamma_{\rho\sigma}\frac{\partial \gamma_{lm}}{\partial x_\rho}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}) \\ + \gamma_{\rho\sigma}\gamma_{lm}\frac{\partial^2}{\partial x_\rho \partial x_\sigma}(p_{il}p_{\kappa m})\end{aligned} \tag{136}$$

The core operator $(\gamma)_{\alpha\beta}$ transforms as a tensor under transformations with transformation matrices $p_{\mu\nu}$ if the components of the transformation matrices satisfy the con-

101 For linear transformations, equation (132) reduces to:

$$(\gamma)_{\alpha\beta} = \sum \pi_{i\alpha}\pi_{\kappa\beta}p_{il}p_{\kappa m}\frac{\partial}{\partial x_\rho}(\gamma_{\rho\sigma}\frac{\partial \gamma_{lm}}{\partial x_\sigma}) = \sum \delta_{\alpha l}\delta_{\beta m}\frac{\partial}{\partial x_\rho}(\gamma_{\rho\sigma}\frac{\partial \gamma_{lm}}{\partial x_\sigma}) = \sum \frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\right).$$

dition that the sum of all terms in expressions (135) and (136) that involve derivatives of $p_{\mu\nu}$ vanish for a given metric field with contravariant components $\gamma_{\mu\nu}$. Collecting such terms, one arrives at the condition:[102]

$$\begin{aligned}&\frac{\partial\gamma_{\rho\sigma}}{\partial x_\rho}\left(\gamma_{lm}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m})\right)+\gamma_{\rho\sigma}\frac{\partial\gamma_{lm}}{\partial x_\sigma}\frac{\partial}{\partial x_\rho}(p_{il}p_{\kappa m})\\&\gamma_{\rho\sigma}\frac{\partial\gamma_{lm}}{\partial x_\rho}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m})+\gamma_{\rho\sigma}\gamma_{lm}\frac{\partial^2}{\partial x_\rho\partial x_\sigma}(p_{il}p_{\kappa m}) = 0\end{aligned}\tag{137}$$

This condition on the transformation matrices $p_{\mu\nu}$ is the condition for what Einstein would later call "non-autonomous" transformations under which the core operator transforms as a tensor (see the introduction to sec. 4.3).[103]

Looking at this condition, one readily sees that it will be satisfied if

$$\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}) = 0\tag{138}$$

for all index combinations. Except for a meaningless summation sign, which Einstein seems to have left in by mistake, and a relabeling of the indices the left-hand side of this equation is just the expression at the top of p. 7R: 7R

$$\sum\frac{\partial}{\partial x_\sigma}(p_{\alpha l}p_{\beta m})\,.\tag{139}$$

This expression is introduced with the comment: "where p is differentiated at least once. $i = \alpha \quad \kappa = \beta$" ("wobei p mindestens einmal abgeleitet wird. $i = \alpha$ $\kappa = \beta$").[104] The restriction to terms in which "p is differentiated at least once" identifies those terms in expressions (135) and (136) on p. 7L that must vanish if the core operator is to transform as a tensor under the coordinate transformation described by the matrix $p_{\mu\nu}$. Unfortunately, condition (138) restricts the allowed transformations to linear transformations, whereas Einstein was looking for non-linear transformation under which the core operator transforms as a tensor.

Einstein now drew a horizontal line and made a fresh start. He wrote down the contraction of the core operator with the covariant metric:

$$\sum_{i\kappa\mu\nu} g_{i\kappa}\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu}\right)\tag{140}$$

---

102 This is a concrete example of condition (114) in the introduction to sec. 4.3.

103 This condition would still need to be corrected for the error made in going from equation (126) to equation (129).

104 To understand the change in the labeling of the indices—from i and k to α and β—note that the core operator (see equation (132)) is obtained by contracting the sum of expressions (135) and (136) with $\pi_{i\alpha}\pi_{\kappa\beta}$. In first-order approximation, $\pi_{i\alpha}$ and $\pi_{\kappa\beta}$ can be replaced by the Kronecker deltas $\delta_{i\alpha}$ and $\delta_{\kappa\beta}$.

writing "scalar" ("Skalar") next to it. The expression will transform as a scalar for transformations under which the core operator transforms as a tensor. Conversely, Einstein may have expected that transformations under which expression (140) transforms as a scalar are transformations under which the core operator transforms as a tensor. He may have felt that the former were easier to find than the latter.

On the next line, however, Einstein returned once more to the condition derived on p. 7L for the transformation matrices $p_{\mu\nu}$ and $\pi_{\mu\nu}$ (see equations (129)–(137)). We can only make sense of the expression Einstein wrote down if we assume that he now focused on infinitesimal transformations. Consider the right-hand of equation (132):

$$\sum \pi_{i\alpha}\pi_{\kappa\beta}\frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p_{il}p_{\kappa m}\gamma_{lm})\right) . \tag{141}$$

Following Einstein's notation on p. 10L (see equation (238)) for an infinitesimal transformation, $p_{il} = \delta_{il} + p^x_{il}$, and neglecting terms smaller than those of first order in p^x_{il}, one can write the product in the innermost parentheses in expression (141) as

$$(\delta_{il} + p^x_{il})(\delta_{\kappa m} + p^x_{\kappa m})\gamma_{lm} = \gamma_{i\kappa} + p^x_{il}\gamma_{l\kappa} + p^x_{\kappa m}\gamma_{im} \tag{142}$$

Inserting this last expression into expression (141) and collecting all terms involving derivatives of the transformation matrices, one finds, to first order,

$$\pi_{i\alpha}\pi_{\kappa\beta}\frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p^x_{il}\gamma_{l\kappa} + p^x_{\kappa m}\gamma_{im})\right) \tag{143}$$

Since only terms involving derivatives of p^x_{il} matter, $\pi_{i\alpha}$ and $\pi_{\kappa\beta}$ can be replaced by Kronecker deltas in first-order approximation. This then gives

$$\frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p^x_{\alpha l}\gamma_{l\beta} + p^x_{\beta l}\gamma_{\alpha l})\right) . \tag{144}$$

If the core operator transforms as a tensor under the transformation described by $p_{\mu\nu}$, the sum of all terms in expressions (144) that involve derivatives of the components of $p^x_{\mu\nu}$ must vanish (cf. the discussion following equation (136)). This condition can be satisfied by requiring that the sum of all terms in

$$\frac{\partial}{\partial x_\rho}\left(\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}(p^x_{\alpha l}\gamma_{l\beta})\right) \tag{145}$$

"in which p is differentiated at least once" ("wobei p mindestens einmal abgeleitet wird") vanish. Einstein wrote down expression (145)—albeit with $p_{\alpha l}$ rather than with $p^x_{\alpha l}$—with this remark next to it, which supports our reconstruction of the purpose behind it. The condition for infinitesimal transformations resulting from expression (145) is much simpler than condition (137) for finite transformations. Einstein's calculations nonetheless break off at this point.

4.3.2 *Generalizing the Constituent Parts of the Core Operator: Divergence and Exterior Derivative Operators (7R–8R)* 7R–8R

Rather than continuing the search for non-autonomous non-linear coordinate transformations under which the core operator transforms as a tensor, Einstein, on pp. 7R–8R, tried to find a generalization of the core operator that would transform as a tensor under ordinary non-linear transformations. In other words, he switched from the first to the second of the two strategies that we distinguished in the introduction of sec. 4.3. He applied this strategy to the two constituent components of the core operator, the divergence and the exterior derivative. On p. 7R, under the heading "Divergence of a tensor" ("Divergenz des Tensors"), he tried to generalize the divergence operator. On pp. 8L-R, under the heading "Exterior derivative of a tensor" ("Erweiterung des Tensors"), he tried to generalize the exterior derivative operator.

To generalize the divergence operator, Einstein started from the ordinary divergence of a second-rank tensor in primed pseudo-Cartesian coordinates on Minkowski spacetime and then wrote down the expression in unprimed arbitrary coordinates that one would get if the divergence in primed coordinates transformed as a tensor under this transformation. In the primed coordinates the Minkowski metric has the standard diagonal form. Since the components of this metric are constants, there will be a simple relation between the metric in unprimed coordinates and the matrices for the transformation between primed and unprimed coordinates. Using this relation, one can eliminate the transformation matrices from the expression for the divergence transformed from primed to unprimed coordinates as if it were a tensor. This expression will then be entirely in terms of components of the metric in unprimed coordinates and their derivatives. Einstein expected that this procedure would yield the generalized divergence operator that he had found on p. 5R (essentially the covariant divergence), but he was unable to prove this conjecture.

These considerations begin beneath the second horizontal line on p. 7R. Under the heading "Divergence of the Tensor" ("Divergenz des Tensors"), Einstein wrote down the ordinary divergence of a second-rank contravariant tensor in a primed coordinate system[105] 7R

$$a'_{\mu} = \sum \frac{\partial T'_{\mu\nu}}{\partial x'_{\nu}} \qquad \mu\text{-Vektor}\,. \tag{146}$$

In the line above this equation, Einstein characterized the primed coordinate system with the remark: "original system ($'$) shall have constant g, γ." ("Ursprüngliches System ($'$) habe konstante g, γ."). Presumably, what he had in mind was a pseudo-Cartesian coordinate system on Minkowski spacetime.

Einstein now applied the same two-step procedure that we encountered on p. 7L. First, he wrote down how a'_{μ} would transform if it were to transform as a vector under transformations from the special primed to arbitrary unprimed coordinates. He then took expression (146) for the vector in primed coordinates and used the standard trans-

105 The quantity a'_{μ} is a concrete example $\mathbf{O}(\partial', g')$ in equation (112).

formation rules to rewrite the building blocks of this vector in terms of their counterparts in the unprimed coordinate system. He thus arrived at the following expression for the vector a_μ "in the unprimed system" ("Im ungestrichenen System"):[106]

$$a_\sigma = \sum \pi_{\mu\sigma} a'_\mu = \sum \pi_{\mu\sigma} \pi_{\nu\tau} \frac{\partial}{\partial x_\tau} (p_{\mu i} p_{\nu\kappa} T_{i\kappa}) \,. \tag{147}$$

He simplified the right-hand side of equation (147), using the same erroneous relation,

$$\ldots \pi_{\nu\tau} \frac{\partial}{\partial x_\tau} (\ldots p_{\nu\kappa} \ldots) = \ldots \pi_{\nu\tau} p_{\nu\kappa} \frac{\partial}{\partial x_\tau} (\ldots) = \ldots \frac{\partial}{\partial x_\kappa} (\ldots) \,, \tag{148}$$

that he had used earlier (cf. equations (127)–(128)). In this way he obtained[107]

$$a_\sigma = \sum \pi_{\mu\sigma} \frac{\partial}{\partial x_\kappa} (p_{\mu i} T_{i\kappa}) = \sum \frac{\partial T_{\sigma\kappa}}{\partial x_\kappa} + \sum_{\mu i\kappa} T_{i\kappa} \pi_{\mu\sigma} \frac{\partial p_{\mu i}}{\partial x_\kappa} \,. \tag{149}$$

Einstein now indicated how he wanted to generalize the ordinary divergence operator: "This sum is to be expressed by the g resp. γ. In doing so one has to use the fact that the primed g and γ are constant." ("Diese Summe ist durch die g bzw. γ auszudrükken. Dabei ist zu benutzen, dass die gestrichenen g bzw. γ konstant sind."). In other words, using the simple form of the metric in the special primed coordinates, he wanted to express the components of the transformation matrices and their derivatives in the last term of equation (149) in terms of the components of the metric and their derivatives in the arbitrary unprimed coordinates. The final step producing the sought-after generalization of the divergence operator is to replace the components of the Minkowski metric in the unprimed coordinates in the resulting expression by components of an arbitrary metric.

Underneath the sentence explaining the aim of his calculation, indicating the connection to the last term of equation (149) by a vertical line, Einstein wrote:

$$\sum T_{i\kappa} \left(\frac{\partial g_{\sigma\kappa}}{\partial x_i} - \frac{1}{2} \frac{\partial g_{i\kappa}}{\partial x_\sigma} \right) . \tag{150}$$

He thus expected that a_σ could be written as:

$$a_\sigma = \sum \frac{\partial T_{\sigma\kappa}}{\partial x_\kappa} + \sum T_{i\kappa} \left(\frac{\partial g_{\sigma\kappa}}{\partial x_i} - \frac{1}{2} \frac{\partial g_{i\kappa}}{\partial x_\sigma} \right) . \tag{151}$$

---

106 Equation (147) is a concrete example of a combination of equations (112) and (113): $\tilde{\mathbf{O}}(\partial, g) \equiv \tilde{T}^{-1} \mathbf{O}(\partial', g') = \tilde{T}^{-1} \mathbf{O}(T(\partial), T(g))$.

107 Correcting Einstein's mistake in going from equation (147) to equation (149), one finds:

$$a_\sigma = \sum \pi_{\mu\sigma} \pi_{\nu\tau} \frac{\partial}{\partial x_\tau} (p_{\mu i} p_{\nu\kappa} T_{i\kappa}) = \frac{\partial T_{\sigma\tau}}{\partial x_\tau} + T_{i\tau} \pi_{\mu\sigma} \frac{\partial p_{\mu i}}{\partial x_\tau} + T_{\sigma\kappa} \pi_{\nu\tau} \frac{\partial p_{\nu\kappa}}{\partial x_\tau} \,.$$

This is a concrete example of equation (113). The first term on the right-hand side corresponds to $\mathbf{O}(\partial, g)$; the last two terms to $\mathbf{C}(\partial, g, p, \pi)$.

One sees immediately that this cannot be correct since the right-hand side is a sum of a contravariant and a covariant term.

Einstein's expectation derives from his experience with the covariant divergence of the stress-energy tensor on p. 5R. If in equation (71) found on p. 5R one sets $\sqrt{G} = 1$, its left-hand side reduces to:

$$\sum \frac{\partial}{\partial x_n}(g_{m\nu} T_{\nu n}) - \frac{1}{2}\sum \frac{\partial g_{\mu\nu}}{\partial x_m} T_{\mu\nu} . \tag{152}$$

Relabeling indices and using that the stress-energy tensor $T_{\mu\nu}$ is symmetric,[108] one can rewrite expression (152) as:

$$\sum \frac{\partial}{\partial x_i}(g_{\sigma\kappa} T_{\kappa i}) - \frac{1}{2}\sum \frac{\partial g_{i\kappa}}{\partial x_\sigma} T_{i\kappa} = \sum g_{\sigma\kappa} \frac{\partial T_{i\kappa}}{\partial x_i} + \sum T_{i\kappa}\left(\frac{\partial g_{\sigma\kappa}}{\partial x_i} - \frac{1}{2}\frac{\partial g_{i\kappa}}{\partial x_\sigma}\right) . \tag{153}$$

Comparing this last expression with Einstein's expectation for the form of a generalized divergence operator in equation (151), one easily recognizes the basic problem. He expected the generalized divergence of a contravariant tensor to be a contravariant vector, whereas the operator he had found on p. 5R turns a contravariant tensor into a covariant vector (see expression (152)).

Einstein did not recognize the problem at first and tried to show that equation (149) for a_σ can indeed be rewritten as equation (151). This can be inferred from the last two lines on p. 7R. He tried to show that

$$\frac{\partial g_{\sigma\kappa}}{\partial x_i} - \frac{1}{2}\frac{\partial g_{i\kappa}}{\partial x_\sigma} \tag{154}$$

in equation (151) is equal to[109]

$$\pi_{\mu\sigma}\frac{\partial p_{\mu i}}{\partial x_\kappa} \tag{155}$$

in equation (149). To this end he eliminated the metric in unprimed coordinates in expression (154) in favor of the metric in primed coordinates, whose components are constants:

$$\sum \frac{\partial}{\partial x_i}(p_{\mu\sigma} p_{\nu\kappa} g'_{\mu\nu}) - \frac{1}{2}\frac{\partial}{\partial x_\sigma}(p_{\mu i} p_{\nu\kappa} g'_{\mu\nu}) \quad . \tag{156}$$

Finally, he wrote down one contribution coming from the second term in expression (156), the one involving a derivative of $p_{\mu i}$, which also occurs in expression (155):

108 At the beginning of the calculation on p. 7R (see equation (146)), $T_{\mu\nu}$ was an arbitrary tensor. At this point in the calculation, however, it becomes essential that $T_{\mu\nu}$ is symmetric.

109 Since $\pi_{\mu\sigma} = \partial x_\sigma / \partial x'_\mu$, σ is a contravariant index. Expression (155) can thus never be equal to expression (154) in which σ is a covariant index.

$$\frac{1}{2}\frac{\partial p_{\mu i}}{\partial x_\sigma} p_{\nu\kappa} g'_{\mu\nu} . \tag{157}$$

At this point the calculation breaks off.

8L The method by which Einstein tried to generalize the ordinary divergence operator on p. 7R does not guarantee that the result will be a tensor. The main problem comes from the final step in which an expression derived for one special metric, the Minkowski metric, is assumed to transform as a tensor for an arbitrary metric (at least under unimodular transformations because of the restriction to $\sqrt{G} = 1$). The deleted calculation at the top of p. 8L may have been an attempt to prove that the method employed on p. 7R actually does produce an object that transforms as a tensor under arbitrary coordinate transformations. If that is indeed the purpose of this calculation, the strategy chosen by Einstein is clear. He tried to prove that a transformation from arbitrary unprimed coordinates to arbitrary double-primed coordinates can be decomposed into two transformations of the type considered on p. 7R, namely a transformation from the unprimed coordinates to special primed coordinates followed by a transformation from these special primed coordinates to the double-primed coordinates. Since any metric can locally be transformed to a Minkowski metric in standard diagonal form, the form of the metric in the special primed coordinates, this would guarantee that the method of p. 7R does indeed produce a tensor.

These considerations may lie behind Einstein's question at the top of p. 8L, "Do symmetrical transformations form a group?" ("Haben symmetrische Transformationen Gruppeneigenschaft?"), and behind the subsequent investigation of a transformation from unprimed to primed to double-primed coordinates. What remains unclear, however, is why Einstein focused on symmetric transformations.

To determine whether symmetric transformations given by

$$x'_\nu = \sum_\sigma p_{\nu\sigma} x_\sigma , \tag{158}$$

with $p_{\nu\sigma} = p_{\sigma\nu}$ form a group, Einstein considered the components

$$p''_{\lambda\sigma} = \sum p'_{\lambda\nu} p_{\nu\sigma} \tag{159}$$

of the matrix for the composite transformation

$$x''_\lambda = \sum_\nu p'_{\lambda\nu} x'_\nu = \sum_{\nu\sigma} p'_{\lambda\nu} p_{\nu\sigma} x_\sigma \tag{160}$$

and switched the indices of these components:

$$p''_{\sigma\lambda} = \sum_\nu p'_{\sigma\nu} p_{\nu\lambda} . \tag{161}$$

He did not pursue this calculation any further. Either he concluded (correctly) that symmetric transformations do not form a group or he did not see how to settle the question either way.

He now turned to rotational transformations, perhaps as an example of a class of transformations that certainly do form a group, or to check whether such transformations are symmetric. He wrote down transformation laws for a rotation over an angle α as well as for its inverse:

$$\begin{aligned} x' &= x\cos\alpha + y\sin\alpha \\ y' &= -x\cos\alpha + y\sin\alpha \\ x &= x'\cos\alpha - y'\sin\alpha \\ y &= x'\sin\alpha + y'\cos\alpha \end{aligned} \tag{162}$$

These expressions show that rotation does not belong to the class of symmetric transformations. Perhaps this is why he deleted the calculation at the top of p. 7R. Another possibility is that he realized that the restriction to symmetric transformations was not necessary to show that the method of p. 7R produces a tensor.

Under the heading "Exterior derivative of the Tensor" ("Erweiterung des Tensors"), Einstein now turned to the second differential operator relevant to generalizing the core operator. This takes up the remainder of p. 8L and the first two lines on p. 8R. As in the case of generalizing the divergence operator, Einstein's starting point is the ordinary exterior derivative of a contravariant second-rank tensor in special relativity. He wrote: "In ordinary space [i.e., Minkowski spacetime in pseudo-Cartesian coordinates][110]

$$\Delta'_{\mu\nu\rho} = \frac{\partial T'_{\mu\nu}}{\partial x'_{\rho}}, \tag{163}$$

is a tensor of three manifolds [i.e., of third rank]" ("Im gew. [gewöhnlichen] Raum ist … Tensor von 3 Mannigfaltigkeiten"). He then "introduced transformations with constant coefficients" ("Subst[itutionen] von konst. Koeffizienten eingeführt")

$$\Delta'_{\mu\nu\rho}[=]\sum\pi_{\rho\sigma}\frac{\partial}{\partial x_{\sigma}}(p_{\mu\alpha}p_{\nu\beta}T_{\alpha\beta}). \tag{164}$$

and confirmed that "for such transformations $\partial T_{\alpha\beta}/\partial x_{\sigma}$ is also a tensor" ("Für solche Transformationen ist $\partial T_{\alpha\beta}/\partial x_{\sigma}$ auch Tensor"). As indicated by the arrows in equation (164), this is because the components $p_{\mu\nu}$ of the transformation matrix can put in front of the derivative operator $\partial/\partial x_{\sigma}$.

Einstein now tried to generalize the tensor $\Delta'_{\mu\nu\rho}$. He started by asking the question: "What is this tensor called when arbitrary substitutions are admitted?" ("Wie heisst dieser Tensor, wenn bel[iebige] Subst[itutionen] zugelassen werden?"). Clearly he was not familiar with the notion of a covariant derivative at this point. Einstein used the same two-step procedure that he had used on p. 7R (see equation (147)). First, he wrote down how $\Delta'_{\mu\nu\rho}$ would transform if it transformed as a tensor under transfor-

110 The quantity $\Delta'_{\mu\nu\rho}$ is a concrete example of $\mathbf{O}(\partial', g')$ in equation (112).

mations from special primed to arbitrary unprimed coordinates. He then took expression (163) for $\Delta'_{\mu\nu\rho}$ and used the standard transformation rules to rewrite its building blocks in terms of their counterparts in unprimed coordinates. He thus arrived at the following expression for the tensor $\Delta_{\mu\nu\rho}$ in unprimed coordinates[111]

$$\Delta_{\mu\nu\rho} = \sum_{\mu\nu\rho} \pi_{m\mu}\pi_{n\nu}p_{r\rho}\Delta'_{mnr} = \sum \pi_{m\mu}\pi_{n\nu}p_{r\rho}\pi_{r\alpha}\frac{\partial}{\partial x_\alpha}(p_{m\delta}p_{n\varepsilon}T_{\delta\varepsilon}) \tag{165}$$

Einstein initially wrote $\pi_{\rho\alpha}$ but eventually corrected it to $\pi_{r\alpha}$. The right-hand side of equation (165) gives a sum of three terms:[112]

$$\frac{\partial T_{\mu\nu}}{\partial x_\rho} + \sum \pi_{m\mu}\pi_{n\nu}p_{r\rho}\pi_{r\alpha}\frac{\partial p_{n\varepsilon}}{\partial x_\alpha}p_{m\delta}T_{\delta\varepsilon} + \sum \pi_{m\mu}\pi_{n\nu}p_{r\rho}\pi_{r\alpha}p_{n\varepsilon}\frac{\partial p_{m\delta}}{\partial x_\alpha}T_{\delta\varepsilon}\,. \tag{166}$$

Using that $\pi_{m\mu}p_{m\delta} = \delta_{\mu\delta}$, Einstein simplified the second term, still with $\pi_{\rho\alpha}$ instead of $\pi_{r\alpha}$ and omitting $T_{\delta\varepsilon}$:

$$\pi_{n\nu}\frac{\partial p_{n\varepsilon}}{\partial x_\alpha}\pi_{\rho\alpha}p_{r\rho}\,. \tag{167}$$

This expression does not allow for further simplification. This may be what drew Einstein's attention to the error in equation (165), which he then corrected. The correct expressions (165)-(166) can be simplified further. This yields:

$$\frac{\partial T_{\mu\nu}}{\partial x_\rho} + \sum\left(\pi_{n\nu}\frac{\partial p_{n\varepsilon}}{\partial x_\rho}\right)T_{\mu\varepsilon} + \sum\left(\pi_{m\mu}\frac{\partial p_{m\delta}}{\partial x_\rho}\right)T_{\delta\nu}\,. \tag{168}$$

To generalize the exterior derivative of $T_{\mu\nu}$, one proceeds in the same way as in generalizing the divergence of $T_{\mu\nu}$ on the basis of expression (149).

Using that the metric in primed coordinates is the Minkowski metric in standard diagonal form, one first expresses the components of the transformation matrices and their derivatives in the last two terms of equation (168) in terms of the components of the Minkowski metric and their derivatives in the arbitrary unprimed coordinates. In the resulting expression, one then substitutes the components of an arbitrary metric for the components of the Minkowski metric in unprimed coordinates.

8R At the top of p. 8R, Einstein tried to find the relation between the transformation matrices and the Minkowski metric in the unprimed coordinates. This relation is given by the first equation on p. 8R:

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} = \sum_{\beta\alpha} g_{\rho\beta}\pi_{\alpha\beta}\frac{\partial p_{\alpha\sigma}}{\partial x_\tau} + \sum_{\alpha\beta} g_{\alpha\sigma}\pi_{\beta\alpha}\frac{\partial p_{\beta\rho}}{\partial x_\tau}\,. \tag{169}$$

---

111 Equation (165) is a concrete example of a combination of equations (112) and (113): $\tilde{\mathbf{O}}(\partial, g) \equiv \tilde{T}^{-1}\mathbf{O}(\partial', g') = \tilde{T}^{-1}\mathbf{O}(T(\partial), T(g))$.

112 Expression (166) is a concrete example of the right-hand side of equation (113): $\mathbf{O}(\partial, g) + \mathbf{C}(\partial, g, p, \pi)$.

Although the derivation of this equation is not recorded in the notebook, it is easily reconstructed. It is basically the same calculation as in equations (163)–(168), only for $g_{\mu\nu}$ instead of $T_{\mu\nu}$. The starting point of the derivation is the observation that in the primed coordinates in which the Minkowski metric takes on its standard diagonal form, the exterior derivative of the metric vanishes:

$$\frac{\partial g'_{\alpha\beta}}{\partial x'_\gamma} = 0 . \tag{170}$$

The contraction of the left-hand side of this equation with the transformation matrices $p_{\alpha\rho}p_{\beta\sigma}p_{\gamma\tau}$ obviously still vanishes:

$$\sum p_{\alpha\rho}p_{\beta\sigma}p_{\gamma\tau}\frac{\partial g'_{\alpha\beta}}{\partial x'_\gamma} = 0 . \tag{171}$$

Expressing the primed quantities in terms of their unprimed counterparts, one finds that

$$\sum p_{\alpha\rho}p_{\beta\sigma}p_{\gamma\tau}\left(\pi_{\gamma\lambda}\frac{\partial}{\partial x_\lambda}(\pi_{\alpha\mu}\pi_{\beta\nu}g_{\mu\nu})\right) = 0 , \tag{172}$$

which can be rewritten as

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} + p_{\beta\sigma}\frac{\partial \pi_{\beta\nu}}{\partial x_\tau}g_{\rho\nu} + p_{\alpha\rho}\frac{\partial \pi_{\alpha\mu}}{\partial x_\tau}g_{\mu\sigma} = 0 . \tag{173}$$

Since $p_{\beta\sigma}\pi_{\beta\nu} = \delta_{\sigma\nu}$ and, consequently,

$$0 = \frac{\partial}{\partial x_\mu}(p_{\beta\sigma}\pi_{\beta\nu}) = p_{\beta\sigma}\frac{\partial \pi_{\beta\nu}}{\partial x_\mu} + \pi_{\beta\nu}\frac{\partial p_{\beta\sigma}}{\partial x_\mu} , \tag{174}$$

equation (173) is equivalent to

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} - g_{\rho\nu}\pi_{\beta\nu}\frac{\partial p_{\beta\sigma}}{\partial x_\tau} - g_{\mu\sigma}\pi_{\alpha\mu}\frac{\partial p_{\alpha\rho}}{\partial x_\tau} = 0 . \tag{175}$$

Bringing the second and the third term to the right-hand side and relabeling indices ($\nu\beta \to \beta\alpha$ in the second term, $\mu\alpha \to \alpha\beta$ in the third term), one finds an expression for the exterior derivative of the covariant metric,

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} = g_{\rho\beta}\pi_{\alpha\beta}\frac{\partial p_{\alpha\sigma}}{\partial x_\tau} + g_{\alpha\sigma}\pi_{\beta\alpha}\frac{\partial p_{\beta\rho}}{\partial x_\tau} , \tag{176}$$

which is just equation (169) given at the top of p. 8R. Underneath this equation, Einstein wrote down a similar equation for the contravariant metric:[113]

113 It looks as if Einstein first started to write down equation (177) next to equation (169) rather than underneath it.

$$\frac{\partial\gamma_{\mu\nu}}{\partial x_\sigma} = \sum_{\alpha\beta}\gamma_{\mu\alpha}p_{\beta\alpha}\frac{\partial\pi_{\beta\nu}}{\partial x_\sigma} + \sum_{\alpha\beta}\gamma_{\alpha\nu}p_{\beta\alpha}\frac{\partial\pi_{\beta\mu}}{\partial x_\sigma}. \tag{177}$$

The derivation of this equation is fully analogous to the derivation of equation (176). The only difference is that the starting point is now $\partial\gamma'_{\alpha\beta}/\partial x'_\gamma = 0$ rather than $\partial g'_{\alpha\beta}/\partial x'_\gamma = 0$.[114]

Einstein did not proceed any further. With hindsight, however, knowing that the generalization that Einstein was looking for is just the covariant derivative, one can easily complete his chain of reasoning. With the help of equation (169) and two equations like it with different permutations of the indices ρ, σ, and τ, one can show that the relation between the transformation matrices and the Minkowski metric in the unprimed coordinates that Einstein was looking for is given by

$$\pi_{\alpha\beta}\frac{\partial p_{\alpha\sigma}}{\partial x_\tau} = \begin{Bmatrix}\beta\\ \sigma\tau\end{Bmatrix} = \frac{1}{2}\gamma_{\beta\alpha}\left(\frac{\partial g_{\alpha\sigma}}{\partial x_\tau} + \frac{\partial g_{\alpha\tau}}{\partial x_\sigma} - \frac{\partial g_{\sigma\tau}}{\partial x_\rho}\right), \tag{178}$$

where the curly brackets represent the Christoffel symbols of the second kind. This can easily be verified by inserting equation (178) back into equation (169).[115] Inserting equation (178) into expression (168), one finds the generally-covariant analogue of the exterior derivative of the contravariant tensor $T_{\mu\nu}$:[116]

$$\begin{aligned}&\frac{\partial T_{\mu\nu}}{\partial x_\rho} + \sum\left(\pi_{n\nu}\frac{\partial p_{n\varepsilon}}{\partial x_\rho}\right)T_{\mu\varepsilon} + \sum\left(\pi_{m\mu}\frac{\partial p_{m\delta}}{\partial x_\rho}\right)T_{\delta\nu}\\ &\qquad = \frac{\partial T_{\mu\nu}}{\partial x_\rho} + \sum\begin{Bmatrix}\nu\\ \varepsilon\rho\end{Bmatrix}T_{\mu\varepsilon} + \sum\begin{Bmatrix}\mu\\ \delta\rho\end{Bmatrix}T_{\delta\nu}\end{aligned} \tag{179}$$

Inserting equation (178) into the right-hand side of the equation in footnote 107, one finds the covariant divergence of $T_{\mu\nu}$:

$$\frac{\partial T_{\sigma\tau}}{\partial x_\tau} + \pi_{\mu\sigma}\frac{\partial p_{\mu i}}{\partial x_\tau}T_{i\tau} + \pi_{\nu\tau}\frac{\partial p_{\nu\kappa}}{\partial x_\tau}T_{\sigma\kappa} = \frac{\partial T_{\sigma\tau}}{\partial x_\tau} + \begin{Bmatrix}\sigma\\ i\tau\end{Bmatrix}T_{i\tau} + \begin{Bmatrix}\tau\\ \kappa\tau\end{Bmatrix}T_{\sigma\kappa}. \tag{180}$$

---

114 Equation (177) can also be obtained by substituting the contravariant metric $\gamma_{\mu\nu}$ for the contravariant tensor $T_{\mu\nu}$ in equation (123), using equation (174) and the fact that $\partial\gamma'_{\alpha\beta}/\partial x'_\gamma = 0$ and by relabeling indices.

115 Inserting equation (178) into the right-hand side of equation (169), one recovers the left-hand side:

$$\sum_{\beta\alpha}g_{\rho\beta}\pi_{\alpha\beta}\frac{\partial p_{\alpha\sigma}}{\partial x_\tau} + \sum_{\alpha\beta}g_{\alpha\sigma}\pi_{\beta\alpha}\frac{\partial p_{\beta\rho}}{\partial x_\tau} = \sum g_{\rho\beta}\begin{Bmatrix}\beta\\ \sigma\tau\end{Bmatrix} + \sum g_{\alpha\sigma}\begin{Bmatrix}\alpha\\ \rho\tau\end{Bmatrix} = \frac{\partial g_{\rho\sigma}}{\partial x_\tau}.$$

116 The final expressions in equations (179) and (180) are concrete examples of the quantities $\mathbf{O}_{\text{gen}}(\partial, g) \equiv \mathbf{O}(\partial, g) + \mathbf{D}(\partial, g)$ defined in equation (117).

These last two equations show how close Einstein came to finding the correct generally-covariant generalizations of the two constituents of the core operator, the divergence and the exterior derivative, using the second one of the two strategies that we distinguished in the introduction of sec. 4.3.

Why did Einstein not pursue this calculation beyond the first two lines on p. 8R? It seems unlikely that the complexity of having to solve equation (60) for $\pi_{\alpha\beta}(\partial p_{\alpha\sigma}/\partial x_\tau)$ would have deterred him. On pp. 14R–18R, we shall see Einstein pursue far more cumbersome calculations with great tenacity. A more plausible answer is that Einstein realized at this point, if not earlier, that the generalization of the exterior derivative he was in the process of constructing cannot be used to build a generalized core operator that could serve as the left-hand side of the gravitational field equations. The problem is that the exterior derivative of the metric vanishes. On p. 5R, Einstein had already found that the covariant divergence of the metric vanishes, but that does not mean that the generalization of the core operator, which is essentially the divergence of the exterior derivative of the metric, vanishes. If the exterior derivative of the metric vanishes, however, the core operator vanishes as well.

Equation (177), the second equation on p. 8R, is, in fact, the statement that the covariant exterior derivative of the contravariant metric vanishes. This can be seen as follows. From equations (174) and (178) it follows that

$$p_{\beta\sigma}\frac{\partial\pi_{\beta\nu}}{\partial x_\mu} = -\pi_{\beta\nu}\frac{\partial p_{\beta\sigma}}{\partial x_\mu} = -\begin{Bmatrix}\nu\\ \sigma\mu\end{Bmatrix}. \tag{181}$$

Substituting this expression into equation (177), one finds,

$$\frac{\partial\gamma_{\mu\nu}}{\partial x_\sigma} = -\sum\gamma_{\mu\alpha}\begin{Bmatrix}\nu\\ \alpha\sigma\end{Bmatrix} - \sum\gamma_{\alpha\nu}\begin{Bmatrix}\mu\\ \alpha\sigma\end{Bmatrix} \tag{182}$$

Comparison with equation (179) shows that equation (182) expresses the vanishing of the covariant exterior derivative of the metric.[117]

Einstein did not have to find the relation between the transformation matrices and the metric and rewrite equation (177) in the form of equation (182) to see that the generalization of the exterior derivative acting on the metric would vanish. It is, in fact, a direct consequence of the method that Einstein used to construct this generalization. Whatever the exact form of the sought-after operator acting on the metric in the arbitrary unprimed coordinates, its form in the special primed coordinates used to construct it is $\partial\gamma'_{\mu\nu}/\partial x'_\rho$ (cf. equation (163)). The primed coordinates were chosen in such a way that the metric—be it the Minkowski metric or an arbitrary metric—takes

117 When Grossmann introduced the Christoffel symbols in his part of the *Entwurf* paper, he added a footnote saying: "On the basis of these formulae one can easily prove that the exterior derivative of the fundamental tensor vanishes identically" ("Auf Grund dieser Formeln beweist man leicht, dass die Erweiterung des Fundamentaltensors identisch verschwindet," Einstein and Grossmann 1913, part 2, sec. 2).

on the form of the standard diagonal Minkowski metric in these coordinates. So the generalized exterior derivative of the metric vanishes in the special primed coordinates. Now this quantity was constructed to transform as a tensor under arbitrary coordinate transformations. So it will vanish in all coordinate systems.[118]

At this point, Einstein had no choice but to abandon his second strategy for finding field equations on the basis of the core operator: generalizing this operator to an expression that transforms as a tensor under arbitrary (autonomous) coordinate transformations does not work. He returned to the first strategy of finding non-autonomous non-linear transformations under which the core operator itself—if necessary with correction terms—transforms as a tensor.

8R–9R

4.4 *Trying to Extract Field Equations and a Gravitational Stress-Energy Tensor from the Beltrami Invariants (8R–9R)*

On pp. 7L-8R Einstein had examined the transformation properties of candidate field equations based on the core operator, the natural analogue of the Poisson equation in a theory in which the gravitational potential is represented by a tensor rather than a scalar. Einstein's approach on these pages had thus been along the lines of what we call the physical strategy. On pp. 8R–9R, Einstein returned to the mathematical strategy, more specifically to the exploration of the Beltrami invariants introduced on p. 6L. He tried to extract the core operator from the second Beltrami invariant, using (some power of) the determinant of the metric as the arbitrary scalar function in the definition of this invariant. The connection between the core operator and the Beltrami invariant might throw light on the covariance properties of the former. Einstein's investigation of the covariance properties of the core operator on pp. 7L–R had remained inconclusive.

On p. 8R, Einstein returned to the basic expression for the first and the second Beltrami invariants. The first Beltrami invariant can be used to find a candidate for the quantity representing gravitational energy-momentum, the second to find a candidate for the left-hand side of the field equations. On p. 9L Einstein managed to write the second Beltrami invariant as a sum of two contributions, the first of which is the contraction of the metric with the core operator. On the bottom half of p. 9L, Einstein tried to relate the second contribution to gravitational energy-momentum. This is the first time in the notebook that Einstein, drawing on his experience with the 1912 static the-

---

118 In the *Entwurf* paper, Einstein mentioned this problem as one of the obstacles to formulating generally-covariant field equations: "These operations [i.e., the divergence and the exterior derivative operators] degenerate if they are applied to the fundamental tensor $g_{\mu\nu}$. From this it seems to follow that the equations sought will be covariant only with respect to a particular group of transformations, which for the time being, however, is unknown to us" ("Aber es degenerieren diese Operationen, wenn sie an dem Fundamentaltensor $g_{\mu\nu}$ ausgeführt werden. Es scheint daraus hervorzugehen, daß die gesuchten Gleichungen nur bezüglich einer gewissen Gruppe von Transformationen kovariant sein werden, welche Gruppe uns aber vorläufig unbekannt ist." Einstein and Grossmann 1913, part 1, sec. 5).

ory,[119] introduces the notion that gravitational energy-momentum should enter the field equations on equal footing with the energy-momentum of matter. Expecting gravitational energy-momentum to be represented by a generally-covariant tensor, Einstein turned to the first Beltrami invariant to find a candidate for the stress-energy tensor of the gravitational field. The contraction of the metric with this supposed gravitational stress-energy tensor, however, turns out to be slightly different from the second contribution to the expression for the second Beltrami invariant, and Einstein abandoned the idea of interpreting this contribution in terms of gravitational energy-momentum.

On p. 9R Einstein tried to find the infinitesimal non-autonomous transformations under which this contribution to the second Beltrami invariant transforms as a scalar. The first contribution, the contraction of the metric and the core operator, would then be the difference between two scalars (for this restricted class of transformations) and therefore be such a scalar itself. This in turn would suggest that the core operator transform as a tensor under these transformations. Since the rationale behind the return to the Beltrami invariants on p. 8R was presumably to avoid non-autonomous transformations, which Einstein had found difficult to handle (see pp. 7L–8R), it is not surprising that the Beltrami invariants no longer explicitly appear in the notebook after these calculations on pp. 8R–9R. Einstein, however, continued to use the restriction to unimodularity in his calculations on the following pages. This suggests that he still hoped to find some connection between the field equations and the Beltrami invariants.

Underneath the first horizontal line on p. 8R, Einstein substituted (some power α 8R
of) the determinant G of the metric for the arbitrary function φ in the definition of the first and the second Beltrami invariants (see equations (79) and (80), respectively):

$$\varphi_1 = \gamma_{\mu\nu}\frac{\partial G}{\partial x_\mu}\frac{\partial G}{\partial x_\nu}\,, \tag{183}$$

$$\varphi_2 = \frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\sqrt{G}\frac{\partial}{\partial x_\nu}G^\alpha\right)\,. \tag{184}$$

Since G is a scalar only under unimodular transformations, the Beltrami invariants φ_1 and φ_2 above are no longer generally-covariant scalars but invariants under this restricted class of transformations only. To establish the connection with the core operator,

119 In (Einstein 1912b, sec. 4), it was pointed out that the field equation originally proposed for the theory for static gravitational fields, $\Delta c = kc\sigma$ (where the variable speed of light c doubles as the gravitational potential, k is a constant, and σ is the mass density), is in conflict with the action-equals-reaction principle and thereby with energy-momentum conservation. Einstein remedied the problem by adding the gravitational energy density to the source term: $\Delta c = k\left\{c\sigma + \frac{1}{2k}\frac{\mathrm{grad}^2 c}{c}\right\}$.

$$\sum \frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}\right) \tag{185}$$

(see equation (118)), Einstein rewrote $\partial G/\partial x_\nu$ as

$$\frac{\partial G}{\partial x_\nu} = \sum_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\nu}G_{i\kappa} = \sum G\frac{\partial g_{i\kappa}}{\partial x_\nu}\gamma_{i\kappa} = -G\sum g_{i\kappa}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}, \tag{186}$$

where $G_{i\kappa}$ is the minor of $g_{i\kappa}$. In the second step, Einstein used that $\gamma_{i\kappa} = G_{i\kappa}/G$, and in the third step that $\partial/\partial x_\nu(\sum g_{i\kappa}\gamma_{i\kappa}) = 0$. Next to this expression he wrote "of zeroth power" ("nullter Potenz").[120]

Inserting the first expression for $\partial G/\partial x_\nu$ in equation (186) into equation (183), Einstein arrived at:

$$\varphi_1 = \sum_{i\kappa lm\mu\nu}\gamma_{\mu\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial g_{lm}}{\partial x_\nu}G_{i\kappa}G_{lm}\right), \tag{187}$$

"or" ("oder"), as he wrote next to it, using the second expression for $\partial G/\partial x_\nu$ in equation (186),

$$\sum \gamma_{\mu\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial g_{lm}}{\partial x_\nu}\gamma_{i\kappa}\gamma_{lm}\right). \tag{188}$$

A factor G^2 is omitted in this last expression. This is inconsequential: since both φ_1 and G are scalars under unimodular transformations, φ_1/G^2 is too.

After drawing a horizontal line, Einstein turned to the second Beltrami invariant,

$$\varphi_2 = \sum \frac{\partial}{\partial x_\mu}\left(\sqrt{G}\gamma_{\mu\nu}\frac{\partial G^\alpha}{\partial x_\nu}\right). \tag{189}$$

Once again, he omitted an inconsequential factor $\sqrt{G}$ (cf. equation (184)).[121] With the help of equation (186), Einstein rewrote this as

120 This is the only place in the notebook where the word "Potenz" occurs. Einstein only wrote "Potenz" after writing and deleting first "of zeroth kind" ("nullter Art") and then "of zeroth order" ("nullter Ordnung"). At the top of p. 9L he switched back to "zeroth order" ("nullter Ordnung"). In (Bianchi 1910, Ch. II, sec. 22), the "order" ("Ordnung") of a "differential parameter" ("Differentialparameter")—i.e., an expression constructed out of the metric and its derivatives and a number of arbitrary functions and their derivatives—is defined as the highest-order derivative of the arbitrary functions occurring in it. Since there are no arbitrary functions in φ_1 and φ_2 in equations (183) and (184), these quantities are of zeroth order in this sense.

121 The expression written next to equation (189), $\partial/\partial x_\mu(\sqrt{G}\gamma_{\mu\nu}\partial\psi/\partial x_\nu)$, is likewise a scalar under unimodular transformations.

$$\alpha\sum\frac{\partial}{\partial x_\mu}\left(\sqrt{G}\gamma_{\mu\nu}G^{\alpha-1}\frac{\partial g_{i\kappa}}{\partial x_\nu}G_{i\kappa}\right)\approx\sum\frac{\partial}{\partial x_\mu}\left(G^{\alpha+\frac{1}{2}}\gamma_{\mu\nu}\gamma_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\nu}\right). \tag{190}$$

As indicated by the proportionality sign, the overall factor α is dropped from the expression. Einstein now set $\alpha = -1/2$ and transferred the differentiation operator $\partial/\partial x_\nu$ from the covariant to the contravariant metric using that $\partial/\partial x_\nu(\sum g_{i\kappa}\gamma_{i\kappa}) = 0$. The resulting expression contains the core operator:

$$\sum\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\gamma_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\nu}\right) = -\sum\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}g_{i\kappa}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu}\right). \tag{191}$$

At the bottom of the page, Einstein briefly turned to the first Beltrami invariant and wrote down a "Different expression for the above scalar φ_1" ("Anderer Ausdruck für obigen Skalar φ_1"):

$$\sum g_{\mu\mu'}\gamma_{\mu\nu}\frac{\partial G}{\partial x_\nu}\gamma_{\mu'\nu'}\frac{\partial G}{\partial x_{\nu'}} \tag{192}$$

(which is indeed equivalent to equation (183) since $g_{\mu\mu'}\gamma_{\mu\nu}\gamma_{\mu'\nu'} = \gamma_{\nu\nu'}$). The phrase "different expression for φ_1" ("Anderer Ausdruck für φ_1") is repeated two lines farther down. Einstein returned to this expression on p. 9L to extract a candidate for the stress-energy tensor of the gravitational field.

Einstein drew a horizontal line and copied the final expression for φ_2 from equation (190),

$$\sum\frac{\partial}{\partial x_\mu}\left(G^{\alpha+\frac{1}{2}}\gamma_{\mu\nu}\gamma_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\nu}\right). \tag{193}$$

Underneath this expression he began to evaluate one of the derivatives in expression (192),

$$\frac{\partial G}{\partial x_\nu} = -\sum g_{i\kappa}\frac{\partial G_{i\kappa}}{\partial x_\nu}, \tag{194}$$

but then deleted the erroneous right-hand side.

Einstein continued his investigation of the Beltrami invariants on p. 9L. He began 9L
by rewriting the first Beltrami invariant (183) modulo a factor G^{-2}. Starting from expression (188) on p. 8R, he transferred the derivative operators from the covariant to the contravariant metric, using that $\partial/\partial x_\mu(\sum g_{i\kappa}\gamma_{i\kappa}) = 0$. He thus arrived at:[122]

122 The quantity φ_1 in equation (195) needs to be multiplied by G^2 to obtain the first Beltrami invariant φ_1 as defined in equation (183). See footnote 120 for a discussion of the term "zeroth order" ("nullter Ordnung") written next to equation (195).

$$\varphi_1 = \sum g_{i\kappa} g_{lm} \gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\mu} \frac{\partial \gamma_{lm}}{\partial x_\nu} . \tag{195}$$

He similarly rewrote expression (190) for the second Beltrami invariant, setting $\alpha = -1/2$ as he had done on p. 8R:

$$\varphi_2 = \sum \frac{\partial}{\partial x_\mu} \left(\cancel{G^{\left(\alpha+\frac{1}{2}\right)}} g_{i\kappa} \gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} \right) . \tag{196}$$

Einstein expanded this expression to

$$\varphi_2 = \sum g_{i\kappa} \frac{\partial}{\partial x_\mu} \left(\gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} \right) + \underbrace{\sum \gamma_{\mu\nu} \frac{\partial g_{i\kappa}}{\partial x_\mu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu}} . \tag{197}$$

The first term is the core operator (185) contracted with the covariant metric. The second term required further attention. Einstein tried to use the relation

$$0 = \sum \left(\frac{\partial g_{i\kappa}}{\partial x_\mu} \gamma_{i\kappa} + g_{i\kappa} \frac{\partial \gamma_{i\kappa}}{\partial x_\mu} \right) \tag{198}$$

to deal with it. Differentiating this relation, he did indeed recover, up to a contraction with $\gamma_{\mu\nu}$, the second term on the right-hand side of equation (197) but at the price of introducing three other terms:

$$0 = \sum \left(\frac{\partial^2 g_{i\kappa}}{\partial x_\mu \partial x_\nu} \gamma_{i\kappa} + \frac{\partial g_{i\kappa}}{\partial x_\mu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} + . + g_{i\kappa} \frac{\partial^2 \gamma_{i\kappa}}{\partial x_\mu \partial x_\nu} \right) \tag{199}$$

Rather than rewriting the second Beltrami invariant with the help of equation (199), Einstein tried to interpret the second term in equation (197) for φ_2 with the help of the first Beltrami invariant modulo a factor G^{-2}, i.e., the quantity φ_1 at the top of p. 9L (see equation (195)).

In the passage in the middle of p. 9L, set off by two horizontal lines, Einstein tried to interpret the difference between φ_2 and the core operator contracted with $g_{i\kappa}$ as minus a candidate gravitational stress-energy tensor contracted with $g_{i\kappa}$. As was explained in the introduction to this subsection, the second Beltrami invariant would then in all likelihood[123] yield a candidate for the left-hand side of the field equations which is (*i*) a tensor under unimodular transformations and (*ii*) equal to the core operator minus the gravitational stress-energy tensor. Setting this candidate equal to the stress-energy tensor for matter, one sees that such field equations satisfy the requirement that all energy-momentum enters the field equations on the same footing. Einstein naturally assumed at this point that gravitational energy-momentum like the

123 In all likelihood, because it obviously cannot be ruled out that the expression is not a tensor even though its contraction with the metric tensor is a scalar. Its contraction with an *arbitrary* second-rank tensor might not be.

energy-momentum of matter would be represented by a tensor.[124] By analogy to both the stress-energy tensor for the electromagnetic field and the one for the gravitational field of his 1912 static theory,[125] he furthermore expected the gravitational stress-energy tensor to be quadratic in first-order derivatives of the metric. Any such object, transforming as a tensor at least under unimodular transformations, would have to be constructed out of the first Beltrami invariant, multiplied possibly by other scalars under unimodular transformations such as the determinant G of the metric. The quantity φ_1 in equation (195) is such an object. Moreover, φ_1 looks very similar to the term in φ_2 to be written as the contraction of $g_{i\kappa}$ with the gravitational stress-energy tensor.[126] Einstein thus tried to extract a gravitational stress-energy tensor from φ_1.

Einstein began this attempt with expression (192) on p. 8R. Dividing this equation by G^2, one arrives at the first equation in the passage set off between two horizontal lines on the bottom half of p. 9L:

$$\varphi_1 = \frac{1}{G^2}\sum g_{\mu\mu'}\,\gamma_{\mu\nu}\frac{\partial G}{\partial x_\nu}\,\gamma_{\mu'\nu'}\frac{\partial G}{\partial x_{\nu'}}. \tag{200}$$

The “presumable gravitation tensor” (“vermutlicher Gravitationstensor”) that can be read off from this expression is:

$$\frac{1}{G^2}\sum_{\nu\nu'}\gamma_{\mu\nu}\frac{\partial G}{\partial x_\nu}\gamma_{\mu'\nu'}\frac{\partial G}{\partial x_{\nu'}} = \sum_{\nu\nu' ii'\kappa\kappa'}\gamma_{\mu\nu}\frac{\partial g_{i\kappa}}{\partial x_\nu}\gamma_{i\kappa}\gamma_{\mu'\nu'}\frac{\partial g_{i'\kappa'}}{\partial x_{\nu'}}\gamma_{i'\kappa'}. \tag{201}$$

(In the second step, Einstein used equation (186).) For the remainder of the argument on p. 9L, however, Einstein used the expression[127]

$$\sum\gamma_{\mu\nu}\gamma_{\mu'\nu'}\frac{\partial\psi}{\partial x_\nu}\frac{\partial\psi}{\partial x_{\nu'}}, \tag{202}$$

defining ψ through

$$\lg G = \psi. \tag{203}$$

---

124 (Einstein and Grossmann 1914, 218, footnote 1) is the first place where Einstein explicitly stated in print that the assumption that gravitational energy-momentum can be represented by a tensor is erroneous. In this footnote he identified this assumption as the flaw in an argument in (Einstein 1914a) that appeared to restrict the covariance of the *Entwurf* field equations to linear transformations. For discussion of this argument and its flaws, see (Norton 1984, sec. 5), “What Did Einstein Know …” sec. 2 and “Untying the Knot …” sec. 3.3 (both in this volume).

125 (Einstein 1912b, 456–457).

126 Using $\frac{\partial g_{i\kappa}}{\partial x_\mu} = -g_{il}g_{\kappa m}\frac{\partial\gamma_{lm}}{\partial x_\mu}$, one can rewrite the second contribution to φ_2 in equation (197) as $\sum\gamma_{\mu\nu}\frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu} = -\sum\gamma_{\mu\nu}g_{il}g_{\kappa m}\frac{\partial\gamma_{lm}}{\partial x_\mu}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu}$, which closely resembles the expression for φ_1 in equation (195).

127 On p. 8R, Einstein had written the second Beltrami invariant in terms of this function ψ (see footnote 121).

He drew a line from expression (202) to the expression on the left-hand side of equation (201) and encircled these two expressions. On the next line, he explicitly made the claim that this choice of a gravitational stress-energy tensor is unique: "[This] is the only tensor in which we differentiate only once" ("Ist der einzige Tensor, in dem nur einmal diff[erenziert] wird").

To see whether his gravitational stress-energy tensor (202) would be acceptable from a physical point of view as well, Einstein, writing "divergence calculated" ("Divergenz gebildet"), substituted it for the stress-energy tensor $T_{\mu\nu}$ of matter in equation (71),

$$\sum_{\nu n}\frac{\partial}{\partial x_n}(\sqrt{G}g_{m\nu}T_{\nu n})+\frac{1}{2}\sqrt{G}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu}=0\,, \tag{204}$$

for the energy-momentum balance between matter and gravitational field.

On p. 5R, Einstein derived this equation for the stress-energy tensor of pressureless dust. He then postulated the same equation for the stress-energy tensor of any matter. Gravitational energy-momentum, however, plays a special role and one cannot simply substitute the gravitational stress-energy tensor for $T_{\mu\nu}$ in equation (204).[128] On p. 9L, Einstein did not recognize the special status of gravitational energy-momentum and demanded that expression (202), his candidate for a gravitational stress-energy tensor, like any other stress-energy tensor $T_{\mu\nu}$, satisfy the energy-momentum balance equation (204):

$$\sum\frac{\partial}{\partial x_{\mu}{}'}\left(\sqrt{G}g_{m\mu}\gamma_{\mu\nu}\gamma_{\mu'\nu'}\frac{\partial\psi}{\partial x_\nu}\frac{\partial\psi}{\partial x_{\nu'}}\right)=\frac{1}{2}\sum\sqrt{G}\frac{\partial g_{\mu\mu'}}{\partial x_m}\gamma_{\mu\nu}\gamma_{\mu'\nu'}\frac{\partial\psi}{\partial x_\nu}\frac{\partial\psi}{\partial x_{\nu'}}\,. \tag{205}$$

Einstein began to simplify both sides of this equation. Using (in slightly modernized notation involving the Kronecker delta) $\sum g_{m\mu}\gamma_{\mu\nu}=\delta_{m\nu}$, he wrote the left-hand side as:

$$\sum\frac{\partial}{\partial x_{\mu}{}'}\left(\sqrt{G}\gamma_{\mu'\nu'}\frac{\partial\psi}{\partial x_m}\frac{\partial\psi}{\partial x_{\nu'}}\right)= \tag{206}$$

He used that

$$\frac{\partial g_{\mu\mu'}}{\partial x_m}\gamma_{\mu\nu}\gamma_{\mu'\nu'}=-g_{\mu\mu'}\frac{\partial\gamma_{\mu\nu}}{\partial x_m}\gamma_{\mu'\nu'}, \tag{207}$$

and that $\sum g_{\mu\mu'}\gamma_{\mu'\nu'}=\delta_{\mu\nu}$ to rewrite the right-hand side of equation (205) as

128 Einstein subsequently recognized that gravitational energy-momentum cannot be handled in the same way as the energy-momentum of matter. On p. 13R, he took a first step in this direction (see sec. , especially the discussion following equation (419)). On p. 19R, he had essentially arrived at the treatment of gravitational energy-momentum that he would use and defend in the ensuing years (see the discussion following equation (481) in sec. 5.4.2; see also pp. 20L, 21L, 24R–26R).

$$= -\frac{1}{2}\sum\sqrt{G}\frac{\partial\gamma_{\nu\nu'}}{\partial x_m}\frac{\partial\psi}{\partial x_\nu}\frac{\partial\psi}{\partial x_{\nu'}} . \tag{208}$$

At this point, Einstein abandoned the ill-conceived condition (205). He also abandoned his attempt to interpret the second term in equation (197) for the Beltrami invariant φ_2 as the contraction of $g_{i\kappa}$ with the gravitational stress-energy tensor (202) extracted from φ_1. Perhaps Einstein had come to realize these two expressions are not quite the same.[129] However, he retained the notion that the left-hand side of the field equations be the sum of two terms, each transforming as a tensor, one term being the core operator, the other term representing gravitational energy-momentum.[130]

At the bottom of p. 9L and the top of p. 9R, Einstein returned to the investigation of the covariance properties of the core operator through its relation with the Beltrami invariant φ_2 in equation (196).[131] The second term in expression (197) for φ_2, which Einstein had tried to interpret as a correction term to the core operator representing gravitational energy-momentum, now had to be dealt with in a new way.[132]

At the top of p. 9R, Einstein copied equation (196) for the second Beltrami invariant φ_2 (see the line connecting the two expressions for φ_2 on pp. 9L–R) leaving the exponent α undetermined rather than setting $\alpha = -1/2$: 9R

$$\varphi_2 = \sum\frac{\partial}{\partial x_\mu}\left(G^{\alpha+\frac{1}{2}}g_{i\kappa}\gamma_{\mu\nu}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu}\right) . \tag{209}$$

In the top right corner of p. 9R, using equation (186) for $\partial G/\partial x_\nu$, Einstein calculated the derivative of $G^{\alpha+1/2}$

$$\frac{\partial G^{\alpha+\frac{1}{2}}}{\partial x_\mu} = \left(\alpha+\frac{1}{2}\right)G^{\alpha+\frac{1}{2}}\sum\frac{\partial g_{\rho\sigma}}{\partial x_\mu}\gamma_{\rho\sigma} . \tag{210}$$

With the help of this relation, φ_2 can be rewritten as:[133]

---

129 The former can be written as $\sum g_{lm}\gamma_{\mu\nu}\frac{\partial\gamma_{il}}{\partial x_\mu}\frac{\partial\gamma_{\kappa m}}{\partial x_\nu}$, the latter as $\sum g_{lm}\gamma_{\mu\nu}\frac{\partial\gamma_{i\kappa}}{\partial x_\mu}\frac{\partial\gamma_{lm}}{\partial x_\nu}$ (cf. footnote 126).

130 Exploiting this general feature, Einstein developed a strategy for finding field equations compatible with the conservation principle. An embryonic version of this strategy can be found on p. 13R. On pp. 26L–R, he used the mature version of this strategy to find the *Entwurf* field equations.

131 At the bottom of p. 9L, Einstein wrote $\varphi_2 = \sum$, drew and then deleted a line connecting this incomplete expression to equation (199) in the middle of the page. A completed version of the expression occurs at the top of p. 9R. The final pair of equations on p. 9L, $a'_\mu = p_{\mu\nu}a_\nu$ and $\alpha'_\mu = \pi_{\mu\nu}\alpha_\nu$, give the transformation laws for contravariant and covariant vectors, respectively (see equations (119) and (120)).

132 From a modern perspective the question arises why Einstein continued to concentrate on the covariance properties of the core operator itself rather than on the covariance properties of the sum of the core operator and the gravitational stress-energy (pseudo-)tensor. The answer to this question is that Einstein tacitly assumed (see footnote 124) that both terms of this sum would separately transform as a tensor.

$$\varphi_2 = \left(\alpha + \frac{1}{2}\right) G^{\alpha + \frac{1}{2}} \sum g_{i\kappa} \gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} \gamma_{\rho\sigma} \frac{\partial g_{\rho\sigma}}{\partial x_\mu} + G^{\alpha + \frac{1}{2}} \sum \frac{\partial}{\partial x}\left(g_{i\kappa} \gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} \right). \tag{211}$$

As is indicated by the grouping of the factors in the expression under the first summation sign, this summation can be rewritten as (cf. equation (186))

$$\sum g_{i\kappa} \gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu} \gamma_{\rho\sigma} \frac{\partial g_{\rho\sigma}}{\partial x_\mu} = -\frac{1}{G^2} \sum \gamma_{\mu\nu} \frac{\partial G}{\partial x_\nu} \frac{\partial G}{\partial x_\nu}. \tag{212}$$

As Einstein noted, this means that the first term on the right-hand side of equation (211) is a scalar: "Obvious because $\partial G / \partial x_\nu$ vector of the second kind [i.e., a covariant vector]" ("Selbstverst[ändlich] weil … Vektor zweiter Art").

The second term on the right-hand side of equation (211) can be written as $G^{\alpha + 1/2}$ times the sum of two terms (see equation (197)): the core operator (185) contracted with g_{ik} and the term

$$\gamma_{\mu\nu} \frac{\partial g_{i\kappa}}{\partial x_\mu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu}, \tag{213}$$

which Einstein had tried in vain on p. 9L to write as the contraction of the metric with a gravitational stress-energy tensor.

