On pp. 26L–R, Einstein derived the identity that is at the heart of the derivation of the *Entwurf* field equations in (Einstein and Grossmann 1913). His approach on these pages is very similar to his approach on p. 24R (cf. the discussion following expression (698) in sec. 5.6.1). He substituted the left-hand side of some linearized field equations for the stress-energy tensor $T_{\mu\nu}$ in the expression

$$\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} \tag{756}$$

for the gravitational force density and tried to rewrite the resulting expression as the divergence of the gravitational stress-energy density. In addition to divergence terms, he found terms that are contractions of $\partial g_{\mu\nu}/x_m$ and terms quadratic in first-order derivatives of the metric. By adding the latter to the linearized field equations, Einstein arrived at exact field equations that guarantee that the gravitational force density is exactly equal to the divergence of the gravitational stress-energy density.

The calculation on pp. 26L–R is thus very similar to the calculation on p. 24R, but differs from it in two important respects. First, Einstein no longer set the determinant of the metric equal to unity, which can be seen as an indication that he had meanwhile given up hope to recover the new candidate field equations from the November tensor as he had still tried to do on p. 25L for the field equations of p. 24R. Second, Einstein did not start, as he had done on p. 24R (see expression (683)) from a specific expression for (the divergence of) the gravitational stress-energy pseudo-tensor. Einstein read off both the expression for the left-hand side of the field equations and the expression for the gravitational stress-energy pseudo-tensor from the identity obtained by rewriting expression (756) after substitution of the left-hand side of the linearized field equations for the stress-energy tensor.

At the top of p. 26L, Einstein began by writing down the energy-momentum balance between matter and gravitational field,[366]

$$\frac{\partial}{\partial x_n}(\sqrt{G}g_{\mu\nu}T_{\nu n}) - \frac{1}{2}\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} = 0\,, \tag{757}$$

or, as he called it, the “system of the equations for matter” (“System der Gleichungen für Materie”) and, on the next line, the (contravariant) stress-energy tensor for pressureless dust,

$$T_{\mu\nu} = \rho\frac{dx_\mu}{d\tau}\frac{dx_\nu}{d\tau}\,. \tag{758}$$

Equation (757) shows that the exact expression for the gravitational force density is

$$-\frac{1}{2}\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu}\,, \tag{759}$$

366 In the first term of equation (757), $g_{\mu\nu}$ should be $g_{m\nu}$ (see equation (71)).

but in the calculations on the remainder of the page Einstein ignored the factor $-\frac{1}{2}\sqrt{G}$, a simplification that is easily corrected for at the end of the calculation.

Under the heading "derivation of the gravitation equations" ("Ableitung der Gravitationsgleichungen"), Einstein now substituted the left-hand side of linearized field equations based on a core operator,

$$\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right) = \kappa T_{\mu\nu}, \tag{760}$$

for the stress-energy tensor in the crude expression (756) for the force density,

$$\frac{\partial g_{\mu\nu}}{\partial x_m}\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right), \tag{761}$$

also ignoring, as he had done on several earlier occasions (see pp. 19R, 20L, 21L, 24R, and 25R), the gravitational constant κ. Einstein set out to rewrite expression (761) as a sum of terms of two kinds, divergence terms (marked '+' and '×' on pp. 26L–R) and terms that are contractions with $\partial g_{\mu\nu}/x_m$ (marked 'o' on pp. 26L–R[367]).

Einstein first rewrote expression (761) as

$$\left.\frac{\partial g_{\mu\nu}}{\partial x_m}\right|\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right) = \frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\frac{\partial g_{\mu\nu}}{\partial x_m}\right) - \sqrt{G}\gamma_{\alpha\beta}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\frac{\partial^2 g_{\mu\nu}}{\partial x_m\partial x_\alpha}. \tag{762}$$

The first term on the right-hand side is a divergence term. It is underlined and marked '+.' Einstein proceeded to rewrite the second term as

$$-\frac{\partial}{\partial x_m}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\right) + \frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial}{\partial x_m}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right). \tag{763}$$

Once again, the first term is a divergence term, which is underlined and marked '×.' The second term gives three terms:

$$\frac{1}{2}\frac{\partial g_{\sigma\tau}}{\partial x_m}\gamma_{\sigma\tau}\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\gamma_{\alpha\beta} + \frac{\partial\gamma_{\alpha\beta}}{\partial x_m}\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta} + \frac{\partial g_{\mu\nu}}{\partial x_\alpha}\sqrt{G}\gamma_{\alpha\beta}\frac{\partial^2\gamma_{\mu\nu}}{\partial x_m\partial x_\beta}. \tag{764}$$

This expression extends beyond the right margin of p. 26L and is continued on the facing page, p. 26R. The first term in expression (764) is obtained with the help of the relation

$$\frac{\partial\sqrt{G}}{\partial x_m} = \frac{1}{2\sqrt{G}}\frac{\partial G}{\partial x_m} = \frac{1}{2\sqrt{G}}\left(G\gamma_{\sigma\tau}\frac{\partial g_{\sigma\tau}}{\partial x_m}\right), \tag{765}$$

which Einstein had encountered several times before (see pp. 6L, 8R, and 9R, and equation (87)). By relabeling indices ($\sigma\tau\mu\nu \to \mu\nu\sigma\tau$), Einstein could show that this term can be written as a contraction of $\partial g_{\mu\nu}/x_m$ and a term quadratic in first-order derivatives of the metric,

367 Except in one case (see expression (766) below) which Einstein apparently forgot to mark.

$$\frac{1}{2}\frac{\partial g_{\mu\nu}}{\partial x_m}\gamma_{\mu\nu}\sqrt{G}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial \gamma_{\sigma\tau}}{\partial x_\beta}\gamma_{\alpha\beta}\,. \tag{766}$$

The term is underlined, but Einstein for some reason neglected to mark it 'o' as he did with other terms of this kind.

The second term in expression (764) is of the same kind, although it takes a little more work to show this. Substituting $(\partial/\partial x_\alpha) = g_{\alpha\sigma}\gamma_{\alpha'\sigma}(\partial/\partial x_{\alpha'})$ and $(\partial/\partial x_\beta) = g_{\beta\tau}\gamma_{\beta'\tau}(\partial/\partial x_{\beta'})$, Einstein rewrote this term as

$$\frac{\partial \gamma_{\alpha\beta}}{\partial x_m}g_{\alpha\sigma}g_{\beta\tau}\;\big|\;\gamma_{\alpha'\sigma}\gamma_{\beta'\tau}\;\;\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_{\alpha'}}\frac{\partial \gamma_{\mu\nu}}{\partial x_{\beta'}}\,, \tag{767}$$

which, with the help of the relation $(\partial\gamma_{\alpha\beta}/\partial x_m)g_{\alpha\sigma}g_{\beta\tau} = -(\partial g_{\sigma\tau}/\partial x_m)$, he then rewrote as

$$-\frac{\partial g_{\sigma\tau}}{\partial x_m}\sqrt{G}\gamma_{\alpha\sigma}\gamma_{\beta\tau}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\,. \tag{768}$$

So, this term does indeed also have the form of a contraction of $\partial g_{\mu\nu}/\partial x_m$ and a term quadratic in first-order derivatives of the metric. It was underlined and marked 'o' accordingly.

At the bottom of p. 26R, Einstein turned to the third term in expression (764). This term contributes one '+'-term and two 'o'-terms. Einstein began by rewriting it as

$$\frac{\partial}{\partial x_\beta}\left(\frac{\partial \gamma_{\mu\nu}}{\partial x_m}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\sqrt{G}\gamma_{\alpha\beta}\right) - \frac{\partial \gamma_{\mu\nu}}{\partial x_m}\frac{\partial}{\partial x_\beta}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\right)\,. \tag{769}$$

The first term is a divergence term. It is underlined and marked '+'. Rewriting it as

$$\frac{\partial}{\partial x_\alpha}\left(\frac{\partial g_{\mu\nu}}{\partial x_m}\frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\sqrt{G}\gamma_{\beta\alpha}\right)\,, \tag{770}$$

one sees that it is equal to this term in equation (762).

The second term in expression (769) is a contraction with $\partial\gamma_{\mu\nu}/x_m$ rather than with $\partial g_{\mu\nu}/x_m$. Einstein therefore rewrote it as (cf. expression (767))[368]

$$-\frac{\partial \gamma_{\mu\nu}}{\partial x_m}g_{\mu\sigma}g_{\nu\tau}\big|\gamma_{\mu'\sigma}\gamma_{\nu'\tau}\frac{\partial}{\partial x_\beta}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\right)\,, \tag{771}$$

and then set $-(\partial\gamma_{\mu\nu}/\partial x_m)g_{\mu\sigma}g_{\nu\tau}$ equal to $\partial g_{\sigma\tau}/\partial x_m$. His next move was to bring $\gamma_{\mu'\sigma}$ and $\gamma_{\nu'\tau}$ within the scope of the differentiation $\partial/\partial x_\beta$ in order to turn the derivative of $g_{\mu\nu}$ into a derivative of $\gamma_{\mu\nu}$ (as in expression (761)). Expression (771) thus turns into[369]

368 In expression (771), $g_{\mu\nu}$ should be $g_{\mu'\nu'}$.

369 Expression (772) originally had $\gamma_{\mu'\sigma}\gamma_{\nu'\tau}$, but the primes were crossed out.

$$\frac{\partial g_{\sigma\tau}}{\partial x_m}\left|\frac{\partial}{\partial x_\beta}\left(\gamma_{\mu\sigma}\gamma_{\nu\tau}\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\right)-\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial \gamma_{\mu\sigma}\gamma_{\nu\tau}}{\partial x_\beta}\right. . \tag{772}$$

He then rewrote the two terms to the right of the vertical line as[370]

$$-\frac{\partial}{\partial x_\beta}\left(\frac{\partial \gamma_{\sigma\tau}}{\partial x_\alpha}\gamma_{\alpha\beta}\sqrt{G}\right)+2\sqrt{G}\gamma_{\alpha\beta}g_{\mu\nu}\frac{\partial \gamma_{\mu\sigma}}{\partial x_\alpha}\frac{\partial \gamma_{\nu\tau}}{\partial x_\beta} . \tag{773}$$

He underlined both terms and marked them 'o.' The first term is (minus) the core operator that formed the starting point of this whole calculation (cf. equations (760)–(761)).

Einstein now collected the 'o'-terms on the left-hand side and the '+/×'-terms on the right-hand side. The 'o'-terms come from the left-hand side of equation (762) (with a factor 2 because of the identical contribution from the first term in expression (773)), from expressions (766) and (768), and from the second term in expression (773) (contracted with $\partial g_{\sigma\tau}/\partial x_m$). These terms add up to

$$\begin{aligned}\frac{\partial g_{\mu\nu}}{\partial x_m}\Bigg[&2\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\right)-\frac{1}{2}\sqrt{G}\gamma_{\mu\nu}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial \gamma_{\sigma\tau}}{\partial x_\beta}\\&+\sqrt{G}\gamma_{\alpha\mu}\gamma_{\beta\nu}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial \gamma_{\sigma\tau}}{\partial x_\beta}-2\sqrt{G}\gamma_{\alpha\beta}g_{\sigma\tau}\frac{\partial \gamma_{\mu\sigma}}{\partial x_\alpha}\frac{\partial \gamma_{\nu\tau}}{\partial x_\beta}\Bigg].\end{aligned} \tag{774}$$

The '+/×'-terms come from the first term on the right-hand side of equation (762) (with a factor 2 because of the identical contribution from expression (770)) and from the first term in expression (763):

$$2\frac{\partial}{\partial x_\alpha}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial \gamma_{\sigma\tau}}{\partial x_\beta}\frac{\partial g_{\sigma\tau}}{\partial x_m}\right)-\frac{\partial}{\partial x_m}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial \gamma_{\sigma\tau}}{\partial x_\beta}\right) . \tag{775}$$

Regrouping the 'o'-terms in expression (774),[371] setting them equal to the '+/×'-terms in expression (775), and dividing both sides by 2, one arrives at the identity

---

370 For the first term, he used the relation $\gamma_{\mu\sigma}\gamma_{\nu\tau}\frac{\partial g_{\mu\nu}}{\partial x_\alpha} = -\frac{\partial \gamma_{\sigma\tau}}{\partial x_\alpha}$. The second term can be rewritten as a sum of two identical terms

$$\begin{aligned}-\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial(\gamma_{\mu\sigma}\gamma_{\nu\tau})}{\partial x_\beta} &= -\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial \gamma_{\mu\sigma}}{\partial x_\beta}\gamma_{\nu\tau}-\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\alpha}\frac{\partial \gamma_{\nu\tau}}{\partial x_\beta}\gamma_{\mu\sigma}\\&= \sqrt{G}\gamma_{\alpha\beta}\frac{\partial \gamma_{\nu\tau}}{\partial x_\alpha}\frac{\partial \gamma_{\mu\sigma}}{\partial x_\beta}g_{\mu\nu}+\sqrt{G}\gamma_{\alpha\beta}\frac{\partial \gamma_{\mu\sigma}}{\partial x_\alpha}\frac{\partial \gamma_{\nu\tau}}{\partial x_\beta}g_{\mu\nu}.\end{aligned}$$

371 The physical reasoning behind this regrouping will become clear below.

$$\begin{aligned}&\frac{\partial g_{\mu\nu}}{\partial x_m}\Bigg[\left(\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right)-\sqrt{G}\gamma_{\alpha\beta}g_{\sigma\tau}\frac{\partial\gamma_{\mu\sigma}}{\partial x_\alpha}\frac{\partial\gamma_{\nu\tau}}{\partial x_\beta}\right)\\&+\frac{1}{2}\sqrt{G}\left(\gamma_{\alpha\mu}\gamma_{\beta\nu}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}-\frac{1}{2}\gamma_{\mu\nu}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\right)\Bigg]\\&=\frac{\partial}{\partial x_\alpha}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\frac{\partial g_{\sigma\tau}}{\partial x_m}\right)-\frac{1}{2}\frac{\partial}{\partial x_m}\left(\sqrt{G}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\right),\end{aligned}\tag{776}$$

which Einstein wrote down at the bottom of pp. 26L–R as the "summary" ("Zusammenfassung") of his calculations. Underneath this identity, he wrote: "This is the contra-form" ("Dies ist die Kontra-Form"). It is from this identity—given as equation (12) in Einstein's part of (Einstein and Grossmann 1913) and derived in sec. 4.3 of Grossmann's part—that both the contravariant form of the field equations and the contravariant form of the gravitational stress-energy pseudo-tensor of the *Entwurf* theory can be read off.

To identify the exact expressions for the field equations and the pseudo-tensor we need the exact relations between the left-hand side of the field equations, the gravitational force density, and the gravitational stress-energy pseudo-tensor. We can no longer afford to ignore factors $\sqrt{G}$. Consider once again equation (757), the vanishing of the covariant divergence of the mixed tensor density $\sqrt{G}g_{m\nu}T_{\nu n}$. This equation can be written as the *ordinary* divergence of the sum of the stress-energy density of matter and gravitational field if

$$-\frac{1}{2}\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_m}T_{\mu\nu} = \frac{\partial}{\partial x_n}(\sqrt{G}g_{m\nu}t_{\nu n}),\tag{777}$$

where $t_{\mu\nu}$ is the contravariant form of the gravitational stress-energy pseudo-tensor. Multiplying both sides by -2κ, one arrives at

$$\sqrt{G}\frac{\partial g_{\mu\nu}}{\partial x_m}(\kappa T_{\mu\nu}) = \frac{\partial}{\partial x_n}(\sqrt{G}g_{m\nu}(-2\kappa t_{\nu n})).\tag{778}$$

The identity (776) guarantees that this equation holds if both the left-hand side of the field equations (to be substituted for $\kappa T_{\mu\nu}$ in equation (778)) and (-2κ times) the pseudo-tensor $t_{\mu\nu}$ are suitably chosen. Comparing the left-hand sides of equations (776) and (778), one sees that one must choose the expression

$$\begin{aligned}&\frac{1}{\sqrt{G}}\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{G}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right)-\gamma_{\alpha\beta}g_{\sigma\tau}\frac{\partial\gamma_{\mu\sigma}}{\partial x_\alpha}\frac{\partial\gamma_{\nu\tau}}{\partial x_\beta}\\&+\frac{1}{2}\left(\gamma_{\alpha\mu}\gamma_{\beta\nu}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}-\frac{1}{2}\gamma_{\mu\nu}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\right),\end{aligned}\tag{779}$$

i.e., the expression in square brackets in expression (776) divided by $\sqrt{G}$, as the left-hand side of the field equations. This is indeed the left-hand side of the *Entwurf* field equations. To bring the right-hand side of equation (776) in form that can be compared with the right-hand side of equation (778), one has to relabel the summation index α by n, substitute $(\partial/\partial x_m) = g_{m\nu}\gamma_{\alpha\nu}(\partial/\partial x_\alpha)$ in the first term, and substitute $(\partial/\partial x_m) = g_{m\nu}\gamma_{n\nu}(\partial/\partial x_n)$ in the second term. Comparing the resulting expression,

$$\frac{\partial}{\partial x_n}\left(\sqrt{G}g_{m\nu}\left[\gamma_{n\beta}\gamma_{\alpha\nu}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}-\frac{1}{2}\gamma_{n\nu}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}\right]\right), \tag{780}$$

to the right-hand side of equation (778), one sees that one must choose the expression

$$\gamma_{\alpha\nu}\gamma_{\beta n}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta}-\frac{1}{2}\gamma_{\nu n}\gamma_{\alpha\beta}\frac{\partial g_{\sigma\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\sigma\tau}}{\partial x_\beta} \tag{781}$$

as the gravitational stress-energy pseudo-tensor $-2\kappa t_{\nu n}$. This is the definition of this quantity given in equation (13) of (Einstein and Grossmann 1913).[372] Notice that the expression in parentheses on the second line of expression (779) is equal to $-2\kappa t_{\mu\nu}$. If we now introduce the notation $D_{\mu\nu}(\gamma)$ for the expression on the first line,[373] the left-hand side of the field equations can be written as $D_{\mu\nu}(\gamma)-\kappa t_{\mu\nu}$, and the field equations themselves as

$$D_{\mu\nu}(\gamma) = \kappa(T_{\mu\nu}+t_{\mu\nu}), \tag{782}$$

which is the form in which the *Entwurf* field equations are given in equation (18) of (Einstein and Grossmann 1913).[374] Commenting on this equation (ibid., p. 17), Einstein pointed out that any acceptable field equations must be such that the stress-energy of matter and the stress-energy of the gravitational field enter the equations in the exact same way.[375]

Before pp. 26L–26R, this requirement had not explicitly played a role in Einstein's search for suitable field equations. But the way in which Einstein grouped the terms on the left-hand side of the identity (776)—with the terms in the first set of parentheses giving $D_{\mu\nu}(\gamma)$ and those in the second giving $-2\kappa t_{\mu\nu}$ — suggests that Einstein did consider this requirement when he wrote down the calculations on pp. 26L–26R.

One can understand why Einstein would have been pleased with these new candidate field equations. They satisfied the correspondence principle and they satisfied the conservation principle, not just in linear approximation but exactly. Since the new field equations were not extracted from some quantity of broad covariance with the help of a suitable coordinate restriction, it remained unclear whether they satisfy the relativity principle and the equivalence principle. The one encouraging result on this score (erroneous as it turns out) was that the divergence of the gravitational stress-energy pseudo-tensor vanishes for the rotation metric, a necessary condition for this

372 In the paper, the contravariant form is denoted by $\vartheta_{\mu\nu}$, and the covariant form by $t_{\mu\nu}$.

373 This is in keeping with (Einstein and Grossmann 1913), where this same quantity is introduced in equation (15) as $\Delta_{\mu\nu}(\gamma)$.

374 In (Einstein and Grossmann 1913), they are written as $\Delta_{\mu\nu}(\gamma) = \kappa(\Theta_{\mu\nu}+\vartheta_{\mu\nu})$.

375 A similar result holds in the final version of Einstein's earlier theory for static fields (see Einstein 1912b, 457) and in general relativity in its final form (see Einstein 1916, 807–808).

metric to be a vacuum solution of the *Entwurf* field equations.[376] More importantly, Einstein had not been able to find any acceptable field equations along the lines of his mathematical strategy that satisfied the relativity principle and the equivalence principle. And he had at best been able to show in linear approximation that these candidates satisfied the conservation principle. It is thus not surprising that Einstein gave up his attempt to construct field equations out of the Riemann tensor and decided to publish, in his joint paper with Marcel Grossmann, the field equations found along the lines of his physical strategy.

ACKNOWLEDGMENTS

The first draft of this commentary was prepared in the early 1990s by a working group of the *Arbeitsstelle Albert Einstein* (see preface). The working group—joined early on in its work on the notebook by John Norton and John Stachel and later by Michel Janssen—did not have to start from scratch. It had John Norton's "How did Einstein find his field equations?" (Norton 1984) to go on, as well as drafts of the annotation of the notebook prepared for Vol. 4 of *The Collected Papers of Albert Einstein*, both the footnotes added to the transcription (CPAE 4, Doc. 10) and the editorial note, "Einstein's Research Notes on a Generalized Theory of Relativity" (CPAE 4, 192–199). The joint work was continued in a number of workshops hosted by the *Max-Planck-Institut für Bildungsforschung* and later by the *Max-Planck-Institut für Wissenschaftsgeschichte*. On the basis of all this material, Michel Janssen and Jürgen Renn wrote the final version of the commentary (with the exception of sec. 4.5.8, which was written by Tilman Sauer). They produced the first half in close collaboration, partly at the University of Minnesota, partly (courtesy of Bernhard Schutz) at the *Max-Planck-Institut für Gravitationsphysik* (*Albert Einstein Institut*) in Golm. Michel Janssen wrote the second half (secs. 5 and 6) during extended stays at the *Max-Planck-Institut für Wissenschaftsgeschichte* in the late 1990s in close interaction with the scientists at the institute.

WHAT WAS EINSTEIN'S "FATEFUL PREJUDICE"?

In the later pages of the notebook, as Einstein let general covariance slip away, he devised and abandoned a new proposal for his gravitational field equations. This same proposal, revived nearly three years later, opened passage to his final theory. In abandoning it in the notebook, Einstein had all but lost his last chance of deliverance. This chapter reports and develops our group's accounts of this decision. Einstein's later accounts of this decision blame it upon what he called the "fateful prejudice" of misinterpreting the Christoffel symbols. We suggest that Einstein's aberrant use and understanding of coordinate systems and coordinate conditions was as important as another fateful prejudice.

INTRODUCTION

Under a decade of analysis, discussion and reflection, Einstein's Zurich Notebook has yielded. Strategies that were once enigmatic and pages that were once obscure have become familiar. For the great part, we understand the problems Einstein approached, how he sought to solve them, when these efforts succeeded, when they failed and even the hesitations behind the smallest markings. In other parts we may follow a calculation line by line but our view of his hopes and plans remain distant. Or he may abandon a calculation with just a few symbols surviving on the page. They can be deciphered only through luck or clairvoyance.

The boundary that fences in the clear from the obscure has grown so that less and less escapes it. The intriguing puzzles of the notebook remain at this boundary. They cannot be solved with the assurance that the weight of evidence admits no alternative. But they are not so distant that we must despair of any solution. We understand just enough of these puzzles to sense that a complete solution lies within our grasp. We may even articulate one or more candidates that are both plausible and attractive. Yet the evidence we cull from the notebook and elsewhere remains sufficient to encourage us, but insufficient to enable a final decision.

My purpose in this chapter is to review two of these problems. I will draw heavily on ideas that have circulated freely in our group and have grown, mutated and contracted as they passed between us.[1] This chapter will report on these communal ideas,

1 I gratefully acknowledge thoughtful discussion and responses on this chapter and its proposals from the members of this group (who are also co-authors in this volume) and also from Jeroen van Dongen.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 2
Einstein's Zurich Notebook: Commentary and Essays.

while it gives my own particular viewpoint on them and adds a conjecture. Many of the ideas in this chapter are not reflected in our joint commentary because my viewpoints and conjecture represent a minority opinion. At the boundary, where categorical evidence is elusive, our intuitions and sensibilities decide. They differ as we pass through the group. We do not all know the same Einstein.

Two Puzzles

The problems meet on page 22R of the notebook. There we find Einstein generating the very same gravitational field equations of near general covariance that will reappear briefly in his publication of 4 November 1915, when he ruefully returned to general covariance. This supplies our first puzzle:

- Why were these field equations rejected in the notebook, when they were deemed admissible in November, 1915?

These equations did not employ the Ricci tensor as gravitation tensor, as would the source free field equations of Einstein's final theory. Famously, Einstein and Grossmann had mentioned but discarded this possibility in their joint *Entwurf* paper. The equations on page 22R employ a different gravitation tensor, which we have come to call informally the "November tensor." It was carefully and apparently successfully contrived to avoid exactly the problems they imagined for the Ricci tensor.

The calculations on page 22R differ in no essential way from those Einstein would publish in 1915. The calculations on the surrounding pages do differ. The absolute differential calculus makes it easy to write down expressions that are generally covariant; they hold in all coordinate systems. In the modern literature we routinely restrict these expressions to specialized coordinate systems by imposing freely chosen coordinate conditions. As Einstein's calculations in the notebook progressed, he became quite adept at the purely mathematical aspects of applying these conditions. Careful analysis of the pages show that his use of these conditions came to differ considerably from the modern usage and possibly with fatal consequences. Our second puzzle is to understand these differences:

- Did Einstein *choose* to use coordinate conditions in an idiosyncratic way later in the notebook? Or was he unaware of the modern usage?

In solving these puzzles, more is at stake than merely deciphering a few pages of a notebook that may not have long occupied Einstein. These pages mark Einstein's all but last chance to rescue himself from the misconceptions that led him to his *Entwurf* theory and to more than two years of distress as his greatest discovery eluded him. A solution to these puzzles will tell us if Einstein's final slide into the abyss rested on simple blunders, lack of imagination or creative misunderstandings that have yet to be appreciated in the historical literature.

Four Parts

This chapter is divided into four parts. In the first, I will review the circumstances that induced Einstein to the proposal of the "November tensor" T^{x}_{il} as gravitation tensor. Its rejection in the notebook will be explained partially by drawing on a proposal of Jürgen Renn's. At the time of the notebook, as Einstein later recalled, he failed to see that the Christoffel symbols were the natural expression for the components of the gravitational field, his "fateful prejudice." As a result, he was unable to see how to recover a stress-energy tensor for the gravitational field and the associated conservation laws from the "November tensor." The calculation just proved too complicated. This problem was resolved in November 1915 when Einstein had developed more powerful mathematical methods.

The second part outlines the puzzle surrounding Einstein's use of coordinates. I will distinguish the standard way in which coordinate conditions are used from the way that Einstein came to use them later in the notebook. It is so different that our group labels coordinate conditions used this way as "coordinate restrictions." This non-standard use of coordinate restrictions can aid us in explaining the notebook rejection of the "November tensor," if in addition we assume that Einstein was unaware that the same mathematical manipulations could be used in the modern manner as coordinate conditions. The evidence available to us admits no final decision over Einstein's awareness of this usage. I will suggest however that there are sufficient indications to make his supposed lack of awareness implausible and that page 22R of the notebook might well mark a transition from the use of coordinate conditions to coordinate restrictions.

The third part develops a conjecture on what might lie behind Einstein's idiosyncratic use of coordinate conditions in the notebook. In his later hole argument, Einstein erred in tacitly according an independent reality to coordinate systems. It is now speculated he may have committed this same error within the notebook while using coordinate conditions to extract the Newtonian limit from the "November tensor." The outcome would be that his theory overall would seem to gain no added covariance from the use of coordinate conditions rather than coordinate restrictions, to which Einstein reverted for their greater simplicity. Once again, the available evidence admits no final decision. I will suggest however that the conjecture is plausible since it requires us to suppose no additional errors by Einstein; he merely needs to follow through consistently on the misapprehensions we know he harbored in the context of the hole argument.

The fourth part offers a summary conclusion.

1. THE PUZZLE OF THE GRAVITATION TENSORS

Why did Einstein abandon the gravitational field equations in the notebook on page 22R that he later deemed suitable for publication on 4 November 1915? This is our first puzzle. In the first section of this part I will review the essential background to this puzzle. In the pages preceding page 22R, Einstein considered and rejected the natural candidate for a gravitation tensor, the Ricci tensor. It fell to misconceptions about static fields and the form of gravitational field equations in the case of weak fields. In the second section of this part I will describe how the proposal of page 22R was contrived ingeniously to circumvent the illusory flaws he had imagined for the Ricci tensor. In the third section I will review Einstein's later recollections concerning the notebook rejection and the central role that, as I shall call it, "{} prejudice" played in them. Drawing on a proposal by Jürgen Renn, I will advance what I believe is a plausible account of its significance. The difficulty was the recovery of an expression for the stress-energy tensor of the gravitational field and its associated conservation law. Because Einstein did not recognize that the Christoffel symbols are the natural structure for representing the components of the gravitational field, he thought this recovery required the algebraic expansion of the Christoffel symbols. That yielded such a surfeit of terms that Einstein despaired of completing the calculation. This difficulty, along with others to be reviewed in later parts of this chapter, led Einstein to abandon the proposed gravitation tensor. In 1914, in the course of his work on the *Entwurf* theory, Einstein developed more powerful variational methods. These enabled him to complete the calculation and to see the significance of the Christoffel symbols.

1.1 Background: The Rejection of the Ricci Tensor

The Entwurf Papers

In the *Entwurf* paper, Einstein and Grossmann famously report their failure to find generally covariant gravitational field equations. Their search had focused on finding a gravitation tensor, $G_{\mu\nu}$, constructed from the metric tensor and its derivatives, to be used in the gravitational field equations

$$G_{\mu\nu} = \kappa T_{\mu\nu}, \tag{1}$$

where $T_{\mu\nu}$ is the stress-energy tensor and κ is a constant. The absolute differential calculus of Ricci and Levi-Civita supplied the natural structure from which generally covariant gravitation tensors can readily be constructed. It is the Riemann tensor, written in Einstein's paper of 4 November 1915 (Einstein 1915a) as[2]

2 My policy with notation will be to follow the conventions used at the time of the work discussed. In November 1915, Einstein indicated contravariant and covariant components of a tensor by raised and lowered indices. Summation over repeated indices was *not* implied. The notation for the Riemann tensor and Christoffel symbols do not respect this raising and lowering convention.

$$(ik,lm) = \frac{\partial}{\partial x_m}\begin{Bmatrix} il \\ k \end{Bmatrix} - \frac{\partial}{\partial x_1}\begin{Bmatrix} im \\ k \end{Bmatrix} + \sum_\rho \begin{Bmatrix} il \\ \rho \end{Bmatrix}\begin{Bmatrix} \rho m \\ k \end{Bmatrix} - \begin{Bmatrix} im \\ k \end{Bmatrix}\begin{Bmatrix} \rho l \\ k \end{Bmatrix}, \tag{2}$$

where the Christoffel symbols of the second kind are

$$\begin{Bmatrix} il \\ k \end{Bmatrix} = \frac{1}{2}\sum_r g^{kr}\begin{bmatrix} il \\ r \end{bmatrix} = \frac{1}{2}\sum_r g^{kr}\left(\frac{\partial g_{ir}}{\partial x_k} + \frac{\partial g_{rl}}{\partial x_k} - \frac{\partial g_{il}}{\partial x_r}\right).$$

(The term $[il/r]$ is the Christoffel symbol of the first kind and is defined implicitly in this expression.) The Ricci tensor is the first nontrivial contraction, unique up to sign, of the Riemann tensor, written by Einstein as

$$G_{im} = \sum_{kl}(ik,lm). \tag{3}$$

Einstein later chose this tensor as the gravitation tensor in the source free case.

Einstein and Grossmann had revealed that they had considered this candidate for the gravitation tensor in preparing the *Entwurf* paper. They explained, in Grossmann's words, "...it turns out that this tensor does *not* reduce to the [Newtonian] expression $\Delta\phi$ in the special case of an infinitely weak, static gravitational field."[3] Einstein and Grossmann's explanation proved all too brief. It did not even mention the use of the coordinate conditions that are expected by the modern reader and that must be stipulated to restrict the coordinate systems of a generally covariant theory to those coordinate systems in which Newton's equations can hold. This omission even led to the supposition in the early history of this episode that Einstein was unaware of his freedom to apply these coordinate conditions.

With its earliest analyses,[4] we learned from the Zurich Notebook that Einstein understood all too well how to reduce generally covariant gravitational field equations to a Newtonian form by restricting the coordinate systems under consideration. In particular, he knew how to select what we now call "harmonic coordinates" to reduce the Ricci tensor to an expression analogous to the Newtonian $\Delta\phi$. With deeper analysis as developed in our commentary, the notebook provides a detailed account of how Einstein tested the Ricci tensor against his other expectations and how he was led to reject it.

Two Misconceptions: The Static Field…

What precluded acceptance of the Ricci tensor as the gravitation tensor were two interrelated expectations that proved to be incompatible with Einstein's final theory. On the basis of several apparently sound arguments, Einstein expected that static

---

3 "Allein es zeigt sich, daß sich dieser Tensor im Spezialfall des unendlich schwachen statischen Schwerefeldes nicht auf den Ausdruck $\Delta\phi$ reduziert." (Einstein and Grossmann 1913, 256–257)

4 See (Norton 1984) and also (Stachel 1980).

gravitational fields would be represented by a spatially flat metric, whose coefficients in a suitable coordinate system would be

$$g^{STAT}_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2(x,y,z) \end{bmatrix}, \tag{4}$$

where the g^{STAT}_{44} component $c^2(x,y,z)$ is some function of the three spatial coordinates $(x,y,z) = (x_1,x_2,x_3)$. The spatial flatness is represented by the constant value -1 for the other non-zero components, g^{STAT}_{11}, g^{STAT}_{22}, and g^{STAT}_{33}. This spatial flatness is not realized in general in the final theory.

We can understand exactly why Einstein would fail to anticipate this lack of spatial flatness. His explorations were based on the principle of equivalence, which asserted that a transformation to uniform acceleration in a Minkowski spacetime yielded a homogenous gravitational field (see Norton 1985). The Minkowski metric in standard coordinates is given by

$$g^{SR}_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & c^2 \end{bmatrix} \tag{5}$$

for c now a constant interpreted as the speed a light. If one transforms to a coordinate system in uniform acceleration, the metric reverts to a form Einstein associated with a homogeneous gravitational field, $g^{HG}_{\mu\nu}$, which has the form of $g^{STAT}_{\mu\nu}$, but in which c is a linear function of the spatial coordinates, x_1, x_2, x_3. If the acceleration is in the direction of the $x_1 = x$ coordinate, for example, then $c = c_0 + ax$, for c_0 and a arbitrary constants whose values are set by the particulars of the transformation, so that

$$g^{HG}_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & (c_0 + ax)^2 \end{bmatrix} \tag{6}$$

Einstein's early strategy in his work on gravitation had been to recover the properties of arbitrary gravitational field by judiciously generalizing those of $g^{HG}_{\mu\nu}$. His mistake, in 1912 and 1913, was to fail to anticipate that the spatial flatness of $g^{HG}_{\mu\nu}$, was not a property of all static fields, but a very special peculiarity of $g^{HG}_{\mu\nu}$.