On the remainder of p. 9R Einstein investigated under which (infinitesimal) unimodular non-autonomous transformations expression (213) would be invariant. Under such a restricted class of transformations the core operator contracted with $g_{i\kappa}$ and multiplied by $G^{\alpha + 1/2}$ would also be a scalar since, by virtue of equations (211), (212) and (197), it is equal to

$$G^{\alpha + \frac{1}{2}} g_{i\kappa} (\gamma)_{i\kappa} = \varphi_2 - \left(\alpha + \frac{1}{2}\right) G^{\alpha - \frac{3}{2}} \sum \gamma_{\mu\nu} \frac{\partial G}{\partial x_\nu} \frac{\partial G}{\partial x_\nu} - G^{\alpha + \frac{1}{2}} \sum \gamma_{\mu\nu} \frac{\partial g_{i\kappa}}{\partial x_\mu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu}, \tag{214}$$

where we used Einstein's notation $(\gamma)_{i\kappa}$ of p. 7L for the core operator (see equation (130)). The first two terms on the right-hand side transform as scalars under arbitrary unimodular transformations. The left-hand side will thus transform as a scalar under the restricted class of unimodular transformations under which the third term on the right-hand side transforms as a scalar. Presumably, the core operator would then transform as a tensor under these transformations. Einstein thus set out to determine exactly how the class of unimodular transformations would have to be further restricted. As he wrote on the second line below equation (211): "Substitutions must be restricted more" ("Subst[itutionen] müssen mehr eingeschränkt werden").[134]

To find the condition for non-autonomous transformations leaving expression (213) invariant, Einstein used the usual two-step procedure.[135] He started with the expression in primed coordinates

133 The factor $(\alpha + 1/2) G^{\alpha + 1/2}$ in front of the summation sign was added later. In the second term $\partial / \partial x$ should be $\partial / \partial x_\mu$.

$$\sum \gamma'_{\mu\nu} \frac{\partial g'_{i\kappa}}{\partial x'_{\mu}} \frac{\partial \gamma'_{i\kappa}}{\partial x'_{\nu}} . \tag{215}$$

Using the transformation laws for the various ingredients of this expression (see equations (119) and (120) repeated at the bottom of p. 9L), he wrote expression (215) in terms of quantities in unprimed coordinates:

$$\sum \gamma'_{\mu\nu} \frac{\partial g'_{i\kappa}}{\partial x'_{\mu}} \frac{\partial \gamma'_{i\kappa}}{\partial x'_{\nu}} = \sum p_{\mu\alpha} p_{\nu\beta} \gamma_{\alpha\beta} \pi_{\mu l} \pi_{\nu m} \frac{\partial}{\partial x_l} (\pi_{i\delta} \pi_{\kappa\varepsilon} g_{\delta\varepsilon}) \frac{\partial}{\partial x_m} (p_{i\delta'} p_{\kappa\varepsilon'} \gamma_{\delta'\varepsilon'}) , \tag{216}$$

The right-hand side can be simplified by using that the matrices p and π are each other's inverse (see equations (123) and (124)):

$$\sum \gamma_{lm} \frac{\partial}{\partial x_l} (\pi_{i\delta} \pi_{\kappa\varepsilon} g_{\delta\varepsilon}) \frac{\partial}{\partial x_m} (p_{i\delta'} p_{\kappa\varepsilon'} \gamma_{\delta'\varepsilon'}) . \tag{217}$$

At this point, Einstein simplified the derivation by restricting himself to infinitesimal transformations. With the help of the Kronecker delta, the transformation matrices can then be written as

$$\begin{aligned} \pi_{i\delta} &= \delta_{i\delta} + \pi^x_{i\delta} , \\ p_{i\delta'} &= \delta_{i\delta} + p^x_{i\delta'} . \end{aligned} \tag{218}$$

For such infinitesimal transformations, expression (217) reduces to:

$$\sum \gamma_{lm} \frac{\partial g_{\delta\varepsilon}}{\partial x_l} \frac{\partial \gamma_{\delta\varepsilon}}{\partial x_m} + \text{terms of order } p^x \text{ and } \pi^x . \tag{219}$$

Einstein denoted these infinitesimal correction terms as "transformation infinitely small" ("Transformation unendlich klein"). Expression (219) shows that expression (213) transforms as a scalar, if the sum of all terms of order p^x and π^x vanish.[136] This then is the condition on the transformation matrices for infinitesimal non-autonomous transformations leaving expression (213) invariant.

---

134 The calculation on p. 9R thus provides the first example of a strategy that Einstein routinely availed himself of in investigating the covariance properties of candidate field equations extracted from the Riemann tensor (cf. the discussion in sec. 4.1). Rather than trying to find the class of non-autonomous transformations under which the candidate field equations themselves transform as a tensor, he tried to find the class of non-autonomous transformations under which the coordinate restriction with the help of which these field equations could be constructed out of an object of broad covariance transformed as a tensor. In this case that coordinate restriction is to transformations leaving expression (213) invariant.

135 See the introduction to sec. 4.3 for a discussion of how in general one finds the condition for non-autonomous transformations (i.e., transformations for which the transformation matrices depend on the metric and its derivatives) under which a given expression transforming as a tensor under (ordinary) linear transformations retains such transformation behavior under non-linear transformations.

136 This is a concrete example of the condition $\mathbf{C}(\partial, g, p, \pi) = 0$ in sec. 4.3 (see equation (114)).

This condition consists of four terms, which are obtained by differentiating one of the four transformation matrices in expression (217) and replacing the remaining three by Kronecker deltas:[137]

$$\sum \gamma_{lm} \frac{\partial \pi^x_{i\delta}}{\partial x_l} \frac{\partial \gamma_{i\kappa}}{\partial x_m} g_{\delta\kappa}\,, \tag{220}$$

$$\sum \gamma_{lm} \frac{\partial \pi^x_{\kappa\varepsilon}}{\partial x_l} \frac{\partial \gamma_{i\kappa}}{\partial x_m} g_{i\varepsilon}\,, \tag{221}$$

$$\sum \gamma_{lm} \frac{\partial p^x_{i\delta}}{\partial x_m} \frac{\partial g_{i\kappa}}{\partial x_l} \gamma_{\delta\kappa}\,, \tag{222}$$

$$\sum \gamma_{lm} \frac{\partial p^x_{\kappa\varepsilon}}{\partial x_m} \frac{\partial g_{i\kappa}}{\partial x_l} \gamma_{i\varepsilon}\,. \tag{223}$$

Einstein wrote the last two expressions next to the first two, separating the two pairs by a vertical line.

By rewriting expression (220) as[138]

$$\sum \gamma_{lm} \frac{\partial p_{\delta i}}{\partial x_l} \frac{\partial g_{\delta\kappa}}{\partial x_m} \gamma_{i\kappa} \tag{224}$$

(where the superscript "x" was dropped), Einstein showed that it was equal to expression (222) written next to it.[139] Similarly, expression (221) is equal to expression (223) written next to it. The condition for infinitesimal non-autonomous transformations under which expression (213) transforms as a scalar can thus be written as the vanishing of the sum of expressions (222) and (223):

$$\sum \gamma_{lm} \frac{\partial p^x_{i\delta}}{\partial x_m} \frac{\partial g_{i\kappa}}{\partial x_l} \gamma_{\delta\kappa} + \sum \gamma_{lm} \frac{\partial p^x_{\kappa\varepsilon}}{\partial x_m} \frac{\partial g_{i\kappa}}{\partial x_l} \gamma_{i\varepsilon} = 0\,. \tag{225}$$

An additional condition on the transformation coefficients was the requirement that the transformations be unimodular. Einstein thus turned to the determinant

137 Lacking the Kronecker delta, Einstein indicated this procedure as follows. For the term in which the first of the four coefficients $\pi_{i\delta}$, $\pi_{\kappa\varepsilon}$, $p_{i\delta'}$, and $p_{\kappa\varepsilon'}$ in expression (217) is differentiated he wrote underneath expression (219): "$1\ \kappa = \varepsilon\ \ i = \delta'\ \ \kappa = \varepsilon'$."

138 Equation (224) can be obtained from (220) with the help of (in modernized notation) $\gamma_{i\kappa,m} g_{\delta\kappa} = -\gamma_{i\kappa} g_{\delta\kappa,m}$ and $\pi^x_{i\delta} = -p^x_{\delta i}$. The latter relation follows from $p_{\delta\alpha}\pi_{i\alpha} = (\delta_{\delta\alpha} + p^x_{\delta\alpha})(\delta_{i\alpha} + \pi^x_{i\alpha}) = \delta_{\delta i} + p^x_{\delta i} + \pi^x_{i\delta} = \delta_{\delta i}$.

139 Expressions (222) and (224) turn into one another if the summation indices l and m and the summation indices δ and i are switched.

$$\begin{vmatrix} 1+p_{11} & p_{12} & p_{13} & p_{14} \\ p_{21} & 1+p_{22} & p_{23} & p_{24} \\ p_{31} & p_{32} & 1+p_{33} & p_{34} \\ p_{41} & p_{42} & p_{43} & 1+p_{44} \end{vmatrix} \tag{226}$$

of the transformation matrix for the infinitesimal transformation in equation (218).[140] To first order in $p_{\mu\nu}$, the determinant (226) is equal to

$$1 + p_{11} + p_{22} + p_{33} + p_{44} \,. \tag{227}$$

So the condition that an infinitesimal transformation be unimodular is simply that the trace of $p_{\mu\nu}$ (and of $\pi_{\mu\nu}$) vanish:

$$\begin{aligned} \sum p^x_{\alpha\alpha} &= 0\,, \\ \sum \pi^x_{\alpha\alpha} &= 0\,. \end{aligned} \tag{228}$$

As with the conditions for non-autonomous transformations on pp. 7R and 8R, Einstein made no attempt to find transformation matrices depending on the metric that satisfy the conditions (225) and (228). So the calculation of p. 9R did not lead to the identification of any specific non-autonomous transformations under which the core operator would transform as a tensor.

4.5 *Exploring the Covariance of the Core Operator under Hertz Transformations (10L–12R, 41L–R)*

On the preceding pages, Einstein had investigated the covariance properties of the core operator (130),

$$\sum \frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}\right), \tag{229}$$

and of expression (213),

$$\sum \gamma_{\mu\nu}\frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}, \tag{230}$$

by deriving the conditions for non-autonomous transformations under which these objects transform as tensors.[141] None of these investigations had been carried through

140 Following Einstein, we have dropped the subscript "x."

141 See the introduction of sec. 4.3 for discussion of the concept of non-autonomous transformation. On p. 7L, Einstein examined expression (229), deriving conditions (137) and (145) for non-autonomous transformations—finite and infinitesimal, respectively—under which the expression would transform as a tensor. On p. 9R, he examined expression (230), deriving conditions (225) and (228) for infinitesimal unimodular non-autonomous transformations under which this expression would transform as a scalar.

to the end. Errors were made and left uncorrected. Einstein had not even begun the task of finding non-autonomous transformations that would actually be solutions of such conditions. On pp. 10L–11L, however, he made a sustained effort to find infinitesimal unimodular non-autonomous transformations under which a much simpler object, the Hertz expression,

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_\nu}, \tag{231}$$

transforms as a vector. The task at hand was still to determine the covariance properties of the core operator. By focusing on the Hertz expression first, Einstein could split this task into two separate and more manageable tasks. The core operator (229) can be written as the sum of two terms, the first of which contains the Hertz expression:

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_\mu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu} + \sum \gamma_{\mu\nu}\frac{\partial^2 \gamma_{i\kappa}}{\partial x_\mu \partial x_\nu}. \tag{232}$$

10L–R On pp. 10L–10R, Einstein focused on the first term, deriving the condition for unimodular non-autonomous transformations under which the Hertz expression transforms as a vector. We shall call such transformations “Hertz transformations.” Einstein only dealt with infinitesimal Hertz transformations, which simplified his calculations considerably. The restriction to unimodular transformations in the calculations on these and the following pages indicates that he still wanted to connect the core operator to the second Beltrami invariant φ_2 (see equations (209)–(214)).

On p. 10L, in a first attempt to derive the condition for Hertz transformations, Einstein made a mistake he only discovered on p. 10R after he had already moved on to the second term in expression (232). By that time, he had convinced himself that rotation in Minkowski spacetime is a Hertz transformation. Not surprisingly, therefore, when Einstein had derived the correct condition for Hertz transformations, he carefully checked once more whether the class of Hertz transformation include the important special cases of rotation and uniform acceleration in Minkowski spacetime before returning to the investigation of the second term in expression (232).

11L On p. 11L, Einstein established that the matrices $p_{\mu\nu}$ and $\pi_{\mu\nu}$ for transformations to rotating frames in Minkowski spacetime with infinitesimally small angular velocity do indeed satisfy the conditions for infinitesimal Hertz transformations. He noticed that the transformation matrices for *finite* rotations satisfy these conditions for *infinitesimal* transformations as well. From this he seems to have drawn the erroneous conclusion that finite transformations to rotating coordinates in Minkowski spacetime are also Hertz transformations (see sec. 4.5.2). Einstein immediately recognized, however, that transformations to uniformly accelerating coordinate systems in Minkowski spacetime are not Hertz transformations, not even for infinitesimally small accelerations. He initially thought he could circumvent this problem by modifying the transformation (see sec. 4.5.3). So the class of Hertz transformations initially did seem to include rotation and uniform acceleration in Minkowski spacetime.

On p. 11R, Einstein turned to the second term in expression (232) for the core operator (see sec. 4.5.4). He imposed the "Hertz restriction," i.e., the condition that the Hertz expression vanish.[142] Under this restriction, expression (232) reduces to its second term. Einstein now checked whether this term transforms as a tensor under Hertz transformations. He discovered that it does not. At the bottom of p. 11R, he wrote: "Leads to difficulties" ("Führt auf Schwierigkeiten"). The class of Hertz transformations thus needs to be restricted further. If the metric is set equal to the Minkowski metric in its standard diagonal form, the condition expressing this further restriction reduces to the requirement that the matrices $p_{\mu\nu}$ and $\pi_{\mu\nu}$ of the infinitesimal transformations be anti-symmetric. It turns out that the requirement of anti-symmetry is all that is needed to satisfy the conditions defining the class of infinitesimal Hertz transformations as well. In other words, the core operator transforms as a tensor under all infinitesimal anti-symmetric transformations from an inertial pseudo-Cartesian coordinate system in Minkowski spacetime. 11R

At the top of p. 12L, Einstein therefore made an "attempt" ("Versuch") to find anti-symmetric transformations corresponding to infinitesimal rotation in Minkowski spacetime. He went back to p. 11L and noted how the transformation matrix for infinitesimal rotation needs to be changed to make it anti-symmetric. He realized that this is not feasible. The transformation matrix for infinitesimal uniform acceleration is not anti-symmetric either—be it in its original form, or in the modified form introduced on p. 11L. It seems that at this point Einstein deleted the modified form and accepted that the Hertz restriction rules out the important special case of uniform acceleration in Minkowski spacetime. 12L

The upshot then was that the strategy Einstein adopted on p. 10L to study the covariance of the core operator by splitting it into the two terms (see expression (232)) did not produce any physically interesting transformations, not even infinitesimal non-autonomous ones, under which the core operator would transform as a tensor. Einstein's first reaction was to change the definition of the core operator by inserting an extra factor of $\sqrt{G}$. Such extra factors, however, do not affect the argument on pp. 9R–12L. Rather than going through this argument again, Einstein, as he did on p. 11L, turned his attention to the important test cases of rotation and acceleration in Minkowski spacetime. On pp. 12L–R, he carefully examined rotation (see sec. 4.5.6). 12L–R,
On pp. 12R, 41L–R, he systematically studied (autonomous) infinitesimal unimodular transformations with a view to recovering the transformation to uniformly accelerating frames in Minkowski spacetime. His attempt, however, to find a unimodular transformation corresponding to acceleration failed (sec. 4.5.7). Since the case of uniform acceleration was drawn from his 1912 static theory, Einstein now reexamined an important insight connecting the 1912 theory based on one potential (the variable speed of light) and the metric theory based on ten potentials (the components of the metric tensor). This is the insight that the equation of motion of a test particle in a gravitational field can be obtained from a variational principle with the line element serv- 41L–R

142 See sec. 4.1 for the definition of a coordinate restriction.

ing as the Lagrangian. A consideration of constrained motion on a curved surface probably reassured him that this insight was sound (sec. 4.5.8).

4.5.1 *Deriving the Conditions for Infinitesimal Hertz Transformations (10L–R)*

10L At the top of p. 10L, Einstein wrote down the transformation law for the Hertz expression:

$$\sum \frac{\partial \gamma'_{\mu\nu}}{\partial x'_{\nu}} = \sum \pi_{\nu\sigma} \frac{\partial}{\partial x_{\sigma}} (p_{\mu\alpha} p_{\nu\beta} \gamma_{\alpha\beta}). \tag{233}$$

The structure of this quantity is considerably simpler than that of expression (213) on p. 9R. The condition for non-autonomous transformations under which the Hertz expression transforms as a vector will likewise be considerably simpler than condition (225) on p. 9R, for non-autonomous transformations under which expression (213) transforms as a scalar. Condition (225) is the one referred to in the header of p. 10L: "For comparison with this condition" ("Zum Vergleich mit dieser Bedingung"). Einstein applied his usual two-step procedure to find the condition characterizing what we called "Hertz transformations," i.e., unimodular non-autonomous transformations under which the Hertz expression transforms as a vector.[143]

Einstein rewrote the right-hand side of equation (233) as

$$\sum p_{\mu\alpha} \frac{\partial \gamma_{\alpha\sigma}}{\partial x_{\sigma}} + \sum \gamma_{\alpha\sigma} \frac{\partial p_{\mu\alpha}}{\partial x_{\sigma}}, \tag{234}$$

where he used that the matrices $\pi_{\nu\sigma}$ and $p_{\nu\beta}$ —connected by the line in equation (233)—are the inverse of one another and assumed that $\sum \pi_{\nu\sigma}(\partial p_{\nu\beta}/\partial x_{\sigma})$ vanishes. This assumption holds for infinitesimal unimodular transformations (see note 148 below) but not in general, as Einstein soon came to realize.[144]

Einstein was now ready for the first step of his two-step procedure. For non-autonomous transformations under which the Hertz expression transforms as a vector, the transformation of the Hertz expression from primed to unprimed coordinates is given by:

$$\frac{\partial \gamma_{\kappa\lambda}}{\partial x_{\lambda}} = \pi_{\mu\kappa} \frac{\partial \gamma'_{\mu\nu}}{\partial x'_{\nu}}. \tag{235}$$

Einstein omitted this step and immediately wrote down the second step, expressing the right-hand side in terms of unprimed quantities. Using the abbreviation α_{κ} for the Hertz expression,[145] and using equations (233)–(234), he wrote:

---

143 On p. 10L Einstein only gives the condition for infinitesimal Hertz transformations. See footnote 146 below for a self-contained derivation of the condition for finite transformations. See the introduction to sec. 4.3 for general discussion of the two-step procedure.

144 Einstein had made use of the relation $\sum \pi_{\nu\sigma}(\partial p_{\nu\beta}/\partial x_{\sigma}) = 0$ in situations in which this was not warranted before (see equation (128) and footnote 98).

$$\alpha_\kappa = \sum \pi_{\mu\kappa} p_{\mu\alpha} \frac{\partial \gamma_{\alpha\sigma}}{\partial x_\sigma} + \sum \pi_{\mu\kappa} \frac{\partial p_{\mu\alpha}}{\partial x_\sigma} \gamma_{\alpha\sigma} . \tag{236}$$

The first term on the right-hand side is equal to α_κ . Einstein thus concluded that the condition for non-autonomous transformations under which the Hertz expression transforms as a tensor is:

$$\sum \pi_{\mu\kappa} \frac{\partial p_{\mu\alpha}}{\partial x_\sigma} \gamma_{\alpha\sigma} = 0 . \tag{237}$$

For infinitesimal unimodular transformations this is correct (see note 148 below), but in general, there will be additional terms.[146]

To simplify condition (237), Einstein restricted himself to infinitesimal transformations,

$$\begin{aligned} p_{\mu\nu} &= \delta_{\mu\nu} + p^x_{\mu\nu} \\ \pi_{\mu\nu} &= \delta_{\mu\nu} + \pi^x_{\mu\nu} \end{aligned} \tag{238}$$

with $p^x_{\mu\nu} = -\pi^x_{\nu\mu}$ (see p. 9R and footnote 138). As he wrote underneath the second term on the right-hand side of equation (236): “for infinitesimal transformations” (“für infinitesimale Transformationen”)

$$\sum \frac{\partial p^x_{\kappa\alpha}}{\partial x_\sigma} \gamma_{\alpha\sigma} = 0 . \tag{239}$$

This equation, he continued, “Is a system of four conditions for the p^x if this should always vanish. Furthermore, the determinant should always be equal to 1.

145 On p. 6R, Einstein had used the notation α_κ for a covariant vector (see equation (88)).

146 The condition for *finite* Hertz transformations will be important for understanding Einstein’s argument on p. 11L (see sec. 4.5.2). The derivation of this condition is fully analogous to the derivation of condition (237) for infinitesimal Hertz transformations. For finite transformations, equation (236) needs to be replaced by:

$$\alpha_\kappa = \pi_{\mu\kappa} \alpha'_\mu = \pi_{\mu\kappa} \left(\frac{\partial \gamma'_{\mu\nu}}{\partial x'_\nu} \right) = \pi_{\mu\kappa} \pi_{\nu\sigma} \frac{\partial}{\partial x_\sigma} (p_{\mu\alpha} p_{\nu\beta} \gamma_{\alpha\beta})$$

This gives a sum of three terms

$$\alpha_\kappa = \pi_{\mu\kappa} \pi_{\nu\sigma} p_{\mu\alpha} p_{\nu\beta} \frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma} + \pi_{\mu\kappa} \pi_{\nu\sigma} \frac{\partial p_{\mu\alpha}}{\partial x_\sigma} p_{\nu\beta} \gamma_{\alpha\beta} + \pi_{\mu\kappa} \pi_{\nu\sigma} p_{\mu\alpha} \frac{\partial p_{\nu\beta}}{\partial x_\sigma} \gamma_{\alpha\beta} ,$$

which can be rewritten as

$$\alpha_\kappa = \alpha_\kappa + \pi_{\mu\kappa} \frac{\partial p_{\mu\alpha}}{\partial x_\sigma} \gamma_{\alpha\sigma} - \frac{\partial \pi_{\nu\sigma}}{\partial x_\sigma} p_{\nu\beta} \gamma_{\kappa\beta} ,$$

where in the third term on the right-hand side the relation $\pi_{\nu\sigma}(\partial p_{\nu\beta}/\partial x_\sigma) = -(\partial \pi_{\nu\sigma}/\partial x_\sigma) p_{\nu\beta}$ was used, which follows from $\partial/\partial x_\sigma(\pi_{\nu\sigma} p_{\nu\beta})$. Hence the condition for *finite* Hertz transformations is:

$$\pi_{\mu\kappa} \frac{\partial p_{\mu\alpha}}{\partial x_\sigma} \gamma_{\alpha\sigma} - \frac{\partial \pi_{\nu\sigma}}{\partial x_\sigma} p_{\nu\beta} \gamma_{\kappa\beta} = 0 .$$

$\sum p^x_{\alpha\alpha} = 0$.” (“Ist für die p^x ein System von 4 Bedingungen, wenn dies stets verschwinden soll. Ferner soll Determinante stets gleich 1 sein. $\sum p^x_{\alpha\alpha} = 0$.”).

As Einstein notes here, for infinitesimal unimodular transformations

$$\det(p) = \det(\pi) = 1 . \tag{240}$$

It follows that the trace of the matrices $p^x_{\mu\nu}$ and $\pi^x_{\mu\nu}$ vanishes:[147,148]

$$\sum p^x_{\alpha\alpha} = \sum \pi^x_{\alpha\alpha} = 0 . \tag{241}$$

Together, equations (239) and (241) thus determine the class of infinitesimal Hertz transformations (i.e., infinitesimal unimodular non-autonomous transformations under which the Hertz expression transforms as a vector).

Raising the question, “Is it possible to have both?” (“Ist beides möglich?”), Einstein now set out to solve equations (239) and (241) for the transformation matrix $p^x_{\mu\nu}$ in the special case that $\gamma_{\mu\nu}$ in equation (239) is a constant diagonal metric (be it Euclidean or Minkowskian). He first considered the two-dimensional and then the three-dimensional case.

Einstein introduced the coordinate transformations

$$\begin{aligned} x' &= X(x, y), \\ y' &= Y(x, y). \end{aligned} \tag{242}$$

The corresponding differentials can be written as:

$$\begin{aligned} dx' &= \frac{\partial X}{\partial x}dx + \frac{\partial X}{\partial y}dy, \\ dy' &= \frac{\partial Y}{\partial x}dx + \frac{\partial Y}{\partial y}dy. \end{aligned} . \tag{243}$$

From this one can read off the matrix

$$p_{\mu\nu} = \begin{pmatrix} \frac{\partial X}{\partial x} & \frac{\partial X}{\partial y} \\ \frac{\partial Y}{\partial x} & \frac{\partial Y}{\partial y} \end{pmatrix} . \tag{244}$$

Condition (241) then reduces to[149]

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} = 2 . \tag{245}$$

To the right of equation (245), Einstein specified that the metric be diagonal[150]

147 Cf. equation (227). The condition is illustrated by a simple example written underneath it:

$$\begin{matrix} 1+\varepsilon_1 & & \\ & 1+\varepsilon_2 & \end{matrix} \quad 1 + \varepsilon_1 + \varepsilon_2 = 1$$

$$\begin{matrix} \gamma_{11} = 1 & \gamma_{22} = 1 \\ \multicolumn{2}{c}{\gamma_{12} = 0} \end{matrix} \quad . \tag{246}$$

Inserting these values into condition (239), one finds:

$$\begin{aligned} \frac{\partial p_{1\alpha}^{x}}{\partial x_{\sigma}}\gamma_{\alpha\sigma} &= \frac{\partial p_{11}^{x}}{\partial x_{1}}\gamma_{11} + \frac{\partial p_{12}^{x}}{\partial x_{2}}\gamma_{22} = \frac{\partial p_{11}^{x}}{\partial x_{1}} + \frac{\partial p_{12}^{x}}{\partial x_{2}} = 0, \\ \frac{\partial p_{2\alpha}^{x}}{\partial x_{\sigma}}\gamma_{\alpha\sigma} &= \frac{\partial p_{21}^{x}}{\partial x_{1}}\gamma_{11} + \frac{\partial p_{22}^{x}}{\partial x_{2}}\gamma_{22} = \frac{\partial p_{21}^{x}}{\partial x_{1}} + \frac{\partial p_{22}^{x}}{\partial x_{2}} = 0. \end{aligned} \tag{247}$$

Inserting equation (244) for $p_{\mu\nu}$ into equation (247), one finds:

$$\begin{aligned} \frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 X}{\partial y^2} &= 0, \\ \frac{\partial^2 Y}{\partial x^2} + \frac{\partial^2 Y}{\partial y^2} &= 0. \end{aligned} \tag{248}$$

Einstein omitted the terms with p_{12}^{x} and p_{21}^{x} in equation (247) at this point and used the erroneous set of equations

$$\frac{\partial^2 X}{\partial x^2} = 0, \quad \frac{\partial^2 Y}{\partial y^2} = 0 . \tag{249}$$

---

148 It turns out that for infinitesimal unimodular transformations $\sum \pi_{\nu\sigma}(\partial p_{\nu\beta}/\partial x_{\sigma}) = 0$ and that equation (234) is correct. This, in turn, means that conditions (239)–(241) correctly specify the class of infinitesimal Hertz transformations. The aborted calculation in the top-right corner of p. 10L suggests that Einstein realized this. He began by writing down the term he had omitted in going from equation (233) to equation (234):

$$\sum \pi_{\nu\sigma} p_{\mu\alpha} \frac{\partial p_{\nu\beta}}{\partial x_{\sigma}} \gamma_{\alpha\beta} .$$

Underneath this expression, he wrote:

$$\sum \frac{\partial \pi_{\nu\sigma}}{\partial x_{\sigma}} .$$

One can indeed transfer the derivative operator $\partial/\partial x_{\sigma}$ in expression above from $p_{\nu\beta}$ to $\pi_{\nu\sigma}$. This follows from:

$$0 = \frac{\partial}{\partial x_{\sigma}}(\pi_{\nu\sigma} p_{\nu\beta}) = \pi_{\nu\sigma}\frac{\partial p_{\nu\beta}}{\partial x_{\sigma}} + \frac{\partial \pi_{\nu\sigma}}{\partial x_{\sigma}} p_{\nu\beta} .$$

Condition (241) for infinitesimal unimodular transformations implies that $\partial \pi_{\nu\sigma}/\partial x_{\sigma}$ vanishes:

$$\frac{\partial \pi_{\nu\sigma}}{\partial x_{\sigma}} = \frac{\partial \pi_{\nu\sigma}^{x}}{\partial x_{\sigma}} = -\frac{\partial p_{\sigma\nu}^{x}}{\partial x_{\sigma}} = -\frac{\partial p_{\sigma\sigma}^{x}}{\partial x_{\nu}} = 0 .$$

where we used that $\pi_{\nu\sigma}^{x} = p_{\sigma\nu}^{x}$ (see footnote 138) and that

$$\frac{\partial p_{\sigma\nu}^{x}}{\partial x_{\sigma}} = \frac{\partial}{\partial x_{\sigma}}\left(\frac{\partial x'_{\sigma}}{\partial x_{\nu}}\right) = \frac{\partial}{\partial x_{\nu}}\left(\frac{\partial x'_{\sigma}}{\partial x_{\sigma}}\right) = \frac{\partial p_{\sigma\sigma}^{x}}{\partial x_{\nu}} .$$

This concludes the proof that the expression in the top-right corner of p. 10L vanishes for infinitesimal unimodular transformations and that the transition from equation (233) to equation (234) is justified in this case.

149 Einstein originally wrote X' and Y' and then deleted the primes.

Einstein eventually discovered his error. The calculation on pp. 10L–R based on equations (249) is deleted and a fresh start is made at the bottom of p. 10R, based on the correct set of equations (248) (see equations (290)–(291) below). But first we shall discuss the deleted calculations on pp. 10L–R

Integrating equations (249), Einstein arrived at

$$\frac{\partial X}{\partial x} = \psi(y) \qquad \frac{\partial Y}{\partial y} = \chi(x) \tag{250}$$

with arbitrary functions ψ and χ. The unimodularity condition (245) requires that:

$$\psi(y) + \chi(x) = 2\,. \tag{251}$$

Einstein concluded that ψ and χ would "both [be] constant" ("beide konstant."). So the only infinitesimal Hertz transformations in the two-dimensional case are linear transformations.

In an attempt to find non-linear transformations, Einstein turned to the next simplest case, a Euclidean space of "three dimensions" ("drei Dimensionen") with a constant diagonal metric. Starting point of the calculation is the coordinate transformation (cf. equation (242)):

$$\begin{aligned} x' &= X(x, y, z), \\ y' &= Y(x, y, z), \\ z' &= Z(x, y, z). \end{aligned} \tag{252}$$

The matrix $p_{\mu\nu}$ is thus given by (cf. equation (244)):

$$p_{\mu\nu} = \begin{pmatrix} \frac{\partial X}{\partial x} & \frac{\partial X}{\partial y} & \frac{\partial X}{\partial z} \\ \frac{\partial Y}{\partial x} & \frac{\partial Y}{\partial y} & \frac{\partial Y}{\partial z} \\ \frac{\partial Z}{\partial x} & \frac{\partial Z}{\partial y} & \frac{\partial Z}{\partial z} \end{pmatrix}. \tag{253}$$

The analogue of equation (245), expressing unimodularity, is

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} + \frac{\partial Z}{\partial z} = 3\,, \tag{254}$$

while the analogues of conditions (249)—again with omission of non-diagonal terms of $p^x_{\mu\nu}$ — are

$$\frac{\partial^2 X}{\partial x^2} = 0, \qquad \frac{\partial^2 Y}{\partial y^2} = 0, \qquad \frac{\partial^2 Z}{\partial z^2} = 0\,. \tag{255}$$

150 He first wrote down the Euclidean metric $\mathrm{diag}(1, 1)$ and later changed it to the Minkowski metric $\mathrm{diag}(-1, 1)$.

Integrating these equations, Einstein wrote (cf. equation (250)):

$$\frac{\partial X}{\partial x} = \psi_1(y, z)\,, \tag{256}$$

$$\frac{\partial Y}{\partial y} = \psi_2(x, z)\,, \tag{257}$$

$$\frac{\partial Z}{\partial z} = \psi_3(x, y)\,. \tag{258}$$

Inserting these expressions into equation (254) and introducing

$$\psi_i^x \equiv \psi_i - 1\ \ , \tag{259}$$

he obtained:

$$\psi_1^x(y, z) + \psi_2^x(x, z) + \psi_3^x(x, y) = 0\,. \tag{260}$$

Taking the derivative of equation (260) with respect to z and dropping the superscript x, Einstein found, at the bottom of p. 10L:

$$\frac{\partial\psi_1}{\partial z} + \frac{\partial\psi_2}{\partial z} = 0\,. \tag{261}$$

At the top of p. 10R, Einstein integrated this last equation, writing the result as 10R

$$\psi_1 + \psi_2 = \chi_3(x, y)\,. \tag{262}$$

Taking the derivative of equation (260) with respect to x and y, one similarly finds

$$\psi_2 + \psi_3 = \chi_1(y, z)\,, \tag{263}$$

and

$$\psi_1 + \psi_3 = \chi_2(x, z)\,, \tag{264}$$

respectively. Einstein explicitly wrote down equation (263), but not equation (264).

Since both $\psi_1(y, z)$ and $\psi_2(z, x)$ depend on z, while their sum, according to (262), does not, Einstein could write them in the form

$$\psi_1(y, z) = \psi_1(y) + \zeta\,, \tag{265}$$

$$\psi_2(z, x) = \psi_2(x) - \zeta\,, \tag{266}$$

where ζ is some function of z. He used equation (260) to write ψ_3 as:

$$\psi_3(x, y) = -\psi_1(y) - \psi_2(x)\,. \tag{267}$$

Now insert equations (265)–(267) into the equations (256)–(258), keeping in mind that *all* ψ_is in equations (265)–(267) are actually ψ_i^xs related to the ψ_is in equations (256)–(258) through $\psi_i = 1 + \psi_i^x$.

$$\frac{\partial X}{\partial x} = 1 + \psi_1^x(y) + \zeta\,, \tag{268}$$

$$\frac{\partial Y}{\partial y} = 1 + \psi_2^x(x) - \zeta\,, \tag{269}$$

$$\frac{\partial Z}{\partial z} = 1 - \psi_1^x(y) - \psi_2^x(x)\,. \tag{270}$$

Integrating these equations, one finds[151]

$$X = x(1 + \psi_1^x(y) + \zeta) + \omega_1(y, z)\,, \tag{271}$$

$$Y = y(1 + \psi_2^x(x) - \zeta) + \omega_2(x, z)\,, \tag{272}$$

$$Z = z(1 - \psi_1^x(y) - \psi_2^x(x)) + \omega_3(x, y)\,. \tag{273}$$

Einstein now considered a special case. Writing “Specified” (“Spezialisiert”), he set $\psi_1^x(y)$, $\psi_2^x(x)$, and the quantities ω_i to zero and $\zeta = \alpha z$, with $\alpha \ll 1$. Equations (271)–(273) then reduce to:[152]

$$\begin{aligned} X &= x + \alpha xz, \\ Y &= y - \alpha yz, \\ Z &= z. \end{aligned} \tag{274}$$

Next to this transformation, Einstein wrote: “Is torsion and, in the case $z = t$, uniform rotation. Torsion very special case.” (“Ist Torsion & im Falle $z = t$ gleichformige Drehung. Torsion ganz spezieller Fall.”). The transformation (274) is indeed a very special case of the much more general transformation (271)–(273); it does not, however, correspond to torsion, nor, with $z = t$, to rotation.

The transformation setting an inertial pseudo-Cartesian coordinate system in Minkowski spacetime rotating with angular velocity ω is given by:

$$\begin{aligned} x' &= x\cos\omega t + y\sin\omega t, \\ y' &= -x\sin\omega t + y\cos\omega t, \\ t' &= t. \end{aligned} \tag{275}$$

---

151 Instead of equations (271)–(273), Einstein wrote down the equations:

$$\begin{aligned} X &= x(\psi_1(y) + \zeta) = x(-\eta + \zeta) + \omega_1(y, z), \\ Y &= y(\psi_2(x) - \zeta) = y(-\zeta + \xi) + \omega_2(z, x), \\ Z &= -z(\psi_1(y) - \psi_2(z)) = z(-\xi + \eta) + \omega_3(x, y), \end{aligned}$$

where $\xi \equiv \psi_2(x)$ and $\eta \equiv -\psi_1(y)$. These equations contain a number of mistakes. In the third line, $\psi_1(y) - \psi_2(z)$ should be $\psi_1(y) + \psi_2(x)$. In all three lines, ψ_i^x and ψ_i are conflated and the integration constants ω_i are missing after the first equality sign. Einstein also defined and then deleted the quantities $\delta x \equiv \psi_1$ and $\delta y \equiv \psi_2$ (cf. equation (373) at the bottom of p. 12R where δx is essentially defined as dX.).

152 As a consequence of Einstein’s conflation of ψ_i^x and ψ_i (see the preceding note), the notebook has $X = \alpha xz$, $Y = -\alpha yz$ and $Z = 0$ instead of equations (274).

For infinitesimal ω, this transformation reduces to:

$$\begin{aligned} x' &= x + \omega y t, \\ y' &= y - \omega x t, \\ t' &= t, \end{aligned} \tag{276}$$

which is clearly not the same as transformation (274) with $z = t$. Einstein did not realize this until later.

He did, however, realize at this point that he had made an error in evaluating condition (239) for the special case of a constant diagonal metric.[153] Under the header, "Conditions of integrability" ("Integrabilitätsbedingungen"), he partly corrected this error:[154]

$$\frac{\partial p^x_{xx}}{\partial x} + \frac{\partial p^x_{yx}}{\partial y} + \cdot = \frac{\partial}{\partial x}\frac{\partial X}{\partial x} + \frac{\partial}{\partial y}\frac{\partial Y}{\partial x} + \frac{\partial}{\partial z}\frac{\partial Z}{\partial x} = 0\,. \tag{277}$$

This condition, however, is still satisfied by the solutions of the erroneous conditions (255) that Einstein had used up to this point.[155] A line drawn from the header above equation (277) to these solutions (see equations (271)–(273) and footnote 151), suggests that Einstein actually checked this. This would explain why he initially simply proceeded with the next part of his investigation of the transformation properties of the core operator.

On the next line he wrote the contraction of the core operator (130) with some arbitrary covariant tensor $T_{i\kappa}$:[156]

$$\sum T_{i\kappa}\frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu}\frac{\partial \gamma_{i\kappa}}{\partial x_\nu}\right) = \text{Skalar}\,. \tag{278}$$

The core operator will transform as a tensor under all transformations under which its contraction with $T_{i\kappa}$ transforms as a scalar. When the Hertz restriction (i.e., $\sum \partial\gamma_{\mu\nu}/\partial x_\mu = 0$) is imposed, the contraction (278) reduces to:

153 See equation (248) for the correct form of the condition in the two-dimensional case and equation (255) for the incorrect form in the three dimensional case used by Einstein in his derivation of the general transformation (271)–(273).

154 The crucial residual error in the equation below is that it has $\partial p^x_{yx}/\partial y$ instead of $\partial p^x_{xy}/\partial y$. Inserting $\gamma_{\mu\nu} = \mathrm{diag}(1, 1, 1)$ into condition (239), $\sum(\partial p^x_{\kappa\alpha}/\partial x_\sigma)\gamma_{\alpha\sigma} = 0$, one finds $\frac{\partial p^x_{xx}}{\partial x} + \frac{\partial p^x_{xy}}{\partial y} + \frac{\partial p^x_{xz}}{\partial z} = \frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 X}{\partial y^2} + \frac{\partial^2 X}{\partial z^2}$ for the $\kappa = 1$ component instead of equation (277) in the notebook.

155 Inserting equations (271)–(273) into the three terms on the right-hand side of equation (277), one finds zero, $\partial\psi^x_2(x)/\partial x$, and $-\partial\psi^x_2(x)/\partial x$, respectively.

156 So far Einstein had used Latin letters for contravariant objects (see, e.g., equation (146) for a_μ and $T_{\mu\nu}$ on p. 7R)

$$\sum T_{i\kappa}\gamma_{\mu\nu}\frac{\partial^2\gamma_{i\kappa}}{\partial x_\mu \partial x_\nu}. \tag{279}$$

The Hertz restriction is invariant under Hertz transformations. Hence, if Einstein could show that expression (279) transforms as a scalar under infinitesimal Hertz transformations, he would have shown that the core operator transforms as a tensor under such transformations. This is precisely the problem that Einstein takes up at the top of p. 11R, where he raises the question whether expression (279) is a scalar. On p. 10R, however, he did not proceed beyond equation (278).

Expressions (277) and (278) were deleted and Einstein returned to condition (239) for infinitesimal Hertz transformations. It was probably at this point that in the upper-right corner of p. 10R, he wrote down the $\kappa = 1$ component of condition (239) for the special case of a diagonal Euclidean metric:

$$\frac{\partial p_{11}}{\partial x_1}+\frac{\partial p_{12}}{\partial x_2}+\frac{\partial p_{13}}{\partial x_3} = 0. \tag{280}$$

Inserting equation (253) for $p_{\mu\nu}$ into equation (280), one finds:

$$\frac{\partial^2 X}{\partial x^2}+\frac{\partial^2 X}{\partial y^2}+\frac{\partial^2 X}{\partial z^2} = 0. \tag{281}$$

For the $\kappa = 2$ and $\kappa = 3$ components, one similarly finds:

$$\frac{\partial^2 Y}{\partial x^2}+\frac{\partial^2 Y}{\partial y^2}+\frac{\partial^2 Y}{\partial z^2} = 0, \tag{282}$$

$$\frac{\partial^2 Z}{\partial x^2}+\frac{\partial^2 Z}{\partial y^2}+\frac{\partial^2 Z}{\partial z^2} = 0. \tag{283}$$

Einstein, however, still continued to use the transformations (271)–(273) he found as a solution of conditions (255), an erroneous version of conditions (281)–(283) and similar conditions for Y and Z. Inserting equation (271) for X into equation (281), he found:

$$\Delta X = 0 = \frac{\partial^2\omega_1}{\partial y^2}+\frac{\partial^2\omega_1}{\partial z^2}. \tag{284}$$

The solution of this harmonic differential equation is:

$$\omega_1 = \alpha+\beta y+\gamma z+\delta yz+\varepsilon(y^2-z^2). \tag{285}$$

He added one more line,[157]

$$\delta x = \text{konst.}+\alpha_1 z\langle\delta y\rangle+\alpha_2 y\langle\delta z\rangle+\quad, \tag{286}$$

before he realized that the replacement of conditions (255) by conditions (281)–(283) invalidated much of the subsequent calculation on pp. 10L–R. He deleted this calcu-

157 Cf. equation (373) at the bottom of p. 12R where δx is essentially defined as dX.

lation—equations (245)–(286), with the exception of equation (280) at the top of p. 10R—and made a fresh start.

Einstein went back to the two-dimensional case examined on p. 10L. The unimodularity condition (241) for this case can still be written as (see equation (245)):

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} = 2 , \tag{287}$$

He then turned to condition (239) for non-autonomous transformations with $\gamma_{\mu\nu} = \delta_{\mu\nu}$ (see equations (247)–(248)). For the first component of condition (239), he now correctly wrote:

$$\frac{\partial p_{11}}{\partial x_1} + \frac{\partial p_{12}}{\partial x_2} = 0 . \tag{288}$$

Substituting

$$p_{11} = \frac{\partial X}{\partial x} \qquad p_{12} = \frac{\partial X}{\partial y} \tag{289}$$

(cf. equation (244)) into in equation (288), he found:

$$\frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 X}{\partial y^2} = 0 . \tag{290}$$

For the second component of condition (239), he similarly wrote

$$\frac{\partial^2 Y}{\partial x^2} + \frac{\partial^2 Y}{\partial y^2} = 0 . \tag{291}$$

Equations (290) and (291) are easily solved:

$$X = \alpha_1 xy + \alpha_2 (x^2 - y^2) + x , \tag{292}$$

$$Y = \beta_1 xy + \beta_2 (x^2 - y^2) + y . \tag{293}$$

Einstein started to calculate $p_{11} = \partial X / \partial x$ for these coordinate transformations, but proceeded no further than

$$p_{11} = \alpha_1 y + 2 . \tag{294}$$

He then substituted equations (292)–(293) into the unimodularity condition (287) and found

$$\alpha_1 y + 2\alpha_2 x + \beta_1 x - 2\beta_2 y = 0 . \tag{295}$$

The constants of integration α_1, α_2, β_1, and β_2 thus have to satisfy

$$\beta_1 = -2\alpha_2 , \tag{296}$$

$$\alpha_1 = 2\beta_2 . \tag{297}$$

Equations (292)–(293) with conditions (296)–(297) give the general form for infinitesimal Hertz transformations for the special case of the two-dimensional Euclidean metric $\gamma_{\mu\nu} = \delta_{\mu\nu}$.

11L

4.5.2 *Checking Whether Rotation in Minkowski spacetime Is a Hertz Transformation (11L)*

On p. 11L Einstein checked whether transformations to uniformly rotating and uniformly accelerating frames in Minkowski spacetime are included in the class of (infinitesimal) Hertz transformations that he had studied on pp. 10L–R. At the top of the page, under the header "Rotation" ("Drehung"), he dealt with the former; under a horizontal line in the middle of the page, under the header "Acceleration" ("Beschleunigung"), he dealt with the latter. Einstein concluded that both infinitesimal and finite rotations in Minkowski spacetime are Hertz transformations. This is true for infinitesimal but not for finite rotations. Einstein also found, however, that uniform accelerations in Minkowski spacetime, whether infinitesimal or finite, are not Hertz transformations (see sec. 4.5.3).

The condition for some unimodular non-autonomous transformation to be a Hertz transformation (i.e., a unimodular transformation under which the Hertz expression, $\partial\gamma_{\mu\nu}/\partial x_\nu$, transforms as a vector) is:

$$\pi_{\mu\kappa}\frac{\partial p_{\mu\alpha}}{\partial x_\sigma}\gamma_{\alpha\sigma} - \frac{\partial \pi_{\nu\sigma}}{\partial x_\sigma}p_{\nu\beta}\gamma_{\kappa\beta} = 0 \tag{298}$$

(see footnote 146). For infinitesimal transformations the second term vanishes and this condition reduces to:

$$\frac{\partial p_{\kappa\alpha}}{\partial x_\sigma}\gamma_{\alpha\sigma} = 0 \tag{299}$$

(see equation (239)). For infinitesimal transformation the condition for unimodularity reduces to the requirement that the trace of $p^x_{\mu\nu} \equiv p_{\mu\nu} - \delta_{\mu\nu}$ and $\pi^x_{\mu\nu} \equiv \pi_{\mu\nu} - \delta_{\mu\nu}$ vanish:

$$p^x_{\alpha\alpha} = \pi^x_{\alpha\alpha} = 0\,. \tag{300}$$

(see equation (241)).

At the top of p. 11L, next to a drawing indicating rotation, Einstein wrote down the transformation from an inertial pseudo-Cartesian coordinate system in Minkowski spacetime to a coordinate system uniformly rotating with angular velocity ω:[158]

$$\begin{aligned} x' &= x\cos\omega t + y\sin\omega t \\ y' &= -x\sin\omega t + y\cos\omega t \\ t' &= t\,. \end{aligned} \tag{301}$$

158 Anticipating the next step in the calculation, Einstein wrote $dt' = dt$ instead of $t' = t$.

The differentials of the coordinates transform as:

$$\begin{aligned} dx' &= \cos\omega t\ dx + \sin\omega t\ dy + (-x\sin\omega t + y\cos\omega t)\omega dt \\ dy' &= -\sin\omega t\ dx + \cos\omega t\ dy + (-x\cos\omega t - y\sin\omega t)\omega dt \\ dt' &= \quad 0 \quad dx + \quad 0 \quad dy \qquad\qquad + \qquad\qquad dt. \end{aligned} \tag{302}$$

For an infinitesimal rotation, equation (302) reduces to:

$$\begin{aligned} dx' &= \qquad dx + \omega t\ dy + y\omega\ dt \\ dy' &= -\omega t\ dx + \qquad dy - x\omega\ dt \\ dt' &= \qquad\qquad\qquad\qquad dt, \end{aligned} \tag{303}$$

from which one can read off the components of the transformation matrix $p_{\alpha\beta}$, the "table of p" ("Tabelle der p"):[159]

$$p_{\alpha\beta} = \begin{pmatrix} 1 & \omega t & y\omega \\ -\omega t & 1 & -x\omega \\ 0 & 0 & 1 \end{pmatrix}. \tag{304}$$

For this matrix, the trace $p^x_{\alpha\alpha}$ vanishes, and so does $\pi^x_{\alpha\alpha}$.[160] Hence, condition (300) is satisfied. Inserting the diagonal Minkowski metric for $\gamma_{\alpha\beta}$ in equation (299), one readily verifies that $p_{\alpha\beta}$ in equation (304) satisfies conditions (299) as well:

$$\frac{\partial p_{\kappa 1}}{\partial x} + \frac{\partial p_{\kappa 2}}{\partial y} - \frac{\partial p_{\kappa 3}}{\partial t} = 0 \tag{305}$$

for $\kappa = 1, 2, 3$. It follows that infinitesimal rotations are indeed infinitesimal Hertz transformations. Next to his "table of p" Einstein accordingly wrote: "Correct" ("Stimmt").

In what looks like a later addition to the page, Einstein checked whether finite rotations are Hertz transformations too. In the lower-left part of p. 11L, Einstein wrote down the "table of the p" ("Tafel der p") for a finite rotation, which can be read off from equation (302):[161]

$$p_{\mu\nu} = \begin{pmatrix} \cos\omega t & \sin\omega t & (-x\sin\omega t + y\cos\omega t)\omega \\ -\sin\omega t & \cos\omega t & (-x\cos\omega t - y\sin\omega t)\omega \\ 0 & 0 & 1 \end{pmatrix}. \tag{306}$$

Inverting this matrix, one finds the corresponding "table of the π" ("Tafel der π"):[162]

159 The 13-component originally had an additional term $-x\omega t$. This term should be $-x\omega^2 t$ and can therefore be neglected. The 23-component likewise has a deleted term $-y\omega t$, which should be $-y\omega^2 t$. The expressions $-y\omega$ and $x\omega$ underneath the 31- and 32-components were added later (see equation (343) in sec. 4.5.5).

160 It follows from $p_{\mu\alpha}\pi_{\nu\alpha} = \delta_{\mu\nu}$ that $\pi^x_{\mu\nu} = -p^x_{\nu\mu}$ (see footnote 138).

161 Einstein omitted a factor ω in p_{13} and p_{23}.

$$\pi_{\mu\nu} = \begin{pmatrix} \cos\omega t & \sin\omega t & 0 \\ -\sin\omega t & \cos\omega t & 0 \\ -y\omega & x\omega & 1 \end{pmatrix}. \tag{307}$$

Einstein noted that the second term in condition (298) for finite Hertz transformations vanishes for this transformation matrix. He noted that

$$\sum \frac{\partial \pi_{\mu\nu}}{\partial x_\nu} = 0 \tag{308}$$

is "always fulfilled" ("immer erfüllt"). Since the transformation to rotating coordinates is also unimodular— $\det(p_{ik}) = 1$ for the matrix in equation (306)—Einstein presumably concluded that finite rotations, like infinitesimal ones, are Hertz transformations. This conclusion, however, is not warranted.

The problem is that the *first* term of equation (298) does not vanish for finite rotations. Substituting the diagonal Minkowski metric for $\gamma_{\alpha\sigma}$ in the first term of equation (298), one finds

$$\pi_{\mu\kappa}\left(\frac{\partial p_{\mu 1}}{\partial x} + \frac{\partial p_{\mu 2}}{\partial y} - \frac{\partial p_{\mu 3}}{\partial t}\right). \tag{309}$$

Since $\partial p_{\mu 1}/\partial x = \partial p_{\mu 2}/\partial y = \partial p_{33}/\partial t = 0$, this expression reduces to

$$-\pi_{1\kappa}\frac{\partial p_{13}}{\partial t} - \pi_{2\kappa}\frac{\partial p_{23}}{\partial t}. \tag{310}$$

This expression does not vanish for the coefficients $p_{\mu\nu}$ in equation (306) for a finite rotation. For $\kappa = 1$, for instance, it is equal to $x\omega^2$.[163] It follows that condition (298)

---

162 The notebook has $\pi_{31} = y$ and $\pi_{32} = x$. The inversion is done with the formula $\pi_{ik} = (-1)^{i+k}(\Delta_{ik}/p)$, where Δ_{ik} is the co-factor of p_{ik} and $p \equiv \det(p_{ik}) = 1$. The expression for π_{31} is found as follows:

$$\begin{aligned} \pi_{31} &= \begin{vmatrix} \sin\omega t & (-x\sin\omega t + y\cos\omega t)\omega \\ \cos\omega t & (-x\cos\omega t - y\sin\omega t)\omega \end{vmatrix} \\ &= \omega\{\sin\omega t(-x\cos\omega t - y\sin\omega t) - \cos\omega t(-x\sin\omega t + y\cos\omega t)\} \\ &= -\omega y \end{aligned}$$

A completely analogous calculation gives $\pi_{32} = \omega x$. Inserting equations (306) and (307) into $p_{\mu\alpha}\pi_{\nu\alpha}$, one readily verifies that this gives $\delta_{\mu\nu}$.

163 Using equation (306), one finds that

$$\frac{\partial p_{13}}{\partial t} = \omega^2(-x\cos\omega t - y\sin\omega t), \quad \frac{\partial p_{23}}{\partial t} = \omega^2(x\sin\omega t - y\cos\omega t)$$

Inserting these expressions into the $\kappa = 1$ component of expression (310) and using equation (307), one finds

$$-\pi_{11}\frac{\partial p_{13}}{\partial t} - \pi_{21}\frac{\partial p_{23}}{\partial t} = -\omega^2\{\cos\omega t(-x\cos\omega t - y\sin\omega t) - \sin\omega t(x\sin\omega t - y\cos\omega t)\},$$

which is equal to $\omega^2 x$.

is not satisfied in the case of finite rotations in Minkowski spacetime, which means that these transformations cannot be Hertz transformations.[164]

4.5.3 *Checking Whether Acceleration in Minkowski Spacetime is a Hertz Transformation (11L)* 11L

On the lower half of p. 11L, under the heading "Acceleration" ("Beschleunigung"), Einstein checked whether a transformation to a uniformly accelerated frame in Minkowski spacetime is a Hertz transformation. He started from the transformation equations that he had found for this case in the course of the work on his theory for static gravitational fields:[165]

$$\begin{aligned} \xi &= x + \frac{c}{2}\frac{dc}{dx}t^2 \\ \tau &= ct, \end{aligned} \tag{311}$$

where c is the variable speed of light that served as the gravitational potential in Einstein's static theory. Einstein assumed c to be of the form[166]

$$c = e^{ax}. \tag{312}$$

In the notebook, Einstein used (x, t) instead of (ξ, τ) and (x', t') instead of (x, t). The transformation (311) then becomes:

$$\begin{aligned} x &= x' + \frac{c(x')}{2}\frac{dc(x')}{dx'}t'^2 \\ t &= ct'. \end{aligned} \tag{313}$$

With the ansatz (312)—in terms of x' rather than x—the transformation (313) turns into:

$$\begin{aligned} x &= x' + \frac{a}{2}e^{2ax'}t'^2 \\ t &= e^{ax'}t'. \end{aligned} \tag{314}$$

Inverting this transformation while neglecting terms quadratic in a and smaller, Einstein found

---

164 A more direct way to arrive at this conclusion is to note that the Hertz expression, $\partial\gamma_{\mu\nu}/\partial x_\nu$, vanishes for the standard diagonal Minkowski metric but not for the Minkowski metric in rotating coordinates. The contravariant form of the latter is given by:

$$\gamma_{\mu\nu} = \begin{pmatrix} -1+\omega^2y^2 & -\omega^2xy & 0 & \omega y \\ -\omega^2xy & -1+\omega^2x^2 & 0 & -\omega x \\ 0 & 0 & -1 & 0 \\ \omega y & -\omega x & 0 & 1 \end{pmatrix}$$

For this metric, the Hertz expression is: $\partial\gamma_{\mu\nu}/\partial x_\nu = (-\omega^2x, -\omega^2y, 0, 0) \neq 0$.

165 See (Einstein 1912b, 456).

166 Initially, Einstein wrote $c = c_0e^{ax}$ but then deleted the factor c_0.

$$\begin{aligned} x' &= x - \frac{a}{2}t^2 \\ t' &= t(1-ax). \end{aligned} \tag{315}$$

As he had done for rotation, Einstein considered the infinitesimal transformation

$$\begin{aligned} dx' &= dx - atdt \\ dt' &= -atdx + (1-ax)dt. \end{aligned} \tag{316}$$

From the transformation matrix

$$p_{ij} = \begin{pmatrix} 1 & -at \\ -at & 1-ax \end{pmatrix}, \tag{317}$$

one immediately sees that its elements do not satisfy the two conditions (239) and (241) for infinitesimal Hertz transformations (see also equations (299) and (300)). Inserting $\gamma_{\mu\nu} = \delta_{\mu\nu}$ in equation (239), we find that the $\kappa = 1$ component is:

$$\frac{\partial p^x_{11}}{\partial x_1} + \frac{\partial p^x_{12}}{\partial x_2} = -a \neq 0 \quad , \tag{318}$$

Condition (241) is not satisfied either:

$$\sum p^x_{\alpha\alpha} = -ax \neq 0 \,. \tag{319}$$

Both problems could be fixed by setting:

$$p_{11} = 1 + ax \,. \tag{320}$$

It looks as if Einstein considered this modification. He changed the first line of equation (316) to

$$dx' = (1 + \langle 2 \rangle x)dx - atdt \,, \tag{321}$$

and added the remark: "is also correct for a suitable shift of scale" ("stimmt auch bei geeigneter Massstabverschiebung"). He subsequently deleted this remark.

For the time being, however, Einstein seems to have been satisfied that he could ensure in this fashion that transformations to uniformly accelerating frames in Minkowski spacetime would be included in the class of Hertz transformations. The modification (320) of the transformation matrix (316), however, is not allowed. The form of the transformation (311), of which transformation (316) is a special case, was derived from the equivalence of the propagation of light in the two systems (ξ, τ) and (x, t)[167]

$$d\xi^2 - d\tau^2 = dx^2 - c^2dt^2 \,. \tag{322}$$

With the adjustment (320) this fundamental equation would no longer be valid.

167 See (Einstein 1912a, sec. 1).

4.5.4 *Trying to Find Hertz Transformations under which the Core Operator Transforms as a Tensor (11R)* 11R

Having satisfied himself for the time being that the class of Hertz transformations includes transformations to rotating and uniformly accelerating frames in Minkowski spacetime, Einstein once again turned his attention to the core operator. Picking up on an idea that had made its first appearance on p. 10R (see equations (278)–(279)), Einstein examined under which transformations the contraction of the core operator and some arbitrary covariant second-rank tensor would transform as a scalar.

On p. 10R, Einstein had written this contraction as (see equation (278)):

$$\sum T_{i\kappa} \frac{\partial}{\partial x_\mu}\left(\gamma_{\mu\nu} \frac{\partial \gamma_{i\kappa}}{\partial x_\nu}\right) = \text{Skalar} . \tag{323}$$

At the top of p. 11R Einstein wrote down a very similar expression (down to the labeling of the indices),

$$\sum T^x_{i\kappa} \gamma_{\mu\nu} \frac{\partial}{\partial x_\mu} \frac{\partial}{\partial x_\nu}(\gamma_{i\kappa}) , \tag{324}$$

and asked: “Is this a scalar?” (“Ist dies ein Skalar?”). If $T_{i\kappa}$ in equation (323) is replaced by $T^x_{i\kappa}$,[168] and, more importantly, if the Hertz restriction,

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_\nu} = 0 , \tag{325}$$

is imposed, the expressions on 10R and 11R are equivalent. So if expression (324) transforms as a scalar under Hertz transformations, so will expression (323). Einstein set out to find what further coordinate restrictions over and above the Hertz restriction would be needed for expression (324) to transform as a scalar.

To this end he once again used his two step procedure.[169] He wrote expression (324) in primed coordinates, and expressed its various components in unprimed coordinates:

$$S = \sum \pi_{i\alpha_1} \pi_{\kappa\alpha_2} T^x_{\alpha_1\alpha_2} p_{\mu\beta_1} p_{\nu\beta_2} \gamma_{\beta_1\beta_2} \pi_{\mu\sigma} \frac{\partial}{\partial x_\sigma}\left[\pi_{\nu\tau} \frac{\partial}{\partial x_\tau}(p_{i\varepsilon_1} p_{\kappa\varepsilon_2} \gamma_{\varepsilon_1\varepsilon_2})\right] . \tag{326}$$

Einstein connected the factors $p_{\mu\beta_1}$ and $\pi_{\mu\sigma}$ by a solid V-shaped line to indicate that they combine to form (in modern notation) $\delta_{\beta_1\sigma}$, Underneath this line, he wrote $\beta_1 = \sigma$. He likewise connected $p_{\nu\beta_2}$ and $\partial / \partial x_\sigma$ by a dashed V-shaped line and directly underneath wrote

---

168 It is not clear why Einstein added an ‘x’ added to $T_{i\kappa}$ at this point. This superscript was Einstein standard notation for first-order deviations from constant values. The argument on p. 11R works with both $T_{i\kappa}$ and $T^x_{i\kappa}$.