…and the Field Equations for Weak Fields

Einstein's second expectation concerned how the gravitational field equations (1) would reduce to the Newtonian limit. In the weak field case, one supposes that one can find coordinate systems in which the metric adopts the form

$$g_{\mu\nu} = g^{SR}_{\mu\nu} + \varepsilon_{\mu\nu} \tag{7}$$

The quantities $\varepsilon_{\mu\nu}$ are of first order of smallness. For this weak field, Einstein supposed that the gravitation tensor of (1) would reduce to[5]

$$\Gamma_{\mu\nu} = \sum_{\alpha\beta} \frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\right) + \begin{pmatrix}\text{terms of}\\ \text{second order}\\ \text{and higher}\end{pmatrix}. \tag{8}$$

If the gravitation tensor reduced to this form in the weak field, then all that would remain to first order is the first term of (8), so that the gravitational field equations would reduce to the near-Newtonian expression

$$\sum_{\alpha\beta} \gamma^{SR}_{\alpha\beta} \frac{\partial^2}{\partial x_\alpha \partial x_\beta} g_{\mu\nu} = \left(\frac{1}{c^2}\left(\frac{\partial}{\partial x_4}\right)^2 - \left(\frac{\partial}{\partial x_1}\right)^2 - \left(\frac{\partial}{\partial x_2}\right)^2 - \left(\frac{\partial}{\partial x_3}\right)^2\right) g_{\mu\nu} = \kappa T_{\mu\nu} \tag{9}$$

or more simply expressed

$$\Box g_{\mu\nu} = \kappa T_{\mu\nu}.$$

It turns out that these most natural of intermediates in the transition to Newton's law of gravitation are not realized by the final theory. In it, the weak field equations corresponding to (9) include an extra trace term. See (Einstein 1922, 87).

$$\Box g_{\mu\nu} = \kappa(T_{\mu\nu} - (1/2) g_{\mu\nu} T). \tag{9'}$$

These two expectations concerning the static field and weak field are closely connected. In particular, as Einstein showed in Einstein (Einstein 1913, 1259), one recovers a spatially flat static metric $g^{STAT}_{\mu\nu}$ if one solves the weak field equation (9) for the case a of a time independent field produced by a static, pressureless dust

5 I revert to the notation of (Einstein and Grossmann 1913). Summation is *not* implied by repeated indices. All indices are written as subscript with the covariant and contravariant forms of a tensor represented by Latin and Greek letters respectively. Thus the modern $g_{\mu\nu}$ is written as $g_{\mu\nu}$, but the modern $g^{\mu\nu}$ is written as $\gamma_{\mu\nu}$. Coordinate indices are written as subscript as well.

cloud.[6] This recovery of a spatially flat solution is blocked by the added trace term T in (9') in the final theory.

That Prove Fatal

On page 19L of the notebook, Einstein showed that he knew how to reduce the Ricci tensor to the weak field form required by (9). Using a standard device in the literature, he simply restricted his coordinate systems to those in which the harmonic condition

$$\sum_{\kappa l} \gamma_{\kappa l} \begin{bmatrix} \kappa l \\ i \end{bmatrix} = 0 \tag{10}$$

is satisfied. He immediately found that he could eliminate all the second derivative terms that were not required by the operator (8) for the Newtonian limit. Disaster ensued over the pages 19R–21R for this promising combination of Ricci tensor as gravitation tensor and harmonic coordinate systems. Einstein sought to bring this combination into accord with his expectations (4) for static fields and for the weak field equations (9). He failed and inevitably so. The coordinate systems used to bring the static field into the form of $g^{STAT}_{\mu\nu}$ in (4) are not harmonic. That coordinate system does, however, satisfy a formally similar coordinate condition

$$\sum_{\kappa} \frac{\partial \gamma_{\kappa\alpha}}{\partial x_\kappa} = 0. \tag{11}$$

(We call this "Hertz condition" in this volume since it is mentioned by Einstein in a letter to Paul Hertz of 22 August 1915 (CPAE 8, Doc. 111).) What makes this condition attractive is that it entails the weak field form of the energy momentum conservation law[7]

$$\sum_{\nu} \frac{\partial \Theta_{\kappa\alpha}}{\partial x_\nu} = 0. \tag{12}$$

Einstein even realized that he could retain this form of the energy conservation law and the harmonic condition if he added the trace term in T in (9'), but the modified field equations were no longer compatible with his expectations for the weak static

6 The prediction of spatial flatness is almost immediate. The stress energy tensor $T_{\mu\nu}$ for this static dust cloud will satisfy $T_{\mu\nu} = 0$ excepting T_{44}. Thus we have immediately for all values of μ, ν excepting 4,4, that $\Delta g_{\mu\nu} = 0$ for all spacetime. With finite values at spatial infinity as a boundary condition, these last equations solve to yield $g_{\mu\nu} = \text{constant}$ for all μ, ν excepting 4,4, as required by $g^{STAT}_{\mu\nu}$ of (4).

7 $\Theta_{\mu\nu}$ is the contravariant form of the stress-energy tensor $T_{\mu\nu}$. The condition (11) combined with the field equation (9) yields the weak field form of the energy conservation law through

$$\kappa \sum_{\nu} \frac{\partial \Theta_{\mu\nu}}{\partial x_\nu} = \sum_{\nu} \frac{\partial}{\partial x_\nu}\left(\sum_{\alpha\beta} \gamma^{SR}_{\alpha\beta} \frac{\partial^2}{\partial x_\alpha \partial x_\beta} \gamma_{\mu\nu}\right) = \sum_{\nu\alpha\beta} \gamma^{SR}_{\alpha\beta} \frac{\partial^2}{\partial x_\alpha \partial x_\beta} \left(\frac{\partial \gamma_{\mu\nu}}{\partial x_\nu}\right) = 0.$$

field $g^{STAT}{}_{\mu\nu}$, so they could not stand. Harmonic coordinate systems no longer appear in the notebook.

1.2 The "November Tensor"

The outcome of Einstein's investigations of the Ricci tensor was disappointing. But his creative energies were far from spent. He then turned immediately to another proposal for a gravitation tensor, the one he would publish on 4 November 1915, upon his return to general covariance. It is laid out on page 22R of the notebook. Einstein shows how it is possible to split off a part of the Ricci tensor that is not a generally covariant tensor, but at least transforms tensorially under unimodular transformations.

Unimodular Transformations

The class of unimodular transformations has a simple defining property. A coordinate transformation $x_\alpha \to x'_\beta$ is fully specified by the associated matrix of differential coefficients $\partial x'_\beta / \partial x_\alpha$. A transformation is unimodular if the determinant of this matrix is unity:

$$\mathrm{Det}\left(\frac{\partial x'_\beta}{\partial x_\alpha}\right) = 1. \tag{13}$$

Unimodular transformations preclude transformations that uniformly expand the coordinate system, such as $x'_\alpha = 2x_\alpha$. They are volume preserving in spacetime.[8]

The coefficients of the metric tensor transform according to

$$g'_{\mu\nu} = \left(\frac{\partial x_\alpha}{\partial x'_\mu}\right)\left(\frac{\partial x_\beta}{\partial x'_\nu}\right) g_{\alpha\beta}.$$

Taking the determinants of these quantities we find that the (positive valued)[9] determinant G transforms according to

$$\sqrt{G'} = \mathrm{Det}\left(\frac{\partial x_\alpha}{\partial x'_\mu}\right)\sqrt{G}.$$

It now follows immediately that $\sqrt{G'} = \sqrt{G}$ for unimodular transformations, that is, when (13) holds. This equality tells us that $\sqrt{G}$ transforms as a scalar under unimodular transformation, as do functions of it such as $\log\sqrt{G}$. We can easily form unimodular vectors from this quantity. The coordinate derivative $\partial\phi / \partial x_i$ of a generally covariant scalar ϕ is a generally covariant vector. Similarly, the coordinate derivative

---

8 They are volume preserving in the coordinate space. A volume element $dx_1 dx_2 dx_3 dx_4$ for a region bounded by the four coordinate differentials dx_α in coordinate space is preserved since it transforms according to the rule $dx'_1 dx'_2 dx'_3 dx'_4 = \mathrm{Det}\,(\partial x'_\beta / \partial x'_\alpha) dx_1 dx_2 dx_3 dx_4$. The invariant volume element of a metrical spacetime, $\sqrt{G} dx_1 dx_2 dx_3 dx_4$ is also preserved since $\sqrt{G}$ is an invariant under unimodular transformation.

9 In other places, it is written as $-g$.

of a unimodular scalar is a unimodular vector. Therefore $\dfrac{\partial \log \sqrt{G}}{\partial x_i}$ is a unimodular vector. This result is the key to Einstein's plan.

Proposal: A Unimodular Tensor....

On page 22R of the notebook, Einstein took the Ricci tensor T_{il} and expressed it as the sum of two parts. He wrote

$$T_{il} = \underbrace{\left(\frac{\partial T_i}{\partial x_l} - \sum \begin{Bmatrix} il \\ \lambda \end{Bmatrix} T_\lambda\right)}_{\text{tensor 2nd rank}} - \underbrace{\sum_{\kappa l} \left(\frac{\partial \begin{Bmatrix} il \\ \kappa \end{Bmatrix}}{\partial x_\kappa} - \begin{Bmatrix} i\kappa \\ \lambda \end{Bmatrix} \begin{Bmatrix} l\lambda \\ \kappa \end{Bmatrix} \right)}_{\text{presumed gravitation tensor } T^x_{il}.} \tag{14}$$

His purpose is quite clear. And if there were any doubt, the proposal is explained in detail in (Einstein 1915a). The first term of T_{il} is a just the covariant derivative of the unimodular vector

$$T_i = \frac{\partial \log \sqrt{G}}{\partial x_i}$$

and therefore a tensor under unimodular transformations. Since the Ricci tensor T_{il} transforms as a tensor under all transformations, Einstein could infer that the second term of (14) must also transform as a tensor under unimodular transformations.[10] This second term, denoted as T^x_{il}, is chosen by Einstein as a candidate gravitation tensor. Because of its reappearance in November 1915, we have labeled it the "November tensor" in this volume. Its selection is compatible with Einstein's ambitions for extending the principle of relativity to acceleration. While not supplying general covariance, covariance under unimodular transformations is sufficiently expansive to capture transformations between inertial and accelerated coordinate systems. As Einstein shows in (Einstein 1915a, 786), these acceleration transformations include ones that set the spatial coordinate axes into rotation as well as ones that accelerate its spatial origin without rotation.[11]

…that Gives the Newtonian Limit and Energy Conservation

The remainder of the page explains why Einstein was attracted to this new candidate. He had been unable to reduce the entire Ricci tensor to the form (8) without employing a coordinate condition, the harmonic condition, that brought fatal problems. Ein-

10 The result is automatic. The quantity T^x_{il} can be expressed as a difference of two quantities, each of which are tensors at least under unimodular transformations.

stein now showed that he could reduce the tensor T^x_{il} to the form (8) if he considered coordinate systems which satisfied the coordinate condition (11) introduced above.

As Einstein proceeded to show, with the assumption of this condition, the candidate gravitation tensor T^x_{il} reduced to

$$-2T^x_{il} = \sum_{\alpha\beta}\gamma_{\alpha\beta}\frac{\partial^2 g_{il}}{\partial x_\alpha \partial x_\beta} + \left(\text{terms quadratic in } \frac{\partial g_{\mu\nu}}{\partial x_\alpha}\right). \tag{15}$$

In the weak field of (7), the terms quadratic in

$$\frac{\partial g_{\mu\nu}}{\partial x_\alpha}$$

will all be of order ε^2 and thus of the second order of smallness; the first term of (15) agrees with the first term of (8) in quantities of first order. The candidate tensor T^x_{il} has been reduced to the requisite form (8). In addition, the reduction has been effected by just the condition (11) needed to enforce energy conservation in the weak field. As Einstein had already found, that coordinate condition, in conjunction with the weak field equations (9) entailed energy conservation in the weak field form (12).

11 This last compatibility is not straightforward. The choice of T^x_{il} as gravitation tensor is not compatible with Einstein's favorite examples of a field produced by uniform, rectilinear acceleration in Minkowski spacetime, the static, homogeneous field, $g^{HG}_{\mu\nu}$, given as (6). One finds by explicit calculation that $g^{HG}_{\mu\nu}$ is not a solution of the source free field equations $T^x_{il} = 0$. This failure is already suggested by that fact that T^x_{il} is only a tensor under unimodular transformations and that the transformation from $g^{SR}_{\mu\nu}$ to $g^{HG}_{\mu\nu}$ is not unimodular. (Unimodular transformations preserve the determinant of the metric. But Det $(g^{SR}_{\mu\nu}) = c^2 = \text{constant}$, whereas $\text{Det}(g^{HG}_{\mu\nu}) = (c_0 + ax)^2 \neq \text{constant}$.) Now $g^{SR}_{\mu\nu}$ is obviously a solution of the source free field equations $T^x_{il} = 0$. So we cannot infer from the covariance properties of T^x_{il} that $g^{HG}_{\mu\nu}$ is also a solution.

If Einstein was aware of this problem, he did not find it immediately fatal to T^x_{il} as gravitation tensor. The problem should have been apparent as soon as Einstein contemplated a gravitation tensor covariant only under unimodular transformations. Yet he proceeded on page 22R with the elaborate recovery of the Newtonian limit. Again there is no trace of a concern over the homogeneous field, $g^{HG}_{\mu\nu}$, in the pages surrounding and following. (The concern is directed towards the coordinate restriction (11) and the rotation field $g^{ROT}_{\mu\nu}$ defined below.) The failure amounts to a failure of his principle of equivalence. But Einstein had already reconciled himself to such a failure in his theories of 1912 and it arose again in his *Entwurf* theory. See (Norton 1985, §4.3).

In the text I have explained his apparent indifference by assuming that he adopted the position expressed later in (Einstein 1915a, 786). Employing the same gravitation tensor T^x_{il}, the theory of that paper was also covariant under unimodular transformations. In order to affirm that the theory satisfied the relativity of motion, he observed (in part) that the coordinate transformation $x' = x - \tau_1$, $y' = y - \tau_2$, $z' = z - \tau_3$, $t' = t$, with τ_1, τ_2 and τ_3 arbitrary functions of t, is unimodular. We might note that this transformation corresponds to a large class of unidirectional accelerations. While the class does not include the transformation from $g^{SR}_{\mu\nu}$ to $g^{HG}_{\mu\nu}$, Einstein may well have simply assumed that it did include related transformation of comparable physical significance.

…Or Does It?

Einstein could hardly hope for a more satisfactory outcome. He was burdened by strict and unforgiving requirements on static fields and the weak field limit. Yet he found gravitational field equations of very broad covariance compatible with both. So satisfactory is this resolution that Einstein published it in November 1915 upon his return to general covariance. T^x_{il} is the gravitation tensor he proposed in his communication of 4 November to the Prussian Academy (Einstein 1915a). On 4 November, he had little choice. The natural gravitation tensors, the Ricci tensor and then the Einstein tensor, were still unavailable to him. He was still bewitched by his early, mistaken expectations concerning static fields and the weak field limit. These expectations were dispelled after that communication, over the course of that November. A rapid series of communications first brought him his successful explanation of the anomalous motion of Mercury and then his final, generally covariant field equations.

In the 4 November communication, Einstein paused to explain the transient charms of the "November tensor" T^x_{il}. He closed the communication of 4 November by showing (§4) that the coordinate condition (11), in the case of weak fields, reduces his field equations to the form (9).

Yet Einstein's achievement on page 22R of the Zurich Notebook proves to be as puzzling as it is impressive. For the proposal disappears as rapidly as it appeared; it receives no further serious consideration in the notebook.[12] The difficulties that led to its dismissal cannot be those that defeated the combination of the Ricci tensor and the choice of harmonic coordinate systems. These were the misleading expectations about static fields and the weak field limit. The gravitation tensor T^x_{il} was compatible with both. Why did Einstein so rapidly discard this promising candidate for his gravitation tensor? What changed to make it acceptable in November 1915?

1.3 The {} Prejudice

We have fragments of evidence that allow us to answer these questions. Some come from the pages of the notebook surrounding page 22R. The most important come in Einstein's later recollections.

A Letter to Sommerfeld of 28 November 1915

Einstein's most complete account comes in all too brief remarks in this letter. Having recounted the final field equations of his theory, Einstein continued:

> Of course it is easy to write down these generally covariant equations. But it is hard to see that they are the generalization of Poisson's [Newtonian] equations and not easy to see that they allow satisfaction of the conservation laws.

12 We shall see below in section 3.7 that T^x_{il} is reevaluated on the following page 23L, but now with the coordinate restriction (11) replaced by another. The candidate gravitation tensor reappears briefly on page 25L in an incomplete attempt to compute the stress energy tensor of the gravitational field associated with this gravitation tensor.

> Now one can simplify the whole theory significantly by choosing the reference system so that $\sqrt{-g} = 1$. Then the equations take on the form
>
> $$-\sum_{1}\frac{\partial\left\{\begin{matrix} im \\ 1 \end{matrix}\right\}}{\partial x_1}+\sum_{\alpha\beta}\left\{\begin{matrix} i\alpha \\ \beta \end{matrix}\right\}\left\{\begin{matrix} m\beta \\ \alpha \end{matrix}\right\} = -\kappa\left(T_{im}-\frac{1}{2}g_{im}T\right).$$
>
> I had already considered these equations 3 years ago with Grossmann up to the second term on the right hand side, but had then arrived at the result that they did not yield Newton's approximation, which was erroneous. What supplied the key to this solution was the realization that it is not
>
> $$\sum g^{l\alpha}\frac{\partial g_{\alpha i}}{\partial x_m}$$
>
> but the associated Christoffel symbols $\left\{\begin{matrix} im \\ 1 \end{matrix}\right\}$ that are to be looked upon as the natural expression for the "components" of the gravitational field. If one sees this, then the above equation becomes simplest conceivable, since one is not tempted to transform it by multiplying out [*Ausrechnen*] the symbols for the sake of general interpretation.[13]

Which equations had he considered three years before? "…[T]hese equations…up to the second term on the right hand side…," that is, excluding the trace term in T, coincide with the choice of the "November tensor" T^{x}_{il} as gravitation tensor on page 22R. Einstein tells Sommerfeld that he had considered these equations with Grossmann and that detail is affirmed by the appearance of Grossmann's name on the top of page 22R.[14]

The Fateful Prejudice

The elements of the account Einstein laid out to Sommerfeld reappear in other places in Einstein's writing. In his publication, (Einstein 1915a, 778), he also recounted his misidentification of the "'components' of the gravitational field." He recalled how he

---

13 "Es ist natürlich leicht, diese allgemein kovarianten Gleichungen hinzusetzen, schwer aber, einzusehen, dass sie Verallgemeinerungen von Poissons Gleichungen sind, und nicht leicht, einzusehen, dass sie den Erhaltungssätzen Genüge leisten. Man kann nun die ganze Theorie eminent vereinfachen, indem man das Bezugssystem so wählt, dass $\sqrt{-g} = 1$ wird. Dann nehmen die Gleichungen die Form an, […]. Diese Gleichungen hatte ich schon vor 3 Jahren mit Grossmann erwogen/ bis auf das zweite Glied der rechten Seite, war aber damals zu dem Ergebnis gelangt, dass sie nicht Newtons Näherung liefere, was irrtümlich war. Den Schlüssel zu dieser Lösung lieferte mir die Erkenntnis, dass nicht […] sondern die damit verwandten Christoffel'schen Symbole […] als natürlichen Ausdruck für die "Komponente" des Gravitationsfeldes anzusehen ist. Hat man dies gesehen, so ist die obige Gleichung denkbar einfach, weil man nicht in Versuchung kommt, sie behufs allgemeiner Interpretation umzuformen durch Ausrechnen der Symbole." Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153).

14 Presumably Einstein alludes to his earlier recovery of these equations in the introduction to his paper of 4 November 1915. Einstein recalls his work three years earlier with Grossmann and then claims: "In fact we had already then come quite close to the solution of the problem given in the following." ("In der Tat waren wir damals der im nachfolgenden gegebenen Lösung des Problems bereits ganz nahe gekommen.") (Einstein 1915a, 778)

had reformulated the energy conservation law in his earlier work, (Einstein 1914c). In the absence of non-gravitational forces, the law is just the vanishing of the covariant divergence of the stress-energy tensor $T_{\mu\nu}$. It could be re-expressed as[15]

$$\sum_{\nu} \frac{\partial \mathfrak{T}_{\nu}^{\sigma}}{\partial x_{\nu}} - \begin{Bmatrix} \nu\sigma \\ \tau \end{Bmatrix} \mathfrak{T}_{\tau}^{\nu} = \sum_{\nu} \frac{\partial \mathfrak{T}_{\nu}^{\sigma}}{\partial x_{\nu}} - \frac{1}{2} g^{\tau\mu} \frac{\partial g_{\mu\nu}}{\partial x_{\sigma}} \mathfrak{T}_{\tau}^{\nu} = 0,$$

where the tensor density $\mathfrak{T}_{\nu}^{\sigma} = \sqrt{-g} T_{\nu}^{\sigma}$. Einstein now reflected upon his earlier error:

> This conservation law had earlier induced me to view the quantities
>
> $$\frac{1}{2} \sum_{\mu} g^{\tau\mu} \frac{\partial g_{\mu\nu}}{\partial x_{\sigma}}$$
>
> as the natural expression for the components of the gravitational field, even though it is obvious, in view of the formulae of the absolute differential calculus, to introduce the Christoffel symbols
>
> $$\begin{Bmatrix} \nu\sigma \\ \tau \end{Bmatrix}$$
>
> instead of those quantities. This was a fateful prejudice.[16]

Einstein continues to argue for the naturalness of this choice. The Christoffel symbols are symmetric in the indices ν and σ and they reappear in the geodesic equation. However he does not explain precisely how this "prejudice" led him astray. For convenience, I will call this the "$\{\}$ prejudice."

A letter written to Lorentz the following January repeats and slightly clarifies the role of the $\{\}$ prejudice.

> I had already considered the present equations [of the final theory, not of 4 November] in their essentials 3 years ago with Grossmann, who had made me aware of Riemann's tensor. But since I had not recognized the formal meaning of the $\{\}$, I could achieve no overview and could not prove the conservation laws.[17]

The Problems Collected

If we assemble the clues, we find Einstein giving two reasons for his rejection of the "November tensor" T_{il}^{x} when he worked with Grossmann:[18]

---

15 Einstein refers back to the results in (Einstein 1914c). There the energy conservation law was written in terms of the covariant divergence of $T_{\mu\nu}$. In his paper of 4 November 1915, Einstein had discarded a term in $\sqrt{-g}$ to simplify the result at the expense of reducing its covariance to unimodular transformations only.

16 "Diese Erhaltungsgleichung hat mich früher dazu bereleitet, die Größen [eq.] als den natürlichen Ausdruck für die Komponenten des Gravitationsfeldes anzusehen, obwohl es im Hinblick auf die Formeln des absoluten Differenzialkalküls näher liegt, die Christoffelschen Symbole [eq.] statt jener Größen einzuführen. Dies war ein verhängnisvolles Vorurteil." (Einstein 1915a, 782)

17 "Die jetzigen Gleichungen hatte ich im Wesentlichen schon vor 3 Jahren zusammen mit Grossmann, der mich Riemanns Tensor aufmerksam machte, in Betracht gezogen. Da ich aber die formale Bedeutung der $\{\}$ nicht erkannt hatte, konnte ich keine Übersichtlichkeit erzielen und die Erhaltungssätze nicht beweisen." Einstein to Hendrik A. Lorentz, 1 January 1916 (CPAE 8, Doc. 177).

- He was unable to recover the Newtonian limit.
- The {} prejudice precluded recognition of the inherent simplicity of the equations and the recovery of the energy conservation law.

Both elements of Einstein's account are puzzling. A straightforward reading of page 22R shows Einstein recovering the Newtonian limit in exactly the same way as in his later publication of 4 November 1915. A more careful analysis will be needed, but that will be postponed to later parts of this chapter. Einstein's remarks about the {} prejudice are also puzzling at first. Einstein had a perfectly acceptable expression for the energy conservation law. It is just the vanishing of the covariant divergence of $T_{\mu\nu}$ and was introduced by Einstein on page 5R of the notebook. I believe that these last remarks admit a fairly simple explication.

Recovering Energy Conservation

To understand why this prejudice was fateful, we need to recall a major difference between Einstein's work in the notebook and in November 1915. Here I draw heavily on the insights of Jürgen Renn and Michel Janssen.[19] By 1915 Einstein had developed techniques of considerably greater sophistication for recovering energy conservation than he had used in 1913. Also, when Einstein talks of proving the conservation laws, we must understand him to mean a little more than merely recovering the standard result that the covariant divergence of $T_{\mu\nu}$ vanishes. We must understand an important part of the recovery to be the identification of a stress-energy tensor for the gravitational field, $t_{\mu\nu}$, that will figure in an alternate form of the energy conservation law (as given in Einstein and Grossmann 1913, 17)

$$\sum_{\mu\nu} \frac{\partial}{\partial x_\nu}\{\sqrt{-g}\ \gamma_{\sigma\mu}(T_{\mu\nu} + t_{\mu\nu})\} = 0.$$

At the time of the *Entwurf* theory, Einstein employed a simple device for generating this stress-energy tensor. It had been used on pages 19R, 20L and 21L of the notebook in the weak field, while Einstein weighed the fate of the Ricci tensor as gravitation tensor. Einstein took the expression for the gravitational force density in the weak field (7),

$$\frac{1}{2}\sum_{\mu\nu} \frac{\partial g_{\mu\nu}}{\partial x_\sigma}\Theta_{\mu\nu},$$

where $\Theta_{\mu\nu}$ is the contravariant form of the stress-energy tensor $T_{\mu\nu}$. He then substituted for $\Theta_{\mu\nu}$ using the gravitational field equation for the weak field (9). A simple

18 Since recollections are not infallible, there is always a possibility that the first difficulty with the Newtonian limit was misremembered and really pertained only to his problem with the Ricci tensor. We need not have such concerns for the {} prejudice. Since it was published on 4 November 1915, the notion was clearly formulated before Einstein had realized the problems with the Newtonian limit associated with his assumptions about the static field and the weak field equations.

19 See "Untying the Knot …" (What Did Einstein Know).

manipulation that preserved only terms of lowest order in the derivatives of $g_{\mu\nu}$ allowed this force density to be rewritten as the divergence of a tensor $t_{\alpha\sigma}$:[20]

$$\frac{1}{2}\sum_{\mu\nu\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\sigma}\left(\gamma_{\alpha\beta}\frac{\partial^2}{\partial x_\alpha \partial x_\beta}\gamma_{\mu\nu}\right)$$
$$= \frac{1}{2}\sum_{\mu\nu\alpha\beta\rho\tau}\frac{\partial}{\partial x_\beta}\left(\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\sigma}\frac{\partial \gamma_{\mu\nu}}{\partial x_\alpha} - \frac{1}{2}\delta_{\beta\sigma}\gamma_{\rho\tau}\frac{\partial g_{\mu\nu}}{\partial x_\rho}\frac{\partial \gamma_{\mu\nu}}{\partial x_\tau}\right) = \frac{1}{2}\gamma_{\alpha\beta}\frac{\partial t_{\alpha\sigma}}{\partial x_\beta}$$

$$\frac{1}{2}\sum_{\mu\nu\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\sigma}\left(\gamma_{\alpha\beta}\frac{\partial^2}{\partial x_\alpha \partial x_\beta}\gamma_{\mu\nu}\right)$$
$$= \frac{1}{2}\sum_{\mu\nu\alpha\beta\rho\tau}\frac{\partial}{\partial x_\beta}\left(\gamma_{\alpha\beta}\frac{\partial g_{\mu\nu}}{\partial x_\sigma}\frac{\partial \gamma_{\mu\nu}}{\partial x_\alpha} - \frac{1}{2}\delta_{\beta\sigma}\gamma_{\rho\tau}\frac{\partial g_{\mu\nu}}{\partial x_\rho}\frac{\partial \gamma_{\mu\nu}}{\partial x_\tau}\right) = \frac{1}{2}\frac{\partial}{\partial x_\beta}(\gamma_{\alpha\beta}t_{\alpha\sigma}).$$

Einstein identified that tensor with the stress-energy tensor of the gravitational field.

This equation holds only for quantities of second order of smallness (ε^2) in the metric tensor of (7) of the weak field. The major part of Einstein's strategy for deriving his *Entwurf* field equations was to determine what quantities must be added to the gravitation tensor of the weak field equations (9) to make the relation between force density and the divergence of $t_{\alpha\sigma}$ exact, that is, true for all orders. This strategy reappears after page 22R, on pages 24R and 25R, and then in the full derivation of the *Entwurf* gravitational field equations by this strategy on pages 26L–26R.

Why the $\{\}$ *Prejudice Was Fateful*

Now we can understand why the $\{\}$ prejudice was fateful as Einstein inspected the candidate gravitation tensor T_{il}^{x} on page 22R. On his account, he was unable to see how to recover the Newtonian limit, a problem we shall return to. He also needed to assure himself that the gravitation tensor was compatible with energy conservation and that included admission of a well-defined stress-energy tensor $t_{\alpha\sigma}$ for the gravitational field. Following his standard practice, that would mean that he must be able to reformulate the expression for gravitational force density as a divergence. We can immediately see the problem Einstein would face. The tensor T_{il}^{x} is expressed fully in terms of Christoffel symbols, with each representing a sum of three terms in

$$\frac{\partial g_{\mu\nu}}{\partial x_\tau}.$$

The product of two Christoffel symbols would yield nine of these derivative terms.[21] Faced with so many terms, we could well imagine Einstein's sense that he had no

20 The symbol $\delta_{\beta\sigma}$, where $\delta_{\beta\sigma} = 1$ when $\beta = \sigma$ and zero otherwise, was not then used by Einstein, but is introduced here for simplicity.

21 Einstein's *Entwurf* gravitation tensor has one second derivative term and three first derivative terms. Unless there are duplications, the November tensor would have three second derivative terms and nine first derivative terms.

overview (as he wrote to Lorentz above) or that this was certainly not the simplest conceivable equation (as he wrote to Sommerfeld above). We could well imagine that this difficulty, along with failure of the Newtonian limit, would be sufficient grounds for him to abandon the candidate tensor.

What changed by November 1915? In the course of 1914, Einstein developed powerful variational methods for recovering energy conservation and expressions for the stress-energy tensor of the gravitational field. (Einstein and Grossmann 1914; Einstein 1914c). He applied those to his field equations of 4 November 1915, and found that the expressions took on just about the simplest form one could expect—as long as all quantities were expressed in terms of the Christoffel symbols. His field Lagrangian was just

$$\sum_{\sigma\tau\alpha\beta} g^{\sigma\tau} \begin{Bmatrix} \sigma\beta \\ \alpha \end{Bmatrix} \begin{Bmatrix} \tau\alpha \\ \beta \end{Bmatrix}.$$

It is one of the simplest fully contracted expressions quadratic in the Christoffel symbols. (The Lagrangian must be quadratic if it is to return field equations linear in the second derivatives of the metric tensor.) His expression for the canonical stress-energy tensor of the gravitational field was scarcely more complicated.

Einstein's analysis in the notebook began with a force density

$$\frac{1}{2}\sum_{\mu\nu} \frac{\partial g_{\mu\nu}}{\partial x_\sigma} \Theta_{\mu\nu}$$

expressed in terms of the derivatives of the metric tensor. It overwhelmed him and he abandoned it. Einstein's analysis in November 1915 retained the Christoffel symbols and, using his more powerful methods, yielded just about the simplest expressions he could expect. In hindsight, Einstein diagnosed the error to lie in his starting point. Had he not misidentified the components of the gravitational field, would he have resisted the temptation to expand the Christoffel symbols? Would he have come to see that he had the right equations before him?

Einstein used the term "prejudice"—a belief not properly grounded in evidence. It is a fitting label for the error we reconstruct. He was not assured that energy conservation would fail for this tensor in the notebook. He had no firm proof, no result around which to maneuver. He merely balked at a very complicated calculation that could have, in principle, been completed. He had no good reason to abandon the tensor other than the hunch that the true way could not be that complicated. And he later found that it was not at all complicated when viewed from another perspective.

2. COORDINATE CONDITIONS AND COORDINATE RESTRICTIONS

On page 22R of the notebook, Einstein shows how to use the coordinate condition (11) to reduce the gravitation tensor T_{il}^{x} to the requisite Newtonian form (8). Why does he report to Sommerfeld that he and Grossmann had originally thought the resulting gravitational field equations incompatible with the Newtonian limit? In this part of the chapter and in the part to follow, I will describe two explanations, both requiring that Einstein did not use coordinate conditions in the modern way. The explanation to be developed in this part is the simpler of the two. It asserts that Einstein understood field equations to be compatible with the Newtonian limit if they had the form (8) not just in some specialized coordinate systems, but in all coordinate systems. A cursory inspection would reveal that T_{il}^{x} does not have this form (8), rendering it incompatible with the Newtonian limit.

For this account to be tenable, we must now explain why page 22R displays the apparently successful reduction of the tensor T_{il}^{x} to the Newtonian form (8) using coordinate condition (11). This part will supply that explanation by suggesting that Einstein did not use the coordinate condition (11) in the standard way, as it was later in Einstein's paper of 4 November 1915. It was not a condition just to be invoked in the case of the Newtonian limit. It was a postulate to be used universally. In part one of this section, I will review the these two ways of using conditions such as (11). In this volume, we reserve the term "coordinate condition" for the standard usage and "coordinate restriction" for the other usage suggested here. This notion of coordinate restriction was introduced by Jürgen Renn and Tilman Sauer.[22] We will see in the second section of this part that there is clear evidence that Einstein used coordinate restrictions in the notebook on page 22 and afterwards.

In the third section of this part, I will describe how we can use the notion of coordinate restrictions to explain why Einstein abandoned the gravitation tensor T_{il}^{x}. To do so, we need a further assumption. Einstein did not just use (11) as a coordinate restriction on page 22. We must assume that he was unaware of the other possibility of using (11) as a coordinate condition. Then his rejection of T_{il}^{x} as gravitation tensor is automatic; it does not have the Newtonian form (8). This account is the majority viewpoint within our group.

The account depends upon the assumption that Einstein was unaware of the possibility of using (11) as a coordinate condition. In the fourth section of this part, I will explain why I do not believe the assumption. There is no single piece of evidence that allows us to decide either way on the assumption. It lies on the boundary. However I believe that there are so many indications that speak against it, that their combined weight makes the assumption untenable. The most plausible account, I believe, is that page 22 of the notebook marks a turning point. Prior to it, Einstein used coordinate conditions; after he reverted to the use of coordinate restrictions.

2.1 Two Uses of One Equation

Four Equations Select a Coordinate System…

The equations of a generally covariant spacetime theory hold in arbitrary coordinate systems. In applying the theory, we may pick the coordinate system freely. The four coordinates are just four real valued functions x_{α} defined on the spacetime manifold.

22 See "Pathways out of Classical Physics …" (in vol. 1 of this series).

Therefore a coordinate system can be chosen with four conditions $x_\alpha(p) = f_\alpha(p)$, where the $f_\alpha(p)$ are four arbitrary real valued functions of suitable differentiability defined over events p. Thus four arbitrary conditions are associated with the choice of a coordinate system.

This simple fact about coordinate systems is often rendered as the much looser idea that there are four degrees of freedom in a generally covariant theory associated with the freedom of choice of the coordinate system.[23] These four degrees of freedom are more usually exploited indirectly by specifying four differential conditions on quantities defined in spacetime. Examples are the harmonic condition (10) and the condition (11) used on page 22R. They do not fully exhaust the freedom. Since they are differential conditions on the metric, they do not force a unique choice of coordinate system; differential equations admit many solutions according to the choice of boundary conditions. So each of (10) and (11) admit many coordinate systems. For example, if one admits a coordinate system x_α, it also admits any coordinate system linearly related to it. This follows immediately from the covariance of (10) and (11) under linear coordinate transformations.

In the case of the harmonic condition (10), the relation between the different forms of the condition can be made more explicit. We can define the natural, generally covariant analog of the d'Alembertian operator $\square$ used in (9) as follows. If φ is a scalar, we take its covariant derivative twice and contract with $\gamma_{\mu\nu}$ over the two resulting indices. In Einstein's notation of 1913, this gives

$$\square\varphi = \sum_{\alpha\beta\rho\sigma} \gamma_{\alpha\beta}\frac{\partial^2\varphi}{\partial x_\alpha \partial x_\beta} - \gamma_{\alpha\beta}\begin{bmatrix}\alpha\beta\\ \rho\end{bmatrix}\gamma_{\rho\sigma}\frac{\partial\varphi}{\partial x_\sigma}.$$

If we now form $\square x_\tau$ for each of the four coordinates, we quickly see that the harmonic condition (10) is equivalent to[24]

$$\square x_\tau = \sum_{\alpha\beta\rho\sigma} \gamma_{\alpha\beta}\frac{\partial^2 x_\tau}{\partial x_a \partial x_\beta} - \gamma_{\alpha\beta}\begin{bmatrix}\alpha\beta\\ \rho\end{bmatrix}\gamma_{\rho\sigma}\frac{\partial x_\tau}{\partial x_\sigma} = 0. \tag{10'}$$

23 This slogan—four degrees of freedom associated with the choice of coordinates—must be approached with some caution. It does not mean we can adjoin any four equations we like to our theory under the guise of choosing the coordinate system. Adding the single equation $R = 0$, where R is the curvature scalar, does a great deal more than restrict the coordinate system. One might imagine that restricting the equations to first order derivatives in $g_{\mu\nu}$ would protect us from these problems, since, at any event in spacetime, we can always transform such derivatives to zero. But it does not. Imagine that we have 100 such conditions, $C_1 = 0$, $C_2 = 0$, …, $C_{100} = 0$ that more than exhaust the freedom to choose coordinates. They can be disguised as a single equation $(C_1)^2 + \ldots + (C_{100})^2 = 0$.