169 See the introduction to sec. 4.3 for a general discussion of this procedure and equations (215)–(217) for a concrete example involving a scalar.

$$\sum p_{\nu\beta_2}\frac{\partial\pi_{\nu\tau}}{\partial x_\sigma}\gamma_{\beta_1\beta_2} = -\sum\pi_{\nu\tau}\frac{\partial p_{\nu\beta_2}}{\partial x_\sigma}\underset{\sigma}{\gamma_{\beta_1\beta_2}} = 0. \tag{327}$$

In the first step he used that

$$0 = \frac{\partial}{\partial x_\sigma}(p_{\nu\beta_2}\pi_{\nu\tau}) = p_{\nu\beta_2}\frac{\partial\pi_{\nu\tau}}{\partial x_\sigma} + \pi_{\nu\tau}\frac{\partial p_{\nu\beta_2}}{\partial x_\sigma}. \tag{328}$$

He replaced β_1 in $\gamma_{\beta_1\beta_2}$ by σ, using that $p_{\mu\beta_1}\pi_{\mu\sigma} = \delta_{\beta_1\sigma}$. Expression (327) has exactly the form of the last term in equation (236) at the top of p. 10L. At that point, Einstein had drawn the conclusion that the vanishing of this expression (see equation (237)) was the condition for non-autonomous transformation under which the Hertz expression transforms as a tensor. Equation (237) does indeed express the Hertz restriction for infinitesimal transformations, but not for finite ones (see the discussion following equation (237) and footnote 148). In the second step in equation (327), Einstein nonetheless used equation (237).

On the basis of equation (327), Einstein could move $\pi_{\nu\tau}$ outside the scope of the differential operator $\partial/\partial x_\sigma$ in equation (326). As he wrote: "hence $\pi_{\nu\tau}$ can be taken outside" ("also $\pi_{\nu\tau}$ heraus setzbar"). The factor $\pi_{\nu\tau}$ combines with $p_{\nu\beta_2}$ to give $\delta_{\tau\beta_2}$. In a separate box Einstein summarized the simplifications $p_{\mu\beta_1}\pi_{\mu\sigma} = \delta_{\beta_1\sigma}$ and $\pi_{\nu\tau}p_{\nu\beta_2} = \delta_{\tau\beta_2}$ in equation (326):

$$\begin{aligned}\beta_1 &= \sigma\\ \beta_2 &= \tau.\end{aligned} \tag{329}$$

With these simplifications, equation (326) becomes:

$$S' = \sum\pi_{i\alpha_1}\pi_{\kappa\alpha_2}T^x_{\alpha_1\alpha_2}\gamma_{\sigma\tau}\frac{\partial}{\partial x_\sigma}\frac{\partial}{\partial x_\tau}(p_{i\varepsilon_1}p_{\kappa\varepsilon_2}\gamma_{\varepsilon_1\varepsilon_2}). \tag{330}$$

Underneath this equation Einstein wrote: "Let us restrict ourselves to an infinitesimal substitution" ("Beschränken wir uns auf infinitesimale Substitution"). Whether Einstein realized it or not, this immediately takes care of the problem that to arrive at equation (330) he had used the Hertz restriction in a form that only holds for infinitesimal transformations.

Einstein's task now was to identify all those terms in equation (330) that would have to vanish for the right-hand side to reduce to expression (324) that he had started from. These are all terms in which the elements $p_{\mu\nu}$ of the transformation matrix are differentiated at least once.[170] The condition determining under which subclass of infinitesimal Hertz transformations expression (324) transforms as a scalar is obtained by setting the sum of all these terms equal to zero. If in a product of several matrix elements $p_{\mu\nu}$ of an infinitesimal transformation one is differentiated, all others can be replaced by Kronecker deltas. Equation (330) can thus be rewritten as:

170 Einstein had made this observation twice on p. 7R in comments on equations (139) and (145).

$$\begin{aligned} S' &= \delta_{i\alpha_1}\delta_{\kappa\alpha_2}T^x_{\alpha_1\alpha_2}\gamma_{\sigma\tau}\frac{\partial}{\partial x_\sigma}\frac{\partial}{\partial x_\tau}(p_{i\varepsilon_1}\delta_{\kappa\varepsilon_2}\gamma_{\varepsilon_1\varepsilon_2} + \delta_{i\varepsilon_1}p_{\kappa\varepsilon_2}\gamma_{\varepsilon_1\varepsilon_2}) \\ &= T^x_{i\kappa}\gamma_{\sigma\tau}\frac{\partial}{\partial x_\sigma}\frac{\partial}{\partial x_\tau}(p_{i\varepsilon_1}\gamma_{\varepsilon_1\kappa} + p_{\kappa\varepsilon_2}\gamma_{i\varepsilon_2}) \end{aligned} \tag{331}$$

As Einstein put it: "If one of the p's is differentiated at all, for instance $p_{i\varepsilon_1}$, then one has to set $\kappa = \varepsilon_2$, $i = \alpha_1$, $\kappa = \alpha_2$" ("Dann muss, falls überhaupt eines der p diff wird, z. B. $p_{i\varepsilon_1}$ $\kappa = \varepsilon_2$, $i = \alpha_1$, $\kappa = \alpha_2$ gesetzt werden"). The second step in equation (331) is indeed to set $\alpha_1 = i$, $\alpha_2 = \kappa$ and to set $\varepsilon_2 = \kappa$ if $p_{i\varepsilon_1}$ is differentiated and $\varepsilon_1 = i$ if $p_{\kappa\varepsilon_2}$ is. Einstein could thus rewrite equation (330) as:[171]

$$S' = \sum T^x_{i\kappa}\frac{\partial}{\partial x_\sigma}\frac{\partial}{\partial x_\tau}\gamma_{\sigma\tau}(p_{i\varepsilon_1}\gamma_{\varepsilon_1\kappa} + p_{\kappa\varepsilon_2}\gamma_{\varepsilon_2 i}) + S, \tag{332}$$

adding: "where p is to be differentiated at least once" ("wobei p mindestens einmal zu differenzieren ist"). The last term, S, is obtained if the two differential operators both act on $\gamma_{\varepsilon_1\kappa}$ or $\gamma_{\varepsilon_2 i}$ instead of at least one of them acting on $p_{i\varepsilon_1}$ or $p_{\kappa\varepsilon_2}$. For S to be a scalar, the sum of all terms containing derivatives of $p_{\mu\nu}$ in the first term on the right-hand side of equation (332) should vanish.

Einstein first considered the expression[172]

$$T_{i\kappa}\frac{\partial}{\partial x_\sigma}\left(\gamma_{\sigma\tau}\frac{\partial p_{i\varepsilon_1}}{\partial x_\tau}\gamma_{\varepsilon_1\kappa}\right). \tag{333}$$

Since $\partial p_{i\varepsilon_1}/\partial x_\tau = \partial p_{i\tau}/\partial x_{\varepsilon_1}$ (see footnote 148) this can be rewritten as:

$$T_{i\kappa}\frac{\partial}{\partial x_\sigma}\left(\gamma_{\sigma\tau}\frac{\partial p_{i\tau}}{\partial x_{\varepsilon_1}}\gamma_{\varepsilon_1\kappa}\right). \tag{334}$$

Because of the Hertz restriction, $\partial\gamma_{\mu\nu}/\partial x_\nu = 0$, $\gamma_{\sigma\tau}$ can be taken outside the scope of $\partial/\partial x_\sigma$ and $\gamma_{\varepsilon_1\kappa}$ can be taken inside the scope of $\partial/\partial x_{\varepsilon_1}$. Einstein thus arrived at:

$$\sum T_{i\kappa}\gamma_{\sigma\tau}\frac{\partial}{\partial x_\sigma}\frac{\partial}{\partial x_{\varepsilon_1}}(p_{i\tau}\gamma_{\varepsilon_1\kappa}). \tag{335}$$

He repeated this result on the next line,

$$T_{i\kappa}\frac{\partial}{\partial x_\sigma}\gamma_{\sigma\tau}\frac{\partial^2}{\partial x_{\varepsilon_1}\partial\sigma}(p_{i\tau}\gamma_{\varepsilon_1\kappa}, \tag{336}$$

171 The second term in parentheses in equation (332) is written underneath the first. Both S and $\gamma_{\sigma\tau}$ in equation (332) are interlineated. Note that $\gamma_{\sigma\tau}$ is placed within the scope of the differential operators $\partial/\partial x_\sigma$ and $\partial/\partial x_\tau$, whereas in equations (330) and (331) it was not. Because of the Hertz restriction, however, $\partial\gamma_{\sigma\tau}/\partial x_\sigma = \partial\gamma_{\sigma\tau}/\partial x_\tau = 0$, so this makes no difference.

172 Three lines farther down, Einstein added: "Already sum over ε_1" ("Schon Summe über ε_1"), drawing a line from expression (333) to this comment. The comment refers, perhaps, to the similarity between the sum over ε_1 in $(\partial p_{i\varepsilon_1}/\partial x_\tau)\gamma_{\varepsilon_1\kappa}$ in expression (333) and the sum over α in equation (239), one of the conditions for infinitesimal Hertz transformations.

but did not pursue the calculation any further. He went back to equation (332) and, contrary to what he did in expression (333), treated the two derivative operators $\partial/\partial x_\sigma$ and $\partial/\partial x_\tau$ on an equal footing. For the term with $p_{i\varepsilon_1}\gamma_{\varepsilon_1\kappa}$ in equation (332) he wrote:

$$\sum T_{i\kappa}\gamma_{\sigma\tau}\left(\frac{\partial p_{i\varepsilon_1}}{\partial x_\sigma}\frac{\partial\gamma_{\varepsilon_1\kappa}}{\partial x_\tau}+\frac{\partial p_{i\varepsilon_1}}{\partial x_\tau}\frac{\partial\gamma_{\varepsilon_1\kappa}}{\partial x_\sigma}+\frac{\partial^2 p_{i\varepsilon_1}}{\partial x_\sigma\partial x_\tau}\gamma_{\varepsilon_1\kappa}\right). \tag{337}$$

He indicated that the term with $p_{\kappa\varepsilon_2}\gamma_{\varepsilon_2 i}$ gives a similar contribution by noting: "+ the same with i & κ exchanged" ("+ dasselbe mit vert[auschten] i & κ").

Here the calculation seems to break off abruptly with Einstein concluding: "Leads to difficulties" ("Führt auf Schwierigkeiten."). However, the considerations at the top of p. 12L (and some additions to p. 11L resulting from them) can be seen as a natural continuation of the search on p. 11R for Hertz transformations under which the core operator transforms as a tensor. Einstein may therefore only have added this final remark on p. 11R after running into difficulties on pp. 12L and 11L.

4.5.5 *Checking Whether Rotation in Minkowski Spacetime Is a Hertz Transformation Under Which the Core Operator Transforms as a Tensor (12L, 11L)*

At the bottom of p. 11R, Einstein had derived a condition determining under which subclass of infinitesimal Hertz transformations expression (323)—the contraction of the core operator and an arbitrary second-rank covariant tensor—transforms as a scalar. He had found that, given the metric field, the matrices $p_{\mu\nu}$ for such transformations must satisfy the condition that the sum of expression (337) and a similar expression obtained by switching the indices i and κ vanish. For the special case of a flat diagonal metric, $\gamma_{\mu\nu} = \delta_{\mu\nu}$, this condition reduces to:

$$\gamma_{\sigma\tau}\left(\frac{\partial^2 p_{i\kappa}}{\partial x_\sigma\partial x_\tau}+\frac{\partial^2 p_{\kappa i}}{\partial x_\sigma\partial x_\tau}\right) = 0, \tag{338}$$

which is satisfied if $p^x_{\mu\nu} \equiv (p_{\mu\nu}-\delta_{\mu\nu})$ is anti-symmetric, i.e., $p^x_{\mu\nu} = -p^x_{\mu\nu}$.[173]

12L At the top of p. 12L, under the heading: "Attempt. Infinitesimal transformation is anti-symmetric. Rotation modified" ("Versuch. Infinitesimale Transformation ist schief symmetrisch. Drehung modifiziert"), Einstein turns to the investigation of anti-symmetric infinitesimal transformations. This quickly aborted attempt can thus be seen as a natural continuation of the considerations on p. 11R.

Einstein wrote down the transformation law for the differentials dx_μ under an infinitesimal coordinate transformation:

$$dx'_\nu = dx + p^x_{\nu\kappa}dx_k. \tag{339}$$

173 In that case, conditions (239) and (241) for infinitesimal Hertz transformations found on p. 10L are automatically satisfied as well, the latter because $p^x_{\kappa\sigma}$ is traceless, the former because (cf. footnote 148): $\partial p^x_{\kappa\sigma}/\partial x_\sigma = -\partial p^x_{\sigma\kappa}/\partial x_\sigma = -\partial p^x_{\sigma\sigma}/\partial x_\kappa$, which once again vanishes because $p^x_{\kappa\sigma}$ is traceless.

and noted the condition of anti-symmetry

$$p^x_{\nu\kappa} = -p^x_{\kappa\nu}\,. \tag{340}$$

As on p. 10L, he expressed the coefficients of the transformation in terms of the functions X_μ describing the coordinate transformation (cf. equations (242)–(244)),

$$p_{\nu\kappa} = \frac{\partial X_\nu}{\partial x_\kappa}\,, \tag{341}$$

with the help of which he rewrote condition (340) as

$$\frac{\partial X_\nu}{\partial x_\kappa} = -\frac{\partial X_\kappa}{\partial x_\nu}\,. \tag{342}$$

The comment "Rotation modified" ("Drehung modifiziert") at the top of p. 12L indicates that Einstein was interested in the special case of rotation in Minkowski spacetime at this point. If the matrix $p^x_{\mu\nu}$ for this transformation were anti-symmetric—which, of course, it is not—an infinitesimal rotation in Minkowski spacetime would be an example of a non-autonomous transformation under which expression (323) transforms as a scalar. It would then, presumably, also be a transformation under which the core operator transforms as a tensor. Einstein thus explored whether the matrix $p^x_{\mu\nu}$ for rotation can meaningfully be made anti-symmetric.

If this was indeed the point of modifying the matrix $p^x_{\mu\nu}$ for rotation, Einstein had already achieved his goal without such modification. What he appears to have overlooked is that infinitesimal rotations in Minkowski spacetime already are infinitesimal Hertz transformations under which expression (323) transforms as a scalar. That they are Hertz transformations was shown in p. 11L (see sec. 4.5.2). Moreover, the matrix $p^x_{\mu\nu}$ for such transformations satisfies condition (338). After all, $p^x_{\mu\nu}$ is linear in x_μ and condition (338) involves only second-order derivatives of $p^x_{\mu\nu}$. It is true that condition (340) is not satisfied, since $p^x_{\mu\nu} \neq p^x_{\nu\mu}$, but that condition, although sufficient, is not necessary to meet condition (338). Hence, Einstein did not need to modify $p^x_{\mu\nu}$ for rotation at all.

Einstein seems to have missed this and returned to p. 11L to see whether the matrix 11L
(304) for $p^x_{\mu\nu}$ for infinitesimal rotation in Minkowski spacetime could be made anti-symmetric. As he indicated underneath the matrix on p. 11L, he replaced $p^x_{31} = p^x_{32} = 0$ by $-\omega y$ and ωx, respectively:

$$\begin{matrix} 1 & \omega t & +y\omega \\ -\omega t & 1 & -x\omega \\ 0 & 0 & 1 \\ -\omega y & +\omega x\,. & \end{matrix} \tag{343}$$

With this anti-symmetrized matrix the differential of the time coordinate transforms as:

$$dt' = -y\omega dx + x\omega dy + dt\,. \tag{344}$$

Einstein wrote this equation in a separate box in the left margin of p. 11L. For this equation to be a coordinate transformation, dt' has to be an exact differential, i.e., it must be possible to write it as:

$$dt' = \frac{\partial\varphi}{\partial x}dx + \frac{\partial\varphi}{\partial y}dy + \frac{\partial\varphi}{\partial t}dt\,. \tag{345}$$

Comparison of equations (345) and (344) gives $\partial\varphi/\partial x = -y\omega$ and $\partial\varphi/\partial y = x\omega$. This implies that

$$\frac{\partial^2\varphi}{\partial x\partial y} \neq \frac{\partial^2\varphi}{\partial y\partial x}\,. \tag{346}$$

Hence dt' in equation (345) is not an exact differential. Einstein seems to have gone through this same argument himself, although the only trace of this in the notebook are the terms

$$\frac{\partial\varphi}{\partial x} \quad \frac{\partial\varphi}{\partial y} \quad \frac{\partial\varphi}{\partial z}\,, \tag{347}$$

written underneath equation (344) in the same separate box. In any event, he concluded that a transformation characterized by equation (344), which would yield an antisymmetric matrix $p^x_{\mu\nu}$, is "impossible" ("unmöglich"). This is the last word in the separate box on p. 11L, and it signals the end of this whole line of reasoning, which started on p. 10L and ended with the first horizontal line on p. 12L. Einstein seems to have reached the conclusion that the core operator does not transform as a tensor under infinitesimal rotations in Minkowski spacetime.

Initially, Einstein, it seems, considered changing the form of the core operator. Following the first horizontal line on p. 12L, Einstein changed the core operator (130) on p. 7L to:

$$\frac{1}{\sqrt{G}}\sum\frac{\partial}{\partial x_\mu}\left\{\sqrt{G}\gamma_{\mu\nu}\frac{\partial\gamma_{i\kappa}}{\partial x_\nu}\right\}. \tag{348}$$

The extra factors of $\sqrt{G}$ make this expression resemble the second Beltrami invariant more closely (cf. equation (82) on p. 6L). Einstein did not even begin the search for non-autonomous transformations under which this modified core operator transforms as a tensor. Instead he drew another horizontal line and turned to a closer examination of the important special case of rotation in Minkowski spacetime that had spelled trouble for the original form of the core operator.

4.5.6 *Deriving the Exact Form of the Rotation Metric (12L–R)*

12L In the middle of p. 12L, under the heading, "The Rotational Field in First Approximation" ("Drehungsfeld in erster Annäherung"), Einstein wrote down the line element

$$g_{11}dx^2 + \ldots + g_{44}dt^2 = ds^2\,, \tag{349}$$

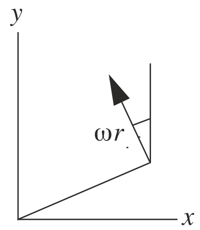
and defined H, the "Lagrangian function" ("Lagrange'sche Funktion") for a point particle in a metric field, in terms of a potential term Φ and a kinetic term L:

$$\Phi - L = H = \frac{ds}{dt}. \tag{350}$$

The accompanying diagram (see below) and the subsequent calculations make it clear that Einstein considered the motion of the particle in a coordinate system $x_\mu = (x, y, z, t)$ rotating counterclockwise at constant angular velocity ω around the z-axis, coinciding with the z'-axis of an inertial coordinate system $x'_\mu = (x', y', z', t')$. The line element in the inertial coordinate system is given by:

$$ds^2 = \eta_{\mu\nu}dx'_\mu dx'_\nu = (1 - \mathbf{v}'^2)dt'^2 \tag{351}$$

where $\eta_{\mu\nu} \equiv \mathrm{diag}(-1, -1, -1, 1)$ (coordinates are chosen such that $c = 1$) and $v'_i = \dot{x}'_i = dx'_i/dt'$.



The relation between velocity in the inertial frame and velocity in the rotating frame is given by:

$$\mathbf{v}' = \mathbf{v} + \vec{\omega} \times \mathbf{x} = \begin{pmatrix} \dot{x} - \omega y \\ \dot{y} + \omega x \\ \dot{z} \end{pmatrix} = \begin{pmatrix} \dot{x} - \omega r \sin\omega t \\ \dot{y} + \omega r \cos\omega t \\ \dot{z} \end{pmatrix}, \tag{352}$$

where $\vec{\omega} \equiv (0, 0, \omega)$ and $r^2 \equiv x^2 + y^2$.

With the help of equation (351) and the transformation equation $dt' = dt$, the Lagrangian (350) can be written as

$$H = \sqrt{\frac{ds^2}{dt^2}} = \sqrt{1 - \mathbf{v}'^2} \approx 1 - \frac{\mathbf{v}'^2}{2}. \tag{353}$$

Comparison with $H = \Phi - L$ leads to the identification $2L = \mathbf{v}'^2$. Einstein presumably arrived at this equation simply on the basis of the interpretation of L as the kinetic energy. Using equation (352), he found:

$$2L = (\dot{x} - \omega r \sin\omega t)^2 + (\dot{y} + \omega r \cos\omega t)^2 + \dot{z}^2, \tag{354}$$

which he expanded to:

$$2L = \dot{x}^2 + \dot{y}^2 + \dot{z}^2 - 2\omega r \sin\omega t \dot{x} + 2\omega r \cos\omega t \dot{y} + \omega^2 r^2. \tag{355}$$

Substituting $x = r\cos\omega t$ and $y = r\sin\omega t$ (see equation (352)) and introducing the potential energy $\Phi = A$,[174] Einstein wrote the Lagrangian H as

$$\Phi - L = A - \frac{\omega^2 r^2}{2} - \frac{\dot{x}^2 + \dot{y}^2 + \dot{z}^2}{2} + \omega y\dot{x} - \omega x\dot{y}\,. \tag{356}$$

Given equation (350), Einstein could find ds^2/dt^2 by squaring equation (356). Writing "ds^2/dt [dt should be dt^2] calculated up to and including ω^2 & $\dot{x}^2$" ("ds^2/dt berechnet bis und mit ω^2 u. $\dot{x}^2$"), he arrived at:

$$\begin{aligned}\frac{ds^2}{dt^2} &= A^2 + \omega^2 y^2\dot{x}^2 + \omega^2 x^2\dot{y}^2 - A\omega^2 r^2 \\ &\quad - \left(A - \frac{\omega^2 r^2}{2}\right)(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) + 2A\omega y\dot{x} - 2A\omega x\dot{y}\end{aligned} \tag{357}$$

A simpler way of finding an expression for ds^2/dt^2 is to use equations (351) and (352):

$$\frac{ds^2}{dt^2} = 1 - \mathbf{v}'^2 = 1 - \omega^2 r^2 - \dot{x}^2 - \dot{y}^2 - \dot{z}^2 + 2\omega y\dot{x} - 2\omega x\dot{y}\,. \tag{358}$$

If we neglect terms containing *both* ω^2 and $\dot{x}_i^2$ in eq. (357) and insert $A = 1$, we recover equation (358).

12R At the top of p. 12R, Einstein used equation (357) in combination with $ds^2 = g_{\mu\nu}dx_\mu dx_\nu$, the expression for the line element in rotating coordinates, to identify the components of $g_{\mu\nu}$, the Minkowski metric in rotating coordinates:

$$\begin{array}{llll} g_{11} = -\left(A - \cancel{\frac{\omega^2 r^2}{2}}\right) + \omega^2 y^2 & g_{12} = 0 & g_{13} = 0 & g_{14} = 2A\omega y \\ g_{21} = 0 & g_{22} = -\left(A - \cancel{\frac{\omega^2 r^2}{2}}\right) + \omega^2 x^2 & g_{23} = 0 & g_{24} = -2A\omega x \\ g_{31} = 0 & g_{32} = 0 & g_{33} = -\left(A - \cancel{\frac{\omega^2 r^2}{2}}\right) & g_{34} = 0 \\ g_{41} = 2A\omega y & g_{42} = -2A\omega x & g_{43} = 0 & g_{44} = A^2 - A^2\omega^2 r^2 \end{array} \tag{359}$$

This matrix contains several errors. First, the ω^2-terms in g_{11} and g_{22} come from terms in equation (357) containing both ω^2 and $\dot{x}_i^2$, which are negligible. This mistake was partly corrected.[175] Second, the factors of 2 in g_{14}, g_{24}, g_{41}, and g_{42} should be 1. The term $2A\omega y dx dt$ in (dt^2 times) equation (357), for instance, should be set equal to $g_{14}dx_1 dx_4 + g_{41}dx_4 dx_1$, leading to the identification $g_{14} = g_{41} = A\omega y$.[176] Immediately below the matrix (359), Einstein noted that $A = 1$ (cf. note 174)

174 As follows directly from equation (353) and as Einstein subsequently realized (see p. 12R), A cannot be chosen freely but has to be equal to 1.

175 The term $\omega^2 r^2/2$ in the expressions for g_{11}, g_{22}, and g_{33} may have been deleted in the course of Einstein's evaluation of the determinant of this metric.

Next, Einstein computed the determinant G of (359), again retaining only terms up to order ω^2 or $\dot{x}_i^2$. Since so many of the elements of the matrix (359) are zero, there are only a few contributions to its determinant:

$$G = g_{11}g_{22}g_{33}g_{44} - g_{11}g_{33}(g_{42}^2 + g_{41}^2)\,. \tag{360}$$

Inserting the values given in the matrix (359) into this expression, setting $A = 1$, and neglecting terms smaller than of order ω^2 or $\dot{x}_i^2$, we find a result very similar to the following expression in the notebook at this point:[177]

$$G = \left[\left(-1 + \frac{\omega^2 r^2}{2} + \omega^2 y^2\right)\left\{\left(1 - \frac{\omega^2 r^2}{2} - \omega^2 x^2 - \frac{\omega^2 r^2}{2} - \omega^2 r^2\right) + 4\omega^2 x^2\right\}\right. \\ \left. + 4\omega^2 y^2.\right. \tag{361}$$

Einstein rewrote the right-hand side of this equation as:

$$= -1 + \frac{\omega^2 r^2}{2} + \omega^2 y^2 + \frac{\omega^2 r^2}{2} + \omega^2 x^2 + \frac{\omega^2 r^2}{2} + \omega^2 r^2 - 4\omega^2 x^2 + 4\omega^2 y^2 \tag{362}$$

and then as:

$$= -1 + 2.5\omega^2 r^2 - \langle \omega^2 r^2 \rangle - 3\omega^2 x^2 + 5\omega^2 y^2\,. \tag{363}$$

These last two equations inherit the errors made in equation (361) (see note 177). Einstein may have realized that these equations contained some errors. He subsequently deleted all three equations (361)–(363). However, he retained the main result of his calculation on the lower half of p. 12L and the upper half of p. 12R, expression (359) for the Minkowski metric in rotating coordinates, which still contains several errors.

4.5.7 *Trying to Find Infinitesimal Unimodular Transformations Corresponding to Uniform Acceleration (12R, 41L–R)*

In the middle of p. 12R, under the heading, "Substitutions with Determinant 1. Infin- 12R
itesimal in 2 Variables" ("Substitutionen mit Determinante 1. Infinitesimal in 2 Variablen"), Einstein wrote down the transformation law for coordinate differentials,

$$\begin{aligned} dx' &= dx + (p_{11}^x dx + p_{12}^x dy), \\ dy' &= dy + (p_{21}^x dx + p_{22}^x dy), \end{aligned} \tag{364}$$

under the transformation

176 Einstein made the same mistake on p. 42R (see footnote 308) and in the Einstein-Besso manuscript (CPAE 4, Doc. 14, pp. [41–42]). Largely due to this error, Einstein convinced himself at that point that the rotation metric is a solution of the field equations of his *Entwurf* theory (see Janssen 1999, 145–146, and "What Did Einstein Know …" sec. 3 (in this volume).

177 Expression (361) contains a number of errors. First, the last three minus signs in the second expression in ordinary brackets were all corrected from plus signs. The first two should indeed be minus signs but the third should be a plus sign. Secondly, the terms $4\omega^2 x^2$ and $4\omega^2 y^2$, coming from the second term in equation (360), should both be inside the curly brackets with a minus sign.

$$\begin{aligned} x' &= x + X(x, y), \\ y' &= y + Y(x, y), \end{aligned} \tag{365}$$

with (cf., e.g., p. 10L and equations (242)–(244)):

$$p^x_{ij} = \begin{pmatrix} \frac{\partial X}{\partial x} & \frac{\partial X}{\partial y} \\ \frac{\partial Y}{\partial x} & \frac{\partial Y}{\partial y} \end{pmatrix} . \tag{366}$$

Next to the transformation law (364), he wrote the unimodularity condition, i.e., the condition that the determinant of the transformation matrix equals 1 (cf. equations (240)–(241)):

$$p^x_{11} + p^x_{22} = 0 . \tag{367}$$

With the help of equation (366), this condition turns into

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} = 0 , \tag{368}$$

which is automatically satisfied if there is a generating function $\psi(x, y)$ determining X and Y via

$$X = \frac{\partial \psi}{\partial y}, \qquad Y = -\frac{\partial \psi}{\partial x} . \tag{369}$$

With the help of equation (366), the coefficients p^x_{ij} can also be expressed in terms of ψ:[178]

$$\begin{aligned} p_{11} &= \frac{\partial^2 \psi}{\partial x \partial y}, \qquad & p_{12} &= \frac{\partial^2 \psi}{\partial y^2}, \\ p_{21} &= -\frac{\partial^2 \psi}{\partial x^2}, \qquad & p_{22} &= -\frac{\partial^2 \psi}{\partial x \partial y}. \end{aligned} \tag{370}$$

Using these expressions, Einstein rewrote the first line of the transformation (364) as

$$dx' = \left(1 + \frac{\partial^2 \psi}{\partial x \partial y}\right) dx + \frac{\partial^2 \psi}{\partial y^2} dy . \tag{371}$$

He did not bother to write down the corresponding equation for dy'. Equation (371) in turn can be rewritten as

$$dx' = dx + \frac{\partial}{\partial x}\left(\frac{\partial \psi}{\partial y}\right) dx + \frac{\partial}{\partial y}\left(\frac{\partial \psi}{\partial y}\right) dy = dx + d\left(\frac{\partial \psi}{\partial y}\right) = dx + dX . \tag{372}$$

178 In these equations, p_{ij} should be p^x_{ij}.

This last expression already follows directly, of course, from equation (365). Writing δx and δy for X and Y and using equation (369), Einstein wrote

$$\delta x = \frac{\partial\psi}{\partial y}, \qquad \delta y = -\frac{\partial\psi}{\partial x}. \tag{373}$$

He could thus write transformation (365) as

$$\begin{aligned} x' &= x + \frac{\partial\psi}{\partial y}, \\ y' &= y - \frac{\partial\psi}{\partial x}, \end{aligned} \tag{374}$$

which appear at the bottom of p. 12R enclosed in a box.

In another part of the notebook, on pp. 41L–R, immediately following Einstein's earliest considerations on gravitation (see sec. 2), Einstein did the same calculation as on the bottom half p. 12R but this time pursued it a little further. At the bottom of p. 41L, he examined some specific choices for the generating function ψ. At the top of p. 41R, he chose one of the coordinates to be the time coordinate and compared the transformation for a particular choice of ψ with the transformation to a uniformly accelerated frame of reference, a transformation familiar from his papers on the static gravitational field. It seems plausible that the calculation on pp. 41L–R is just a continuation of the one on p. 12R. The calculation breaks off after Einstein failed to recover the transformation to a uniformly accelerating frame of reference in this manner. 41L–R

Below the horizontal line in the middle of p. 41L, under the heading, "Simplest Substitutions, whose Determinant = 1" ("Einfachste Substitution, deren Determinante = 1"), Einstein, as on p. 12R, began by writing down the transformation equations (364) for coordinate differentials, albeit in a more compact form than on p. 12R and leaving open the dimension of the space(-time) under consideration: 41L

$$dx'_\nu = dx_\nu + \sum p^x_{\nu\sigma} dx_\sigma . \tag{375}$$

As on p. 12R (see equation (366)), Einstein used the relations $p^x_{\mu\nu} = \partial X_\mu / \partial x_\nu$. Underneath equation (375), Einstein wrote: "X_ν are homogeneous and of second degree in the coordinates. Only two coordinates are being transformed" ("X_ν sind homogen u. zweiten Grades in den Koordinaten. Es werden nur zwei Koordinaten transformiert"). These comments suggest that Einstein was interested at this point in the special case of uniform acceleration, which he explicitly considered at the top of p. 41R. In that case only two coordinates, x and t, transform non-trivially. Moreover, the function X in $x' = x + X$ (cf. equation (365)) has to be proportional to t^2 and cannot have a constant term to get the desired form $x' = x + f(x)t^2$. In other words, X has to be "of second degree" and "homogeneous."

Einstein began by writing down the condition of unimodularity (cf. equations (367)–(368))

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} = 0\,, \tag{376}$$

which is satisfied automatically if there is a generating function $\psi(x, y)$ such that (cf. equation (369))

$$X = \frac{\partial \psi}{\partial y}, \qquad Y = -\frac{\partial \psi}{\partial x}. \tag{377}$$

As before (see equation (370)), the relation between the matrix p^x_{ij} and the function ψ is given by

$$\begin{aligned} p^x_{11} &= \frac{\partial^2 \psi}{\partial x \partial y}, & p^x_{12} &= \frac{\partial^2 \psi}{\partial y^2}, \\ p^x_{21} &= -\frac{\partial^2 \psi}{\partial x^2}, & p^x_{22} &= -\frac{\partial^2 \psi}{\partial x \partial y}. \end{aligned} \tag{378}$$

Up to this point the argument on p. 41L is identical to the argument on p. 12R.

Einstein now considered two specific choices for the generating function, namely $\psi = r^3$ and $\psi = r^2 x$. For these two cases he evaluated the four elements of the matrix in equation (378). Using that $r \equiv \sqrt{x^2 + y^2}$, so that $\partial r / \partial x = x / r$ and $\partial r / \partial y = y / r$, one recovers the results given by Einstein at this point, except for an overall factor of 3 in the case of $\psi = r^3$. Einstein effectively did the calculation with $\psi = r^3 / 3$. This function gives:

$$\begin{aligned} \frac{\partial \psi}{\partial x} &= rx & \frac{\partial^2 \psi}{\partial x^2} &= r + \frac{x^2}{r} \\ & & \frac{\partial^2 \psi}{\partial x \partial y} &= \frac{xy}{r} \\ \frac{\partial \psi}{\partial y} &= ry & \frac{\partial^2 \psi}{\partial y^2} &= r + \frac{y^2}{r} \end{aligned} \tag{379}$$

The function $\psi = r^2 x$ gives:

$$\begin{aligned} \frac{\partial \psi}{\partial x} &= r^2 + 2x^2 & \frac{\partial^2 \psi}{\partial x^2} &= 6x \\ & & \frac{\partial^2 \psi}{\partial x \partial y} &= 2y \\ \frac{\partial \psi}{\partial y} &= 2xy & \frac{\partial^2 \psi}{\partial y^2} &= 2x \end{aligned} \tag{380}$$

To the right of equations (376)–(378), Einstein wrote down two matrices

$$\begin{pmatrix} 1 & y \\ \cdot & 1 \end{pmatrix}, \qquad \begin{pmatrix} y & x \\ \langle \varphi(x) \rangle 0 & -y \end{pmatrix}, \tag{381}$$

which appear to be related to the considerations at the top of p. 41R. Apart from the 21-component, the second matrix is proportional to the matrix p^x_{ij} for $\psi = r^2x$, which is found upon substitution of equation (380) into equation (378):

$$p^x_{ij} = 2\begin{pmatrix} y & x \\ -3x & -y \end{pmatrix}. \tag{382}$$

As we shall see below, Einstein probably changed the 21-component of the second of the two matrices (381) to zero in the course of his calculations on p. 41R.

At the top of p. 41R (the first four lines in the top left corner and the first two in the top right corner), Einstein examined the transformation generated by $\psi = y^2x$, a modification of the function $\psi = r^2x$ considered at the bottom of p. 41L. Replacing y by t, he then compared this transformation to the transformation to a uniformly accelerated frame that he had considered in the context of his 1912 theory for static gravitational fields. 41R

Inserting equation (378) into equation (375) for two dimensions and setting $\psi = r^2x$, one finds, using equation (380):

$$\begin{aligned} dx' &= dx + p^x_{11}dx + p^x_{12}dy \\ &= dx + \frac{\partial^2\psi}{\partial x\partial y}dx + \frac{\partial^2\psi}{\partial y^2}dy \\ &= dx + 2ydx + 2xdy, \\ dy' &= dy + p^x_{21}dx + p^x_{22}dy \\ &= dy - \frac{\partial^2\psi}{\partial x^2}dx - \frac{\partial^2\psi}{\partial x\partial y}dy \\ &= dy - 6xdx - 2ydy. \end{aligned} \tag{383}$$

This result corresponds to the matrix p^x_{ij} in equation (382) above.

Einstein wrote at the top of p. 41R:

$$\begin{aligned} dx' &= dx + \alpha(ydx + xdy), \\ dy' &= dy - \alpha ydy. \end{aligned} \tag{384}$$

This corresponds to the matrix

$$p^x_{ij} = \alpha\begin{pmatrix} y & x \\ 0 & -y \end{pmatrix}, \tag{385}$$

which, except for the factor α, is the second of the two matrices (381) on p. 41L. It seems that Einstein adjusted his choice of the function ψ to get the matrix p^x_{ij} in equation (385) instead of the one in equation (382). It is easily seen that to achieve this $\psi = r^2x$ should be replaced by $\psi = y^2x$. If that is done, one finds (cf. equation (379)–(380)):

$$\frac{\partial\psi}{\partial x} = y^2 \qquad \frac{\partial\psi}{\partial y} = 2yx \qquad \frac{\partial^2\psi}{\partial x^2} = 0 \qquad \frac{\partial^2\psi}{\partial x\partial y} = 2y \qquad \frac{\partial^2\psi}{\partial y^2} = 2x \tag{386}$$

Using these results in equation (383) and writing α instead of 2, one finds Einstein's equation (384).

Einstein now replaced y by t[179] and integrated equations (384), using that $tdx + xdt = d(xt)$:

$$\begin{aligned} x' &= x + \alpha xt, \\ t' &= t - \alpha\frac{t^2}{2}. \end{aligned} \tag{387}$$

He compared this transformation to the transformation to a uniformly accelerating frame

$$\begin{aligned} x' &= x + \frac{1}{2}c\frac{\partial c}{\partial x}t^2, \\ t' &= ct, \end{aligned} \tag{388}$$

which he had obtained in the context of his theory for static fields of 1912 (Einstein 1912b, 456) and which he had already used on p. 11L (see equation (311)). The expressions for t' in equations (387) and (388) are quite different. So even after changing the generating function from $\psi = r^2x$ (with $r^2 \equiv x^2 + t^2$) to $\psi = t^2x$, Einstein was unable to recover the transformation to a uniformly accelerating frame of reference by integrating the infinitesimal unimodular transformation (383) generated by ψ. On the remainder of p. 41R, Einstein went through a calculation showing that motion constrained to a curved surface in three-dimensional space is along a geodesic (see sec. 4.5.8). The purpose of this calculation may simply have to been to reassure himself after the disappointing results of p. 12R and pp. 41L-R that at least the conceptual basis of his theory was sound.

41R

4.5.8 *Geodesic Motion along a Surface (41R)*

On p. 41R, starting with the expression $m(d^2x/dt^2)$, Einstein considered the motion of a particle in three-dimensional space constrained to move on a two-dimensional surface, but otherwise free of external forces. He proved that the trajectory of such a particle is a geodesic of the surface by showing that the line element of the trajectory is an extremal on the surface. Einstein had earlier recognized that the equation of motion of a particle in a static gravitational field follows from a variational principle

179 The second line of equation (387) originally had y instead of t.

for a four-dimensional line element.[180] At this point, he presumably realized that a similar result holds for the equation of motion in a general gravitational field.[181] In his earlier lecture notes on mechanics, Einstein had also treated constrained motion along a surface, but the concept of a geodesic line is not to be found in any of his published writings up to this point.[182] It is not entirely clear why Einstein considered the problem of constrained motion in this context. Einstein had long been familiar with the link between the physical concept of constrained motion and the geometric concept of a geodesic line from a course on infinitesimal geometry that he had taken as a student at the ETH with Carl Friedrich Geiser.[183]

Einstein started from the x-component of Newton's equation of motion for a particle of mass m, constrained to move on the surface $f(x, y, z) = 0$.

$$m\frac{d^2x}{dt^2} = \lambda\frac{\partial f}{\partial x}. \tag{389}$$

The analogous equations for the y– and z–components are indicated by dashed lines. As is clear from the accompanying figure, reproduced below, the right-hand side of this equation is the normal force that constrains the particle to move along the surface $f = 0$. This normal force is proportional to the gradient of f, which defines the normal direction, and which must be multiplied by a Lagrange multiplier λ determined by the magnitude of the force.

Einstein next absorbed m into a new Lagrange multiplier λ', and then changed independent variables, substituting the arc length s for the time t.[184] He thus arrived at

$$\frac{d^2x}{ds^2} = \lambda''\frac{\partial f}{\partial x}, \tag{390}$$

where $\lambda'' = (dt^2/ds^2)\lambda'$.

The rest of the proof is intended to show that this is the equation of a geodesic line on the curved surface $f = 0$.[185] Einstein wrote down the equation for the surface,

$$f = 0, \tag{391}$$

---

180 See the "Nachtrag" to (Einstein 1912b).

181 See Einstein to Ludwig Hopf, 16 August 1912: "The work on gravitation is going splendidly. Unless everything is just an illusion, I have now found the most general equations" ("Mit der Gravitation geht es glänzend. Wenn nicht alles trügt, habe ich nun die allgemeinsten Gleichungen gefunden." CPAE 5, Doc. 416).

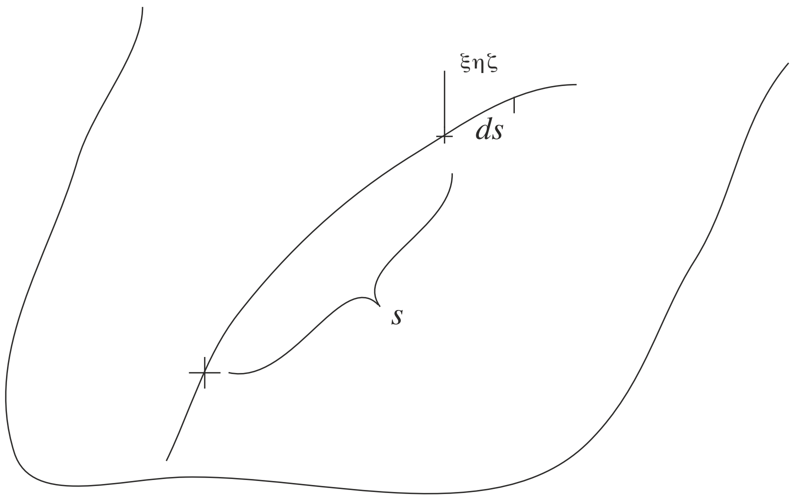
182 See CPAE 3, Doc. 1, [34–38], [75–76].

183 Einstein had registered for this course in winter semester 1897/1898 (see CPAE 1, Appendix E). Marcel Grossmann's notes on these lectures contain a page with very similar calculations (Bibliothek ETH, Zurich, Hs. 421:15).

184 There are no forces parallel to the surface, hence the speed of the point particle is constant.

185 Cf. Grossmann's notes on Geyser's lectures as well as very similar passages in Einstein's lecture notes on mechanics (CPAE 3, Doc. 4, [pp. 75ff.]).

drew a horizontal line, and sketched the figure below.



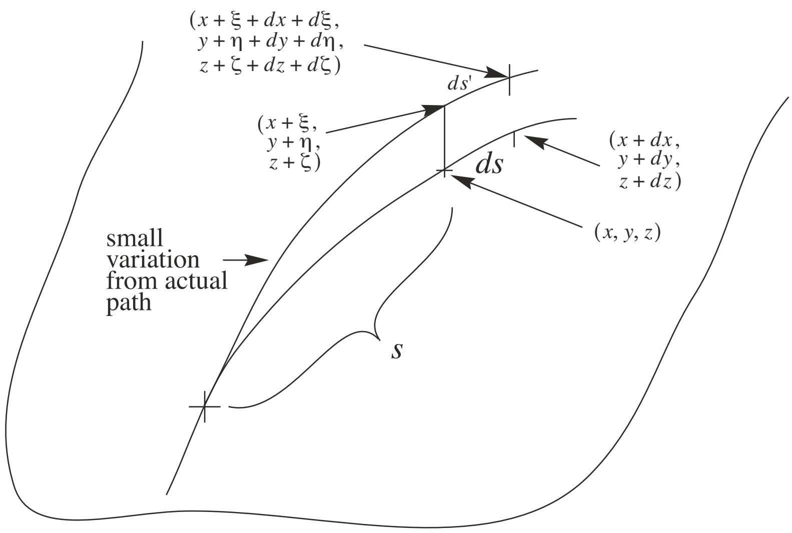
He then wrote down the coordinates:

$$x + \xi,$$
$$y + \eta,$$
$$z + \zeta. \tag{392}$$

The coordinates $(x(s), y(s), z(s))$ refer to points on the actual path. To prove that this path is a geodesic, he considered a nearby curve, produced by small variations (ξ, η, ζ). Thus a point with coordinates $(x + \xi, y + \eta, z + \zeta)$ is a point on this nearby curve. Next, Einstein considered a nearby point on the actual path, with coordinates $(x + dx, y + dy, z + dz)$, and a corresponding point on the path obtained through variation. He only wrote down the *x*-coordinate of the latter point:

$$x + \xi + \cancel{\frac{dx}{ds}}dx + d\xi\,. \tag{393}$$

Since Einstein was considering constrained motions, the path obtained through variation must also lie in the surface $f = 0$, i.e., $(x + \xi, y + \eta, z + \zeta)$ must also be the coordinates of a point on the surface $f = 0$. One can bring out the meaning of Einstein's figure more clearly by adding the path obtained through variation and labeling the various points.



Einstein now calculated the square of the line element ds' for the path obtained through variation, discarding terms of order $d\xi^2$:

$$\begin{aligned} ds'^2 &= (dx + d\xi)^2 + \cdot + \cdot \\ &= ds^2 + 2(dx d\xi + . + .) \\ &= ds^2\Big(1 + 2\Big(\frac{dx}{ds}\frac{d\dot{\xi}}{ds} + . + .\Big)\Big). \end{aligned} \tag{394}$$

He then took the square root of this equation:

$$ds' = ds\Big(1 + \Big(\frac{dx}{ds}\frac{d\dot{\xi}}{ds} + . + .\Big)\Big) \ . \tag{395}$$

Substituting $\dot{x}$ for dx/ds and $\dot{\xi}$ for $d\xi/ds$, he wrote the variation in the line element as:

$$ds' - ds = (\dot{x}\dot{\xi} + \cdot + \cdot)ds \, . \tag{396}$$

For a geodesic $\delta\int ds$ vanishes, which means that:

$$\int(\dot{x}\dot{\xi} + \cdot + \cdot)ds = 0 \, . \tag{397}$$

Through integration by parts Einstein transformed this equation into:

$$\int(\ddot{x}\xi + \cdot + \cdot)ds = 0 \, , \tag{398}$$

which will hold if the acceleration, with components ($\ddot{x}$, $\ddot{y}$, $\ddot{z}$), is perpendicular to the variation, with components (ξ , η , ζ). Since these variations are arbitrary (except that they have to lay within the surface), they should be perpendicular to the normal to the surface:

$$\frac{\partial f}{\partial x}\xi + \frac{\partial f}{\partial y}\eta + \frac{\partial f}{\partial z}\zeta = 0 \quad . \tag{399}$$

Hence, as Einstein wrote, “if” (“wenn”) condition (399) holds, then the actual path will be a geodesic: “from which the assertion” (“woraus die Behauptung”).

13L–R 4.6 *Emergence of the Entwurf Strategy (13L–R)*

On pp. 6L–12R (and pp. 41L–R), Einstein had tried in vain to find field equations invariant under a broad enough class of transformations—autonomous or non-autonomous[186]—to meet the requirements of the relativity principle and the equivalence principle (see sec. 1.1). He had pursued a combination of what we have called the mathematical and the physical strategy (see sec. 1.2).

Mathematically, the generally-covariant second Beltrami invariant (80), with (some power of) the determinant G of the metric playing the role of the arbitrary scalar function φ in its definition, looked like an especially promising point of departure. Field equations constructed out of the Beltrami invariant in this way are invariant under arbitrary (autonomous) unimodular transformations. On p. 12R and p. 41R, however, just prior to the entries on pp. 13L–R, Einstein had reached the conclusion that the important special case of an (autonomous) transformation to a uniformly accelerating frame of reference is not a unimodular transformation, not even infinitesimally. This must have been an important setback.

From a physics point of view, the core operator (118), which for weak fields reduces to the d’Alembertian acting on the metric, looked most promising. The drawback was that the core operator does not transform as a tensor under any autonomous non-linear transformations. It might, however, transform as a tensor under a class of non-autonomous non-linear transformation that would include the important special cases of rotation and uniform acceleration in Minkowski spacetime (see pp. 11L–12L). And even if this turned out not to be true for the core operator taken by itself, it might still be true for the sum of the core operator and some correction terms. Such correction terms were needed anyway to guarantee energy-momentum conservation (see p. 9L and sec. 4.4, especially the passage following equation (199)). With the help of such terms, it might furthermore be possible to connect field equations based on the core operator to the Beltrami invariants, which would throw light on their covariance properties. The Hertz restriction—the restriction to Hertz transformations, i.e., non-autonomous transformations under which the Hertz expression (231) transforms

186 See the introduction to sec. 4.3 for discussion of the distinction and footnote 94 for the origin of the terminology.

as a vector—played an important role in connecting the core operator to the Beltrami invariants. On p. 11L, Einstein had found that, at least infinitesimally, rotation in Minkowski spacetime was a Hertz transformation. He had also found, however, that uniform acceleration in Minkowski spacetime is not.

Still, the physically motivated core operator clearly held more promise overall than the mathematically more elegant Beltrami invariants. It is not surprising therefore that Einstein, on pp. 13L–R, bracketed the problem of the covariance of the field equations for the time being. He now began looking for field equations based on the core operator initially demanding only that such equations be invariant under arbitrary autonomous unimodular linear transformations. Presumably, he would check later whether these equations were also invariant under non-autonomous non-linear transformations such as uniform rotation and acceleration in Minkowski spacetime as was required by the equivalence principle. That Einstein restricted himself to unimodular transformations suggests that he eventually still wanted to connect the field equations to the Beltrami invariants.

On p. 13L, Einstein began an inventory of expressions involving the metric and its derivatives that transform as vectors and tensor under linear transformations and out of which he could therefore construct the correction terms to the core operator on the left-hand side of the field equations. On p. 13R, he substituted the core operator for the stress-energy tensor of matter in expression (74) for the energy-momentum balance between matter and field derived on p. 5R. In this way, it seems, Einstein hoped to identify the correction terms to the core operator that would guarantee the compatibility of the field equations with energy-momentum conservation. A variant of this strategy would subsequently lead to the *Entwurf* field equations. On p. 13R, however, Einstein quickly gave up on this line of reasoning. Marcel Grossmann then handed him a new mathematical quantity, which was far more promising than the Beltrami invariants. At the top of the very next page, p. 14L, the Riemann tensor makes its first appearance in the notebook. Pp. 14L–24L along with pp. 42L–43L are given over to attempts to extract field equations from this quantity along the lines of the mathematical strategy (see sec. 5). Only after these attempts had failed did Einstein return to the strategy we see emerging on pp. 13L–R (see p. 24R and pp. 26L–R and secs. 5.6.1 and 6).

4.6.1 *Bracketing the Generalization to Non-linear Transformations: Provisional Restriction to Linear Unimodular Transformations (13L)*

On p. 13L, under the heading, "Differential Covariants for Linear Substitutions, if one sets $G = 1$" ("Differentialkovarianten für lineare Substitutionen, falls $G = 1$ gesetzt wird"), Einstein started an inventory of quantities constructed out of the metric tensor and its derivatives that transform as vectors or tensors under (unimodular) linear transformations. All quantities that made it onto the list on p. 13L involve one and only one first-order derivative of the metric. Hence, they all fall under the heading "First Order" ("Erster Ordnung") on the third line of p. 13L. Originally, this heading was numbered "1)" but the number was subsequently deleted and no quantities involving second-order derivatives of the metric are listed. This may be because Einstein was 13L interested in constructing a stress-energy tensor for the gravitational field, which is a quantity quadratic in first-order derivatives of the metric (see sec.).

In addition to the “order” (“Ordnung”), Einstein also considered the “degree” (“Grad”) and the “multiplicity” (“Mannigfaltigkeit”) of the expressions he constructed. The degree of an expression is the number of factors of $g_{\mu\nu}$ and $\gamma_{\mu\nu}$ it contains. Its multiplicity is simply its rank.[187] Einstein denoted every free index of the vectors and tensors he constructed either by a dot (for a contravariant index) or a dash (for a covariant index). A contravariant vector is accordingly called a “point vector” (“Punktvektor”), a covariant vector a “plane vector” (“Ebenenvektor”).[188] Similarly, a tensor with two covariant and one contravariant index, for instance, is called a “ · · – tensor.” Einstein distinguished two ways of forming such vectors and tensors, “internal” (“Innere”) and “exterior” (“Aussere”) differentiation. In the case of “inner” differentiation, the index of the derivative operator is contracted with one of the indices of the components of the metric, so that a four-divergence is formed. In the case of “outer” differentiation, the index of the derivative operator is different from the indices of the components of the metric, so that a four-gradient is formed. With this explanation of Einstein’s terminology the list on p. 13L becomes largely self-explanatory.

The first item on the list is the Hertz expression, a point vector of first order and first degree obtained through “internal” differentiation:

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_\nu} \qquad \text{Punktvektor.} \tag{400}$$

Note that $\gamma_{\mu\nu}$ cannot be replaced by $g_{\mu\nu}$ in this expression since that would involve contraction over two covariant indices. The next items on the list are therefore

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_i} \qquad \cdot \ \cdot \ - \ \text{Tensor,} \tag{401}$$

and[189]

$$\sum \frac{\partial g_{\mu\nu}}{\partial x_i} \qquad - \ - \ \cdot \ \text{Tensor,} \tag{402}$$

both obtained through “external” differentiation.

On the next line, Einstein turned to expressions of “first order” and “second degree” (“zweiten Grades”) and began by writing down the four different possible

---

187 Einstein used this same terminology on p. 8L (see equation (163)).

188 This terminology may have been inspired by Grassmann’s “Ausdehnungslehre” (Grassmann 1862). For evidence of Einstein’s reading of Grassmann in this period, see Einstein to Michele Besso, 13 May 1911 (CPAE 5, Doc. 267), and Einstein to Conrad Habicht, 7 July 1913 (CPAE 5, Doc. 450). Later in the notebook Einstein used this same terminology for tensors as well (see, e.g., pp. 17L–R).

189 Expression (402) is, in fact, in Einstein’s terminology, a $---$Tensor . Einstein inadvertently may have thought for a moment that the character of the three indices in expression (402) would be just the opposite of those in expression (401).

vectors of this kind that can be obtained by contracting expressions (400)–(402) with $g_{\mu\nu}$ and $\gamma_{\mu\nu}$ in various ways:[190]

$$\sum g_{\mu\sigma}\frac{\partial\gamma_{\mu\nu}}{\partial x_\nu} \qquad \text{Ebenenvektor}, \tag{403}$$

$$\sum g_{\mu\nu}\frac{\partial\gamma_{\mu\nu}}{\partial x_i} \qquad \text{Ebenenvektor}, \tag{404}$$

$$\sum \gamma_{\mu\nu}\frac{\partial g_{\mu\nu}}{\partial x_i} \qquad \text{Ebenenvektor}, \tag{405}$$

$$\sum \gamma_{\mu i}\frac{\partial g_{\mu\nu}}{\partial x_i} \qquad \text{Ebenenvektor}, \tag{406}$$

Expressions (404) and (405) are connected by a curly bracket. Not only are they equal to one another (because of the relation $\partial/\partial x_i(g_{\mu\nu}\gamma_{\mu\nu}) = 0$), they both vanish because of the restriction to unimodular coordinates (for which $G = 1$) and the relation

$$g_{\mu\nu}\frac{\partial\gamma_{\mu\nu}}{\partial x_i} = \frac{1}{G}\frac{\partial G}{\partial x_i} \tag{407}$$

(cf. equation (87)).

Finally, under the heading, "In addition the tensors of third multiplicity" ("Dazu die Tensoren dritter Mannigfaltigkeit"), Einstein wrote down all third-rank tensors of first order and second degree that can be constructed out of expressions (400)–(402). The Hertz expression (400) can be turned into a tensor of this kind through multiplication with either the covariant or the contravariant metric,

$$\sum {}^{g_{i\kappa}}_{\gamma_{i\kappa}}\frac{\partial\gamma_{\mu\nu}}{\partial x_\nu}, \tag{408}$$

giving, in Einstein's terminology, a "$- - \cdot$ tensor" and a "$\cdot\ \cdot\ \cdot$ tensor," respectively. Expressions (401) and (402) can be turned into third-rank tensors of first order and second degree by contracting them with $g_{\mu\nu}$ and $\gamma_{\mu\nu}$. This leads to the last four expressions on p. 13L:

$$\sum g_{\kappa\mu}\frac{\partial\gamma_{\mu\nu}}{\partial x_i} \qquad - \cdot - \ \text{[Tensor]}, \tag{409}$$

$$\sum \gamma_{\kappa i}\frac{\partial\gamma_{\mu\nu}}{\partial x_i} \qquad \cdot\ \cdot\ \cdot \ \text{[Tensor]}, \tag{410}$$

$$\sum \gamma_{\kappa\mu}\frac{\partial g_{\mu\nu}}{\partial x_i} \qquad \cdot - - \ \text{[Tensor]}, \tag{411}$$

190 Einstein omitted the summation sign in expression (406).

$$\sum \gamma_{\kappa i} \frac{\partial g_{\mu\nu}}{\partial x_i} \qquad \cdot -- \text{[Tensor]}. \tag{412}$$

4.6.2 *Trying to Find Correction Terms to the Core Operator to Guarantee Compatibility of the Field Equations With Energy-Momentum Conservation (13R)*

13R The starting point of the considerations on p. 13R is equation (74) for the energy-momentum balance between matter and gravitational field derived on p. 5R. This equation is equivalent to the vanishing of the covariant derivative of the matter stress-energy tensor $T_{\mu\nu}$. In unimodular coordinates (for which $\sqrt{G} = 1$) the left-hand side of equation (74) can be written as

$$\sum_{\mu\nu} \frac{\partial}{\partial x_\mu}(g_{m\nu} T_{\mu\nu}) - \frac{1}{2} \sum \frac{\partial g_{\mu\nu}}{\partial x_m} T_{\mu\nu}. \tag{413}$$

Inserting the core operator (see, e.g., expression (324) on p. 11R),

$$\gamma_{\alpha\beta} \frac{\partial^2 \gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta}, \tag{414}$$

for the contravariant stress-energy tensor $T_{\mu\nu}$ in expression (413) and adding an equality sign, one finds the first line of p. 13R:

$$\sum_{\alpha\beta\mu\nu} \frac{\partial}{\partial x_\mu}\left(g_{m\nu} \gamma_{\alpha\beta} \frac{\partial^2 \gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta}\right) - \frac{1}{2} \sum \frac{\partial g_{\mu\nu}}{\partial x_m} \gamma_{\alpha\beta} \frac{\partial^2 \gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta} = \quad . \tag{415}$$

On the next line, Einstein wrote “Third-order derivatives do not appear, if

$$\sum_\mu \frac{\partial \gamma_{\mu\nu}}{\partial x_\mu} = 0 \text{.”} \tag{416}$$

(“Dritte Ableitungen treten nicht auf, wenn … = 0 ist.”). Equation (416) is the by now familiar Hertz restriction. On the remainder of p. 13R, Einstein rewrote expression (415) using this restriction.

Why was Einstein interested in expression (415)? The simplest answer is that he wanted to find what further restrictions, if any, would be needed to guarantee that the field equations

$$\gamma_{\alpha\beta} \frac{\partial^2 \gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta} = \kappa T_{\mu\nu} \tag{417}$$

—understood either as exact or as weak-field equations—be compatible with energy-momentum conservation, i.e., with the vanishing of the covariant derivative of $T_{\mu\nu}$, or, in unimodular coordinates, the vanishing of expression (413). If the field equations (417) hold, the vanishing of expression (413) for $T_{\mu\nu}$ implies that expression (415) for the core operator (414) must also vanish. It is unlikely, however, that this was the point of Einstein’s considerations on p. 13R.

Einstein already knew that the exact field equations cannot be obtained by simply setting the core operator equal to the stress-energy tensor of matter as in equation (417). Energy-momentum conservation requires an additional term on the left-hand side that can be interpreted as gravitational energy-momentum density (see p. 9L and the discussion in sec. 4.4, especially equations (199)–(208)). In other words, Einstein expected the exact field equations to have the form

$$\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta} - \kappa t_{\mu\nu} = \kappa T_{\mu\nu}, \tag{418}$$

where the quantity $t_{\mu\nu}$, which represents gravitational energy-momentum, is assumed to be quadratic in first-order derivatives of the metric. In a weak-field approximation, this additional term can be neglected and equations (418) reduce to equations (417). On p. 13R, however, terms quadratic in first-order derivatives of the metric are *not* neglected. This strongly suggests that Einstein was implicitly using field equations of the form of equation (418). This in turn would mean that Einstein expected expression (415) to be equal, not to zero, but to

$$\sum\frac{\partial}{\partial x_\mu}(g_{m\mu}\kappa t_{\mu\nu}) - \frac{1}{2}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}\kappa t_{\mu\nu}. \tag{419}$$

The equality of expressions (415) and (419) would guarantee the compatibility of energy-momentum conservation (in the form of the vanishing of expression (413)) and field equations of the form (418). Presumably, what Einstein tried to do on p. 13R was to rewrite expression (415) in the form of equation (419) and identify $t_{\mu\nu}$. For one thing, this would explain his concern with the elimination of third-order derivatives from expression (415). Since $t_{\mu\nu}$ only contains first-order derivatives of the metric, expression (419) will contain no derivatives higher than of second order. As we pointed out in sec. 4.6.1, this may also be why Einstein only listed quantities of "first order" ("Erster Ordnung") on p. 13L.