24 To see the equivalent, notice that the first term of (10') vanishes for any coordinate system. The second term vanishes if (10) holds. So (10) entails (10'). Conversely, if (10') holds, its second term must vanish, which immediately entails (10).

One sees from this equation that the harmonic condition cannot fix the coordinate system uniquely.[25] If the condition is satisfied by x_τ, it will also be satisfied by any linear transform of it. Other transforms will also be admissible. The condition cannot fix the coordinate system up to linear transformation unless one invokes further restrictive conditions (see Fock 1959, §93).

We know that Einstein was aware of this form (10') of the harmonic condition on coordinate systems, then routinely available in the literature on infinitesimal geometry as the "isothermal" coordinates. At the bottom of page 19L on which he introduced the condition in form (10), he wrote "…Holds for coordinates which satisfy the eq[uation] $(\Delta\varphi = 0)$."

We see how equations (10) and (11) allow us choose a restricted set of coordinates. There are two ways relevant to our present interests that these equations may be used: as coordinate conditions and as coordinate restrictions.

…As Coordinate Conditions

Einstein later used a standard procedure for recovering the Newtonian limit from his generally covariant general theory of relativity. See for example, (Einstein 1922, 86–87). That theory must revert to Newton's theory of gravitation in the special circumstance of weak static fields, that is, under the assumption that the metric has the form (7) and is static. In addition, Newton's theory is not generally covariant, but is covariant under Galilean transformation only.[26] Therefore the covariance of Einstein's theory must be restricted if Newton's theory is to be recovered.

That covariance is already restricted in part by the presumption that the metric have the form (7). That form is not preserved under arbitrary transformations. The restriction to the weak field metric (7) is not, however, sufficient to reduce the covariance of the theory to the Galilean covariance of Newton's theory. That form is preserved by any transformation which introduces small changes of order of the $\varepsilon_{\mu\nu}$ to the coefficients of the metric. This last freedom is eliminated by imposing a coordinate condition, such as the harmonic condition (10). We have already seen the direct effect of this condition. It eliminates all second derivative terms from the Ricci tensor beyond those in the Newtonian like form (8). In so far as Einstein expected his *Entwurf* theory to have broad covariance, he must have believed the restriction of the metric to the weak field form (7) was sufficient restriction on its covariance for the recovery of the weak field limit.

A coordinate condition is used only in the special circumstances of the Newtonian limit; it is not imposed universally on the theory.

---

25 Notice that the operator $\sum_{\alpha\beta\rho\sigma} \gamma_{\alpha\beta}\begin{bmatrix}\alpha\beta\\ \rho\end{bmatrix}\gamma_{\rho\sigma}\frac{\partial}{\partial x_\sigma}$ is invariant under linear transformation.

26 At least, this is the way it seemed to Einstein in the 1910s. Cartan and Friedrichs later showed that Newtonian theory could be given a generally covariant formulation, so that the problem of recovering the Newtonian limit from Einstein's theory takes on a different cast. See (Havas 1964) and also "The Story of Newstein …" (in vol. 4 of this series).

...As Coordinate Restrictions

The same equation (10) and (11) can be used in a different way. Einstein's goal in the notebook is a theory with sufficient covariance to satisfy a generalized principle of relativity. General covariance supplies more covariance than he needs; it includes covariance under transformations not associated with changes of states of motion, such as the transformation from Cartesian spatial coordinates to radial coordinates. So Einstein can afford to use the generally covariant expressions of the Ricci Levi Civita calculus merely as intermediates. If those expressions are not themselves suitable for his theory, then he can simplify them to generate others of somewhat less covariance that are. The generation of the November tensor T_{il}^{x} on page 22R is an example. The Ricci tensor itself appeared unsuitable as a gravitation tensor. There proved to be a way of splitting the tensor into two parts each of which is a tensor under unimodular transformations. Since Einstein was willing to accept unimodular covariance instead of general covariance, he could select one of these parts as his gravitation tensor.

The equations (10) and (11) could be used in the same way. If the Ricci tensor or the tensor T_{il}^{x} proved unsuitable as a gravitation tensor, why not sacrifice a little more covariance to produce expressions that are suitable? Conjoining (10) or (11) to their associated tensors produces simpler expressions. The tensor T_{il}^{x}, for example is reduced to (15). If Einstein selected this reduced form as his gravitation tensor, then he assured recovery of the Newtonian limit. The gravitation tensor has the required form (8).

The cost of using equations (10) and (11) in this way is a further sacrifice of covariance. The final equations will have no more covariance than the coordinate restrictions (10) and (11). Whether these have sufficient covariance to support an extension of the principle of relativity cannot easily be read by inspecting equations (10) and (11). It is a matter of computation.

2.2 The Evidence for Einstein's Use of Coordinate Restrictions

There is strong evidence that Einstein used equation (11) and another similar restriction as a coordinate restriction, that is, as a universal restriction not limited to the special case of the Newtonian limit.

The Non-Linear Transformation of Equation (11)

The first piece of evidence is on page 22L. There Einstein undertakes a simple calculation. He writes down two equations. The second is $|p_{\mu\nu}| = 1$. Since, in Einstein's notation,

$$|p_{\mu\nu}| = \frac{\partial x'_{\mu}}{\partial x_{\nu}},$$

this is just the condition that the transformation $x_{\nu} \rightarrow x'_{\mu}$ be unimodular. The first is equation (11) in the primed coordinate system. Einstein then expands this equation in terms of unprimed quantities and the coefficients of the transformation $p_{\mu\nu}$ and their inverses.

The calculation is incomplete and its outcome obscure. Its purpose is not obscure and that is all that matters here. Einstein is checking the covariance of equation (11) within the domain of unimodular transformations. If Einstein intended (11) to be a coordinate condition, it is hard to see why he would concern himself with its transformation properties. The role of equation (11) as a coordinate condition is merely to assist in reducing the covariance of the theory to enable recovery of the Newtonian limit. Galilean covariance only is required in that Newtonian limit. Einstein can be assured of this much covariance. Galilean transformations are a subset of the linear coordinate transformations. Einstein can determine rapidly that equation (11), used as a coordinate condition, will give him that much covariance. The calculation is trivial. It merely requires noticing that the coefficients

$$|p_{\mu\nu}| = \frac{\partial x'_{\mu}}{\partial x_{\nu}}$$

and their inverses

$$\pi_{\mu\nu} = \frac{\partial x_{\nu}}{\partial x'_{\mu}}$$

are constants under linear transformation. Therefore the quantity in equation (11) transforms as a vector under linear transformation since

$$\sum_{\kappa}\frac{\partial \gamma'_{\kappa\alpha}}{\partial x'_{\kappa}} = \sum_{\kappa\rho\sigma\tau}\pi_{\kappa\rho}\frac{\partial(p_{\kappa\sigma}p_{\alpha\tau}\gamma_{\sigma\tau})}{\partial x_{\rho}} = \sum_{\kappa\rho\sigma\tau}p_{\kappa\sigma}p_{\alpha\tau}\pi_{\kappa\rho}\frac{\partial\gamma_{\sigma\tau}}{\partial x_{\rho}} = \sum_{\sigma\tau}p_{\alpha\tau}\frac{\partial\gamma_{\sigma\tau}}{\partial x_{\sigma}},$$

where we use $\sum_{\kappa}P_{\kappa\sigma}\pi_{\kappa\rho} = \delta_{\sigma\rho}$. Hence, if this quantity vanishes in one coordinate system as (11) requires, it will vanish in any coordinate system to which one transforms with a linear transformation.

Einstein cannot have had this simple linear case in mind on page 22L. For the calculation there clearly allows non-constancy of the coefficients $p_{\mu\nu}$; he does not eliminate the derivative terms

$$\frac{\partial P_{\mu\alpha}}{\partial x_i},$$

which vanish automatically for linear transformations. This concern is unintelligible if equation (11) is being used as a coordinate condition. The concern is explained quite simply if that equation is being used as a coordinate restriction. The quantity in (15), the tensor T_{il}^{x} after reduction by coordinate restriction (11), is his gravitation tensor. He is computing its covariance the easy way. By its construction, this candidate gravitation tensor will transform as a tensor under unimodular transformations that leave equation (11) unchanged. If the candidate gravitation tensor is to allow a generalization of the principle of relativity, its covariance must include non-linear transformations.

The Theta Requirement

The result of the calculation on page 22L cannot have been encouraging for the combination of the tensor T_{il}^{x} and condition (11) receive no further serious attention in the notebook. Instead, on page 23L, Einstein introduced another way of recovering the Newtonian like expression (8) from T_{il}^{x} that did not require use of equation (11). That it not be required was apparently of some importance since, in a document of pure calculation with essentially no explanatory text at all, Einstein went to the trouble to explain in writing

$$\text{“}\sum \frac{\partial \gamma_{\kappa\alpha}}{\partial x_{\kappa}} = 0 \text{ is not necessary.”}$$

In its place Einstein introduced a coordinate restriction of another type. He constructed the quantity

$$\vartheta_{i\kappa\lambda} = \frac{1}{2}\left(\frac{\partial g_{i\kappa}}{\partial x_{\lambda}} + \frac{\partial g_{\kappa\lambda}}{\partial x_{i}} + \frac{\partial g_{\lambda i}}{\partial x_{\kappa}}\right) \tag{16}$$

and required that transformations between coordinates be so restricted that this quantity $\theta_{i\kappa\lambda}$ transform as a tensor. (We shall call this the "theta requirement," the "theta condition" or the "theta restriction" according to its interpretation.) He then proceeded to show by adding and discarding terms in $\theta_{i\kappa\lambda}$ from T_{il}^{x} how one could construct a quantity

$$\sum \frac{\partial}{\partial x_{\kappa}}\left(\gamma_{\kappa\alpha}\frac{\partial g_{il}}{\partial x_{\alpha}}\right) + \sum \gamma_{\rho\alpha}\gamma_{\kappa\beta}\frac{\partial g_{i\kappa}}{\partial x_{\alpha}}\frac{\partial g_{l\rho}}{\partial x_{\beta}} \tag{17}$$

that is a tensor under unimodular transformations for which $\theta_{i\kappa\lambda}$ transforms tensorially. Einstein's efforts have produced another expression in the form of (8), apparently yet another candidate for the gravitation tensor, at least in the Newtonian limit.

Its Relation to Rotational Covariance…

Through another part of the notebook we also learn what apparently interested Einstein in the requirement that $\theta_{i\kappa\lambda}$ transforms tensorially. The simplest requirement of this type would be to ask that the quantity $\partial g_{i\kappa}/\partial x_{\lambda}$ transform as a tensor. But that, perhaps, was an excessively restrictive. It is easy to see that this quantity transforms as a tensor only under linear transformations of the coordinate systems. If one sought a natural weakening of this requirement, the simplest weakening is to consider just the symmetric part of $\partial g_{i\kappa}/\partial x_{\lambda}$, which is (up to multiplicative factor) the quantity $\theta_{i\kappa\lambda}$.[27] One might hope that the weakened requirement would now admit other interesting transformations, such as those to coordinate systems in uniform rotation. More explicitly, these are the transformations that take the coordinates $x_{\alpha} = (x, y, z, t)$ to a new coordinate system $x'_\alpha = (x', y', z', t')$ in uniform rotation at angular velocity ω about the z axis

$$x' = x\cos\omega t + y\sin\omega t \quad y' = -x\sin\omega t + y\cos\omega t \quad z' = z \quad t' = t. \tag{18}$$

That this is Einstein's hope is revealed, apparently, by calculations on pages 42L–42R of the notebook. Einstein sets up and solves the following problem: what are all the metrics of unit determinant that satisfy the conditions[28]

$$\frac{\partial g_{ik}}{\partial x_4} = 0 \text{ and } \vartheta_{i\kappa\lambda} = \frac{1}{2}\left(\frac{\partial g_{i\kappa}}{\partial x_\lambda} + \frac{\partial g_{\kappa\lambda}}{\partial x_i} + \frac{\partial g_{\lambda i}}{\partial x_\kappa}\right) = 0? \tag{19}$$

The problem posed by Einstein is a reformulation of this more interesting problem: assume we start from the metric $g^{SR}_{\mu\nu}$. To which time (= x_4 coordinate) independent metrics can we transform by means of unimodular coordinate transformations for which $\theta_{i\kappa\lambda}$ transforms as a tensor? Since $g^{SR}_{\mu\nu}$ has constant coefficients, we have $\theta_{i\kappa\lambda} = 0$, so that the requirement that $\theta_{i\kappa\lambda}$ transforms as a tensor reduces to the requirement that $\theta_{i\kappa\lambda}$ remain the zero tensor. Thus the metrics to which we can transform must satisfy (19). Apparently Einstein hoped that these transformations would include the unimodular transformation (18), so that this class of metrics would include what we can call a "rotation field", the form of the metric $g^{SR}_{\mu\nu}$ that results when it is transformed by the rotation transformation (18)

$$g^{ROT}_{\mu\nu} = \begin{bmatrix} -1 & 0 & 0 & \omega y' \\ 0 & -1 & 0 & -\omega x' \\ 0 & 0 & -1 & 0 \\ \omega y' & -\omega x' & 0 & c^2 - \omega^2(x'^2 + y'^2) \end{bmatrix}. \tag{20}$$

…Is Not Close Enough

And Einstein's hopes were almost realized. The result of his calculation was that the two conditions (19) were satisfied by a metric whose coefficients in its *covariant* form equaled those of the *contravariant* form of $g^{ROT}_{\mu\nu}$ that is $\gamma^{ROT}_{\mu\nu}$. This was close to showing that the transformations under consideration would allow the transformation from $g^{SR}_{\mu\nu}$ to $g^{ROT}_{\mu\nu}$. But it is not good enough for a mathematical result such as this to be close. It either succeeds or fails—and this one failed. Einstein revealed his frustration by remarking in one of the few textual comments in the notebook of calculations, "Schema of γ for a rotating body identical with the adjacent g- schema!" The

27 Another advantage is that the symmetrized form $\theta_{\iota\kappa\lambda}$ of $\partial g_{i\kappa}/\partial x_\lambda$ is very similar in structure to the Christoffel symbols, so that the Christoffel symbols in T^x_{il} can readily be rewritten in terms of $\theta_{i\kappa\lambda}$, easing the course of the calculations.

28 Einstein also suppresses the x_3 coordinate.

exclamation remark is very unusual and flags Einstein's surprise and, probably, disappointment.[29]

The Theta Requirement is Not a Coordinate Condition

We can reconstruct the content of these calculations fairly confidently. But their purpose is quite mysterious if we assume that the theta requirement is simply a coordinate condition being used to reduce T_{il}^{x} to the Newtonian form (8) for the case of the Newtonian limit. There are two problems. First, if the theta requirement has this purpose, then there is no need to investigate its covariance under rotation transformations (18) or, for that matter, to contrive the condition to have this covariance. Linear covariance is sufficient for the Newtonian limit and it is obvious without calculation that the theta condition has that much covariance.[30] Nonetheless, lack of rotational covariance seems to have been fatal to the proposal of the theta condition.

The second problem is that the reduction of T_{il}^{x} to (17) is not the calculation that would be undertaken if the theta condition were a coordinate condition. In that case, one would merely seek the expression to which T_{il}^{x} reduced in coordinate systems compatible with the condition. Expression (17) is not that expression. In generating it, Einstein freely added terms in $\theta_{i\kappa\lambda}$ so contrived as not to disturb the covariance of the resulting expression under these transformations. One cannot revert to T_{il}^{x} merely by relaxing the constraint of the theta restriction. In short, (17) is guaranteed to transform tensorially under these restricted transformations, but it is not the quantity one would seek if one chose T_{il}^{x} as the gravitation tensor and sought its Newtonian limit through a coordinate condition.

Both these problems are resolved immediately if we assume that Einstein is using the theta requirement as a coordinate restriction. The expression (17) is his candidate gravitation tensor. It can have no more covariance than the theta condition, so an investigation of the latter's covariance is, indirectly, an investigation of the covariance of the candidate gravitation tensor. Moreover T_{il}^{x} is merely an intermediate used in the construction of the candidate gravitation tensor (17). There is no need to ensure that this latter expression be a form of T_{il}^{x} in a restricted class of coordinates. Einstein's goal is merely a quantity of Newtonian form (8) with as much covariance as the theta condition. Einstein can add terms in theta freely if they allow a simpler final result, for these terms do not compromise the covariance of the result.

29 That this result proved fatal to the proposal of the theta restriction is confirmed by the calculations that follow on page 43L. There Einstein attempts to define a contravariant form of $\theta_{i\kappa\lambda}$ and begins to check whether it might be able to reduce the tensor T_{il}^{x} if used in the same way as $\theta_{i\kappa\lambda}$ in the original theta restriction. Presumably Einstein chose a contravariant form of $\theta_{i\kappa\lambda}$ as a replacement of the failed $\theta_{i\kappa\lambda}$ in the hope that a calculation analogous to that on pages 42L–42R would yield the correct covariant form of $g_{\mu\nu}^{ROT}$.

30 The deep concern with the covariance of the theta condition is also evident on the page facing the one on which the theta restriction is introduced. That facing page, 23R, is given over to computation of the transformation behavior of $\theta_{i\kappa\lambda}$ under infinitesimal transformations.

2.3 The Problem of the Newtonian Limit

How can the notion of coordinate restriction help us understand why Einstein rejected T^x_{il} as a candidate gravitation tensor in the notebook? In particular, how can it help us to understand Einstein's remark to Sommerfeld that the tensor did not yield the Newtonian limit when page 22R of the notebook appears to contain the calculation that shows how to recover the Newtonian limit? That is, it shows how to use equation (11) to reduce T^x_{il} to a Newtonian form, just as Einstein would in his paper of 4 November 1915.

The answer is simple. The expression T^x_{il} does not have the Newtonian form (8) and that may already be sufficient to explain Einstein's remark. Indeed, in addition to problems of energy conservation, Einstein may also have succumbed at this point to the temptation to multiply out the Christoffel symbols in an effort to get closer to an expression of the Newtonian form (8). If equation (11) is being used as a coordinate restriction in this effort, then T^x_{il} has ceased to be Einstein's candidate gravitation tensor. The new gravitation tensor is its reduced form, expression (15). While the formal manipulation of the reduction to expression (15) is the same in the notebook and in the 4 November 1915, paper, their interpretations would be very different. In 1915, the calculation shows how to recover the Newtonian limit from T^x_{il}. In the notebook, the calculation merely used T^x_{il} as an intermediate to generate a new candidate gravitation tensor, expression (15).

What was the fate of this new candidate gravitation tensor? It does not survive beyond page 22R. The notion of coordinate restriction can help us surmise its fate. If expression (15) is to be used as a gravitation tensor, it is of the greatest importance to determine its covariance. As we have seen, that is determined indirectly by investigating the covariance of the coordinate restriction (11). Presumably this was Einstein's goal on the facing page 22L when he probed the covariance of equation (11). We do not know how far Einstein went in these investigations. But we do know the results he would have found had he persisted. It is not too hard to see that coordinate restriction (11) is not covariant under rotation transformation (18). The simplest way to see this is to substitute $g^{ROT}_{\mu\nu}$ directly into (11). Since (11) vanishes for $g^{SR}_{\mu\nu}$, if it is covariant under rotation transformation (18), then it must also vanish for $g^{ROT}_{\mu\nu}$. But it does not. We have

$$\sum_{\kappa}\frac{\partial\gamma^{ROT}_{\kappa\alpha}}{\partial x'_{\kappa}} = \left(-\frac{\omega^2}{c^2}x', -\frac{\omega^2}{c^2}y', 0, 0\right) \neq 0.$$

We know that the rotation transformation (18) and the rotation field $g^{ROT}_{\mu\nu}$ became a topic of continued concern to Einstein on the pages following page 22. The rotation field enters indirectly on page 23L through the connection of the theta condition to the rotation field on pages 42L–42R. The rotation field is explicitly the subject of pages 24L, 24R and 25L.

It is natural to suppose that Einstein somehow came to see that his coordinate restriction (11) lacked rotational covariance, although we cannot identify a particular calculation in the notebook that unequivocally returns the result. The supposition that he had found the result would explain the strategy of the introduction of the theta condition on page 23L. Having found that his coordinate restriction (11) fails to satisfy rotational covariance, Einstein would respond by introducing a new coordinate restriction explicitly contrived to have rotational covariance. The theta condition is formulated directly as a covariance condition—Einstein will consider coordinate systems for which $\theta_{i\kappa\lambda}$ transforms as a tensor. As we saw above, the quantity $\theta_{i\kappa\lambda}$ was plausibly chosen exactly because it might yield covariance under rotation transformation (18). And we saw that Einstein remarked with evident satisfaction on page 23L that equation (11) was not needed, affirming his goal of replacing it with the theta condition.

This account of the failure of T_{il}^{x} as a gravitation tensor in the notebook is both simple and appealing. It depends crucially on one assumption: *Einstein was unaware of how to use conditions like (11) as a coordinate condition at the time of the writing of the notebook*. Without this assumption, we cannot use the notion of coordinate restrictions to explain Einstein's remark that the candidate gravitation tensor T_{il}^{x} does not yield the Newtonian limit. For, if he then understood the use of coordinate conditions, the calculation of page 22R supplied everything needed for recovery of the Newtonian limit. We must assume that he was unaware of the use to which his formal manipulation could be put.

2.4 Was Einstein Unaware of Coordinate Conditions?

I know of no evidence that decisively answers this question. So my final assessment is that we just do not know. There are weak indications, however, that point in both directions and I will try to assess them here. My view is that the case for the negative is stronger; that is, I find it most credible that Einstein was aware of possibility of using coordinate conditions.

In the Notebook

Requirements that may be either coordinate conditions or coordinate restrictions play a major role in the notebook on pages 19–23. The harmonic condition/restriction persists on pages 19–21, the requirement (11) on page 22 and then the theta requirement on page 23. The theta requirement was used as coordinate restriction and Einstein's calculation admitted no alternative interpretation of its use as a coordinate condition because of the way he added terms in $\theta_{i\kappa\lambda}$ in the course of his calculation. The calculation that used requirement (11) on page 22R is compatible with the requirement being used as either coordinate condition or coordinate restriction *or both*; the interest in the non-linear transformation of (11) on page 22L suggests its use as a coordinate restriction. There seems to be no indication that lets us decide whether the harmonic condition is used as a coordinate condition or restriction.[31] In particular, if it were used as a coordinate restriction, we might expect Einstein at some point to check its covariance in the way that he checked the covariance of requirement (11) and the theta restriction. The pages 19–21 contain no such check. Was that because he was using the requirement as a coordinate condition so that it needed no such check?

Or was is that he was too preoccupied with the ultimately fatal difficulty of recovering the Newtonian limit and energy conservation to proceed to a test of covariance?

While Einstein certainly used coordinate restrictions in the notebook, nothing in the above precludes his awareness of coordinate conditions and that he may have *also* thought of using the harmonic requirement and equation (11) as coordinate restrictions.

"Presumed Gravitation Tensor"

Of the fragments of relevant evidence in the notebook, the most important is Einstein's labeling on page 22R. There, as we saw above in expression (14), Einstein splits the Ricci tensor into two parts. The first is easily seen to be a tensor under unimodular transformation. Therefore the second is also such a tensor. Einstein labels this second quantity "Vermutlicher Gravitationstensor T_{il}^{x}" —"presumed gravitation tensor. T_{il}^{x}".

If Einstein is unaware of the use of coordinate conditions, then the identification of T_{il}^{x} as a gravitation tensor is very hard to understand. It does not have the Newtonian form (8). The derivative of the Christoffel symbol will immediately contribute three second derivative terms in the metric tensor, two more than (8) allows. This failure is not difficult to see. A Christoffel symbol is the sum of three first derivative terms. Its derivative will contain three second derivative terms in the metric tensor. Perhaps a novice in these calculations might overlook it. But Einstein is not a novice in these calculations at this stage in the notebook. In the pages preceding in the notebook he has become increasingly adept at more and more elaborate calculations involving the expansion of Christoffel symbols. On the following page 23L he devises the theta requirement. It depends on the recognition that the quantity $\theta_{i\kappa\lambda}$ and a Christoffel symbol have very similar structures so that the latter could be reexpressed profitably in terms of the former.

31 We might clutch at straws. If the harmonic requirement is used as a coordinate condition merely for the Newtonian limit, one needs to recover only the second derivative terms in the metric tensor and not the full reduced expression with first derivative terms, as Einstein does on page 19L. Or is this just Einstein being thorough and carrying a simple computation through to completion, wondering, perhaps, if the full result has an especially simple form? If the harmonic requirement were used as a coordinate restriction, then the full result would be needed, but that would still not preclude the possibility that Einstein weighed the use of the harmonic requirement as both coordinate condition and coordinate restriction. At the top of page 19R Einstein decomposes the harmonic requirement in the weak field into two equations comprising five conditions in all. That is one more than is allowed for a coordinate condition but admissible for coordinate restrictions. But since one of the new equation sets is just energy momentum conservation in the weak field, the decomposition is not necessarily an illegitimate strengthening of a coordinate condition as supplementing it with a physical requirement he demands on other grounds. Alternately but in the same spirit, that same condition, which is just equation (11) in the weak field, is a differential condition that must be satisfied by any static metric of form (4), as Einstein has already found earlier on page 39R of the notebook. On this same page 19R, he calls the harmonic requirement a "Nebenbedingung"—a "supplementary condition." If the requirement is a coordinate restriction, that is an odd label for what is as much a physical postulate as the original gravitational field equations they modify. But then perhaps that is the right way to view their action—as a universal supplement to those equations.

Perhaps this was just an oversight by Einstein. Perhaps it was haste that led him to label a manifestly inadmissible term as his presumed gravitation tensor. This supposition of haste becomes harder and harder to reconcile with what we know. At least the top half of page 22R is fairly neatly written and compact in argument, suggesting that it is not a live calculation but the record of deliberations elsewhere. Perhaps they record the outcome of a meeting with Grossmann—this is suggested by Grossmann's name on the top of the page and Einstein's later report to Sommerfeld of 28 November 1915, that he and Grossmann together had considered the gravitation tensor of this page. Einstein's failure to notice the two additional second derivative terms would have to survive whatever deliberation or meeting that produced the result and its transcription.

Yet more curious is the success of the equation (11) in reducing the tensor T_{il}^{x} to the Newtonian form (8). If Einstein chose T_{il}^{x} as a candidate gravitation tensor in haste, what sublime good fortune came with the equation (11). It just happens to be a restriction compatible both with the form he demanded for the static field and with energy conservation in the weak field, the problems that proved fatal to the harmonic requirement. And it just happened to the one that rescued his poor choice of T_{il}^{x} as gravitation tensor and allowed him to use it as an intermediate on the way to a better choice. On the supposition that Einstein was unaware of the use of coordinate conditions, we cannot presume that he already knew that equation (11) would effect this reduction. For if he already knew that, he would not label T_{il}^{x} his presumed gravitation tensor. It would just be an intermediate as the Ricci tensor itself is.

The supposition of haste and unanticipated good fortune seems necessary to make the page compatible with a lack of awareness of the use of coordinate conditions. I find this supposition incredible. I find it much more credible that Einstein simply wrote what he meant. He chose T_{il}^{x} as his gravitation tensor, fully aware of the surplus second derivative terms and fully aware, by the time of the writing of page 22R, that they could be eliminated by the condition (11). That condition (11) has this power need longer be a fortuitous coincidence. After the failure of the harmonic requirement, we may suppose that Einstein sought a tensor that could be reduced to the Newtonian form by equation (11), for that was the requirement that was manifestly compatible with energy conservation in the weak field. Surely what attracted Einstein to the gravitation tensor T_{il}^{x} was exactly the fact that condition (11) allowed its reduction to the Newtonian form (8) and its selection as a presumed gravitation tensor resulted from working backwards from this result.

If we accept this last version of the story, then we accept that Einstein intended to use requirement (11) on page 22R as a coordinate condition and only later considered using it as a coordinate restriction.

Einstein's Later Discussion and Treatment of Coordinate Conditions

If the content of the notebook allows no final decision, we might look for evidence elsewhere. If Einstein were unaware of the use of coordinate conditions and this played some role in his failure, we might expect some trace of it in his later recollections and writings. He would have failed to see what later became his standard method for recovery of the Newtonian limit. Many of the errors of the notebook and *Entwurf* theory are mentioned later. He remarks both in correspondence and in his publications on his surprise that static fields turn out not to be spatially flat, (see Norton 1984, §8). He eventually also puts some effort into explaining to his correspondents how he erred in the "hole argument" and an enduring trace of this correction was his publication of the "point-coincidence argument," see section 3.2 below and (Norton 1987). I know of no place in which Einstein directly allows that he was unaware of the use of coordinate conditions when he devised the *Entwurf* theory.

What were the errors he corrected when he returned to the tensor T^x_{il}? A problem with the Newtonian limit accrues a brief mention in his letter to Sommerfeld. The real force of Einstein's correction in that letter lies in his confession of the $\{\}$ prejudice. That he regarded this error as decisive is affirmed by the fact that it also is discussed at some length in the text of the paper of 4 November 1915, as we say above. In stark contrast, the use of coordinate conditions gets no mention in this correspondence. In the 4 November paper, the correct use of coordinate conditions is introduced with an indifference that suggests he thinks their use entirely obvious.[32] His *complete* discussion is merely:

> [Through this previous equation] the coordinate system is still not determined, in that four equations are needed for their determination. Therefore we may arbitrarily stipulate for the first approximation
>
> $$\sum_{\alpha\beta} \frac{\partial g^{\alpha\beta}}{\partial x_\beta} = 0.^{33} \qquad [(11)]$$

If Einstein had suffered a failure to see that equation (11) could be used this way for almost three years, would he not offer some elaboration if only to assure readers that the manipulation is admissible? Or should we assume that Einstein was feeling too vulnerable at this crucial time in his theory's development to admit all his former errors?[34]

---

32 This nonchalant attitude persisted into his review article (Einstein 1916, E§21), where the recovery of the Newtonian limit is formally incomplete exactly because Einstein neglects to invoke a coordinate condition. Einstein considers just the first term of the tensor T^x_{il} as part of his recovery of the Newtonian limit. He observes correctly that from it one recovers Poisson's equation of Newtonian theory, $\Delta g_{44} = \kappa\rho$ (where Δ is the Laplacian, κ a constant and ρ the mass density) by considering just the 44 component in the case of a time (x_4) independent field. That observation is insufficient for the recovery of the Newtonian limit. One must also establish that the remaining components of the field equations do not impose further conditions that restrict Poisson's equation in a way incompatible with the Newtonian limit. This further step requires a coordinate condition and that Einstein simply neglects to introduce or even mention. Einstein's later textbook exposition (Einstein 1922, 87) does give a serviceable account of how coordinate conditions are used to reduce the gravitational field equations to a Newtonian form, but without any special care that would suggest he thought the matter delicate.

33 "Hierdurch ist das Koordinatensystem noch nicht festgelegt, indem zur Bestimmung desselben 4 Gleichungen nötig sind. Wir dürfen deshalb für die erste Näherung willkürlich festsetzen [(11)]." (Einstein 1915a, 786)

The Entwurf Theory

What is striking about the *Entwurf* theory is that it does not require coordinate conditions for the recovery of the Newtonian limit. Its gravitation tensor already has the Newtonian form (8). So merely presuming a weak field of form (7) indirectly introduces enough of a restriction on the coordinate system to allow recovery of the Newtonian limit.

This striking feature of the *Entwurf* theory and Einstein's silence on coordinate conditions would be explained quite simply by the supposition that Einstein was then unaware of the use of coordinate conditions. But both could also be explained in another way. If he decided in favor of the *Entwurf* field equations for other reasons, then he might well never mention the use of coordinate conditions simply because he had no occasion to. Indeed, even in his later theory which did require them, he seemed quite reluctant to say anything more than the absolute minimum about them.

One thing that we cannot infer from the *Entwurf* theory and his writings associated with it is that Einstein was somehow naive about coordinate systems and how one might introduce a specialized coordinate system. We shall see below in section 3.6 that Einstein explained both in print and correspondence that he understood that equations of restricted covariance must correspond to generally covariant equations if they are to be anything more than just a restriction on the choice of coordinate system. He also made quite clear that he understood the subtleties of introducing specialized coordinate systems. That is, they might be introduced in two ways. In one way, one merely chooses to consider a restricted class of the coordinate systems already available; this decision does not alter the geometry of the spacetime. In the second way, one demands that this geometry must be such that it admits a coordinate system of a particular type; this demand indirectly applies a further and often profound restriction to the geometry of the spacetime.

If Einstein was unaware of the possibility of using coordinate conditions, it was not part of a broader blindness or lack of sophistication concerning coordinate systems.

What is More Plausible?

Since none of these items of evidence is decisive, we should also ask after the plausibility of different answers. Here our personal Einsteins speak as much as evidence. One might be comfortable with an Einstein unaware of the possibility of coordinate conditions. They never appear unequivocally in the notebook—although the labeling of T_{il}^{x} on page 22R as the "presumed gravitation tensor" is, in my view, very hard to explain if the initial intent was not to use a coordinate condition. So perhaps, on a principle of parsimony, we attribute the least knowledge we need to Einstein.

I find the supposed lack of awareness quite implausible. Coordinate systems and covariance requirements are Einstein's great strength and the locus of his deepest

---

34 Einstein did not explain in this paper where his "hole argument" against general covariance had erred. Below (see section 3.7) I will suggest that this reticence may have reflected a difficulty in seeing clearly what the problem was and this difficult will be a part of the account developed there.

reflection. As we shall recall below in section 3.4, the essential goal in devising his general theory of relativity was the elimination of the preferred inertial coordinate systems of Newtonian theory and special relativity, which is in turn sustained by their limited covariance. It is fundamental to his entire research project that his final theory not harbor them. So how then is Einstein to recover the Newtonian limit from his theory? He must introduce specialized assumptions that obtain only in the case of the Newtonian limit and restores the characteristically Newtonian elements. One assumption is that the metric field have the specialized weak form of (7). He must also reduce the covariance of theory and thereby reintroduce exactly the preferred coordinate systems he had labored so hard to eliminate. Einstein's knew how to restrict covariance. It is done partly in the coordinate dependence of the metric given as (7). It is done explicitly through a set of four equations such as the harmonic requirement or equation (11). But is it really possible that Einstein would fail to notice that he need only impose these covariance restricting requirements in the circumstances of the Newtonian limit? He would see that a specialized form of the metric is admissible in these special circumstances. But he must somehow overlook that a restriction of covariance in these special circumstances is also admissible.

Mistakes and oversights are all too common in science. We enter them into the historical record readily when we have evidence for them. This is one for which we have no unequivocal evidence and we have indications that speak against it. It must happen in Einstein's area of greatest expertise and concern. And it must not be a momentary lapse. It must persist[35] into the development of the *Entwurf* at least up to the development of his general arguments against general covariance later in 1913.

A Transition from Coordinate Conditions to Coordinate Restrictions?

Our evidence on Einstein's awareness or lack of awareness of the use of coordinate conditions remains incomplete. Yet all these considerations make it most credible that Einstein was aware of their use and could have considered using requirements such as the harmonic and equation (11) as both coordinate conditions and coordinate restrictions. Let us go a little further. If we had to choose a single narrative that would fit best with the progression of calculations in the notebook, it would be this.

When the harmonic requirement is introduced on page 19L, it is used as a coordinate condition, with Einstein perhaps reserving the possibility of using it as a coordinate restriction if that should prove viable and simpler. On page 22R, requirement (11) is introduced as a coordinate condition with T^x_{il}, chosen as the gravitation tensor. However he is unable to see how to use T^x_{il} as his gravitation tensor. So he decides he must look for simpler expressions. He reverts to use of requirement (11) as a coordinate restriction so that he can use the simpler gravitation tensor (15), the

35 Thoughts of the use of condition (11) did not leave Einstein after the *Entwurf* theory was completed. As late as August 1915, he recalled in a letter to Paul Hertz how he had struggled with this condition, Einstein to P. Hertz, 22 August 1915, (CPAE 8, Doc. 111). Presumably this continued presence facilitated revival of T^x_{il} in November 1915.

reduced form of T_{il}^{x}. That also proves inadmissible, presumably because of its restricted covariance. So, on the following page, Einstein introduces the theta restriction, which can only be a coordinate restriction. It is especially contrived to have the covariance that requirement (11) lacked.

What makes it credible that page 22R is the turning point is Einstein's labeling of T_{il}^{x} as the "presumed gravitation tensor" when he must have known already that equation (11) would reduce it to the Newtonian form. That suggests that equation (11) was first introduced as a coordinate condition. The investigation of its covariance properties on page 22L marks the decision to treat the requirement as a coordinate restriction.[36] In the earlier pages 19–21, the harmonic requirement could have been either coordinate condition or restriction. Nothing in the calculations would have committed Einstein to either. The lack of interest in the covariance properties of the harmonic requirement suggests that Einstein had less interest in its use as a coordinate restriction.

If these suppositions are correct, then they bear directly on the "mathematical" and "physical strategy" we describe Einstein as using elsewhere in these volumes. The use of coordinate conditions would be associated with the mathematical strategy in its purest form. If recovery of the Newtonian limit will be through the harmonic condition, for example, then Einstein is able to use the full Ricci tensor as his gravitation tensor and not a simpler reduced form. With his failure to see that the Ricci tensor or that T_{il}^{x} are viable gravitation tensors, Einstein begins to withdraw from the mathematical strategy towards the physical strategy. The use of coordinate restrictions represents an intermediate stage in that withdrawal. He is still trying to use the gravitation tensors naturally suggested by the mathematical formalism, but now in reduced form. The failure of these last efforts leads him to revert to the physical strategy.

3. A CONJECTURE: THE HOLE ARGUMENT AND THE INDEPENDENT REALITY OF COORDINATE SYSTEMS

The Puzzle Continues

If we accept that Einstein knew about the possibility of using coordinate conditions, page 22R once again presents us with a troubling puzzle. In his later recollection to

36 Is there a trace of two stages of calculation on page 22R? The calculations there are divided by a horizontal rule. The calculations above the rule deal only with the term in T_{il}^{x} that contains second derivatives of the metric tensor and its reduction by equation (11) to the Newtonian form (8). Those below deal with expansion of the terms quadratic in the Christoffel symbols in T_{il}^{x}. The calculations above the rule are the ones needed if equation (11) is to be used as a coordinate condition; in the Newtonian limit all that matters are the terms in the second derivatives of the metric. The ones below are needed in addition if (11) is used as a coordinate restriction; they give the full expression for the reduced form of T_{il}^{x}. The calculations above the rule are neater and, as I suggested earlier, may just report discussions and calculations conducted elsewhere. Those below the rule are massively corrected and have the look of live calculations. Were they undertaken later after Einstein had decided to revert from the use of (11) as a coordinate condition to a coordinate restriction?

Sommerfeld, Einstein reports that he had been unable to recover the Newtonian limit from the gravitation tensor T^x_{il}. But page 22R contains just the calculation that seems to do this. As we saw in section 2, the remark could be explained using the notion of coordinate restrictions. But that explanation fails if we accept that Einstein was aware of the use of coordinate conditions. So how can we reconcile his later recollection with the content of the notebook?

There is a further aspect of page 22R that bears cautious reflection. Page 22R should have been a great triumph for Einstein. He had labored since page 14L through calculations of great complexity in an effort to recover a gravitation tensor from the Riemann tensor. The problem seemed to yield on page 19L with the introduction of the harmonic condition and the easy reduction of the Ricci tensor to a quantity of Newtonian form (8). But the success faded over the following pages in the face of a final hitch that grew to be fatal. He could not see how to reconcile the harmonic condition with the form he expected for the static field, the weak field equations and energy conservation in the weak field. On page 22R he finally had the answer to that last hitch. By choosing T^x_{il} as his gravitation tensor, he could replace the harmonic condition with condition (11) and this new condition resolved all the earlier problems, since it was both compatible with the form expected for static fields and with energy conservation in the weak field. The solution was so unobjectionable that he published it upon his return to general covariance in November 1915. But in the notebook, that successful solution is just abandoned and apparently quite hastily. His later recollections explain this decision in terms of the $\{\}$ prejudice. Just when he had everything else working, he gave up because, on the best reconstruction, he could not see how to extract an energy-momentum tensor for the gravitational field from the tensor. He gave up more than just the gravitation tensor T^x_{il}. He seems to have given up the use of coordinate conditions entirely and with it the easy access to the gravitation tensors of broad covariance naturally suggested by the mathematical formalism. If the $\{\}$ prejudice was all there was to it, Einstein had lost his customary tenacity and become fickle or faint hearted or both.

Might there have been a further difficulty that compromised the recovery of the Newtonian limit and that he did not report?

Another Error?

Might we find another error or misconception that Einstein may have committed that would give answers to both the above questions? Of course it is always possible to invent hidden errors varying from the trivial slip to the profound confusion, tailor made to fit this or that aberration. The real difficulty is to establish that the error was really committed.

If there is such an error, we would expect it to be somehow associated with the use and understanding of coordinate systems. We do know of a serious misconception concerning coordinate systems that drove Einstein away from general covariance during the years of the *Entwurf* theory. This was the misconception that supported the hole argument. Months after the completion of the *Entwurf* theory, Einstein introduced this argument as a way of showing that the achievement of general covariance in his gravitation theory would be physically uninteresting. After he had returned to general covariance Einstein explained the error of the hole argument. He had unwittingly accorded an independent reality to spacetime coordinate systems and this had compromised his understanding of what is represented physically in a transformation of the fields of his theory.[37] In our histories to date, this error affected Einstein only through the hole argument and thus well after Einstein's turn away from general covariance in 1912 and 1913. However Einstein's theory was, on his own report, dependent intimately and fundamentally on the transformation of fields and spacetime coordinates. Is it possible that Einstein's misconception on the independent reality of coordinate systems had earlier damaging effects?

The Conjecture

The conjecture to be advanced here is that Einstein's misconception about the independent reality of coordinate systems did not just exert its harmful influence with Einstein's discovery of the hole argument, well after the *Entwurf* theory was in place. Rather I shall urge that it decisively misdirected Einstein's investigations at a much earlier stage, the time of the calculation of the notebook. I believe that it can explain why Einstein abandoned the use of coordinate conditions so precipitously, why he would have judged the calculation concerning the Newtonian limit of page 22R to be a failure and why he acquiesced so readily to the gravely restricted covariance of the *Entwurf* theory. Einstein failed to see this error until 1915. Until then it precluded his use of coordinate conditions. It led him to expect that any coordinate condition must have sufficient covariance to support an extension of the principle of relativity to acceleration.

More specifically, I will suggest that when Einstein applied a coordinate condition such as (11), he unwittingly accorded an independent existence to the coordinate systems picked out by the condition. Then, merely by repeating the same way of thinking about transformations as used in the hole argument, he would end up entertaining extraordinary expectations for each of these special coordinate systems. If some metric field $g_{\mu\nu}$ is a solution of his field equations in one of these special coordinate systems, then he would expect all its transforms (in a sense I will make clear below) $g'_{\mu\nu}$ also to be realizable as solutions in this coordinate system. A failure of the coordinate system to admit these transforms would appear as an objectionable, absolute property of the coordinate system. Such properties are just the type that Einstein had denounced in the inertial systems of classical physics and special relativity and which he prom-

37 More precisely stated: A particular set of coordinate values in a coordinate system will designate a definite physical event in spacetime. In Einstein's later view and our modern view, the physical event designated depends on the metric field; an alteration of the metric field changes which physical event is designated by these coordinate values. Einstein initially believed, however, that these same coordinate values could continue to pick out the same physical event even though the metrical field in that coordinate system was changed. That is, the coordinate system's power to pick out events is independent of the metrical field.

ised his new theory would eliminate. Now the transforms $g'_{\mu\nu}$ will only be admissible in the special coordinate system if they are compatible with the coordinate condition that defines the special coordinate system. Thus the covariance of theory as a whole had effectively been reduced to the covariance of the coordinate condition used in extracting the Newtonian limit. That condition had to be of sufficient covariance to support Einstein's hopes for a generalization of the principle of relativity to acceleration. In spite of proposals of great ingenuity in his preparation for the *Entwurf* theory, Einstein could find no combination of gravitational field equations of broad covariance and coordinate condition that satisfied these extraordinary demands.

The effect of the misconception conjectured is that coordinate conditions would lose their appeal. If a coordinate condition was used to extract the Newtonian limit, the covariance of the theory as a whole would now be reduced to that of the coordinate condition. As a result, Einstein would acquire no additional covariance for his theory in using a requirement as a coordinate condition rather than a coordinate restriction. The advantage of the latter, however, is that it delivers a gravitation tensor of considerably simpler form. Therefore I suggest that Einstein's recognition of this outcome, quite plausibly on page 22R itself, would explain why he so precipitously abandoned coordinate conditions in the notebook. The extraction of the Newtonian limit from tensor T^x_{il} via equation (11), whether it is construed as a coordinate condition or restriction, would fail for the same reason. Equation (11) would fail to have sufficient covariance.

Its Tacit Character

In the hole argument, the independent reality of the coordinate systems has a tacit, hidden character. Indeed Einstein found it hard to express explicitly what he meant. Even something as simple as the exact steps of his construction really only became clear with publication of the fourth version of the argument. It was not until after his return to covariance and possibly some prompting from his correspondents that he seemed able to give a clear account of where the argument erred. We must surely presume that, at the time of the hole argument, Einstein was simply not aware that his manipulations presumed an independent reality for his coordinate systems. It is an essential part of the present conjecture that he was not aware of the corresponding presumption earlier at the time of the calculations of the notebook. The hole argument was first offered in a hasty, ill-digested form that still led to a powerful conclusion, the inadmissibility of general covariance. The same would be true in the notebook. A similarly hasty check of the covariance of the coordinate condition would suffice to convince Einstein that disaster had struck. Its haste would allow him to overlook that his conclusion depended upon an assumption about the independent reality of coordinate systems that he would surely never endorse if it were articulated clearly.

In the Sections to Follow…

I will layout the background, context and elaboration of the conjecture. In section 3.1, I will describe the hole argument and, in section 3.2, how Einstein later diagnosed his error as the improper attribution of an independent reality to coordinate systems. In section 3.3 I will lay out the content of the conjecture in greater detail. Einstein's treatment of coordinate systems founders since it ends up ascribing absolute properties to certain coordinate systems. In section 3.4, I will review Einstein's insistence on the inadmissibility of such absolute properties, for that inadmissibility is what defeats his use of coordinate conditions. In section 3.5, I will review Einstein's early remarks on the restricted covariance of his *Entwurf* theory and his recognition that the restricted equations must correspond to generally covariant equations. I will use Einstein's mistaken attitude to the independent reality of the coordinate systems to explain his evident indifference towards finding those equations. During the reign of the *Entwurf* theory, Einstein gave several accounts of the introduction of specialized coordinate systems. In section 3.6, I will review these remarks to show that they are compatible with the present conjecture concerning Einstein's attitude to coordinate systems. Finally in section 3.7, I will review our evidence concerning the conjecture. I will conclude that we have neither decisive evidence in favor of it or against it, but weaker indications that both benefit and harm it.

3.1 The Hole Argument

Its Fullest Statement

Einstein and Grossmann's *Entwurf* paper was published mid 1913 as a separatum by Teubner (Einstein and Grossmann 1913).[38] There they reported their failure to find acceptable, generally covariant gravitational field equations. By late 1913, Einstein had found what soon became his favored vehicle for excusing this lack of general covariance, the "hole argument," which purported to show that all generally covariant gravitational field equations would be physically uninteresting.[39] Of its four presen-

38 In a letter of 28 May 1913 to Paul Ehrenfest, Einstein promises that paper will appear "in at least a few weeks" (CPAE 5, Doc. 441).

39 The earliest written and unambiguously dated mention of the hole argument is in a letter of 2 November 1913, from Einstein to Ludwig Hopf, (CPAE 5, Doc. 480). Einstein is not likely to have had the hole argument in hand much earlier than this. The hole argument supplanted another means of exonerating his theory's lack of general covariance, a consideration based on the law of conservation of energy-momentum. We know from a letter of 16 August 1913, from Einstein to Lorentz that Einstein only hit upon this earlier consideration on 15 August (CPAE 5, Doc. 470). For further discussion see (Norton 1984, §5). (The hole argument is also mentioned in the printed version of a lecture delivered on 9 September to the 96th annual meeting of the Schweizerische Naturforschende Gesellschaft in Frauenfeld (Einstein 1914b, 289). But we cannot be assured that Einstein had the hole argument at the time of the lecture since the printed version of the lecture was published many months later on 16 March 1914, see (CPAE 4, 484). Also the hole argument is not mentioned in another, briefer, printed version of the talk (Einstein 1913). That briefer version does call for a restriction on the basis of the conservation laws. It is curious that the mention of the hole argument in the printed version of (Einstein 1914b) appears in the context of the discussion of the conservation laws. In this longer and presumably later version, did Einstein strike out the consideration based on the conservation laws and write in a mention of the hole argument?)

tations, the clearest is the final version of November 1914:

> *§12. Proof of the Necessity of a Restriction on the Choice of Coordinates.*
>
> We consider a finite region of the continuum Σ, in which no material process takes place. Physical occurrences in Σ are then fully determined, if the quantities $g_{\mu\nu}$ are given as functions of the x_ν in relation to a coordinate system K used for description. The totality of these functions will be symbolically denoted by $G(x)$.
>
> Let a new coordinate system K' be introduced, which agrees with K outside Σ, but deviates from it inside Σ in such a way that the $g'_{\mu\nu}$ related to the K' are continuous everywhere like the $g_{\mu\nu}$ (together with their derivatives). We denote the totality of the $g'_{\mu\nu}$ symbolically with $G'(x')$. $G'(x')$ and $G(x)$ describe the same gravitational field. In the functions $g'_{\mu\nu}$ we replace the coordinates x'_ν with the coordinates x_ν, i.e. we form $G'(x)$. Then, likewise, $G'(x)$ describes a gravitational field with respect to K, which however does not agree with the real (or originally given) gravitational field.
>
> We now assume that the differential equations of the gravitational field are generally covariant. Then they are satisfied by $G'(x')$ (relative to K'), if they are satisfied by $G(x)$ relative to K. Then they are also satisfied by $G'(x)$ relative to K. Then relative to K there exist the solutions $G(x)$ and $G'(x)$, which are different from one another, although both solutions agree in the boundary region, *i.e. occurrences in the gravitational field cannot be uniquely determined by generally covariant differential equations for the gravitational field*. [Einstein's emphasis][40]

A Notational Convenience

The content, interpretation and significance of the hole argument has been examined extensively elsewhere.[41] Thus I will concentrate on those aspects of importance to the present conjecture. The argument depends on exploiting the defining property of a covariance group to generate new solutions of the gravitational field equations from old solutions. Assume that a transformation from coordinate system x^μ to x'^μ is

---

40 "§12. Beweis von der Notwendigkeit einer Einschränkung der Koordinatenwahl.
Wir betrachten einen endlichen Teil Σ des Kontinuums, in welchem ein materieller Vorgang nicht stattfindet. Das physikalische Geschehen in Σ ist dann vollständig bestimmt, wenn in bezug auf ein Funktion der x, gegeben werden. Die Gesamtheit dieser Funktionen werde symbolisch durch $G(x)$ bezeichnet.
Es werde ein neues Koordinatensystem K' eingeführt, welches außerhalb Σ mit K übereinstimme, innerhalb Σ aber von K abweiche, derart, daß die auf K' bezogenen $g'_{\mu\nu}$ wie die $g_{\mu\nu}$ (nebst ihren Ableitungen) überall stetig sind. Die Gesamtheit der $g'_{\mu\nu}$ bezeichnen wir symbolisch durch $G'(x')$. $G'(x')$ und $G(x)$ beschreiben das nämliche Gravitationsfeld. Ersetzen wir in den Funktionen $g'_{\mu\nu}$ die Koordinaten x'_ν durch die Koordinaten x_ν, d. h. bilden wir $G'(x)$, so beschreibt $G'(x)$ ebenfalls ein Gravitationsfeld bezüglich K, welches aber nicht übereinstimmt mit dem tatsächlichen (bzw. ursprünglich gegebenen) Gravitationsfelde.
Setzen wir nun voraus, daß die Differentialgleichungen des Graviationsfeldes allgemein kovariant sind, so sind sie für $G'(x')$ erfüllt (bezüglich K'), wenn sie bezüglich K für $G(x)$ erfüllt sind. Sie sind dann die voneinander verschiedenen Lösungen $G(x)$ und $G'(x)$, trotzdem an den Gebietsgrenzen beide Lösungen übereinstimmten, d. h. *durch allgemein kovariante Differentialgleichungen für das Gravitationsfeld dann das Geschehen in demselben nicht eindeutig festgelegt werden*." (Einstein 1914c, 1067)

41 See, for example, (Stachel 1980, §§3–4; Norton 1984, §5; 1987).

within the covariance group of the gravitational field equation and that a metric field $g_{\mu\nu}(x_\alpha)$ in the coordinate system x_μ satisfies the field equations. It follows that the metric $g'_{\mu\nu}(x'_\alpha)$ in the coordinate system x'_μ, defined by the tensor transformation law

$$g'_{\mu\nu} = \frac{\partial x_\alpha}{\partial x'_\mu}\frac{\partial x_\beta}{\partial x'_\nu}g_{\alpha\beta} \tag{21}$$

is also a solution of the field equations. These two solutions of the field equations are merely representations in different coordinate systems of the same gravitational field; it is represented by $g_{\mu\nu}(x_\alpha)$ in the coordinate system x_α and by $g'_{\mu\nu}(x'_\alpha)$ in the coordinate system x'_α. In an attempt to reduce distracting notational complications, Einstein represented the two metrics as "$G(x)$" and "$G'(x')$". His point was to draw attention to the functional dependence of the $g_{\mu\nu}$ on the coordinates x_α with the latter considered as variables; and the functional dependence of the $g'_{\mu\nu}$ on x'_α. The device is helpful, since it suppresses the various indices that play no role in Einstein's argument. I will use it below but with lower case g instead of upper case G:

$$\begin{aligned} g_{\mu\nu}(x_\alpha) &\text{ is represented by } g(x) \\ g_{\mu\nu}(x'_\alpha) &\text{ is represented by } g(x') \\ g'_{\mu\nu}(x'_\alpha) &\text{ is represented by } g'(x'). \end{aligned} \tag{22}$$

How the Argument Works

This functional dependence allows Einstein to generate a further solution of the gravitational field equations that is, apparently, physically distinct from the original field described by $g(x)$ and $g'(x')$. It is constructed by considering the solution $g'(x')$ as a set of ten functions of the four independent variables comprising the coordinate system x'. One then replaces the independent variables x' by x, so that Einstein recovers a new field in the original coordinate system x, which is $g'(x)$. Now $g'(x')$ is a solution of the gravitational field equations not because of any special properties of the coordinate system x' but merely because of the functional dependence of the $g'(x')$ on the independent variables x'. That functional form is all that generally covariant gravitational field equations consider in determining whether $g'(x')$ is admissible. By construction, $g'(x)$ shares exactly the same functional dependence on its independent variables as $g'(x')$. Thus if $g'(x')$ is a solution of the field equations so is $g'(x)$.[42]

Einstein can now complete his argument. He has two solutions of his gravitational field equations $g(x)$ and $g'(x)$, both in the *same* coordinate system x. These two solutions were constructed from the transformation x to x'. This transformation had a special property. By supposition the transformation is the identity everywhere but inside a matter free region of spacetime Σ (the "hole"), where it comes smoothly to differ from the identity. This special property confers a corresponding property on the two solutions $g(x)$ and $g'(x)$: they agree outside the hole, but they come smoothly to disagree within, for the g and g' are different functions within that hole. And since they are defined in the same coordinate system, this difference entails, Einstein urged, that they represent physically distinct gravitational fields. The result is a violation of determinism. The metric field and matter distribution outside the matter free hole fails to determine how the metric field will extend into the hole; it may extend as $g(x)$ or $g'(x)$. Einstein deemed this circumstance sufficiently troublesome to warrant rejection of all generally covariant gravitational field equations, for all generally covariant field equations will admit solution pairs $g(x)$ and $g'(x)$.

The Hole Construction

For our purposes what is important is that Einstein saw in the general covariance of the gravitational field equations an immediate license to construct the field $g'(x)$ from $g(x)$. This construction will be the focus of our attention, so I will restate it:

> *If*
>
> (a) a transformation x to x' is within the covariance group of the gravitational field equations and
>
> (b) a metric field $g(x)$ in the coordinate system x satisfies the field equations,
>
> *then*
>
> the metric field $g'(x)$ is also a solution of the gravitational field equations in the *original* coordinate system x, where the functions g' are defined by the tensor transformation law (21).

Einstein's Difficulty in Expressing the Argument

Einstein found it very hard to make clear that his hole argument depended essentially on the use of the hole construction. Rather, the three earlier versions of the hole argu-

---

42 An example illustrates the reasoning. The metric

$$g'(x') = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & (x'^1)^2 \end{bmatrix}$$

happens to be a solution of the generally covariant gravitational field equations $R_{\mu\nu} = 0$, where $R_{\mu\nu}$ is the Ricci tensor, in a coordinate system x'. What makes this g' a solution is the way that each coefficient of g' depends functionally on the coordinates x'. All coefficients are 0 or -1 excepting g'_{44} which is the square of the coordinate x'^1. We find $R_{\mu\nu}$ vanishes if we compute it for a g' with this functional dependence. It now follows immediately that the metric

$$g'(x) = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & (x^1)^2 \end{bmatrix}$$

in the coordinate system x is also a solution since it shares this same functional dependence.

ment seemed to depend on merely noticing that the two coordinate representations $g(x)$ and $g'(x')$ of the same gravitational field employed different functions. In that case the hole argument becomes the elementary blunder of failing to notice that the one gravitational field has different representations in different coordinate systems. I take this as evidence that, in his own work, Einstein did not clearly distinguish the two types of transformations $g(x)$ to $g'(x')$ and $g(x)$ to $g'(x)$. His invocation of the transformation law (21) could refer to either, without the need for explanation or apology. As we shall see below, Einstein's early presentations of the hole argument merely invoked (21) and Einstein must have presumed that readers would follow him and understand the transformation under consideration to be $g(x)$ to $g'(x)$.

The hole argument appears in Einstein's 1914 addendum to (Einstein and Grossmann 1913) where the crucial passage reads "...one can obtain $\gamma'_{\mu\nu} \neq \gamma_{\mu\nu}$ [for the metric field $\gamma_{\mu\nu}$] for at least a part of [the hole] L ...it follows...that more than one system of the $\gamma_{\mu\nu}$ is associated with the same [matter distribution]."[43] In a later version (Einstein and Grossmann 1914, 218), the corresponding passage reads "at least for a part of [the hole] L $\gamma_{\mu\nu}' \neq \gamma_{\mu\nu}$ ... so that more than one system of $\gamma_{\mu\nu}$ is associated with the same system of [stress-energy tensor] $\Theta_{\mu\nu}$ ..." Again, in the version of the hole argument of Einstein in (Einstein 1914a), the corresponding passage reads "... even though we do have $\mathfrak{T}_{\sigma\nu}' = \mathfrak{T}_{\sigma\nu}$ everywhere [for stress-energy tensor density $\mathfrak{T}_{\sigma\nu}$], the equations $g_{\mu\nu}' = g_{\mu\nu}$ are certainly not all satisfied in the interior of [the hole] Φ. This proves the assertion."[44] Fortunately Einstein gave a cryptic but sufficient clue in this last instance that he intended the failure of the equality $g_{\mu\nu}' = g_{\mu\nu}$ to be understood in the manner of the hole construction above, for he appended a footnote to the sentence containing the inequality $g_{\mu\nu}' = g_{\mu\nu}$ that read: "The equations are to be understood in such a way that the same numerical values are always assigned to the independent variables x'_ν on the left sides as to the variables x_ν on the right sides."

These presentations were sufficiently ambiguous to confuse the early historical literature on the hole argument. It interpreted Einstein as believing that the two coordinate representations of the same field, $g(x)$ and $g'(x')$, somehow represented physically distinct fields. One of the achievements of Stachel in his path-breaking paper (Stachel 1980) was to demonstrate that Einstein was not guilty of this novice blunder.[45]

43 "Daß wenigstens für einen Teil von L $\gamma'_{\mu\nu} \neq \gamma_{\mu\nu}$ ist. … zu dem nämlichen System der $\Theta_{\mu\nu}$ mehr als ein System der $\gamma_{\mu\nu}$ gehört. (Einstein and Grossmann 1913; translation from CPAE 4E, 289)

44 "… so ist zwar überall $\mathfrak{T}_{\sigma\nu}' = \mathfrak{T}_{\sigma\nu}$, dagegen werden im Inneren von Φ die Gleichungen $g_{\mu\nu}' = g_{\mu\nu}$ sicherlich nicht alle erfüllt sein. Hieraus folgt die Behauptung." (Einstein 1914a, 178; translated in CPAE 4E, 285)

45 As Stachel showed, the transformation from $g(x)$ to $g'(x')$ corresponded to what we now call a passive transformation in which the coordinate system changes but not the field. The transformation of the hole construction from $g(x)$ to $g'(x)$ corresponds to an active transformation in which the coordinate system remains unchanged but the field alters. See (Norton 1987; 1989, §2). However, as I argue in (Norton 1989, §5), it is possible to remain faithful to Einstein's purpose and wording without explicitly introducing the notions of active and passive transformations.

3.2 The Error of the Hole Argument: The Independent Reality of Coordinate Systems

Why the Hole Argument Fails

Of course the hole argument fails to establish that all generally covariant gravitational field equations are physically uninteresting. The standard resolution allows that the two fields $g(x)$ and $g'(x)$ are mathematically distinct but counters that they represent the same physical field. Thus the hole argument does not show that the field and matter distribution outside the hole leave the field within underdetermined. It just shows that the mathematical description of the field within the hole is undetermined. After his return to general covariance, Einstein argued for the physical equivalence of the fields $g(x)$ and $g'(x)$ with his "point-coincidence argument;" the two fields are equivalent since they must agree on the disposition of all coincidences, such as the intersections of the world lines of particles.[46] Alternatively, following the approach favored in Göttingen by the Hilbert school, we could argue for the equivalence of the two fields by noting that they agree on all invariant properties.[47]

Letters to Ehrenfest and Besso Explain Einstein's Error

The point coincidence argument explains how we should understand the system described in the hole argument. But it does not diagnose the error of thought that lured Einstein to interpret the system differently prior to November 1915. That diagnosis came in Einstein's letters in late 1915 and early 1916 when he explained to his correspondents how he had erred in the hole argument. In preparing his correspondent Paul Ehrenfest for the point coincidence argument, Einstein explained in a letter of 26 December 1915:

> In §12 of my work of last year, everything is correct (in the first three paragraphs) up to the italics at the end of the third paragraph. One can deduce no contradiction at all with the uniqueness of occurrences from the fact that both systems $G(x)$ and $G'(x)$, related to the same reference system, satisfy the conditions of the grav. field. The apparent force of this consideration is lost immediately if one considers that
>
> (1) the reference system signifies nothing real
>
> (2) that the (simultaneous) realization of the two different g- systems (better said, two different gravitational fields) in the same region of the continuum is impossible according to the nature of the theory.
>
> In the place of §12 steps the following consideration. The physical reality of world occurrences (in opposition to that dependent on the choice of reference system) consists *in spacetime coincidences*... [Einstein's emphasis][48]

He wrote an essentially identical explanation to his friend Michele Besso a little over a week later on 3 January 1916:

---

46 See (Norton 1987; Howard and Norton 1993, §7) for a proposal on the origin of the point-coincidence argument.

47 See (Howard and Norton 1993) for the proposal of a premature communication of this viewpoint to an unreceptive Einstein by Paul Hertz in the late summer of 1915.

> Everything was correct in the hole argument up to the last conclusion. There is no physical content in two different solutions $G(x)$ and $G'(x)$ existing with respect to the *same* coordinate system K. To imagine two solutions simultaneously in the same manifold has no meaning and the system K has no physical reality. In place of the hole argument we have the following. *Reality* is nothing but the totality of spacetime point coincidences... [Einstein's emphasis][49]

Ehrenfest proved difficult to convince of the correctness of Einstein's new way of thinking over the hole argument and Einstein needed to enter into a more detailed exchange that centered on the example of light from a star passing through an aperture onto a photographic plate.[50] In his letter of 5 January 1916, Einstein noted the instinctive attractiveness of the notion of the reality of the coordinate system:

> I cannot blame you that you still have not seen the admissibility of generally covariant equations, since I myself needed so long to achieve full clarity on this point. Your problem has its root in that you instinctively treat the reference system as something "real."[51]

Surely we are to read in this that Einstein too was misled by this instinct.

On Being Real

We learn from these letters that Einstein was under the influence of a deep-seated prejudice at the time of formulation of the hole argument: he improperly accorded a physical reality to coordinate systems. It can often be difficult to decipher precisely what is meant by an attribution of reality or non-reality—one need only recall the extended debates over realism in philosophy of science to be reminded of these diffi-

---

48 "In §12 meiner Arbeit vom letzten Jahre ist alles richtig (in den ersten 3 Absätzen) bis auf das am Ende des dritten Absatzes gesperrt Gedruckte. Daraus, dass die beiden Systeme $G(x)$ und $G'(x)$, auf das gleiche Bezugssystem bezogen, den Bedingungen des Grav. Feldes genügen, folgt noch gar kein Widerspruch gegen die Eindeutigkeit des Geschehens. Das scheinbar Zwingende dieser Überlegung geht sofort verloren, wenn man bedenkt, dass
1) das Bezugssystem nichts Reales bedeutet
2) dass die (gleichzeitige) Realisierung zweier verschiedener g- Systeme (besser gesagt zweier verschiedener Grav. Felder) in demselben Bereiche des Kontinuums der Natur der Theorie nach unmöglich ist.
An die Stelle des §12 hat folgende Überlegung zu treten. Das physikalisch Reale an dem Weltgeschehen (im Gegensatz zu dem von der Wahl des Bezugssystem Abhängigen) besteht *in raumzeitlichen Koinzidenzen*." Einstein to Paul Ehrenfest, 26 December 1915 (CPAE 8, Doc. 173). Adjusted translation from (Norton 1987, 169).

49 "An der Lochbetrachtung war alles richtig bis auf den letzten Schluss. Es hat keinen physikalischen Inhalt, wenn inbezug auf dasselbe Koordinatensystem K zwei verschiedene Lösungen $G(x)$ und $G'(x)$ existieren. Gleichzeitig zwei Lösungen in dieselbe Mannigfaltigkeit hineinzudenken, hat keinen Sinn und das System K hat ja keine physikalische Realität. Anstelle der Lochbetrachtung tritt folgende Überlegung. *Real* ist physikalisch nichts als die Gesamtheit der raumzeitlichen Punktkoinzidenzen." Einstein to Michele Besso, 3 January 1916 (CPAE 8, Doc. 178).

50 For details, see (Norton 1987, §4).

51 "Das Du die Zulässigkeit allgemein kovarianter Gleichungen noch nicht eingesehen hast, kann ich Dir nicht verübeln, weil ich selbst so lange brauchte, um über diesen Punkt volle Klarheit zu erlangen. Deine Schwierigkeit hat ihre Wurzel darin, dass Du instinktiv das Bezugssystem als etwas "Reales" behandelst." Einstein to Paul Ehrenfest, 5 January 1916 (CPAE 8, Doc. 180).

culties. But in this case the attribution of reality has quite precise consequences. When Einstein accords physical reality to a coordinate system x, this entails that the coordinate system can support two distinct fields, $g(x)$ and $g'(x)$. In particular, Einstein is committed to the x in each system of metrical coefficients representing the *same* coordinate system. This sameness entails that the two mathematical structures, $g(x)$ and $g'(x)$, represent different physical fields. Some particular set of coordinate values, such as $x^{\alpha} = (0,0,0,0)$, will pick out the same point of spacetime in each field. But, since the g and g' are different functions of the same coordinates in a neighborhood of the point, they will each attribute different properties to that point, revealing that they represent different physical fields.

In Einstein's later view it no longer makes sense to say that x represents the same coordinate system in each structure $g(x)$ and $g'(x)$. Thus we can no longer conclude that some particular set of coordinate values picks out the same point in each field and the inference to their physical distinctness is blocked.

Einstein's misconception about the independent reality of coordinate systems was clearly firmly in place towards the end of 1913, the time of his creation of the hole argument.[52] Nothing we have seen indicates that this misconception arose at that time. Rather his description of its "instinctive" character suggests that Einstein had tacitly harbored this misconception beforehand. Might this misconception have misdirected Einstein's work on his *Entwurf* theory at an earlier stage? In the following I will conjecture that it did in a quite precise way.

3.3 The Conjecture: How the Independent Reality of Coordinate Systems Defeats the Use of Coordinate Conditions

I have urged that Einstein knew about the possibility of coordinate conditions, that he used them in the notebook and then abandoned them in favor of the use of coordinate restrictions. I have even suggested that this transition may have taken place on page 22R of the notebook, in which the same requirement (11) might have been used first as a coordinate condition and then as a coordinate restriction. I now conjecture that Einstein abandoned the use of coordinate conditions because of the same error committed in the context of the hole argument. Einstein unwittingly attributed an independent reality to the coordinate systems introduced by coordinate conditions. The effect was that he mistakenly believed that the covariance of his entire theory was reduced to that of the coordinate condition. The reversion to coordinate restrictions is now natural. He mistakenly thought that using coordinate conditions to recover the

52 In describing Einstein's earlier misconception I will speak of his belief that the coordinate system has "*independent* reality," which is to be understood as asserting reality independent of the metrical field. This is because Einstein's later denial of the physical reality of the coordinate system can only apply to a reality independent of the metric. For it is entirely compatible with Einstein's later views that a coordinate system can reflect an element of reality, but only if it does so indirectly by virtue of its relation to the metric defined on the spacetime. For example, the possibility of a coordinate system in which the metrical coefficients are all constant, reflects a real property of the spacetime, its flatness.

Newtonian limit provided no greater covariance for this theory and the use of coordinate restrictions had the advantage of simplifying the equations of his theory.

The Example of T^x_{il}

To see how this notion of the independent reality of coordinate systems would defeat the use of coordinate conditions, we will look at the example of coordinate condition (11) applied to the candidate gravitation tensor T^x_{il}. The example illustrates clearly the general argument. It is also of interest in itself since I believe Einstein may well have fallen into the general mistake outlined while considering this very example.

Einstein's essential purpose in considering a structure as complicated at T^x_{il} is to achieve the broadest covariance possible for his gravitational field equations. By construction, T^x_{il} is covariant under unimodular transformations. We have seen that one particular unimodular transformation comes to special prominence in the pages immediately following the proposal of the gravitation tensor T^x_{il}. That is the transformation (18) to uniformly rotating coordinates that brings a rotation field g^{SR} (20) into being in a Minkowski spacetime.[53]

The simple reading of this covariance of the gravitational field equations in the case of a Minkowski spacetime is that it admits the transformation of $g^{SR}(x)$ to the rotation field $g^{ROT}(x')$ under the coordinate transformation (18). They are just the same Minkowski spacetime represented in two coordinate systems x and x'. However we have already seen that when Einstein speaks of such a simple transformation he may actually be referring to a more complicated transformation. In the context of the hole argument, as we saw above, when Einstein wrote about the transformation of a metric g under the transformation of the coordinates x to x', he did not just refer to the transformation of $g(x)$ to $g'(x')$. He also tacitly referred to construction of a new solution of the field equations $g'(x)$ in the original coordinate system x. Indeed Einstein seemed to treat the construction of the new field $g'(x)$ as an automatic consequence of the covariance of the gravitational field equations—so much so that, in three of four presentations of the hole argument, Einstein appears just to refer to the transformation $g(x)$ to $g'(x')$ whereas he intended to refer to the construction of the new field $g'(x)$. Thus Einstein would read the covariance of his gravitational field equations under transformation (18) as the license to take the solution $g^{SR}(x)$ of these equations and construct a new solution $g^{ROT}(x)$, both in the same coordinate system x.