Note that on this reading Einstein must have come to realize that gravitational energy-momentum has a special status. On p. 9L he had still demanded that the quantity $t_{\mu\nu}$ representing gravitational energy-momentum satisfy equation (74) posited for *all* energy-momentum on p. 5R (cf. footnote 128). In that case the right-hand side of equation (415) would simply be equal to zero rather than to expression (419).

When the Hertz restriction (416) is imposed, the left-hand side of equation (415) reduces to

$$\frac{\partial}{\partial x_\mu}(g_{m\nu}\gamma_{\alpha\beta})\frac{\partial^2\gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta} - \frac{1}{2}\frac{\partial g_{\mu\nu}}{\partial x_m}\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta}, \tag{420}$$

which no longer contains any third-order derivatives of the metric. Regrouping terms, one can rewrite this expression in the way Einstein wrote it on the third line of p. 13R:

$$\sum\left(\frac{\partial g_{m\nu}}{\partial x_\mu} - \frac{1}{2}\frac{\partial g_{\mu\nu}}{\partial x_m}\right)\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta} + \sum_{\mu\nu\alpha\beta} g_{m\nu}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\mu}\frac{\partial^2\gamma_{\mu\nu}}{\partial x_\alpha \partial x_\beta}. \tag{421}$$

Einstein concentrated on the second summation in this expression. Using

$$\frac{\partial}{\partial x_\mu}\Big(\sum_\nu g_{\lambda\nu}\gamma_{\mu\nu}\Big) = 0 \tag{422}$$

and the Hertz restriction (416), he arrived at:

$$\sum \gamma_{\mu\nu}\frac{\partial g_{\lambda\nu}}{\partial x_\mu} = 0\,. \tag{423}$$

He tried to rewrite the second summation in expression (421) in such a way that he could apply equation (423) to the term $(\partial g_{m\nu}/\partial x_\beta)\gamma_{\mu\nu}$, but quickly realized that this was not feasible. He began by pulling out the differentiation with respect to x_α, thus arriving at:[191,192]

$$\frac{\partial}{\partial x_\alpha}\left(g_{m\nu}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\mu}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\quad\right) - \frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\mu}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\,. \tag{424}$$

He then used relation (422) to rewrite the first term as:

$$-\frac{\partial}{\partial x_\alpha}\left(\frac{\partial g_{m\nu}}{\partial x_\beta}\gamma_{\mu\nu}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\mu}\right)\,. \tag{425}$$

Here the calculation breaks off.

Einstein did not return to considerations of energy-momentum conservation until p. 19R. At that point he had further deepened his understanding of the special status of gravitational energy-momentum. Interpreting the second term in expression (413) as the gravitational force density, he tried to rewrite that term as the divergence of the quantity $t_{\mu\nu}$ representing the gravitational energy-momentum density (see the discussion following equation (484) in sec. 5.4.2). Later in the notebook (on p. 24R and, more systematically, on pp. 26L-R), he used this insight to derive field equations that are automatically compatible both with energy-momentum conservation and with Newtonian theory for static weak fields (see sec. 5.6.1 and sec. 6). This led him to the *Entwurf* field equations. The notion that energy-momentum conservation requires coordinate restrictions over and above the ones needed to recover Newtonian theory for static weak fields stayed with Einstein right up until his introduction of generally-covariant field equations in November 1915.[193]

191 Einstein drew a line connection expression (424) with the second summation in expression (421).

192 In this equation $\partial g_{\mu\nu}/\partial x_\alpha$ should be $\partial g_{m\nu}/\partial x_\alpha$. Because of the Hertz restriction there is no term with $\partial^2\gamma_{\alpha\beta}/\partial x_\alpha \partial x_\mu$.

193 Einstein later compared the Hertz restriction with coordinate restrictions in (Einstein and Grossmann 1914), which not only circumscribe the covariance of the *Entwurf* theory but also guarantee energy-momentum conservation (see Einstein to Paul Hertz, 22 August 1915 [CPAE 8, Doc. 111]). For further discussion of the role of coordinate restrictions in determining covariance properties, recovering Newtonian theory, and guaranteeing energy-momentum conservation, see “Untying the Knot ...” sec. 1.1 (in this volume).

5. EXPLORATION OF THE RIEMANN TENSOR (14L–25R, 42L–43L)

5.1 *Introduction* (14L–25R, 42L–43L)

14L–25R, 42L–43L

A new stage in Einstein's search for gravitational field equations began on p. 14L of the notebook with the systematic exploration of the Riemann tensor along the lines of the mathematical strategy.[194] In the course of this exploration, Einstein considered various gravitational field equations based on the Ricci tensor that he would publish in his communications to the Prussian Academy of November 1915 (Einstein 1915a, b, d). He even considered, albeit only in linear approximation, the crucial trace term that occurs in the final version of the field equations. However, the episode that, from a modern point of view, begins so promisingly on p. 14L with the introduction of the Riemann tensor ends disappointingly on p. 26L with the derivation of the *Entwurf* field equations along the lines of the physical strategy. What happened on these pages that made Einstein abandon the mathematical strategy and return to the physical strategy?

The analysis of pp. 14L–25R and related material on pp. 42L–43L, the last three pages of the part starting from the other end of the notebook, reveals a pattern that holds the key to our answer to this question. Einstein's starting point invariably is some expression of broad if not general covariance constructed out of the Riemann tensor. To extract from these expressions field equations that reduce to the Poisson equation of Newtonian theory in the special case of weak static fields, Einstein introduced various coordinate restrictions.[195] With the help of these he could eliminate unwanted terms with second-order derivatives of the metric. The left-hand sides of the resulting field equations consist of a term with a core operator (i.e., a term that, in linear approximation, reduces to the d'Alembertian acting on the metric), and terms quadratic in first-order derivatives of the metric, which vanish in linear approximation. Einstein then checked whether these field equations and the coordinate restrictions used in their construction satisfy his other heuristic requirements,[196] in particular whether they are compatible with energy-momentum conservation and whether they are covariant under a wide enough class of coordinate transformations (autonomous or non-autonomous[197]) to be compatible with the equivalence principle and a generalized relativity principle. All candidates considered by Einstein failed at least one of these tests. Finding coordinate restrictions of sufficiently broad covariance turned out to be particularly difficult.

---

194 See sec. 1.2 for a characterization of the difference between the mathematical and the physical strategy.

195 See sec. 4.1 for a discussion of the notion of a coordinate restriction.

196 See sec. 1.1 for a discussion of what we identified as the four major heuristic principles: the correspondence principle, the conservation principle, the relativity principle and the equivalence principle.

197 See sec. 4.1 for the definitions of the notions of autonomous and non-autonomous and transformations.

Eventually, Einstein switched back to the physical strategy. He developed the considerations of energy-momentum conservation on p. 13R into a method for generating field equations guaranteed both to have the desired form in linear approximation, and to be compatible with energy-momentum conservation. Field equations constructed in this manner have the same general form as the candidate field equations that Einstein had extracted from the Riemann tensor by eliminating unwanted second-order derivative terms with the help of coordinate restrictions. This suggested that the field equations generated by this new method could also be produced by the mathematical strategy. It remained unclear, of course, from which generally-covariant expression they could be extracted and whether the necessary coordinate restrictions would be of sufficiently broad covariance and would themselves be compatible with energy-momentum conservation. However, it must have been encouraging that the physical strategy yielded field equations, satisfactory on all other counts, of exactly the form that Einstein had come to expect while pursuing the mathematical strategy in his exploration of the Riemann tensor. And as far as the unknown covariance properties of the equations were concerned, the mathematical strategy, for all its promise on this score, had not allowed Einstein to make any real progress either. It thus becomes understandable that Einstein eventually gave up the idea of constructing field equations out of the Riemann tensor and instead adopted the *Entwurf* equations.

5.2 *General Survey (14L–25R, 42L–43L)*

14L At the top of p. 14L Einstein wrote down the fully covariant form of the Riemann tensor. He wrote Grossmann's name right next to it, suggesting that it was Grossmann who had drawn his attention to this tensor and its importance. Einstein proceeded to form the covariant form of the Ricci tensor by contracting the Riemann tensor over two of its four indices. He looked at the terms involving second-order derivatives of the metric and immediately noticed that in addition to a core-operator term the Ricci tensor contains three other second-order derivative terms that should not occur in the Newtonian limit. So the natural way of extracting a second-rank tensor from the Riemann tensor did not seem to produce a suitable candidate for the left-hand side of the field equations (sec. 5.3.1[198]).

14R–16R On pp. 14R–16R, Einstein explored a different way of extracting a two-index object from the Riemann tensor that, if not generally covariant, at least promised to be a tensor under unimodular transformations. In close analogy to his treatment of the Beltrami invariant on p. 9L, he computed the curvature scalar by fully contracting the Riemann tensor. Setting the determinant of the metric equal to unity, he succeeded in rewriting the curvature scalar as the contraction of the metric with a symmetric two-index object denoted (on p. 16L) by T_{ik}. Einstein presumably expected that T_{ik}

198 In this general survey we shall give a reference at the end of each brief summary of a calculation or a line of reasoning in this part of the notebook to the subsection where the calculation or the argument just summarized is discussed in much greater detail.

would turn out to be a tensor under unimodular transformations. Unfortunately, T_{ik} still contains two terms with unwanted second-order derivatives of the metric in addition to a core-operator term (sec. 5.3.2).

On the following pages (pp. 17L–18R), Einstein investigated the relation between the two expressions that he had formed out of the Riemann tensor. Since T_{ik} gives the curvature scalar when contracted with the covariant metric, it is itself a contravariant object. To facilitate comparison between T_{ik} and the covariant Ricci tensor, Einstein (on p. 17L) first formed the contravariant version of the latter. He tried to simplify the resulting expression using that covariance under unimodular transformations is all that matters for the comparison with T_{ik}. This meant that he could assume the determinant of the metric to be a constant. He abandoned this calculation as "too involved." On p. 17R he formed the covariant version of T_{ik} instead and started to bring the covariant Ricci tensor into a form in which it could be compared with this version of T_{ik}, again assuming the determinant of the metric to be a constant. This calculation also turned out to be complicated, and was abandoned as well (sec. 5.3.3). 17L–18R

Since neither the Ricci tensor nor T_{ik} had the form required by the correspondence principle, Einstein began to investigate the possibility of obtaining suitable candidates for the left-hand side of the field equations by restricting the range of admissible coordinates. On p. 19L he showed that the terms in the Ricci tensor with unwanted second-order derivatives can be eliminated by imposing the harmonic coordinate restriction (sec. 5.4.1).[199] He then checked whether these field equations and this coordinate restriction are compatible with his other heuristic requirements. 19L

On p. 19R, Einstein examined in linear approximation the harmonic restriction and the field equations constructed with the help of it. Einstein confirmed that the weak-field field equations are compatible with his conservation principle: with the help of these equations, the term giving the gravitational force density in the energy-momentum balance between matter and gravitational field can be written as the divergence of a quantity representing gravitational stress-energy density. To guarantee compatibility between the weak-field equations and energy-momentum conservation, however, Einstein had to impose an additional coordinate restriction, a linear approximation of the Hertz restriction.[200] Together, the harmonic restriction and the Hertz restriction imply that the trace of the weak-field metric has to vanish. In turn, this implies that the trace of the stress-energy tensor for matter has to vanish (sec. 5.4.2). 19R

To avoid these consequences, Einstein (on p. 20L) modified the weak-field equations by adding a term proportional to the trace of the weak-field metric. This term was 20L

199 Considering p. 19L in isolation, one would think that Einstein was simply applying the harmonic coordinate condition in the modern sense to recover the Poisson equation in the limit of weak static fields. This interpretation is even compatible with the whole passage dealing with the Ricci tensor in harmonic coordinates (pp. 19L–21R). The interpretation is incompatible, however, with Einstein's usage of coordinate conditions elsewhere in the notebook, both on pages preceding and on pages following the examination of the harmonic coordinate condition (cf. especially p. 23L). These other pages suggest that what Einstein had in mind throughout the notebook were coordinate restrictions rather than coordinate conditions in the modern sense. Cf., e.g., our discussion at the end of sec. 5.5.4.

200 See sec. 4.1 for the introduction of this coordinate restriction.

introduced in such a way that Einstein could now use the harmonic restriction to satisfy both the conservation principle and the correspondence principle. From a purely mathematical point of view, the resulting weak-field equations are the Einstein field equations of the final theory of November 1915 in linear approximation. As Einstein
21L checked briefly on p. 20L and more carefully on p. 21L, with these modified field equations the gravitational force density can still be written as the divergence of gravitational stress-energy density (sec. 5.4.3).

The modified weak-field equations, however, do not allow the spatially flat metric that Einstein continued to use to represent static fields.[201] Given this disparity, Einstein reconsidered his presupposition concerning the form of the metric of weak static
21R fields. On p. 21R he presented a seductive but ultimately fallacious argument that corroborated his prior beliefs on this point. The argument was based on the dynamics of point particles (recapitulated on p. 20R) and Galileo's principle that all bodies fall with the same acceleration in a given gravitational field. This powerful physical argument seemed to rule out the harmonic restriction (secs. 5.4.4 and 5.4.6).

22R Einstein, however, was not ready to give up his attempt to extract the left-hand side of the field equations from the Riemann tensor. On p. 22R, at the suggestion of Grossmann perhaps, whose name once again appears at the top of the page, he turned to a different coordinate restriction that might help him achieve his goal. First, he noticed that the Ricci tensor can be split into two parts, each of which by itself transforms as a tensor under unimodular transformations. Einstein took one of these as his new candidate for the left-hand side of the field equations. We call this part the November tensor, because it is the left-hand side of the field equations published in the first of Einstein's four papers of November 1915[202] (sec. 5.5.1). The November tensor still contains terms with unwanted second-order derivatives of the metric. Einstein eliminated these by imposing the Hertz restriction. The calculations on p. 19R had shown that the Hertz restriction is compatible with energy-momentum conservation in the weak-field case without the need for an additional trace term in the weak-field equations.[203]

22L Given Einstein's understanding of the status of coordinate restrictions at the time, the logical next step was to investigate the group of transformations allowed by the Hertz restriction. On the facing page (p. 22L) Einstein did indeed derive the condition for non-autonomous transformations leaving the Hertz restriction invariant. Earlier in the notebook (pp. 10L–11L), he had already found that the Hertz restriction rules out uniform acceleration in the important special case of Minkowski spacetime (sec. 5.5.3).[204] He nonetheless held on to the Hertz restriction for the time being.

---

201 This form of the static metric is also incompatible with the harmonic coordinate restriction, but it is unclear whether Einstein realized that at this point.

202 (Einstein 1915a).

203 Unlike the harmonic restriction, the Hertz restriction as well as the restriction to unimodular transformations are compatible with Einstein's assumptions concerning the form of the weak-field static metric (cf. footnote 201 above).

The elimination of terms with unwanted second-order derivatives of the metric from the November tensor had left Einstein (at the bottom of p. 22R) with a candidate for the left-hand side of the field equations containing numerous terms quadratic in first-order derivatives. On p. 23L he added another coordinate restriction to the Hertz 23L
restriction to eliminate some of these terms. Just as he had obtained the November tensor by splitting the Ricci tensor into two parts each of which transforms as a tensor under unimodular transformations, Einstein (on p. 23L) obtained yet another candidate for the left-hand side of the field equations by splitting the November tensor into various parts, each of which transforms as a tensor under a class of unimodular transformations under which a quantity which we shall call the ϑ-expression transforms as a tensor. Restricting the allowed transformations to such ϑ-transformations, Einstein found that he could eliminate all but one of the terms quadratic in first-order derivatives of the metric from the November tensor. He furthermore discovered that the restriction to ϑ-transformations sufficed to eliminate the terms with unwanted second-order derivatives as well. There was no need to add the Hertz restriction to the ϑ-restriction. Einstein thus abandoned the Hertz restriction and focused on the ϑ-restriction instead.

On p. 23R Einstein began to investigate the covariance properties of the ϑ-expres- 23R
sion. As with the Hertz restriction, he derived the condition for non-autonomous transformations leaving the ϑ-expression invariant (sec. 5.5.5). He did not attempt, however, to find the most general (non-autonomous) transformations satisfying this condition. Instead, he focused on the important special case of a vanishing ϑ-expression. The ϑ-expression vanishes, for instance, for the Minkowski metric in standard diagonal form. According to Einstein's heuristic principles, it should therefore also vanish for the Minkowski metric in accelerated frames of reference (sec. 5.5.6). It was thus natural for Einstein to investigate what metric fields are allowed by the condition that the ϑ-expression vanish.

On pp. 42L–43L,[205] Einstein addresses just this problem, further limiting himself 42L–43L
to time-independent metric fields and hence to uniformly accelerated frames of reference. The main result of his investigation was both promising and puzzling. He discovered that the ϑ-expression vanishes for a metric, which we shall call the ϑ–metric, whose covariant components are the contravariant components of the rotation metric, i.e., the Minkowski metric in rotating coordinates (sec. 5.5.6). Einstein tried to come to terms with this result in various ways.

First, on the bottom half of p. 42R and again at the bottom of p. 43LA, he inserted 42R–43LA
the suggestive ϑ–metric into the Lagrangian for a point particle moving in a metric field and began to compute the Euler-Lagrange equations. Presumably, the idea was to check whether the components of the ϑ–metric and its derivatives could be given

204 Contrary to what Einstein had concluded on p. 11L (see sec. 4.5.2), the Hertz restriction also rules out finite transformation to rotating frames in Minkowski spacetime.

205 These pages are found toward the end of the part starting from the other end of the notebook. At the beginning of sec. 5.5.6 we address the question of the temporal order of the calculations on pp. 42L–43L at one end of the notebook and those on pp. 23L–24L at the other.

a physical interpretation in terms of centrifugal and Coriolis forces. Einstein broke off this calculation without reaching a definite conclusion (sec. 5.5.7).

24L A variant of this approach can be found on p. 24L, the page immediately following the introduction of the ϑ-restriction. This time he took the energy-momentum balance between matter and gravitational field as his starting point rather than the Lagrangian for a point particle moving in a metric field (sec. 5.5.9).

43LA Einstein tried a different approach on p. 43LA. He replaced the covariant components of the metric in the ϑ-expression by the corresponding contravariant ones. Since the original ϑ-expression vanishes for the rotation metric if only its co- and contravariant components are interchanged, the new version will vanish for the rotation metric itself. This approach did not work either. After three failed attempts to come to terms with the ϑ-metric, Einstein gave up the ϑ-restriction, though not the idea of extracting field equations from the November tensor (sec. 5.5.8).

24R Although the actual calculation has not been preserved in the notebook, there are strong indications that Einstein at this point did for field equations extracted from the November tensor what he had done earlier (on pp. 19R, 20L, and 21L) for field equations extracted directly from the Ricci tensor. He confirmed that in linear approximation these field equations can be used to write the gravitational force density as the divergence of a quantity representing gravitational stress-energy density. At the top of p. 24R, Einstein wrote down an expression that is most naturally interpreted as the end result of this calculation and noted that it vanishes for the rotation metric. Given some errors in the expression for the rotation metric on p. 24R, one can understand how Einstein reached this conclusion. When these errors are corrected, one sees that the expression, in fact, does not vanish for the rotation metric (see the first half of sec. 5.6.1).

It is the next step that Einstein took on p. 24R that marks the beginning of Einstein's return to the physical strategy abandoned on p. 13R. So far Einstein had only verified in linear approximation that various candidate field equations allowed him to write the gravitational force density as the divergence of the gravitational stress-energy density. It was not at all clear whether this result would also hold exactly. On p. 24R Einstein introduced an ingenious new approach to this problem. Rather than starting from some candidate field equations and using them to rewrite the gravitational force density as a divergence without neglecting terms of one order or another, Einstein started from the expression for the divergence of the stress-energy density obtained in linear approximation and determined which higher-order terms need to be added to the linearized field equations such that this divergence becomes exactly equal to the gravitational force density. This is the strategy that Einstein used to derive the *Entwurf* equations (see pp. 26L–R).[206] It is in this context that it was very important for Einstein to check whether the expression at the top of p. 24R would vanish exactly for the rotation metric. This is a necessary condition for the rotation metric to be a

206 For a comparison between this method of finding candidate field equations and the method used on pp. 19L–23L, see the introduction to sec. 5.6.

solution of field equations constructed with the help of the new strategy. Once he had derived the new field equations, he checked directly whether the rotation metric is a solution and discovered that it is not. However, he also discovered that he had erroneously cancelled two terms in his construction of the new field equations which opened up the possibility that the rotation metric would be a solution of the corrected equations (see the second half of sec. 5.6.1).

On p. 25L Einstein tried to recover his new candidate field equations from the 25L
November tensor by imposing an appropriate coordinate restriction. It seems to have been Einstein's hope at this point that he could derive the same field equations following either the physical or the mathematical strategy (sec. 5.6.2).

Material at the top of p. 25R shows that Einstein considered a variant of the ϑ- 25R
restriction, which we shall call the $\hat{\vartheta}$-restriction, to extract field equations from the November tensor. It is unclear whether he was still trying to recover the field equations found on p. 24R in this way. Einstein went back to his calculations on p. 23L, where he had applied the original ϑ-restriction to the November tensor, and indicated the changes that would need to be made if the ϑ-restriction were replaced by the $\hat{\vartheta}$-restriction. Returning to p. 25R, he checked whether the $\hat{\vartheta}$-expression vanishes for the rotation metric, as required by the equivalence and relativity principles. He discovered that it does not, which is probably why he abandoned the $\hat{\vartheta}$-restriction (sec. 5.6.3). This marks the end of Einstein's pursuit of the mathematical strategy in the notebook.

On the remainder of p. 25R, Einstein started tinkering with the field equations he had found on p. 24R to ensure that the rotation metric would be a solution. Einstein convinced himself that a slightly modified version of the equations satisfies this requirement. These modified equations, however, are not well-defined mathematically (they involve contractions over pairs of covariant indices among other things). It is unclear whether Einstein came to recognize this (sec. 5.6.4). He abandoned these ill-defined equations when he found that it is not possible to rewrite the gravitational force density as the divergence of gravitational stress-energy density with their help (sec. 5.6.5).

On the next page (p. 26L), Einstein made a fresh start with the physical strategy. A possible indication that he had meanwhile abandoned his hope of recovering field equations found in this manner from the Riemann tensor is that he no longer set the determinant of the metric equal to unity, as he had still done on pp. 24R–25R in the hope perhaps to connect the field equations of p. 24R to the November tensor. The exploration of the Riemann tensor had nonetheless been fruitful (independently of the developments of November 1915). Even though it had failed to produce satisfactory field equations with a well-defined covariance group, it had given Einstein a clear idea of the structure any such field equations would have after unwanted terms in the Ricci tensor or the November tensor had been eliminated by imposing the appropriate coordinate restrictions. He had found a strategy to generate field equations of this form that automatically satisfy the correspondence and conservation principles. Given the difficulties Einstein had run into trying to make sure that the relativity and equivalence principles are satisfied as well, one can understand that he decided to bracket those problems for the time being.

14L–18R

5.3 *First Attempts at Constructing Field Equations out of the Riemann Tensor* (14L–18R)

On p. 14L the Riemann tensor appears for the first time in the notebook. Einstein immediately considered the Ricci tensor as a candidate for the left-hand side of the field equations, but ran into the problem that it contains unwanted terms with second-order derivatives of the metric. On the following pages (pp. 14R–18R), Einstein extracted another candidate for the left-hand side of the field equations from the curvature scalar and compared the result to the Ricci tensor. Unfortunately, this new candidate also contains unwanted second-order derivative terms. Moreover, its relation to the Ricci tensor remained unclear.

14L

5.3.1 *Building a Two-Index Object by Contraction: the Ricci Tensor (14L)*

At the top of p. 14L Einstein wrote down the definitions of the Christoffel symbols of the first kind,

$$\begin{bmatrix} \mu\ \nu \\ l \end{bmatrix} = \frac{1}{2}\left(\frac{\partial g_{\mu l}}{\partial x_\nu} + \frac{\partial g_{\nu l}}{\partial x_\mu} - \frac{\partial g_{\mu\nu}}{\partial x_l}\right), \tag{426}$$

and of the fully covariant Riemann tensor,

$$\begin{aligned}(i\kappa, lm) = {} & \frac{1}{2}\left(\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l} + \frac{\partial^2 g_{\kappa l}}{\partial x_i \partial x_m} - \frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m} - \frac{\partial^2 g_{\kappa m}}{\partial x_i \partial x_l}\right) \\ & + \sum_{\rho\sigma} \gamma_{\rho\sigma}\left(\begin{bmatrix} i\ \ m \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ \ l \\ \rho \end{bmatrix} - \begin{bmatrix} i\ \ l \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ \ m \\ \rho \end{bmatrix}\right).\end{aligned} \tag{427}$$

Next to the Riemann tensor Einstein wrote “Grossmann Tensor vierter Mannigfaltigkeit,” indicating that it was his friend and colleague Marcel Grossmann who introduced him to these mathematical objects. Grossmann’s sources for the Christoffel symbols and the Riemann tensor[207] were in all probability (Christoffel 1869) and (Riemann 1867).[208] These are the sources cited for the Riemann tensor in Grossmann’s section of the *Entwurf* paper,[209] where it appears in almost identical form.[210] A comparison of the notation used for the Christoffel symbols and the Riemann tensor

207 It should be emphasized that by calling the expressions (426) and (427) “Christoffel symbols” and “Riemann tensor,” we do not mean to suggest that these were the terms used by contemporary authors.

208 For further discussion of Riemann’s paper, see, e.g., (Reich 1994, sec. 2.1.3). Grossmann was aware of Riemann’s and Beltrami’s work in non-Euclidean geometry at least as early as 1904, as the introductory paragraph of (Grossmann 1904) shows.

by various contemporary authors[211] further supports this conjecture.[212] The square brackets for the Christoffel symbols were introduced by Christoffel himself, and, according to the survey in (Reich 1994), this notation was taken up again only in 1912 by Friedrich Kottler and then in the *Entwurf* paper itself, which cites (Kottler 1912) (Einstein and Grossmann 1913, 23 and 30). The notation for the Riemann tensor used in Christoffel's paper is $(gkhi)$, i.e., it does not have the comma, which appears in equation (427). The comma was used by Riemann whose notation was $(\iota\iota', \iota''\iota''')$. Also the occurrence of the word "Mannigfaltigkeit," a phrase used by Riemann that does not appear anywhere in Christoffel's paper, suggests that Einstein and Grossmann consulted Riemann's paper in addition to Christoffel's.

There is yet another indication, however, that the actual expressions were directly taken from Christoffel's paper. In the top right corner, Einstein wrote the expression

$$\frac{\partial}{\partial x_\kappa}\begin{bmatrix} i & l \\ & m \end{bmatrix} - \frac{\partial}{\partial x_i}\begin{bmatrix} \kappa & l \\ & m \end{bmatrix}, \tag{428}$$

which gives exactly the four second-order derivative terms of the Riemann tensor in equation (427), if the definition of the Christoffel symbols in equation (426) is inserted. Just this derivation of the Riemann tensor in terms of derivatives and products of the Christoffel symbols was given on the relevant page (p. 54) of (Christoffel 1869), where the Riemann tensor was first published.

The Riemann tensor formed a promising starting point for Einstein's search for gravitational field equations. The first task was to construct from the fourth-rank Riemann tensor an expression that could be used as the left-hand side of field equations with the second-rank stress-energy tensor on the right-hand side.

---

209 (Einstein and Grossmann 1913, 35). In the case of Riemann the reference is to "Riemann, Ges. Werke, S. 270". The page number does not make sense for the first edition of 1876 nor for the second edition of 1892. In the first edition Riemann's "Commentatio" starts on p. 370; in the second on p. 91. It seems probable that Einstein and Grossmann used the first edition and that "270" is a misprint and should be "370." Among other things, the second edition differs from the first in the German notes to the latin text of the "Commentatio." Unfortunately, the reference in the *Entwurf* paper is Einstein's most explicit reference to Riemann. In (Einstein and Fokker 1914, p. 325), for instance, he simply referred to the "bekannten Riemann-Christoffelschen Tensor." In (Einstein 1914b, 1053) and in (Einstein 1916, 799), the phrase "Riemann-Christoffel tensor" occurs in (sub)section headings without any reference to the literature.

210 In the *Entwurf* paper, the indices ρ and σ in the second part of equation (427) are interchanged (Einstein and Grossmann 1913, 35).

211 See (Reich 1994, 232) for a survey of the tensor analytic notation employed by various authors.

212 Some indirect confirmation of the conjecture comes from the draft of a letter from Felix Klein to Einstein of 20 March 1918. Commenting on a set of lecture notes he promised to send Einstein, Klein wrote: "You will probably immediately agree with what I have to say about Riemann, Beltrami, and Lipschitz; it seems to me that Grossmann at the time instructed you too much from the point of view of the school of Christoffel more narrowly" ("Was ich von Riemann, Beltrami, und Lipschitz erzähle, wird wohl gleich ihren Beifall haben; es scheint mir, dass Grossmann Sie s. Z. zu einseitig vom Standpunkte der engeren Christoffelschen Schule aus instruiert hat." CPAE 8, Doc. 487, note 26).

The most natural way to obtain such an expression is to contract over two indices, thus forming the second-rank Ricci tensor. This is exactly what Einstein did on the next line

$$\sum \gamma_{\kappa l}(i\kappa, lm)\,. \tag{429}$$

He put a question mark next to this expression, presumably to indicate that he wanted to check whether this would be an acceptable candidate for the left-hand side of the field equations

It can be seen immediately that there is a problem with the correspondence principle. Upon contraction, the first of the four second-order derivative terms in equation (427) gives the core-operator term

$$\sum \gamma_{\kappa l}\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l}\,, \tag{430}$$

but the other three terms should not occur in the Newtonian limit. In fact, at the bottom of the page, underneath a horizontal line, Einstein wrote down these three bothersome terms

$$\sum_\kappa \left(\frac{\partial^2 g_{\kappa\kappa}}{\partial x_i \partial x_m} - \frac{\partial^2 g_{i\kappa}}{\partial x_\kappa \partial x_m} - \frac{\partial^2 g_{m\kappa}}{\partial x_\kappa \partial x_i}\right)\,, \tag{431}$$

set them equal to zero, and remarked that they "should vanish" ("Sollte verschwinden").[213]

Einstein not only considered the second-order derivative terms in the Ricci tensor, he also started to rewrite the first-order derivative terms. First, he introduced the relation[214]

$$\begin{aligned}\sum \gamma_{\kappa l}\begin{bmatrix}\kappa & l\\ & \rho\end{bmatrix} &= \sum \gamma_{\kappa l}\left[\frac{\partial g_{\kappa\rho}}{\partial x_l} + \frac{\partial g_{l\rho}}{\partial x_\kappa} - \frac{\partial g_{\kappa l}}{\partial x_\rho}\right]\\ &= -\frac{\partial \lg G}{\partial x_\rho} + 2\sum_{\kappa l}\gamma_{\kappa l}\frac{\partial g_{\kappa\rho}}{\partial x_l}\,,\end{aligned} \tag{432}$$

where G is the determinant of the metric.[215] He inserted (the corrected version of[216]) this relation into one of the two terms in the Ricci tensor with a product of Christoffel symbols

213 In deriving this expression, Einstein apparently assumed a weak-field metric with components $\mathrm{diag}(1, 1, 1, 1)$ to zeroth order, which would explain why the contracting metric does not appear explicitly in the equation.

214 A factor $1/2$ is missing in the expressions following the equality signs.

215 The introduction of G into the expression for the Ricci tensor would come to play an important role on p. 22R.

216 See footnote 214.

$$
\begin{aligned}
&\sum \gamma_{\kappa l}\gamma_{\rho\sigma}\begin{bmatrix} i & m \\ & \sigma \end{bmatrix}\begin{bmatrix} \kappa & l \\ & \rho \end{bmatrix} \\
&= \frac{1}{4}\sum \gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_m} + \frac{\partial g_{m\sigma}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\sigma}\right)\left[-\frac{\partial \lg G}{\partial x_\rho} + 2\sum_{\kappa l}\gamma_{\kappa l}\frac{\partial g_{\kappa\rho}}{\partial x_l}\right].
\end{aligned}
\tag{433}
$$

In the next step, without writing down their definition, Einstein used the Christoffel symbols of the second kind,

$$
\begin{Bmatrix} i & m \\ & \rho \end{Bmatrix} = \gamma_{\rho\sigma}\begin{bmatrix} i & m \\ & \sigma \end{bmatrix} = \frac{1}{2}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_m} + \frac{\partial g_{m\sigma}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\sigma}\right), \tag{434}
$$

again following the notation of Christoffel's 1869 paper. With the help of equations (432) and (434), and the following relation between Christoffel symbols of the first and the second kind,

$$
\begin{aligned}
\gamma_{\kappa l}\begin{bmatrix} \kappa & m \\ & \rho \end{bmatrix} &= \frac{1}{2}\gamma_{\kappa l}\left(\frac{\partial g_{\kappa\rho}}{\partial x_m} + \frac{\partial g_{m\rho}}{\partial x_\kappa} - \frac{\partial g_{\kappa m}}{\partial x_\rho}\right) \\
&= \gamma_{\kappa l}\frac{\partial g_{\kappa\rho}}{\partial x_m} + \frac{1}{2}\gamma_{\kappa l}\left(\frac{\partial g_{m\rho}}{\partial x_\kappa} - \frac{\partial g_{\kappa m}}{\partial x_\rho} - \frac{\partial g_{\kappa\rho}}{\partial x_m}\right) \\
&= \gamma_{\kappa l}\frac{\partial g_{k\rho}}{\partial x_m} - \gamma_{\kappa l}\begin{bmatrix} m & \rho \\ & \kappa \end{bmatrix} \\
&= \gamma_{\kappa l}\frac{\partial g_{\kappa\rho}}{\partial x_m} - \begin{Bmatrix} m & \rho \\ & l \end{Bmatrix},
\end{aligned}
\tag{435}
$$

he rewrote the relevant part of the Ricci tensor as[217]

$$
\begin{aligned}
&\sum \gamma_{\kappa l}\gamma_{\rho\sigma}\left(\begin{bmatrix} i & m \\ & \sigma \end{bmatrix}\begin{bmatrix} \kappa & l \\ & \rho \end{bmatrix} - \begin{bmatrix} i & l \\ & \sigma \end{bmatrix}\begin{bmatrix} \kappa & m \\ & \rho \end{bmatrix}\right) \\
&= \sum_\rho - \begin{Bmatrix} i & m \\ & \rho \end{Bmatrix}\frac{\partial \lg G}{\partial x_\rho} + 2\sum_{\kappa l\rho}\begin{Bmatrix} i & m \\ & \rho \end{Bmatrix}\gamma_{\kappa l}\frac{\partial g_{\kappa\rho}}{\partial x_l} \\
&\quad - \sum_{\rho l\kappa}\begin{Bmatrix} i & l \\ & \rho \end{Bmatrix}\left(\frac{\partial g_{\kappa\rho}}{\partial x_m}\right)\gamma_{\kappa l} + \sum_{\rho l}\left\{\begin{Bmatrix} i & l \\ & \rho \end{Bmatrix}\begin{Bmatrix} \rho & m \\ & l \end{Bmatrix}\right\}.
\end{aligned}
\tag{436}
$$

217 A factor $\frac{1}{2}$ is missing in the first two terms on the right-hand side (cf. footnote 214).

In summary, p. 14L introduces a set of new invariant-theoretical quantities taken from the mathematical literature that looked promising for constructing gravitational field equations. In his first exploration of these new possibilities, however, Einstein had also hit upon a serious obstacle, viz. the problem of unwanted second-order derivative terms in addition to a core-operator term.

14R–16R 5.3.2 *Extracting a Two-Index Object from the Curvature Scalar (14R–16R)*

On the following five pages, Einstein computed the curvature scalar from the Riemann tensor. He simplified the calculation by setting the determinant of the metric equal to unity. As becomes clear toward the end (on p. 16L), the aim of the calculation was to produce an object which transforms as a scalar under unimodular transformations and which is the contraction of the metric and a new two-index object. Einstein presumably expected that this object would transform as a second-rank tensor under unimodular transformations. It would thus be another candidate for the left-hand side of the field equations. Unfortunately, the object, like the Ricci tensor, contains unwanted second-order derivative terms.

At the top of p. 14R, Einstein fully contracted the Riemann tensor to form the curvature scalar:

$$\varphi = \gamma_{im}\gamma_{\kappa l}(i\kappa, lm)\,. \tag{437}$$

Inserting expression (427) for the fully covariant Riemann tensor on p. 14L into this equation, one arrives at the expression

$$\varphi = \sum_{im\kappa l}\gamma_{im}\gamma_{\kappa l}\left(\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l} - \frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m}\right) + \sum_{\rho\sigma im\kappa l}\gamma_{\rho\sigma}\gamma_{im}\gamma_{\kappa l}\left(\begin{bmatrix} i\ m \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ l \\ \rho \end{bmatrix} - \begin{bmatrix} i\ l \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ m \\ \rho \end{bmatrix}\right) \tag{438}$$

16R

14R 15L

15R (incorrect)
16L (correct)

15R (top)

given at the top of p. 14R. The lines and arrows underneath this expression provide a flow-chart for the calculation on the next five pages. They are meant to show at a glance exactly which terms in the expression for φ are dealt with on which pages.

14R Einstein first dealt with the second summation in equation (438). On p 14R he expanded and simplified the first of the two terms in this summation,

$$\gamma_{\rho\sigma}\gamma_{im}\gamma_{\kappa l}\begin{bmatrix} i\ m \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ l \\ \rho \end{bmatrix}\,. \tag{439}$$

This is equal to 1/4 times the sum of the underlined terms on p. 14R

$$\gamma_{\rho\sigma}\frac{\partial \lg G}{\partial x_\sigma}\frac{\partial \lg G}{\partial x_\rho}+3\frac{\partial \lg G}{\partial x_\sigma}\frac{\partial \gamma_{\sigma\alpha}}{\partial x_\alpha}+\frac{\partial \lg G}{\partial x_\sigma}\frac{\partial \gamma_{\rho\alpha}}{\partial x_\alpha}+4g_{\kappa\rho}\frac{\partial \gamma_{\kappa\alpha}}{\partial x_\alpha}\frac{\partial \gamma_{\rho\beta}}{\partial x_\beta}\,. \tag{440}$$

On p. 15L he expanded and simplified the second term, 15L

$$\gamma_{\rho\sigma}\gamma_{im}\gamma_{\kappa l}\begin{bmatrix} i\ l \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ m \\ \rho \end{bmatrix}, \tag{441}$$

the result being 1/4 times the sum of the underlined terms on p. 15L

$$\begin{aligned}\gamma_{\kappa l}\frac{\partial \gamma_{m\rho}}{\partial x_l}\frac{\partial g_{m\rho}}{\partial x_\kappa}+\gamma_{im}\frac{\partial \gamma_{\kappa\rho}}{\partial x_i}\frac{\partial g_{\kappa\rho}}{\partial x_m}+\gamma_{\rho\sigma}\frac{\partial \gamma_{\kappa m}}{\partial x_\sigma}\frac{\partial g_{\kappa m}}{\partial x_\rho}\\ +g_{\kappa\rho}\frac{\partial \gamma_{\kappa m}}{\partial x_\sigma}\frac{\partial \gamma_{\rho\sigma}}{\partial x_m}+g_{m\rho}\frac{\partial \gamma_{m\kappa}}{\partial x_\sigma}\frac{\partial \gamma_{\rho\sigma}}{\partial x_\kappa}\,.\end{aligned} \tag{442}$$

Einstein further simplified expressions (440) and (442) by setting $G = 1$ and by grouping together identical terms in expression (442). At the top of p. 15R, he wrote: 15R
"The second sum [in equation (438)] thus reduces, in the case that one is allowed to set $G = 1$, to" ("Die zweite Summe reduziert sich also in dem Falle, dass $G = 1$ gesetzt werden darf, auf"):

$$\frac{1}{4}\cdot\left(4g_{\kappa\rho}\frac{\partial \gamma_{\kappa\alpha}}{\partial x_\alpha}\frac{\partial \gamma_{\rho\beta}}{\partial x_\beta}+3\gamma_{\kappa l}\frac{\partial \gamma_{m\rho}}{\partial x_\kappa}\frac{\partial g_{m\rho}}{\partial x_l}+2g_{\kappa\rho}\frac{\partial \gamma_{\kappa m}}{\partial x_\sigma}\frac{\partial \gamma_{\rho\sigma}}{\partial x_m}\right). \tag{443}$$

With the help of some auxiliary calculations on p. 16R, in which he used that 16R
$g_{im}d\gamma_{im} = d\lg G = 0$ for $G = 1$, Einstein then rewrote the two terms in the first summation in equation (438). Underneath equation (443) on p. 15R, he wrote: "If the 15R
determinant $G = 1$, one has furthermore" ("Wenn Determinante $G = 1$, es ist ferner"):

$$\sum\gamma_{im}\gamma_{\kappa l}\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l} = \sum g_{im}\gamma_{\kappa l}\frac{\partial^2 \gamma_{im}}{\partial x_\kappa \partial x_l}, \tag{444}$$

and

$$-\sum\gamma_{im}\gamma_{\kappa l}\frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m} = -\sum g_{il}\frac{\partial \gamma_{im}}{\partial x_\kappa}\frac{\partial \gamma_{\kappa l}}{\partial x_m}-\sum g_{il}\frac{\partial \gamma_{l\alpha}}{\partial x_\alpha}\frac{\partial \gamma_{i\beta}}{\partial x_\beta}+\sum g_{il}\gamma_{im}\frac{\partial^2 \gamma_{\kappa l}}{\partial x_\kappa \partial x_m}, \tag{445}$$

Einstein erroneously thought that the first term on the right-hand side of equation (445), a term that originally had an extra factor 2, cancelled by the third term of expression (443), which originally did not have the factor $1/4$ in front of it. Moreover, in the last term in equation (445), x_m originally seems to have been x_l. All in all, Einstein arrived at the (erroneous) expression

$$\begin{aligned}&3\sum g_{\kappa\rho}\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\alpha}\frac{\partial\gamma_{\rho\beta}}{\partial x_\beta}+\sum g_{im}\gamma_{\kappa l}\frac{\partial^2\gamma_{im}}{\partial x_\kappa\partial x_l}\\&+\sum g_{il}\gamma_{im}\frac{\partial^2\gamma_{\kappa l}}{\partial x_\kappa\partial x_l}+3\sum\gamma_{\kappa l}\frac{\partial\gamma_{m\rho}}{\partial x_\kappa}\frac{\partial g_{m\rho}}{\partial x_l}.\end{aligned}\tag{446}$$

for the curvature scalar in coordinates such that $G = 1$.[218] Einstein proceeded to rewrite this expression as the contraction of $g_{\kappa\lambda}$ with a new two-index object that would be a candidate for the left-hand side of the field equations. It is immediately clear, however, that these new candidate field equations would suffer from the same problem that Einstein had already encountered on p. 14L with the Ricci tensor. The second term in expression (446) gives rise to a core-operator term in the field equations, but the third term produces additional second-order derivative terms. Directly underneath the troublesome third term in expression (446), Einstein wrote

$$\sum\frac{\partial^2\gamma_{\kappa l}}{\partial x_\kappa\partial x_l} = 0 \quad ? \tag{447}$$

He may have considered imposing an additional constraint to make sure that the offending term vanishes. In passing we note that equation (447) is a weakening of the Hertz restriction

$$\frac{\partial\gamma_{kl}}{\partial x_l} = 0\,, \tag{448}$$

which Einstein had already used on p. 10L–11L, i.e., before he began his exploration of the Riemann tensor.

As we have seen, the calculations on p. 15R contain several errors. Einstein cor-
16L rected some of these, but then made a fresh start at the top of the next page (p. 16L). Using again that $g_{m\rho}d\gamma_{m\rho} = d\lg G = 0$ if $G = 1$, he rewrote the second term of expression (443) as

$$\frac{3}{4}\gamma_{\kappa l}\frac{\partial\gamma_{m\rho}}{\partial x_\kappa}\frac{\partial g_{m\rho}}{\partial x_l} = -\frac{3}{4}g_{m\rho}\gamma_{\kappa l}\frac{\partial^2\gamma_{m\rho}}{\partial x_\kappa\partial x_l}\,. \tag{449}$$

Substituting this result into expression (443) and adding the various terms in expressions (443)–(445), he arrived at the (correct) expression

$$\frac{1}{4}g_{\kappa\rho}\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\kappa\rho}}{\partial x_\alpha\partial x_\beta}-\frac{1}{2}g_{\kappa\rho}\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\rho\beta}}{\partial x_\alpha}+\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_\alpha\partial x_\beta} \tag{450}$$

for the Riemann curvature scalar in coordinates such that $G = 1$. In this expression one only needs to rewrite the last term[219] in order to pull out a common factor $g_{\kappa\rho}$ and to extract the two-index object

218 The corrected version is given below as expression (450).

$$T_{i\kappa} = \frac{1}{4}\gamma_{\alpha\beta}\frac{\partial^2\gamma_{i\kappa}}{\partial x_\alpha \partial x_\beta} - \frac{1}{2}\frac{\partial\gamma_{i\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\kappa\beta}}{\partial x_\alpha} + \frac{1}{2}\gamma_{\kappa\beta}\frac{\partial^2\gamma_{i\alpha}}{\partial x_\alpha \partial x_\beta} + \frac{1}{2}\gamma_{i\alpha}\frac{\partial^2\gamma_{\kappa\beta}}{\partial x_\alpha \partial x_\beta}. \tag{451}$$

Einstein apparently assumed that $T_{i\kappa}$ is a contravariant tensor under unimodular transformations since it produces a scalar under unimodular transformation when contracted with $g_{i\kappa}$.[220]

Unfortunately, $T_{i\kappa}$ still contained unwanted second-order derivative terms in addition to a core-operator term. Immediately below the expression for T_{ik}, Einstein wrote down the identity

$$\frac{\partial}{\partial x_\alpha}\frac{\partial}{\partial x_\beta}(\gamma_{i\alpha}\gamma_{\kappa\beta}) = \gamma_{i\alpha}\frac{\partial^2\gamma_{\kappa\beta}}{\partial x_\alpha \partial x_\beta} + \gamma_{\kappa\beta}\frac{\partial^2\gamma_{i\alpha}}{\partial x_\alpha \partial x_\beta} + \frac{\partial\gamma_{i\alpha}}{\partial x_\alpha}\frac{\partial\gamma_{\kappa\beta}}{\partial x_\beta} + \frac{\partial\gamma_{i\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\kappa\beta}}{\partial x_\alpha}, \tag{452}$$

probably in an attempt to eliminate the unwanted second-order derivative terms from T_{ik}. He did not pursue this attempt any further.

The upshot then is that a promising alternative way of generating a candidate for the left-hand side of the field equations from the Riemann tensor eventually led to the same problem that Einstein had encountered with the Ricci tensor on p. 14L. In deriving these new candidate field equations he had already imposed the condition $G = 1$, but additional constraints would be needed to eliminate unwanted second-order derivative terms. He may have considered one such constraint, equation (447), a weakening of the Hertz restriction.

5.3.3 *Comparing $T_{i\kappa}$ and the Ricci Tensor (17L–18R)* 17L–18R

On pp. 17L–18R, Einstein investigated the relation between the two two-index objects he had constructed out of the Riemann tensor on the preceding pages, the Ricci tensor and the object T_{ik}, which promised to be a tensor under unimodular transformations. On p. 17R he compared the contravariant forms of the two expressions, which meant that he had to raise the covariant indices of the Ricci tensor. On pp. 17R–18R he com-

---

219 Immediately above it, the term was restored to the form $g_{\kappa\rho}\gamma_{\kappa\alpha}\frac{\partial^2\gamma_{\rho\beta}}{\partial x_\alpha \partial x_\beta}$, in which it was originally written in equation (445). Einstein symmetrized this expression in κ and ρ: $g_{\kappa\rho}\left(\frac{1}{2}\gamma_{\kappa\alpha}\frac{\partial^2\gamma_{\rho\beta}}{\partial x_\alpha \partial x_\beta} + \frac{1}{2}\gamma_{\rho\beta}\frac{\partial^2\gamma_{\alpha\kappa}}{\partial x_\alpha \partial x_\beta}\right)$, so that the object left after pulling out the common factor $g_{\kappa\rho}$ will be symmetric in κ and ρ. A simpler way to rewrite the last term of expression (450) as the contraction of $g_{\kappa\rho}$ with an expression that is symmetric in κ and ρ is to multiply it by $\frac{1}{4}g_{\kappa\rho}\gamma_{\kappa\rho}$ (cf. the top of p. 17R, the last term in expression (458)).

220 To prove that $T_{i\kappa}$ is a contravariant tensor (under unimodular transformations), one would, of course, have to show that its contraction with an *arbitrary* covariant tensor produces a scalar (under unimodular transformations). Notice, however, that Einstein did make sure that $T_{i\kappa}$ is symmetric (see the preceding note). Any anti-symmetric contribution to $T_{i\kappa}$ would vanish upon contraction with the metric, no matter whether $T_{i\kappa}$ is a tensor or not.

pared the covariant forms, which meant that he had to lower the contravariant indices of T_{ik}. The resulting expressions quickly became so cumbersome that Einstein abandoned both calculations.

17L On p. 17L, Einstein formed the contravariant Ricci tensor and started to expand the first-order derivative terms. The calculations are very similar to the ones on the preceding pages. Directly underneath the heading "Point tensor of gravitation" ("Punkttensor der Gravitation"), he wrote down the symbol for the fully covariant Riemann tensor introduced on p. 14L, and noted that this is a "plane tensor" ("Ebenentensor"),

$$(i\kappa, lm) = \text{Ebenentensor vierter Mannigfaltigkeit}\,. \tag{453}$$

He then formed the contravariant Ricci tensor, and noted that this is a "point tensor" ("Punkttensor"),

$$\sum_{i\kappa lm} \gamma_{\kappa l}\gamma_{ip}\gamma_{mq}(i\kappa, lm) = \text{Punkttensor}\,. \tag{454}$$

The prefixes "Punkt-" and "Ebene-" were introduced on p. 13L to distinguish between contravariant and covariant indices, albeit only in the context of linear transformations for which $G = 1$.[221] On p. 13L only the terms "Punktvektor" and "Ebenenvektor" occur explicitly. The terms "Punkttensor" and "Ebenentensor" occur here on p. 17L for the first time, although they were implied on p. 13L by the convention of using dots and dashes to denote contravariant ("Punkt") and covariant ("Ebene") indices, respectively, for vectors as well as tensors.[222] Einstein did not use this terminology in any of his published writings.

Einstein went on to expand and simplify the "point tensor" (454). He first wrote down an incorrect expression for the Riemann tensor,

$$(i\kappa, lm) = \frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l} - \frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m} + \sum_{\rho\sigma}\gamma_{\rho\sigma}\left\{\begin{bmatrix} i\ m \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ l \\ \rho \end{bmatrix} - \begin{bmatrix} i\ l \\ \sigma \end{bmatrix}\begin{bmatrix} \kappa\ m \\ \rho \end{bmatrix}\right\}. \tag{455}$$

The four second-order derivative terms in equation (427) for the Riemann tensor cannot be grouped together in this way. They can, when the Riemann tensor is fully contracted to form the curvature scalar, as was done on p. 14R. This suggests that Einstein read off equation (455) from expression (438) for the curvature scalar which formed the starting point of his calculations on pp. 14R–16R. The error does not affect the rest of the calculation, since Einstein did not get beyond rewriting the first-order derivative terms in equation (455).

The further manipulation of the contravariant Ricci tensor on this page is very similar to that of the covariant Ricci tensor and of the curvature scalar on the preceding pages. He first considered the first term in the second summation in equation (455) contracted with $\gamma_{kl}\gamma_{ip}\gamma_{mq}$ (see equation (454)), which he expanded to

---

221 See the discussion of p. 13L in sec. 5.6.1.

222 On pp. 28L and 29L, the terms "Punkttensor" and "kontravarianter Tensor" are used interchangeably.

$$\frac{1}{4}\gamma_{\kappa l}\gamma_{ip}\gamma_{mq}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_m}+\frac{\partial g_{m\sigma}}{\partial x_i}-\frac{\partial g_{im}}{\partial x_\sigma}\right)\left(\frac{\partial g_{\kappa\rho}}{\partial x_l}+\frac{\partial g_{l\rho}}{\partial x_\kappa}-\frac{\partial g_{\kappa l}}{\partial x_\rho}\right). \tag{456}$$

He then pulled one pair of γ factors ($\gamma_{ip}\gamma_{mq}$) inside the first set of parentheses and the other pair into the second. In the resulting terms he used the relation $g_{ij}\gamma_{ik} = \delta_{jk}$ to move the differentiation over from the g 's to the γ 's. He also set the determinant of metric equal to unity again, writing "$\lg G$ set to zero" ("$\lg G = 0$ gesetzt "), in which case the last term in the second set of parentheses in expression (456) vanishes upon contraction with $\gamma_{\kappa l}$. The next step was to move the factor $\gamma_{\rho\sigma}$ from the second set of parentheses to the first. The expression could then be simplified further through contractions of the form $g_{ij}\gamma_{ik} = \delta_{jk}$. In this way, Einstein rewrote expression (456) as

$$\frac{1}{4}\left(\gamma_{mq}\frac{\partial\gamma_{\rho p}}{\partial x_m}+\gamma_{ip}\frac{\partial\gamma_{\rho q}}{\partial x_i}-\gamma_{\rho\sigma}\frac{\partial\gamma_{pq}}{\partial x_\sigma}\right)\left(g_{\kappa\rho}\frac{\partial\gamma_{\kappa l}}{\partial x_l}+g_{l\rho}\frac{\partial\gamma_{\kappa l}}{\partial x_\kappa}\right). \tag{457}$$

Einstein drew a horizontal line, and turned to the second term in the second summation in equation (455), proceeding in much the same way as he had with the first term. However, after two lines he broke off the calculation with the comment, written at the bottom of the page, that it was "too involved" ("zu umständlich").

On pp. 17R–18R, Einstein took a slightly different approach. Under the heading "Plane tensor constructed in two different ways" ("Auf zwei Arten Ebenentensor gebildet"), he tried to bring the covariant versions of the Ricci tensor and the object $T_{i\kappa}$ of p. 16L (with a minor modification) into a form in which they could be compared to one another. The calculation extends over the following three pages (17R–18R). Again it breaks off before yielding a definite result. 17R–18R

Einstein began by considering what he called the "first way" ("1. Art") of forming a covariant tensor. This refers to the object $T_{i\kappa}$ extracted from the curvature scalar on pp. 14R–16R. He presumably went back to p. 16L, to expression (450) for the curvature scalar under the condition that $G = 1$. Rewriting the last term in this expression in a slightly different way than was done on p. 16L, one arrives at[223]

$$\frac{1}{4}g_{\kappa\rho}\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\kappa\rho}}{\partial x_\alpha\partial x_\beta}-\frac{1}{2}g_{\kappa\rho}\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\rho\beta}}{\partial x_\alpha}+\frac{1}{4}g_{\kappa\rho}\gamma_{\kappa\rho}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_\alpha\partial x_\beta}, \tag{458}$$

which is $1/4$ times the contraction of $g_{\kappa\rho}$ with the expression in square brackets at the top of p. 17R, 17R

$$\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\kappa\rho}}{\partial x_\alpha\partial x_\beta}-2\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\rho\beta}}{\partial x_\alpha}+\gamma_{\kappa\rho}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_\alpha\partial x_\beta}. \tag{459}$$

223 See footnote 219 above.

With minor modifications, this is the object T_{ik} defined on p. 16L. Apart from an overall factor of 4 and the labeling of its free indices, it only differs from the object constructed on p. 16L in its last term.

The expression at the top of p. 17R gives the covariant version of this object,

$$\sum g_{\kappa\sigma} g_{\rho\tau}\left[\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\kappa\rho}}{\partial x_\alpha \partial x_\beta} - 2\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\beta}\frac{\partial\gamma_{\rho\beta}}{\partial x_\alpha} + \gamma_{\kappa\rho}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_\alpha \partial x_\beta}\right]. \tag{460}$$

On the next two lines, Einstein wrote down equivalent expressions for all three terms in expression (460), using the relation $g_{ij}\gamma_{ik} = \delta_{jk}$ and relations that can be derived from it through differentiation.[224]

Einstein now turned to the "second way" ("2. Art") of forming a covariant tensor, which is contracting the Riemann tensor to form the Ricci tensor. Einstein had already started this calculation on p. 14L, but he made a fresh start on this page.

Using the expressions for the terms with products of Christoffel symbols on the facing page (p. 17L, cf. expression (456)), he wrote the Ricci tensor as

$$\begin{aligned}
&\frac{1}{2}\sum\gamma_{\kappa l}\left(\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l} + \frac{\partial^2 g_{\kappa l}}{\partial x_i \partial x_m} - \frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m} - \frac{\partial^2 g_{\kappa m}}{\partial x_i \partial x_l}\right) \\
&+\frac{1}{4}\sum_{kl\rho\sigma}\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_m} + \frac{\partial g_{m\sigma}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\sigma}\right)\left(\frac{\partial g_{\kappa\rho}}{\partial x_l} + \frac{\partial g_{l\rho}}{\partial x_\kappa} - \frac{\partial g_{\kappa l}}{\partial x_\rho}\right) \\
&-\frac{1}{4}\sum_{kl\rho\sigma}\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_l} + \frac{\partial g_{l\sigma}}{\partial x_i} - \frac{\partial g_{il}}{\partial x_\sigma}\right)\left(\frac{\partial g_{\kappa\rho}}{\partial x_m} + \frac{\partial g_{m\rho}}{\partial x_\kappa} - \frac{\partial g_{\kappa m}}{\partial x_\rho}\right).
\end{aligned} \tag{461}$$

Further simplification of this expression was facilitated by his previous investigation of the Ricci tensor on p. 14L. Without further calculation Einstein noted that the first two terms in the second set of parentheses on the second line are identical and "can be combined" ("vereinigt sich"), and that the third term "vanishes" ("fällt weg"), which indicates that he once again imposed the condition that the determinant G is a constant. These results had explicitly been derived on p. 14L (cf. equation (432)). Einstein could therefore immediately rewrite the second line as

$$\frac{1}{2}\sum_{kl\rho\sigma}\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_m} + \frac{\partial g_{m\sigma}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\sigma}\right)\frac{\partial g_{\kappa\rho}}{\partial x_l} = -\frac{1}{2}\sum\frac{\partial\gamma_{\rho\sigma}}{\partial x_\rho}\left(\frac{\partial g_{i\sigma}}{\partial x_m} + \frac{\partial g_{m\sigma}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\sigma}\right). \tag{462}$$

His increased facility in handling these expressions is also manifest in his treatment of the third line of expression (461). He started to rewrite the contraction of

224 It takes a short calculation very similar to the one rehearsed in the last four lines of p. 16R to show that the first term can be rewritten as $-\gamma_{\alpha\beta}\frac{\partial^2 g_{\tau\sigma}}{\partial x_\alpha \partial x_\beta} + 2\gamma_{\alpha\beta}\gamma_{\kappa\rho}\frac{\partial g_{\rho\tau}}{\partial x_\beta}\frac{\partial g_{\kappa\sigma}}{\partial x_\alpha}$. Einstein might have done this calculation on a separate piece of paper.

$\gamma_{\kappa l}\gamma_{\rho\sigma}$ with the term in the second set of parentheses, but then he noticed that he could simplify the expression more easily by a symmetry argument. He marked four terms in the expression by wiggly lines,

$$-\frac{1}{4}\sum_{kl\rho\sigma}\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_l}+\frac{\partial g_{l\sigma}}{\partial x_i}-\frac{\partial g_{il}}{\partial x_\sigma}\right)\left(\frac{\partial g_{\kappa\rho}}{\partial x_m}+\frac{\partial g_{m\rho}}{\partial x_\kappa}-\frac{\partial g_{\kappa m}}{\partial x_\rho}\right). \tag{463}$$

The first two underlined terms are antisymmetric in l and σ, the last two in κ and ρ. Upon contraction with $\gamma_{\kappa l}\gamma_{\rho\sigma}$, the two remaining terms become symmetric in κ and ρ and l and σ, respectively. So, the product of the underlined terms in one set of parentheses with the non-underlined term in the other produces the contraction of an expression anti-symmetric with an expression symmetric in the same pair of indices. These products thus vanish, and expression (463) reduces to

$$-\frac{1}{4}\sum\gamma_{\kappa l}\gamma_{\rho\sigma}\frac{\partial g_{l\sigma}}{\partial x_i}\frac{\partial g_{\kappa\rho}}{\partial x_m}-\frac{1}{4}\sum\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_l}-\frac{\partial g_{il}}{\partial x_\sigma}\right)\left(\frac{\partial g_{m\rho}}{\partial x_\kappa}-\frac{\partial g_{\kappa m}}{\partial x_\rho}\right), \tag{464}$$

the expression written at the bottom of the page. Einstein rewrote the first term as

$$\frac{1}{4}\frac{\partial\gamma_{\rho\sigma}}{\partial x_i}\frac{\partial g_{\sigma\rho}}{\partial x_m}. \tag{465}$$

At the top of the next page (p. 18L), he inserted the results found on p. 17R (see equation (462) and expression (464)–(465)) into expression (461) for the Ricci tensor and arrived at[225] 18L

$$\begin{aligned}&\frac{1}{2}\gamma_{\kappa l}\left(\frac{\partial^2 g_{im}}{\partial x_\kappa\partial x_l}+\frac{\partial^2 g_{\kappa l}}{\partial x_i\partial x_m}-\frac{\partial^2 g_{il}}{\partial x_\kappa\partial x_m}-\frac{\partial^2 g_{\kappa m}}{\partial x_i\partial x_l}\right)\\ &-\frac{1}{2}\frac{\partial\gamma_{\sigma\rho}}{\partial x_\rho}\left(\frac{\partial g_{i\sigma}}{\partial x_m}+\frac{\partial g_{m\sigma}}{\partial x_i}-\frac{\partial g_{im}}{\partial x_\sigma}\right)+\frac{1}{4}\frac{\partial\gamma_{\rho\sigma}}{\partial x_i}\frac{\partial g_{\rho\sigma}}{\partial x_m}\\ &-\frac{1}{4}\gamma_{\kappa l}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\sigma}}{\partial x_l}-\frac{\partial g_{l\sigma}}{\partial x_i}\right)\left(\frac{\partial g_{m\rho}}{\partial x_\kappa}-\frac{\partial g_{\kappa m}}{\partial x_\rho}\right).\end{aligned} \tag{466}$$

On pp. 18L–R, Einstein tried to simplify this expression still further. Thus, in the first two lines of "auxiliary calculations" ("Nebenrechnungen") on p. 18R, he showed that the condition that the determinant of the metric is constant allows one to rewrite the second term in the first line of expression (466) as 18L–R

225 The expression $\frac{\partial g_{i\sigma}}{\partial x_l}-\frac{\partial g_{l\sigma}}{\partial x_i}$ on the third line should be $\frac{\partial g_{i\sigma}}{\partial x_l}-\frac{\partial g_{il}}{\partial x_\sigma}$, i.e., the expression should be anti-symmetric in l and σ, not in i and l.

$$-\frac{1}{2}\frac{\partial\gamma_{\kappa\rho}}{\partial x_i}\frac{\partial g_{\kappa\rho}}{\partial x_m}. \tag{467}$$

This expression (without the minus sign) is given on the last line of p. 18L. By the same token, the last term on the second line is equivalent to

$$-\frac{1}{4}\gamma_{\rho\sigma}\frac{\partial^2 g_{\rho\sigma}}{\partial x_i \partial x_m}, \tag{468}$$

the expression written underneath this term, except for the fact that Einstein mistakenly wrote $\gamma_{\rho\sigma}$ instead of $g_{\rho\sigma}$.