Applying the Hole Construction

Einstein would see this construction as an automatic part of the covariance of his field equations, although its construction requires some manipulation as codified in what I called the "hole construction" above. We may pause here for a moment to affirm that the construction of the new solution $g^{ROT}(x)$ follows directly from the hole con-

53 I shall continue to use the abbreviation (22), so that $g^{SR}(x)$ stands for $g^{SR}_{\mu\nu}(x_\alpha)$.

struction, although Einstein would surely not have resorted to such a labored development. The two antecedent conditions (a) and (b) are satisfied as:

a) If T^{x}_{il} is chosen as the gravitation tensor, then the gravitational field equations are covariant under the transformation (18) from inertial to uniformly rotating coordinates, for this is a unimodular transformation.

b) $g^{SR}(x)$ is a solution of the source free field equations $T^{x}_{il} = 0$.[54]

It now follows that $g^{ROT}(x)$ will also be a solution of the source free field equations in the original coordinate system x.

The Independent Reality of the Coordinate Systems x^{LIM} of the Newtonian Limit…

In his evaluation of T^{x}_{il}, Einstein would have a particular class of coordinate systems in mind as admitting g^{SR} as a solution. These are the coordinate systems in which the candidate gravitation tensor T^{x}_{il} reduces to (8) in preparation for recovery of the Newtonian limit. Let us label one of these coordinate systems x^{LIM}. Thus Einstein's field equations must admit both $g^{SR}(x^{LIM})$ and $g^{ROT}(x^{LIM})$ as solutions of the source free field equations in the same coordinate system x^{LIM}.

While these results follow from a straightforward application of Einstein's 1913 understanding of covariance and coordinate systems, they have brought us close to disaster for the candidate gravitation tensor T^{x}_{il}. To complete the journey to disaster we now must now ask what it would mean to say that these source free field equations must admit both $g^{SR}(x^{LIM})$ and $g^{ROT}(x^{LIM})$ as solutions. In Einstein's *later* view (and the modern view), this could mean nothing more than the following: there exists coordinate systems x in which $g^{SR}(x)$ solves the source free field equations; and there exists coordinate systems y in which $g^{ROT}(y)$ solves the source free field equations. But there can be no physical sense in the notion that the coordinate systems x and y are the same coordinate systems. Yet the Einstein of 1912 and 1913 would be committed to the notion that the coordinate systems x^{LIM} appearing in each solution are the same coordinate systems.

There is only one resource available to give meaning to this sameness. The coordinate systems x^{LIM} of the Newtonian limit are introduced and identified in calculation by satisfaction of the coordinate condition (11). If it is really the same coordinate systems x^{LIM} appearing in each of $g^{SR}(x^{LIM})$ and $g^{ROT}(x^{LIM})$, then coordinate condition (11) must be satisfied by both $g^{SR}(x^{LIM})$ and $g^{ROT}(x^{LIM})$. In hindsight, we know that this demand is excessive. But, I conjecture, the Einstein of 1912 and 1913 did not realize this. There is a natural robustness to the application of coordinate conditions such as (11) in the modern sense that is easily mistaken for the troublesome use of the condition that I attribute to Einstein. It was legitimate in 1912 and 1913 and remains legitimate today to use the same coordinate condition to pick out the coordinate systems for the Newtonian limit in a diverse array of distinct physical situations: in the source free case, in the case of static fields, in the case of fields with propagat-

54 $g^{SR}_{\mu\nu}$ has all constant coefficients; so all its derivatives vanish and T^{x}_{il} along with them.

ing gravitational waves, in the case of a field produced by a single mass or in the case of a field produced by distributed matter; and in many more cases. Now we might use a condition such as the harmonic coordinate condition rather than Einstein's (11) but that difference is inessential to the point. In using the same harmonic condition in each of these distinct physical cases, we routinely say that we choose harmonic coordinates. Are we always aware that the harmonic coordinates of a Minkowski spacetime are not the same in any physical sense as the harmonic coordinates of a Minkowski spacetime perturbed ever so slightly by the most minute of gravitational waves? Proceeding with the tacit assumption of the independent reality of coordinate systems, Einstein could easily overlook this subtlety. It would surely be quite natural for him to presume that his coordinate condition (11) would pick out the same coordinate systems x^{LIM} in all these cases and also in the case of g^{SR} and g^{ROT}.

Treated this way, the coordinate condition (11) becomes a physical postulate that picks out a real entity, the class of coordinate systems x^{LIM}, much as the gravitational field equations pick out the gravitational fields that can be realized physically. This character of the coordinate condition (11) does not compromise our freedom to stipulate the coordinate systems that we will use in describing our fields. We are still free to choose which coordinate systems we will use and that choice can be made by accepting or rejecting a coordinate condition such as (11). But that choice is among entities that enjoy some physical reality.

…Brings Disaster and Explains Why Einstein Would Check the Covariance of His Coordinate Condition

Thus I infer that the Einstein of 1912 and 1913 would expect that the condition (11) picks out the same coordinate systems x^{LIM} in the cases of the solutions $g^{SR}(x^{LIM})$ and $g^{ROT}(x^{LIM})$. This is the disastrous conclusion. While the coordinate condition (11) holds for $g^{SR}(x^{LIM})$, we saw above that it fails for $g^{ROT}(x^{LIM})$. Einstein has arrived at a contradiction that serves as a *reductio ad absurdum* of his choice of T_{il}^{x} as gravitation tensor and the expectation that his theory is covariant under all unimodular transformations. If the theory has that degree of covariance, $g^{ROT}(x^{LIM})$ must be a solution of its source free field equations in the coordinate system x^{LIM}. But it is not. The proposed gravitation tensor has failed.

This is a failure of coordinate condition (11) to have sufficient covariance. Under the normal understanding of coordinate conditions, Einstein would have no reason to check the covariance of (11). But if Einstein accords independent reality to the coordinate system x^{LIM}, then the natural outcome is to check its covariance. If the present conjecture is correct, this explains why Einstein checked the covariance of condition (11) on page 22L, the one facing the page on which condition (11) is used to reduce T_{il}^{x} to a Newtonian form.

This contradiction between the expected and actual covariance of Einstein's theory would appear to have a particular character to Einstein, a conflict between the covariance of his theory and the ability to recover the Newtonian limit. Upon choosing T_{il}^{x} as the gravitation tensor, his entire gravitation theory would be covariant at least under unimodular transformations. That is, the gravitational field equations are covariant under unimodular transformations and the remaining equations governing energy-momentum conservation, the motion of particles and the electromagnetic field are generally covariant. However if the theory admits coordinate systems in which the Newtonian limit can be realized, then the theory loses its broad covariance. In particular, it loses covariance under transformations to uniform rotation, so that Einstein could no longer conceive of uniform rotation as a rest state, in contradiction with his requirement of a generalized principle of relativity.

The Problem Generalized

The power attributed to the coordinate condition (11) does not depend on any specific properties of the gravitation tensor T_{il}^{x} or the coordinate condition (11). The arguments rehearsed here would proceed equally with any candidate gravitation tensor of suitably broad covariance and any coordinate condition able to reduce that gravitation tensor to the form (8). Again, the argument does not require that the transformation be a rotation transformation (18). Any transformation in the covariance group of the gravitational field equations could be used. Thus, if the conjecture is correct, Einstein must have held very restrictive expectations for the covariance of his emerging general theory of relativity, whatever its gravitation tensor might be.

To find these expectations, we generalize the argument above for any gravitation tensor, any transformation in the covariance group of the resulting field equations and any coordinate condition that reduces the gravitation tensor to the form (8). For the case of the gravitation tenor T_{il}^{x}, the coordinate condition (11) picks out the class of coordinate systems x^{LIM} in which the Newtonian limit obtains and the gravitation tensor has form (6). Correspondingly for some gravitation tensor $G_{\mu\nu}$ of broad covariance, a coordinate condition $C_{\alpha} = 0$ will pick out the coordinate systems in which the Newtonian limit obtains and the gravitation tensor reduces to form (8). Since rotation transformation (18) is in the covariance group of T_{il}^{x}, Einstein would expect through the hole construction that the two metrics g^{SR} and g^{ROT}, related by this transformation, are admissible as solutions in this coordinate system x^{LIM}. But this can only obtain if the coordinate condition (11) is covariant under rotation transformation (18). Correspondingly, if g and g' are solutions of the (source free) gravitational field equations based on the gravitation tensor $G_{\mu\nu}$, Einstein would expect, through the hole construction, that they are solutions of the reduced gravitational field equations in the limit coordinate system. But this can only obtain if the coordinate condition $C_{\alpha} = 0$ is covariant under the transformation that takes g to g'. That is, Einstein would expect the following results (C1), (C2) and (C3), to obtain:

> (C1) The covariance of the theory as a whole is limited to the covariance of the coordinate condition used to pick out the coordinate systems in which the Newtonian limit is realized.

For the covariance of that coordinate condition delimits the transformations admissible for solution of the field equations in those coordinate systems.

(C2) The covariance of the gravitational field equations, *after* they have been reduced by the coordinate condition to the form (8), defines the covariance of the theory as a whole.

For these reduced gravitational field equations just result from the conjunction of the unreduced gravitational field equations and the coordinate condition so that their covariance is limited by the covariance of the coordinate condition. (In both (C1) and (C2), if the unreduced gravitational fields equations have restricted covariance, then these conditions also limit the covariance of the theory as a whole.)

(C3) In a viable theory, the coordinate condition used and the resulting reduced gravitational field equations will still exhibit broad covariance, including covariance under the rotation transformations (18), so that they admit $g_{\mu\nu}^{ROT}$ as a solution.

If the covariance required in (C1) or (C2) does not include acceleration transformations, such as the rotation transformation (18), then the theory fails to meet the demands of a generalized principle of relativity. It harbors covariance restricting coordinate systems akin to the objectionable, absolute inertial systems of classical mechanics and special relativity (see below).

If the present conjecture is correct, Einstein would adopt (C1), (C2) and (C3). The immediate outcome would be that there is no gain is using a requirement like (11) as a coordinate condition rather than a coordinate restriction. In either use, the equation will impose the same restriction on his gravitation theory's covariance. But the advantage of using coordinate restrictions is that they allow for simpler gravitational field equations.

Moreover, let us suppose that Einstein came to see (C1), (C2) and (C3) as a part of his evaluation of the candidate gravitation tensor T_{il}^{x} on page 22R. Then his natural response would be to discontinue the use of coordinate conditions, as he does after page 22R. Indeed his construction of the theta condition on page 23L would be a natural next step. He abandons coordinate conditions in favor of coordinate restrictions, so he contrives a coordinate restriction specifically to have the rotational covariance lacked by (11).

3.4 The Problem of Absolute Coordinates

The cause of the difficulty is the coordinate systems x^{LIM}, essential for the recovery of the Newtonian limit. Throughout his scientific life Einstein had railed against the objectionable, absolute properties of inertial coordinate systems. The coordinate systems x^{LIM} had now adopted just those objectionable properties and Einstein could not tolerate their presence in his theory. Einstein had made quite clear that the fundamental goal of his general theory of relativity was to eliminate exactly these preferred systems of coordinates.

His Denunciations Persist from his Early Work…

Typical of his denunciations of such systems were his remarks written in the early days of the *Entwurf* theory:

> The theory presently called "the theory of relativity" [special relativity] is based on the assumption that there are somehow preexisting "privileged" reference systems K with respect to which the laws of nature take on an especially simple form, even though one raises in vain the question of what could bring about the privilegings of these reference systems K as compared with other (e.g., "rotating") reference systems K'. This constitutes, in my opinion, a serious deficiency of this theory.[55]

The privileging of the reference system K in special relativity resides in the fact that only in K do free bodies move inertially (the "specially simple form" of the laws of motion of free bodies), whereas in K' they move under the influence of a rotation field. K and K' cannot switch roles. K cannot admit a rotation field while bodies move inertially in K'. Of course Einstein was not referring in these remarks to the special coordinate systems x^{LIM} introduced in the Zurich Notebook. However, these special coordinate systems have exactly the properties that Einstein found objectionable in K: the coordinate systems x^{LIM} admit g^{SR} so that free bodies will move inertially in x^{LIM}. But x^{LIM} does not admit the rotation field g^{ROT}.

The presence of such absolute coordinate systems would cut Einstein to the quick. In the course of nearly half a century of writing on the general theory of relativity, Einstein found the need to reappraise much of what he wrote on the foundations of his theory. His vacillations on Mach's principle are probably the best known instance. But he never wavered in his insistence that the absolute of the inertial system must be eliminated. These sentiments supported the need for a generalization of the principle of relativity to acceleration when Einstein wrote his explanatory texts:

> All of the previous considerations have been based upon the assumption that all inertial systems are equivalent for the description of physical phenomena, but that they are preferred, for the formulation of the laws of nature, to spaces of reference in a different state of motion. We can think of no cause for this preference for definite states of motion to all others, according to our previous considerations, either in the perceptible bodies or in the concept of motion; on the contrary, it must be regarded as an independent property of the

---

55 "Die gegenwärtig als "Relativitätstheorie" bezeichnete Theorie ist auf die Annahme gegründet, daß es gewissermaßen präexistierende "bevorzugte" Bezugssysteme K gebe, auf die bezogen die Naturgesetze eine besonders einfache Form annehmen, trotzdem man vergeblich die Frage aufwirft, wodurch die Bevorzugungen jener Bezugsysteme K gegenüber anderen Bezugssystemen K' (z. B. "rotierenden") bedingt sein könnte. Es liegt hierin meiner Ansicht nach ein schwerer Mangel dieser Theorie." (Einstein 1914a, 176; translation in CPAE 4E, 282). Again writing at the time of the *Entwurf* theory, Einstein expressed similar sentiments when he spoke of "...reference systems with respect to which freely moving mass points carry out rectilinear uniform motion (inertial systems). What is unsatisfactory is that it remains unexplained *how* the inertial systems can be privileged with respect to other systems." ("… Bezugssysteme zu entschlüpfen, in bezug auf welche kräftefrei bewegte Massenpunkte eine geradlinig gleichförmige Bewegung ausführen (Inertialsysteme). Das Unbefriedigende liegt dabei darin, daß unerklärt bleibt, *wieso* die Inertialsystemen ausgezeichnet sein können.") Einstein's parentheses and emphasis, (Einstein 1913, 1260; translation in CPAE 4E, 219).

> spacetime continuum. The principle of inertia, in particular, seems to compel us to ascribe physically objective properties to the spacetime continuum. Just as it was consistent from the Newtonian standpoint to make both the statements, *tempus est absolutum, spatium est absolutum,* so from the standpoint of the special theory of relativity we must say, *continuum spatii et temporis est absolutum*. In this latter statement *absolutum* means not only "physically real," but also "independent in its physical properties, having a physical effect, but not itself influenced by physical conditions."[56]

…To His Final Years

These sentiments persist essentially unchanged in the final years of his life. In a letter of 28 December 1950, Einstein explained to D. W. Sciama his concern over the latter's theory of restricted covariance; the equations held in coordinate systems in the set M but not in the forbidden set M^x:

> We now ask: on what basis can natural laws hold with respect to M but not with respect to M^x? (Logically considered, both sets M and M^x are after all completely equivalent.) If one takes the theory really seriously, there is only <u>one</u> answer: the preference for M over M^x is an independent physical property of space, which must be added as a postulate to the field equations, so that the physical theory as a whole can have a clear meaning. Newton recognized this with complete clarity ("Spacium est absolutum"). In fact, each theory based on a subgroup introduces an "absolute space", only one that is "less absolute" than classical mechanics.
>
> It was first achieved in G. R., that a space with independent (absolute) properties is avoided. There first are the laws, as they are expressed through the field equations, *complete* and require no augmenting assumptions over physical space. "Space" subsists then only as the continuum property of the physical-real (field), not as a kind of container with independent existence, in which physical things are placed.[57]

These same sentiments would apply to x^{LIM}. In resisting admission of g^{ROT}, the coordinate system would be restoring independent, absolute properties to spacetime, properties that went beyond what was given through the field equations. Einstein

---

56 "Alle bisherigen Überlegungen beruhen auf der Voraussetzung, daß die Inertialsysteme für die physikalische Beschreibung gleichberechtigt, den Bezugsräumen von anderen Bewegungszuständen für die Formulierung der Naturgesetze aber überlegen seien. Für diese Bervorzugung bestimmter Bewegungszustände vor allen anderen kann gemäß unseren bisherigen Betrachtungen in den wahrnehmbaren Körpern bzw. in dem Begriff der Bewegung eine Ursache nicht gedacht werden; sie muß vielmehr auf eine selbständige, d. h. durch nichts anderes bedingte Eigenschaft des raumzeitlichen Kontinuums zurückgeführt werden. Insbesondere scheint das Trägheitsgesetz dazu zu zwingen, dem Raum-Zeit-Kontinuum physikalisch-objektive Eigenschaften zuzuschreiben. War es vom Standpunkt Newtons konsequent, die beiden Begriffe auszusprechen; "Tempus absolutum, spatium absolutum", so muß man auf dem Standpunkt der speziellen Relativitätstheorie von "continuum absolutum spatii et temporis est" sprechen. Dabei bedeutet "absolutum" nicht nur "physikalisch-real", sondern auch "in ihren physikalischen Eigenschaften selbständig, physikalisch bedingend, aber selbst nicht bedingt"." From the popular (Einstein 1917, Ch.XXI) and the textbook (Einstein 1922, 55).

57 The typescript of the letter is EA 20–469. The autograph manuscript, EA 20 470, contains an extra sentence given in parentheses here as the second sentence, ("Logically considered..."). (EA 20–469 denotes the item with control number 20–469 in the Einstein Archive.)

would shortly characterize just such behavior as a reversion to the flawed viewpoints of Antiquity. To George Jaffé on 19 January 1954, he wrote:

> You consider the transition to the special theory of relativity as the most essential of all the ideas of the theory of relativity, but not the transition to the general theory of relativity. I hold the reverse to be true. I see the essential in the conquest of the inertial system, a thing that acts on all processes but experiences no reaction from them. This concept is in principle no better than that of the central point of the world in Aristotelian physics.[58]

3.5 The Structure and Program of the Entwurf Theory

Explaining Einstein's Indifference to General Covariance

According to the accounts developed in this volume, at the time of the creation of his *Entwurf* theory, Einstein thought rather differently from his later views on coordinate systems. There appears to be a trace of this difference in his early discussion of the limited covariance of his *Entwurf* theory. That is, he was curiously indifferent about discovering the generally covariant gravitational field equations that he believed must correspond to his *Entwurf* equations. Once Einstein has developed general arguments against the admissibility of general covariance, we need not search for a reason for this indifference. But these arguments emerged only later in 1913, after the *Entwurf* was published. We need some explanation for this indifference in the intervening months.

The accounts discussed in this paper supply them. The *Entwurf* equations would be recovered from generally covariant equations by application of a coordinate condition. So, if Einstein accorded an independent reality to the coordinate systems so introduced, then his indifference would be explained by the misapprehension that his theory overall would gain no added covariance from the transition to these generally covariant equations. Or, more simply, if Einstein was just unaware of the use of coordinate conditions, then he would be unaware of how to retain the *Entwurf* gravitational field equations for the essential case of the Newtonian limit, so the generally covariant equations would appear unusable within his theory.

The Restricted Covariance of the Entwurf theory

Einstein's exploration of T_{il}^{x} and the theta restriction are some of his final efforts in the Zurich Notebook to recover gravitational field equations from covariance considerations. These efforts halt decisively on pages 26L–26R, where Einstein laid out in capsule the derivation of the gravitational field equations of the *Entwurf* theory. This derivation uses no covariance considerations at all. It is based essentially on the

58 "Sie betrachten den Uebergang zur speziellen Relativitätstheorie als den wesentlichen Gedanken der Relativität überhaupt, nicht aber den Uebergang zur allgemeinen Relativitätstheorie. Ich halte das Umgekehrte für richtig. Das Wesentliche sehe ich in der Ueberwindung des Inertialsystems, eines Dinges das auf alle Vorgänge wirkt, von diesen aber keine Rückwirkung erfährt. Dieser Begriff ist im Prinzip nicht besser als der des Weltmittelpunktes in der Aristotelischen Physik." (EA 13 405)

demand of the Newtonian limit and energy-momentum conservation. Einstein and Grossmann arrived at a gravitation tensor of form (8)

$$\sum_{\alpha\beta}\frac{1}{\sqrt{-g}}\cdot\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\sqrt{-g}\cdot\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right)-\sum_{\alpha\beta\tau\rho}\gamma_{\alpha\beta}g_{\tau\rho}\frac{\partial\gamma_{\mu\tau}}{\partial x_\alpha}\frac{\partial\gamma_{\nu\rho}}{\partial x_\beta}$$
$$+\frac{1}{2}\sum_{\alpha\beta\tau\rho}\gamma_{\alpha\mu}\gamma_{\beta\nu}\frac{\partial g_{\tau\rho}}{\partial x_\alpha}\frac{\partial\gamma_{\tau\rho}}{\partial x_\beta}-\frac{1}{4}\sum_{\alpha\beta\tau\rho}\gamma_{\mu\nu}\gamma_{\alpha\beta}\frac{\partial g_{\tau\rho}}{\partial x_\alpha}\frac{\partial\gamma_{\tau\rho}}{\partial x_\beta}.$$

Unfortunately Einstein and Grossmann were unable to specify the covariance group of the resulting gravitational field equations. They were able to assure the reader only of covariance under linear transformation. Of course Einstein was apologetic over their failure to discover the covariance of these equations. In closing his critique of any gravitation theory based on a scalar gravitation potential, Einstein candidly conceded how this omission had crippled Einstein's program:

> Of course, I must admit that, for me, the most effective argument for the rejection of such a theory rests on the conviction that relativity holds not only with respect to orthogonal linear substitutions but also with respect to a much wider group of substitutions. But already the mere fact that we were not able to find the (most general) group of substitutions associated with our gravitational equations makes it unjustifiable for us to press this argument.[59]

What is puzzling is that the deficiency could be set aside with such a simple disclaimer. The driving force of Einstein's program was the conviction that the relativity of motion must be extended to acceleration and that this would be realized by a theory covariant under non-linear coordinate transformations, for only the latter corresponded to transformations to accelerated states of motion.

To see just how puzzling this is, we need to recall two of Einstein's commitments at this time. First we are assured by Einstein's remarks in a letter to Lorentz of 14 August 1913 of his continued commitment to a broader covariance and his alarm at his continued failure to affirm the broader covariance of the theory:

> *But the gravitational equations themselves unfortunately do not have the property of general covariance*. Only their covariance under *linear* transformations is assured. However the whole trust in the theory rests on the conviction that acceleration of the reference system is equivalent to a gravitational field. Therefore if all the systems of equations of the theory, thus also equation (18) [gravitational field equations], do not admit still other transformations aside from the linear, then the theory contradicts its own starting point; it's left hanging in the air. [Einstein's emphasis][60]

It is a measure of Einstein's frustration and desperation that the following day—15 August 1913[61]—he fell into an embarrassing error. He thought that he could

59 "Ich muß freilich zugeben, daß für mich das wirksamste Argument dafür, daß eine derartige Theorie zu verwerfen sei, auf der Überzeugung beruht, daß die Relativität nicht nur orthogonalen linearen Substitutionen gegenüber besteht, sondern einer viel weiteren Substitutionsgruppe gegenüber. Aber wir sind schon deshalb nicht berechtigt, dieses Argument geltend zu machen, weil wir nicht imstande waren, die (allgemeinste) Substitutionsgruppe ausfindig zu machen, welche zu unseren Gravitationsgleichungen gehört." (Einstein and Grossmann 1913, I§7; translation in CPAE 4E, 170–171)

establish from the requirement of energy conservation that his gravitation theory could be at *most* covariant under linear transformations. He retracted this trivially flawed argument in a paper published the following May (Einstein and Grossmann 1914, 218), but not before the argument had appeared several times in print.[62]

Correspondence with Generally Covariant Equations

Second, Einstein expressed his belief that his *Entwurf* field equations must correspond to generally covariant equations. Having presented his *Entwurf* gravitational field equations, he continued:

> It is beyond doubt that there exists a number, even if only a small number, of generally covariant equations that correspond to the above equations, but their derivation is of no special interest either from a physical or from a logical point of view, as the arguments presented in point 8 clearly show.[63] However, the realization that generally covariant equations corresponding to [these gravitational field equations] must exist is important to us in principle. Because only in that case was it justified to demand the covariance of the rest of the equations of the theory with respect to arbitrary substitutions. On the other hand, the question arises whether those other equations might not undergo specialization owing to the specialization of the reference system. In general, this does not seem to be the case.[64]

Although Einstein does not make explicit what the relation of correspondence is between the *Entwurf* equations and their generally covariant counterparts, it would surely be that the former are recovered from the latter by some kind of coordinate condition or restriction.

While these remarks come from a paper of January 1914, we have no reason to doubt that they reflected Einstein's feelings just a few months earlier at the time of completion of the *Entwurf* paper. They provide a natural interpretation of remarks

---

60 "*Aber die Gravitationsgleichungen selbst haben die Eigenschaft der allgemeinen Kovarianz leider nicht*. Nur deren Kovarianz *linearen* Transformationen gegenüber ist gesichert. Nun beruht aber das ganze Vertrauen auf die Theorie auf der Überzeugung, dass Beschleunigung des Bezugssystems einem Schwerefeld äquivalent sei. Wenn also nicht alle Gleichungssysteme der Theorie, also auch Gleichungen (18) ausser den linearen noch andere Transformationen zulassen, so widerlegt die Theorie ihren eigenen Ausgangspunkt; sie steht dann in der Luft." (CPAE 5, Doc. 467)

61 The dating is derived from Einstein's report to Lorentz in a letter of 16 August 1913 (CPAE 5, Doc. 470).

62 For discussion see (Norton 1984, §6).

63 In his point 8, Einstein had stated the hole argument and the argument against general covariance based on the conservation of energy-momentum.

64 "Es ist zweifellos, daß diesen Gleichungen eine, wenn auch geringere Zahl von allgemein kovarianten Gleichungen entspricht, deren Aufstellung aber weder vom physikalischen noch vom logischen Standpunkte von besonderem Interesse ist, wie aus den unter 8 gegebenen Überlegungen deutlich hervorgeht. Prinzipiell wichtig aber ist uns die Erkenntnis, daß den Gleichungen (6) entsprechende allgemein kovariante existieren müssen. Denn nur in diesem Falle war es gerechtfertigt, die Kovarianz der übrigen Gleichungen der Theorie beliebigen Substitutionen gegenüber zu fordern. Es entsteht andererseits die Frage, ob jene anderen Gleichungen durch die Spezialisierung des Bezugssystems keine Spezialisierung erfahren. Dies scheint im allgemeinen nicht der Fall zu sein." (Einstein 1914a, 179; translation in CPAE 4E, 286)

made by Einstein when he reflected on their failure to find generally covariant gravitational field equations:

> To be sure, it cannot be negated a priori that the final, exact equations of gravitation could be of higher than second order. Therefore there still exists the possibility that the perfectly exact differential equations of gravitation could be covariant with respect to *arbitrary* substitutions. But given the present state of our knowledge of the physical properties of the gravitational field, the attempt to discuss such possibilities would be premature. For that reason we have to confine ourselves to the second order, and we must therefore forgo setting up gravitational equations that are covariant with respect to arbitrary transformations. [Einstein's emphasis][65]

Einstein cannot mean by this that the higher order equations are incompatible with the *Entwurf* equations. For then solutions of the *Entwurf* equations would not be solutions of the higher order equations, so that each would admit a different class of physical fields. In this case, the selection of the *Entwurf* equations is just the selection of the wrong equations. It is hard to imagine that Einstein would dismiss correcting such an outright error by calling the correction "premature." But the dismissal is more intelligible if these higher order equations are the generally covariant equations that reduce to the *Entwurf* equations with the application of a coordinate condition or restriction. For then all solutions of the *Entwurf* equations would be solutions of the higher order equations; transition to the higher order equations would merely admit more coordinate representations of the same physical fields into the theory.

The Incongruity of Einstein's Approach…

If Einstein held these two views at the time of publication of the *Entwurf* theory and he also held to an essentially modern view of coordinate systems and coordinate conditions, then his assessment of the theory's state and his further development of the theory is quite mysterious. For the sole effect of a coordinate condition, in this modern view, is to obscure the covariance of the theory. As long as the coordinate condition does not extend beyond the four equations routinely allowed, it does not preclude any physical field; it merely reduces the range of coordinate representations of each

65 "A priori kann allerdings nicht in Abrede gestellt werden, daß die endgültigen, genauen Gleichungen der Gravitation von höherer als zweiter Ordnung sein könnten. Es besteht daher immer noch die Möglichkeit, daß die vollkommen exakten Differentialgleichungen der Gravitation *beliebigen* Substitutionen gegenüber kovariant sein könnten. Der Versuch einer Diskussion derartiger Möglichkeiten wäre aber bei dem gegenwärtigen Stande unserer Kenntnis der physikalischen Eigenschaften des Gravitationsfeldes verfrüht. Deshalb ist für uns die Beschränkung auf die zweite Ordnung geboten und wir müssen daher darauf verzichten, Gravitationsgleichungen aufzustellen, die sich beliebigen Transformationen gegenüber als kovariant erweisen." (Einstein and Grossmann 1913, I.§5; translation in CPAE 4E, 160) Michel Janssen has suggested an alternative interpretation: Einstein may merely mean that his *Entwurf* field equations might be good empirical approximations in the domain of weaker fields for some set of generally covariant gravitational field equations of higher order. If this interpretation is correct, we still have ample evidence from his other remarks that Einstein also expected the *Entwurf* field equations to be recoverable from generally covariant equations by means of a coordinate condition. See, for example, the remarks quoted in section 3.6.

physical field.[66] In so far as the field equations, after reduction by the coordinate condition, are intended to yield the Newtonian limit, they need only exhibit covariance under linear transformation. It might just happen that the reduced field equations exhibited greater covariance so that they might play a direct role in the generalization of the principle of relativity. But there is no reason to expect this. The only sure way to expand the covariance of the theory is to find the unreduced, generally covariant form of the gravitational field equations. That is the obvious and natural way to develop the *Entwurf* theory.

This was not Einstein's approach. Rather than seeking out these generally covariant equations, he let all his hopes hang on a slender thread: the *Entwurf* equation might just have sufficient covariance to support a generalized principle of relativity. So Einstein devoted his efforts to two tasks, both of which came to fruition after he had hit upon the hole argument. First he sought to discover the extent of the covariance of his *Entwurf* equations, describing this as the most important problem to be solved in the context of this theory.

> ...the equation of the gravitational field that we have set up do not possess this property [of general covariance]. For the equations of gravitation we have only been able to prove that they are covariant with respect to arbitrary *linear* transformations; but we do not know whether there exists a general group of transformations with respect to which the equation are covariant. The question as to the existence of such a group for the system of equations (18) and (21) [gravitational field equations] is the most important question connected with the considerations presented here. [Einstein's emphasis][67]

These efforts culminated in the discovery with Grossmann (Einstein and Grossmann 1914) that the covariance of his theory extends to what they call "adapted coordinate systems;" that is, coordinate systems that satisfy

$$\sum_{\alpha\beta\mu\nu} \frac{\partial^2}{\partial x_\nu \partial x_\alpha}\left(\sqrt{-g}\gamma_{\alpha\beta} g_{\sigma\mu} \frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\right) = 0. \tag{23}$$

Second he threw himself into the task of establishing that whatever limited covariance the *Entwurf* theory may have is good enough, for further covariance would be

66 For example, if our "field equation" is just a flatness requirement, the vanishing of Riemann-Christoffel curvature tensor, then one of its solutions is a Minkowski spacetime, whose coordinate representations include $g^{SR}_{\mu\nu}$ and $g^{ROT}_{\mu\nu}$. The effect of a coordinate condition such as (11) is not to eliminate a physical possibility such as this solution. It precludes the representation $g^{ROT}_{\mu\nu}$ with which is it incompatible; but it admits $g^{SR}_{\mu\nu}$.

67 "… daß die von uns aufgestellten Gleichungen des Gravitationsfeldes diese Eigenschaft nicht besitzen. Wir haben für die Gravitationsgleichungen nur beweisen könne, daß sie beliebigen linearen Transformationen gegenüber kovariant sind; wir wissen aber nicht, ob es eine allgemeine Transformationsgruppe gibt, der gegenüber die Gleichungen kovariant sind. Die Frage nach der Existenz einer derartigen Gruppe für das Gleichungssystem (18) bzw. (21) ist die wichtigste, welche sich an die hier gegebenen Ausführungen anknüpft." (Einstein and Grossmann 1913, I.§6; translation in CPAE 4E, 167) The continuation of the letter to Lorentz of 14 August 1913, quoted above describes some of his efforts to uncover these covariance properties.

physically uninteresting. Here Einstein had more success than his material warranted. He first showed in a trivially flawed and soon retracted argument that one can expect no more than linear covariance. Then the hole argument showed that generally covariance would be physically uninteresting and his analyses of 1914 showed that the *Entwurf* theory has the maximum covariance compatible with the hole argument.[68]

… is Explained

While Einstein's approach is baffling if we assume that he had a modern understanding of coordinate systems and coordinate conditions, it becomes entirely reasonable in the light of the conjecture of this part. He believed his *Entwurf* field equations to result from some set of unknown generally covariant equations reduced by a coordinate condition, presumably what turned out to be the adapted coordinate condition (23). In accord with (C1) and (C2), Einstein would pay no penalty in using the reduced form of the field equations in his theory. The covariance of the theory as a whole is just the covariance of the reduced equations (or, equivalently, the covariance of the coordinate condition (23). So the reduced form of these equations is not obscuring the true covariance of the theory as a whole, contrary to the modern view. And, since the effect of a coordinate condition (23) is just to restrict the covariance of the generally covariant equations, the reduced equations are not eliminating any physical fields; the limitation is just that each physical field arises in the theory in fewer coordinate representations. Thus, with the completion of the *Entwurf* theory in mid 1913, Einstein could have entered into the search for the generally covariant equations that correspond to his *Entwurf* equations. But there would have been little to gain from finding them. Finding them would not alter the covariance of the theory as a whole and it would not admit into the theory any new physical fields.[69]

There was a more pressing problem that had to absorb his immediate attention. Einstein did not know the covariance of the *Entwurf* theory. According to (C3), Einstein hoped that this covariance would extend to include transformations representing acceleration, for otherwise Einstein's hopes of extending the principle of relativity to acceleration would not be met by his theory. More was at stake. Einstein believed that his *Entwurf* gravitational field equation were unique; that is, they were the only equations employing a gravitation tensor of form (8) compatible with energy-momentum conservation.[70] Thus if the *Entwurf* equations failed to have sufficient covariance, then Einstein's entire project would be called into doubt. He could not just reject the

68 For discussion, see (Norton 1984, §6).

69 Or more simply, if Einstein was unaware of the use of coordinate conditions, the use of the generally covariant field equations, unsupplemented by adapted coordinate condition (23), would be incompatible with recovery of the Newtonian limit, since those equations would be unlikely to have the Newtonian form (8).

70 The uniqueness of these equations is suggested by the description of the identities (12) of Einstein and Grossmann (Einstein and Grossmann 1913, §5) used in the derivation of these equations as "uniquely determined" and then directly affirmed by Einstein (Einstein 1914b, 289). See (Norton 1984, §4) for discussion; the equations prove not to be unique, although this is not easy to see.

Entwurf field equations and seek a better alternative. He now believed that he had no option other than the *Entwurf* equations. Thus Einstein had to find the covariance of the *Entwurf* equations and, if his efforts to extend the principle of relativity were to succeed, it had to include acceleration transformations.

Thus the conjecture explains exactly the direction of Einstein's research on completion of the *Entwurf* theory.[71] He would gain nothing of significance from finding the generally covariant equations corresponding to his *Entwurf* equations. The problem urgently needing his attention was the discovery of the extent of the covariance of his *Entwurf* equations. These efforts of discovery soon transformed into the arguments that sought to established the need, in physical terms, for a restriction on covariance: that is, the arguments from the conservation laws and the hole argument. As Einstein's remarks from early 1914 quoted above indicate, these arguments establish that the quest for the generally covariant equations is of "no special interest"—a conclusion that I urge had already been forced implicitly by his according independent physical reality to the coordinate systems arising in the process of extracting the Newtonian limit.

3.6 Einstein's Pronouncements on the Selection of Specialized Coordinate Systems

The conjecture advanced here requires that Einstein's 1912–1915 understanding of coordinate systems in quite irregular. It is essential that this conjecture be compatible with Einstein's pronouncements on coordinate systems from this period. As it turns out, Einstein made few such pronouncements—so few, that it was initially thought in the history of science literature that Einstein was unaware of how to use four conditions to constrain the choice of coordinate systems. My purpose in this section is to review Einstein's most important pronouncements on the selection of specialized coordinate systems from this period and to show that they are quite compatible with the conjecture advanced here, although they neither speak for nor against it.

Two Ways to Introduce Specialized Coordinate Systems

Best known of these pronouncements is a distinction made in (Einstein 1914a, 177–178). Since this last pronouncement turns out to be a somewhat awkward statement of the same distinction explained more clearly in a later letter to Lorentz, I shall consider the later remarks first. In a letter of 23 January 1915 to Lorentz, Einstein sought to explain that his "choice of coordinates makes no assumption physically about the world." He used a "geometric comparison" to illustrate the possibilities:

> I have a surface of unknown kind upon which I want to carry out geometrical investigations. If I require that a coordinate system (p, q) on the surface can be so chosen that
>
> $$ds^2 = dp^2 + dq^2$$

71 A supposed lack of awareness of the use of coordinate conditions would also explain this direction.

then I thereby assume that the surface can be developed onto a plane. However if I require only that the coordinates can be so chosen that

$$ds^2 = A(p,q)dp^2 + B(p,q)dq^2$$

i.e. that the coordinates are orthogonal, I thereby assume nothing about the nature of the surface; one can realize them on any surface.[72]

Einstein's remark is a commonplace of differential geometry and applies equally in the geometry of two-dimensional surfaces and in the geometry of spacetimes. In presuming the existence of a particular coordinate system, we might be tacitly restricting the geometry of the space, or we might not. So, as in Einstein's first example, if we assume that there is a coordinate system in which the metrical coefficient $g_{\mu\nu}$ are constant, then we are assuming that the space is also metrically flat.[73] For constancy of the $g_{\mu\nu}$ is necessary and sufficient for metrical flatness. Other coordinate systems, however, can be realized in any space, so that the presumption of their existence does not restrict the geometric properties of the space.

To proceed to Einstein's (1914) remarks, we express the constraint that picks out a coordinate system in which the metrical coefficients are all constant as

$$\frac{\partial\gamma_{\alpha\beta}}{\partial x_\kappa} = 0. \tag{24}$$

This condition is equivalent to metrical flatness, which is a condition that can be given in invariant or generally covariant form, that is, as the vanishing of the Riemann-Christoffel curvature tensor

$$R^{\alpha}_{\beta\mu\nu} = 0. \tag{24'}$$

However the now familiar

$$\sum_\kappa \frac{\partial\gamma_{\kappa\alpha}}{\partial x_\kappa} = 0 \tag{11}$$

consumes just the four degrees of freedom available in selection of a coordinate system in any four-dimensional spacetime and thus places no restriction on its geometry. Whatever (11) states cannot be re-expressed by a non-vacuous invariant or generally covariant relation.

---

72 "Es liegt mir eine Fläche unbekannter Art vor, auf der ich geometrische Untersuchungen machen will. Verlange ich, es solle auf der Fläche ein Koordinatensystem (p,q) so gewählt werden, dass $ds^2 = dp^2 + dq^2$, [s]o setzte ich damit voraus, dass die Fläche auf eine Ebene abwickelbar sei. Verlange ich aber nur, dass die Koordinaten so gewählt seien, dass $ds^2 = A(p,q)dp^2 + B(p,q)dq^2$ ist, d. h. dass die Koordinaten orthogonal seien, so setzte ich damit über die Natur der Fläche nichts voraus; man kann dies auf jeder Fläche erzielen." Einstein to H. A. Lorentz, 23 January 1915 (CPAE 8, Doc. 47).

73 That a surface "can be developed onto a plane" is synonymous with flatness.

Working Backwards

This is the distinction that Einstein describes in (Einstein 1914a). The difference is that Einstein starts with an expression of restricted covariance and then works backwards, asking if the expression came from a generally covariant expression by restriction of the coordinate system.

> If we are given equations connecting any quantities whatsoever[74] that are valid only for a special choice of the coordinate system, then one has to distinguish between two cases:
>
> 1. To these equations there correspond generally covariant equations, i.e. equations valid with respect to arbitrary reference systems;
>
> 2. There are no generally covariant equations that can be deduced from the equations given for the specially chosen reference frame.
>
> In case 2, the equations say nothing about the things described by the quantities in question; they only restrict the choice of reference system. If the equations say anything at all about the things represented by the quantities, then we are dealing with case 1, i. e., in that case, there always exist generally covariant equations between the quantities.[75]

The constraint (24) is an instance of a non-generally covariant equation of case 1. Its existence does restrict the quantities involved, for it entails the flatness of the metric. Thus there is a corresponding generally covariant relation (24'). The requirement (11), however, generates no restriction on these quantities and thus corresponds to no (non-vacuous) generally covariant requirement.

The distinction outlined here does not bear on the reading of coordinate restrictions I urge Einstein held in 1912–1915. The requirement (11), places no restriction on the geometric properties represented by the metric $g_{\mu\nu}$. That is an issue independent of how the requirement picks out particular coordinate systems. To parrot Einstein, the requirement "says nothing" about the metrical quantities, but it certainly "says some-

74 Einstein's footnote: "Of course, the transformation properties of the quantities themselves must be considered here as being given for arbitrary transformations." ("Die Transformationseigenschaften der Größen selbst müssen natürlich hierbei als für beliebige Transformationen gegeben betrachtet werden.")

75 "Wenn Gleichungen zwischen irgendwelchen Größen gegeben1) [see previous note] sind, die nur bei spezieller Wahl des Koordinatensystems gültig sind, so sind zwei Fälle zu unterscheiden:
1. Es entsprechen den Gleichungen allgemein kovariante, d. h. bezüglich beliebiger Bezugssysteme gültige Gleichungen;
2. es gibt keine allgemein kovarianten Gleichungen, die aus den für spezielle Wahl des Bezugssystems gegebenen Gleichungen gefolgert werden können.
Im Falle 2 sagen die Gleichungen über die durch die Größen dargestellten Dinge gar nichts aus; sie beschränken nur die Wahl des Bezugssystems. Sagen die Gleichungen über die durch die Größen dargestellten Dinge überhaupt etwas aus, so liegt stets der Fall 1 vor, d. h. es existieren dann stets allgemein kovariante Gleichungen zwischen den Größen." (Einstein 1914a, 177–178; translation in CPAE 4E, 284) Einstein's purpose is to assert that his non-generally covariant gravitational field equations of the *Entwurf* theory do make some assertion about the quantities involved. Thus they are an instance of case 1. and there must exist corresponding generally covariant equations.

thing" about the coordinate systems, for it admits some and precludes others. Deciding just what it says about them is the issue that defeated Einstein in 1912–1915.

Specialized Coordinate Systems and Nordström's Theory of Gravitation

There is an important instance of case 1 in (Einstein and Fokker 1914), submitted for publication in February 1914, a month after the submission of (Einstein 1914a). Their work pertains to Nordström's latest theory of gravitation, which Einstein judged the most viable of the gravitation theories then in competition with the Einstein and Grossmann *Entwurf* theory.[76]

Nordström's theory had been developed by Nordström and Einstein as a Lorentz covariant theory of gravitation. With Fokker, Einstein now showed that the theory could be recovered in the generally covariant framework of the *Entwurf* theory, complete with its generally covariant energy conservation law. In place of the Einstein-Grossmann gravitational field equations, Einstein and Fokker adopted the single field equation $R = kT$, where R is the Riemann curvature scalar, T the trace of the stress-energy tensor and k a constant. That single equation would be insufficient to fix the ten coefficients of the metric tensor, so additional constraints were needed. "It turns out," Einstein and Fokker observed in their introductory summary, "that one arrives at the Nordström theory instead of the Einstein-Grossmann theory, if one makes the sole assumption that it is possible to choose preferred coordinate systems in such a way that the principle of the constancy of the speed of light obtains."[77] They interpreted the presumption of such a coordinate system as equivalent to assuming the existence of coordinate systems in which the spacetime's line element has the form[78]

$$ds^2 = \phi^2(dx_1^2 + dx_2^2 + dx_3^2 - dx_4^2). \tag{25}$$

That a spacetime admits a line element of this form greatly restricts its geometry; it is equivalent to conformal flatness. As Einstein suggests, this restriction can be written in generally covariant form. It was later found to be equivalent to the vanishing of the Weyl conformal tensor.

Einstein does not mention the Nordström theory in remarks in a letter to Planck 7 July 1914, written about six months after publication of Einstein and Fokker's paper. However his remarks describe exactly the specialized coordinate system introduced in the Einstein-Fokker formulation of the Nordström theory.

> There is a fundamental difference between that specialization of the reference system that classical mechanics or [special] relativity theory introduces and that which I apply in

76 For an account of Nordström's theories, see (Norton 1992; 1993).

77 "Es erweist sich hierbei, daß man zur Nordströmschen Theorie statt zur Einstein-Großmannschen gelangt, wenn man die einzige Annahme macht, es sei eine Wahl bevorzugter Bezugssysteme in solcher Weise möglich, daß das Prinzip von der Konstanz der Lichtgeschwindigkeit gewahrt ist." (Einstein and Fokker 1914, 321)

78 Then a light signal, for which $ds^2 = 0$, propagates with unit coordinate velocity. For example, if it propagates along the x_1 axis, the light signal satisfies $dx_1/dx_4 = \pm 1$.

> the theory of gravitation. That is, one can always introduce the latter, no matter how the $g_{\mu\nu}$ may be chosen. However the specialization introduced by the principle of the constancy of the speed of light presumes differential relations between the $g_{\mu\nu}$, and indeed relations whose physical interpretation would be very difficult. The satisfaction of these relations cannot be enforced for every given manifold through suitable choice of the reference system. According to the latter understanding, there are two heterogeneous conditions for the $g_{\mu\nu}$
>
> 1) the analog of Poisson's equation
>
> 2) the conditions that enable the introduction of a system of constant c.[79]

These two "heterogeneous conditions" correspond exactly with the two laws of the Nordström theory. The first, the field equation $R = kT$, is the analog of Poisson's equation. The second is the presumption that we can introduce a coordinate system in which the line element takes the conformally flat form (25). Its introduction is enabled by further conditions, which were later found to be expressible as "differential relations between the $g_{\mu\nu}$," the vanishing of the Weyl conformal tensor.

3.7 Was Einstein Really Defeated by According an Independent Reality to Coordinate Systems?

That is, is the conjecture of this part true? In sum, the answer is similar to the one given in section 2.4 to the question of whether Einstein was aware of coordinate conditions. There is no decisive piece of evidence for or against, but there are indications that point in both directions. Again, our ultimate assessment depends in some significant measure on issues of plausibility. My view is that the latter favor the conjecture.

The Notebook and the Entwurf Theory

If we accept that Einstein was aware of the use of coordinate conditions in the notebook and later, then we have several incongruities to explain. Why does he abandon their use so precipitously? Why does his later correspondence discount a perfectly serviceable extraction of the Newtonian limit from the candidate gravitation tensor T_{il}^{x}? Why is his discussion of the *Entwurf* theory, prior to his discovery of general arguments against general covariance so indifferent to the recovery of the generally

---

79 "Es gibt einen prinzipiellen Unterschied zwischen derjenigen Spezialisierung des Bezugssystems, welche die klassische Mechanik bezw. die Relativitätstheorie einführt und zwischen derjenigen, welche ich in der Gravitationstheorie anwende. Die letztere kann man nämlich stets einführen, wie auch die $g_{\mu\nu}$ gewählt werden mögen. Diese durch das Prinzip der Konstanz der Lichtgeschwindigkeit eingeführte Spezialisierung dagegen setzt Differenzialbeziehungen zwischen den $g_{\mu\nu}$ voraus, und zwar Beziehungen, deren physikalische Interpretation sehr schwierig sein dürfte. Das Erfülltsein dieser Beziehungen kann nicht für jede gegebene Mannigfaltigkeit durch passende Wahl des Bezugssystems erzwungen werden. Es gibt nach letzterer Auffassung zwei heterogene Bedingungen für die $g_{\mu\nu}$
1) das Analogon der Poisson'schen Gleichung
2) die Bedingungen, welche die Einführung eines Systems von konstantem c ermöglichen." Einstein to Max Planck, 7 July 1914 (CPAE 8, Doc. 18).

covariant gravitational field equations he allowed must exist? The conjecture of this part supplies an explanation that answers all of these questions.

Before we embrace that explanation, however, we should note that there is no direct evidence that Einstein did accord an independent reality to coordinate systems in the relevant context of the Newtonian limit. That is, we do not have unequivocal remarks by Einstein announcing it or a calculation whose only reasonable interpretation is that independence. It is hard to know how seriously to take this omission. Since Einstein was not using coordinate conditions to recover the Newtonian limit in his *Entwurf* theory, he had no occasion to undertake calculations that would unequivocally display an independent reality accorded his limit coordinate systems. What Einstein does give us are the manipulations of the hole argument. It is quite evident that he does there accord independent reality to the coordinate systems and his later admissions affirm this. Similarly, there were few occasions for Einstein to discuss how coordinate conditions could be used to recover the Newtonian limit, for this was not the construction he used in the *Entwurf* theory. On the few occasions in which he discussed general principles surrounding specialization of the coordinate system (see section 3.6 above), he makes no mention of an independent reality of the specialized coordinate systems. But then we would not expect him to. In section 3.1 we saw Einstein's difficulty in making explicit just how the manipulation of the hole argument depended on the independent reality of the coordinate system. If Einstein had such difficulty describing that independent reality when it was the essential point of the calculation, why should we expect him to express it clearer elsewhere?

Einstein's Later Discussion

Once Einstein had discovered his errors and returned to general covariance, he again had the opportunity to admit that he had accorded an independent reality to his coordinate systems. There were two prime occasions for such admission: his paper of 4 November 1915, and his letter to Sommerfeld of 28 November, in which he explained his rejection of the candidate gravitation tensor T_{il}^{x}. In both places, however, he emphasized the $\{\}$ prejudice as the source of his mistake. What is odd about both sources is that neither seek to explain the most public conceptual error of his *Entwurf* theory, the hole argument. At the time of the 4 November paper, Einstein had not yet discovered his misconception about static fields. As far as we know, the hole argument was the only foundational error of principle in the *Entwurf* theory, short of the ultimate mistake of choosing the *Entwurf* equations of restricted covariance. Since the error of the hole argument and the conjectured misuse of coordinate conditions are closely related, hesitancy in discussing the one should be expected to accompany hesitancy in discussing the other. And there was great hesitancy.

There are early published remarks that amount to the briefest retraction of the hole argument. But they offer little to explain the error of the argument. They appear in Einstein's celebrated computation of the anomalous motion of Mercury, in a paper presented to the Berlin Academy on 18 November 1915. There Einstein considers the gravitational field of a point mass at the origin of spatial coordinates, which he takes to be the sun. Solving for this case, even in lower order approximation, involves a system analogous to the hole of the hole argument. The field is constrained by Minkowskian boundary conditions at spatial infinity, just as the field in the hole is constrained by the surrounding matter distribution. In addition the field of the sun is constrained by the requirements that it be static and spatially symmetric about the origin. These additional requirements do not preclude all transformations; a spatial radial coordinate r could be arbitrarily transformed as long as the transformation does not disturb the limit at spatial infinity and preserves unit modulus by, say, corresponding adjustments elsewhere. Einstein remarked:

> We should however bear in mind that for a given solar mass the that the $g_{\mu\nu}$ are still not completely determined mathematically by the equations (1) and (3).[80] This follows since these equations are covariant with respect to arbitrary transformations of determinant 1. We may assume, however, that all these solutions can be reduced to one another through such transformations, so that they differ from one another only formally but not physically (for given boundary conditions). As a result of this conviction, I am satisfied for the present to derive a solution without being drawn into the question of whether it is the only possible [solution].[81]

If the covariance of the field equations is to block determination of the field in this case, it must be through the hole construction, so we have many solutions mathematically in the one coordinate system. Einstein parries the threat by observing that these solutions "differ from one another only formally but not physically" and the same remark would serve as an escape from the hole argument. Only a quite attentive reader would see the connection and even then such a reader may well find the remark unconvincing. Certainly Ehrenfest needed a more elaborate account of the failure of the hole argument before he was satisfied.[82] Yet Einstein concluded by explicitly disavowing any further discussion This neglect is striking in comparison to the careful self diagnosis elaborated as the $\{\}$ prejudice.

Why might he be reluctant to discuss the error of the hole argument? He may just have been reluctant to relive a painful experience, especially if he saw no benefit from it. Or perhaps he had some difficulty formulating precisely what the error was, even after he knew of it. It was sufficient that he knew that the hole construction did not produce physically distinct fields. If he had suffered this difficulty it would explain why he delayed detailed discussion of the error of the hole argument for nearly two

80 Einstein's equations are $T^x_{il} = 0$ and $|g_{\mu\nu}| = 1$, which are covariant under unimodular transformations.

81 "Es ist indessen wohl zu bedenken, daß die $g_{\mu\nu}$ bei gegebener Sonnenmasse durch die Gleichungen (1) und (3) mathematisch noch nicht vollständig bestimmt sind. Es folgt dies daraus, daß diese Gleichungen bezüglich beliebiger Transformationen mit der Determinate 1 kovariant sind. Es dürfte indessen berechtigt sein, vorauszusetzen, daß alle diese Lösungen durch solche Transformationen aufeinander reduziert werden können, daß sie sich also (bei gegebenen Grenzbedingungen) nur formell, nicht aber physikalisch voneinander unterscheiden. Dieser Überzeugung folgend begnüge ich mich vorerst damit, hier eine Lösung abzuleiten, ohne mich auf die Frage einzulassen, ob es die einzig mögliche sei." (Einstein 1915b, 832)

82 See section 3.2 and (Norton 1987, §4).

months after his public announcement of his return to general covariance. As far as we know from documents available to us, the first detailed discussion comes in his letter of 26 December 1915, to Ehrenfest (see section 3.2).

Whatever may have underpinned his reluctance to discuss the error of the hole argument, the same reason would surely induce a similar reluctance to discuss the closely related error conjectured here.

Einstein's Letter to de Sitter

According to the conjecture of this part, there is a close connection between two of Einstein's errors: the notebook rejection of the candidate gravitation tensor T_{il}^{x} and the hole argument. We would hope to see some trace of that connection. Such a trace may appear in a letter Einstein wrote to de Sitter on 23 January 1917.

To see how this letter can be interpreted, we must recall Einstein's return to general covariance in the fall of 1915. In several places, Einstein listed the clues that forced him to accept the inadequacy of his *Entwurf* theory.[83] In particular, Einstein had erroneously convinced himself that the *Entwurf* theory was covariant under rotation transformation (18).[84] The discovery of this error cast Einstein into despair over his theory, as he confided to his astronomer colleague Erwin Freundlich in a letter of 30 September 1915 (CPAE 8, Doc 123). In it, he was reduced to a despondent plea for help. He was not frozen into inactivity, however. A little over a month later, on 4 November, he announced his return to general covariance and the adoption of T_{il}^{x} as his gravitation tensor.

That one discovery of the lack of rotational covariance of the *Entwurf* theory seems to have been a powerful stimulus. Two things followed rapidly after it. He returned to general covariance (and therefore rejected the hole argument) and he readmitted the gravitation tensor T_{il}^{x} as gravitation tensor. If the original rejection of T_{il}^{x} had been due to improperly according independent reality to coordinate systems, then we may readily conceive natural scenarios that connect the two. For example, lack of rotational covariance would be fatal to Einstein's hopes of generalizing the principle of relativity to acceleration. So if he now realized that his *Entwurf* theory could not supply it, he might well return to the last candidate gravitation tensors considered in the context of the rotation transformation (18). That would be T_{il}^{x} and the related proposals around page 22 of the notebook. Now wiser and desperate and suspicious of all his methods and presumptions, Einstein might just finally be able to see past his objection to the coordinate condition (11) to the recognition that there was something improper in the core of his objection, his interpretation of what I have called the hole construction. That realization would have simultaneously allowed him to see that the hole argument does not succeed in showing the inadmissibility of gen-

83 See (Norton 1984, §7).

84 Janssen (1999) supplies a fascinating chronicle of this episode. It includes display of calculations in Einstein's hand apparently from June 1913 in which Einstein erroneously affirms that $g_{\mu\nu}^{ROT}$ is a solution of the *Entwurf* gravitational field equations and then a repetition of the same calculation probably from late September 1915 in which Einstein finds the error.

erally covariant gravitational field equations. For it also depends on the same interpretation of the hole construction. Because of the close connection between the two errors, some such scenario among many obvious variants is credible.

As we saw in section 3.2, Einstein gave several accounts of the error of the hole argument. None mentioned above contain autobiographical remarks on how Einstein found the error. There is one exception, a recollection in a letter of 23 January 1917, to de Sitter concerning the errors of Einstein (Einstein 1914c)

> ...there were the following two errors of reasoning [in (Einstein 1914c)]:
>
> 1) The consideration of §12 [the hole argument] is incorrect, since occurrences can be uniquely determined without the same being true for the functions used for their description.
>
> 2) In §14 at the top of page 1073 is a defective consideration.
>
> I noticed my mistakes from that time when I calculated directly that my field equations of that time were *not* satisfied in a rotating system in a Galilean space. Hilbert also found the second error.[85]

Here Einstein assures us that he found the errors of his 1914 review article, with the hole argument listed as the first of the two errors, because he discovered the lack of rotational covariance of his *Entwurf* field equations.[86] Without the conjecture of this part, it is hard to see why Einstein would proceed without great detours from that lack of rotational covariance to the rejection of the hole argument.

What is More Plausible?

In the absence of decisive evidence, we once again ask after the plausibility of the conjecture. To my mind, the one factor that speaks against the conjecture is this very lack of evidence. Things might have transpired as conjectured without more decisive evidence surviving. Einstein was not obligated to annotate his private calculations or later recount every misstep, so as to save the labor of future historians. The resulting paucity of evidence, however, is also compatible with a simpler explanation: things just did not go as conjectured. One factor makes this case a little different from the earlier deliberations on Einstein's supposed unawareness of the use of coordinate conditions: the conjecture ties Einstein's misturnings to the error of the hole argu-

85 "… folgende zwei Denkfehler waren darin:
1) Die Betrachtung des §12 ist unrichtig, weil das Geschehen eindeutig bestimmt sein kann, ohne dass die zu seiner Beschreibung dienenden Funktionen es sind.
2) In §14 ist oben auf Seite 1073 eine fehlerhafte Überlegung.
Ich merkte meine damaligen Irrtümer daran, dass ich direkt ausrechnete, dass meine damaligen Feldgleichungen für ein in einem Galileischen Raume rotierendes System *nicht* erfüllt waren. Den zweiten Fehler hat auch Hilbert gefunden." (CPAE 8, Doc. 290)

86 By a "Galilean space," Einstein refers to a Minkowski spacetime in the coordinates of (5). The second error is presumably the one Einstein discusses with Hilbert in a letter of 30 March 1916, to Hilbert (CPAE 8, Doc. 207) and concerns the failure of a variation operator to commute with coordinate differentiation. For discussion, see (Norton 1984, end of §6).

ment. In that case we have no doubt of Einstein's reticence to leave later traces of his error and that reticence would carry over to the related rejection of the tensor T^x_{il}. But now we tread on dangerous ground. We offer an account that also predicts that it will be difficult to find evidence for that account. Such accounts can be correct. They can also be a signal that a defective account has been protected illegitimately from refutation. There are earnest accounts of how our small planet is routinely visited by aliens intent on abductions. They face a sustained lack of concrete evidence. So we are assured that no irrefutable evidence of the visits survives because of a massive government conspiracy or the ingenuity and thoroughness of the aliens in eradicating all such traces!

These serious hesitations should be weighed against the need for some account of Einstein's twisted path. Again we risk a pitfall. If we are willing to multiply the errors Einstein is supposed to have committed, there is scarcely any pathway that we could not explain. What is appealing about the conjecture is that it requires us to posit no new errors. Aside from outright blunders of calculation and self deception, as documented in (Janssen 1999), Einstein was led astray for nearly three years by two groups of misconceptions. The first surrounded his presumptions on the form of the static metric and the weak field equations. The second pertained to the hole argument and the independent reality of the coordinate systems.

To arrive at the second, we need only ask that Einstein was consistent and thorough in his support of the misconception the hole argument. Then just one error leads Einstein to reject the use of coordinate conditions, to acquiesce to the gravely restricted covariance of the *Entwurf* theory and not to pursue its generally covariant generalization. The recognition of that same error both frees Einstein from the hole argument late in 1915 and allows him to propose T^x_{il} as his gravitation tensor.[87] If I must choose an account, I find this one plausible.

CONCLUSION

Why did Einstein reject the candidate gravitation tensor T^x_{il} in the notebook? His own answer emphasized his "fateful prejudice," the $\{\}$ prejudice. He did not see that the Christoffel symbols are the natural expression for the components of the gravitational field. As a result he could not properly relate the gravitation tensor to the requirement of energy conservation. Instead he was tempted to multiply out the Christoffel symbols to recover expressions explicitly in the metric tensor that would prove unwieldy.

That may well have been all that it took to convince Einstein to abandon the proposal. We must then discount as unrelated his anomalous concern with questions of

87 For comparison, consider the alternative account in which Einstein is just unaware of the use of coordinate conditions. This awareness must come if T^x_{il} is to be admissible as a gravitation tensor. So the preparation for the new proposals of November 1915 must include recognition of two independent errors, that of the hole argument and the neglect of coordinate conditions.

covariance on the pages surrounding page 22R on which the gravitation tensor is analyzed. While Einstein had clearly mastered the mathematical manipulations needed to apply a coordinate condition to expressions of general or near general covariance, his treatment of them suggests that his interpretation of the conditions was idiosyncratic. His concern for their covariance properties cannot be reconciled with his later attitude to them. So we have presumed that his treatment and interpretation of these coordinate condition supplied a further fateful prejudice that precluded admission of the candidate gravitation tensor T_{il}^{x} by somehow obstructing his extraction of the Newtonian limit. The supposition of this additional fateful prejudice makes Einstein appear far less capricious. In finding the gravitation tensor T_{il}^{x} he had circumvented the tangled cluster of problems he had imagined facing the Ricci tensor as gravitation tensor. We suppose that he abandoned the new proposal not just because the calculation looked complicated but because deeper matters of principle also seemed to speak against it.

Just how did Einstein's treatment of coordinate conditions defeat him? There is clear evidence in the notebook that Einstein used the requirements as what we call "coordinate restrictions": they are not just applied in the case of the Newtonian limit but universally. That alone does not explain why Einstein would think his candidate gravitation tensor unable to yield the Newtonian limit in a satisfactory manner. We have found two additional hypotheses that would supply the explanation. The first supposes an obtuse Einstein, overlooking a natural option. It supposes he just persistently failed to see that coordinate conditions could be invoked selectively as part of the restriction on covariance imposed in recovery of the Newtonian limit. The second, which I favor, portrays an excessively acute Einstein, zealously consistent even in his errors. He would soon improperly accord an independent reality to coordinate systems in the hole argument and the conjecture is that he did the same thing earlier in applying coordinate conditions. Both hypotheses have the same outcome. Einstein would come to an impossible demand: the requirement that reduces the candidate gravitation tensor to a Newtonian form must have sufficient covariance to support a generalization of the principle of relativity to acceleration. The first is a dim Einstein, felled by overlooking a standard device in general relativity that he later used without apology. The second is an Einstein of Byzantine sophistication, pursuing his errors, even when only dimly aware of them, to their farthest catastrophe. Perhaps another Einstein, the real Einstein, neither dim nor Byzantine, still waits to be discovered.

MICHEL JANSSEN

WHAT DID EINSTEIN KNOW AND WHEN DID HE KNOW IT? A BESSO MEMO DATED AUGUST 1913

1. THE CHALLENGE OF THE BESSO MEMO

The *Nachlass* of Einstein's close friend and confidant Michele Besso (1873–1955) contains four pages, written on a folded sheet, with what appear to be Besso's notes of discussions with Einstein about a preliminary version of general relativity known in the historical literature as the "*Entwurf*" ("outline") theory.[1] The first two pages of this Besso memo are reproduced in facsimile in Figs. 1 and 2.[2] Of the various points recorded in the memo two in particular are bound to catch the eye of a modern historian of relativity.

First, under point "b) 2." on the first page, Besso writes:

> If through rotation of a hollow sphere one produces a Coriolis field inside of it, then a centrifugal field is produced [...] that is not the same as the one that would occur in a rotating rigid system with the same Coriolis field. One can therefore not think of rotational forces as produced by the rotation of the fixed stars …[3]

The basic result that Besso is alluding to in the first sentence (as will be explained in detail in sec. 3) is that the 'rotation metric'[4] is not a vacuum solution of the *Entwurf* field equations, the field equations of severely restricted covariance of the *Entwurf* theory. And, as Besso indicates in the second sentence, if the rotation metric is not a solution, then the theory fails to relativize rotation along Machian lines.

Second, Einstein and Besso seem to have been on the brink of resolving what is essentially the well-known "hole argument."[5] This argument was first mentioned in

---

1 The name derives from the title of (Einstein and Grossmann 1913), the paper in which Einstein and his former classmate Marcel Grossmann first presented a theory of gravitation based on the metric tensor.

2 For a facsimile reproduction of all four pages of the Besso memo, see (Renn 2005, 127–130).

3 "Stellt man durch Rotation einer Hohlkugel ein Coriolisfeld in deren Innerem her, so entsteht ein Centrifugalfeld [...] welches nicht dem gleich ist, der in einem rotierenden starren System von gleichem Coriolisfeld statt finden würde. Man kann also die Rotationskräfte sich nicht hervorgebracht denken durch die Rotation der Fixsterne …"

4 I use this phrase as short-hand for the metric describing the geometry of Minkowski spacetime viewed from a uniformly rotating Cartesian coordinate system. See note 67 below for the explicit form of this metric.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 2
Einstein's Zurich Notebook: Commentary and Essays.

a) Zur Planetenbew. in der Nordströmschen Theorie:

weiss ich nicht, wie das $\frac{d}{dt}$ zu verstehen ist (ob φ als zeitl. const. vor das Diff.zeichen zu nehmen ist?) — nein, mit dem bewegten Punkt zu verstehen!

Es ergibt sich das Feld wie bei Newton

die Flächengeschwindigkeit eine Constante. ~~Wo bleibt da noch Platz für ein Unterschied gegen die Newtonsche Bewegung?~~

Bedeutung der Coordinaten? (Kommt nicht in Betracht bei den cycl. Integrationen)

b) 1. Abgehendes Licht von einem isolierten Leuchtkörper geht von ihm mit immer grösserer Geschwindigkeit ab, hat aber immer kleinere Energie. Wie kommt diese Energie auf den Leuchtkörper zurück? — Ob Energie ins Unendliche abfliessen würde wissen wir nicht weil wir keine strenge Lösung für diesen Fall haben.

2. Stellt man durch Rotation einer Hohlkugel ein Coriolisfeld in deren Innerem her, so entsteht ein Centrifugalfeld (unabhängig von der Grösse der Hohlkugel), welches nicht gleich dem ist, der in einem rotierenden starren System von gleichem Coriolisfeld stattfinden würde.

Man kann also die Rotationskräfte nicht hervorgebracht denken durch die Rotation der Fixsterne gemäss den Einst.schen Grav.-Gleichungen, sondern muss für diese annehmen wie für die Gleichungen der Mechanik, dass sie nur für ein passend gewähltes System

Figure 1: Besso Memo, p. 1.
Reproduced with permission of the Besso Family Trust, Geneva, Switzerland

5 The classic historical discussions of Einstein's hole argument are (Stachel 1989, secs. 3–4), and (Norton 1984, sec. 5).

correspondence in November 1913 and first published in January 1914.[6] The argument was supposed to show that field equations for the metric field cannot be generally covariant, if the metric field is to be uniquely determined by its sources. At the bottom of the second page of the memo, Besso offers an escape from the hole argument:

> It is, however, not necessary that the [components of the metric] g themselves are determined uniquely, only the observable phenomena in the gravitation space, e.g., the motion of a material point, must be.[7]

This escape is then rejected in a comment appended to this passage.

Without any further information, I would not have hesitated dating Besso's memo to the fall of 1915. The two points singled out above strongly suggest that it belongs to the period between late September, when Einstein discovered the problem of rotation in his *Entwurf* theory,[8] and late October, when Einstein replaced the *Entwurf* field equations by equations of much broader covariance than the hole argument would seem to allow.[9]

Dating the memo to October 1915, however, is completely at odds with Besso's own dating of the document. In the top-right corner of the first page of the memo, Besso wrote: "28 VIII 13." With the apparent exception of the two passages quoted above, the available evidence supports Besso's own dating, as I will show in detail in sec. 2. I can understand the temptation to chalk it up to a slip on Besso's part. Acceptance of Besso's date poses some serious challenges for the reconstruction of Einstein's path to general relativity. With regard to both the problem of rotation and the hole argument the Besso memo raises the troubling question usually associated with politicians rather than scientists: what did he know and when did he know it?

Consider some of the other evidence we have pertaining to the problem of rotation. Writing to Freundlich in September 1915, Einstein made it sound as if he had just discovered that the rotation metric is not a vacuum solution of the *Entwurf* field equations. And reflecting on the tumultuous events of November 1915 in oft-quoted letters written shortly afterwards, he also talked about the problem of rotation as if it were a recent discovery that had precipitated the demise of the *Entwurf* theory.[10] Until late September 1915, it seems, Einstein had been under the impression that the rotation metric *is* a vacuum solution of the *Entwurf* field equations. The 1913 portion of the so-called Einstein-Besso manuscript contains a calculation, erroneous as it turns out, with which Einstein explicitly confirmed that this is the case.[11] Further

---

6 See Einstein to Ludwig Hopf, 2 November 1913 (CPAE 5, Doc. 480) and the "Comments" ("Bemerkungen") added to the journal version of the *Entwurf* paper (Einstein and Grossmann 1914a).

7 "Es ist allerdings nicht nötig, dass die g selbst eindeutig bestimmt sind, sondern nur die im Gravitationsraum beobachtbaren Erscheinungen, z.B. die Bewegung des materiellen Punktes, müssen es sein."

8 Einstein first reported the problem in a letter to Erwin Freundlich of 30 September 1915 (CPAE 8, Doc. 123).

9 Einstein published these equations in (Einstein 1915a), submitted to the Prussian Academy of Sciences on 4 November 1915.

10 See Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153) and Einstein to H. A. Lorentz, 1 January 1916 (CPAE 8, Doc. 177).

elaboration of the *Entwurf* theory in 1914 (and possibly another erroneous calculation) reinforced this belief.[12] The Machian account of rotation based in part on this (specious) result is hailed as one of the great triumphs of the *Entwurf* theory in the introduction of the lengthy exposition of the theory published in November 1914 (Einstein 1914e, 1031–1032). But if we accept the date of the Besso memo, Einstein already knew in August 1913 that the rotation metric is *not* a vacuum solution of the *Entwurf* field equations! How can this be reconciled with the other available evidence?

Similar questions can be raised about the hole argument. If the Besso memo is indeed from August 1913, the argument discussed in these pages is the earliest extant version of the hole argument. As we saw, Besso explicitly recognized that the field equations need not determine the metric field uniquely, only such things as particle trajectories. It may seem but a small step from particle trajectories to *intersections of* particle trajectories. With this modification we arrive at the core of the so-called "point-coincidence argument" with which Einstein explained the failure of the hole argument in correspondence of late 1915 and early 1916.[13] But if Einstein and Besso came this close to the resolution of the hole argument in August 1913, why did Einstein proceed to publish the argument no less than four times in 1914?