Einstein performed another auxiliary calculation on p. 18R to expand the third line of expression (466). Multiplying the end result of this auxiliary calculation by minus $1/4$, one arrives at the expression

$$-\frac{1}{4}\left(\frac{\partial\gamma_{l\sigma}}{\partial x_m}\frac{\partial g_{i\sigma}}{\partial x_l}+\frac{\partial\gamma_{\rho\sigma}}{\partial x_i}\frac{\partial g_{m\rho}}{\partial x_\sigma}-\frac{\partial\gamma_{l\sigma}}{\partial x_m}\frac{\partial g_{l\sigma}}{\partial x_i}\right)-\frac{1}{4}\gamma_{\kappa l}\gamma_{\rho\sigma}\frac{\partial g_{i\sigma}}{\partial x_l}\frac{\partial g_{m\rho}}{\partial x_\kappa}, \tag{469}$$

written directly underneath this term in expression (466) on p. 18L. At this point Einstein gave up and crossed out his calculations on pp. 18L and 18R in their entirety. The relation between the Ricci tensor and the two-index object T_{ik}, the two candidates for the left-hand side of the field equations that Einstein had considered in his first explorations of the Riemann tensor, still remained unclear.

19L–21R

5.4 *Exploring the Ricci tensor in Harmonic Coordinates (19L–21R)*

The mathematical strategy which Einstein had been following since the introduction of the Riemann tensor on p. 14L had still not yielded a viable candidate for the left-hand side of the gravitational field equations. The two expressions considered on the preceding pages (14L–18R), the Ricci tensor and the object T_{ik}, both contain, in addition to the desired core-operator term, unwanted second-order derivative terms. On p. 18R Einstein used the restriction to unimodular coordinates, which allowed him to set $G = 1$, to eliminate one of these unwanted terms (cf. eqs. (466)-(467)). On p. 19L Einstein eliminated all unwanted second-order derivative terms through an appropriate choice of coordinates. In this way he reduced the Ricci tensor to the sum of a core-operator term and terms quadratic in the first-order derivatives of the metric. Today these coordinates are called "harmonic coordinates" and the corresponding condition is called the "harmonic coordinate condition." Let us reiterate that Einstein understood coordinate conditions not in the modern sense of selecting at least one member from each possible equivalence class of metrics,[226] but as restrictions on the covariance group of the field equations. That is why we adopted the phrase coordinate restric-

226 Two metrics are in the same equivalence class if and only if a coordinate transformation exists that maps one onto the other.

tion.[227] With the help of the harmonic restriction, Einstein was finally able to extract from the Riemann tensor field equations that satisfy the correspondence principle.

On p. 19R, Einstein began to examine these new field equations and the harmonic restriction in a weak-field approximation. He made sure the new field equations were compatible with energy-momentum conservation by checking that the gravitational force on a cloud of dust particles can be written as the divergence of a quantity representing gravitational stress-energy density. To ensure compatibility between the field equations and energy-momentum conservation, Einstein imposed an extra condition on the metric tensor. The combination of this extra condition—a linearized version of the Hertz restriction—and the harmonic restriction leads to the unacceptable result that the trace of the weak-field metric has to be a constant.

On p. 20L, Einstein modified the weak-field equations to avoid this implication. By adding a term with the trace of the weak-field metric, he ensured that the requirements of the correspondence principle and the conservation principle are both satisfied by imposing the harmonic restriction. From a purely mathematical point of view, the left-hand side of these modified weak-field equations is, in fact, the linearized Einstein tensor. At the bottom of p. 20L and on p. 21L, Einstein used the new weak-field equations to rewrite the gravitational force as a divergence, thus convincing himself that the addition of the trace term to the field equations does not destroy their compatibility with energy-momentum conservation. There was, however, a different problem. The modified weak-field equations of p. 20L are incompatible with Einstein's presupposition concerning static gravitational fields.[228]

It is no coincidence therefore that, on p. 20R, Einstein reexamined the dynamics of point particles moving in a metric field. The purpose of this calculation becomes clear on p. 21R. Einstein checked whether his presupposition concerning static gravitational fields was actually justified. On p. 21R, using elements of his discussion of the dynamics of point particles on p. 20R, he developed what appeared to be a very strong argument in support of his views on the static field. This (fallacious) argument led him to give up the harmonic restriction and the field equations constructed with its help.

5.4.1 *Extracting Field Equations from the Ricci Tensor Using Harmonic Coordinates (19L)* 19L

On p. 19L, as is announced in the first line: "Renewed calculation of the plane tensor[229]" ("Nochmalige Berechnung des Ebenentensors"), Einstein re-calculated the quantity given by the expression

227 For further discussion, see sec. 4.1.

228 This presupposition is also incompatible with the harmonic coordinate restriction, but it is unclear whether Einstein realized that at this point.

229 See sec. 5.3.3, for a discussion of Einstein's usage of the term "Ebenentensor" for covariant tensors.

$$\left.\begin{array}{l}\frac{1}{2}\left(\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l}+\frac{\partial^2 g_{\kappa l}}{\partial x_i \partial x_m}-\frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m}-\frac{\partial^2 g_{\kappa m}}{\partial x_i \partial x_l}\right) \\ -\frac{1}{4}\sum_{\kappa l \rho\sigma}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\rho}}{\partial x_l}+\frac{\partial g_{l\rho}}{\partial x_i}-\frac{\partial g_{il}}{\partial x_{\sigma\rho}}\right)\left(\frac{\partial g_{\kappa\sigma}}{\partial x_m}+\frac{\partial g_{m\sigma}}{\partial x_\kappa}-\frac{\partial g_{\kappa m}}{\partial x_\sigma}\right)\end{array}\right|\gamma_{\kappa l}. \tag{470}$$

This expression gives an incomplete version of the fully covariant Riemann tensor (see, e.g., equation (427)) contracted with the contravariant metric γ_{kl}. In other words, it is an incomplete version of the Ricci tensor, which Einstein had already investigated on p. 14L and on pp. 17R–18R.[230] What is missing is another term with products of Christoffel symbols. This was not just an oversight on Einstein's part. The missing term vanishes if the condition

$$\gamma_{\kappa l}\begin{bmatrix}\kappa & l \\ & i\end{bmatrix} = \gamma_{\kappa l}\left(2\frac{\partial g_{il}}{\partial x_\kappa}-\frac{\partial g_{\kappa l}}{\partial x_i}\right) = 0 \tag{471}$$

is imposed, which Einstein actually wrote down two lines further down. This is the condition that we today call the harmonic coordinate condition. The point of introducing this condition and the purpose of the whole calculation becomes clear in the line immediately following expression (470). On this line, Einstein wrote down the first of the four second-order derivative terms in expression (470),

$$\frac{1}{2}\gamma_{kl}\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l}, \tag{472}$$

which has the form of a core operator, underlined it, and noted that it would "remain" ("bleibt stehen"). Exactly how this comes about is recapitulated in the calculation that follows.

Einstein indicated that he wanted to take the derivative of the condition with free index i in equation (471) with respect to x_m and then do the same with the indices i and m interchanged. Adding the two equations, Einstein got[231]

---

230 Expression (470) differs from the expressions for the Riemann tensor and the Ricci tensor given earlier (cf. equations (427), (455), and (461)) in that the indices ρ and σ in the terms with products of Christoffel symbols (such as the last line of expression (470)) have been switched, in accordance with the labeling of these indices in the *Entwurf* paper (Einstein and Grossmann 1913, 35). This could be an indication that some time elapsed between these earlier calculations and the ones starting on p. 19L.

231 In the very last terms in equations (473) and (474), the derivative should be with respect to x_m rather than x_i.

$$2\gamma_{\kappa l}\left(\frac{\partial^2 g_{il}}{\partial x_\kappa \partial x_m} + \frac{\partial^2 g_{\kappa m}}{\partial x_i \partial x_l} - \frac{\partial^2 g_{\kappa l}}{\partial x_i \partial x_m}\right)$$
$$+ \frac{\partial \gamma_{\kappa l}}{\partial x_m}\left(2\frac{\partial g_{il}}{\partial x_\kappa} - \frac{\partial g_{\kappa l}}{\partial x_i}\right) + \frac{\partial \gamma_{\kappa l}}{\partial x_i}\left(2\frac{\partial g_{m\kappa}}{\partial x_l} - \frac{\partial g_{\kappa l}}{\partial x_i}\right) = 0. \tag{473}$$

This relation allowed Einstein to replace the three bothersome second-order derivative terms in expression (470) by an expression

$$-\frac{1}{2}\gamma_{\kappa l}(\quad) = \frac{1}{4}\left(\frac{\partial \gamma_{\kappa l}}{\partial x_m}\left(2\frac{\partial g_{il}}{\partial x_\kappa} - \frac{\partial g_{\kappa l}}{\partial x_i}\right) + \frac{\partial \gamma_{\kappa l}}{\partial x_i}\left(2\frac{\partial g_{m\kappa}}{\partial x_l} - \frac{\partial g_{\kappa l}}{\partial x_i}\right)\right) \tag{474}$$

containing only first-order derivatives.

Einstein now turned his attention to the "second term" ("zweites Glied"), i.e., the second line of expression (470). He invoked the same symmetry argument as on p. 17R (cf. the discussion following expression (463) above). He marked the symmetric and anti-symmetric terms in the index pairs (l, ρ) and (κ, σ) by straight and wiggly lines, respectively, and immediately wrote down the only two non-vanishing contributions, one coming from the symmetric parts,

$$-\frac{1}{4}\gamma_{\rho\sigma}\frac{\partial g_{l\rho}}{\partial x_i}\frac{\partial g_{\kappa\sigma}}{\partial x_m}\gamma_{\kappa l}, \tag{475}$$

and one coming from the anti-symmetric parts,

$$-\frac{1}{4}\gamma_{\rho\sigma}\left(\frac{\partial g_{i\rho}}{\partial x_l} - \frac{\partial g_{il}}{\partial x_\rho}\right)\left(\frac{\partial g_{m\sigma}}{\partial x_\kappa} - \frac{\partial g_{\kappa m}}{\partial x_\sigma}\right)\gamma_{\kappa l}$$
$$= -\frac{1}{2}\gamma_{\rho\sigma}\gamma_{\kappa l}\frac{\partial g_{i\rho}}{\partial x_l}\frac{\partial g_{m\sigma}}{\partial x_\kappa} + \frac{1}{2}\gamma_{\rho\sigma}\gamma_{\kappa l}\frac{\partial g_{il}}{\partial x_\rho}\frac{\partial g_{m\sigma}}{\partial x_\kappa}. \tag{476}$$

He now underlined the terms that form the Ricci tensor: the core-operator term in expression (472), the right-hand side of equation (474), expression (475), and the right-hand side of equation (476). A short auxiliary calculation showed that expression (475) and the last term in equation (474) cancel each other.[232] He added the remaining underlined terms and concluded that "the covariant tensor [the Ricci tensor], multiplied by 2, thus takes the form" ("Der mit 2 multiplizierte Ebenentensor erhält also die Form")

232 The two terms only cancel if the final index in equation (474) is corrected (see the preceding note). Einstein probably realized the index was wrong at this point, although he did not correct it.

$$\begin{aligned}&\gamma_{\kappa l}\frac{\partial^2 g_{im}}{\partial x_\kappa \partial x_l}-\frac{1}{2}\frac{\partial\gamma_{\kappa l}}{\partial x_m}\frac{\partial g_{\kappa l}}{\partial x_i}+\frac{\partial\gamma_{\kappa l}}{\partial x_m}\frac{\partial g_{il}}{\partial x_\kappa}+\frac{\partial\gamma_{\kappa l}}{\partial x_i}\frac{\partial g_{m\kappa}}{\partial x_l}\\ &-\gamma_{\rho\sigma}\gamma_{\kappa l}\frac{\partial g_{i\rho}}{\partial x_l}\frac{\partial g_{m\sigma}}{\partial x_\kappa}+\gamma_{\rho\sigma}\gamma_{\kappa l}\frac{\partial g_{il}}{\partial x_\rho}\frac{\partial g_{m\sigma}}{\partial x_\kappa}.\end{aligned} \tag{477}$$

This is the result Einstein wanted on this page: in harmonic coordinates, the Ricci tensor is the sum of a core-operator term, which is the only remaining second-order derivative term, and terms quadratic in first-order derivatives. He seems to have checked this carefully, for at the bottom of the page he wrote: “Result certain. Valid for coordinates which satisfy the equation $\Delta\varphi = 0$” (“Resultat sicher. Gilt für Koordinaten, die der Gl. $\Delta\varphi = 0$ genügen”). These coordinates were well-known and were called “isothermal coordinates” in the contemporary literature.[233] They are now commonly known as “harmonic coordinates.” Einstein’s notation suggests that he (or Grossmann) found the coordinate condition $\Delta\varphi = 0$ in the literature.[234]

19R

5.4.2 *Discovering a Conflict between the Harmonic Coordinate Restriction, the Weak-Field Equations, and Energy-Momentum Conservation (19R)*

On p. 19L, the mathematical strategy had finally born fruit. Einstein had found a way of constructing field equations out of the Ricci tensor that satisfy the correspondence principle. He now had to check whether these field equations and the harmonic restriction used in their construction also satisfy his other heuristic requirements. Unfortunately, in the course of checking the conservation principle on p. 19R, he discovered a problem.

The considerations on p. 19R are all in the context of a first-order, weak-field approximation. The metric is assumed to be the sum of a diagonalized Minkowski metric and small deviations from this metric. With the help of an imaginary time coordinate, introduced explicitly further down on the page, the zeroth order metric can be written as $\mathrm{diag}(1, 1, 1, 1)$.

Einstein began by writing down the harmonic restriction (see equation (471)) in this weak-field approximation, writing: “For the first approximation our additional condition is” (“Für die erste Annäherung lautet unsere Nebenbedingung”)[235]

---

233 See, e.g., (Bianchi 1910, sec. 36-37) or (Wright 1908, sec. 57).

234 Einstein had already used this condition in a different but equivalent form on p. 6L (see equation (83)), but it is unclear whether he recognized the equivalence.

235 Einstein’s notation here and in the following is awkward. He used the same summation index κ for two different summations, and did not explicitly distinguish between the diagonal zeroth-order metric and the first-order metric with small deviations from it. Introducing the more explicit notation $g_{\mu\nu} \equiv \delta_{\mu\nu} + \bar{g}_{\mu\nu}$ where $\delta_{\mu\nu}$ is the Kronecker delta and $\bar{g}_{\mu\nu} \ll 1$, one can rewrite equation (478) more carefully as: $\delta^{\kappa\kappa'}\left(2\frac{\partial\bar{g}_{i\kappa}}{\partial x_{\kappa'}}-\frac{\partial\bar{g}_{\kappa\kappa'}}{\partial x_i}\right)$.

$$\sum_{\kappa} \gamma_{\kappa\kappa}\left(2\frac{\partial g_{i\kappa}}{\partial x_{\kappa}} - \frac{\partial g_{\kappa\kappa}}{\partial x_i}\right) = 0. \tag{478}$$

Einstein conjectured that this condition "can *perhaps* be decomposed into" ("Zerfällt *vielleicht* in") the following two conditions,[236]

$$\sum \gamma_{\kappa\kappa}\frac{\partial g_{i\kappa}}{\partial x_{\kappa}} = 0,^{237} \tag{479}$$

a condition equivalent, at least in first-order approximation, to the Hertz restriction, and

$$\sum \gamma_{\kappa\kappa} g_{\kappa\kappa} = \text{konst},^{238} \tag{480}$$

a condition on the trace of the weak-field metric.

As will become clear below, Einstein wanted to ensure energy-momentum conservation by imposing the linearized Hertz restriction (479). On p. 19L he had introduced the harmonic restriction (478) to satisfy the correspondence principle. The combination of these two restrictions implies equation (480), which was unacceptable to Einstein. Einstein became aware of these implications in the course of his considerations concerning energy-momentum conservation on the remainder of this page.

On the next line, Einstein wrote down the "equations" ("Gleichungen")

$$\sum \gamma_{\kappa\kappa}\frac{\partial^2 g_{im}}{\partial x_{\kappa}^2} = \kappa\rho_0 \frac{dx_i}{ds}\frac{dx_m}{ds} g_{ii} g_{mm},^{239} \tag{481}$$

which are just the field equations of p. 19L in first-order approximation. The left-hand side is the core-operator term of the reduced Ricci tensor (see expression (477)). To first order, this is the only term that contributes. The right-hand side gives the covariant version of the stress-energy tensor for pressureless dust, multiplied by the gravitational constant κ .

For Einstein, energy-momentum conservation required that the density of the four-force of the gravitational field on the pressureless dust can be written as the four-divergence of a quantity that can be interpreted as representing gravitational stress-energy

236 The combination of these two new conditions is, in fact, stronger than the original condition.

237 Using the notation introduced in footnote 235, one would write equation (479) as: $\delta^{\kappa\kappa'}\frac{\partial \bar{g}_{i\kappa}}{\partial x_{\kappa'}} = 0$.

238 Using the notation introduced in footnote 235, one would write this equation as: $\delta^{\kappa\kappa'}\bar{g}_{\kappa\kappa'} = 0$. In other words, the condition is that the trace of $\bar{g}_{i\kappa}$ vanish. This is the form in which the condition is written at the top of the next page (p. 20L): $\sum g^{x}_{\kappa\kappa} = 0$.

239 Einstein erroneously wrote $\frac{dx_m}{dx_s}$ instead of $\frac{dx_m}{ds}$. Using the notation introduced in footnote 235, one would write this equation as: $\delta^{\kappa\kappa'}\frac{\partial^2 \bar{g}_{im}}{\partial x_{\kappa}\partial x_{\kappa'}} = \kappa\rho_0\frac{dx_{i'}}{ds}\frac{dx_{m'}}{ds}\delta_{ii'}\delta_{mm'}$.

density. Einstein checked whether his new field equations would actually allow him to rewrite the gravitational force density in the form of such a divergence.[240]

The expression for the force density

$$\frac{1}{2}\sqrt{G}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T^b_{\mu\nu}\,, \tag{482}$$

was introduced on p. 5R (see expression (67) above). Here $T^b_{\mu\nu}$ is the (contravariant) stress-energy tensor for pressureless dust. The force density gives the rate at which four-momentum is transferred from the gravitational field to the pressureless dust. As such it enters into the energy-momentum balance between matter and gravitational field for which Einstein had introduced the equation

$$\sum_{\nu n}\frac{\partial}{\partial x_n}(\sqrt{G}g_{m\nu}T_{\nu n})-\frac{1}{2}\sqrt{G}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu}=0 \tag{483}$$

on the next line on p. 5R (see equation (71); the superscript b was silently dropped). This equation is equivalent to the statement that the covariant divergence of the stress-energy tensor $T_{\mu\nu}$ vanishes. If (minus) the force density can be written as the divergence of gravitational stress-energy density, then equation (483) can be written as the vanishing of the *ordinary* divergence of the sum of quantities representing the stress-energy density of matter (pressureless dust in this case) and of the gravitational field, respectively. To find out whether some candidate field equations allow such rewriting of the force density, one substitutes their left-hand side (divided by κ) for the stress-energy tensor in the second term of equation (483) and tries to rewrite the resulting expression as a divergence.

In the first-order approximation considered on p. 19R, the second term in equation (483) reduces to

$$-\frac{1}{2}\frac{\partial g_{im}}{\partial x_\sigma}T_{im}\,. \tag{484}$$

This expression, while not actually written down on p. 19R, provides the link between equation (481), giving the field equations in first-order approximation, and the equation written on the next line. Eliminating T_{im} from expression (484) with the help of equation (481) and neglecting a factor -2κ, one arrives at the equation that Einstein did write,[241]

$$\sum_{\kappa im}\gamma_{\kappa\kappa}\frac{\partial^2 g_{im}}{\partial x_\kappa^2}\frac{\partial g_{im}}{\partial x_\sigma} = \sum_{\kappa im}\gamma_{\kappa\kappa}\left[\frac{\partial}{\partial x_\kappa}\left(\frac{\partial g_{im}}{\partial x_\kappa}\frac{\partial g_{im}}{\partial x_\sigma}\right)-\frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\frac{\partial^2 g_{im}{}^2}{\partial x_\kappa}\right)\right]. \tag{485}$$

240 A completely analogous consideration can be found in the *Entwurf* paper (Einstein and Grossmann 1913, 15). In his second static theory of 1912, Einstein likewise made sure that the (ordinary three-)force density could be written as the divergence of a gravitational stress tensor (Einstein 1912b, 456).

Since the right-hand side of this equation does indeed have the form of a divergence, Einstein concluded that "energy-momentum conservation holds in the relevant approximation" ("Energie- u. Impulssatz gilt mit der in Betr[acht] kommenden Annäherung").

Einstein still had to check whether the harmonic restriction (see equation (478)) and the two conditions into which it had tentatively been split (see equations (479) and (480)) are also compatible with energy-momentum conservation. Presumably, the second part of the comment immediately following Einstein's conclusion that "energy-momentum conservation holds in the relevant approximation" refers to this issue: "uniqueness and additional conditions" ("Eindeutigkeit u. Nebenbedingungen"). As to the first part of this comment, Einstein apparently hoped that his heuristic requirements would uniquely determine the field equations. This may well have been the motive for his (inconclusive) investigation on pp. 17L–18R of the relation between the Ricci tensor and the two-index object extracted from the curvature scalar on pp. 14R–16R. Einstein, however, did not actually address the uniqueness problem on p. 19R. The question regarding the additional conditions appears to have been more pressing.

He once again wrote down the linearized field equations, this time in the more compact form[242]

$$\Box g_{im} = \kappa\rho_0 \frac{dx_i}{d\tau}\frac{dx_m}{d\tau} . \tag{486}$$

The considerations on the remainder of the page suggest that Einstein discovered the following problem. In first-order approximation, covariant derivatives become ordinary derivatives and the energy-momentum balance between pressureless dust and gravitational field reduces to the conservation law

$$\frac{\partial}{\partial x_m}\left(\rho_0 \frac{dx_i}{d\tau}\frac{dx_m}{d\tau}\right) = 0 . \tag{487}$$

The easiest way to ensure that the field equations (486) are compatible with equation (487) is to impose the linearized Hertz restriction[243]

---

241 Einstein apparently substituted the covariant object on the left-hand side of equation (481) for the contravariant tensor T_{im} in expression (484). Correcting this and using the notation introduced in footnote 235, one would write equation (485) as

$$\delta^{\kappa\kappa'}\frac{\partial^2\bar{\gamma}_{im}}{\partial x_\kappa \partial x_{\kappa'}}\frac{\partial \bar{g}_{im}}{\partial x_\sigma} = \delta^{\kappa\kappa'}\left[\frac{\partial}{\partial x_\kappa}\left(\frac{\partial\bar{\gamma}_{im}}{\partial x_{\kappa'}}\frac{\partial \bar{g}_{im}}{\partial x_\sigma}\right) - \frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\frac{\partial\bar{\gamma}_{im}}{\partial x_{\kappa'}}\frac{\partial \bar{g}_{im}}{\partial x_\kappa}\right)\right].$$

242 The equation has covariant indices on the left- and contravariant indices on the right-hand side. Since indices are raised and lowered with the Kronecker delta in this approximation, this does not really matter. Using the notation introduced in footnote 235, one could write the equation more carefully as: $\Box\bar{\gamma}_{im} = \kappa\rho_0\frac{dx_i}{d\tau}\frac{dx_m}{d\tau}$. Einstein also wrote dx_τ instead of $d\tau$ again (cf. footnote 239).

$$\frac{\partial g_{im}}{\partial x_m} = 0 . \tag{488}$$

Equations (486) and (488) immediately imply equation (487):

$$\kappa \frac{\partial}{\partial x_m}\left(\rho_0 \frac{dx_i}{d\tau}\frac{dx_m}{d\tau}\right) = \frac{\partial}{\partial x_m}(\Box g_{im}) = \Box\left(\frac{\partial g_{im}}{\partial x_m}\right) = 0 . \tag{489}$$

As we have seen (cf. equation (479)), the linearized Hertz restriction is just one of the two restrictions in the tentative decomposition of the harmonic restriction given at the top of the page. But now a problem arises, which lies neither with the Hertz restriction nor with the harmonic restriction taken by itself, but with the combination of the two. Together these two restrictions imply equation (480), which says that the trace of the linearized metric has to be a constant.

This was objectionable for two reasons. First, through the field equations, it imposes the condition that the trace of the stress-energy tensor vanish (cf. equation (486)), which is clearly violated in the case under consideration, viz. pressureless dust.[244] Secondly, the trace of the metric $\mathrm{diag}(\pm 1, \pm 1, \pm 1, c^2(x,y,z))$, which Einstein used to represent static fields (see p. 6R and p. 39L), is obviously not a constant.

To avoid these problems, Einstein considered giving up the Hertz restriction. That means that it is no longer guaranteed that the divergence of the stress-energy tensor vanishes. The calculations at the bottom of p. 19R suggest that Einstein was prepared to consider the possibility that this divergence is non-vanishing. The result of these calculations, however, convinced him that was not an option. And from this he inferred that the Hertz restriction, which is the natural way of forcing the divergence of the stress-energy tensor to vanish, also had to be retained.

Einstein wrote down the "continuity condition" ("Kontinuitätsbedingung") for a cloud of pressureless dust, with "density of material points" ("Dichte materieller Punkte") $\rho_0/\sqrt{1-\mathfrak{q}^2/c^2}$,[245]

$$-\frac{\partial}{ic\partial t}\left(\frac{\rho_0 ic}{\sqrt{1-\frac{\mathfrak{q}^2}{c^2}}}\right) = \frac{\partial}{\partial x}\left(\frac{\rho_0 \mathfrak{q}_x}{\sqrt{1-\frac{\mathfrak{q}^2}{c^2}}}\right) + \frac{\partial}{\partial y}\left(\frac{\rho_0 \mathfrak{q}_y}{\sqrt{1-\frac{\mathfrak{q}^2}{c^2}}}\right) + \frac{\partial}{\partial z}\left(\frac{\rho_0 \mathfrak{q}_z}{\sqrt{1-\frac{\mathfrak{q}^2}{c^2}}}\right) . \tag{490}$$

---

243 Or rather (see the preceding note) that: $\partial\bar{\gamma}_{im}/\partial x_m = 0$. This relation is equivalent to equation (488), which with the help of the notation introduced in footnote 235 can be written as: $\delta^{mm'}(\partial\bar{g}_{im}/\partial x_{m'}) = 0$.

244 In the second of his four communications to the Prussian Academy of November 1915, Einstein briefly revived the condition that the stress-energy tensor for matter be traceless (Einstein 1915b, 799) as it is for the electromagnetic stress-energy tensor. At that point he suggested that this constraint can be reconciled with the non-vanishing of the trace of the stress-energy tensor for pressureless dust by assuming that gravity plays an essential role in the constitution of matter. For discussion, see, e.g., "Untying the Knot …" sec. 7 (in this volume).

245 Einstein only wrote an abbreviated form of this equation indicating the last two terms by dots.

To combine the continuity equation with equation (487), expressing energy-momentum conservation for a cloud of pressureless dust, Einstein introduced the four-velocity[246]

$$\mathfrak{w}_i \equiv \frac{dx_i}{d\tau} = \frac{\dot{x}_i}{\sqrt{1-\frac{\mathfrak{q}^2}{c^2}}}, \tag{491}$$

in which the relation $d\tau = dt\sqrt{1-\mathfrak{q}^2/c^2}$ (with $\mathfrak{q} \equiv (\dot{x}, \dot{y}, \dot{z})$) between proper time and coordinate time has been used, and in which the dot indicates differentiation with respect to t. With the imaginary time coordinate $u = ict$, the $\mathfrak{w}_u$-component becomes $ic/\sqrt{1-\mathfrak{q}^2/c^2}$. Using this new notation, Einstein rewrote the continuity equation as[247]

$$\frac{\partial}{\partial x}(\rho_0\mathfrak{w}_x) + \frac{\partial}{\partial y}(\rho_0\mathfrak{w}_y) + \frac{\partial}{\partial z}(\rho_0\mathfrak{w}_\mathfrak{z}) + \frac{\partial}{\partial u}(\rho_0\mathfrak{w}_u) = 0 \ . \tag{492}$$

Similarly, the x-component of the divergence of the stress-energy tensor for pressureless dust (see equation (487)) can be rewritten as

$$\begin{aligned}\frac{\partial}{\partial x_j}(\rho_O\mathfrak{w}_x\mathfrak{w}_j) &= \frac{\partial}{\partial x}(\rho_0\mathfrak{w}_x\mathfrak{w}_x) + \frac{\partial}{\partial y}(\rho_0\mathfrak{w}_x\mathfrak{w}_y) + \frac{\partial}{\partial z}(\rho_0\mathfrak{w}_x\mathfrak{w}_z) + \frac{\partial}{\partial u}(\rho_0\mathfrak{w}_x\mathfrak{w}_u)\\ &= \left[\frac{\partial}{\partial x}(\rho_0\mathfrak{w}_x) + \frac{\partial}{\partial y}(\rho_0\mathfrak{w}_y) + \frac{\partial}{\partial z}(\rho_0\mathfrak{w}_z) + \frac{\partial}{\partial u}(\rho_0\mathfrak{w}_u)\right]\mathfrak{w}_x\\ &\quad + \rho_0\mathfrak{w}_x\frac{\partial\mathfrak{w}_x}{\partial x} + \rho_0\mathfrak{w}_y\frac{\partial\mathfrak{w}_x}{\partial y} + \rho_0\mathfrak{w}_z\frac{\partial\mathfrak{w}_x}{\partial z} + \rho_0\mathfrak{w}_u\frac{\partial\mathfrak{w}_x}{\partial u}.\end{aligned} \tag{493}$$

The term in square brackets vanishes because of the continuity equation. Bringing the remaining terms over to the left-hand side, one arrives at the final equation of p. 19R,[248]

$$\begin{aligned}&\frac{\partial}{\partial x}(\rho_0\mathfrak{w}_x\mathfrak{w}_x) + \frac{\partial}{\partial y}(\rho_0\mathfrak{w}_x\mathfrak{w}_y) + \frac{\partial}{\partial z}(\rho_0\mathfrak{w}_x\mathfrak{w}_z) + \frac{\partial}{\partial u}(\rho_0\mathfrak{w}_x\mathfrak{w}_u)\\ &-\rho_0\mathfrak{w}_x\frac{\partial\mathfrak{w}_x}{\partial x} - \rho_0\mathfrak{w}_y\frac{\partial\mathfrak{w}_x}{\partial y} - \rho_0\mathfrak{w}_z\frac{\partial\mathfrak{w}_x}{\partial z} - \rho_0 w_u\frac{\partial\mathfrak{w}_x}{\partial u} = 0.\end{aligned} \tag{494}$$

Einstein noticed that the last four terms on the left-hand side add up to

$$-\rho\frac{D\mathfrak{w}_x}{D\tau}. \tag{495}$$

---

246 He wrote $\mathfrak{w}_i$ and $\mathfrak{w}_m$ above the relevant terms on the right-hand side of equation (486); and he wrote $\mathfrak{w}_x$ and $\mathfrak{w}_u$ for the expressions $\dot{x}/\sqrt{\quad}$ and $ic/\sqrt{\quad}$ in the lower right-hand corner of the page.

247 In the notebook the third term is indicated only by a dot.

248 In the notebook the last two terms on both the first and the second line are indicated only by dots.

The vanishing of this expression and the corresponding y- and z-components is the condition that the dust particles move on geodesics in what in this first-order approximation is Minkowski spacetime. Looking back at equation (493), we thus see that the vanishing of the divergence of the stress-energy tensor follows directly from the continuity equation and the equations of motion for the dust cloud.[249] It was therefore not an option for Einstein to drop the divergence requirement. The easiest way to guarantee the divergence requirement was to impose the Hertz restriction (see equations (487)–(489)). So, Einstein wanted to hold on to the Hertz restriction to satisfy the conservation principle and at the same time he wanted to hold on to the harmonic restriction to satisfy the correspondence principle. As Einstein put it: "*both* restrictions are to be retained" ("*Beide* obige Bedingungen sind aufrecht zu erhalten"). He had hit upon a serious problem: the harmonic restriction plus the Hertz restriction implied the unacceptable condition that the trace of the linearized metric be a constant.

5.4.3 *Modifying the Weak-field Equations: the Linearized Einstein Tensor (20L, 21L)*

20L At the top of p. 20L, Einstein once again wrote down the two conditions[250]

$$\sum \frac{\partial g_{i\kappa}}{\partial x_\kappa} = 0, \qquad \sum g^{x}_{\kappa\kappa} = 0. \tag{496}$$

into which he had tentatively decomposed the harmonic restriction at the top of p. 19R (cf. equations (479)–(480)). The harmonic condition was used to reduce the Ricci tensor to the d'Alembertian acting on the metric in the weak-field case. The Hertz restriction was added to make sure that the divergence of the stress-energy tensor vanishes in the weak-field case. The combination of these two restrictions implies that the trace of the metric has to vanish. This is problematic for a couple of reasons. First, if the metric is traceless, the weak-field equations (486) tell us that the stress-energy tensor be traceless as well. This last inference can be avoided by modifying the weak-field equations so as to make their right-hand side traceless. This is precisely what Einstein did on the next line:[251]

249 This cannot have come as a great surprise for Einstein, for it was precisely from the equations of motion for a cloud of pressureless dust that he had derived the equation for energy-momentum conservation (see, e.g., equation (483)) in the first place (see p. 5R).

250 In the second equation Einstein used the superscript "x" to indicate that he was considering first-order deviations from the flat metric. The same convention was used elsewhere in the notebook (see pp. 41L, 10L, 10R, 12L, 12R).

251 Using the notation of footnote 235 along with the d'Alembertian $\Box$ and the stress-energy tensor $T_{i\kappa} = \rho_0 \frac{dx_i}{d\tau}\frac{dx_\kappa}{d\tau}$ (with trace T), one can rewrite this equation more carefully as: $\Box g_{i\kappa} = \kappa\left(T_{i'\kappa'} - \frac{1}{4}\delta^{i'\kappa'}T\right)\delta_{ii'}\delta_{\kappa\kappa'}$. Einstein omitted the gravitational constant κ, and instead of the Kronecker delta $\delta^{i'\kappa'}$, he wrote "for the same i and κ" ("für gleiche i u. κ") underneath the second term on the right-hand side.

$$\sum_{\sigma}\frac{\partial^2 g_{i\kappa}}{\partial x_\sigma^2} = \rho_0\frac{dx_i}{d\tau}\frac{dx_\kappa}{d\tau} - \left(\frac{1}{4}\rho_0\sum\frac{dx_\kappa}{d\tau}\frac{dx_\kappa}{d\tau}\right). \tag{497}$$

With these new weak-field equations, the condition on the trace of the metric tensor no longer implies any condition on the trace of the stress-energy tensor.[252] Still, Einstein must have found the result unsatisfactory, for he crossed out the two lines with equations (496)–(497).

Eq. (497) does indeed only solve part of the problem caused by the combination of the harmonic and the Hertz restrictions. It takes care of the problem that a traceless metric would imply a traceless energy-momentum tensor, but it does not address a second problem, namely that a metric of the form Einstein used to represent static fields is not traceless.

A more satisfactory way to solve the problems would be to modify the weak-field equations in such a way that one avoids the condition that the metric be traceless altogether. This can be done by modifying the field equations in such a way that the harmonic restriction ensures both the elimination of unwanted second-order derivative terms for the Ricci tensor and the vanishing of the divergence of the stress-energy tensor. The combination of the harmonic and the Hertz restriction is thus replaced by the harmonic restriction alone and the problematic condition that the metric be traceless no longer follows. This is exactly the way in which Einstein took care of the problem in the next line.

First he wrote down the harmonic restriction again in first-order approximation (cf. equation (478) and footnote 235 for a more careful notation),

$$\sum\left(\frac{\partial g_{i\kappa}}{\partial x_\kappa} - \frac{1}{2}\frac{\partial g_{\kappa\kappa}}{\partial x_i}\right) = 0, \tag{498}$$

underlining the left-hand side. He introduced the abbreviation

$$\sum g_{\kappa\kappa} = U \tag{499}$$

for the trace of the metric. Instead of adding a term with the trace of the stress-energy tensor to the right-hand side of the weak-field equations as he had done in equation (497), he now added a term with the trace of the metric to the left-hand side. He wrote down a few components of these modified "gravitational equations" ("Gravitationsgleichungen"), indicating the remaining components by a dot and three lines of dashes[253]

252 In the fourth communication of November 1915, Einstein (1915d) similarly added a term with the trace T of the energy-momentum tensor of matter to his field equations to avoid the condition $T = 0$. For discussion, see "Untying the Knot …" sec. 7 (in this volume).

$$\begin{array}{cccccc} \Delta\left(g_{11}-\frac{1}{2}U\right) = T_{11} & & \Delta g_{12} = T_{12} & . & \Delta g_{14} = T_{14} & \\ \rule{2em}{0.4pt}\ \rule{1em}{0.4pt}\ \rule{1.5em}{0.4pt}\ \rule{1.5em}{0.4pt} & & \rule{2em}{0.4pt}\ \rule{2em}{0.4pt} & & \rule{2.5em}{0.4pt}\ \rule{2em}{0.4pt} & \qquad (500) \\ \rule{2em}{0.4pt}\ \rule{1em}{0.4pt}\ \rule{1.5em}{0.4pt}\ \rule{1.5em}{0.4pt} & & \rule{2em}{0.4pt}\ \rule{2em}{0.4pt} & & \rule{2.5em}{0.4pt}\ \rule{2em}{0.4pt} & \\ \rule{2em}{0.4pt}\ \rule{1em}{0.4pt}\ \rule{1.5em}{0.4pt}\ \rule{1.5em}{0.4pt} & & \rule{2em}{0.4pt}\ \rule{2em}{0.4pt} & & \rule{2.5em}{0.4pt}\ \rule{2em}{0.4pt} & \end{array}$$

In modern notation, using the Kronecker delta, these equations can be written more compactly as[254]

$$\Box\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right) = T_{i\kappa}\,. \tag{501}$$

One can now ensure compatibility between the weak-field equations and the vanishing of the divergence of the stress-energy tensor by imposing

$$\frac{\partial}{\partial x_\kappa}\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right) = 0\,. \tag{502}$$

which is just the harmonic restriction (see equation (498)). The calculation for the modified weak-field equations and the harmonic restriction is completely analogous to the calculation for the original weak-field equations and the Hertz restriction (cf. equation (489)),

$$\frac{\partial T_{i\kappa}}{\partial x_\kappa} = \frac{\partial}{\partial x_\kappa}\left(\Box\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right)\right) = \Box\left(\frac{\partial}{\partial x_m}\left(g_{i\kappa}-\frac{1}{2}\delta_{i\kappa}U\right)\right) = 0\,. \tag{503}$$

In other words, Einstein's modification of the weak-field equations removed the need for the Hertz restriction (equation (479)), and thereby the need for the troublesome trace condition (equation (480)).

The modified weak-field equations (500) have exactly the same form as the weak-field equations for the final theory of November 1915.[255] The left-hand side is the linearized version of the Einstein tensor $R_{\mu\nu}-(1/2)g_{\mu\nu}R$. There is no indication in the notebook that Einstein tried to find the exact equations corresponding to the weak-field equations with trace term.

---

253 The Δ used here apparently denotes the d'Alembertian operator $\Delta \equiv \sum_{i=1}^{4}\frac{\partial^2}{\partial x_i^2}$, $(x_4 = ict)$ which had been denoted by the $\Box$ on the preceding page (p. 19R). The notation $\Box$ does not occur anywhere else in the notebook. The use of Δ as the analogue of the Laplace operator or the Laplace-Beltrami operator in four dimensions can also be found at the bottom of p. 19L. For two dimensions it is used on p. 10R, for three dimensions on p. 40L.

254 Strictly speaking, one should write the right-hand side as $T_{i'\kappa'}\delta_{ii'}\delta_{\kappa\kappa'}$, since $T_{i\kappa}$ is a contravariant tensor (cf. footnote 251).

255 (Einstein 1915d).

Einstein did write the modified weak-field equations in an alternative form. Taking the trace on both sides of equation (500), he found

$$2\Delta U = \sum T_{\kappa\kappa} \tag{504}$$

(the factor 2 on the left-hand side should be -1).With the help of this relation, Einstein replaced the term with the trace of the metric on the left-hand side of equation (500) by a term with the trace of the stress-energy tensor on the right-hand side. He obtained, writing “from this equations” (“Hieraus Gleichungen”)

$$\begin{array}{llll} \Delta g_{11} = T_{11} + \frac{1}{2}\sum T_{\kappa\kappa} & \Delta g_{12} = T_{12} & . & \Delta g_{14} = T_{14} \\ \text{\_\_\_\_\_ \_\_\_ \_\_\_\_ \_\_\_\_} & \text{\_\_\_\_\_ \_\_\_\_\_} & & \text{\_\_\_\_\_\_\_ \_\_\_\_\_} \\ \text{\_\_\_\_\_ \_\_\_ \_\_\_\_ \_\_\_\_} & \text{\_\_\_\_\_ \_\_\_\_\_} & & \text{\_\_\_\_\_\_\_ \_\_\_\_\_} \\ \text{\_\_\_\_\_ \_\_\_ \_\_\_\_ \_\_\_\_} & \text{\_\_\_\_\_ \_\_\_\_\_} & & \text{\_\_\_\_\_\_\_ \_\_\_\_\_} \end{array} \tag{505}$$

Einstein partly corrected his error in equation (504). The plus sign in equation (505), however, should be a minus sign. In modern notation, the correct equations can be written more compactly as (cf. equation (501))

$$\Box g_{ij} = T_{ij} - \frac{1}{2}\delta_{ij}\left(\sum T_{\kappa\kappa}\right). \tag{506}$$

Einstein proceeded to check that the modified weak-field equations (in the form of equation (500) rather than in the form of equation (505)) still allow the gravitational four-force density to be written in the form of a divergence. In first-order approximation, the force density is given by (see expression (484)):

$$\frac{1}{2}T_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\sigma}. \tag{507}$$

Using equation (501) to eliminate $T_{i\kappa}$ from this expression, one arrives at

$$-\frac{1}{2}\Delta\left(g_{i\kappa} - \frac{1}{2}\delta_{i\kappa}U\right)\frac{\partial g_{i\kappa}}{\partial x_\sigma} = -\frac{1}{2}\left(\Delta g_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\sigma} - \frac{1}{2}\Delta U\frac{\partial U}{\partial x_\sigma}\right) \tag{508}$$

On p. 19R, Einstein had already established that the first term on the right-hand side can be written in the form of a divergence (see equation (485)). It only remained for him to verify that this is true for the second term as well. He started to rewrite this term at the bottom of p. 20L as

$$\begin{aligned} -\frac{1}{2}\sum \Delta U\frac{\partial g_{\kappa\kappa}}{\partial x_\sigma} &= \cancel{-\frac{1}{2}\sum \frac{\partial^2 g_{\alpha\alpha}}{\partial x_\beta \partial x_\beta}}\frac{\partial g_{\kappa\kappa}}{\partial x_\sigma} = -\frac{1}{2}\sum \Delta U\frac{\partial U}{\partial x_\sigma} \\ &= -\frac{1}{2}\sum\left(\frac{\partial^2 U}{\partial x^2} + . + . + .\right)\frac{\partial U}{\partial x_\sigma} \end{aligned} \tag{509}$$

Although the final expression still does not have the form of a divergence, Einstein concluded that it is "representable in the required form" ("Darstellbar in der verl[angten] Form"). Since the two terms on the right-hand side of equation (508) have the exact same structure and since the result had already been established for the first, this conclusion is obvious.

21L Nevertheless, Einstein made a fresh start with this whole calculation on p. 21L, this time considering both terms in equation (508).[256] At the top of p. 21L Einstein wrote down the right-hand side of equation (508)

$$-\frac{1}{2}\left|\sum_{i\kappa}\Delta g_{i\kappa}\frac{\partial g_{i\kappa}}{\partial x_\sigma}-\frac{1}{2}\sum_{\kappa}\Delta U\frac{\partial U}{\partial x_\sigma}\right. . \tag{510}$$

He rewrote the sum in the second term as

$$\frac{\partial^2 U}{\partial x_\nu^2}\frac{\partial U}{\partial x_\sigma} = \frac{\partial}{\partial x_\nu}\left(\frac{\partial U}{\partial x_\nu}\frac{\partial U}{\partial x_\sigma}\right)-\frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial U}{\partial x_\nu}\right)^2\right), \tag{511}$$

and the one in the first as

$$\frac{\partial^2 g_{i\kappa}}{\partial x_\nu^2}\frac{\partial g_{i\kappa}}{\partial x_\sigma} = \frac{\partial}{\partial x_\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\frac{\partial g_{i\kappa}}{\partial x_\sigma}\right)-\frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\right)^2\right). \tag{512}$$

Inserting these results into expression (510), he wrote the gravitational force density in the required form of a coordinate divergence of gravitational stress-energy density,[257]

$$\begin{aligned}&\sum_{i\kappa\nu}\frac{\partial}{\partial x_\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\frac{\partial g_{i\kappa}}{\partial x_\sigma}\right)-\frac{1}{2}\sum_{i\kappa\nu}\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial g_{i\kappa}}{\partial x_\nu}\right)^2\right)\\ &-\frac{1}{2}\sum_{\nu}\frac{\partial}{\partial x_\nu}\left(\frac{\partial U}{\partial x_\nu}\frac{\partial U}{\partial x_\sigma}\right)+\frac{1}{4}\sum\frac{\partial}{\partial x_\sigma}\left(\left(\frac{\partial U}{\partial x_\nu}\right)^2\right).\end{aligned} \tag{513}$$

At some point, Einstein deleted the second line and wrote that the trace "U must vanish" ("U muss verschwinden"). He probably meant that the *derivatives* of U must vanish. It is unclear why he resurrected this condition on the trace of the metric tensor. He later deleted the remark about U, but did not rescind the deletion of the second line of expression (513).

From the fragmentary calculations on the remainder of the page, one can infer that Einstein somehow wanted to produce an exact analogue of his first-order calculation. Exactly how and for what purpose remains unclear. Perhaps he wanted to verify that the exact field equations allow one to rewrite the gravitational force density as the

---

256 This seemingly redundant calculation may have been done in connection with the calculation at the bottom of p. 21R involving the gravitational stress tensor for Einstein's 1912 static theory.

257 Notice that he did not take into account the factor $-1/2$ in front of expression (510), which was probably only added later.

divergence of the gravitational stress-energy density as well; or he wanted to find the exact expression for the quantity representing gravitational stress-energy density on the basis of the approximative expression that could be read off from expression (513). Whatever the purpose of these calculations, he drew a horizontal line and wrote[258]

$$\frac{\partial g_{i\kappa}}{\partial x_\sigma}\gamma_{\mu\nu}\frac{\partial^2 g_{i\kappa}}{\partial x_\mu \partial x_\nu} = \frac{\partial}{\partial x_\nu}\left(\gamma_{\mu\nu}\frac{\partial g_{i\kappa}}{\partial x_\sigma}\frac{\partial g_{i\kappa}}{\partial x_\mu}\right) - \frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial}{\partial x_\nu}\left(\frac{\partial g_{i\kappa}}{\partial x_\sigma}\gamma_{\mu\nu}\right). \tag{514}$$

Contrary to its linearized analogue (equation (512)), the right-hand side of this equation cannot be written as a divergence. Einstein noted that the last term can be written as

$$-\gamma_{\mu\nu}\frac{\partial g_{i\kappa}}{\partial x_\mu}\frac{\partial^2 g_{i\kappa}}{\partial x_\nu \partial x_\sigma}, \tag{515}$$

if the Hertz restriction,

$$\sum \frac{\partial \gamma_{\mu\nu}}{\partial x_\nu} = 0, \tag{516}$$

is imposed. This still does not make it possible, however, to rewrite the right-hand side of equation (514) as a divergence. At this point, the calculation breaks off.[259]

5.4.4 *Reexamining the Presuppositions Concerning the Static Field (20R, 21R)*

On p. 19R Einstein had found that the compatibility between the field equations constructed out of the Ricci tensor on p. 19L and the correspondence and conservation principles required that the trace of the linearized metric be a constant. This condition was problematic for several reasons, one of which was that this requirement is not satisfied by a metric of the form $\mathrm{diag}(1, 1, 1, c^2(x, y, z))$ which Einstein used to represent weak static fields. On p. 20L Einstein showed that the condition could be avoided by adding a trace term to the weak-field equations, but then these weak-field equations themselves no longer allow a metric of the form $\mathrm{diag}(1, 1, 1, c^2)$ as a solution.[260,261]

---

258 Note that the expression is ill-defined since it contracts over pairs of covariant indices. The corresponding approximative calculations, of course, had the same problem, but there it was only a matter of awkward notation (see notes 241–242).

259 Einstein drew another horizontal line, started to write down, but then immediately deleted, the transformation law of what he referred to as the "second tensor" ("zweiter Tensor transformiert").

260 This is most easily seen when these modified weak-field equations are written in the form of equation (505). Consider a weak-field generated by some static mass distribution. The only non-vanishing component of the stress-energy tensor will be the 44 -component. If the weak-field equations are the ones in equation (505), the metric of a static weak field will deviate from the Minkowski metric in all its diagonal components, and not just in its 44 -component, as Einstein expected.

261 A metric of this form is also incompatible with the harmonic restriction with which the field equations of p. 19L were extracted from the Ricci tensor. It is unclear whether Einstein was aware of this problem at this point.

Before giving up the promising new field equations in the face of these problems, Einstein reexamined whether his presuppositions concerning the static field were actually justified. On p. 21R he found an argument that convinced him they were. The argument involves the dynamics of point particles in a gravitational field, which Einstein reviewed on p. 20R. Einstein argued that, unless the 44 -component is the only variable component of the metric of a static field, particles with different energy, and hence different inertial mass, fall with different accelerations in such fields. He thus saw himself forced to give up the field equations considered on pp. 19L–20L.

20R The discussion on p. 20R of the mechanics of point particles and continuous matter distributions in a gravitational field is essentially the same as the discussions on p. 5R and in (Einstein and Grossmann 1913, sec. 2 and 4). At the top of the page, Einstein wrote down the line element

$$\sum g_{\mu\nu} dx_\mu dx_\nu = d\tau^2 , \tag{517}$$

and introduced the Lagrangian for a point particle of unit mass moving in a given metric field

$$\eta = \frac{d\tau}{dt} = \sqrt{g_{\mu\nu}\dot{x}_\mu \dot{x}_\nu} . \tag{518}$$

This last equation is written here somewhat more compactly than in the notebook. Though he indicated most terms by dots, Einstein expanded the sum under the square root sign,[262] writing (x, y, z, t) for the coordinates x_μ. He continued to do so in most of the equations on this page. His argument is easier to follow, however, if the more compact notation is used.

On the basis of the Euler-Lagrange equations,

$$\frac{\partial\eta}{\partial x_i} - \frac{d}{dt}\left(\frac{\partial\eta}{\partial \dot{x}_i}\right) = 0 , \tag{519}$$

where $i = 1, 2, 3$, the quantities

$$-\frac{\partial\eta}{\partial x_i} = -\frac{1}{2}\frac{dt}{d\tau}\frac{\partial g_{\mu\nu}}{\partial x_i}\frac{dx_\mu}{dt}\frac{dx_\nu}{dt} \tag{520}$$

can be interpreted as the components of the force on the particle,[263] and the quantities

$$-\frac{\partial\eta}{\partial \dot{x}_i} = -\frac{1}{2}\frac{dt}{d\tau}\frac{\partial}{\partial \dot{x}_i}(g_{\mu\nu}\dot{x}_\mu \dot{x}_\nu) = -g_{i\mu}\frac{dx_\mu}{d\tau} \tag{521}$$

as the components of its momentum. The particle's energy is given by the Legendre transform

262 We use a hybrid summation convention here, as did Einstein in the notebook at various places.
263 In the notebook, the factor $1/2$ on the right-hand side is omitted.

$$\begin{aligned}\eta - \sum \frac{\partial\eta}{\partial \dot{x}_i}\dot{x}_i &= \frac{d\tau}{dt} - \left(g_{i\mu}\frac{dx_\mu}{d\tau}\right)\frac{dx_i}{dt} \\ &= \frac{1}{dtd\tau}(d\tau^2 - g_{i\mu}dx_i dx_\mu) \\ &= \frac{1}{dtd\tau}(g_{4\mu}dx_4 dx_\mu) \\ &= g_{4\mu}\frac{dx_\mu}{d\tau}.\end{aligned} \tag{522}$$

Equations (521)–(522) show that "minus momentum and energy form a four-vector" ("Negativer Impuls u. Energie bilden Vierervektor"), whose components can be written as

$$g_{\mu\rho}\frac{dx_\rho}{d\tau}. \tag{523}$$

For a particle that does not have unit mass, this expression has to be "multiplied by [its rest mass] m" ("Noch mit m zu mult[iplizieren]").

Instead of one particle, Einstein now considered a continuous mass distribution. Dividing the four-momentum in expression (523) (multiplied by m) by the volume V, which can be written as[264]

$$V = \frac{1}{\sqrt{G}}\frac{d\tau}{dt}V_0 = \frac{1}{\sqrt{G}}\frac{d\tau}{dt}\frac{m}{\rho_0}, \tag{524}$$

he introduced the four-momentum density[265]

$$g_{\mu\rho}\frac{dx_\rho}{d\tau}\frac{dx_4}{d\tau}\rho_0\sqrt{G}. \tag{525}$$

Einstein now drew a horizontal line and wrote down the contravariant stress-energy tensor for pressureless dust, or, as he called it, the "tensor of material flow" ("Tensor der materiellen Strömung")

$$T_{i\kappa} = \rho_0\frac{dx_i}{d\tau}\frac{dx_\kappa}{d\tau}. \tag{526}$$

He lowered one index and introduced the notation

$$T'_{i\kappa} = \sum_i g_{\nu i}T_{i\kappa}, \tag{527}$$

264 (Einstein and Grossmann 1913, 10). Einstein had already used this equation on p. 5R (see equation (61)).

265 In the notebook, "momentum density" ("Impulsdichte") and "energy density" ("Energiedichte") are introduced separately.

for the "resulting mixed tensor" ("Hieraus gemischter Tensor"), which he explicitly identified as "stress-energy tensor" ("Sp[annungs]-Energie-Tensor"). The components of the four-momentum density introduced in expression (525) are simply the $\mu 4$-component of $\sqrt{G}T_{\mu\nu}'$.

Finally, Einstein wrote down the divergence of this mixed tensor density

$$\frac{\partial}{\partial x_\kappa}(\sqrt{G}g_{\nu i}T_{i\kappa}) . \tag{528}$$

According to the energy-momentum balance between matter and gravitational field, which Einstein had derived on p. 5R on the basis of considerations closely analogous to those on this page, the sum of this divergence and the force density must vanish. The latter is given by the force per unit mass (see equation (520)) multiplied by m and divided by V (see equation (524)). The result is[266]

$$-\frac{1}{2}\sqrt{G}\rho_0\frac{\partial g_{\kappa\lambda}}{\partial x_\nu}\frac{dx_\kappa}{d\tau}\frac{dx_\lambda}{d\tau} = -\frac{1}{2}\sqrt{G}\frac{\partial g_{\kappa\lambda}}{\partial x_\nu}T_{\kappa\lambda}. \tag{529}$$

At the bottom of the page, however, Einstein only wrote down expression (528), the first term in the energy-momentum balanced.

21R At the top of p. 21R, he returned to the consideration of force and energy rather than of force and energy densities. He wrote down an expression equivalent to equation (520), the first component of which gives the "x-component of the ponderomotive force" ("x-Komponente der ponderomotorischen Kraft") on a point particle of unit mass,[267]

$$-\frac{\sum\frac{\partial g_{\mu\nu}}{\partial x_\sigma}\dot{x}_\mu\dot{x}_\nu}{\sqrt{g_{44}+g_{11}\dot{x}^2+\ldots}} , \tag{530}$$

and an expression equivalent to equation (522) for the "energy of the point" ("Energie des Punktes"),

$$\frac{\left(g_{14}\frac{dx}{dt}+g_{24}\frac{dy}{dt}+\cdot+g_{44}\right)}{\sqrt{g_{44}+g_{11}\dot{x}^2+\ldots}} . \tag{531}$$

Right next to this expression, Einstein explicitly wrote down the metric of a static field

266 In the expression for the force density or "force per unit volume" ("Kraft pro Volumeinheit") in the notebook, a factor $\rho_0/2$ is missing.

267 A crossed-out factor of $\rho_0\sqrt{G}$ occurs in the numerator of both this expression and the next, which suggests that Einstein at some point considered force and energy densities.

$$\begin{matrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2 \end{matrix} \,, \qquad (532)$$

which would allow him to recover his 1912 static theory from a theory based on the metric tensor. He noted that the g_{i4}-components "definitely vanish in a static field" ("g_{14} g_{24} … verschwinden sicher im statischen Felde"). In the static case, the numerator in expression (531) for the particle's energy thus reduces to g_{44}. Special relativity tells us that energy is proportional to inertial mass. Galileo's principle, i.e., the principle that the gravitational acceleration is the same for all bodies, tells us that the gravitational force is proportional to inertial mass as well. Expressions (530) and (531), however, imply that, unless all spatial components of the metric are constants, the ratio of force and energy in a static field,

$$\frac{\sum \frac{\partial g_{\mu\nu}}{\partial x_\sigma} \dot{x}_\mu \dot{x}_\nu}{g_{44}} \,, \qquad (533)$$

will depend on the particle's velocity. As Einstein put it: "If the force is supposed to vary like the energy, then g_{11}, g_{22} etc. must vanish for the static field" ("Soll die Kraft sich ändern wie die Energie, so müssen im statischen Felde g_{11}, g_{22} etc. verschwinden").[268] Although not stated explicitly, Einstein's conclusion was that the metric of the static field has to be of the form (532).[269]

This argument has a certain *prima facie* plausibility, but it does not hold up under closer scrutiny. On p. 20R, Einstein had identified a particle's momentum p_i (see equation (521)) and the force F_i acting on it (see equation (520) and expression (530)) in such a way that the spatial components of the geodesic equation, the Euler-Lagrange equations for the Lagrangian in equation (518), can be written in a form reminiscent of Newton's second law

$$\frac{dp_i}{dt} = F_i \,. \qquad (534)$$

For Einstein's argument on p. 21R to be valid one would have to be able to substitute (modulo a proportionality constant) $E\dot{x}_i$ (where the energy E is given by equation (522) or expression (531)) for p_i in equation (534). This substitution, however, is not

---

268 More accurately, the *deviations* of "g_{11}, g_{22} etc." from their constant Minkowskian values must vanish in the static case.

269 Presumably, although this is not made explicit, Einstein only wanted to draw the conclusion that static fields must be of this form *in first-order approximation*. He did not seem the least bit disturbed when in June 1913, in an attempt to calculate the perihelion advance of Mercury on the basis of the *Entwurf* theory, he found that the metric field of the sun in second-order approximation is not spatially flat (cf. [p. 6] of the Einstein-Besso manuscript [CPAE 4, Doc. 14]).

allowed. In other words, there is no reason to think that the antecedent of Einstein's conditional (i.e., "the force varies like energy") is true, and the argument fails.

Einstein drew two figures next to expressions (530)–(531), presumably to illustrate his argument, although their purpose remains unclear. The upshot of Einstein's considerations, however, is unambiguous. He had found an argument, based on a fundamental postulate of classical mechanics and completely independent of the gravitational field equations, that seemed to show that the metric of static gravitational fields has to be spatially flat. This confirmed his ideas about how to recover both Newton's theory and his own 1912 theory for static gravitational fields from the metric theory.[270] A metric of this form, however, was incompatible with the modified weak-field equations introduced on p. 20L.[271] Einstein therefore gave up the idea of constructing field equations out of the Ricci tensor with the help of the harmonic restriction.