After making the case for accepting the date on the Besso memo in sec. 2, I try to answer these questions, for the problem of rotation in sec. 3, for the hole argument in sec. 4. I argue that, despite appearances to the contrary, there is a plausible reconstruction of events that can accommodate the Besso memo quite naturally. This reconstruction, however, does require that we invoke a certain element of opportunism—or expediency, to use a somewhat more neutral term—in Einstein's *modus operandi*. By this I mean that Einstein had a tendency to believe the results he wanted to believe and that he was quite adept at cooking up arguments to suit his needs, arguments he did not necessarily scrutinize all that closely. I want to make it clear right away that I do not use the term "opportunistic" in its pejorative sense. On the contrary, I strongly suspect that the way in which Einstein responded to the problems he ran into with his *Entwurf* theory is quite typical of creative work in theoretical physics and probably in other sciences as well. The reason I want to emphasize Einstein's opportunistic streak is that it has somehow been lost in the dominant tradition in recent Einstein studies, exemplified by the work of John Stachel and John Norton. To a very large extent my paper is squarely within this tradition, but I see it as an important weakness that, at least so far, it has failed to take into account this aspect of Einstein's general *MO*.

2. CAN BESSO'S DATING OF HIS MEMO BE TRUSTED?

2.1 Survey of the New Besso Material Containing the Besso Memo

The Besso memo is part of an assortment of manuscript pages that Laurent Besso showed to Robert Schulmann, then director of the Einstein Papers Project at Boston University, in Lausanne in 1998. The material consists of loose sheets of paper of various sorts and sizes carrying notes and calculations, all in Besso's hand. General relativity is the topic of most—but not all—pages. Leaving aside the Besso memo for a moment, one can divide the pages on general relativity into two groups of about ten pages each, one from (late) 1913 and possibly 1914, and one from 1916. The Besso memo, or so I will argue, belongs to the first group. But let me say a few words about the second group first.

2.1.1 The Second Group of Pages (1916)

There is strong evidence that the second group of new Besso pages related to general relativity is from 1916. There are several references to Einstein's review article on general relativity published in March 1916 (Einstein 1916) and no references to anything published later. The centerpiece of this group of pages is a partial draft of an unpublished essay entitled "The Relativity Principle in an Epistemological Formulation" ("Das Relativitätsprinzip in erkenntnistheoretischer Formulierung"). The remaining pages contain notes, mainly on (Einstein 1916), which Besso probably made while preparing this essay. The essay in turn is probably related to a lecture on Einstein's new theory that Besso was asked to give for the *Physikalische Gesellschaft* in Zurich.[14] This is suggested by the following remark jotted down at the top of the fourth page of the essay:

> Orechiante—whistling Beethoven symphony—the three professional musicians should straighten me out[15]

Besso used the exact same imagery in the draft of a letter to Einstein of late June 1916. The relevant passage explains what Besso meant by the cryptic remark above. At the same time, Besso's self-deprecating comment nicely illustrates how he perceived his relationship with his friend Einstein when it came to matters of science:

> … the devil has gotten into my friends in the Physical Society and they want a talk from me on your latest papers: even though there are at least three people here—Abraham, Grossmann, and Weyl—who know a hundred times more about the topic than I do. I feel like someone for whom Beethoven has whistled his symphony and who now on the basis of that has to whistle after him—someone with the score in front of his eyes, but only being able to read it the way I read sheet music …[16]

---

14 In that case, these pages could be the manuscript referred to in the context of this lecture in (Speziali 1972, 73, fn. 1).

15 "Orechiante—Beethoven symphonie pfeifen—die 3 Fachmusiker sollen mich zurecht weisen"

It seems safe to assume that letter and essay were drafted around the same time. We are thus led to date this whole group of pages to 1916.

Could the troublesome Besso memo be from 1916 as well? More specifically, could the memo have been prepared for Besso's talk to the Zurich Physical Society? One can well imagine that Besso wanted to go over some of the stumbling blocks on Einstein's path to the latest version of the theory. He would have been in an ideal position to do so. The date on the memo could then either simply be a slip or refer to a particularly memorable discussion with Einstein, which Besso, known for his absent-mindedness,[17] nonetheless confused with one of the many other memorable discussions they must have had over the years. This is an extremely unlikely scenario. There is strong evidence that the Besso memo is from 1913. An important part of this evidence is that the memo touches on many of the same topics that are addressed in the first of the two groups of pages that I distinguished above, pages that are almost certainly from 1913–1914.

2.1.2 The First Group of Pages, the Einstein-Besso Manuscript, and the Besso Memo

The contents of the first group of new Besso pages related to general relativity strongly suggest that they belong to the Einstein-Besso manuscript on the perihelion motion of Mercury (CPAE 4, Doc. 14).

When the original 53 pages of the Einstein-Besso manuscript were published, the editors of CPAE 4 divided them into two parts. Part One, which makes up the bulk of the manuscript (about 43 pages), was thought to have been produced in close collaboration during a visit by Besso to Einstein in Zurich in the spring of 1913 (with possible additions by Einstein alone during the remainder of 1913). Part Two, comprising the remaining ten pages, was thought to have been produced by Besso alone some-

16 "… der Teufel ist in die Freunde der physikalischen Gesellschaft gefahren und sie wollen von mir einen Vortrag über deine neuesten Arbeiten: obwohl mindestens drei da sind, Abraham, Grossmann und Weyl, die die Sache hundert mal besser kennen als ich. Ich komme mir vor, wie einer dem Beethoven seine Symphonie vorgepfiffen hätte und der nun daraus nachpfeifen soll—die Partitur zwar vor Augen hat, aber sie eben so lesen kann, wie ich eine Partitur …" Michele Besso to Einstein, draft, 28 June 1916 (CPAE 8, Doc. 229).

17 In a letter of March 1901, Einstein relates a typical example: "Once again, Michele had nothing to do. So his principal sends him to the Casale power station to inspect and check the newly installed lines. Our hero decides to leave in the evening, to save valuable time, of course, but unfortunately he missed the train. The next day he remembered the commission too late. On the third day he went to the train on time, but realized, to his horror, that he no longer knew what he had been told to do; so he immediately wrote a postcard to the office, asking that they should wire him what he was supposed to do! I think he has a screw loose" ("Hatte der Michele einst wieder einmal nichts zu thun. Da schickt ihn sein Prinzipal in die Zentrale Casale, damit er die neu gemachte Leitungen inspiziere und prüfe. Unser Held entschließt sich, abends zu fahren, natürlich um kostbare Zeit zu sparen, versäumte aber leider den Zug. Am nächsten Tag dachte er zu spät an seinen Auftrag. Am dritten Tag ging er zeitig an die Bahn, merkte aber zu seinem Schrecken, daß er nicht mehr wußte, was man ihm aufgetragen hatte; er schrieb also sofort eine Karte ins Bureau, man solle ihm hintelegrafieren, was er zu thun hätte! Ich glaube, der ist nicht normal." Einstein to Mileva Maric, 27 March 1901 [CPAE 1, Doc. 94]).

time between the beginning of 1914 and the demise of the *Entwurf* theory in 1915.[18] The new pages appear to belong to Part Two.

Clear-cut evidence that the original 53 pages of the Einstein-Besso manuscript could not all have been produced in the spring of 1913 was provided by one page (CPAE 4, Doc. 14, [p. 53]) with various references to the article that Einstein prepared for his lecture of 23 September 1913 to the 85th meeting of the *Gesellschaft Deutscher Naturforscher und Ärzte* (*GDNA*) in Vienna. Einstein gave Besso page proofs of the Vienna lecture at some point,[19] but these were certainly not available before late August 1913.[20]

The decision of the editors of CPAE 4 to make January 1914 rather than August 1913 the lower limit for the date of Part Two was based on a letter from Einstein to Besso of early January 1914, which begins:

> Here you finally have your manuscript package. It is really a shame if you do not bring the matter to completion.[21]

The Einstein-Besso manuscript was eventually discovered in the Besso *Nachlass*. It was thus conjectured that Besso left the perihelion calculations with Einstein when he departed Zurich in June 1913 and that early in 1914 Einstein sent them to Besso (perhaps along with material added in the meantime), whereupon Besso added the pages that constitute Part Two of the manuscript. In view of the Besso memo, it is very likely, as I will argue below, that Besso and Einstein met again in late August 1913. This means that some pages—both among the new ones and among both parts of the published portion of the manuscript—may have been produced during this visit.

Most of the material in the first group of the new Besso pages appears to have been intended for a paper on the perihelion problem. First of all, I want to point out that this provides a perfectly respectable explanation for why Einstein never published the result that he and Besso had presumably already obtained in the spring of 1913, viz. that the *Entwurf* theory predicts a secular advance of $18''$ for the perihelion motion of Mercury on top of the Newtonian prediction.[22] The cynical explanation (Earman and Janssen 1993, p. 136) is that Einstein wanted to suppress this result because the

---

18 For a more complete statement than will be given here of the considerations that went into the dating of (what at the time of publication of CPAE 4 was available of) the Einstein–Besso manuscript, see sec. III of the editorial note, "The Einstein-Besso Manuscript on the Motion of Mercury's Perihelion," CPAE 4, 344–359.

19 In the draft of the letter of June 1916 quoted on p. 790 above, Besso referred to "galley proofs" ("Druckbögen") of the Vienna lecture. The reference occurs in a deletion that was silently omitted in the transcription of this document in CPAE 8. The relevant sentence reads: "Secondly, although I have as a paradigm your Vienna lecture ⟨in the old presentation⟩, equations 1d) und 7e′) page 19, ⟨*of the page proofs I have*⟩ I am not able to develop the corresponding relations according to the new gravitational equations" ("Zweitens: trotzdem ich als Paradigma ⟨in der alten Darstellung⟩ deinen wiener Vortrags habe, Gleichungen 1d) und 7e′) Seite 19, ⟨der mir vorliegenden Druckbögen⟩ bringe ich es nicht fertig, die entsprechenden Beziehungen nach den neuen Gravitationsgleichungen zu entwikkeln." My emphasis). In the printed versions of the lecture, (Einstein 1913a, 1914a), equations 1d) und 7e′) occur on p. 1261 and p. 23, respectively. The deleted clause "in the old presentation" presumably refers to the old version of Einstein's gravitational theory, i.e., the *Entwurf* theory.

Entwurf theory could not (yet) account for the full discrepancy of 43″ between the Newtonian prediction and the astronomical observations. A more charitable explanation is that Einstein and Besso agreed that the latter would continue to look for additional effects contributing to the perihelion motion and write up the results. Despite some prodding from Einstein (see the letter of early 1914 quoted above), Besso never completed this project. In December 1914, they were then scooped by Lorentz's student Johannes Droste, who independently found and published the basic result of 18″ (Droste 1914).[23] It seems reasonable to assume that no further additions to the Einstein-Besso manuscript were made after Droste's publication.

The new pages suggest that Besso actually had given up much earlier. The scope of the treatise on the perihelion problem that he envisioned was simply too ambitious. Consider the following table of contents which is among the new pages:

1. General Introduction
2. The equations of motion of ordinary relativity theory
3. Application of the Einsteinian equations of gravitation—they only lend themselves (initially) to iterative approximation.
   First approximation (for the rotation of the sun and for pressure forces)
   Second approximation: for the deviations from the Newtonian law.

	Equations of motion for spherical symmetry
	" " " axial symmetry
3a. Calculation for the case of rest	α. Deviations from Newtonian law etc.
	β. Pressure forces […]
3b. Calculation for the case of rotation	α. Rotation of the sun
	β. Perturbations by Jupiter

4. Scalar theories

20 Einstein submitted the manuscript of his lecture together with a short letter to Alexander Witting, the editor of the *Verhandlungen* of the *GDNA* (CPAE 5, Doc. 464). He did not date this letter and the first digit of the postmark ([-]1.VIII.13) is illegible. In CPAE 5, the date is given as 11 August 1913. Jürgen Renn, however, has argued persuasively that the manuscript was probably not finished until after 15 August 1913. The main text includes an argument against generally-covariant field equations (Einstein 1913a, 1258) that Einstein only found that day. (In a letter to H. A. Lorentz of 16 August 1913 [CPAE 5, Doc. 470], Einstein wrote that he found the argument the day before.) If the manuscript had been completed and sent off earlier, it is puzzling that this argument occurs in the main text whereas the hole argument is only alluded to in a footnote that appears to have been added later (see p. 801 below for the text and the dating of this footnote). This suggests that the illegible first digit of the postmark is a 2 or a 3 rather than a 1. Given that Einstein asked Witting for expedited processing of his manuscript so that he would have page proofs by September 5, it is unlikely that he sent the manuscript on August 31. In short, the most plausible date is 21 August 1913.

21 "Hier erhältst Du endlich Dein Manuskriptbündel. Es ist sehr schade wenn Du die Sache nicht zu Ende führst" Einstein to Michele Besso, after 1 January 1914 (CPAE 5, Doc. 499).

22 The value given in the Einstein-Besso manuscript is actually 1821″ (CPAE 4, Doc. 14, [p. 28]) but there are several indications that Einstein and Besso realized that this result was off by a factor 100 due to an error of a factor 10 in the value they used for the mass of the sun (see CPAE 4, Doc. 14, [p. 30], note 136, and [p. 35], note 161).

23 One might even go as far as to speculate that it was partly due to some lingering resentment over this missed opportunity that Einstein did not acknowledge Besso in his perihelion paper of November 1915 (Einstein 1915b).

5. Four-vector theories
6. Six-vector theories
7. Theory of Abraham
8. Comparison with observations. Introduction of solar oblateness. Mass of Venus out of corrected motion of Mercury.[24]

Calculations for most of the effects listed in sec. 3 (on the *Entwurf* theory) can be found in the published portion of the Einstein-Besso manuscript. Calculations for secs. “3a α” (which give the 18″ mentioned above) and “3b α” take up most of Part One;[25] calculations for secs. “3a β” and “3b β” can be found in Part Two.[26] A discussion, in Besso’s hand, of the iterative approximation procedure mentioned at the beginning of sec. 3 can be found on the verso of a letter from C.-E. Guye to Einstein of 31 May 1913 (CPAE 5, Doc. 443, and CPAE 4, Doc. 14, [p. 16]). Among the newly discovered Besso material, there is a page with a similar discussion of the approximation procedure.[27]

However, of the various alternative theories to be covered in secs. 4–7 in Besso’s table of contents, the Nordström theory is the only one for which any calculations have been preserved.[28] Among the new material there is one page of calculations related to p. 53 of the published portion of the Einstein-Besso manuscript, which summarizes Besso’s analysis of the perihelion motion predicted by the Nordström theory (this is the page with references to the Vienna lecture mentioned on p. 792).[29] Finally, there are no calculations related to solar oblateness[30] or the mass of Venus, two topics to be covered in sec. 8.

25 For an outline of these calculations, see secs. II.1 and II.2 of the editorial note, “The Einstein-Besso Manuscript on the Motion of Mercury’s Perihelion” (CPAE 4, 344–359).

26 See (CPAE 4, Doc. 14, [p. 51]) for calculations of the effect of solar pressure, and [p. 50] and [p. 46] for (badly flawed) calculations of the effect of Jupiter.

27 Following the notation of the *Entwurf* paper, Besso wrote the contravariant components of the metric as $\gamma_{\mu\nu}$ on this page. This supports dating the page to 1913–1914. Einstein adopted the modern notation $g^{\mu\nu}$ in (Einstein 1914e) published in November 1914.

The overly ambitious character of Besso's paper becomes even clearer if we look at a table on another one of the new pages. The table has rows for scalar theories, four-vector theories, and six-vector theories (cf. secs. 4–6 in the table of contents above). Nordström, Laue (with a question mark[31]) and Mie are listed under scalar theories and get one row each. The final row, labeled "tensor theory," is for the *Entwurf* theory. The table has eight columns with the following headers:

> characteristic assumptions | bending of light rays | effect of uniformly moving masses | effect of accelerated masses | perihelion motion | motion of nodes | effect of perturbations on perihelion motion | correction of Leverrier's value for the mass of Venus calculated on the basis of perturbations of Mercury[32]

Besso did not even begin the task of filling out this table.[33] He did, however, produce a draft, replete with deletions as seems to have been his style, of an introductory paragraph leading up to this table. There is another page with what appear to be drafts of yet another introductory paragraph, this time for a somewhat less ambitious version of the paper, focusing more narrowly on the *Entwurf* theory.

How much of the work for Besso's *magnum opus* remained to be done, is further illustrated by two pages with a numbered list of sixteen problem areas that Besso was still planning to address. One of the entries in this list is related to the problem of rotation:

> 15. Final result about centrifugal forces without Coriolis forces? Would that not have astronomical consequences as well?[34]

---

28 There is, however, a page with a calculation of the perihelion advance predicted by a theory proposed in (Hall 1894), in which Newton's $1/r^2$ -law is replaced by a $1/r^{2+\delta}$ -law. Besso's source for this hypothesis was probably (Newcomb 1895), which is explicitly cited on p. 31 of the published portion of the Einstein-Besso manuscript and on one of the new pages. For a brief discussion of the predictions of various alternative gravitational theories for the perihelion motion of Mercury, see (Earman and Janssen 1993, sec. 3).

29 The new page contains a derivation of the expression for the angle between perihelion and aphelion predicted by the Nordström theory given on [p. 53] of the Einstein-Besso manuscript. The perihelion advance (in radians per half a revolution) is given by the deviation of this angle from π . There is a sign error in the relevant expression on [p. 53], see (CPAE 4, Doc. 14, [eq. 372] and note 248 for an analysis of the calculation). The expression on this new page also contains this error.

30 Given the controversy decades later over whether solar oblateness throws off the general relativistic prediction for the advance of Mercury's perihelion by a few seconds of arc (Dicke and Goldenberg 1967; 1974), it is interesting that Besso also considered solar oblateness in 1913–1914.

31 I know of no gravitational theory by Laue, so I can understand Besso's question mark. Perhaps Besso confused Laue with Abraham. There is no row for Abraham's theory, despite its inclusion in Besso's table of contents (sec. 7).

32 "Karakteristische Annahmen | Lichtstrahlen Krüng | Einfluss gleichförmig bewegter Massen | Einfluss beschl. Massen | Perihelbew. | Knotenbew. | Peri Störungsbeeinfl. | Correktion d. Venusmasse von Leverriersch Wert, ermittelt aus den Störgen des Merkur."

33 Part Two of the published portion of the Einstein-Besso manuscript does contain calculations for the motion of nodes, the phenomenon listed in the sixth column, on the basis the *Entwurf* theory (CPAE 4, Doc. 14, [pp. 45–49], and related material on [p. 31] and [pp. 41–42]). For an outline of these calculations, see sec. II.3 of the editorial note, "The Einstein-Besso Manuscript on the Motion of Mercury's Perihelion," (CPAE 4, 344–359).

In the margin, Besso wrote down his answer to the second question:

> Need not be taken into consideration, if one does not want to consider the Oppolzer curvature.[35]

Oppolzer is the astronomer Theodor Egon von Oppolzer (1841–1886). Other than that, I have no idea what Besso meant by this comment. The Besso memo, however, contains a passage in which Besso appears to be making a similar point. In the last full paragraph of the memo, he writes:

> Since, in Einstein's gravitational theory, our noticing the absence of Coriolis and/or centrifugal forces still does not prove that we find ourselves in an allowed frame of reference, we need to take into account, in dealing with the astronomical problem, such a[n allowed?] system of forces imposed from the outside (Schwarzschild-Oppolzer motion of the fixed stars)[36]

I have only the vaguest of notions of what Besso might have meant by this convoluted sentence. I nonetheless find the similarity between these two passages quite striking.

The issue of the relation between centrifugal forces and Coriolis forces apparently continued to exercise Besso. Both in 1914 and in 1916 it crops up in his correspondence with Einstein.[37] As I argued in the final section of (Janssen 1999), the relevant letter from Einstein of 1916 is particularly revealing in this context.[38] Here I want to draw attention to the draft of a letter from Besso to Einstein of March 1914. In early March 1914, Einstein had written to Besso (CPAE 5, Doc. 514) about the analysis of the covariance properties of the *Entwurf* field equations to be published in (Einstein and Grossmann 1914b). In reply, Besso raised the question:

> Does the result you obtained also give a clue perhaps for a more complete treatment of the rotation problem, so that one can get the correct value for the centrifugal force? Unfortunately, my brain, the way it happens to have developed, is much too feeble to answer this question myself, or even to guess from what side it could be attacked. For reasons already discussed, it seems to me (?) of importance for the astronomical problem

34 "15. Definitives Resultat über Centrifugalkräfte ohne Corioliskräfte? Würde das nicht auch astronomisch in Betracht kommen können?"

35 "Kommt nicht in Betracht, wenn man nicht die Oppelzersche Krümmung betrachten will."

36 "Da bei der Einst. Gravitationstheorie durch Constatierung der Abwesenheit von Coriolis oder/und Centrifugalkräften noch nicht bewiesen ist, dass man sich in einem zulässigen Bezugssystem befindet, ist bei der astronomischen Aufgabe ein von aussen aufgeprägtes solches System von Kräften mit zu berücksichtigen (Schwarzschild-Oppolzerschen Fixsternbewegung)."

37 For the sake of completeness, I note that the 1916 portion of the new Besso material also contains a reference to the inertial forces of rotation. On the fourth page of the draft of his essay, Besso wrote sideways in the margin: "That a rotating disc produces a centrifugal and a Coriolis field in its vicinity, and an accelerated mass an acceleration field, are direct consequences of the *principle* of general relativity: *how big* the effects are is given by the *theory* of general relativity" ("Dass eine rot. Scheibe in der Nähe ein Zentrifugal und Coriolisfeld erzeugt, eine beschl. Masse ein Beschleunigungsfeld, sind direkte Konsequenzen des Allg. Relativitäts*prinzips*: *wie gross* die Wirkungen sind ergibt die allgemeine Relativitäts*theorie*.")

38 Einstein to Michele Besso, 31 July 1916 (CPAE 8, Doc. 245).

> as well (since earlier at least it looked as if a system in which there are no Coriolis forces could still be the seat of centrifugal forces or the other way around).[39]

This otherwise maddening passage does seem to make it clear that the comments on Coriolis forces and centrifugal forces in the new Besso material were written earlier. There is no discussion of these issues in any of the extant correspondence between Einstein and Besso prior to this letter. Besso's "for reasons already discussed" must therefore either refer to correspondence that is now lost or, more likely, to discussions he and Einstein had in person.

The new Besso material also contains a page with a derivation of the equations of motion for a point mass in the metric field of the form generated by a rotating mass distribution.[40] The calculation, under the heading "field corresponding to a Coriolis force" ("Feld, welches einer Corioliskraft entspricht"), starts from the general equation of motion of a point mass in a metric field as given in equations (6)–(7) of (Einstein and Grossmann 1913), just as similar calculations in the Einstein-Besso manuscript.[41]

The final page that we need to examine is the verso of the page with the calculation on the Nordström theory discussed earlier (see note 29). The passage written on this page once again touches on the problem of rotation as well as on other themes addressed in the Besso memo. It starts with equation (9b) of the Vienna lecture (Einstein 1913b, 1259). This equation expresses the vanishing of the divergence of the sum of a mixed tensor density describing the energy-momentum density of matter[42] and a similar quantity for the gravitational field. Besso writes:

39 "Gibt das erreichte Resultat vielleicht auch einen Wink für eine vollständigere Behandlung des Drehungsproblems, so dass man den richtigen Wert der Centrifugalkraft bekommen kann? Leider ist mein Kopf, wenigstens so wie er einmal erzogen ist, viel zu schwach, um mir die Frage selbst zu beantworten, oder auch nur zu ahnen, wo man sie angreifen könnte. Aus schon besprochenen Gründen scheint sie (?) mir auch für das astronomische Problem von Bedeutung (weil es früher wenigstens so aussah, dass ein System in welchem keine Corioliskräfte huschen, doch Sitz von Centrifugalkräften sein können oder umgekehrt)" Michele Besso to Einstein, draft, 20 March 1914 (CPAE 5, Doc. 516).

40 This calculation is done on a sheet of paper with the name and address of a Zurich hospital and sanatorium ("'Paracelsus' Neues Privat-Krankenhaus und Augenheilanstalt") printed at the top and the name and address of a nearby pharmacy ("Apotheke Th. Vogel") at the bottom. Following the header there is a printed "Rp.," which suggests that it is a (blank) prescription ("Rezept") form. Besso's calculation appears on the verso of the sheet. On the recto Besso wrote down a list of three short items, the third of which is: "Departure Wednesday evening 11:40" ("Abreise Mittwochabends 11:40"). We know from an entry in Ehrenfest's diaries that Besso's visit with Einstein in the spring of 1913 ended 18 June (CPAE 4, 357, note 57). For what it is worth, this was a Wednesday. In a letter to Jost Winteler, Besso's father-in-law, of 23 June 1913 (CPAE 5, Doc. 447), Einstein mentioned that Besso had suffered from "persistent diarrhea" ("einem hartnäckigen Darmkatharrh") during his visit, which could explain the prescription form.

41 See (CPAE 4, Doc. 14, p. 8, especially [eq. 48] and note 35, and [p. 20], especially [eqs. 133–137]).

42 In (Einstein 1913a, 1258), this quantity is defined as $\mathfrak{T}_{\sigma\nu} \equiv \sqrt{-g}g_{\sigma\mu}\Theta_{\mu\nu}$, where $\Theta_{\mu\nu}$ is Einstein's notation during this period for the contravariant components of the energy-momentum tensor.

Equation (9b) $\sum \frac{\partial}{\partial x_\nu}(\mathfrak{T}_{\sigma\nu} + t_{\sigma\nu}) = 0$

which expresses the conservation laws is of such character that it is only covariant under linear transformations in any case. In this way the linearity of possible transformations of the [field] equations of gravitation has been "proven" and has at the same time been reduced to the conservation laws. *Only* such frames of reference are justified for which the conservation laws hold. It remains an open question, however, whether *all* frames of reference for which the conservation laws hold are justified in the sense of the equations of gravitation. There remains of course the possibility that, through using higher than second-order derivatives, one arrives at different equations of gravitation; if everything that happens, however, is to be determined uniquely by them, there still has to be a criterion for the admissibility of the coordinate system anyway (cf. the one-sided deformation in empty space), for which purpose in Einstein's theory the conservation laws can consistently be used (which definitely was not automatic given the tensorial nature of the gravitational quantities and the full determination of the kinematics by them).

Do the equations of gravitation tell us something about the kinematics of the rotating system? Probably not, because one cannot transform it into a Galilean [system].[43]

Unfortunately, I do not understand Besso's intriguing parenthetical remark "cf. the one-sided deformation in empty space" ("vgl. die einseitige Deformation im leeren Raume"). Most of rest of the passage, however, sounds very familiar. The comment about the possibility of field equations containing higher-order derivatives of the metric echoes a similar comment in the *Entwurf* paper. Einstein had drawn attention to this possibility to argue that such higher-order equations might be generally covariant.[44] The hole argument, to which Besso alludes in the next sentence, would obviously restrict the covariance of such higher-order equations as well. Whereas the hole argument is only alluded to, the other argument against general covariance that Ein-

43 "Gleichung (9b) $\sum \frac{\partial}{\partial x_\nu}(\mathfrak{T}_{\sigma\nu} + t_{\sigma\nu}) = 0$

die die Erhaltungssätze ausdrückt, hat einen solchen Charakter, dass sie jedenfalls nur f. lineare Transf. covariant ist. Damit ist die Linearität der möglichen Transformationen bei den Gravitationsgl. «erwiesen» und gleichzeitig auf die Erhaltungssätze zurückgeführt. Es sind nur solche Bezugssysteme berechtigt, für welche die Erhaltungssätze gelten. Es bleibt aber die Frage offen ob alle Bez. syst. für welche die Erh. s. gelten berechtigte sind im Sinne der Gravitationsgleichungen. Dabei bleibt natürlich unbenommen, dass man durch Mitnahme höheren als die zweiten Ableitungen, andere Gravitationsgl. erhalten kann; soll aber durch dieselben das Geschehen eindeutig bestimmt sein, so muss immerhin noch ein Criterium für die Zulässigkeit des Coordinatensystems vorliegen (vgl. die einseitige Deformation im leeren Raume) als welches Criterium bei der Einst. Theorie die Erhaltungssätze widerspruchsfrei benutzt werden konnten (was durchaus nicht selbstverständlich war bei der Tensornatur der Gravitationsgrössen und der alleinigen Besti[mmu]ng der Kinematik durch dieselbe).

Lehren uns die Gravitationsgl. etwas über die Kinematik des rot. Systems? Wohl nein, da man es nicht auf ein Galileisches transformieren kann."

44 Einstein writes: "A priori one cannot deny the possibility that the final exact equations of gravitation could be of higher than second order. There is still the possibility therefore that the fully exact differential equations of gravitation could be covariant under arbitrary substitutions." ("A priori kann allerdings nicht in abrede gestellt werden, daß die endgültigen, genauen Gleichungen der Gravitation von höherer als zweiter Ordnung sein könnten. Es besteht daher immer noch die Möglichkeit, daß die vollkommen exakten Differentialgleichungen der Gravitation beliebigen Substitutionen gegenüber kovariant sein könnten" [Einstein and Grossmann 1913, 11–12]).

stein advanced in late 1913 is given in some detail at the beginning of this passage. The form of equation (9b) for the energy-momentum conservation law, the argument goes, restricts the covariance of the field equations to linear transformations.[45]

We encounter both these arguments in the Besso memo as well, although this time the argument from energy-momentum conservation is only referred to implicitly while (a prototype of) the hole argument is stated explicitly. At the bottom of the first and the top of the second page of the memo (see Figs. 1 and 2), immediately after the sentence quoted in the introduction about the problem of rotation, Besso writes:

> One can therefore not think of rotational forces as produced by the rotation of the fixed stars according to the Einsteinian [field] equations of gravitation, but one has to assume for them as for Galilean mechanics, that they only hold for an appropriately chosen [coordinate] system (which would be defined through the conservation laws)[46]

To distinguish the crude argument from energy-momentum conservation of late 1913 from a more sophisticated argument from energy-momentum conservation of early 1914, it is important to establish that Besso was under the impression at this point that energy-momentum conservation requires the field equations to be covariant under *linear* transformations only. Fortunately, this can be done with the help of a passage that starts at the bottom of the third and continues at the top of the fourth page of the memo:

> From the gravitational theory … it is then inferred that the position and acceleration (but not the velocity) of masses in each other's vicinity affect the line element; and (recently) that the gravitational field cannot be transformed away anywhere since an accelerated frame of reference (because the conservation laws are not satisfied) is not a justified frame[47]

Since Besso claims that energy-momentum conservation rules out *all* accelerated frames of reference, it is clear that he is referring to the crude rather than to the sophisticated argument. As was pointed out above (see footnote 20), we know that Einstein hit upon the crude argument on 15 August 1913. This strongly supports the date on the Besso memo. On 28 August 1913, Besso had every reason to refer to this argument as something that had only been found "recently" ("neuerdings").

On the second page of the memo, Besso indicated (with two arrows; see Fig. 2) two comments to be appended to the clause "which would be defined through the conservation laws." The second comment once again raises the open question that

---

45 For a concise discussion of this argument and its flaws, see (Norton 1984, sec. 5). This is the argument that was referred to in footnote 20.

46 "Man kann also die Rotationskräfte sich nicht hervorgebracht denken durch die Rotation der Fixsterne gemäss den Einst. schen Grav.-Gleichungen, sondern muss für diese annehmen wie für die Galileische Mechanik, dass sie nur für ein passend gewähltes System gelten (welches durch die Erhaltungssätze definiert wäre)"

47 "Aus der … Grav.-theorie wird dann geschlossen, dass die Lage und die Beschleunigung benachbarter Massen auf das Linienelement von Einfluss ist (nicht aber deren Geschwindigkeit); und (neuerdings) dass an keiner Stelle ein Gravitationsfeld wegtransformiert werden kann, da ein beschleunigtes Bezugssystem (wegen Nichterfüllung der Erhaltungssätze) kein berechtigtes System ist."

Besso had identified in the passage quoted on p. 798: “Is *every* system *that satisfies the conservation laws a justified* system?”[48] Then, as in the passage quoted on p. 798, he goes into what is essentially the hole argument, this time in some detail. Discussion of this passage will be postponed until sec. 4.

2.2 Piecing Together the Case for Accepting the Date on the Besso Memo

What conclusions can be drawn from the preceding survey of the new material about the date of the Besso memo? I think a strong case can be made for accepting Besso’s own dating of the document, even though this does require two additional assumptions: first, that an important footnote alluding to the hole argument was added to the text of the Vienna lecture in early September a few weeks before Einstein actually gave the lecture; second, that Besso visited Einstein in Zurich in late August 1913.

Perhaps the strongest evidence in support of Besso’s date of 28 August 1913 is that he refers to Einstein’s argument against general covariance from energy-momentum conservation of 15 August 1913 as something that was shown “recently” (“neuerdings”). In any case, as we shall see below, the reference to this argument rules out any date after 20 March 1914, when Besso expressed his satisfaction that Einstein had meanwhile replaced this crude argument by a more sophisticated one.[49] Let me emphasize that the memo would still present the puzzles described in the introduction even if it had been written in March 1914 instead of in August 1913.

The combination of the two arguments against general covariance referred to in the memo, the argument from energy-momentum conservation and the hole argument, is characteristic of the period late 1913–early 1914. This provides another reason for accepting the date on the Besso memo, even though 28 August 1913 seems to be a little early given the dates of other texts documenting this state of affairs. Consider the following passage from the printed summary of Einstein’s lecture to the 96th annual meeting of the *Schweizerische Naturforschende Gesellschaft* in Frauenfeld on 9 September 1913, less than two weeks after the date on the Besso memo. Einstein writes:

> On the other hand, it turns out to be logically impossible to formulate equations to determine the gravitational field (i.e., the $g_{\mu\nu}$) that are covariant with respect to arbitrary substitutions. Starting from the conservation laws of momentum and energy, we are led to choose the frame of reference […] in such a way that *only* linear transformations—but contrary to the situation in ordinary relativity theory *arbitrary* linear transformations—leave the equations covariant.[50]

48 “Ist *jedes* System, *welches den Erhaltungssätzen genügt*, ein *berechtigtes* System?”

49 See the quotation on p. 805 below from Besso to Einstein, draft, 20 March 1914.

50 “Dagegen erweist es sich als logisch unmöglich, Gleichungen zur Bestimmung des Gravitationsfeldes (d. h. der $g_{\mu\nu}$) aufzustellen, die bezüglich beliebigen Substitutionen kovariant sind. Wir gelangen, ausgehend von den Erhaltungssätzen des Impulses und der Energie, dazu, das Bezugssystem […] derart zu wählen, dass nur mehr lineare, aber im Gegensatz zur gewöhnlichen Relativitätstheorie beliebige lineare Substitutionen die Gleichungen kovariant lassen” (Einstein 1913b, 138).

Very similar comments can be found in the more extended version of the Frauenfeld lecture first published 15 December 1913 and then reprinted as (Einstein 1914d, see pp. 288–289). Unfortunately, it is not clear for either of these documents how close the printed texts are to what Einstein actually said in his lecture. What makes one suspicious is that the texts must have been completed after Einstein completed the printed text of the Vienna lecture, delivered on 23 September 1913.[51] In the latter, the hole argument is alluded to only in a footnote:

> Over the last few days, I found the proof that such a generally-covariant solution to the problem [of finding suitable gravitational field equations] cannot exist at all.[52]

If this footnote were added *after* the Vienna lecture was delivered, Einstein could not have alluded to the hole argument in Frauenfeld in early September even though such allusions do occur in the printed texts. And, more importantly for my purposes, Besso could not have known about the hole argument on 28 August and the date on the Besso memo would have to be incorrect. If we accept the date on the Besso memo, we therefore have to assume that Einstein added the footnote alluding to the hole argument to the text of his Vienna lecture sometime in early September, a few weeks *before* he delivered the lecture. This assumption is much more natural than it appears to be at first glance. Recall that Einstein submitted the manuscript for the lecture in late August and that he requested that page proofs be ready by September 5 (see note 20).

Unfortunately, the earliest extant correspondence documenting the state of affairs transpiring from these published texts and from the Besso memo (i.e., the combination of the two arguments against general covariance) is from November 1913, two months after the date on the memo. The letter to Hopf, already mentioned in the introduction, is from 2 November 1913. In addition there are two undated letters to Ehrenfest (CPAE 5, Docs. 481 and 484) that can both be dated to November 1913, one to early November, the other to the second half of the month. In this second letter, Einstein put the matter very concisely:

> A unique determination of the $g_{\mu\nu}$ by the [components of the energy-momentum tensor] $T_{\mu\nu}$ is only possible if special coordinate systems are chosen (rigorously provable). Energy-momentum conservation only allows *linear* substitutions.[53]

---

51 In CPAE 4, the texts related to the Frauenfeld lecture (Einstein 1913b; 1914d) are presented as Docs. 15 and 16, respectively, whereas the printed text of the Vienna lecture (Einstein 1913c) is presented as Doc. 17. Since the order of presentation in the Collected Papers is determined by the date of completion of the texts, the order should have been reversed.