21R

5.4.5 *Embedding the Stress Tensor for Static Gravitational Fields into the Metric Formalism (21R)*

For a metric of the form $\mathrm{diag}(-1, -1, -1, c^2)$ Einstein expected his new metric theory to reduce to his 1912 theory for static gravitational fields. That implied that one should also recover the expression for the gravitational stress tensor of the 1912 theory. On the bottom half of p. 21R, Einstein tried to translate the expression for this stress tensor into the language of the metric theory, replacing factors c, c^2, and $1/c^2$ by $\sqrt{-G}$, g_{44}, and γ_{44}, respectively.[272] Exactly what Einstein hoped to achieve remains unclear. His comments and the fact that he deleted the calculation in its entirety do make clear, however, that he was unhappy with the results. Part of the problem may have been that the expression for the stress tensor of the 1912 theory did not seem to agree with the corresponding components of the quantity representing gravitational stress-energy density constructed on p. 21L.

Under the heading "static special case" ("Statischer Spezialfall"), Einstein wrote down the X_x-component of the stress tensor of (the final version of) his 1912 static theory[273]

$$X_x = \frac{1}{c}\frac{\partial c}{\partial x}\frac{\partial c}{\partial x} - \frac{1}{2c}\mathrm{grad}^2 c \ . \tag{535}$$

---

270 In Einstein to Erwin Freundlich, 19 March 1915 (CPAE 8, Doc. 63), Einstein once again addressed the question "whether matter at rest can generate any other gravitational field than a g_{44}-field" ("ob ruhende Materie ein anderes Gravitationsfeld als ein g_{44}-Feld erzeugen kann"). "It cannot" ("Dies ist nicht der Fall"), he wrote. In support of this claim, he presented a calculation done in first-order approximation and based on the *Entwurf* field equations (i.e., on weak-field equations without a trace term). He made no reference to any other arguments for his claim.

271 It is also incompatible with the harmonic restriction (see footnote 261).

272 On p. 39L, Einstein had attempted a similar translation of the field equations of the 1912 theory (see sec. 2.2, equations (9)–(18)).

273 (Einstein 1912b, 456, equation (5)).

Using the relation $\frac{\partial c}{\partial x} = \frac{1}{c}\frac{\partial}{\partial x}\left(\frac{c^2}{2}\right)$, he rewrote this equation as

$$\begin{aligned} 4X_x &= \frac{1}{c^3}\frac{\partial c^2}{\partial x}\frac{\partial c^2}{\partial x} - \frac{1}{2c^3}\mathrm{grad}^2 c^2 \\ &= c\frac{1}{c^2}\frac{1}{c^2}\frac{\partial c^2}{\partial x}\frac{\partial c^2}{\partial x} - \frac{1}{2}\left(c\frac{1}{c^2}\frac{1}{c^2}\mathrm{grad}^2 c^2\right) \end{aligned} \tag{536}$$

He then translated this expression into the language of the metric theory, using that $c = \sqrt{-G}$, $g_{44} = c^2$, and $\gamma_{44} = 1/c^2$ for a metric of the form $\mathrm{diag}(-1, -1, -1, c^2)$. In this way, he arrived at

$$4X_x = \sqrt{-G}\left(\gamma_{44}\gamma_{44}\frac{\partial g_{44}}{\partial x}\frac{\partial g_{44}}{\partial x} - \frac{1}{2}\gamma_{44}\gamma_{44}\left(\sum_\nu \frac{\partial g_{44}}{\partial x_\nu}\frac{\partial g_{44}}{\partial x_\nu}\right)\right) \tag{537}$$

Underneath this expression Einstein wrote: “impossible because of divergence equation” (“Unmöglich wegen Divergenzgleichung”). The “divergence equation” is presumably the equation setting the gravitational four-force density equal to the divergence of gravitational stress-energy density. In the notation of the *Entwurf*, this equation can be written as[274]

$$-\frac{1}{2}\sqrt{-g}\frac{\partial g_{\mu\nu}}{\partial x_\sigma}T^{\mu\nu} = \frac{\partial}{\partial x_\nu}(\sqrt{-g}g_{\sigma\mu}t^{\mu\nu}), \tag{538}$$

where $T^{\mu\nu}$ and $t^{\mu\nu}$ denote the contravariant stress-energy tensor for matter and the corresponding pseudo-tensor for the gravitational field, respectively. On pp. 19R, 20L, and 21L, Einstein had checked, in a first-order approximation and using his candidate (weak) field equations to eliminate the stress-energy tensor for matter, whether the gravitational force density can be rewritten as a divergence. The tentative expression for gravitational stress-energy density constructed on p. 21R confronted Einstein with the converse problem, viz. whether the divergence of the gravitational stress-energy density actually gives the gravitational force density. It is not clear how Einstein could tell without further calculation that this is not possible—if that is in fact what he means by his remark “impossible because of divergence equation”—but Einstein may have reached this conclusion on the basis of a comparison of equation (537) with expression (513) on p. 21L, which (in linear approximation) gives the gravitational force density in the form of the divergence of gravitational stress-energy density.

The translation of equation (536) into equation (537) is not unique. Einstein, in fact, gave an alternative translation of the first term in the expression for the stress tensor

274 Cf., e.g., (Einstein and Grossmann 1913, 16–17, equations (12a) and (18)).

$$\sqrt{-G}\frac{\partial}{\partial x}\left(\frac{1}{c^2}\right)\frac{\partial c^2}{\partial x} = \sum_{i\kappa}\sqrt{G}\frac{\partial \gamma_{i\kappa}}{\partial x}\frac{\partial g_{i\kappa}}{\partial x}\,. \tag{539}$$

Apparently, this expression was not satisfactory either. Einstein deleted this whole calculation by a diagonal line, and wrote: "special case probably incorrect" ("Spezialfall wahrscheinlich unrichtig").

19L–21R

5.4.6 *Synopsis of the Problems with the Harmonic Restriction and the Linearized Einstein Tensor (19L–21R)*

The calculations on p. 21R mark the end of Einstein's consideration of field equations extracted from the Ricci tensor with the help of the harmonic restriction, and of the modified weak-field equations that we now recognize as the Einstein equations of the final theory in linearized form. To conclude this section, we summarize the chain of reasoning that produced this unfortunate turn of events.

On p. 19L, Einstein showed that the harmonic restriction can be used to eliminate unwanted second-order derivative terms from the Ricci tensor. On p. 19R, examining these new field equations in linear approximation, he found that the natural way to make sure that the weak-field equations are compatible with energy-momentum conservation is to impose a further coordinate restriction, viz. the Hertz restriction. The combination of the harmonic restriction and the Hertz restriction implies that the trace of the linearized metric must be a constant. To avoid this implication, Einstein (on p. 20L) added a trace term to the weak-field equations, effectively changing their left-hand side from the linearized Ricci tensor to the linearized Einstein tensor. This modification obviates the need for the Hertz restriction and thus for the condition on the trace of the weak-field metric. Part of the original problem, however, still persists, albeit in a different guise.

One of the difficulties with the restriction on the trace of the metric is that it is not satisfied by a metric of the form $\mathrm{diag}(-1, -1, -1, c^2)$. Einstein believed that his theory would not have a sensible Newtonian limit unless weak static fields can be represented by a metric of this form. At the same time, a metric of this form would allow him to recover his 1912 theory for static gravitational fields from the new metric theory. It was thus a serious problem that the restriction on the trace of the metric rules out a metric of this form.

Unfortunately, with the modification needed to avoid this restriction, the weak-field equations themselves no longer allow a solution with a metric of the form $\mathrm{diag}(-1, -1, -1, c^2)$. On p. 21R, Einstein therefore reexamined whether his presuppositions about the static field were justified. A fallacious argument convinced him that nothing less than Galileo's principle that all bodies fall with the same acceleration requires that the metric of static fields does indeed have the form he had been assuming.[275] This sealed the fate of the harmonic restriction and the linearized Einstein tensor. Einstein only returned to field equations including a trace term by a different route in November 1915.[276]

5.5 *Exploring the Ricci Tensor in Unimodular Coordinates (22L–24L, 42L–43L)*

On p. 22R Einstein considered a new way of extracting a candidate for the left-hand side of the field equations from the Riemann tensor. He started from a new expression for the Ricci tensor, now entirely in terms of the Christoffel symbols and their first-order derivatives. He split this tensor into two parts each of which separately transforms as a tensor under unimodular transformations. Restricting the allowed transformations to unimodular transformations, he took one of these parts as the new candidate for the left-hand side of the field equations and explored it on the following pages. The object returned in the field equations published in the first of Einstein's four communications to the Berlin Academy of November 1915.[277] We therefore call it the November tensor. 22R

The November tensor still contains terms with second-order derivatives of the metric in addition to a core-operator term. On p. 22R, Einstein imposed the Hertz restriction to eliminate those terms (see secs. 5.5.2–5.5.3). This coordinate restriction would return as the coordinate condition (in the modern sense) for the November tensor in (Einstein 1915a). The advantage of the Hertz restriction is that it serves two purposes. It can be used to eliminate unwanted terms with second-order derivatives of the metric, and it ensures that the divergence of the matter stress-energy tensor vanishes in a weak-field approximation (see p. 19R). On p. 19R, Einstein had been forced to introduce two separate conditions for these two purposes—the harmonic restriction and the Hertz restriction. The introduction of the Einstein tensor on p. 20L can be seen as an attempt to eliminate the Hertz restriction. The introduction of the November tensor can likewise be seen as an attempt to eliminate the harmonic restriction.

The expression extracted from the November tensor with the Hertz restriction contains a large number of terms quadratic in first-order derivatives of the metric. On p. 23L, Einstein added a further addition to eliminate most of these terms. He went back to the original form of the November tensor in terms of the Christoffel symbols and imposed a coordinate restriction with which he could eliminate two of the three terms of the Christoffel symbols. This coordinate restriction is to unimodular transformations under which an expression that we call the ϑ-expression transforms as a tensor. We call this restriction the ϑ-restriction. Einstein discovered that the ϑ-restriction not only eliminates many terms with first-order derivatives of the metric but that it also takes care of the unwanted second-order derivatives that he had eliminated earlier with the Hertz restriction. Einstein thus lifted the Hertz restriction and kept only the ϑ-restriction (p. 23L; discussed in sec. 5.5.4). He began to investigate which non-autonomous transformations are allowed by the ϑ-restriction. In the end, he aban- 23L

275 Einstein checked and confirmed this expectation once more in 1915 (see footnote 270). He only realized that a weak static field need not be represented by a spatially flat metric when he calculated the perihelion motion of Mercury in (Einstein 1915c).

276 For discussion, see "Untying the Knot …" secs. 5–6 (in this volume).

277 (Einstein 1915a).

doned the ϑ-restriction because it does not allow transformation to rotating frames in Minkowski spacetime (pp. 23R–24L, 42L–43L; discussed in secs. 5.5.5–5.5.9).

22R 5.5.1 *Extracting the November Tensor from the Ricci Tensor (22R)*

At the top of p. 22R, Einstein wrote down the covariant form of the Ricci tensor in the form[278]

$$T_{il} = \sum_{kl} \frac{\partial}{\partial x_l}\begin{Bmatrix} i & k \\ & k \end{Bmatrix} - \frac{\partial}{\partial x_k}\begin{Bmatrix} i & l \\ & k \end{Bmatrix} + \begin{Bmatrix} i & k \\ & \lambda \end{Bmatrix}\begin{Bmatrix} \lambda & l \\ & k \end{Bmatrix} - \begin{Bmatrix} i & l \\ & \lambda \end{Bmatrix}\begin{Bmatrix} \lambda & k \\ & k \end{Bmatrix}. \tag{540}$$

Contrary to the expressions for the Riemann and Ricci tensors earlier in the notebook, equation (540) is written entirely in terms of Christoffel symbols rather than in terms of the metric tensor and its derivatives. Apparently, it was Marcel Grossmann, whose name appears at the top of the page, who suggested this expression to Einstein. Grossmann may also have suggested some of the further manipulations of this expression on p. 22R. Recall that Grossmann's name was also written next to the first occurrence of the Riemann tensor in the notebook on p. 14L.

Two of the four terms in this new expression for the Ricci tensor can be combined to form a quantity that can easily be seen to be a tensor under unimodular transformations. Under unimodular transformations the determinant G of the metric transforms as a scalar. Hence, $\lg\sqrt{G}$ also transforms as a scalar under such transformations, and the ordinary derivative of this quantity as a vector. Einstein denoted this vector by T_i and wrote that "if G is a scalar, then [...] T_i a tensor of first rank" ("Wenn G ein Skalar ist, dann

$$\frac{\partial \lg\sqrt{G}}{\partial x_i} = T_i \tag{541}$$

Tensor 1. Ranges.").[279] Using the relation

$$\frac{\partial \lg\sqrt{-g}}{\partial x_i} = \begin{Bmatrix} i & \kappa \\ & \kappa \end{Bmatrix}, \tag{542}$$

one can identify two of the four terms of the Ricci tensor as the covariant derivative of the vector T_i. Einstein regrouped the terms in equation (540) accordingly,

278 The summation should be over k and λ rather than over k and l.

279 Note that this is probably the first time that vectors are called "tensors of first rank" (also note that this is all in the context of unimodular transformation only). In (Budde 1914), the generalization of tensors to arbitrary dimension and rank was credited to Grossmann's part of Einstein and Grossmann 1913: "Recently, Mr. Grossmann [...] has proposed a still further reaching generalization. He denotes quantities of arbitrary rank as "tensors," so that vectors, trivectors, and bitensors are also subsumed under the term "tensor;" the generalization consists in extending his definitions to structures of n th rank in m-dimensional space" (Budde 1914, 246). For further discussion, see the appendix to (Norton 1992) and (Reich 1994). The term "rank" ("Rang") appears in the notebook only on this page. On p. 14L the fourth rank Riemann tensor was called "Ebenentensor vierter Mannigfaltigkeit."

$$T_{il} = \left(\frac{\partial T_i}{\partial x_l} - \sum \begin{Bmatrix} i & l \\ & \lambda \end{Bmatrix} T_\lambda\right) - \sum_{k\lambda}\left(\frac{\partial}{\partial x_k}\begin{Bmatrix} i & l \\ & k \end{Bmatrix} - \begin{Bmatrix} i & k \\ & \lambda \end{Bmatrix}\begin{Bmatrix} \lambda & l \\ & k \end{Bmatrix}\right). \tag{543}$$

Under the first term in parentheses he wrote "tensor of second rank" ("Tensor 2. Ranges"); under the second he wrote "presumed tensor of gravitation T^x_{il}" ("Vermutlicher Gravitationstensor T^x_{il}"). Since taking the covariant derivative is a generally-covariant operation and T_i is a first-rank tensor under unimodular transformations, its covariant derivative is a second-rank tensor under unimodular transformations. The second term in parentheses in equation (543), the difference between the full generally-covariant Ricci tensor and the covariant derivative of T_i, will therefore also transform as a tensor under unimodular transformations. Einstein took this quantity,

$$T^x_{il} = \frac{\partial}{\partial x_k}\begin{Bmatrix} i & l \\ & k \end{Bmatrix} - \sum_{k\lambda}\begin{Bmatrix} i & k \\ & \lambda \end{Bmatrix}\begin{Bmatrix} \lambda & l \\ & k \end{Bmatrix} \tag{544}$$

as his new candidate for the left-hand side of the field equations. We shall refer to it as the November tensor.

5.5.2 *Extracting Field Equations from the November Tensor Using the Hertz Restriction (22L–R)*

By imposing the Hertz restriction in addition to the unimodularity restriction, one can reduce the November tensor to the required form of a core operator plus terms with products of first-order derivatives of the metric. This is what Einstein confirmed on the next two lines on p. 22R, as the first step in a "further rewriting of the tensor of gravitation" ("Weitere Umformung des Gravitationstensors"). 22R

The only terms in T^x_{il} with second-order derivatives of the metric occur in the term with derivatives of the Christoffel symbol. Einstein expanded this term to

$$\frac{\partial}{\partial x_k}\begin{Bmatrix} i & l \\ & k \end{Bmatrix} = \frac{1}{2}\frac{\partial}{\partial x_k}\left(\gamma_{k\alpha}\left(\frac{\partial g_{i\alpha}}{\partial x_l} + \frac{\partial g_{l\alpha}}{\partial x_i} - \frac{\partial g_{il}}{\partial x_\alpha}\right)\right), \tag{545}$$

and then eliminated all unwanted second-order derivative terms by assuming the Hertz restriction. "We presuppose" ("Wir setzen voraus"), he wrote, that

$$\sum_\kappa \frac{\partial \gamma_{\kappa\alpha}}{\partial x_\kappa} = 0, \tag{546}$$

adding that "then this [i.e., the right-hand side of equation (545)] is equal to" ("dann ist dies gleich"):

$$-\frac{1}{2}\sum \gamma_{k\alpha}\frac{\partial^2 g_{il}}{\partial x_\alpha \partial x_k} - \frac{1}{2}\sum\left(\frac{\partial \gamma_{k\alpha}}{\partial x_l}\frac{\partial g_{i\alpha}}{\partial x_k} + \frac{\partial \gamma_{k\alpha}}{\partial x_i}\frac{\partial g_{l\alpha}}{\partial x_k}\right). \tag{547}$$

In the notebook, the factors $1/2$ in front of both terms appear above the summation signs and were probably added later. The core-operator term in expression (547) comes from the last term on the right-hand side of equation (545). The first two terms in equation (545) turn into the products of first-order derivative terms in expression (547) with the help of the Hertz restriction and the relation

$$\gamma_{k\alpha}\frac{\partial g_{i\alpha}}{\partial x_l} = -\frac{\partial \gamma_{k\alpha}}{\partial x_l}g_{i\alpha}\,. \tag{548}$$

22L On the bottom half of p. 22L, we find what appears to be an earlier attempt at eliminating unwanted second-order derivative terms from the November tensor with the help of the Hertz restriction. Relabeling the indices in equation (545), one can write the first part of the November tensor as

$$\frac{\partial}{\partial x_l}\begin{Bmatrix} i & m \\ & l \end{Bmatrix} = \frac{1}{2}\frac{\partial}{\partial x_l}\left(\gamma_{\kappa l}\left(\frac{\partial g_{\kappa i}}{\partial x_m} + \frac{\partial g_{\kappa m}}{\partial x_i} - \frac{\partial g_{im}}{\partial x_\kappa}\right)\right)\,. \tag{549}$$

The first two terms on the right-hand side give rise to unwanted second-order derivative terms

$$\frac{1}{2}\gamma_{\kappa l}\left\{\frac{\partial^2 g_{\kappa i}}{\partial x_l \partial x_m} + \frac{\partial^2 g_{\kappa m}}{\partial x_l \partial x_i}\right\}. \tag{550}$$

Except for the factor $1/2$, this is just the expression that Einstein wrote directly underneath the horizontal line on p. 22L. The first term in expression (550), multiplied by a factor 2, can be rewritten as

$$-\frac{\partial \gamma_{kl}\partial g_{ki}}{\partial x_m \partial x_l} + \frac{\partial}{\partial x_m}\left(\gamma_{kl}\frac{\partial g_{ki}}{\partial x_l}\right)\,. \tag{551}$$

In the notebook, the first term, a product of first-order derivatives, is indicated only by a dot (and an expression similar to expression (551) for the second term in equation (550) is omitted altogether). The Hertz restriction ensures that the second term, which can be rewritten as

$$\frac{\partial}{\partial x_m}\left(-\frac{\partial \gamma_{kl}}{\partial x_l}g_{ki}\right)\,, \tag{552}$$

vanishes. As Einstein wrote directly underneath the second term in the expression (551) in the notebook: “suffices, if $\sum \partial\gamma_{\kappa l}/\partial x_l$ vanishes” (“Gen[ü]gt, wenn … verschwindet”).

22R We now return to p. 22R. On the bottom half of the page, Einstein turned his attention to terms in the November tensor (544) with products of first-order derivatives of the metric. He began by expanding the term with a product of Christoffel symbols:

$$\begin{aligned}\begin{Bmatrix} i & k \\ & \lambda \end{Bmatrix}\begin{Bmatrix} \lambda & l \\ & k \end{Bmatrix} &= \frac{1}{4}\gamma_{\lambda\alpha}\gamma_{k\beta}\left(\frac{\partial g_{i\alpha}}{\partial x_k} - \frac{\partial g_{ik}}{\partial x_\alpha} + \frac{\partial g_{\alpha k}}{\partial x_i}\right)\left(\frac{\partial g_{l\beta}}{\partial x_\lambda} - \frac{\partial g_{l\lambda}}{\partial x_\beta} + \frac{\partial g_{\lambda\beta}}{\partial x_l}\right) \\ &= -\frac{1}{4}\gamma_{\lambda\alpha}\gamma_{k\beta}\left(\frac{\partial g_{i\alpha}}{\partial x_k} - \frac{\partial g_{ik}}{\partial x_\alpha}\right)\left(\frac{\partial g_{l\lambda}}{\partial x_\beta} - \frac{\partial g_{l\beta}}{\partial x_\lambda}\right) + \frac{1}{4}\gamma_{\lambda\alpha}\gamma_{k\beta}\frac{\partial g_{\alpha k}}{\partial x_i}\frac{\partial g_{\lambda\beta}}{\partial x_l}.\end{aligned} \tag{553}$$

As in expression (547), the numerical factors were added later. In the second step, Einstein used the same symmetry argument that he had used on pp. 17R and 19L (see the discussion following expression (463)). In the following two lines, Einstein noted that the last term can be rewritten as

$$-\frac{\partial \gamma_{\lambda\alpha}}{\partial x_i}\frac{\partial g_{\lambda\alpha}}{\partial x_l} \tag{554}$$

"or" ("oder") as

$$-\frac{\partial \gamma_{\lambda\alpha}}{\partial x_l}\frac{\partial g_{\lambda\alpha}}{\partial x_i}. \tag{555}$$

Einstein also rewrote the terms with products of first-order derivatives in the first part (547) of the November tensor. Using the relation (in modern notation)

$$\begin{aligned} g^{\alpha\beta}{}_{,i}g_{\alpha l,\beta} &= \frac{1}{2}g^{\alpha\beta}{}_{,i}(g_{\alpha l,\beta} + g_{\beta l,\alpha} - g_{\alpha\beta,l}) + \frac{1}{2}g^{\alpha\beta}{}_{,i}g_{\alpha\beta,l} \\ &= g^{\alpha\beta}{}_{,i}\begin{bmatrix} \alpha & \beta \\ & l \end{bmatrix} + \frac{1}{2}g^{\alpha\beta}{}_{,i}g_{\alpha\beta,l} \end{aligned} \tag{556}$$

and relabeling indices, one can rewrite the expression in parentheses in expression (547) as[280]

$$\frac{\partial \gamma_{\alpha\beta}}{\partial x_l}\frac{\partial g_{i\beta}}{\partial x_\alpha} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\frac{\partial g_{l\beta}}{\partial x_\alpha} = \frac{\partial \gamma_{\alpha\beta}}{\partial x_l}\begin{bmatrix} \alpha & \beta \\ & i \end{bmatrix} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\begin{bmatrix} \alpha & \beta \\ & l \end{bmatrix} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\frac{\partial g_{\alpha\beta}}{\partial x_l} \tag{557}$$

Combining the expressions (547), (557), and (553)–(554), one arrives at

280 This is the first time in the notebook that Einstein introduced the Christoffel symbols to replace ordinary derivatives of the metric. Up to now the calculations in the notebook always proceeded by expanding the Christoffel symbols and by rewriting the tensor expressions in terms of simple derivatives of the metric instead of using the compact Christoffel symbols. Why Einstein proceeded the other way around here is not clear, but it is tempting to speculate that it reflects a first inkling on Einstein's part of the importance of the Christoffel symbols in his gravitational theory.

$$-2T^x_{il} = \gamma_{\alpha\beta}\frac{\partial^2 g_{il}}{\partial x_\alpha \partial x_\beta} - \frac{1}{2}\gamma_{\alpha k}\gamma_{\beta\lambda}\left(\frac{\partial g_{i\alpha}}{\partial x_\beta} - \frac{\partial g_{i\beta}}{\partial x_\alpha}\right)\left(\frac{\partial g_{lk}}{\partial x_\lambda} - \frac{\partial g_{l\lambda}}{\partial x_k}\right)$$
$$\frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\begin{bmatrix}\alpha & \beta \\ & l\end{bmatrix} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_l}\begin{bmatrix}\alpha & \beta \\ & i\end{bmatrix} + \frac{3}{2}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\frac{\partial g_{\alpha\beta}}{\partial x_l} \tag{558}$$

for (minus 2 times) the reduced November tensor (i.e., the November tensor in unimodular coordinates satisfying the Hertz restriction). In the corresponding expression at the bottom of p. 22R in the notebook, the second line contains some errors: above the summation sign in front of the first two terms, Einstein added a factor $1/2$; and the third term has $1/4$ instead of $3/2$.

22L
5.5.3 *Non-autonomous Transformations Leaving the Hertz Restriction Invariant (22L)*

The field equations based on the reduced November tensor (see equation (558)) will be covariant under those unimodular transformations that preserve the Hertz restriction. On the top half of p. 22L, Einstein derived the condition for non-autonomous unimodular transformations leaving the Hertz restriction, and thus the corresponding field equations, invariant.[281] Note that this calculation precedes the calculations showing that the Hertz restriction can be used to eliminate unwanted second-order derivative terms from the November tensor on the bottom half of p. 22L and on p. 22R.

At the top of p. 22L, Einstein began by writing the Hertz restriction in primed coordinates

$$\sum \frac{\partial \gamma'_{\mu\nu}}{\partial x'_\nu} = 0\,. \tag{559}$$

Next to it, he wrote the determinant condition on the transformation matrix $p_{\mu\nu}$ for a unimodular transformation

$$|p_{\mu\nu}| = 1\,. \tag{560}$$

These two equations can be seen as a cryptic statement of the question being addressed on this page: given a metric field satisfying the Hertz restriction in some (unprimed) coordinate system, what are the unimodular coordinate transformations such that the Hertz restriction will be satisfied in the new (primed) coordinate system as well? The answer to this question takes the form of an equation for the transformation matrix $p_{\mu\nu}$ and its inverse $\pi_{\mu\nu}$. This equation involves the components of the metric field in the unprimed system. The transformations preserving the Hertz restriction, the solutions of this equation, will thus depend on which metric field one starts from in the

281 Earlier in the notebook and in a different context (see p. 10L ff.), Einstein had already investigated this question for infinitesimal transformations (see sec. 4.5.1). The calculation on p. 22L closely follows the one on p. 10L.

unprimed system. In other words, these transformations are examples of “non-autonomous transformations.”[282]

To find the equation for these non-autonomous transformations, Einstein transformed equation (559) from x'_μ- to x_μ-coordinates[283]

$$\sum \pi_{\nu i} \frac{\partial}{\partial x_i} \{ p_{\mu\alpha} p_{\nu\beta} \gamma_{\alpha\beta} \} = 0 . \tag{561}$$

Using the relation $\pi_{\nu i} p_{\nu\beta} = \delta_{i\beta}$, he rewrote the left-hand side as

$$p_{\mu\alpha} \frac{\partial \gamma_{\alpha i}}{\partial x_i} + \gamma_{\alpha\beta} \pi_{\nu i} \frac{\partial p_{\mu\alpha} p_{\nu\beta}}{\partial x_i} . \tag{562}$$

The first term vanishes on account of the assumption that forms the starting point of this calculation, viz. that the metric field satisfies the Hertz restriction in the unprimed coordinates. Einstein rewrote the second term as

$$\sum \gamma_{\alpha\beta} \pi_{\underline{\nu} i} \left\{ p_{\mu\alpha} \frac{\partial p_{\nu\beta}}{\partial x_i} + p_{\underline{\nu}\beta} \frac{\partial p_{\mu\alpha}}{\partial x_i} \right\} , \tag{563}$$

and then, on the next line, as

$$\sum \gamma_{\alpha i} \frac{\partial p_{\mu\alpha}}{\partial x_i} + \sum \gamma_{\alpha\beta} \pi_{\nu i} p_{\mu\alpha} \frac{\partial p_{\nu\beta}}{\partial x_i} . \tag{564}$$

The first term in this last expression was familiar to Einstein from the analogous calculation on p. 10L (cf. the second term in equation (234)), which may be why Einstein underlined it. On p. 10L he had found that the vanishing of the first term is the condition for *infinitesimal* unimodular non-autonomous transformations preserving the Hertz restriction. In the infinitesimal case, the second term vanishes (see footnote 148). This is probably why, on p. 22L, he wrote next to the second term in expression (564): “vanishes if funct[ional] det[erminant] = 1.” (“verschwindet, wenn Funkt. Det. = 1.”). For finite transformations, however, this term does not vanish, as Einstein presumably realized, for he included it in an attempt to further simplify the expression in expression (564) on the next line.

The first term in expression (564) can be rewritten as

$$\frac{\partial}{\partial x_i} (\gamma_{\alpha i} p_{\mu\alpha}) - p_{\mu\alpha} \frac{\partial \gamma_{\alpha i}}{\partial x_i} ; \tag{565}$$

the second term as

282 See the discussion in sec. 4.3. Other examples of conditions for “non-autonomous transformations” can be found on pp. 7L, 8R, 10L, and 23R.

283 The transformation matrices are defined as $p_{\alpha\beta} = \partial x'_\alpha / \partial x_\beta$ and $\pi_{\alpha\beta} = \partial x_\beta / \partial x'_\alpha$ (see equations (119)–(120)).

$$\frac{\partial}{\partial x_i}(\gamma_{\alpha\beta}\pi_{\nu i}p_{\mu\alpha}p_{\nu\beta}) - \frac{\partial}{\partial x_i}(\gamma_{\alpha\beta}\pi_{\nu i}p_{\mu\alpha})p_{\nu\beta}\,, \tag{566}$$

which in turn can be rewritten as

$$\frac{\partial}{\partial x_i}(\gamma_{\alpha i}p_{\mu\alpha}) - \gamma_{\alpha\beta}p_{\mu\alpha}p_{\nu\beta}\frac{\partial\pi_{\nu i}}{\partial x_i} - \frac{\partial}{\partial x_i}(\gamma_{\alpha i}p_{\mu\alpha})\,. \tag{567}$$

Adding expressions (565) and (567), one arrives at the expression given on the next line in the notebook:

$$\sum\frac{\partial}{\partial x_i}(\gamma_{\alpha i}p_{\mu\alpha}) - p_{\mu\alpha}\frac{\partial\gamma_{\alpha i}}{\partial x_i} + \frac{\partial}{\partial x_i}(\gamma_{\alpha i}p_{\mu\alpha}) - \gamma_{\alpha\beta}p_{\mu\alpha}p_{\nu\beta}\frac{\partial\pi_{\nu i}}{\partial x_i} - \frac{\partial}{\partial x_i}(\gamma_{\alpha i}p_{\mu\alpha})\,. \tag{568}$$

As Einstein noted, the second term vanishes (because of the Hertz restriction) and the third term cancels with the fifth. What is left is an expression that has basically the same structure as expression (564). On the next line, Einstein reverted to the latter. The upshot then was that the matrix $p_{\mu\nu}$ (and its inverse $\pi_{\mu\nu}$) for some unimodular coordinate transformation from coordinates x_μ to x'_μ must satisfy

$$\gamma_{\alpha i}\frac{\partial p_{\mu\alpha}}{\partial x_i} + \gamma_{\alpha\beta}\pi_{\nu i}p_{\mu\alpha}\frac{\partial p_{\nu\beta}}{\partial x_i} = 0 \tag{569}$$

to ensure that a metric field that satisfies the Hertz restriction in the x_μ-coordinates satisfies the Hertz restriction in the x'_μ-coordinates as well.

This is a rather complex condition. Examining the simpler version for infinitesimal transformations in which case the second term in equation (569) vanishes automatically, Einstein had found that it does not allow a transformation to uniformly accelerated frames of reference in the important special case of Minkowski spacetime (see pp. 10L–11L).[284] He nonetheless continued to use the Hertz restriction (see p. 23L).

23L–R

5.5.4 *Extracting Field Equations from the November Tensor Using the ϑ-Restriction (23L–R)*

At the bottom of p. 22R, Einstein had arrived at a candidate for the left-hand side of the field equations extracted from the November tensor by imposing the Hertz restriction (see eq. (558)). This candidate contains numerous terms with products of first-order derivatives of the metric. Most of these terms come from the product of Chri-
23L stoffel symbols in the second term of the November tensor (544). On p. 23L, Einstein returned to the expression for the November tensor in terms of Christoffel symbols and added a new coordinate restriction to the Hertz condition with which he could eliminate two of the three first-order derivative terms in every Christoffel symbol. In this way he could eliminate most of terms quadratic in first-order derivative terms

284 On p. 11L, Einstein had convinced himself that the Hertz restriction does allow rotations. Rotation, however, is also ruled out by the Hertz restriction (see sec. 4.5.2, especially equations (306)–(310) and notes 163–164)

found at the bottom of p. 22R. This additional coordinate restriction limits the range of allowed coordinate transformations to those unimodular transformations under which a quantity denoted by $\vartheta_{ik\lambda}$, which is essentially the fully symmetrized version of $g_{ik\lambda}$, transforms as a tensor. We call this quantity the "ϑ-expression," the unimodular transformations under which it transforms as a tensor "ϑ-transformations," and the restriction to such transformations the "ϑ-restriction."[285] Einstein's basic strategy on p. 23L was to subtract terms from the November tensor that by themselves transform as tensors under ϑ-transformations. What was left served as Einstein's new candidate for the left-hand side of the field equations. In the course of the calculations on p. 23L, Einstein came to realize that with the ϑ-restriction he did not need the Hertz restriction anymore to eliminate terms with unwanted second-order derivatives of the metric. The ϑ-restriction took care of those terms all by itself. Einstein therefore abandoned the Hertz restriction and focused on the ϑ-restriction.

On the third line of p. 23L, separated from the first two[286] by a horizontal line, Einstein stated the assumption that forms the starting point of the argument on this page, viz. that the quantity[287]

$$\frac{1}{2}\left(\frac{\partial g_{ik}}{\partial x_\lambda}+\frac{\partial g_{k\lambda}}{\partial x_i}+\frac{\partial g_{\lambda i}}{\partial x_k}\right) \tag{570}$$

"be a tensor $\vartheta_{ik\lambda}$" ("sei Tensor $\vartheta_{ik\lambda}$"). In other words, Einstein was interested in transformations under which this ϑ-expression would transform according to the transformation law for a fully covariant third-rank tensor. The next line explicitly gives this transformation law[288]

$$\vartheta'_{ikl} = \sum_{\alpha\beta\gamma}\vartheta_{\alpha\beta\gamma}\frac{\partial x_\alpha}{\partial x'_i}\frac{\partial x_\beta}{\partial x'_k}\frac{\partial x_\gamma}{\partial x'_l}. \tag{571}$$

Einstein used the ϑ-expression to rewrite the Christoffel symbols of the first and second kind as

---

285 The Hertz expression, it turns out, transforms as a vector under ϑ-transformations (see the discussion following eq. (585)).

286 At the top of p. 23L, Einstein began an explicit transformation of the ordinary derivative of the metric: $\frac{\partial g'_{ik}}{\partial x_\lambda} = \pi_{\lambda\alpha}\frac{\partial}{\partial x_\alpha}(\pi_{i\sigma}\pi_{k\tau}g_{\sigma\tau})$ (x_λ on the left-hand side should be x'_λ). The calculation breaks off almost immediately but is taken up again on the facing page, p. 23R, in order to find the condition for "non-autonomous transformations" under which the ϑ-expression is invariant (see sec. 5.5.5).

287 In the notebook, Einstein wrote "-2" above the last plus sign in expression (570). Above many of the plus and minus signs in subsequent expressions on this page the opposite has been written (and, in some cases, has been deleted again). These sign changes are related to Einstein's consideration on p. 25R of a variant of the ϑ-restriction, which we shall call the $\hat{\vartheta}$-restriction (see sec. 5.6.3 for discussion).

288 Note that Einstein deviates from the notation $p_{\alpha\beta}$ and $\pi_{\alpha\beta}$ typically used in the notebook for the transformation matrices $\partial x'_\alpha/\partial x_\beta$ and $\partial x_\beta/\partial x'_\alpha$.

$$\begin{bmatrix} i & l \\ & k \end{bmatrix} = \vartheta_{ilk} - \frac{\partial g_{il}}{\partial x_k} \tag{572}$$

and

$$\begin{Bmatrix} i & l \\ & k \end{Bmatrix} = \gamma_{k\alpha}\left(\vartheta_{il\alpha} - \frac{\partial g_{il}}{\partial x_\alpha}\right), \tag{573}$$

respectively. He substituted the latter expression into the November tensor (cf. equation (544)):

$$T_{il}^{x} = \frac{\partial}{\partial x_k}\left(\gamma_{k\alpha}\left(\vartheta_{il\alpha} - \frac{\partial g_{il}}{\partial x_\alpha}\right)\right) - \gamma_{\lambda\alpha}\gamma_{k\beta}\left(\vartheta_{ik\alpha} - \frac{\partial g_{ik}}{\partial x_\alpha}\right)\left(\vartheta_{l\lambda\beta} - \frac{\partial g_{l\lambda}}{\partial x_\beta}\right). \tag{574}$$

The rationale behind the ϑ-restriction now becomes clear. Any (combination of) term(s) in equation (574) that transforms as a tensor under ϑ-transformations can be subtracted from the November tensor and what is left will still transform as a tensor under ϑ-transformations. Originally, Einstein probably only meant to eliminate terms quadratic in first-order derivatives of the metric from the November tensor. He initially expected that the Hertz restriction would still be needed to eliminate terms with unwanted second-order derivatives. On the next line he explicitly stated the requirement that the Hertz expression,

$$\sum \frac{\partial \gamma_{k\alpha}}{\partial x_k}, \tag{575}$$

"be $= 0$" ("sei $= 0$"). He subsequently added the clause "is not necessary" ("ist nicht nötig").[289]

The end result of the calculation on p. 23L is:

$$\sum \frac{\partial}{\partial x_k}\left(\gamma_{k\alpha}\frac{\partial g_{il}}{\partial x_\alpha}\right) + \sum \gamma_{\rho\alpha}\gamma_{k\beta}\frac{\partial g_{ik}}{\partial x_\alpha}\frac{\partial g_{l\rho}}{\partial x_\beta}. \tag{576}$$

It turns out, as Einstein himself came to recognize, that there is a short-cut to get from eq. (574), which gives the November tensor in terms of the ϑ-expression, to eq. (576). If one sets $\vartheta_{ik\lambda} = 0$ in eq. (574), which amounts to replacing the Christoffel symbols by the truncated Christoffel symbols $-\gamma_{k\alpha}(\partial g_{il}/\partial x_\alpha)$ (see eq. (573)), one arrives at:

289 The evidence for our assumption that this clause was indeed added later is twofold. First, the awkwardness of the syntax of the sentence "$\sum \partial\gamma_{k\alpha}/\partial x_k$ *be* $= 0$ *is* not necessary" (our emphasis) disappears under the assumption. Second, Einstein uses the Hertz restriction in the equation immediately following this sentence.

$$-\frac{\partial}{\partial x_k}\left(\gamma_{k\alpha}\frac{\partial g_{il}}{\partial x_\alpha}\right)-\gamma_{\lambda\alpha}\gamma_{k\beta}\frac{\partial g_{ik}}{\partial x_\alpha}\frac{\partial g_{l\lambda}}{\partial x_\beta}, \tag{577}$$

which is just (minus) Einstein's expression (576).[290] This shows that the ϑ-restriction takes care of the terms with unwanted second-order derivatives in the November tensor as well. Once Einstein recognized this, he presumably added the clause "is not necessary" to his statement (575) of the Hertz restriction and made the necessary corrections to the derivation of eq. (576).

In the original derivation, Einstein used the Hertz restriction in the very first step. He introduced the quantity

$$T_{il}^{xx} = -\gamma_{k\alpha}\frac{\partial^2 g_{il}}{\partial x_k \partial x_\alpha}+\gamma_{k\alpha}\frac{\partial\vartheta_{il\alpha}}{\partial x_k}-\gamma_{\lambda\alpha}\gamma_{k\beta}\frac{\partial g_{ik}}{\partial x_\alpha}\frac{\partial g_{l\lambda}}{\partial x_\beta}+\gamma_{\lambda\alpha}\gamma_{k\beta}\left(\vartheta_{ik\alpha}\frac{\partial g_{l\lambda}}{\partial x_\beta}+\vartheta_{l\lambda\beta}\frac{\partial g_{ik}}{\partial x_\alpha}\right), \tag{578}$$

and remarked that this "is also a tensor" ("ist ebenfalls ein Tensor"). What he meant no doubt was: "transforms as a tensor under ϑ-transformations." The new tensor T_{il}^{xx} differs from T_{il}^{x} by two terms: $\gamma_{\lambda\alpha}\gamma_{k\beta}\vartheta_{ik\alpha}\vartheta_{l\lambda\beta}$ and

$$\frac{\partial\gamma_{k\alpha}}{\partial x_k}\left(-\frac{\partial g_{il}}{\partial x_\alpha}+\vartheta_{il\alpha}\right). \tag{579}$$

290 It is tempting to speculate that these considerations are related to a remark Einstein made in 1915 when he published field equations based on the November tensor. Einstein wrote that earlier he had looked upon the quantities "$\frac{1}{2}\sum_\mu g^{\tau\mu}\frac{\partial g_{\mu\nu}}{\partial x_\nu}$ as the natural expression for the components of the gravitational field although in the light of the formulae of the differential calculus, it is more natural to introduce the Christoffel symbols $\left\{\begin{matrix}\nu\sigma\\ \tau\end{matrix}\right\}$ instead of those quantities. This was a fateful prejudice." ("… als den natürlichen Ausdruck für die Komponenten des Gravitationsfeldes, obwohl es im Hinblick auf die Formeln des absoluten Differentialkalküls näher liegt, die Christoffelschen Symbole … statt jener Größen einzuführen. Dies war ein verhängnisvolles Vorurteil." Einstein 1915a, 782). This point is also emphasized in Einstein's letter to Arnold Sommerfeld of 28 November 1915: "What gave me the key to this solution [the Einstein field equations in their final form] was the insight that not $\sum_\mu g^{l\alpha}\frac{\partial g_{ai}}{\partial x_m}$ but the related Christoffel symbols $\left\{\begin{matrix}\nu\sigma\\ \tau\end{matrix}\right\}$ should be looked upon as the natural expression for the "components" of the gravitational field" ("Den Schlüssel zu dieser Lösung lieferte mir die Erkenntnis, dass nicht …sondern die damit verwandten Christoffel'schen Symbole … als natürlichen Ausdruck für die "Komponente" des Gravitationsfeld anzusehen ist." CPAE 8, Doc. 153). For further discussion, see sec. 5 of "Untying the Knot …" (in this volume).

The first one transforms as a tensor under ϑ-transformations itself. This means that T_{il}^{x} minus this term will still be a tensor under ϑ-transformations. The second one, expression (579), vanishes on account of the Hertz restriction. When Einstein subsequently retracted the Hertz condition, he indicated that $\gamma_{k\alpha}$ should be included within the scope of the derivative $\partial/\partial x_k$ in the first term on the right-hand side of equation (578). He neglected to do so for the second term. This may simply have been an oversight but the fragmentary calculation at the top of p. 23R suggests that Einstein may have realized that $(\partial\gamma_{k\alpha}/\partial x_k)\vartheta_{il\alpha}$ itself transforms as a tensor under ϑ-transformations. So this term can also be subtracted from T_{il}^{x} and the result will still be a tensor under ϑ-transformations.

On the next line, Einstein wrote down the covariant derivative of the ϑ-expression contracted with $\gamma_{k\alpha}$

$$\gamma_{k\alpha}\frac{\partial\vartheta_{il\alpha}}{\partial x_k} - \sum\left(\begin{Bmatrix} k & i \\ & \rho \end{Bmatrix}\vartheta_{\rho l\alpha} + \begin{Bmatrix} k & l \\ & \rho \end{Bmatrix}\vartheta_{i\rho\alpha} + \begin{Bmatrix} k & \alpha \\ & \rho \end{Bmatrix}\vartheta_{il\rho}\right)\gamma_{k\alpha}\,. \tag{580}$$

This expression will also transform as a tensor under ϑ-transformations, as Einstein noted: “Likewise [a tensor]” (“Ebenso”). He substituted equation (573) for the Christoffel symbols into expression (580) and subtracted terms with products of the ϑ-expression and the metric which are themselves tensors under ϑ-transformations. In this way, he arrived at

$$\gamma_{k\alpha}\frac{\partial\vartheta_{il\alpha}}{\partial x_k} + \sum\gamma_{k\alpha}\gamma_{\rho\beta}\left(\frac{\partial g_{ik}}{\partial x_\beta}\vartheta_{\rho\lambda\alpha} + \frac{\partial g_{kl}}{\partial x_\beta}\vartheta_{i\rho\alpha} + \frac{\partial g_{k\alpha}}{\partial x_\beta}\vartheta_{il\rho}\right), \tag{581}$$

and noted that this would “therefore also” (“also auch”) be “a tensor” (“ein Tensor”) under ϑ-transformations.

In modern notation, the last term in expression (581) can be rewritten as

$$g^{k\alpha}g^{\rho\beta}g_{k\alpha,\beta}\vartheta_{il\rho} = g^{\rho\beta}(\log{-g})_{,\beta}\vartheta_{il\rho}\,. \tag{582}$$

The determinant of the metric transforms as a scalar under all unimodular transformation and hence under ϑ-transformations. The derivative of its logarithm therefore transforms as a vector under ϑ-transformations.[291] As Einstein noted, the last term in expression (581) is therefore “itself a tensor” (“an sich ein Tensor”) under ϑ-transformations. It follows that the remaining three terms in expression (581) also form a tensor under ϑ-transformations. Precisely these three terms occur in the expression for T_{il}^{xx}, as Einstein verified by underlining them, both in equation (578) and in expression (581), and by relabeling some of the indices in equation (578). After “subtraction” (“Subtraktion”) of these three terms from the right-hand side of equation (578)

291 On p. 22R, it was explicitly noted that this quantity transforms as a vector under unimodular transformations.

and changing the minus signs in front of the two remaining terms to plus signs, he arrived at

$$\sum \gamma_{k\alpha} \frac{\partial^2 g_{il}}{\partial x_k \partial x_\alpha} + \sum \gamma_{\rho\alpha} \gamma_{k\beta} \frac{\partial g_{ik}}{\partial x_\alpha} \frac{\partial g_{l\rho}}{\partial x_\beta} \tag{583}$$

and noted that this still "is a tensor" ("ist Tensor") under ϑ-transformations. The combination of the Hertz restriction and the ϑ-restriction thus allowed Einstein to extract from the November tensor a candidate for the left-hand side of the field equations that has a remarkably simple form. It is the sum of a core-operator term and a term with a product of first-order derivatives.

It is probably at this point that Einstein noticed the short-cut from eq. (574) to expression (576). Expression (583) only differs from the latter in that $\gamma_{k\alpha}$ in the first term is not included within the scope of $\partial / \partial x_k$. Einstein marked this term to indicate that $\gamma_{k\alpha}$ should be included within the scope of $\partial / \partial x_k$. He did the same with the first term on the right-hand side of eq. (578), which is the starting point of the argument that got him from the November tensor to the new candidate for the left-hand side of the field equations (583). This amounts to rescinding the Hertz restriction, which explains why Einstein wrote "is not necessary" next to statement (575) of this restriction. The unwanted second-order derivatives that he had eliminated on p. 22R by imposing the Hertz restriction were absorbed into expression (580) for the covariant derivative of the ϑ-expression and subtracted from the November tensor. By including $\gamma_{k\alpha}$ within the scope of $\partial / \partial x_k$ in eq. (583), Einstein had thus extracted the following candidate for the left-hand side of the field equations by imposing the ϑ-restriction alone:

$$\sum \frac{\partial}{\partial x_k}\left(\gamma_{k\alpha} \frac{\partial g_{il}}{\partial x_\alpha}\right) + \sum \gamma_{\rho\alpha} \gamma_{k\beta} \frac{\partial g_{ik}}{\partial x_\alpha} \frac{\partial g_{l\rho}}{\partial x_\beta}\,. \tag{584}$$

Without the Hertz restriction, expression (584) inherits one more term involving the ϑ-expression from eq. (574), namely $(\partial \gamma_{k\alpha} / \partial x_k)\ \vartheta_{il\alpha}$ (cf. the discussion following expression (579)). It turns out, however, that this term is a tensor under ϑ-transformations itself, so that expression (584) without this term is still a tensor under ϑ-transformations.[292]

That $\partial \gamma_{k\alpha} / \partial x_k$ —and consequently $(\partial \gamma_{k\alpha} / \partial x_k)\ \vartheta_{il\alpha}$ —are indeed tensors under ϑ-transformations can be seen as follows. Consider the contraction of g^{ik} and ϑ_{ikl}:

292 Note that this correction term would only give rise to terms with products of first-order derivatives of the metric anyway, and hence would not affect the result that the ϑ-restriction can be used to eliminate unwanted second-order derivative terms.

$$
\begin{aligned}
g^{ik}\vartheta_{ikl} &= \frac{1}{2}g^{ik}(g_{ik,\,l}+g_{kl,\,i}+g_{li,\,k}) \\
&= g^{ik}\left(\frac{1}{2}g_{ik,l}+g_{kl,\,i}\right) \\
&= \frac{1}{2}(\log-g)_{,l}-g^{ik}{}_{,i}g_{kl}.
\end{aligned} \tag{585}
$$

Hence, $g^{ik}{}_{,i}g_{kl}$ is the difference between two expressions, $g^{ik}\vartheta_{ikl}$ and $\frac{1}{2}(\log-g)_{,l}$, that are both tensors under ϑ-transformations. It is therefore a tensor under ϑ-transformations itself. It follows that $g^{ik}{}_{,i}$ is a tensor under ϑ-transformations as well, which is the result that we wanted to prove.

Einstein may in fact have gone through a similar calculation. This is suggested by
23R the calculation at the top of p. 23R, where he wrote down the right-hand side of the first line of equation (585),

$$
\gamma_{ik}\left(\frac{\partial g_{ik}}{\partial x_l}+\frac{\partial g_{kl}}{\partial x_i}+\frac{\partial g_{li}}{\partial x_k}\right), \tag{586}
$$

as well as the terms $\sum\gamma_{ik}\frac{\partial g_{li}}{\partial x_k}$, $-\sum g_{li}\frac{\partial\gamma_{ik}}{\partial x_k}$, and $\sum\frac{\partial\gamma_{ik}}{\partial x_k}$, which are all involved in the calculation given in equation (585).[293]

23L To conclude our discussion of p. 23L, we want to emphasize that the calculation on this page nicely illustrates the usage of coordinate restrictions as opposed to coordinate conditions in the notebook. Thinking in terms of coordinate conditions, one would look upon expression (584) as representing the left-hand side of some candidate field equations of broad covariance in coordinates satisfying the ϑ-restriction chosen to facilitate comparison with Newtonian theory. It is not at all clear, however, whether expression (584) actually is the representation of some tensor of broader covariance in the class of coordinate systems determined by the ϑ-restriction. It can be seen as the November tensor in coordinates such that the ϑ-expression vanishes, as follows from the short-cut from equation (574) to equation (576). But the ϑ-restriction only requires that the ϑ-expression transform as a tensor, not that it vanish.

Given that Einstein conceived of the restriction to ϑ-transformations as an essential feature of the theory and not as a feature of a particular representation of the theory, it was of no real interest to him to find the tensor of broader covariance corresponding to expression (584). The relation between expression (584) and tensors of broader covariance, such as the November tensor or the Ricci tensor, is important only in that it allowed Einstein to construct field equations that are invariant under a precisely defined class of coordinate transformations. It is important to keep in mind

293 Another possibility is that this calculation was related to the investigation of a modified ϑ-expression on p. 43LA (cf. footnote 313).

that for Einstein this construction gave field equations, or candidate field equations, in their most general form, not just an expression of field equations of broader covariance in some restricted class of coordinate systems.

5.5.5 *Non-autonomous Transformations Leaving the ϑ-Expression Invariant (23R)* 23R

With the exception of the first few lines, which we tentatively identified as a fragmentary version of the calculation given in equation (585), the purpose of the calculations on p. 23R is to derive the condition for infinitesimal "non-autonomous transformations" leaving the ϑ-expression and thereby the field equations based on expression (584) invariant. As in the case of the corresponding condition for the Hertz restriction (see p. 22L and the discussion in sec. 5.5.3), this condition takes the form of an equation for the transformation matrices $p_{\mu\nu}$ and $\pi_{\mu\nu}$ involving the components of the metric field in the original coordinate system.[294]

After drawing a horizontal line under the fragmentary calculation at the top of the page, Einstein first derived the condition for non-autonomous transformations under which derivatives of the metric transform as tensors.[295] Adding three such equations with cyclically permuted indices, Einstein then derived the corresponding condition for the ϑ-expression.

He began by writing down how derivatives of the metric transform under an arbitrary transformation from unprimed to primed coordinates:[296]

$$\left(\frac{\partial g_{ik}}{\partial x_l}\right)' = \pi_{l\lambda}\frac{\partial}{\partial x_\lambda}(\pi_{i\iota}\pi_{k\kappa}g_{\iota\kappa}) . \tag{587}$$

If $(\partial g_{ik}/\partial x_l)'$ is transformed back to the unprimed system on the assumption that the coordinate transformation relating the two coordinate systems is no longer arbitrary but one under which derivatives of the metric actually transform as tensors, one finds

$$\begin{aligned}\frac{\partial g_{\rho\sigma}}{\partial x_\tau} &= p_{i\rho}p_{k\sigma}p_{l\tau}\frac{\partial g'_{ik}}{\partial x'_l} \\ &= p_{i\rho}p_{k\sigma}p_{l\tau}\pi_{l\lambda}\frac{\partial}{\partial x_\lambda}(\pi_{i\iota}\pi_{k\kappa}g_{\iota\kappa}),\end{aligned} \tag{588}$$

where in the second step equation (587) was used, which is valid for arbitrary transformations. Einstein's own description of the transition from equation (587) to the

294 Although Einstein presumably was interested only in unimodular transformations preserving the ϑ-expression, he did not explicitly impose the condition $|p_{\mu\nu}| = |\pi_{\mu\nu}| = 1$ on the determinant of the transformation matrices, as he had on p. 22L in the case of the Hertz restriction (see equation (560)).

295 This condition can also be found on p. 8R (see equation (169)).

296 The transformation matrices are defined as $p_{\alpha\beta} = \partial x_\alpha'/\partial x_\beta$ and $\pi_{\alpha\beta} = \partial x_\beta/\partial x_\alpha'$ (see equations (119)–(120)). Essentially the same equation had been written down on top of p. 23L, which suggests that Einstein began to examine the transformation properties of the ϑ-expression before he extracted eq (583) from the November tensor with the help of the ϑ-restriction.

expression on second line of equation (588) is more cryptic: "transformed back $p_{i\rho}$ $p_{k\sigma}$ $p_{l\tau}$" ("zurück transformiert $p_{i\rho}$ $p_{k\sigma}$ $p_{l\tau}$").

On the next line, following the comment "in detail" ("ausführlich"), the expression on the second line of equation (588) is expanded. The relation $p_{ij}\pi_{ik} = \delta_{jk}$ is used to simplify the resulting three terms

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} + p_{i\rho}\frac{\partial \pi_{i\iota}}{\partial x_\tau}g_{\iota\sigma} + p_{k\sigma}\frac{\partial \pi_{k\kappa}}{\partial x_\tau}g_{\rho\kappa} \quad . \tag{589}$$

"For infinitesimal transformations" ("Für infinitesimale Transformationen"), one can replace p_{ij} in the last two terms by δ_{ij}. If in addition the summation indices are relabeled, expression (589) reduces to

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} + \frac{\partial \pi_{\rho\alpha}}{\partial x_\tau}g_{\sigma\alpha} + \frac{\partial \pi_{\sigma\alpha}}{\partial x_\tau}g_{\rho\alpha} \,. \tag{590}$$

Substituting this result into equation (588), one arrives at

$$\frac{\partial g_{\rho\sigma}}{\partial x_\tau} = \frac{\partial g_{\rho\sigma}}{\partial x_\tau} + \frac{\partial \pi_{\rho\alpha}}{\partial x_\tau}g_{\sigma\alpha} + \frac{\partial \pi_{\sigma\alpha}}{\partial x_\tau}g_{\rho\alpha} \,. \tag{591}$$

It follows that derivatives of the metric transform as tensors under infinitesimal non-autonomous transformations if and only if the last two terms in equation (591) vanish, i.e., if and only if the matrix π_{ij} for such a transformation satisfies the equation

$$\frac{\partial \pi_{\rho\alpha}}{\partial x_\tau}g_{\sigma\alpha} + \frac{\partial \pi_{\sigma\alpha}}{\partial x_\tau}g_{\rho\alpha} = 0 \tag{592}$$

for the metric field under consideration.

Since $\vartheta_{\rho\sigma\tau}$ is essentially the symmetrized version of $\partial g_{\rho\sigma}/\partial x_\tau$, one can derive the condition for infinitesimal non-autonomous transformations under which $\vartheta_{\rho\sigma\tau}$ transforms as a tensor by adding equation (591) and the two equations obtained from it through cyclic permutation of its indices,

$$\begin{aligned} \frac{\partial g_{\sigma\tau}}{\partial x_\rho} &= \frac{\partial g_{\sigma\tau}}{\partial x_\rho} + \frac{\partial \pi_{\sigma\alpha}}{\partial x_\rho}g_{\tau\alpha} + \frac{\partial \pi_{\tau\alpha}}{\partial x_\rho}g_{\sigma\alpha} \\ \frac{\partial g_{\tau\rho}}{\partial x_\sigma} &= \frac{\partial g_{\tau\rho}}{\partial x_\sigma} + \frac{\partial \pi_{\tau\alpha}}{\partial x_\sigma}g_{\rho\alpha} + \frac{\partial \pi_{\rho\alpha}}{\partial x_\sigma}g_{\tau\alpha} . \end{aligned} \tag{593}$$

As Einstein put it: "Through addition [of the various terms coming] from all three terms [of $\vartheta_{\rho\sigma\tau}$] one obtains" ("Durch Addition aus allen drei Termen erhält man")

$$\vartheta_{\rho\sigma\tau} = \vartheta_{\rho\sigma\tau} + \frac{1}{2}\left[g_{\rho\alpha}\left(\frac{\partial\pi_{\tau\alpha}}{\partial x_\sigma} + \frac{\partial\pi_{\sigma\alpha}}{\partial x_\tau}\right) + g_{\sigma\alpha}\left(\frac{\partial\pi_{\rho\alpha}}{\partial x_\tau} + \frac{\partial\pi_{\tau\alpha}}{\partial x_\rho}\right) + g_{\tau\alpha}\left(\frac{\partial\pi_{\sigma\alpha}}{\partial x_\rho} + \frac{\partial\pi_{\rho\alpha}}{\partial x_\sigma}\right)\right] \tag{594}$$

Einstein only wrote down the right-hand side of this equation, left out the factor $1/2$ in front of the expression in square brackets, and only indicated the last two terms in this expression by a dot. For infinitesimal transformations one can use that[297]

$$\frac{\partial\pi_{\sigma\alpha}}{\partial x_\tau} = \frac{\partial\pi_{\tau\alpha}}{\partial x_\sigma}, \tag{595}$$

in which case the right-hand side of equation (594) reduces to

$$\vartheta_{\rho\sigma\tau} + \left[g_{\rho\alpha}\frac{\partial\pi_{\sigma\alpha}}{\partial x_\tau} + g_{\sigma\alpha}\frac{\partial\pi_{\tau\alpha}}{\partial x_\rho} + g_{\tau\alpha}\frac{\partial\pi_{\rho\alpha}}{\partial x_\sigma}\right]. \tag{596}$$

In the notebook, because of the factor $1/2$ omitted in equation (594), there is an extra factor 2 in front of the expression in square brackets.

It follows that the condition for infinitesimal non-autonomous transformations under which the ϑ-expression transforms as a tensor is that "the [expression in square] brackets [in expression (596)] should vanish for all combinations of $\rho\sigma\tau$" ("Die Klammer soll für alle Kombinationen von $\rho\sigma\tau$ verschwinden"). In other words, the matrix π_{ij} for (the inverse of) such transformations should satisfy the equation

$$g_{\rho\alpha}\frac{\partial\pi_{\sigma\alpha}}{\partial x_\tau} + g_{\sigma\alpha}\frac{\partial\pi_{\tau\alpha}}{\partial x_\rho} + g_{\tau\alpha}\frac{\partial\pi_{\rho\alpha}}{\partial x_\sigma} = 0 \tag{597}$$

for the metric field under consideration. The field equations extracted from the November tensor with the help of the ϑ-restriction will be invariant under all (non-autonomous) coordinate transformations that satisfy this condition.

5.5.6 *Solving the ϑ-Equation (42L–R)* 42L–R

No attempt is made in the notebook to find solutions of the condition for infinitesimal non-autonomous ϑ-transformations given in equation (597). Einstein adopted a

297 For infinitesimal transformations, one has $\partial\pi_{\sigma\alpha}/\partial x_\tau = -\partial p_{\alpha\sigma}/\partial x_\tau$. Using the definition of $p_{\alpha\sigma}$ and changing the order of differentiation, one can then write:

$$\frac{\partial\pi_{\sigma\alpha}}{\partial x_\tau} = -\frac{\partial p_{\alpha\sigma}}{\partial x_\tau} = -\frac{\partial}{\partial x_\tau}\left(\frac{\partial x_\alpha'}{\partial x_\sigma}\right) = -\frac{\partial}{\partial x_\sigma}\left(\frac{\partial x_\alpha'}{\partial x_\tau}\right) = -\frac{\partial p_{\alpha\tau}}{\partial x_\sigma} = \frac{\partial\pi_{\tau\alpha}}{\partial x_\sigma}.$$

Earlier in the notebook, Einstein had already (implicitly) used a very similar relation (see p. 10L and footnote 148).

somewhat different approach to get a sense of the range of transformations allowed by the ϑ-restriction. It is clear upon inspection of its definition (570) that the ϑ-expression vanishes for the Minkowski metric in its standard diagonal form. Any ϑ-transformation will preserve the vanishing of the ϑ-expression. Hence, if transformations to accelerated frames of reference in Minkowski spacetime are ϑ-transformations, the ϑ-expression should also vanish for the Minkowski metric expressed in the coordinates of such accelerated frames. On p. 42L, toward the end of the part starting from the other end of the notebook, Einstein set himself the task of finding the most general form of the metric field $g_{\mu\nu}$ satisfying the equation $\vartheta_{\rho\sigma\tau} = 0$, imposing the additional constraints that the metric be time-independent and that its determinant be equal to unity and suppressing one spatial dimension. Given Einstein's heuristic principles, the general solution should include the Minkowski metric in (uniformly) rotating coordinates. Unfortunately, this turns out not to be the case. What Einstein discovered instead (at the top of p. 42R), is that one does obtain a solution if one simply interchanges the covariant and contravariant components of the rotation metric. We shall call this solution the "ϑ-metric."

Einstein tried to come to terms with this tantalizing result in various ways. One approach was to derive the equations of motion for a particle moving in a gravitational field described by the ϑ-metric and to identify the various components of the ϑ-metric occurring in these equations in terms of inertial forces in rotating frames of reference just as one would for the ordinary Minkowski metric in rotating coordinates. Einstein made two attempts along these lines. In one case, he derived the equations of motion as the Euler-Lagrange equations for the Lagrangian of a particle moving in a metric field (calculations at the bottom of pp. 42R and 43LA; discussed in sec. 5.5.7). In the other, he derived the equations of motion from the energy-momentum balance between matter and gravitational field (p. 24L; discussed in sec. 5.5.9). Neither calculation produced a satisfactory result. Neither did a somewhat different approach which Einstein tried at the top of p. 43LA (discussed in sec. 5.5.8). He replaced the covariant components of the metric in the ϑ-expression by contravariant ones, ensuring that the new expression vanishes for the rotation metric without interchanging its co- and contravariant components. Einstein discovered, however, that the modified ϑ-expression could not be used to eliminate terms with unwanted second-order derivatives of the metric from the November tensor. Moreover, the new expression is mathematically ill-defined. In the end, Einstein was thus forced to give up the ϑ-restriction and the promising candidate (584) for the left-hand side of the field equations constructed with the help of it.

The precise temporal order of the calculations on pp. 23L–24L at one end of the notebook and on pp. 42L–43L at the other remains unclear. There are various indications that Einstein switched back and forth between these two sets of pages. As we already noted, for instance, attempts to interpret the ϑ-metric in terms of inertial forces in rotating frames of reference can be found both on p. 42R–43L and on p. 24L.[298] Several questions remain. Had Einstein already encountered the ϑ-expression in some other context when he used it on p. 23L to extract field equations from the November tensor? If so, it would explain why Einstein's solution of the equation $\vartheta_{\rho\sigma\tau} = 0$ occurs in a different part of the notebook. It would, however, also raise the question why Einstein originally got interested in the ϑ-expression. If the calculation on p. 23L preceded the one on p. 42R,[299] this question does not arise, but in that case it is unclear why Einstein turned over the notebook for the calculation on p. 42R instead of simply continuing his entries on p. 24L ff. Given these uncertainties, it is important to emphasize that the order in which we present these calculations may not fully reflect their temporal order.

After these introductory and cautionary remarks, we turn to the actual calculation on p. 42L. At the top of the page,[300] Einstein wrote down the components of the metric 42L
suppressing one spatial dimension[301]

$$\begin{matrix} g_{11} & g_{12} & g_{14} \\ g_{21} & g_{22} & g_{24} \\ g_{41} & g_{42} & g_{44} \end{matrix} \tag{598}$$

Einstein then set out to find the most general time-independent solution of a set of linear first-order coupled differential equations for this metric field. In modern notation, this set of equations can be written as

$$g_{(\mu\nu,\lambda)} = g_{\mu\nu,\lambda} + g_{\lambda\mu,\nu} + g_{\nu\lambda,\mu} = 0\,, \tag{599}$$

where the indices can take on the values 1, 2, and 4. Although the ϑ-expression is not explicitly mentioned on pp. 42L–43L, equation (599) can also be written as (cf. expression (570))

$$\vartheta_{\mu\nu\lambda} = 0\,. \tag{600}$$

On p. 42R, Einstein explicitly imposed the additional constraint that the determinant of the metric be equal to unity. This condition was probably part of the original prob-

---

298 A possible further connection between these two attempts to interpret the ϑ-metric in terms of inertial forces in rotating frames of reference is the derivation on p. 43LB of the equation of motion for a point mass moving in a metric field from the vanishing of the covariant divergence of the stress-energy tensor for pressureless dust (see sec. 5.5.10)

299 The occurrence in a calculation on p. 43LA of Christoffel symbols, which are otherwise absent from the part that starts from the back of the notebook, suggests that at least this calculation is later than pp. 23L–R (cf. footnote 317).

300 In the top-left corner, Einstein wrote the six independent components of this metric field arranging them in a somewhat peculiar way. The reason behind this is unclear.

301 Underneath the 44-component, he wrote "0," which suggests that Einstein assumed the g_{44}-component to vanish. This is puzzling but would be consistent with the expression written right next to the metric (598) for the determinant of the metric. Perhaps, the components of (598) refer to small deviations of the metric from the flat Minkowski metric $\mathrm{diag}(-1,-1,1)$. This interpretation would be consistent with most of the rest of the calculation on this page, though not with the calculation of the determinant of the metric right next to (598).

lem that Einstein set himself on p. 42L, as is suggested by the fact that in the top right corner there is an expression for the determinant of the metric (598),[302]

$$\begin{aligned} & g_{14}(g_{12}g_{24} - g_{22}g_{14}) \\ & + g_{24}(g_{14}g_{12} - g_{24}g_{12}). \end{aligned} \tag{601}$$

Einstein then listed the index-combinations for all independent components of the set of differential equations in equation (599)

$$\begin{array}{cccccc} \underline{111} & \underline{112} & \underline{114} & \underline{122} & \underline{124} & \underline{144} \\ \underline{222} & \underline{224} & \cancel{233} & \cancel{234} & \underline{244} & , \\ \underline{444}. & & & & & \end{array} \tag{602}$$

He explicitly wrote down the equations corresponding to these index-combinations, with the exception of the last one, a clear indication that Einstein was interested only in time-independent solutions. The equations are grouped together as follows. First, Einstein gave the 111 and 222 components of equation (599), i.e., in modern notation,

$$g_{11,\,1} = 0\,, \tag{603}$$

$$g_{22,\,2} = 0\,. \tag{604}$$

He then gave the components with two indices equal to 4, followed by the ones with one index equal to 4. In the first four of these equations, he included but then deleted terms with derivatives with respect to x_4. In the fifth, he omitted this term altogether. Einstein thus arrived at

$$g_{44,\,1} = 0\,, \tag{605}$$

$$g_{44,\,2} = 0\,, \tag{606}$$

$$2g_{14,\,1} = 0\,, \tag{607}$$

$$2g_{24,\,2} = 0\,, \tag{608}$$

$$g_{14,\,2} + g_{24,\,1} = 0\,. \tag{609}$$

Finally, he wrote down the 112 and 122 components of equation (599),

$$2g_{12,\,1} + g_{11,\,2} = 0\,, \tag{610}$$

$$2g_{12,\,2} + g_{22,\,1} = 0\,. \tag{611}$$

From equations (603) and (604) it follows that g_{11} can only be a function of x_2 and that g_{22} can only be a function of x_1. Einstein thus wrote

302 Einstein either did not finish the calculation or he set g_{44} equal to zero as he indicated in (598) (cf. footnote 301).

$$g_{11} = \varphi(x_2), \tag{612}$$

$$g_{22} = \psi(x_1). \tag{613}$$

Substituting these expressions for g_{11} and g_{22} into equations (610) and (611), he obtained

$$2g_{12,1} = -\varphi'(x_2), \tag{614}$$

$$2g_{12,2} = -\psi'(x_1). \tag{615}$$

From these last two equations it follows that g_{12} has to be linear both in x_1 and x_2. Terms in g_{12} of second-order or higher in x_1 would make $g_{12,1}$ dependent on x_1, which is contrary to equation (614); terms of second-order or higher in x_2 would likewise make $g_{12,2}$ dependent on x_2, which is contrary to equation (615). Hence, g_{12} has to be of the form

$$g_{12} = c_0 + c_1x_1 + c_2x_2 + \alpha x_1x_2, \tag{616}$$

where c_0, c_1, c_2, and α are arbitrary constants. Inserting equation (616) into equations (614) and (615), Einstein found

$$\varphi'(x_2) = -2(c_1 + \alpha x_2), \tag{617}$$

$$\psi'(x_1) = -2(c_2 + \alpha x_1) \tag{618}$$

Integrating these equations and substituting the results into equations (612) and (613), Einstein found[303]

$$g_{11} = \varphi(x_2) = -2\left(c_1x_2 + \frac{\alpha}{2}x_2^2 + \kappa''\right), \tag{619}$$

$$g_{22} = \psi(x_1) = -2\left(c_2x_1 + \frac{\alpha}{2}x_1^2 + \kappa'''\right). \tag{620}$$

Expressions for the components g_{14} and g_{24} can be found in a similar way. From equations (607) and (608) it follows that g_{14} and g_{24} can be written as

$$g_{14} = \hat{\varphi}(x_2), \tag{621}$$

$$g_{24} = \hat{\psi}(x_1), \tag{622}$$

where we introduced the notation $\hat{\varphi}$ and $\hat{\psi}$ to distinguish these functions from the functions φ and ψ above. In the notebook, no such distinction is made. Inserting equations (621) and (622) into equation (609), one finds that

$$\hat{\varphi}'(x_2) + \hat{\psi}'(x_1) = 0, \tag{623}$$

303 The constants κ'' and κ''' in these equations probably only got these designations after the introduction of the constants κ and κ' in the expressions for g_{14} and g_{24}, which occur immediately below equations (619)–(620) in the notebook (cf. equations (626)–(627) below).

which allows the separation

$$\hat{\varphi}'(x_2) = \beta\,, \tag{624}$$

$$\hat{\psi}'(x_1) = -\beta\,, \tag{625}$$

where β is a constant. The notebook has α rather than β at this point, but in subsequent equations Einstein renamed this constant β, presumably to avoid confusion with the constant α introduced in equation (616). Integrating equations (624) and (625) and substituting the results into equations (621) and (622), one finds

$$g_{14} = \hat{\varphi}(x_2) = \beta x_2 + \kappa\,, \tag{626}$$

$$g_{24} = \hat{\psi}(x_1) = -\beta x_1 + \kappa'\,. \tag{627}$$

An expression for g_{44} was not explicitly given in the notebook, but from equations (605) and (606) it immediately follows that g_{44} has to be a constant.

The most general solution of the equations $g_{(\mu\nu,\lambda)} = 0$, under the additional constraint that $g_{\mu\nu,4} = 0$, is thus given by (cf. equations (616), (619)–(620), and (626)–(627))[304]

$$g_{\mu\nu} = \begin{pmatrix} -2\left(c_1 x_2 + \frac{\alpha}{2}x_2^2 + \kappa''\right) & c_0 + c_1 x_1 + c_2 x_2 + \alpha x_1 x_2 & \beta x_2 + \kappa \\ c_0 + c_1 x_1 + c_2 x_2 + \alpha x_1 x_2 & -2\left(c_2 x_1 + \frac{\alpha}{2}x_1^2 + \kappa'''\right) & -\beta x_1 + \kappa' \\ \beta x_2 + \kappa & -\beta x_1 + \kappa' & g_{44} \end{pmatrix} \tag{628}$$

At the bottom of p. 42L Einstein drew a figure indicating rotation around the z-axis. The relation between the calculation on p. 42L and rotation becomes clear on the next page.

42R At the top of page 42R Einstein wrote down a metric—or a "g-system" ("g-Schema") as he called it here—which is obtained from equation (628) by setting the integration constants c_0, c_1, c_2, κ, and κ' equal to zero, $\kappa'' = \kappa''' = 1/2$ and $g_{44} = 1$[305]

$$g_{\mu\nu} = \begin{pmatrix} -(1+\alpha x_2^2) & \alpha x_1 x_2 & \beta x_2 \\ \alpha x_1 x_2 & -(1+\alpha x_1^2) & -\beta x_1 \\ \beta x_2 & -\beta x_1 & 1 \end{pmatrix}. \tag{629}$$

304 The general solution for the 2+1-dimensional case can trivially be turned into a particular solution for the 3+1-dimensional case by adding $g_{\mu 3} = g_{3\mu} = (0, 0, -1, 0)$

305 If $g_{\mu\nu}$ represents small deviations from a flat Minkowski metric (cf. footnote 301), one needs to set $\kappa'' = \kappa''' = 0$ and $g_{44} = 0$ instead.

This is the solution of the equation $\vartheta_{\mu\nu\lambda} = 0$ that we shall refer to as the ϑ-metric. Einstein now imposed the condition that the determinant G of this metric be equal to unity. For G he wrote[306]

$$\begin{aligned} G &= (1+\alpha x_1^2)(1+\alpha x_2^2) - \alpha\beta^2 x_1^2 x_2^2 - \alpha\beta^2 x_1^2 x_2^2 \\ &\quad + (1+\alpha x_2^2)\beta^2 x_1^2 - \alpha^2 x_1^2 x_2^2 + (1+\alpha x_1^2)\beta^2 x_2^2 \\ &= 1 + (\alpha+\beta^2)x_1^2 + (\alpha+\beta^2)x_2^2 \\ &\quad + (\alpha^2 - 2\alpha\beta^2 + \alpha\beta^2 + \alpha\beta^2 - \alpha^2)x_1^2 x_2^2. \end{aligned} \tag{630}$$

Next to this equation, Einstein wrote down the condition that this determinant be equal to unity,

$$\alpha + \beta^2 = 0\,. \tag{631}$$

Using this relation between α and β, he inverted the metric in equation (629) and wrote down the result,

$$\gamma_{\mu\nu} = \begin{pmatrix} -1 & 0 & \beta x_2 \\ 0 & -1 & -\beta x_1 \\ \beta x_2 & -\beta x_1 & 1+\alpha(x_1^2+x_2^2) \end{pmatrix}. \tag{632}$$

which he denoted by γ, next to "g-system" at the top of the page. As Einstein noted in a comment that he wrote next to these expressions of the ϑ-metric in its covariant and contravariant form, "the system of the γ's for a rotating body [is] identical to the g-system given here" ("Schema der γ für rotierenden Körper mit nebenstehendem g-Schema identisch"). This is an intriguing result. The ϑ-restriction does not allow the Minkowski metric in rotating coordinates, but it does allow the ϑ-metric, which is closely related to it. Is that enough to satisfy Einstein's heuristic requirements? Can the ϑ-restriction be modified in such a way that it does allow the rotation metric without the need to switch its co- and contravariant components? These are the questions that are behind the calculations on pp. 42R, 43LA, and 24L that will be discussed in secs. 5.5.7–5.5.10.

Before Einstein began his closer examination of the ϑ-metric, he briefly considered another special case of equation (628). He drew a horizontal line and wrote the non-vanishing components of the metric

306 With the help of the fully anti-symmetric Levi-Civita tensor ε_{ijk} —which is equal to 1 for every even permutation of 1, 2, 3 (or, rather, 4 in this case), equal to -1 for every odd permutation, and equal to 0 otherwise—the determinant G can be written as $G = \varepsilon_{ijk} g_{1i} g_{2j} g_{4k}$. The three terms on the first line of equation (630) correspond to the even permutations 124, 421, and 241; the three terms on the second line to the odd permutations 142, 214, 421. This way of evaluating the determinant is known as Sarrus' rule.

$$\begin{matrix} -1-2c_1x_2 & c_1x_1+c_2x_2 & 0 \\ c_1x_1+c_2x_2 & -1-2c_2x_1 & 0 \\ 0 & 0 & 1. \end{matrix} \tag{633}$$

This metric is obtained from equation (628) by setting the integration constants c_0, α, β, κ, and κ' equal to zero, setting $\kappa'' = \kappa''' = 1/2$ and $g_{44} = 1$.[307] This solution, however, does not satisfy one of Einstein's additional constraints. As he wrote next to the metric (633), "the determinant [of this metric field] is not 1" ("Determinante ist nicht 1"). Einstein then drew another horizontal line and began his closer examination of the tantalizing ϑ-metric of equations (629) and (632).

5.5.7 *Reconciling the ϑ-Metric and Rotation (I): Identifying Coriolis and Centrifugal Forces in the Geodesic Equation (42R, 43LA)*

42R On the bottom half of p. 42R, under the second horizontal line, Einstein first gave a short derivation, similar to the one he gave on pp. 12L–R (see sec. 4.5.6), of the Minkowski metric in rotating coordinates. As in the derivation of the ϑ-metric, with which he wanted to compare the rotation metric, he suppressed one of the spatial dimensions.

Consider a Cartesian coordinate system $x_\mu = (x, y, t)$ in $2+1$-dimensional Minkowski spacetime which is rotating clockwise with angular frequency ω with respect to another Cartesian coordinate system $x_\mu{}' = (x', y', t')$ in which the metric has its usual diagonal form:

$$ds^2 = \eta_{\mu\nu}dx'_\mu dx'_\nu = (\mathbf{v}'^2 - 1)dt'^2. \tag{634}$$

In this equation, $\eta_{\mu\nu} = \text{diag}(1, 1, -1)$, $c = 1$ (in accordance with Einstein's conventions at this point), and the components of $\mathbf{v}'$ are $v'_i = dx'_i/dt' = \dot{x}'_i$ ($i = 1, 2$). The relation between the velocity with respect to the non-rotating frame and the velocity $\mathbf{v}$ with respect to the rotating frame is given by (cf. equation (352)):

$$\mathbf{v}' = \mathbf{v} + \vec{\omega} \times \mathbf{r} = (\dot{x} + \omega y, \dot{y} - \omega x), \tag{635}$$

where $\vec{\omega} \times \mathbf{r}$ is the cross-product of the vectors $\vec{\omega} = (0, 0, -\omega)$ ($-\omega$ because the rotation is clockwise) and $\mathbf{r} = (x, y, 0)$ in three dimensions. Taking the square of equation (635), one finds that

$$\begin{aligned} \mathbf{v}'^2 &= (\dot{x} + \omega y)^2 + (\dot{y} - \omega x)^2 \\ &= \dot{x}^2 + \dot{y}^2 + 2\omega y\dot{x} - 2\omega x\dot{y} + \omega^2 r^2. \end{aligned} \tag{636}$$

The expressions following the equality signs in equation (636) are actually the only ones Einstein explicitly wrote down before giving the matrix for the rotation metric.

307 Again, this metric could be obtained by setting $\kappa'' = \kappa''' = 0$ and $g_{44} = 0$ in the case that the $g_{\mu\nu}$ were deviations. Taken together both special cases exhaust the general solution (up to constants).

As we mentioned above, he had gone through essentially the same derivation on pp. 12L–R. Inserting equation (636) along with $dt' = dt$ into equation (634), one finds that the Minkowski line element in rotating coordinates is given by

$$ds^2 = dx^2 + dy^2 + 2\omega y dx dt - 2\omega x dy dt - (1 - \omega^2 r^2) dt^2 , \tag{637}$$

from which one can read off the components of the metric,

$$g_{\mu\nu} = \begin{pmatrix} 1 & 0 & \omega y \\ 0 & 1 & -\omega x \\ \omega y & -\omega x & -1 + \omega^2 r^2 \end{pmatrix} . \tag{638}$$

Einstein read off the components of the metric from the last line of equation (636), which is probably why he omitted the term -1 in g_{44}. As on pp. 12L–R, he also ended up with additional factors of 2 in g_{14} and g_{24}.[308] When the constant β in equation (629) is set equal to the angular frequency ω (in which case $\alpha = -\omega^2$ according to equation (631)), the contravariant form of the ϑ-metric does indeed turn into the covariant form of the rotation metric in equation (638), as was noted in the top-right corner of p. 42R.[309]

As he had done earlier when he was faced with the conflict between the modified weak-field equations of p. 21R and the static metric (see the discussion in sec. 5.4.4), Einstein turned to particle dynamics to see whether his mathematical results could be given a physically sensible interpretation. In this case, he apparently wanted to check whether the components of the ϑ-metric and their derivatives can be given the same sort of physical interpretation in terms of inertial forces as the components of the usual rotation metric and their derivatives. Although the relevant calculations—at the bottom of p. 42R and again at the bottom of p. 43LA—break off after just a few lines, it seems to be clear that this was their purpose.

Einstein inserted the ϑ-metric in its covariant form (see equation (629)) into the Lagrangian

$$H = \sqrt{\frac{ds^2}{dt^2}} = \sqrt{g_{\mu\nu}\dot{x}_\mu \dot{x}_\nu} \tag{639}$$

for a point mass moving in a given metric field. The result is that

$$H = \sqrt{-\dot{x}^2 - \dot{y}^2 + 2\beta y\dot{x} - 2\beta x\dot{y} \underbrace{- \alpha y^2\dot{x}^2 - \alpha x^2\dot{y}^2 + 2\alpha xy\dot{x}\dot{y}}_{-\alpha(x\dot{y} - y\dot{x})^2} + 1} . \tag{640}$$

Einstein then wrote down the variational principle

308 Einstein made the same mistake on pp. 12L–R (see footnote 176) and in the Einstein-Besso manuscript (CPAE 4, Doc. 14, pp. [41–42]).

309 The two equations are still not completely identical because Einstein wrote the flat Minkowski metric as $\mathrm{diag}(-1, -1, 1)$ in equation (629) and as $\mathrm{diag}(1, 1, -1)$ in equation (638).

$$\delta\int H dt = 0 , \tag{641}$$

and went through a quick derivation of the x-component of the corresponding Euler-Lagrange equations, writing

$$\int\left(\frac{\partial H}{\partial \dot{x}}\delta\dot{x} + \frac{\partial H}{\partial x}\delta x\right)dt = 0 ,\text{[310]} \tag{642}$$

which, upon partial integration, gives

$$-\frac{d}{dt}\left(\frac{\partial H}{\partial \dot{x}}\right) + \frac{\partial H}{\partial x} = 0 . \tag{643}$$

Einstein now began to compute the first term of this Euler-Lagrange equation for the Lagrangian in equation (640). The derivative of H with respect to $\dot{x}$ is given by

$$\frac{\partial H}{\partial \dot{x}} = \frac{-\dot{x} + \beta y + \alpha(x\dot{y} - y\dot{x})y}{\sqrt{-\dot{x}^2 - \dot{y}^2 + 2\beta y\dot{x} - 2\beta x\dot{y} - \alpha(x\dot{y} - y\dot{x})^2 + 1}} . \tag{644}$$

In the notebook, there is a deleted factor of 2 in front of all three terms in the numerator and the denominator was indicated only by a square root sign. On the next line, Einstein took the time derivative of equation (644) in its uncorrected form

$$\frac{d}{dt}\left(\frac{\partial H}{\partial \dot{x}}\right) = -2\ddot{x} + \beta\dot{y} + 2\alpha y(x\ddot{y} - y\ddot{x}) + 2\alpha\dot{y}(x\dot{y} - y\dot{x}) , \tag{645}$$

i.e., with the extra factors of 2 and without the denominator. On the last line of p. 42R, Einstein wrote down the second term of the Euler-Lagrange equation (643) as well, but did not actually evaluate it for the Lagrangian under consideration. The inclusion of the denominator in equation (644), which Einstein had originally omitted, considerably complicates the Euler-Lagrange equations, which may well be why Einstein gave up on this calculation, at least for the time being.

At the top of the next page, p. 43LA, he tried to resolve the apparent conflict between the ϑ-metric and the rotation metric in a different manner (to be discussed in sec. 5.5.8). This new approach, however, turned out not to be viable, and at the bottom of p. 43LA Einstein briefly returned to the approach he had abandoned at the bottom of p. 42R.

43LA Under the heading "dynamics in a symmetric static rotational field" ("Dynamik im symmetrischen statischen Rotationsfeld"), Einstein once again considered the motion of a point mass in the ϑ-metric. The reason he explicitly referred to this case as "symmetric" and "static" may have been that the ϑ-metric is a time-independent solution of an equation in which the fully symmetrized derivative of the metric is set equal to zero (see equation (599)). Using the relation $\alpha + \beta^2 = 0$, which ensures that the determinant of the ϑ-metric is equal to unity (see equation (631)), Einstein was able to write the Lagrangian H of equation (640) more compactly as[311]

310 In the notebook the differential dt was omitted.

$$H = \sqrt{1 - \dot{x}^2 - \dot{y}^2 - 2\beta(x\dot{y} - y\dot{x}) + \beta^2(x\dot{y} - y\dot{x})^2}$$
$$= \sqrt{[1 - \beta(x\dot{y} - y\dot{x})]^2 - \dot{x}^2 - \dot{y}^2}. \tag{646}$$

However, he only wrote down one term of the Euler-Lagrange equations,

$$\frac{\partial H}{\partial x} = \frac{1}{H} \cdot -\beta(x\dot{y} - y\dot{x})\dot{y}\,, \tag{647}$$

before once again breaking off this calculation. This attempt to give physical meaning to the ϑ-metric thus remained inconclusive. On p. 24L, Einstein made another attempt along these lines (see sec. 5.5.9), but first we shall discuss the calculation at the top of p. 43LA.

5.5.8 *Reconciling the ϑ-Metric and Rotation (II): Trying to Construct a Contravariant Version of the ϑ-Expression (43LA)* 43LA

At the top of p. 43LA,[312] Einstein introduced a variant of the ϑ-expression introduced on p. 23L, replacing covariant components of the metric by contravariant ones.[313] Since the original ϑ-expression vanishes for the ϑ-metric, i.e., the rotation metric with its co- and contravariant components switched, this modified ϑ-expression vanishes for the rotation metric itself. The modified ϑ-restriction, i.e., the restriction to unimodular transformations under which the modified ϑ-expression transforms as a tensor, thus allows transformations to rotating coordinates in the important special case of Minkowski spacetime. However, Einstein found that, unlike the original ϑ-restriction, the modified ϑ-restriction could not be used to eliminate terms with unwanted second-order derivatives of the metric from the November tensor. At that point, he abandoned the modified ϑ-expression. He may also have come to realize that the expression is mathematically ill-defined (because of the way in which it mixes co- and contravariant components).

At the top of the page Einstein wrote down the expression

$$g_{ik}\left(\frac{\partial \gamma_{ik}}{\partial x_l} + \frac{\partial \gamma_{kl}}{\partial x_i} + \frac{\partial \gamma_{li}}{\partial x_k}\right). \tag{648}$$

---

311 In the notebook, the last term of the first line has $\dot{x}\dot{y}$ instead of $x\dot{y}$.

312 This is the last page of the part that starts from the back of the notebook (pp. 32L–43L). It contains entries starting from the top and from the bottom of the page (transcribed as 43LA and 43LB respectively), thus suggesting that this is the place where the two parts of the notebook meet. There are, however, six blank pages between p. 43L and p. 31L, the last page of the part that starts from the front of the notebook. The calculation that starts from the bottom of p. 43L is also not a continuation of p. 31L. In this brief calculation, Einstein derived the equation of motion of a particle in a metric field by integrating the energy-momentum balance between matter and gravitational field over the volume of the particle (for discussion see sec. 5.5.10).

313 The fragmentary calculation at the top of p. 23R could be related to the investigation of the modified ϑ-expression on this page (cf. the discussion following equation (585) in sec. 5.5.4 for a different interpretation of this calculation).

The expression in parentheses is obtained (down to the labeling of the indices) by substituting $\gamma_{\mu\nu}$ for $g_{\mu\nu}$ in definition (570) of the ϑ-expression. Farther down on the page, Einstein introduced the quantity $t_{\lambda\alpha\kappa}$ which appears to be defined as ($1/2$ times) this expression

$$t_{\lambda\alpha\kappa} \equiv \frac{1}{2}\left(\frac{\partial\gamma_{\lambda\alpha}}{\partial x_\kappa} + \frac{\partial\gamma_{\alpha\kappa}}{\partial x_\lambda} + \frac{\partial\gamma_{\kappa\lambda}}{\partial x_\alpha}\right). \tag{649}$$

Given the convention in the notebook of using Greek and Latin characters to denote covariant and contravariant quantities, respectively,[314] the notation indicates that $t_{\lambda\alpha\kappa}$ is a contravariant version of ϑ_{ikl}. Solutions of the equation $t_{\lambda\alpha\kappa} = 0$ are obtained simply by interchanging co- and contravariant components in solutions of $\vartheta_{ikl} = 0$. Since the ϑ-metric is a solution of $\vartheta_{ikl} = 0$ (see equations (629) and (632)), the rotating metric is a solution of $t_{\lambda\alpha\kappa} = 0$. The quantity $t_{\lambda\alpha\kappa}$, however, is mathematically ill-defined. Covariant indices in one term occur as contravariant ones in another, and there are summations over pairs of covariant indices. Next to expression (648), Einstein nonetheless wrote "Tensor," presumably to indicate that he wanted to consider a variant of the ϑ-restriction, i.e., a restriction to (unimodular) transformations under which $t_{\lambda\alpha\kappa}$ transforms as a tensor.[315]

At the beginning of the calculation on p. 23L, the ϑ-expression was used to rewrite the Christoffel symbols (see equations (572)–(573)). If $t_{\lambda\alpha\kappa}$, the "contravariant" version of the ϑ-expression, is going to be used in a similar manner, one first needs to lower its indices. Einstein indeed wrote down the expression

$$g_{i\alpha}g_{k\beta}\left(\frac{\partial\gamma_{ik}}{\partial x_l} + \frac{\partial\gamma_{kl}}{\partial x_i} + \frac{\partial\gamma_{li}}{\partial x_k}\right), \tag{650}$$

which again is mathematically ill-defined, and wrote next to it that this is a covariant or "plane tensor" ("Ebenentensor"[316]). Einstein rewrote this expression in such a way that, just as the Christoffel symbols, it contains only derivatives of the covariant components of the metric

---

314 Cf., e.g., on p. 24L where T_{ik} and Θ_{ik} represent the stress-energy tensor for matter in its contravariant and covariant form, respectively. Note that this convention is just the opposite of the one adopted in (Einstein and Grossmann 1913), where all contravariant quantities are indicated by Greek and all covariant ones by Latin characters.

315 Unfortunately, this interpretation does not explain why, as Einstein noted on the next line, (minus) the ill-defined second term of (648), $\sum\gamma_{kl}\frac{\partial g_{ik}}{\partial x_i}$, should be a vector. Maybe Einstein meant (minus) the unproblematic first term, $\sum\gamma_{ik}\frac{\partial g_{ik}}{\partial x_l}$, which is equal to $\frac{\partial\log(-g)}{\partial x_l}$ and hence a vector under all unimodular transformations.

316 The term "Ebenentensor" also appears on pp. 17L, 17R, 19L, and 24R. The term "Ebenenvektor" appears on p. 13L. Cf. the discussion of this terminology following equation (453) above.

$$-\frac{\partial g_{\alpha\beta}}{\partial x_l} - \gamma_{\kappa l} g_{i\alpha} \frac{\partial g_{\kappa\beta}}{\partial x_i} - \gamma_{li} g_{\kappa\beta} \frac{\partial g_{i\alpha}}{\partial x_\kappa} . \tag{651}$$

He then checked whether this modified ϑ-expression can be used to eliminate terms with unwanted second-order derivatives of the metric from the November tensor. He began by writing down the term in the November tensor containing second-order derivatives[317] (cf. equation (544))[318]

$$\frac{\partial}{\partial x_l}\left(\gamma_{l\alpha}\begin{bmatrix} i & \kappa \\ & \alpha \end{bmatrix}\right) . \tag{652}$$

Using the definition of the Christoffel symbol, he rewrote this term as[319]

$$\frac{\partial \gamma_{l\alpha}}{\partial x_l}\begin{bmatrix} i & \kappa \\ & \alpha \end{bmatrix} + \frac{1}{2}\gamma_{l\alpha}\left(\frac{\partial^2 g_{i\alpha}}{\partial x_l \partial x_\kappa} + \frac{\partial^2 g_{\kappa\alpha}}{\partial x_l \partial x_i} - \frac{\partial^2 g_{i\kappa}}{\partial x_l \partial x_\alpha}\right) . \tag{653}$$

Einstein deleted this expression and made a fresh start on the next line, writing the expression in parentheses in expression (652) as[320]

$$\frac{1}{2}\gamma_{\lambda\alpha}\left(\frac{\partial g_{i\alpha}}{\partial x_\kappa} + \frac{\partial g_{\kappa\alpha}}{\partial x_i} - \frac{\partial g_{i\kappa}}{\partial x_\alpha}\right) . \tag{654}$$

If this expression is inserted into expression (652), the first two terms give rise to unwanted second-order derivatives of the metric. Following the strategy on p. 23L, one could try to eliminate these terms by absorbing them into a quantity involving $t_{\lambda\alpha\kappa}$, transforming as a tensor under transformations under which $t_{\lambda\alpha\kappa}$ itself transforms as a tensor. One can then subtract this quantity from the November tensor without losing invariance under this restricted class of transformations. This appears to be the rationale behind the last two lines of this calculation. First, Einstein underlined the first two terms in expression (654) and rewrote them as

317 This is the first and only occurrence of the Christoffel symbol in the part that starts from the end of the notebook. In the part that starts from the beginning of the notebook, the Christoffel symbols are first introduced on p. 14L.

318 The notebook originally had x_α instead of x_l.

319 In the notebook, the Christoffel symbol is indicated only by square brackets and is multiplied by $\frac{\partial \gamma_{\lambda\alpha}}{\partial x_\alpha}$ instead of $\frac{\partial \gamma_{l\alpha}}{\partial x_l}$. The first two occurrences of the index l in the second term were originally λ's.

320 Einstein at this point changed his notation for one of the summation indices in expression (652) from l to λ.

$$-\frac{1}{2}\left(g_{i\alpha}\frac{\partial\gamma_{\lambda\alpha}}{\partial x_\kappa}+g_{\kappa\alpha}\frac{\partial\gamma_{\lambda\alpha}}{\partial x_i}\right). \qquad (655)$$

Underneath this expression he wrote[321]

$$t_{\lambda\alpha\kappa}-\frac{\partial\gamma_{\kappa\alpha}}{\partial x_\lambda}-\frac{\partial\gamma_{\lambda\kappa}}{\partial x_\alpha}, \qquad (656)$$

On the assumption that Einstein did indeed define $t_{\lambda\alpha\kappa}$ as in equation (649), this last expression is equal to $\partial\gamma_{\lambda\alpha}/\partial x_\kappa$, which is part of the first term in expression (655). At this point, it apparently became clear to Einstein that the modified ϑ-expression could not be used to eliminate unwanted second-order derivative terms from the November tensor. Einstein may also have come to realize that $t_{\lambda\alpha\kappa}$ is mathematically ill-defined. In any case, Einstein abandoned this attempt to modify the ϑ-restriction to ensure that it would include transformations to rotating coordinates in Minkowski spacetime. As was already discussed at the end of sec. 5.5.7, he briefly returned to the approach he had tried on p. 42R before giving up on that approach as well.

24L 5.5.9 *Reconciling the ϑ-Metric and Rotation (III): Identifying the Centrifugal Force in the Energy-Momentum Balance (24L)*

On p. 24L, Einstein made yet another attempt to give physical meaning to the components of the ϑ-metric. He checked whether the force on a particle at rest in the gravitational field described by the ϑ-metric can be interpreted as the centrifugal force on a particle at rest in a rotating frame of reference. This strategy is similar to the one behind the aborted calculations at the bottom of pp. 42R and 43LA (see sec. 5.5.7). The new element is that in order to find the equations of motion and the expression for the force on the particle Einstein now substituted the ϑ-metric into the energy-momentum balance between matter and gravitational field rather than into the Lagrangian for a point particle in a metric field.

The energy-momentum balance can be written as the vanishing of the covariant divergence of either the contravariant or the covariant stress-energy tensor. If the Minkowski metric in rotating coordinates is inserted into the equation which sets the covariant divergence of the *contravariant* stress-energy tensor equal to zero, one readily establishes that a term, which can be interpreted as the force on a particle at rest in this coordinate system, is equal to the usual centrifugal force (plus correction terms of higher order in the angular frequency of the rotating coordinate system). What Einstein tried to do on p. 24L was to check whether one can establish an analogous result if the ϑ-metric, i.e., the rotation metric with its co- and contravariant components switched, is inserted into the equation which sets the covariant divergence of the *covariant* stress-energy tensor equal to zero. The result of Einstein's calculation

321 In the notebook, the quantity $t_{\lambda\alpha\kappa}$ was actually written as $t^c_{\lambda\alpha\kappa}$. It is unclear what the letter 'c' stands for.

on p. 24L suggests that one can. The calculation, however, is in error. If the errors are corrected, one sees that one cannot.

At the top of p. 24L, Einstein wrote down an equation which expresses the vanishing of the contravariant stress-energy tensor, denoted by $T_{\mu\nu}$,[322] in the special case that the determinant of the metric is equal to unity,

$$\sum \frac{\partial}{\partial x_n}(g_{m\nu}T_{\nu n}) - \frac{1}{2}\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} = 0 . \tag{657}$$

This equation is obtained (down to the numbering of the indices) from equation (71) derived on p. 5R by setting $\sqrt{G} = 1$. On p. 5R, as in several subsequent publications,[323] this equation was derived as a generalization of the equations of motion that follow from the variational principle $\delta\int(ds/dt)dt = 0$ for one particle to a cloud of pressureless dust described by the stress-energy tensor

$$T_{\mu\nu} = \rho_0 \frac{dx_\mu}{d\tau}\frac{dx_\nu}{d\tau} , \tag{658}$$

which is explicitly given at the top of p. 24L as well. On p. 43LB, Einstein went through this derivation in reverse, showing that the equation of motion for one particle can be obtained by integrating equation (657), with $T_{\mu\nu}$ given by equation (658), over the volume of the particle. This calculation will be discussed in the next subsection (sec. 5.5.10). Einstein could thus look upon equation (657) as giving the equation of motion of a particle in a metric field with a determinant equal to unity. In particular, he could look upon the second term,

$$-\frac{1}{2}\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} , \tag{659}$$

as giving the (density of the) force experienced by a particle in a metric field.[324]

Consider a particle at rest with respect to a rotating coordinate system in Minkowski spacetime. In that case, the stress-energy tensor in equation (658) reduces to

$$T_{\mu\nu} = \mathrm{diag}(0, 0, 0, \rho_0/g_{44}) . \tag{660}$$

For counterclockwise rotation around the z-axis with angular frequency ω, the metric is given by

---

322 We want to remind the reader that the convention used here to distinguish covariant and contravariant quantities is the opposite of the one adopted in (Einstein and Grossmann 1913), where all contravariant quantities are indicated by Greek and all covariant ones by Latin characters.

323 (Einstein and Grossmann 1913, sec. 4), (Einstein 1913, sec. 5).

324 The general interpretation of the second term in equation (657) is that it is "an expression for the effects which are transferred from the gravitational field to the material process [as described by the stress-energy tensor]" ("ein Ausdruck für die Wirkungen, welche vom Schwerefelde auf den materiellen Vorgang übertragen werden;" Einstein and Grossmann 1913, 11). See also the discussion of p. 19R in sec. 5.4.2 (especially expression (482) and equation (483)).

$$g_{\mu\nu} = \begin{pmatrix} -1 & 0 & 0 & \omega y \\ 0 & -1 & 0 & -\omega x \\ 0 & 0 & -1 & 0 \\ \omega y & -\omega x & 0 & 1-\omega^2(x^2+y^2) \end{pmatrix}, \tag{661}$$

Inserting equations (660) and (661) into the $m = 1$ component of expression (659) for the force on the particle, one arrives at

$$-\frac{1}{2}g_{44,\,1}T_{44} = \frac{\rho_0}{g_{44}}\omega^2 x = \rho_0\omega^2 x + O(\omega^4), \tag{662}$$

which, when terms of order ω^4 are neglected, is the x-component of the centrifugal force in ordinary Newtonian theory.

On p. 24L, Einstein performed a variant of this calculation starting from the vanishing of the covariant divergence of the covariant rather than the contravariant stress-energy tensor. Einstein wrote the contravariant $T_{\mu\nu}$ in terms of the covariant $\Theta_{\mu\nu}$,

$$T_{\mu\nu} = \gamma_{\mu\alpha}\gamma_{\nu\beta}\Theta_{\alpha\beta}, \tag{663}$$

and substituted this expression into to equation (657), which then turns into

$$\sum\frac{\partial}{\partial x_n}(\gamma_{n\alpha}\Theta_{\alpha m}) + \frac{1}{2}\frac{\partial\gamma_{\alpha\beta}}{\partial x_m}\Theta_{\alpha\beta} = 0. \tag{664}$$

For the second term Einstein used the result of an auxiliary calculation which appears next to equation (664),

$$\frac{\partial g_{\mu\nu}}{\partial x_m}\gamma_{\mu\alpha}\gamma_{\nu\beta}\Theta_{\alpha\beta} = -g_{\mu\nu}\frac{\partial\gamma_{\mu\alpha}}{\partial x_m}\gamma_{\nu\beta}\Theta_{\alpha\beta} = -\frac{\partial\gamma_{\alpha\beta}}{\partial x_m}\Theta_{\alpha\beta}. \tag{665}$$

He then wrote down the covariant version of the stress-energy tensor for pressureless dust in equation (658)

$$\Theta_{\alpha\beta} = \rho_0 g_{\mu\alpha}g_{\nu\beta}\frac{dx_\mu}{d\tau}\frac{dx_\nu}{d\tau}. \tag{666}$$

Under the heading "Force acting on material point at rest $n = 1$" ("Kraft auf ruhenden materiellen Punkt $n = 1$") he then wrote[325]

---

325 In the notebook only the 1β - and the 44 -components of $\Theta_{\alpha\beta}$ were written down.

$$\begin{array}{ccc} \dfrac{\partial\gamma_{\alpha\beta}}{\partial x_1} & \Theta_{\alpha\beta} & \dfrac{dx}{d\tau} \\[2ex] \begin{matrix} 0 & 0 & 0 \\ 0 & 0 & \beta \\ 0 & \beta & 2\alpha x \end{matrix} & \begin{matrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \rho_0 \end{matrix} & 0\ 0\ 0\ \dfrac{1}{\sqrt{g_{44}}} \end{array} \tag{667}$$

The calculation for the ϑ-metric that Einstein indicated in this manner is completely analogous to the calculation for the rotation metric in equations (659)–(662). Einstein interpreted the second term in equation (664),

$$\frac{1}{2}\frac{\partial\gamma_{\alpha\beta}}{\partial x_m}\Theta_{\alpha\beta}\,, \tag{668}$$

with $\Theta_{\mu\nu}$ given by equation (666), as the (density of the) force experienced by a particle in a metric field. Whereas expression (659) for the force density was a contraction of the *covariant* metric and the contravariant stress-energy tensor, expression (668) is a contraction of the *contravariant* metric and the covariant stress-energy tensor. Since the contravariant components of the ϑ-metric are equal to the covariant components of the rotation metric, expression (668) would give the same result for a particle at rest in the field of the ϑ-metric as expression (659) for a particle at rest in a rotating frame in Minkowski spacetime, *if only* the components of $\Theta_{\mu\nu}$ in the former case were equal to those of $T_{\mu\nu}$ in the latter. Contrary to what is suggested by the expression for $\Theta_{\mu\nu}$ in the expressions (667), however, this last condition does not hold.

For a particle at rest with respect to a given coordinate system, as Einstein explicitly wrote down (see the expressions (667)),

$$\frac{dx_\mu}{d\tau} = \left(0, 0, 0, \frac{1}{\sqrt{g_{44}}}\right), \tag{669}$$

and equation (666) reduces to

$$\Theta_{\alpha\beta} = \rho_0\frac{g_{4\alpha}g_{4\beta}}{g_{44}}\,. \tag{670}$$

The covariant components of the ϑ-metric are given by (cf. equation (629))[326]

326 In the notebook, both on p. 42R and on p. 24L, the ϑ-metric is given for the $2+1$-dimensional case. The generalization to the $3+1$-dimensional case is trivial (cf. footnote 304)

$$g_{\mu\nu} = \begin{pmatrix} -(1+\alpha x_2^2) & \alpha x_1 x_2 & 0 & \beta x_2 \\ \alpha x_1 x_2 & -(1+\alpha x_1^2) & 0 & -\beta x_1 \\ 0 & 0 & -1 & 0 \\ \beta x_2 & -\beta x_1 & 0 & 1 \end{pmatrix}, \tag{671}$$

the contravariant ones by (cf. equation (632))

$$\gamma_{\mu\nu} = \begin{pmatrix} -1 & 0 & 0 & \beta x_2 \\ 0 & -1 & 0 & -\beta x_1 \\ 0 & 0 & -1 & 0 \\ \beta x_2 & -\beta x_1 & 0 & 1+\alpha(x_1^2+x_2^2) \end{pmatrix}, \tag{672}$$

where $\alpha = -\beta^2$ (see equation (631)). Taking the derivative of equation (672) with respect to x_1, one arrives at

$$\frac{\partial\gamma_{\alpha\beta}}{\partial x_1} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\beta \\ 0 & 0 & 0 & 0 \\ 0 & -\beta & 0 & 2\alpha x_1 \end{pmatrix}. \tag{673}$$

The notebook has β instead of $-\beta$ (see the expressions (667)), but this is only a minor discrepancy. Inserting equation (671) into equation (670), however, one immediately notices that $\Theta_{\mu\nu}$ will be considerably more complicated in this case than $\mathrm{diag}(0, 0, 0, \rho_0)$ given in the expressions (667) in the notebook. Inserting the simple expression $\Theta_{\mu\nu} = \mathrm{diag}(0, 0, 0, \rho_0)$ and equation (673) into the $m = 1$ component[327] of expression (668), one arrives at

$$\frac{1}{2}\frac{\partial\gamma_{\alpha\beta}}{\partial x_1}\Theta_{\alpha\beta} = \frac{1}{2}\frac{\partial\gamma_{44}}{\partial x_1}\Theta_{44} = \rho_0\alpha x_1. \tag{674}$$

which is equal to the centrifugal force in Newtonian theory if the identification $\alpha = \omega^2$ is made. This would mean that the ϑ-metric can be interpreted in terms of centrifugal forces just as the rotation metric (cf. equations (659)–(662)). However, when Einstein's expression for $\Theta_{\alpha\beta}$ is corrected, there will be additional terms which spoil this physical interpretation of the ϑ-metric.

It is not entirely clear what conclusion Einstein drew from his calculation on p. 24L. It would seem that initially he felt that he could recover the correct expression for the centrifugal force with the ϑ-metric as well as with the rotation metric. On the

327 In the notebook, the free index in the second term in equation (664) was originally n instead of m. This explain why the header above the expressions (667) in the notebook has "$n = 1$" instead of $m = 1$.

next page, however, he made a fresh start, abandoning the idea of the ϑ-restriction that had led him to consider the ϑ-metric in the first place. This suggests that eventually Einstein came to realize that the calculation on p. 24L was in error and that his third attempt at reconciling the ϑ-metric with his heuristic requirements concerning rotation, like the first two (on pp. 42R–43LA), had failed.

The November tensor, like the Ricci tensor from which it was extracted under the restriction to unimodular coordinate transformations, thus failed to yield acceptable candidates for the left-hand side of the field equations. Einstein had found two different coordinate restrictions, the Hertz restriction and the ϑ-restriction, with which terms containing unwanted second-order derivatives of the metric can be eliminated from the November tensor. He had also discovered, however, that both coordinate restrictions rule out transformations to accelerated frames of reference in the important special case of Minkowski spacetime.

5.5.10 *Relating Attempts (I) and (III) to Reconcile the ϑ-Metric and Rotation: from the Energy-Momentum Balance to the Geodesic Equation (43LB)* 43LB

In a brief calculation starting on p. 43LB, Einstein showed that the vanishing of the covariant divergence of the stress-energy tensor for pressureless dust implies the equations of motion for a point particle in a metric field. On p. 5R, Einstein had proved the converse of this implication. The derivation on p. 43LB essentially goes through this earlier derivation in reverse.[328] The calculation may be connected to Einstein's attempts to interpret the components of the ϑ-metric (see equation (629)) in terms of the inertial forces of rotation. On p. 42R and p. 43LA he tried to do so starting from the equations of motion (see sec. 5.5.7), whereas on p. 24R he started from the energy-momentum balance between matter and gravitational field (see sec. 5.5.9). The point of Einstein's calculation on p. 43LB may have been to reassure himself that these two approaches are equivalent.

The calculation starts from equation (71) of p. 5R for the special case that $\sqrt{G} = 1$:

$$\frac{\partial}{\partial x_n}(g_{m\nu}T_{\nu n}) - \frac{1}{2}\sum\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} = 0 \tag{675}$$

(cf. equation (657) on p. 24L). Next to this equation, Einstein drew a line and wrote $\int dxdydz$ to indicate that he wanted to integrate this equation over three-dimensional space. When the first term of the expression on the left-hand side of equation (675) is integrated over all of space, the first three terms of the summation over n vanish on account of Gauss' theorem (and suitable assumptions about $T_{\mu\nu}$), while the time

328 The same pattern can be found in (Einstein and Grossmann 1913, sec. 4). First, Einstein derives the energy-momentum balance between matter and gravitational field from the equations of motion, closely following the calculation on p 5R; then he mentions that the latter can be recovered from the former by "integration over the filament of the flow" ("Integration über Stromfaden").

derivative in the $n = 4$ term commutes with taking the integral. Using x_t and $T_{\nu t}$ for x_4 and $T_{\nu 4}$, respectively, Einstein could thus write the integral as:

$$\frac{\partial}{\partial x_t}\left(\int g_{\mu\nu} T_{\nu t} dxdydz\right) - \frac{1}{2}\int \frac{\partial g_{\mu\nu}}{\partial x_m} T_{\mu\nu} dxdydz\,. \tag{676}$$

He then substituted

$$T_{\mu\nu} = \rho \frac{dx_\mu}{ds}\frac{dx_\nu}{ds}\,, \tag{677}$$

the stress-energy tensor for pressureless dust, and the relation

$$dxdydz = \frac{V}{\sqrt{G}}\frac{ds}{dt} \tag{678}$$

between the volume $dxdydz$ in the coordinates used and the rest volume $V = d\xi d\eta d\zeta$ of the particles described by $T_{\mu\nu}$. This relation follows from the relation $\sqrt{G} \cdot dxdydzdt = d\xi d\eta d\zeta ds$ written to the far right of equations (675)–(676) in the notebook. Using furthermore that the density ρ is non-vanishing only inside the filament representing the flow of matter, Einstein arrived at

$$\frac{d}{dt}\left(g_{\mu\nu}\rho \frac{dx_\nu}{ds}\frac{dt}{ds} \cdot \frac{ds}{dt}\frac{V}{\sqrt{G}}\right) - \frac{1}{2}\int \frac{\partial g_{\mu\nu}}{\partial x_m}\rho \frac{dx_\mu}{ds}\frac{dx_\nu}{ds} \cdot \frac{V}{\sqrt{G}}\frac{ds}{dt}\,, \tag{679}$$

as is indicated in the line following expression (676) in the notebook.[329] The factors $\sqrt{G}$ should be set equal to 1: if Einstein had not set $\sqrt{G} = 1$ in going from equation (71) to equation (675), the factors $\sqrt{G}$ would simply cancel at this point. Dividing by ρV, Einstein rewrote expression (679) as:

$$\frac{d}{dt}\left(\frac{1}{\sqrt{G}} g_{m\nu}\frac{dx_\nu}{ds}\right) - \frac{1}{2}\frac{1}{\sqrt{G}}\frac{\partial g_{\mu\nu}}{\partial x_m}\frac{dx_\mu}{dt}\frac{dx_\nu}{dt}\frac{dt}{ds}\,. \tag{680}$$

Setting $\dot{x}_\mu \equiv dx_\mu/dt$ and $w \equiv ds/dt$,[330] he rewrote this expression as

$$\frac{d}{dt}\left(\frac{1}{\sqrt{G}}\frac{g_{m\nu}\dot{x}_\nu}{w}\right) - \frac{1}{2}\frac{1}{\sqrt{G}}\frac{\frac{\partial g_{\mu\nu}}{\partial x_m}\dot{x}_\mu \dot{x}_\nu}{w}\,, \tag{681}$$

and, finally, as

$$\frac{d}{dt}\left(\frac{1}{\sqrt{G}}\frac{\partial w}{\partial \dot{x}_m}\right) - \left(\frac{1}{\sqrt{G}}\frac{\partial w}{\partial x_m}\right). \tag{682}$$

---

329 In the second term, Einstein wrote m instead of x_m.

330 The same notation is used in the Einstein-Besso manuscript on the perihelion advance of Mercury (CPAE 4, Doc. 14, e.g., [p. 15], [eq. 105]).

Setting this expression (with $\sqrt{G} = 1$) equal to zero, one recovers the Euler-Lagrange equations for the Lagrangian $H = w = ds/dt$ (see p. 5R and equation (55)). This shows that the equations of motion of a test particle in a metric field can indeed be derived from the energy-momentum balance between matter and gravitational field.

5.6 *Transition to the Entwurf Strategy (24R–25R)*

24R–25R

On pp. 19L–23L, Einstein had extracted various candidates for the left-hand side of the field equations from the Ricci tensor and the November tensor by imposing suitable coordinate restrictions. These coordinate restrictions should (*a*) make it possible to eliminate all unwanted terms with second-order derivatives of the metric, (*b*) be compatible with energy-momentum conservation at least in linear approximation, and (*c*) minimally allow transformations to accelerated frames of reference in Minkowski spacetime. In this way, Einstein's heuristic requirements (the correspondence principle, the conservation principle, the equivalence principle, and the relativity principle) would all at least to some extent be satisfied. All coordinate restrictions he had considered, however, failed on one count or another.

On p. 24R, Einstein proposed yet another candidate for the left-hand side of the field equations. However, while the various candidates proposed on pp. 19L–23L had been products of Einstein's mathematical strategy, the new candidate was a product of the physical strategy.[331] Instead of extracting candidate field equations from the Ricci tensor with various coordinate restrictions, Einstein on p. 24R generated field equations starting from the requirement of energy-momentum conservation. That does not mean that Einstein had now given up on the mathematical strategy altogether. The weak-field equations he started from and the restriction to unimodular transformations in all calculations on p. 24R strongly suggest that Einstein hoped to connect the field equations found through considerations of energy-momentum conservation to the November tensor. On p. 25L Einstein explicitly tried find a coordinate restriction with which he could recover field equations found along the lines of the argument on p. 24R from the November tensor.

At the top of p. 24R, Einstein wrote down an expression that can be identified as the divergence of a quantity representing gravitational stress-energy density. Although the derivation of this expression is not in the notebook, there are enough clues to give a plausible reconstruction of how Einstein arrived at it. As he had done for other linearized field equations on pp. 19R, 20L, and 21L, Einstein used the linearized version of field equations extracted from the November tensor to rewrite, in linear approximation, the gravitational force density as the divergence of the gravitational stress-energy pseudo-tensor. The expression at the top of p. 24R is the result of this calculation.

---

331 See sec. 1.2 for a discussion of these two strategies.

The gravitational stress-energy pseudo-tensor that one finds in this linear approximation looks like a plausible candidate for the exact expression for this quantity. It is understandable therefore that Einstein proceeded to look for terms that would need to be added to the weak-field equations to make sure that the expression at the top of p. 24R becomes *exactly* equal to the gravitational force density (see sec. 5.6.1). Essentially the same method would give him the *Entwurf* field equations on pp. 26L–R and in (Einstein and Grossmann 1913).[332]

Field equations constructed in this manner automatically satisfy both the correspondence principle and the conservation principle. The problem is to determine whether they are covariant under a wide enough class of coordinate transformations to meet the requirements of the relativity and equivalence principles as well. In the case of field equations extracted from the Ricci tensor or the November tensor with the help of coordinate restrictions, this question can, at least in principle, be settled by examining the transformation properties of expressions much simpler than the left-hand side of the field equations, such as the Hertz expression or the ϑ-expression. In the case of the field equations introduced on p. 24R, the construction of the equations is of no help in determining their covariance properties. The construction only guarantees that the equations will be covariant under unimodular linear transformations (unimodular because the determinant of the metric is set equal to unity in all calculations on p. 24R).

At the bottom of p. 24R, Einstein checked whether the rotation metric is a solution of the new field equations. According to the first entry on p. 24R, the expression from which they were derived vanishes for the rotation metric, a necessary condition for the rotation metric to be a solution of the vacuum field equations. This was an encouraging result—itself in error, it turns out—but Einstein discovered that the rotation metric is in fact not a solution of his new field equations. He also discovered, however, that he had erroneously cancelled two terms in his derivation of these equations. There would consequently be additional terms quadratic in first-order derivatives of the metric in the field equations. This in turn opened up the possibility that, once the equations were corrected, the rotation metric would be a solution after all.

Rather than making these corrections, Einstein (on pp. 25L–R) tried to find a coordinate restriction with the help of which (the corrected version of) these new field equations could be recovered from the November tensor (see sec. 5.6.2). In other words, he examined whether the field equations found following the physical strategy could also be found following the mathematical strategy. At the bottom of p. 25L he indicated which terms in the November tensor would have to be eliminated by imposing a coordinate restriction and which ones preserved. At the top of p. 25R, Einstein considered an ingenious modification of the ϑ-restriction, which we shall call the $\hat{\vartheta}$-restriction (see sec. 5.6.3), although it is not clear whether the purpose of the $\hat{\vartheta}$-

332 Einstein had in effect used this method before to derive the final version of the field equations for his theory for static gravitational fields in 1912. In that case, he had also added terms to the original field equations of the theory to make sure that they be compatible with energy-momentum conservation (see Einstein 1912b, 455–456).

restriction was to extract (the corrected version of) the candidate field equations of p 24R from the November tensor. In any case, Einstein failed to connect the November tensor to the physically motivated field equations of p. 24R, a connection that would have helped clarify the covariance properties of the latter.

It is at this point in the notebook that Einstein abandoned the mathematical strategy completely. On the remainder of p. 25R, Einstein started tinkering with the expression found on p. 24R for the left-hand side of field equations to make sure that it vanishes for the rotation metric (see sec. 5.6.4). Undeterred by the fact that the resulting expression is mathematically ill-defined, he checked whether this modified expression still allowed him to write the gravitational force density as the divergence of gravitational stress-energy density. He found that it did not, at least not exactly (see sec. 5.6.5). It may have been because the resulting conflict with energy-momentum conservation already ruled out this ill-defined expression as a candidate for the left-hand side of the field equations, but Einstein made no attempt to connect the modified expression with the November tensor. On p. 25L and at the top of p. 25R, Einstein had used the mathematical strategy to complement the physical strategy that he had used on p. 24R. On the remainder of p. 25R, however, Einstein apparently decided to go exclusively with the physical strategy, which on the very next page gave him the *Entwurf* equations.

5.6.1 *Constructing Field Equations from Energy-Momentum Conservation and Checking Them for Rotation (24R)* 24R

At the top of p. 24R, Einstein wrote down the expression[333]

$$\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\right)-\frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right), \tag{683}$$

and noted that it vanishes for a metric field that he wrote down as

$$\begin{array}{ccc} & g & \\ -1 & 0 & \omega y \\ 0 & -1 & -\omega x \\ -y & -\omega x & 1-\omega^2(x^2+y^2) \end{array} \qquad \begin{array}{ccc} & \gamma & \\ -1+\omega^2 y^2 & \omega x y & \omega y \\ \omega x y & -1+\omega^2 x^2 & -\omega x \\ \omega y & -\omega x & 1. \end{array} \tag{684}$$

He explicitly wrote: “The expression [683] vanishes for the system [684]” (“Der Ausdruck … verschwindet für das System …”). The metric in equation (684) is easily recognized, despite some discrepancies, which are probably due to slips on Einstein’s part, as the rotation metric with one spatial dimension suppressed. It is harder to see what expression (683) represents. This seems to be one of the few places in the notebook where the calculations are not self-contained. Fortunately, a convincing case can be made for the following reconstruction of how Einstein arrived at expression (683).

333 In the notebook, the partial derivative with respect to x_i in the first term in equation (683) is written as an ordinary derivative.

In the field equations extracted from the November tensor with the help of the ϑ-restriction, the term with second-order derivatives of the metric is written as (see, e.g., expression (584) [p. 23L] and expressions (652) and (654) [p. 43LA])[334]

$$\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\right), \tag{685}$$

where the labeling of the indices is chosen with a view to expression (683), the derivation of which we want to reconstruct. In linear approximation this is the only non-negligible term on the left-hand side of these field equations. The linearized version of these equation thus becomes

$$\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\right) = \kappa\Theta_{\alpha\beta}, \tag{686}$$

where $\Theta_{\alpha\beta}$ is the covariant stress-energy tensor in the notation that Einstein used in the notebook.[335] Energy-momentum conservation required that these linearized field equations can be used to rewrite the gravitational force density as the divergence of a quantity representing gravitational stress-energy density.[336] Einstein had checked this for the linearized field equations considered on p. 19R (see equation (481)) and on p. 20L (see equation (500)). A natural explanation of how he arrived at the expression at the top of p. 24R is that he did the same for the linearized field equations (686).

The expression for the force density can be read off from the energy-momentum balance between matter and gravitational field in either its covariant or its contravariant form. On p. 24L, the page immediately preceding the one under consideration here, Einstein had actually considered both possibilities in his attempt to find a physical interpretation for the ϑ-metric (see sec. 5.5.9). These two alternative expressions for the force density are

$$-\frac{1}{2}\frac{\partial g_{\alpha\beta}}{\partial x_\sigma}T_{\alpha\beta}, \tag{687}$$

where $T_{\alpha\beta}$ is the contravariant stress-energy tensor, and

$$\frac{1}{2}\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\Theta_{\alpha\beta} \tag{688}$$

---

334 In the equations extracted from the November tensor with the Hertz restriction (see equation (558) [p. 22R]) and in those extracted from the Ricci tensor with the harmonic restriction (see equation (477) [p. 19L]), the term with second-order derivatives is written as $\gamma_{\alpha\beta}\frac{\partial^2 g_{il}}{\partial x_\alpha \partial x_\beta}$. The two expressions only differ, of course, by a term quadratic in first-order derivatives of the metric.

335 See, e.g., equation (663). In our reconstruction of the derivation of equation (683), we follow the notation of the notebook.

336 Cf. the discussion following equation (481) in sec. 5.4.2.

(cf. expressions (659) and (668), respectively). Note that these expressions are correct only in linear approximation. In the exact version there will be another factor $\sqrt{-g}$ (cf. expression (482)), which in linear approximation can be set equal to unity.

On pp. 19R, 20L, and 21L, Einstein had used expression (687) for the force density but had substituted the left-hand side of the *covariant* linearized field equations for the *contravariant* stress-energy tensor (cf. footnote 241). Using expression (688) instead and eliminating the stress-energy tensor with the help of the linearized field equations (686), one arrives at

$$\frac{1}{2\kappa}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\right). \tag{689}$$

Ignoring the factor 2κ (as Einstein did in the corresponding calculations on pp. 19R, 20L, and 21L), one can rewrite this expression as

$$\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\right)-\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_i\partial x_\sigma}. \tag{690}$$

The first term is identical to the first term in expression (683) written at the top of p. 24R. The second term can be rewritten in the form of the second term in expression (683) if terms of third power in derivatives of the metric are neglected. Such third-power terms would correspond to quadratic terms in the field equations. Since this whole calculation is based on the linearized field equations, such terms can indeed be neglected. One can thus write the second term in expression (690) as

$$\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_i\partial x_\sigma} = \frac{\partial}{\partial x_\sigma}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\right)-\gamma_{i\varepsilon}\frac{\partial^2 g_{\alpha\beta}}{\partial x_\sigma\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}. \tag{691}$$

Once again neglecting terms of third power in derivatives of the metric, one easily establishes that the last term on the right-hand side is equal and opposite to the term on the left-hand side[337]

$$\gamma_{i\varepsilon}\frac{\partial^2 g_{\alpha\beta}}{\partial x_\sigma\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i} = \gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_i\partial x_\sigma}. \tag{692}$$

equation (691) can thus be rewritten as

337 Farther down on p. 24R, Einstein initially cancelled these two terms with one another in a calculation that is supposed to be exact. He later rescinded these calculations. We prove the approximate equality of these two terms in modern notation. Using that $0 = (g^{\mu\rho}g_{\rho\nu})_{,\alpha} = g^{\mu\rho}{}_{,\alpha}g_{\rho\nu}+g^{\mu\rho}g_{\rho\nu,\alpha}$, one can write $g_{\alpha\beta,\varepsilon\sigma}g^{\alpha\beta}{}_{,i} = (-g_{\alpha\mu}g_{\beta\nu}g^{\mu\nu}{}_{,\varepsilon})_{,\sigma}(-g^{\alpha\kappa}g^{\beta\lambda}g_{\kappa\lambda,i})$. If terms of third power in derivatives of the metric are neglected, this reduces to $g_{\alpha\beta,\varepsilon\sigma}g^{\alpha\beta}{}_{,i} = g^{\alpha\beta}{}_{,\varepsilon\sigma}g_{\alpha\beta,i}$. Contracting both sides with $g^{i\varepsilon}$ and switching i and ε on the right-hand side, one arrives at $g^{i\varepsilon}g_{\alpha\beta,\varepsilon\sigma}g^{\alpha\beta}{}_{,i} = g^{i\varepsilon}g^{\alpha\beta}{}_{,i\sigma}g_{\alpha\beta,\varepsilon}$, which is what we set out to prove.

$$\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_i \partial x_\sigma} = \frac{1}{2}\frac{\partial}{\partial x_\sigma}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right). \qquad (693)$$

Substituting this expression for the second term in expression (690), one recovers expression (683) written at the top of p. 24R.

The reconstruction given here of how Einstein arrived at this expression also seems to fit with the deleted phrase on the very first line of p. 24R: "divergence of a plane tensor Θ_{ik}" ("Divergenz eines Ebenentensors Θ_{ik}").[338] The expression in equation (683) is, in fact, the divergence of (-2κ times) the covariant gravitational stress-energy pseudo-tensor of the *Entwurf* theory.[339] The notation Θ_{ik} suggests that Einstein was referring to the stress-energy tensor of matter rather than to the stress-energy pseudo-tensor of the gravitational field, but energy-momentum conservation requires the divergence of the latter to be equal and opposite to the divergence of the former. The deleted phrase at the top of p. 24R thus seems to provide additional support for our reconstruction of the derivation of expression (683).

If there is no matter, energy-momentum conservation requires that the divergence of the stress-energy pseudo-tensor of the gravitational field vanishes. It follows that expression (683) should vanish for vacuum solutions of the field equations, at least in linear approximation. As becomes clear on the bottom half of p. 24R, Einstein tried to find the exact field equations corresponding to the linearized field equations (686) on the assumption that expression (683) is exactly equal to the gravitational force density. In that case, the expression should vanish exactly for vacuum solutions of the field equations. We can thus understand why it was important for Einstein to check whether the expression vanish exactly, for instance, for the rotation metric, which should be a vacuum solution of any acceptable candidate field equations according to Einstein's heuristic principles.

Contrary to Einstein's claim at the top of p. 24R, expression (683) does not vanish for the rotation metric. In the $2+1$-dimensional case, the covariant components of the rotation metric are given by

338 The term "plane tensor" ("Ebenentensor") is used in the notebook for a covariant tensor (cf. p. 17L and the discussion in sec. 5.3.3).

339 Relabeling indices to make it easier to compare the expression in the notebook with the corresponding expressions in the *Entwurf* paper, we can rewrite expression (683) as:

$$\frac{\partial}{\partial x_\nu}\left(\gamma_{\mu\nu}\left[\frac{\partial g_{\tau\rho}}{\partial x_\mu}\frac{\partial \gamma_{\tau\rho}}{\partial x_\sigma} - \frac{1}{2}g_{\mu\sigma}\gamma_{\alpha\beta}\frac{\partial g_{\tau\rho}}{\partial x_\alpha}\frac{\partial \gamma_{\tau\rho}}{\partial x_\beta}\right]\right).$$

The quantity in square brackets is equal to $-2\kappa t_{\mu\sigma}$ as defined in (Einstein and Grossmann 1913, p. 16, equation (14)). Substituting this definition into the expression above and dividing by -2, one arrives at the left-hand side of equation (12b) of the same paper for the special case that $\sqrt{-g} = 1$. Equation (12b) is obtained from equation (12), the left-hand side of which reduces to expression (683) if one sets $\sqrt{-g} = 1$.

$$g_{\mu\nu} = \begin{pmatrix} -1 & 0 & \omega y \\ 0 & -1 & -\omega x \\ \omega y & -\omega x & 1-\omega^2(x^2+y^2) \end{pmatrix}, \tag{694}$$

and the contravariant components by

$$\gamma_{\mu\nu} = \begin{pmatrix} -1+\omega^2 y^2 & -\omega^2 xy & \omega y \\ -\omega^2 xy & -1+\omega^2 x^2 & -\omega x \\ \omega y & -\omega x & 1 \end{pmatrix}. \tag{695}$$

These expressions differ slightly, but significantly as it turns out, from the expressions (684) given in the notebook.

Consider the $\sigma = 1$ component of expression (683) for the metric in equations (694)–(695). One easily verifies that the first term only contributes[340]

$$2\frac{\partial}{\partial x_2}\left(\gamma_{21}\frac{\partial g_{24}}{\partial x_1}\frac{\partial \gamma_{24}}{\partial x_1}\right) = 2\frac{\partial \gamma_{21}}{\partial x_2}\omega^2 = -2\omega^4 x, \tag{696}$$

whereas the second term only contributes[341]

$$-\frac{\partial}{\partial x_1}\left(\gamma_{22}\frac{\partial g_{14}}{\partial x_2}\frac{\partial \gamma_{14}}{\partial x_2}\right) = -\frac{\partial \gamma_{22}}{\partial x_1}\omega^2 = -2\omega^4 x. \tag{697}$$

The $\sigma = 1$ component of expression (683) thus gives $-4\omega^4 x$ for the metric in equations (694)–(695). The $\sigma = 2$ component likewise gives $-4\omega^4 y$.[342] Only the $\sigma = 4$ component vanishes, since the metric is time-independent.

A comparison between the correct expressions for the components of the metric in equations (694)–(695) and Einstein's faulty expression (684) suggests that it was because of the sign errors in γ_{12} and γ_{21} that Einstein came to believe that expression (683) vanishes for the rotation metric. Inserting $\omega^2 xy$ instead of $-\omega^2 xy$ for γ_{21} in equation (696), the contribution coming from equation (696) would cancel the contribution coming from equation (697) and the $\sigma = 1$ component of equation (683) would vanish for the rotation metric.[343]

---

340 There will be identical contributions for $(\alpha = 2, \beta = 4)$ and $(\alpha = 4, \beta = 2)$.

341 There will be identical contributions for $(\alpha = 1, \beta = 4)$ and $(\alpha = 4, \beta = 1)$.

342 The non-vanishing contributions to the $\sigma = 2$ component of expression (683) for this metric are

$$2\frac{\partial}{\partial x_1}\left(\gamma_{12}\frac{\partial g_{14}}{\partial x_2}\frac{\partial \gamma_{14}}{\partial x_2}\right) - \frac{\partial}{\partial x_2}\left(\gamma_{11}\frac{\partial g_{24}}{\partial x_1}\frac{\partial \gamma_{24}}{\partial x_1}\right) = 2\frac{\partial \gamma_{12}}{\partial x_1}\omega^2 - \frac{\partial \gamma_{11}}{\partial x_2}\omega^2 = -4\omega^4 y.$$

343 A similar cancellation would occur in the $\sigma = 2$ component of expression (683) (see the preceding note).

It is interesting to note in this context that the sign error in γ_{12} is the only one of the errors in expression (684) that Einstein repeated on p. 25R where he once again wrote down the components of the rotation metric. What may have happened is that Einstein read off the contravariant components of the rotation metric from the expression for the covariant components of the ϑ-metric on p. 42R (see equation (629)), which would give $\gamma_{12} = \alpha xy$, and then set α equal to ω rather than to $-\omega^2$.

Whatever happened, Einstein somehow convinced himself that expression (683) vanishes exactly for the important special case of the rotation metric.[344] It now made sense for him to look upon equation (683), which he presumably found as the result of a calculation in linear approximation, as the exact expression for the divergence of the gravitational stress-energy density,[345] at least for metric fields with a determinant equal to unity.

It is not entirely clear whether Einstein was aware of this last complication at this point. Perhaps he erroneously continued to use expression (688) for the gravitational force density in linear approximation, even though the calculation on the bottom half of p. 24R was supposed to be exact. It is also possible that he consciously set $\sqrt{-g} = 1$ to facilitate comparison of the result of his calculations with the November tensor, which is a tensor only under unimodular transformations. Einstein would include the factors $\sqrt{-g}$ that were omitted on p. 24R in the derivation of the *Entwurf* equations on p. 26L. Once again it is not clear whether that was because he realized that he should have used the exact expression for the gravitational force density in a calculation that is supposed to be exact or because he was no longer interested in trying to recover his new candidate field equations from the November tensor.

If expression (683) is exactly equal to the divergence of the gravitational stress-energy density and the determinant of the metric is set equal to unity, one can find the exact field equations by going through the derivation of expression (683) given in equations (686)–(693) in reverse, this time without neglecting any terms. More specifically, one can rewrite expression (683) in the form

---

344 In passing we note that Einstein thus missed an early opportunity to discover that the rotation metric is not a solution of the *Entwurf* equations. As was pointed out in footnote 339, expression (683) is the divergence of the gravitational stress-energy pseudo-tensor of the *Entwurf* theory in the special case that $\sqrt{-g} = 1$. The rotation metric has a determinant equal to unity. The vanishing of expression (683) for this metric is therefore a necessary condition for it to be a solution of the *Entwurf* field equations. It expresses energy-momentum conservation in this case. For further discussion of Einstein's struggles with rotation, see (Janssen 1999; 2005, 68–71), and “What Did Einstein Know …” sec. 3 (in this volume).

345 Note the close structural similarity between the expression for gravitational stress-energy density one reads off from expression (683) (see the expression in square brackets in footnote 339) and the gravitational stress tensor of Einstein's 1912 static theory, the 11-component of which Einstein had tried to translate into a gravitational stress-energy (pseudo-)tensor in his metric theory at the bottom of p. 21R (see sec. 5.4.5). This similarity may have been another factor leading Einstein to adopt expression (683) as the *exact* expression for the divergence of the gravitational stress-energy density.

$$\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}(\qquad)_{\alpha\beta} \tag{698}$$

and take the as yet unknown expression in parentheses as the left-hand side of the field equations. After all, substituting the right-hand side of these candidate field equations—the stress-energy tensor $\Theta_{\alpha\beta}$ —for the as yet unknown expression in parentheses above, one recovers (except for an immaterial factor of $\frac{1}{2}$) expression (688) for the gravitational force density

$$\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\Theta_{\alpha\beta}\,. \tag{699}$$

These new field equations thus automatically and exactly satisfy energy-momentum conservation. They guarantee that the gravitational force density is equal to the divergence of the gravitational stress-energy density, in which case the energy-momentum balance between matter and gravitational field can be written as the vanishing of the divergence of the total stress-energy density.

This is exactly Einstein's line of reasoning on p. 24R. With the comment "the above expression yields" ("obiger Ausdruck liefert"), he began to rewrite expression (683) in the form (698):

$$\begin{aligned}&\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\frac{d}{dx_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\right)+\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial^2\gamma_{\alpha\beta}}{\partial x_i\partial x_\sigma}\\ &-\gamma_{i\varepsilon}\frac{\partial^2 g_{\alpha\beta}}{\partial x_\varepsilon\partial x_\sigma}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}-\frac{1}{2}\frac{\partial\gamma_{i\varepsilon}}{\partial x_\sigma}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\end{aligned} \tag{700}$$

In the notebook, Einstein initially (and erroneously) cancelled the second term in this expression against the third.[346] Relabeling the summation indices in the last term, he read off the left-hand side of the field equations from the remaining two terms. "This suggests" ("Hierdurch nahe gelegt"), he wrote,

$$\frac{\partial}{\partial x_i}\left(\gamma_{i\varepsilon}\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\right)-\frac{1}{2}\frac{\partial g_{i\varepsilon}}{\partial x_\alpha}\frac{\partial\gamma_{i\varepsilon}}{\partial x_\beta}\,. \tag{701}$$

Einstein's next step was to check whether expression (701) vanishes for the rotation metric as it should if this metric is to be a vacuum solution of these new field equations. It is not, as Einstein noted on the last two lines of p. 24R: "Tried for the case of a rotating body[.] $\alpha = \beta = 1$ gives $-\omega^2$" ("Probiert am Fall des rot[ierenden] Körpers $\alpha = \beta = 1$ liefert $-\omega^2$").

346 These two terms cancel only if terms of third power in derivatives of the metric are neglected (see equation (692) and footnote 337).

Inserting either our equations (694)–(695) or Einstein's expressions (684)[347] for the components of the rotation metric into the 11 -component of expression (701), one readily verifies this result. The only non-vanishing contributions come from the second term in expression (701)

$$-\frac{\partial g_{24}}{\partial x_1}\frac{\partial \gamma_{24}}{\partial x_1} = -\omega^2 . \tag{702}$$

Einstein's new candidate field equations are therefore unacceptable as they stand. However, Einstein also discovered that the two terms that he had cancelled with one another in his derivation of expression (701) for the left-hand side of his new field equations do in fact not cancel. To the right of expression (700) in the notebook, Einstein did a short calculation to check whether these two terms are equal to one another. He started with the fairly self-evident relation[348]

$$\frac{\partial g_{\alpha\beta}}{\partial x_\sigma}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i} = \frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\frac{\partial g_{\alpha\beta}}{\partial x_i} . \tag{703}$$

This equation expresses that one can simply switch co- and contravariant components of the metric in contractions of two first-order derivatives of this form. One might expect that this is also true for similar contractions of a first-order derivative and a second-order derivative. Differentiating equation (703) with respect to x_ε, however, as Einstein did on the next line,

$$\frac{\partial^2 g_{\alpha\beta}}{\partial x_\varepsilon \partial x_\sigma}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i} + \frac{\partial g_{\alpha\beta}}{\partial x_\sigma}\frac{\partial^2 \gamma_{\alpha\beta}}{\partial x_\varepsilon \partial x_i} = \frac{\partial^2 \gamma_{\alpha\beta}}{\partial x_\varepsilon \partial x_\sigma}\frac{\partial g_{\alpha\beta}}{\partial x_i} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\frac{\partial^2 g_{\alpha\beta}}{\partial x_\varepsilon \partial x_i} , \tag{704}$$

one sees that this is not the case. At this point, Einstein probably rescinded his cancellations in expression (700) with the proof readers' stet mark that he typically used for this purpose.

On the face of it, these two terms in expression (700) would contribute additional terms with unwanted second-order derivatives of the metric to the field equations in equation (701). However, as we already noted in our reconstruction of the derivation of equation (683), the two terms only differ by an expression of third power in first-order derivatives of the metric (see footnote 337). They thus only give rise to another term quadratic in first-order derivatives of the metric in the field equations.

Einstein did not add such a term to expression (701), but he probably realized that his new candidate field equations only needed to be corrected by terms quadratic in first-order derivatives rather than by second-order derivative terms. Otherwise it becomes hard to understand his calculations on the next page. On p. 25L he looked for a new coordinate restriction to extract field equations from the November tensor,

347 The errors in (684) do not matter in this calculation.

348 In modern notation, the proof runs as follows (cf. footnote 337):

$$g_{\alpha\beta,\sigma}g^{\alpha\beta}{}_{,i} = (-g_{\alpha\mu}g_{\beta\nu}g^{\mu\nu}{}_{,\sigma})(-g^{\alpha\kappa}g^{\beta\lambda}g_{\kappa\lambda,i}) = \delta^\kappa_\mu\delta^\lambda_\nu g^{\mu\nu}{}_{,\sigma}g_{\kappa\lambda,i} = g^{\kappa\lambda}{}_{,\sigma}g_{\kappa\lambda,i} .$$

using as his guide that these equations should at least include the two terms in expression (701) and no additional terms with second-order derivatives of the metric.

All in all, Einstein had made important progress on p. 24R. He had found a method to construct exact field equations out of linearized ones by demanding exact compliance with energy-momentum conservation. The first result of this method, however, was problematic. He found that the rotation metric is not a solution of his new field equations. Einstein also realized, however, that he had made an error along the way. It was thus at least conceivable that the correct application of his new method would yield field equations that do allow the rotation metric as a solution.

5.6.2 *Trying to Recover the Physically Motivated Field Equations from the November Tensor (25L)* 25L

On p. 25L, Einstein tried to recover the field equations he had found on p. 24R from the November tensor, not just the two terms explicitly given at the bottom of p. 24R (see expression (701)) but also the additional terms coming from the erroneously cancelled terms in expression (700) for the gravitational force density from which he had read off these new field equations.

At the top of p. 25L, Einstein wrote down the November tensor (see equation (544))

$$\frac{\partial}{\partial x_k}\begin{Bmatrix}\alpha & \beta \\ & k\end{Bmatrix} - \begin{Bmatrix}\alpha & \lambda \\ & \mu\end{Bmatrix}\begin{Bmatrix}\beta & \mu \\ & \lambda\end{Bmatrix}. \tag{705}$$

A first indication that his purpose was to recover his new candidate field equations from this object is that he changed the free indices i and l in the original expression for the November tensor to α and β, the free indices in expression (701) for the left-hand side of the new candidate field equations. Using the definitions of the Christoffel symbols, Einstein rewrote (2 times) expression (705) as

$$\begin{gathered}\frac{\partial}{\partial x_k}\gamma_{k\lambda}\left[\frac{\partial g_{\alpha\lambda}}{\partial x_\beta} + \frac{\partial g_{\beta\lambda}}{\partial x_\alpha} - \underline{\frac{\partial g_{\alpha\beta}}{\partial x_\lambda}}\right] - \frac{1}{2}\gamma_{\mu\sigma}\gamma_{\lambda\tau}\left[\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda} - \frac{\partial g_{\alpha\lambda}}{\partial x_\sigma}\right]\left[\frac{\partial g_{\beta\tau}}{\partial x_\mu} - \frac{\partial g_{\beta\mu}}{\partial x_\tau}\right] \\ -\frac{1}{2}\underline{\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\lambda\sigma}}{\partial x_\alpha}\frac{\partial g_{\mu\tau}}{\partial x_\beta}}\end{gathered} \tag{706}$$

From the way the product of Christoffel symbols in expression (705) was rewritten in expression (706), it is clear that Einstein once again used the symmetry argument that he had already used several times before in this calculation (on pp. 17R, 19L, and 22R; see the discussion following expression (463)). The two terms that Einstein underlined in expression (706) are easily recognized as (minus) the two terms of the new candidate field equations in equation (701). For the first term this is just a matter of relabeling indices. For the second term it is shown by the calculation immediately following expression (706) in the notebook. Using that

$$\gamma_{\lambda\tau}\frac{\partial g_{\lambda\sigma}}{\partial x_\alpha} = -\frac{\partial\gamma_{\lambda\tau}}{\partial x_\alpha}g_{\lambda\sigma} \tag{707}$$

and that

$$\gamma_{\mu\sigma}g_{\lambda\sigma}\frac{\partial g_{\mu\tau}}{\partial x_\beta} = \frac{\partial g_{\lambda\tau}}{\partial x_\beta}, \tag{708}$$

Einstein rewrote (-2 times) the last term in expression (706) as

$$\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\lambda\sigma}}{\partial x_\alpha}\frac{\partial g_{\mu\tau}}{\partial x_\beta} = -\frac{\partial\gamma_{\lambda\tau}}{\partial x_\alpha}\frac{\partial g_{\lambda\tau}}{\partial x_\beta} = -\frac{\partial\gamma_{\lambda\tau}}{\partial x_\beta}\frac{\partial g_{\lambda\tau}}{\partial x_\alpha}. \tag{709}$$

In the notebook, the relations (707) and (708) are given underneath the relevant terms on the left-hand side of equation (709). Dividing the right-hand side of equation (709) by 2, one recovers the second term in expression (701).

This was a promising start. The next task would be to identify those terms in the November tensor that still need to be added to the field equations based on expression (701) because of the erroneous cancellation of two terms in expression (700) for the gravitational force density. These terms would have to come from the second of the three terms in expression (706). This is the term that Einstein turned to next. It can be rewritten as

$$-\frac{1}{2}\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda}\left(\frac{\partial g_{\beta\tau}}{\partial x_\mu}-\frac{\partial g_{\beta\mu}}{\partial x_\tau}\right)+\frac{1}{2}\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\alpha\lambda}}{\partial x_\sigma}\left(\frac{\partial g_{\beta\tau}}{\partial x_\mu}-\frac{\partial g_{\beta\mu}}{\partial x_\tau}\right). \tag{710}$$

The second term in this expression is equal and opposite to the first, as one easily verifies by relabeling indices ($\lambda\sigma\mu\tau \rightarrow \sigma\lambda\tau\mu$). Expression (710) can thus be rewritten as

$$-\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda}\frac{\partial g_{\beta\tau}}{\partial x_\mu}+\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda}\frac{\partial g_{\beta\mu}}{\partial x_\tau}, \tag{711}$$

which is the expression written on the next line in the notebook. To facilitate comparison with the two cancelled terms in expression (700), Einstein contracted expression (711) with $\partial\gamma_{\alpha\beta}/\partial x_i$, which appears next to it separated by a vertical line. If the terms in expression (711) were part of the left-hand side of the field equations, this contraction would give their contribution to the gravitational force density. Einstein rewrote the first term in expression (711) as

$$-\frac{\partial\gamma_{\mu\sigma}}{\partial x_\lambda}\frac{\partial\gamma_{\lambda\tau}}{\partial x_\mu}g_{\alpha\sigma}g_{\beta\tau}, \tag{712}$$

which, upon contraction with $\dfrac{\partial\gamma_{\alpha\beta}}{\partial x_i}$ gives

$$+\frac{\partial\gamma_{\mu\sigma}}{\partial x_\lambda}\frac{\partial\gamma_{\lambda\alpha}}{\partial x_\mu}\frac{\partial g_{\alpha\sigma}}{\partial x_i}. \tag{713}$$

The calculation was not pursued any further.

Einstein drew a horizontal line and schematically rewrote (parts of) the three terms in expression (706) for the November tensor at the top of the page[349]

$$\begin{array}{ll} \frac{\partial}{\partial x_k}\left(\gamma_{k\lambda}\frac{\partial g_{\alpha\beta}}{\partial x_\lambda}\right) & -\frac{1}{2}\;\underline{\qquad\qquad} \\ & -\frac{1}{2}\;\underline{\qquad\qquad} \end{array} \tag{714}$$

The first term in equation (714) is the last of the three terms with second-order derivatives of the metric in equation (706) and the only one that occurs in the candidate field equations on p. 24R (see equation (701)). The problem is to find a coordinate restriction with the help of which the other two second-order derivative terms in the November tensor can be eliminated. Application of this coordinate restriction will also eliminate some of the terms quadratic in first-order derivatives that are schematically indicated in the last two terms in expression (714). A suitable coordinate restriction, however, should preserve the last term in its entirety (i.e., the second underlined term in expression (706)) as well as the part of the second term corresponding to the erroneously cancelled terms in expression (700). In this way the field equations of p. 24R could be extracted from the November tensor.

Labeling the three terms in expression (706) for the November tensor a, b, and c, respectively, and using a prime to distinguish parts that should be preserved from parts that should be eliminated, one can schematically write expression (706) as[350]

$$a - a' - b + b' + c'. \tag{715}$$

The signs of a' and c' reflect that the signs with which the corresponding expressions occur in the November tensor are the opposite of the signs with which they occur in the field equations of p. 24R. Stated in terms of expression (715), the problem is to find a coordinate restriction such that a and b can be eliminated and the left-hand side of the field equations becomes:

$$a' - b' - c'. \tag{716}$$

Since Einstein did not pursue the calculation on p. 25L any further it is hard to interpret the material at the bottom of the page, but the reasoning leading to equations

---

349 In the notebook, some of the indices in the first term in expression (714) are barely legible. They have been transcribed on the assumption that Einstein copied this term from the corresponding term in expression (706).

350 More explicitly, $a' \equiv \frac{\partial}{\partial x_k}\left(\gamma_{k\lambda}\frac{\partial g_{\alpha\beta}}{\partial x_\lambda}\right)$ and $c' \equiv \frac{1}{2}\frac{\partial\gamma_{\lambda\tau}}{\partial x_\beta}\frac{\partial g_{\lambda\tau}}{\partial x_\alpha}$.

(715) and (716) above at least provides a plausible interpretation of the two lines at the bottom the p. 25L,

$$\begin{array}{ccc} a - a' & -b + b' & +c' \\ a' & -b' & -c'. \end{array} \tag{717}$$

It remains unclear why next to this expression he wrote down the terms

$$\begin{gathered} 2\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda}\frac{\partial g_{\mu\tau}}{\partial x_\beta} \\ +\frac{\partial g_{\beta\tau}}{\partial x_\mu}\frac{\partial g_{\lambda\sigma}}{\partial x_\alpha}. \end{gathered} \tag{718}$$

These terms can be identified as coming from the expression

$$-\frac{1}{2}\gamma_{\mu\sigma}\gamma_{\lambda\tau}\frac{\partial g_{\lambda\sigma}}{\partial x_\alpha}\left(\frac{\partial g_{\beta\tau}}{\partial x_\mu}-\frac{\partial g_{\beta\mu}}{\partial x_\tau}\right)+\frac{1}{2}\gamma_{\mu\sigma}\gamma_{\lambda\tau}\left(\frac{\partial g_{\alpha\sigma}}{\partial x_\lambda}-\frac{\partial g_{\alpha\lambda}}{\partial x_\sigma}\right)\frac{\partial g_{\mu\tau}}{\partial x_\beta}, \tag{719}$$

which Einstein neglected in his expansion of (twice) the product of Christoffel symbols in equation (706) on the basis of the symmetry argument that he had come to use routinely in this calculation. Both terms vanish identically, since they are contractions of a part that is symmetric and a part that is anti-symmetric in the same index pair. Perhaps Einstein wanted to include these terms because the application of the coordinate restriction he was looking for at this point would preserve some of the terms in equation (719) while eliminating others. Even on this interpretation, however, it remains unclear what special appeal the two terms in equation (718) had for Einstein or why they appear with a factor 2 rather than with a factor $1/2$ as in equation (717).

Despite these uncertainties, it seems clear that the purpose of Einstein's calculations on p. 25L was to find a way of extracting the physically motivated field equations of p. 24R from the November tensor.[351] The material on the bottom half of the page strongly suggests that Einstein hoped to achieve this goal by finding a coordinate restriction that would allow him to eliminate all terms from the November tensor that do not occur in these new field equations.

At the top of the next page, p. 25R, Einstein considered a variant of the ϑ-restriction, with the help of which he had eliminated unwanted terms from the November tensor on p. 23L. There is no indication, however, that Einstein specifically introduced or used this restriction to recover the field equations of p. 24R and its correction terms from the November tensor.

351 This is similar to Einstein's attempt on pp. 9L–9R to connect the physically motivated core operator to the mathematically well-defined second Beltrami invariant.

5.6.3 *The $\hat{\vartheta}$-Restriction (25R, 23L)* 25R, 23L

The fragmentary material at the top of p. 25R—various arrays of numbers, the components of the rotation metric, and several equations—can all be understood as part of a variant of the calculations on p. 23L and pp. 42L–R involving what we have called the ϑ-restriction. We shall call this variant the $\hat{\vartheta}$-restriction. This interpretation of the material on p. 25R also explains the alternate signs in many of the expressions on p. 23L. Einstein, it seems, went back to p. 23L and indicated what would need to be changed in his earlier calculation if the ϑ-restriction were replaced by the $\hat{\vartheta}$-restriction. Most of what is actually written down at the top of p. 25R is aimed at determining whether the $\hat{\vartheta}$-restriction allows transformations to rotating frames of reference in Minkowski spacetime. It does not, which is probably why the $\hat{\vartheta}$-restriction was quickly abandoned.

The basic idea of the ϑ-restriction (see sec. 5.5.4) was to absorb terms that need to be eliminated from the November tensor into the so-called ϑ-expression. The November tensor was then split into various parts that separately transform as tensors under ϑ-transformations, i.e., those unimodular transformations under which the ϑ-expression transforms as a tensor. Subtracting the parts containing the terms that need to be eliminated, one arrives at candidate field equations that are invariant under ϑ-transformations.

Looking at the first term of the November tensor, which Einstein had just reexamined on p. 25L (cf. expressions (705)–(706) on p. 25L),

$$\frac{\partial}{\partial x_k}\begin{Bmatrix}\alpha & \beta \\ & k\end{Bmatrix} = \frac{\partial}{\partial x_k}\left(\gamma_{k\lambda}\frac{1}{2}\left[\frac{\partial g_{\alpha\lambda}}{\partial x_\beta} + \frac{g_{\beta\lambda}}{\partial x_\alpha} - \frac{g_{\alpha\beta}}{\partial x_\lambda}\right]\right), \tag{720}$$

one sees that the unwanted terms with second-order derivatives of the metric come from the first two terms in the Christoffel symbol

$$\begin{bmatrix}\alpha & \beta \\ & \lambda\end{bmatrix} = \frac{1}{2}\left(\frac{\partial g_{\alpha\lambda}}{\partial x_\beta} + \frac{g_{\beta\lambda}}{\partial x_\alpha} - \frac{g_{\alpha\beta}}{\partial x_\lambda}\right). \tag{721}$$

These terms can be absorbed into the ϑ-expression, defined as (see expression (570))

$$\vartheta_{\alpha\beta\lambda} \equiv \frac{1}{2}\left(\frac{g_{\alpha\lambda}}{\partial x_\beta} + \frac{g_{\beta\lambda}}{\partial x_\alpha} + \frac{g_{\alpha\beta}}{\partial x_\lambda}\right). \tag{722}$$

With the help of the ϑ-expression, the Christoffel symbols of the first kind can be written as (see equation (572))

$$\begin{bmatrix}\alpha & \beta \\ & \lambda\end{bmatrix} = \vartheta_{\alpha\beta\lambda} - \frac{\partial g_{\alpha\beta}}{\partial x_\lambda}. \tag{723}$$

The two unwanted terms can also be absorbed into a slightly different expression, which we shall call the $\hat{\vartheta}$-expression, and which we define as

$$\hat{\vartheta}_{\alpha\beta\lambda} \equiv \frac{1}{2}\left(\frac{g_{\alpha\lambda}}{\partial x_\beta} + \frac{g_{\beta\lambda}}{\partial x_\alpha} - 2\frac{g_{\alpha\beta}}{\partial x_\lambda}\right) . \tag{724}$$

With the help of the $\hat{\vartheta}$-expression, the Christoffel symbols of the first kind can be written as

$$\begin{bmatrix} \alpha & \beta \\ & \lambda \end{bmatrix} = \hat{\vartheta}_{\alpha\beta\lambda} + \frac{1}{2}\frac{\partial g_{\alpha\beta}}{\partial x_\lambda} . \tag{725}$$

The $\hat{\vartheta}$-expression was not written down explicitly in the notebook. In the upper right
25R corner of p. 25R, however, we find the schematic array of numbers

$$\begin{array}{ccc} & & +1 \\ +1 & +1 & -1 \\ & & -2 \end{array} . \tag{726}$$

Note that this is essentially a matrix with three rows and three columns. The first two columns just have $+1$ on all three rows. Comparison of the matrix (726) with equations (721), (722), and (724) suggests the following interpretation of these numbers. The three rows may represent the coefficients of the three terms in the ϑ-expression, the Christoffel symbol, and the $\hat{\vartheta}$-expression, respectively.

One can use either the ϑ-expression or the $\hat{\vartheta}$-expression in combination with the corresponding coordinate restriction to eliminate unwanted terms from the November tensor. The pluses and minuses written above many of the signs in expressions on
23L p. 23L suggest that Einstein actually went back to p. 23L to see what would need to be changed in his earlier calculations if the ϑ-expression were replaced by the $\hat{\vartheta}$-expression. He began with expression (570), the definition of the ϑ-expression (see also equation (722)), where he wrote -2 above the last plus sign,

$$\frac{1}{2}\left(\frac{\partial g_{ik}}{\partial x_\lambda} + \frac{\partial g_{k\lambda}}{\partial x_i} \overset{-2}{+} \frac{\partial g_{\lambda i}}{\partial x_k}\right) . \tag{727}$$

In this way the expression turns into the definition of the $\hat{\vartheta}$-expression (see equation (724)).

Einstein then wrote plus signs above the minus signs in equations (572) and (573) to indicate that he wanted to express the Christoffel symbols of the first and the second kind in terms of this new $\hat{\vartheta}$-expression,

$$\begin{bmatrix} i & l \\ & k \end{bmatrix} = \vartheta_{ilk} \overset{+}{-} \frac{\partial g_{il}}{\partial x_k} , \tag{728}$$

$$\begin{Bmatrix} i & l \\ & k \end{Bmatrix} = \gamma_{k\alpha}\left(\vartheta_{il\alpha} \overset{+}{-} \frac{\partial g_{il}}{\partial x_\alpha}\right) . \tag{729}$$

Comparing equation (728) to equation (725), reading $\hat{\vartheta}$ for ϑ, one sees that there is a factor $1/2$ missing in front of the derivative of the metric in equation (728). Equation (729) inherits this error from equation (728). This may be why Einstein subsequently deleted the plus signs in these two equations. He went through the rest of the calculation on p. 23L, however, on the assumption that the Christoffel symbols are related to the $\hat{\vartheta}$-expression according to equations (728)-(729). He added pluses and minuses to equations (574) and (578), and to expression (581), making only one minor error. He neglected to change the minus sign in the first term in equation (578) to a plus sign. Because of these errors, he found that the field equations extracted from the November tensor with the help of the $\hat{\vartheta}$-restriction are exactly the same as those extracted with the help of the ϑ-restriction (see expression (584)).

Einstein had abandoned these field equations because of problems with the ϑ-restriction (see secs. 5.5.6–5.5.9). Perhaps these problems could be avoided with the $\hat{\vartheta}$-restriction. In particular, it would be interesting to know whether the $\hat{\vartheta}$-expression, unlike the ϑ-expression, vanishes for the rotation metric. In that case the $\hat{\vartheta}$-restriction, unlike the ϑ-restriction, would at least allow transformations to rotating coordinates in the important special case of Minkowski spacetime (cf. the discussion at the beginning of sec. 5.5.6).

At the top of p. 25R, Einstein once again wrote down the covariant and contravariant components of the rotation metric in the $2+1$-dimensional case (cf. equation (694)–(695)) 25R

$$
\begin{array}{ccc}
-1 & 0 & \omega y \\
0 & -1 & -\omega x \\
\omega y & -\omega x & 1-\omega^2(x^2+y^2) \\
\hline
-1+\omega^2 y^2 & \omega^2 xy & \omega y \\
\omega^2 xy & -1+\omega^2 x^2 & -\omega x \\
\omega y & -\omega x & -1 .
\end{array}
\tag{730}
$$

He also wrote down several components of an equation that can more compactly be written as

$$
-2\hat{\vartheta}_{\alpha\beta\lambda} = 2\frac{g_{\alpha\beta}}{\partial x_\lambda} - \frac{g_{\alpha\lambda}}{\partial x_\beta} - \frac{g_{\beta\lambda}}{\partial x_\alpha} = 0 . \tag{731}
$$

The choice of index combinations for which equation (731) was examined on p. 25R confirms that the purpose of Einstein's calculations at this point was to check whether the metric (730) satisfies equation (731), i.e., whether the $\hat{\vartheta}$-expression vanishes for the rotation metric. Notice that expression (730) for the components of the metric is still not completely accurate. Comparing expression (730) to expression (684) for the rotation metric, one sees that most of the errors on p. 24L have been corrected on p. 25R, but that γ_{12} and γ_{21} still have the wrong sign[352] (as does γ_{44} which was given correctly on p. 24L).

To the left of expression (730), Einstein schematically wrote down equation (731) for the index combinations 112 and 121 :

$$2\begin{matrix}1\;1\\2\end{matrix} - \begin{matrix}1\;2\\1\end{matrix} - \begin{matrix}1\;2\\1\end{matrix}\,, \tag{732}$$

$$2\begin{matrix}1\;2\\1\end{matrix} - \begin{matrix}1\;2\\1\end{matrix} - \begin{matrix}1\;1\\2\end{matrix}\,. \tag{733}$$

Both components give the same equation,

$$\frac{\partial g_{12}}{\partial x_1} - \frac{\partial g_{11}}{\partial x_2} = 0\,. \tag{734}$$

This equation is obviously satisfied by the metric (730) as are all components of equation (731) involving only the indices 1 and 2 . Only components in which at least one index is equal to 4 need to be examined. To the right of equation (730), Einstein wrote down equation (731) for three such components, corresponding to the index combinations 124 , 224 , and 441 .[353]

$$2\frac{\partial g_{12}}{\partial x_4} - \frac{\partial g_{14}}{\partial x_2} - \frac{\partial g_{24}}{\partial x_1} = 0 \tag{735}$$

$$\frac{\partial g_{22}}{\partial x_4} - \frac{\partial g_{24}}{\partial x_2} = 0\,, \tag{736}$$

$$\frac{\partial g_{44}}{\partial x_1} - \frac{\partial g_{14}}{\partial x_4} = 0\,. \tag{737}$$

The metric (730) satisfies the first and the second equation, but not the third. Equation (737), the last of the five components of equation (731) given in the notebook, gives

$$\frac{\partial g_{44}}{\partial x_1} - \frac{\partial g_{14}}{\partial x_4} = -2\omega^2 x\,. \tag{738}$$

The $\hat{\vartheta}$-expression therefore does not vanish for the rotation metric. At this point, Einstein seems to have abandoned the $\hat{\vartheta}$-expression and the corresponding $\hat{\vartheta}$-restriction.

In the calculation on the next two lines of p. 25R, the metric that we have called the ϑ-metric briefly resurfaces (for discussion, see sec. 5.6.4). Recall that Einstein

---

352 See the discussion following equation (697) in sec. 5.6.1 for a possible explanation of why Einstein made this particular error.

353 To the left of equation (735), Einstein wrote $\begin{matrix}12\\4\end{matrix}$ to indicate that he was considering the 124 -component of equation (731).

had found the ϑ-metric on p. 42R as a solution of the equation $\vartheta_{\alpha\beta\lambda} = 0$, the analogue of equation (731) for the original ϑ-restriction. The ϑ-metric is obtained by interchanging co- and contravariant components of the rotation metric (see sec. 5.5.6). Despite considerable effort (see pp. 42R, 43LA, 24L and the discussion in secs. 5.5.7 and 5.5.9), Einstein had been unable to find a satisfactory physical interpretation for this metric.

A possible explanation for the reoccurrence of the ϑ-metric on p. 25R is that Einstein checked whether the $\hat{\vartheta}$-expression, like the original ϑ-expression, vanishes for the ϑ-metric. Since $g_{44} = 1$ for the ϑ-metric, equation (737), the 441-component of the equation $\hat{\vartheta}_{\alpha\beta\lambda} = 0$ which was not satisfied by the rotation metric, is trivially satisfied by the ϑ-metric. The ϑ-metric, however, does not satisfy equation (734), the 121-component of the equation $\hat{\vartheta}_{\alpha\beta\lambda} = 0$,[354]

$$\frac{\partial g_{12}}{\partial x_1} - \frac{\partial g_{11}}{\partial x_2} = -\omega^2 y - 2\omega^2 y = -3\omega^2 y. \tag{739}$$

So the $\hat{\vartheta}$-expression does not vanish for the ϑ-metric either. There would thus be no reason for Einstein to resume his efforts to make sense of this peculiar metric. But if Einstein, as we conjectured, did return to the ϑ-metric in this context, it may have given him the idea for another calculation involving the ϑ-metric, which can be found on the next two lines of p. 25R and which we shall turn to below.

5.6.4 *Tinkering with the Field Equations to Make Sure That the Rotation Metric Is a Solution (25R)* 25R

Underneath the material at the top of p. 25R discussed in the preceding subsection, in the two lines above the first horizontal line on p. 25R, Einstein once again wrote down the candidate for the left-hand side of the field equations that he had found on p. 24R (see equation (701))

$$\frac{\partial}{\partial x_\varepsilon}\left(\gamma_{\varepsilon i}\frac{\partial g_{\alpha\beta}}{\partial x_i}\right) - \frac{1}{2}\frac{\partial \gamma_{\lambda\tau}}{\partial x_\alpha}\frac{\partial g_{\lambda\tau}}{\partial x_\beta}. \tag{740}$$

At the bottom of p. 24R he had noted that the 11-component of this expression does not vanish for the rotation metric (see equation (702)). He now inserted the ϑ-metric, i.e., the rotation metric with its co- and contravariant components switched, into the 11-component of equation (740).[355] This gives

$$\frac{\partial}{\partial x_\varepsilon}\left(\gamma_{\varepsilon 2}\frac{\partial g_{11}}{\partial x_2}\right) - \frac{\partial \gamma_{24}}{\partial x_1}\frac{\partial g_{24}}{\partial x_1}. \tag{741}$$

The second term gives $-\omega^2$ for the ϑ-metric as it does for the rotation metric. The first term vanishes for the rotation metric since $g_{11} = -1$, but it does not for the ϑ-

354 Einstein's sign error in g_{12} changes the last two steps in equation (739) to $\omega^2 y - 2\omega^2 y = -\omega^2 y$.
355 For a possible connection between this calculation and the calculations at the top of p. 25R, see the discussion at the end of sec. 5.6.3.

metric which has $g_{11} = -1 + \omega^2 y^2$. In the case of the ϑ-metric, the first term in equation (741) can thus be written as

$$\frac{\partial}{\partial x_\varepsilon}(\gamma_{\varepsilon 2}\ 2\omega^2 y) = \frac{\partial}{\partial x_1}(\gamma_{12}\ 2\omega^2 y) + \frac{\partial}{\partial x_2}(\gamma_{22}\ 2\omega^2 y)\,. \tag{742}$$

Einstein initially confused co- and contravariant components of the ϑ-metric and substituted $\omega^2 xy$ for γ_{12} and $-1 + \omega^2 x^2$ (or rather $-1 + \omega x^2$) for γ_{22}. He subsequently corrected these errors and substituted 0 and -1 for γ_{12} and γ_{22}, respectively. In the notebook, equation (742) was thus written as

$$\frac{\partial}{\partial x_\varepsilon}(\gamma_{\varepsilon 2}\ 2\omega y) = \frac{\partial}{\partial x_1}(\underset{0}{\cancel{\omega^2 xy}} \cdot\ 2\ \omega^2 y) + \frac{\partial}{\partial y}((-1 \cancel{+\omega x^2})\ \cdot\ 2\omega^2 y\,. \tag{743}$$

Even with Einstein's corrections, this equation still contains some minor errors.[356] Einstein also seems to have dropped the minus sign in the second term on the right-hand side at this point. This can be inferred from the fact that he clearly was under the impression that the 11-component of expression (740) would vanish for the ϑ-metric, if only the coefficient of the second term of the expression were changed from $-1/2$ to -1.[357] Inserting the ϑ-metric into this modified version of expression (740) and substituting $2\omega^2$ instead of $-2\omega^2$ for its first term, one arrives at

$$\frac{\partial}{\partial x_\varepsilon}\left(\gamma_{\varepsilon i}\frac{\partial g_{11}}{\partial x_i}\right) - \frac{\partial \gamma_{\lambda\tau}}{\partial x_1}\frac{\partial g_{\lambda\tau}}{\partial x_1} = 2\omega^2 - 2\omega^2 = 0\,. \tag{744}$$

Einstein's sign error can easily be corrected. Rather than changing the coefficient $-1/2$ of the second term in expression (740) to -1, Einstein should have changed it to 1.

If an expression vanishes for the ϑ-metric, it is only a matter of interchanging co- and contravariant components of the metric to obtain an expression that vanishes for the rotation metric.[358] On the next line of p. 25R, after drawing a horizontal line, Einstein therefore wrote down the expression

$$\frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i}\frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right) - \frac{\partial \gamma_{\lambda\tau}}{\partial x_\alpha}\frac{\partial g_{\lambda\tau}}{\partial x_\beta}\,, \tag{745}$$

which is obtained by interchanging co- and contravariant components of the metric in expression (740) and changing the factor $1/2$ in the second term to 1. Einstein assumed that the 11-component of this new expression vanishes for the rotation metric. This expression thus seemed to be a promising new candidate for the left-hand side of the field equations.[359] Mathematically, however, it is ill-defined: α and β appear as contravariant indices in the first term and as covariant ones in the second, and the

356 On the left-hand side, ω should be ω^2 and in the last term on the right-hand side, a closing bracket is missing.

357 This in turn can be inferred from his comment "$\alpha = 1\ \ \beta = 1$ correct" ("$\alpha = 1\ \ \beta = 1$ stimmt") farther down on p. 25R (see the paragraph following expression (748)).

358 Einstein had used this same insight to construct a modified ϑ-expression on p. 43LA (see sec. 5.5.8)

summations over i and ε are summations over pairs of covariant indices. Einstein had concocted expression (745) to meet the requirement that the rotation metric be a vacuum solution of the field equations and had done so at the expense of basic mathematical requirements.

Einstein still had to check whether all components of expression (745) vanish for the rotation metric. So far, he had only convinced himself that the 11-component does. In principle, one would have to check six index combinations: 11, 12, 14, 22, 24, and 44.[360] Upon inspection of expression (745), however, one easily sees that the 24-component will be equal to the 14-component for this particular metric, and that the 22-component will be equal to the 11-component. It thus suffices to check whether the remaining four components vanish.

Einstein first considered the index combination "$\alpha = 4 \;\; \beta = 1$." The second term in expression (745) vanishes because the metric is time-independent. The first term can only contribute for "$i = 2$," as Einstein noted, since otherwise $\partial\gamma_{41}/\partial x_i = 0$. Even for $i = 2$, however, there will be no contribution, as Einstein also noted,

$$\frac{\partial}{\partial x_\varepsilon}(g_{\varepsilon 2}\omega) = 0\,. \tag{746}$$

Einstein then turned to the index combination "$\alpha = 4 \;\; \beta = 4$." The second term in expression (745) again vanishes because the metric is time-independent. Consider the first term

$$\frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i}\frac{\partial\gamma_{44}}{\partial x_i}\right). \tag{747}$$

Since $\gamma_{44} = 1$, this term also vanishes. Einstein initially seems to have inserted $\gamma_{44} = 1 - \omega^2(x^2 + y^2)$ instead, which would explain the expressions

$$\begin{array}{ll} i = 1 & \quad i = 2 \\ -2\omega^2 x, & \end{array} \tag{748}$$

which he wrote down and deleted. He then simply wrote: "vanishes" ("verschwindet").

For the next index combination, "$\alpha = 1 \;\; \beta = 1$," which he wrote down after drawing another horizontal line, Einstein just wrote: "correct" ("stimmt"). After all, he had constructed expression (745) so that its 11-component would vanish for the

---

359 On the face of it, it may seem somewhat dubious to simply change the coefficient of the second term in expression (740) to make the expression vanish for the ϑ-metric. Einstein knew, however, that there should be additional terms quadratic in first-order derivatives of the metric in expression (740) coming from the terms that he had neglected in its derivation. Einstein's hope at this point may have been that these correction terms would only result in a change of the coefficient of the second-term in expression (740) as it stood.

360 In the $3 + 1$-dimensional case, the components 13, 23, 33 and 34 trivially vanish. All other components are equal to the corresponding ones in the $2 + 1$-dimensional case.

rotation metric (see equation (744)). As we already pointed out, the 11-component does in fact not vanish,

$$\frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i}\frac{\partial \gamma_{11}}{\partial x_i}\right) - \frac{\partial \gamma_{\lambda\tau}}{\partial x_1}\frac{\partial g_{\lambda\tau}}{\partial x_1} = g_{22}\frac{\partial^2 \gamma_{11}}{\partial x_2^2} - 2\frac{\partial \gamma_{24}}{\partial x_1}\frac{\partial g_{24}}{\partial x_1} = -4\omega^2 . \tag{749}$$

Finally, Einstein considered the index combination "$\alpha = 1 \;\; \beta = 2$." One easily sees that the second term in equation (745) once again vanishes. Given the sign error in the 12-component of $\gamma_{\mu\nu}$ in expression (730), Einstein wrote the possible contributions coming from the first term in expression (745) as

$$\begin{array}{cc} i = 1 & i = 2 \\ \dfrac{\partial}{\partial x_\varepsilon}(g_{\varepsilon 1}\ \omega^2 y) & \dfrac{\partial}{\partial x_\varepsilon}(g_{\varepsilon 2}\ \omega^2 x). \end{array} \tag{750}$$

Both these terms vanish. Einstein could thus concluded that the 12-component of equation (745) also "vanishes" ("verschwindet") for the rotation metric.

Einstein had now checked all independent components of equation (745) and concluded: "Equation satisfied" ("Gleichung erfüllt"). Making the right errors in the right places, he had convinced himself that the ill-defined expression in equation (745) finally gave him field equations with the rotation metric as a vacuum solution, a test that so many other promising candidates had failed.

25R 5.6.5 *Testing the Newly Concocted Field Equations for Compatibility with Energy-Momentum Conservation (25R)*

In the last four lines of p. 25R, Einstein checked whether the ill-defined new field equations based on expression (745), which looked promising from the point of view of the equivalence principle, would satisfy the conservation principle as well. As he had done for several other candidate field equations,[361] he checked whether these field equations could be used to write the gravitational force density as the divergence of gravitational stress-energy density. A few lines of calculation show that this can easily be done in linear approximation, but that the equality cannot hold exactly. Einstein thereupon abandoned these field equations. In the course of this short calculation, Einstein may also have come to realize that the equations were mathematically unacceptable to begin with.

In linear approximation, the gravitational force density can be written as the contraction of a derivative of the metric with the left-hand side of the linearized field equations. If one uses the covariant field equations, one has to use the contravariant metric; if one uses the contravariant field equations, one has to use the covariant metric (cf. expressions (687) and (688)). Einstein, however, wrote the force density as a contraction of the first term in expression (745), which has contravariant free indices, and the derivative of the contravariant metric,

---

361 See p. 19R, 20L, 21L, 24L and 25L, and the discussion following equation (481) in sec. 5.4.2.

$$\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma} \frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right). \tag{751}$$

He thereby further compounded the problem that his new field equations are ill-defined. In expression (751) the summations over α and β are over pairs of contravariant indices, while the summations of over ε and i are over pairs of covariant ones.

Oblivious to these problems, it seems, Einstein proceeded to rewrite expression (751) in the form of a divergence. First he rewrote it as[362]

$$\frac{\partial}{\partial x_\varepsilon}\left(\frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma} g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right) - \frac{\partial^2 \gamma_{\alpha\beta}}{\partial x_\varepsilon \partial x_\sigma} g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_i} \tag{752}$$

The first term has the required form of a divergence, so Einstein could focus on the second term, which he rewrote as

$$-\frac{\partial}{\partial x_\sigma}\left(\frac{\partial \gamma_{\alpha\beta}}{\partial x_\varepsilon} g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_i}\right) + \frac{\partial \gamma_{\alpha\beta}}{\partial x_\varepsilon} \frac{\partial \gamma_{\alpha\beta}}{\partial x_i} \frac{\partial g_{\varepsilon i}}{\partial x_\sigma} + \frac{\partial \gamma_{\alpha\beta}}{\partial x_\varepsilon} g_{\varepsilon i} \frac{\partial^2 \gamma_{\alpha\beta}}{\partial x_i \partial x_\sigma}. \tag{753}$$

The first term again has the required form of a divergence. The second term is of third power in derivatives of the metric and vanishes in linear approximation. Rather than deleting this term, however, Einstein underlined it, a clear indication that he wanted to make this seemingly approximative calculation exact. But first he turned his attention to the third term in expression (753), which he rewrote as[363]

$$\frac{\partial}{\partial x_i}\left(\frac{\partial \gamma_{\alpha\beta}}{\partial x_\varepsilon} g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma}\right) - \frac{\partial \gamma_{\alpha\beta}}{\partial x_\sigma} \frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i} \frac{\partial \gamma_{\alpha\beta}}{\partial x_\varepsilon}\right). \tag{754}$$

He underlined both terms. This is the end of the calculation. Einstein was clearly dissatisfied with the result, for in the lower left corner of p. 25R, to the left of equations (753) and (754), he wrote: “impossible” (“unmöglich”).

The reason for Einstein’s dissatisfaction must have been that the calculation in equations (751)–(754) convinced him that his new candidate field equations are incompatible with the *exact* equality of the gravitational force density and the divergence of gravitational stress-energy density. In linear approximation the calculation seems to show that the equations are compatible with this equality.[364] The last term in expression (754) is equal and opposite to expression (751) that Einstein started from. Bringing this term to the left-hand side and dividing both sides by a factor 2, Einstein would have succeeded in writing his ill-defined expression for the gravitational force density as a sum of three terms that all have the required form of a divergence (i.e., the first terms in expressions (752), (753), and (754)) and a term of third power in deriv-

362 In the notebook, the expressions in parentheses in equations (752) and (753) as well as the first expression in parentheses in equation (754) are indicated by pairs of parentheses only.

363 One of the derivatives $\partial/\partial x_\varepsilon$ in the last term should be $\partial/\partial x_i$.

364 In fact, the calculation shows nothing of the sort, since both the field equations and the expression that was used for the gravitational force density in this calculation are mathematically ill-defined. Einstein, however, appears to have been unaware, at least initially, of these problems.

atives of the metric that vanishes in linear approximation (i.e., the second term in expression (753)). The equality would hold exactly if this last term could be interpreted as (minus) the contraction of $\partial\gamma_{\alpha\beta}/\partial x_\sigma$ with the term quadratic in first-order derivatives of the metric in the field equations. Comparison of the second term in expression (753) to the second term in expression (745), the left-hand side of the candidate field equations under consideration, shows that the former cannot be interpreted in this way,[365]

$$\frac{\partial\gamma_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\frac{\partial g_{\varepsilon i}}{\partial x_\sigma} \neq \frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\left(\frac{\partial g_{\lambda\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\lambda\tau}}{\partial x_\beta}\right). \tag{755}$$

This is probably why Einstein concluded that it was “impossible” (“unmöglich”) to write the gravitational force density as the divergence of gravitational stress-energy density.

Einstein’s remark may also refer, at least in part, to the more fundamental problem that expressions (751)–(754) as well as the new candidate field equations themselves are mathematically ill-defined. Whatever the case may be, Einstein at this point abandoned these ill-defined field equations and on the next page (p. 26L) made a fresh start with the method for generating field equations automatically satisfying energy-momentum conservation that he had introduced on p. 24R.

19L–25R 5.7 *Conclusion: Cutting the Gordian Knot (19L–25R)*

Of all attempts to find suitable gravitational field equations recorded in the notebook, the one on p. 25R was clearly the most desperate. As was shown in detail in secs. 5.6.4–5.6.5, the attempt is riddled with errors. One can, however, also look upon Einstein’s calculations on this page in a more positive way. They reveal very clearly which of the various requirements that had to be satisfied by putative field equations weighed most heavily for Einstein at this point. Looking at p. 25R from this perspective, one is struck by the fact that, even though many of the expressions considered by Einstein were not even well-defined mathematically, he continued to adhere strictly to

365 It may be interesting to note that such an interpretation would have been possible had Einstein contracted $\frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\right)$ with $\frac{\partial g_{\alpha\beta}}{\partial x_\sigma}$, as he should have done, rather than with $\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}$ (cf. the discussion in the paragraph with equation (751) above). In that case, the second term in equation (753) would change to $\frac{\partial g_{\alpha\beta}}{\partial x_\varepsilon}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\frac{\partial g_{\varepsilon i}}{\partial x_\sigma} = \left(\frac{\partial g_{\lambda\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\lambda\tau}}{\partial x_\beta}\right)\frac{\partial g_{\alpha\beta}}{\partial x_\sigma}$, where the term in parentheses is indeed equal to minus the second term in equation (745). With this modification of the calculation in equations (751)–(754), however, the last term in equation (754) would change to $\frac{\partial\gamma_{\alpha\beta}}{\partial x_\sigma}\frac{\partial}{\partial x_\varepsilon}\left(g_{\varepsilon i}\frac{\partial\gamma_{\alpha\beta}}{\partial x_i}\right)$ and would no longer be equal to the expression in equation (751). Consequently, the equality of gravitational force density and divergence of gravitational stress-energy density would not even hold in linear approximation. It seems unlikely that Einstein considered this alternative.

three requirements. First and foremost, there was the correspondence principle. The field equations should consist of a core operator, i.e., a term with second-order derivatives of the metric that reduces to the d'Alembertian acting on the metric in linear approximation, and terms quadratic in first-order derivatives of the metric that vanish in linear approximation. Then there was the conservation principle in the very specific form that the field equations should make it possible, not just in linear approximation but exactly, to write the gravitational force density as the divergence of gravitational stress-energy density. Finally, there was the demand that the rotation metric be a vacuum solution of the field equations. Einstein was willing, it seems, to weaken, if only temporarily, the much stronger demands of his relativity and equivalence principles that the field equations be invariant under (autonomous or non-autonomous) transformations to arbitrarily accelerated frames of reference. The focus on these three requirements, which constrain even the very problematic calculations on p. 25R, made the task of finding suitable field equations much more manageable.

The strategy that Einstein had used on pp. 19L–23L and again on p. 25L and at the top of p. 25R of extracting field equations from expressions of broad covariance by imposing coordinate restrictions had failed several times. With hindsight, one can see that most of the problems come from Einstein using coordinate restrictions rather than coordinate conditions in the modern sense to make sure that the field equations satisfy the correspondence principle. Einstein had found three different coordinate restrictions (the harmonic restriction, the Hertz restriction, and the ϑ-restriction) with the help of which the correspondence principle could be satisfied. The covariance properties of these coordinate restrictions, however, proved to be intractable. Since Einstein used coordinate restrictions rather than coordinate conditions, this meant that the covariance properties of the field equations themselves became intractable as well. It thus remained unclear whether these equations satisfy the demands of the equivalence and relativity principles. Moreover, Einstein had not been able to confirm that the coordinate restrictions and the associated field equations would be compatible with the exact validity of energy-momentum conservation.

In this situation something had to give. Einstein, it seems, cut the Gordian knot by weakening two of his heuristic principles. He weakened the equivalence principle to the requirement that the field equations at least allow the rotation metric. He weakened the relativity principle to the obvious minimal requirement that the field equations at least have well-defined transformation properties. On p. 24R Einstein had found candidate field equations imposing the correspondence and conservation principles and bracketing the problem of satisfying the remaining two principles. On pp. 26L–R, he turned this derivation into a powerful method for generating field equations that automatically meet the requirements of the correspondence and conservation principles. What probably made this option all the more appealing was that Einstein believed (mistakenly as was shown in sec. 5.6.1) that the expression that forms the starting point of the calculation on p. 24R vanishes exactly for the rotation metric, a necessary condition for the resulting field equations to satisfy the weakened version of the equivalence principle.

26L–R

6. DERIVATION OF THE *ENTWURF* EQUATIONS (26L–R)