52 "In den letzten Tagen fand ich den Beweis dafür, daß eine derartige allgemein kovariante Lösung überhaupt nicht existieren kann" (Einstein 1913a, 1257).

53 "Eine eindeutige Bestimmung der $g_{\mu\nu}$ aus den $T_{\mu\nu}$ ist nur bei Wahl spezieller Koordinatensysteme möglich (streng beweisbar). Die Impuls-[E]nergie-Erhaltung lässt nur lineare Substitutionen zu." Einstein to Paul Ehrenfest, second half of November 1913 (CPAE 5, Doc. 484). In both these letters to Ehrenfest, Einstein briefly explored the consequences of the restriction of the covariance of the field equations to linear transformations in geometrical terms. Einstein also refers to these ideas in the printed text of the Frauenfeld lecture (Einstein 1914d, 289).

Neither in this letter nor in the letters to Ehrenfest and Hopf from early November does Einstein say exactly when he found these results. It is thus perfectly conceivable that he already had them two months earlier, as we are forced to accept if we accept the date on the Besso memo, and that he actually did present them in his lecture in Frauenfeld in early September. Given all available evidence, I would say that this is not only conceivable but actually quite plausible.

A third consideration in support of accepting the date on the Besso memo is that Besso's date is consistent with the date one would assign to the memo on the basis of various connections with the group of new Besso pages belonging to the Einstein-Besso manuscript. These pages can firmly be dated to the period 1913–1914, and most of them can plausibly be dated more narrowly to late 1913. For instance, in the drafts (mentioned on p. 795) of an introductory paragraph for a paper on various astronomical predictions of the *Entwurf* theory, Besso refers to the *Entwurf* paper as "Z. f. M. & P. … *1913*" (my emphasis). This is the reprint of the *Entwurf* paper in the *Zeitschrift für Mathematik und Physik* (Einstein and Grossmann 1914a). In the first part of the Einstein-Besso manuscript of June 1913 (CPAE 4, Doc. 14, [p. 8]), Besso used the page numbers of the original separatum (Einstein and Grossmann 1913). The journal version was not published until 30 January 1914. This suggests that Besso wrote this page in late 1913, expecting the journal version to become available before the end of the year.

There is a particularly striking connection between the memo and one of the new pages of the Einstein-Besso manuscript with calculations for the Nordström theory on the recto (see note 29) and a discussion of the covariance of the field equations on the verso (see p. 798). The calculations on the recto are related both to the page on the Nordström theory in the published part of the Einstein-Besso manuscript (CPAE 4, Doc. 14, [p. 53]) and to the first entry of the Besso memo (see Fig. 1):[54]

> a) On the motion of planets in the Nordström theory:
> I do not know how to interpret d/ds (whether φ can be put in front of the differentiation since it is constant in time)—*no*, to be interpreted as co-moving with the point!
> The field comes out as in Newton[:] the area velocity [is] a constant. ⟨Where does that leave room for deviation from the Newtonian motion?⟩ Meaning of the coordinates? (Does not play a role given the cyclical integration)[55]

The discussion of the covariance of the field equations on the verso of this new page closely matches the corresponding discussion in the Besso memo.[56] First comes the (crude) argument from energy-momentum conservation, then the question whether

54 It may seem that the connection between the memo and the Vienna lecture through p. 53 of the Einstein-Besso manuscript amounts to an argument *against* accepting the date on the memo. 28 August, one could argue, is too late for Besso to have had access to the manuscript of the lecture, which Einstein probably submitted 21 August, and too early to have had access to page proofs, which Einstein probably did not receive until early September (see note 20 for the argument in support of these dates). It could well be, however, that the entry on the Nordström theory is somewhat earlier than the two pages of calculations that have been preserved. The questions raised in the memo are rather elementary and could refer to an earlier attempt to do these calculations.

all frames of reference in which the conservation laws hold are justified, and then the hole argument. Moreover, in both cases it is mentioned in this context that a rotating frame is not a justified frame.

I already drew attention to the striking similarity between a comment on the problem of rotation on the last page of the Besso memo and an entry in a list of open questions to be addressed in Besso's ambitious paper on the perihelion problem (see p. 795). In both cases, Besso comments on the problematic relation between centrifugal forces and Coriolis forces in Einstein's theory; in both cases, he emphasizes the astronomical relevance of the problem; and, for what it is worth, in both cases he refers to the astronomer Oppolzer.

There is one question though that still needs to be answered before we can feel comfortable accepting the date on the Besso memo and move on to the discussion of the resulting problems for reconstructing Einstein's path to general relativity. The question is this: how did Besso find out about Einstein's two arguments against general covariance in late August 1913.[57] Neither argument had been published yet. The argument from energy-momentum conservation was probably included in the page proofs of the Vienna lecture, but it is extremely unlikely that Besso would have read those by 28 August 1913. And, as we have seen (see the footnote quoted on p. 801), even in the final text of the Vienna lecture there is no more than an allusion to the hole argument.[58] There are also no letters from Einstein to Besso during this period explaining these arguments. But then no letters survive from the period between March 1912 and the end of 1913. There are two letters from Einstein to Besso of early 1914 and a draft of Besso's reply to the second and then there is another gap from late March 1914 to February 1915. So it is possible that there were more letters that are now lost, in one of which Einstein explained these arguments. It is much

55 "a) Zur Planetenbew. in der Nordströmschen Theorie
weiss ich nicht wie das d/ds zu verstehen ist (ob φ als zeitl. const. vor das Diff. zeichen zu nehmen ist)—nein, mit dem bewegten Punkt zu verstehen!
Es ergibt sich das Feld wie bei Newton[:] die Flächengeschwindigkeit eine Constante. ⟨Wo bleibt da noch Platz für ein Unterschied gegen die Newtonsche Bewegung?⟩ Bedeutung der Coordinaten? (Kommt nicht in Betracht bei der cycl. Integration[)]."
The quantity φ represents the scalar gravitational potential in the Nordström theory. In the Einstein-Besso manuscript, the perihelion motion is derived in part from a quantity called the "area velocity" (see CPAE 4, Doc. 14, [p. 8], note 38). If the area velocity is constant, Kepler's area law holds and there is no perihelion motion.

56 For reasons similar to those given in note 54, the passage in the memo is presumably earlier than the other passage, which starts with equation (9b) from the Vienna lecture.

57 Given everything we know about the interaction between Einstein and Besso, we can safely rule out the possibility that Einstein got these arguments from Besso.

58 Given that the first three of the four published versions of the hole argument are notoriously cryptic, the Besso memo reflects a remarkably thorough understanding of how the argument is supposed to work (as will become clear in sec. 4). It is also remarkable, that Besso, as we have seen (see p. 798), realized that the hole argument undercuts Einstein's claim in the *Entwurf* paper that higher-order gravitational field equations might be generally covariant.

more likely, however, that Einstein explained them to Besso in person during a visit by the latter to Zurich around 28 August 1913.[59]

This would provide a natural explanation for a striking feature of the Besso memo that I did not emphasize so far. At several points the memo records a certain back and forth: a question is raised to which an answer is appended (see, e.g., the entry on the Nordström theory quoted on p. 802) or an argument is put forward to which a counter-argument is appended. The most striking example in the latter category is the passage on the hole argument (see Fig. 2 for a facsimile reproduction and sec. 4 for a transcription and discussion). First, the argument is stated. In the next paragraph a counter-argument is given. Appended to this paragraph is a comment purporting to refute the counter-argument, which begins: "Of no use" ("Nützt nichts"). This same phrase is appended to a passage at the top of the page (although in that case it was subsequently deleted and replaced by another comment). A natural explanation for this back and forth is that Besso recorded Einstein's responses to some of the points he raised.

There is no direct independent evidence that Besso visited Einstein in Zurich in late August 1913,[60] but it is not at all implausible that such a visit took place. And all three extant letters between Einstein and Besso of 1914 yield important indirect evidence for this conjecture. The strongest evidence comes from the second of these letters. Einstein writes:

> The strict equivalence of inertial and gravitational mass, also of the gravitational field, I had, I believe, already proven by the time of your visit.[61]

The editors of CPAE 5 identify this visit as Besso's well-documented visit of June 1913, but they refer to an addendum to the published version of the Vienna lecture as the place where Einstein first published the result he mentions (Einstein 1914b). The result clearly belongs to the period of the Vienna lecture and not to the period shortly after the completion of the *Entwurf* paper. Hence, it is much more likely that Einstein is referring to a visit by Besso in late August than to the visit in June.

A second visit by Besso in August 1913 also fits better with Einstein's first letter to Besso of 1914, the one with which he presumably sent the Einstein-Besso manuscript. After exhorting Besso to finish the work on the perihelion problem, he writes:

---

59 The other possibility—of a visit during this period by Einstein to Besso in Görz, Austria (now Gorizia, Italy)—can be ruled out. In a letter to Freundlich received on 26 August 1913, Einstein wrote from Zurich: "I will be here until the middle of September, with the exception of September 7 & 8 when I have to give a talk in Frauenfeld." ("Ich bin bis Mitte September hier, ausgenommen den 7. & 8. September, wo ich in Frauenfeld einen Vortrag zu halten habe." Einstein to Erwin Freundlich, before 26 August 1913 [CPAE 5, Doc. 472]).

60 As I pointed out above, one of the new Besso pages is written on letterhead of a Zurich hospital, which would lead one to think that this page was written in Zurich. It may have been written, however, during Besso's visit of June 1913 (see note 40).

61 "Die strenge Aequivalenz der trägen und schweren Masse, auch des Gravitationsfeldes, hatte ich, glaube ich, schon zur Zeit deines Besuches bewiesen." Einstein to Michele Besso, ca. 10 March 1914 (CPAE 5, Doc. 514).

> I have not found out much since. But I have shown rigorously that the measure for the inertial as well as the gravitational mass of closed systems is given by the total rest energy of the system including its gravitational energy.[62]

The result mentioned in this passage is the same as the result mentioned in the letter of March 1914. This is obviously not the only result since Besso's visit of June 1913 that is worth mentioning. One need only think of the arguments against general covariance. If Einstein and Besso got together again in August 1913, it would presumably be in reference to this later visit, that Einstein writes that he has "not found out much since," which makes much more sense.[63]

I already pointed out that the draft of Besso's reply to Einstein's letter of March 1914 (see p. 796) requires us to assume either that some correspondence between Einstein and Besso is missing or that they had the opportunity to discuss the problem of rotation in person. A visit by Besso to Zurich in August 1913 would take care of that problem as well. It would also explain Besso's remarkably sharp grasp of the new stage of the *Entwurf* theory that was reached with Einstein's new treatment of the theory's covariance properties in (Einstein and Grossmann 1914b). In his letter of March 1914, Einstein briefly explained these developments to Besso. In the draft of his reply, Besso wrote (in a passage immediately preceding the passage quoted on p. 796):

> You already had the fundamental insight that the conservation laws represent the condition for positing an admissible coordinate system; but it did not appear to be ruled out that a restriction to Lorentz transformations was thereby essentially already given, so that nothing interesting epistemologically comes out of it. Now everything is fundamentally completely satisfactory.[64]

Besso's clear appreciation of the situation becomes readily understandable when we assume that he and Einstein had the opportunity in August 1913 to discuss the earlier stage of the theory in person.

The upshot of the discussion in this section then is that we have very good reason to believe (a) that the date on the Besso memo is accurate, and (b) that the memo reflects discussions between Einstein and Besso during a visit by the latter to Zurich around 28 August 1913. Of course, I largely avoided the two troublesome passages in

---

62 "Ich habe seitdem wenig herausgefunden. Strenge bewiesen habe ich aber, dass sowohl für die schwere wie für die träge Masse abgeschlossener Systeme die gesamte Ruheenergie des Systems mit Einschluss der Schwereenergie massgebend ist." Einstein to Michele Besso, after 1 January 1914 (CPAE 5, Doc. 499).

63 A slight discrepancy remains: the letter of January 1914 suggests that Einstein only found the result in question *after* Besso's last visit, whereas the letter of March 1914 suggests that he had already found the result *by the time of* this visit. In the letter of March 1914, however, Einstein also indicates that he is not entirely sure.

64 "Du hattest schon principiell eingesehen, dass die Erhaltungssätze die Bedingung für die Aufstellung eines zulässigen Coordinatensystems darstellen; aber es schien nicht ausgeschlossen, dass schon dadurch, im Wesentlichen, die Beschränkung auf die Lorentztransformationen gegeben sei, so dass nichts erkenntnistheoretisch besonders interessantes herauskam. Nun ist alles principiell vollkommen befriedigend." Michele Besso to Einstein, draft, 20 March 1914 (CPAE 5, Doc. 516).

the memo quoted in the introduction. In the remainder of this paper, I will focus on those two passages.

3. THE BESSO MEMO AND THE PROBLEM OF ROTATION

Consider, once again, the comments on the problem of rotation on the first page of the Besso memo (see Fig. 1 for a facsimile reproduction):

> If through rotation of a hollow sphere one produces a Coriolis field inside of it, then a centrifugal field, independent of the size of the hollow sphere, is produced that is not the same as the one that would occur in a rotating rigid system with the same Coriolis field. One can therefore not think of rotational forces as produced by the rotation of the fixed stars according to the Einsteinian gravitational [field] equations[65]

As will become clear below, this passage requires a serious modification of the reconstruction I gave in (Janssen 1999) of Einstein's struggles with rotation in the period 1913–1915. At the same time, however, it confirms a conjecture in my paper about the Machian motivation behind the specific way in which Einstein checked, both in 1913 and in 1915, whether or not the rotation metric is a vacuum solution of the *Entwurf* field equations. The strongest evidence for this conjecture offered in my paper came from a letter written after the fact.[66] The Besso memo provides contemporary evidence.

Let me first reiterate briefly how Einstein checked whether the rotation metric is a vacuum solution of the *Entwurf* field equations (see Janssen 1999, secs. 5–9, for details). The rotation metric has several components proportional to ω, the constant angular frequency with which the coordinate system rotates in Minkowski spacetime, and (in its covariant form) only one component with a term proportional to ω^2.[67] For a slowly rotating frame, the terms proportional to ω can be looked upon as small first-order deviations from the standard diagonal Minkowski metric; the term proportional to ω^2 as a second-order deviation. It is clear upon inspection that,

65 "Stellt man durch Rotation einer Hohlkugel ein Coriolisfeld in deren Innerem her, so entsteht ein Centrifugalfeld, unabhängig von der Grösse der Hohlkugel, welches nicht dem gleich ist, der in einem rotierenden starren System von gleichem Coriolisfeld statt finden würde. Man kann also die Rotationskräfte sich nicht hervorgebracht denken durch die Rotation der Fixsterne gemäss den Einst.schen Grav.-Gleichungen"

66 Einstein to Michele Besso, 31 July 1916 (CPAE 8, Doc. 245), quoted and analyzed in (Janssen 1999, sec. 11).

67 In a Cartesian coordinate system $x^\mu = (x, y, z, t)$ (with $\mu = 1, 2, 3, 4$ and with units such that the velocity of light $c = 1$), rotating counterclockwise around its z-axis with respect to some inertial frame in Minkowski spacetime, the Minkowski line element is given by:

$$ds^2 = g_{\mu\nu}dx^\mu dx^\nu = -dx^2 - dy^2 - dz^2 + (1-\omega^2 r^2)dt^2 + 2\omega y dx dt - 2\omega x dy dt$$

(where $r^2 \equiv x^2 + y^2 + z^2$). For a quick derivation of this expression, see p. 42R of the Zurich Notebook (discussed in "Commentary …" [in this volume], sec. 5.5.7). The non-vanishing components of the metric can easily be read off from the line element: $g_{11} = g_{22} = g_{33} = -1$, $g_{44} = 1 - \omega^2 r^2$, $g_{14} = g_{41} = \omega y$, and $g_{24} = g_{42} = -\omega x$.

to first order in ω, the rotation metric is a vacuum solution of the *Entwurf* field equations (Janssen 1999, 141–142). To check whether this is also true to second order in ω, Einstein used the same iterative approximation procedure that he used in his perihelion calculations (both in the Einstein-Besso manuscript and in Einstein 1915b). The second-order terms in the vacuum *Entwurf* field equations are of two kinds: terms with second-order derivatives of second-order terms in the metric, and terms with products of first-order derivatives of first-order terms in the metric. Inserting the ω-terms of the rotation metric into the latter and solving for the ω^2-term in the one component of the metric that has an ω^2-term in the case of the rotation metric, Einstein checked whether this ω^2-term is the same as the ω^2-term in the rotation metric. In 1913, he convinced himself that it is.[68] In 1915, he redid the calculation and discovered that it is not.[69] He reported the result in a letter to Erwin Freundlich of 31 September 1915 (CPAE 8, Doc. 123), calling it "*a blatant contradiction*" ("*ein flagranter Widerspruch*"). Rotation thus became the nemesis of the *Entwurf* theory.

I now turn to the Machian motivation behind Einstein's use of his iterative approximation procedure in this context. Inserting the rotation metric into the geodesic equation, one sees that the ω-terms give the Coriolis force, while the ω^2-term gives the centrifugal force (Janssen 1999, sec. 11). The "Coriolis field" mentioned in the quoted passage of the Besso memo accordingly refers to the ω-terms in a metric of the form of the rotation metric, and the "centrifugal field" refers to the ω^2-term in such a metric. In the Einstein-Besso manuscript, Einstein had, in first-order approximation and using Minkowskian boundary conditions at infinity, already solved the *Entwurf* field equations for a material source consisting of a hollow thin shell rotating with angular frequency ω (CPAE 4, Doc. 14, [pp. 36–37]). He referred to these calculations in a letter to Mach of June 1913 (to which I will return below), so it is clear that this calculation was done either during or shortly after Besso's visit to Zurich of June 1913. Einstein found that, to first order in ω, the metric field inside the rotating shell has the same form as the rotation metric. Contrary to what Besso claims in his memo, this metric is not independent of the size of the shell, but by choosing the

---

68 The relevant calculations can be found in the Einstein-Besso manuscript (CPAE 4, Doc. 14, [pp. 41–42]).

69 (A version of) this calculation has been preserved on a sheet of paper that Einstein subsequently used for the draft of a letter to Otto Naumann (CPAE 8, Doc. 124). The draft is from early October 1915, the calculation probably from late September 1915. On the verso of this document there is an aborted attempt to circumvent the problem. The calculation on the recto shows that the standard transformation to rotating coordinates in Minkowski spacetime leads to a metric field that is *not* a vacuum solution of the *Entwurf* field equations. On the verso, Einstein modified this transformation, presumably to check whether this would lead to a metric field that is. It is possible that Einstein had tried this strategy before, even though no records of such attempts survive. Given how quickly he gave up on it in 1915, it is unlikely, I would say, that he ever found an acceptable escape from the problem of rotation along these lines. One other calculation that might be related to the problem of rotation should be mentioned here. This calculation can be found in the 1913 portion of the Einstein-Besso manuscript (CPAE 4, Doc. 14, [pp. 43–44]). Unfortunately, the purpose of this calculation remains unclear.

radius and the mass of the shell appropriately, its metric field near the center can nonetheless be used to mimic the part of the rotation metric giving rise to the Coriolis force. The *Entwurf* theory thus seemed to provide the resources necessary to produce a Machian account of Newton's rotating bucket experiment.[70] If the inertial forces in a rotating frame in Minkowski spacetime can be interpreted as gravitational forces in a frame at rest, the rotation with respect to absolute space in Newton's explanation of the bucket experiment can be replaced by the relative rotation of the bucket with respect to the rest of the universe. Einstein's first-order calculations for a rotating hollow shell showed that the Coriolis force can be interpreted as a gravitational force due to rotating distant masses. Inserting the Coriolis field, the ω-terms in the rotation metric, into the second-order vacuum field equations and solving for the ω^2-terms, Einstein hoped to show that the centrifugal force can be interpreted as due to the gravitational field produced by this first-order field. This, I conjectured, is what lies behind Einstein's use of his iterative approximation procedure to check whether the rotation metric is a vacuum solution of the *Entwurf* field equations.

Rephrasing the quoted passage from the Besso memo using the terminology introduced above, one sees both why it provides strong evidence in support of this conjecture and why it is hard to square with everything else we know about Einstein's struggles with rotation. Starting from the ω-terms of the rotation metric (more precisely: from a Coriolis field inside a rotating shell mimicking the Coriolis field in a rotating coordinate system in Minkowski spacetime) and using the vacuum *Entwurf* field equations to calculate the ω^2-term, one finds an ω^2-term (the centrifugal field inside the rotating shell) that is *not* the same as the ω^2-term of the rotation metric (the centrifugal field in a rotating coordinate system in Minkowski spacetime). This is precisely the "blatant contradiction" that Einstein reported to Freundlich over two years later!

What was Einstein's response to Besso's claim? That is the question that will occupy us for most of the remainder of this section. One possibility that can be ruled out immediately is that Einstein *carefully* redid the calculation himself. If he had, he would have found that Besso was right. And the assumption that Einstein in August 1913 knew *for a fact* that the rotation metric is not a vacuum solution of the *Entwurf* field equations would render the developments of 1914–1915 completely incomprehensible. I believe that Einstein was quite capable of fooling himself, but not that he was *in denial* for two years about the problem of rotation.

So Einstein did not check Besso's claim, at least not carefully. The interesting question then becomes: did he accept it or not? Before I address that question, I want to examine (and reject) one concrete scenario in which Einstein made a half-hearted attempt to check Besso's claim and satisfied himself that it was false alarm.

70 At this point I need to add the usual disclaimer that I am concerned only with Einstein's reading of Mach, not with what Mach actually may or may not have said. See (Barbour and Pfister 1995) for further discussion.

In this scenario, the calculations in the Einstein-Besso manuscript with which Einstein confirmed that the rotation metric is a vacuum solution of the *Entwurf* field equations were done not in June 1913, as has so far been assumed, but in late 1913 *in response* to the claim in the Besso memo. As I emphasized in sec. 2, these pages could in principle have been written any time between June 1913 and January 1914 (when Einstein presumably sent the whole package to Besso). There is, however, a good argument against redating these particular pages. Examining Einstein's calculations on these pages, one gets the impression that he was so convinced that the rotation metric is a vacuum solution of the *Entwurf* field equations that he made the right errors in the right places to arrive at the result he expected all along (Janssen 1999, sec. 8). The analysis of the Zurich Notebook in this volume provides a good explanation for why *in June 1913* Einstein would have been so confident. When Einstein first derived and decided to publish the *Entwurf* field equations, he felt that these were the *only* equations that agree with Newtonian theory in the static weak-field limit while at the same time being compatible with energy-momentum conservation. Convinced of the existence of field equations satisfying *all* his heuristic requirements, Einstein must have had the strong expectation that the rotation metric would be a vacuum solution of the *Entwurf* field equations. This requirement had played a particularly important role in Einstein's search for such equations.[71] It is therefore much more likely that the calculations on [pp. 41–42] of the Einstein-Besso manuscript were done in June 1913, when Einstein was supremely confident that the rotation metric was a vacuum solution, than that they were done in August 1913, when Besso's calculations called this into question.

It is, of course, *conceivable* that Einstein in August 1913 was still sufficiently convinced that the rotation metric would be a vacuum solution to dismiss Besso's claim out of hand, trusting his own calculation of June 1913 over Besso's. In and of itself this would not even be that unreasonable. Besso's contributions to the Einstein-Besso manuscript contain several egregious mathematical errors.[72] If Einstein simply dismissed Besso's claim, the story I told in (Janssen 1999) does not have to be changed much. All that needs to be added is that Einstein missed yet another opportunity to discover that the rotation metric is not a vacuum solution of the *Entwurf* field equations.

---

71 See the Zurich Notebook, pp. 42L–43L, p. 24R, and p. 25R, discussed in "Commentary …" (in this volume), secs. 5.5.6–5.5.9, sec. 5.6.1, and sec. 5.6.4, respectively. On p. 24R, Einstein missed his first opportunity to discover that the rotation metric is not a vacuum solution of the *Entwurf* field equations. Since the *Entwurf* field equations are constructed so as to guarantee energy-momentum conservation, the divergence of $t_{\mu\nu}$, the mixed tensor density representing gravitational energy-momentum density in the *Entwurf* theory, vanishes for every vacuum solution of these field equations. The divergence of $t_{\mu\nu}$ does *not* vanish for the rotation metric, which implies that the rotation metric cannot be a vacuum solution of the *Entwurf* field equations. At the top of p. 24R, however, Einstein wrote that an expression that can be identified as the divergence of $t_{\mu\nu}$ *does* vanish for the rotation metric.

72 Compare, for instance, Einstein's impeccable derivation of the metric inside a rotating shell on pp. 36–37 of the manuscript to Besso's bungled derivation of the metric inside a rotating ring on p. 50 (see CPAE 4, Doc. 14, note 234).

The most plausible scenario, however, if we take into account all available source material, is that Einstein *accepted* Besso's claim. Recall that on 15 August 1913, less than two weeks before the discussions recorded in the Besso memo, Einstein had found the (fallacious) argument from energy-momentum conservation[73] that convinced him that it was a desirable rather than a problematic feature of the *Entwurf* theory that its field equations seemed to be invariant under linear transformations only. On the basis of this argument, Einstein was prepared to accept that the rotation metric is not a solution of these equations. This sounds like a perfectly natural scenario. Einstein clearly believed at this point that the *Entwurf* field equations are not invariant under the non-linear transformation to a rotating coordinate system. Does it not simply follow from this that the rotation metric cannot be a vacuum solution of these equations?

What complicates matters is that this does *not* follow, as I emphasized in (Janssen 1999, sec. 2). The statement that some field equations are invariant under rotation is much stronger than the statement that the rotation metric is a solution of these equations. The former is a statement about an *arbitrary* metric expressed in two coordinate systems rotating with respect to one another, the latter is a statement about a *specific* metric, the Minkowski metric, in two such coordinate systems. In late 1913–early 1914, Einstein could therefore consistently have held both the (mistaken) belief that the rotation metric is a vacuum solution of the *Entwurf* field equations and the (correct) belief that these equations are not invariant under rotation.

Long before the discovery of the Besso memo, Jürgen Renn (private communication) already rejected this analysis of the situation as "logical hair-splitting." The Besso memo, I think, has proven Renn right. The most plausible scenario, I now believe, is that Einstein, without careful consideration, accepted Besso's claim that the rotation metric is not a vacuum solution of the *Entwurf* field equations, and that he accepted it largely *because* he believed that the equations were not invariant under rotation anyway.

There is clear evidence, however, that less than two weeks earlier Einstein had been keenly aware of the logical picture I painted above. My analysis of the situation essentially turns on the distinction between "autonomous" ("selbständige") and "non-autonomous" ("unselbständige") transformations that Einstein himself made in a letter to Lorentz of 14 August 1913. "Autonomous transformations" are the usual type of transformations from old to new coordinates, in which the latter are simply functions of the former. "Non-autonomous transformations" are coordinate transformations in which the new coordinates depend not only on the old coordinates but also on the components of a specific metric field expressed in terms of the old coordinates. Although Einstein had not used the term "non-autonomous transformations" before, the notion already played an important role in the Zurich Notebook.[74] It was further developed in 1914 when Einstein began to analyze the covariance properties of the *Entwurf* field

73 See p. 798 for Besso's statement of the argument.

equations in terms of "justified" ("berechtigte") transformations between "adapted" ("angepasste") coordinate systems (Einstein and Grossmann 1914b, 221).

When Einstein first explicitly introduced the distinction between "autonomous" and "non-autonomous" transformations in his letter to Lorentz, the lack of covariance of the *Entwurf* field equations had become something of an embarrassment for him. He wrote:

> *But the gravitational* [field] *equations themselves unfortunately do not have the property of general covariance*. Only their covariance with respect to *linear* transformations is guaranteed. The entire confidence one has in the theory, however, rests on the conviction that acceleration of the frame of reference is equivalent to a gravitational field. Hence, if not all sets of equations of the theory, hence also equations (18) [one of the forms in which the "Entwurf" field equations are given in *(*Einstein and Grossmann 1913)], allow other transformations besides linear ones, then the theory refutes its own starting point and is left hanging in the air.[75]

After explaining the distinction between "autonomous" and "non-autonomous" transformations in the next paragraph, he continued:

> The existence of "autonomous" non-linear transformations [that preserve the form of the "Entwurf" field equations] is the simpler possibility; but that possibility does not seem to obtain, although I would not know how to prove this. The existence of "non-autonomous" non-linear transformations, however, already suffices to avoid a conflict a posteriori with the equivalence hypothesis.[76]

This suggests that Einstein wanted to do for the *Entwurf* field equations what he had done for several candidate field equations in the Zurich Notebook, viz. to check whether they allow transformations to uniformly rectilinearly accelerated frames as well as to uniformly rotating frames in the special case of Minkowski spacetime. Hence, on 14 August 1913, Einstein was fully aware of the possibility that the *Entwurf* field equations might not be invariant under *autonomous* transformations to rotating coordinates, while still being invariant under *non-autonomous* transformations to rotating coordinates in the special case that the metric in the old coordinates is the standard diagonal Minkowski metric.

---

74 See, e.g., p. 22L and p. 23R, discussed in "Commentary …" (in this volume), secs. 5.5.3 and 5.5.5, respectively). For general discussion of "non-autonomous transformations" see "Commentary …" (in this volume), the introduction to sec. 4.3.

75 "*Aber die Gravitationsgleichungen selbst haben die Eigenschaft der allgemeinen Kovarianz leider nicht*. Nur deren Kovarianz *linearen* Transformationen gegenüber ist gesichert. Nun beruht aber das ganze Vertrauen auf die Theorie auf der Überzeugung, dass Beschleunigung des Bezugssystems einem Schwerefeld äquivalent sei. Wenn also nicht alle Gleichungssysteme der Theorie, also auch Gleichungen (18), ausser den linearen noch andere Transformationen zulassen, so widerlegt die Theorie ihren eigenen Ausgangspunkt; sie steht dann in der Luft." Einstein to Lorentz, 14 August 1913 (CPAE 5, Doc. 467).

76 "Die Existenz "selbständiger" nicht linearer Transformationen ist die einfachere Möglichkeit; dies scheint aber nicht zuzutreffen, ohne dass ich dies zu beweisen wüsste. Es genügt aber schon die Existenz "unselbständiger" nicht linearer Transformationen, um mit der Aequivalenzhypothese nicht nachträglich in Konflikt zu geraten." Ibid.

Two days later, Einstein wrote to Lorentz again, telling him that the previous day he had hit upon the argument from energy-momentum conservation that, he felt, made it fully respectable that the *Entwurf* field equations appear to be invariant only under (autonomous) linear transformations. The tone of this second letter is markedly different from that of the first. The first letter, more than any other document I know of, shows Einstein deeply troubled by the lack of general covariance of his field equations. The second shows him greatly relieved. This second letter concludes:

> Only now does the theory please me, after this ugly dark spot seems to have been removed.[77]

The darkest hour had been right before the dawn.

Einstein was probably quite happy to abandon his quest for non-autonomous non-linear transformations leaving the *Entwurf* field equations invariant. What he conveniently neglected to mention in the first letter to Lorentz was that he had already tried this strategy during his search for suitable field equations recorded in the Zurich Notebook, and that despite extensive efforts it had never gotten him anywhere (see, e.g., "Commentary …" (in this volume), sec. 4.3.1–4.3.2[78] and secs. 5.5.5–5.5.9). He had now found an argument that seemed to show that invariance under autonomous linear transformations was enough. The *Entwurf* field equations, he felt, no longer needed to be invariant under non-autonomous transformations to rotating systems.[79]

77 "Erst jetzt macht mir die Theorie Vergnügen, nachdem dieser hässliche dunkle Fleck beseitigt zu sein scheint." Einstein to H. A. Lorentz, 16 August 1913 (CPAE 5, Doc. 470). Translation from (Norton 1984, sec. 5).

78 Einstein was quite happy to switch from looking for non-autonomous transformations under which the expression $\frac{\partial}{\partial x_\alpha}\left(\gamma_{\alpha\beta}\frac{\partial\gamma_{\mu\nu}}{\partial x_\beta}\right)$ transforms as a tensor to finding a suitable generalization of this expression that would transform as a tensor under ordinary autonomous transformations.

79 I can think of one other consideration that indicates that Einstein did not want to bother anymore with non-autonomous transformations once he had found his argument from energy-momentum conservation. The argument supposedly restricts the covariance of the field equations to those transformations preserving the form $\frac{\partial}{\partial x_\nu}(\mathfrak{T}_{\sigma\nu} + t_{\sigma\nu}) = 0$ of the law of energy-momentum conservation. Under Einstein's (erroneous) assumption that $t_{\sigma\nu}$ has the same transformation character as $\mathfrak{T}_{\sigma\nu}$, this law is indeed invariant only under linear transformations as far as *autonomous* transformations are concerned. But it might be invariant under *non*-linear *non-autonomous* transformations. In fact, it is precisely this possibility that Einstein exploited in (Einstein and Grossmann 1914b) and (Einstein 1914e), where the covariance properties of the *Entwurf* field equations are analyzed in terms of "justified" transformations between "adapted" coordinates. If we assume that Einstein in late 1913 still remembered and believed the (erroneous) result he had recorded in the Zurich Notebook, viz. that $\partial t_{\sigma\nu}/\partial x_\nu = 0$ for the rotation metric (see note 71 above), he would even have had an example of such a non-linear non-autonomous transformation preserving the form of the equation $\frac{\partial}{\partial x_\nu}(\mathfrak{T}_{\sigma\nu} + t_{\sigma\nu}) = 0$, viz. the transformation to rotating coordinates in the important special case where the old metric in the old coordinates is the Minkowski metric in its standard diagonal form.

The rotation metric no longer *needed* to be a solution. If Besso now told him that it *was* not a solution, so be it.

There still seems to be one weighty objection to this reconstruction of events. If the rotation metric was not a vacuum solution of the *Entwurf* field equations, then Einstein's hopes for a Machian account of Newton's bucket experiment were dashed. The Besso memo shows that even Besso clearly saw that implication. There is ample contemporary evidence for Einstein's Machian hopes for the *Entwurf* theory. And Einstein's recollections a few years later indicate that these Machian hopes became especially important once he had convinced himself that generally-covariant field equations were not to be had. In November 1916, Einstein wrote to Willem de Sitter:

> Psychologically, this conception [of a full relativity of inertia] played an important role for me, since it gave me the courage to continue to work on the problem when I absolutely could not find covariant field equations.[80]

In view of this letter, it is hard to believe that Einstein would have given up the hope that his theory would provide a Machian account of the bucket experiment just when he had come to accept that the covariance of the *Entwurf* field equations is extremely limited. These considerations then would seem to rule out that, in August 1913, Einstein would have accepted, even if only temporarily, that the rotation metric is not a vacuum solution of the *Entwurf* field equations. Comparison of two letters to Mach, however, one from June 1913 and one from December 1913, shows a remarkable change in Einstein's conception of what made his theory Machian. This change fits exactly with the reconstruction given above of Einstein's reaction to Besso's claim in the memo of August 1913.

First consider Einstein's letter to Mach of June 1913. In this letter, as in the letter from December 1913, Einstein acknowledged the inspiration he had drawn from Mach's work in formulating the *Entwurf* theory. If the theory's prediction of the bending of light could be confirmed during the solar eclipse of 1914,[81] Einstein enthusiastically told Mach, then

> your brilliant studies about the foundations of mechanics receive […] beautiful confirmation. For it necessarily follows [from the theory] that *inertia* has its origin in a form of *interaction* between bodies, completely in the sense of your considerations about Newton's bucket experiment.[82]

---

80 "Psychologisch hat diese Auffassung bei mir eine bedeutende Rolle gespielt; denn sie gab mir den Mut, an dem Problem weiterzuarbeiten, als es mir absolut nicht gelingen wollte, kovariante Feldgleichungen zu erlangen." Einstein to Willem de Sitter, 4 November 1916 (CPAE 8, Doc. 273). The letter is Einstein's first contribution to the famous Einstein–De Sitter debate. See the editorial note, "The Einstein–De Sitter–Weyl–Klein Debate," (CPAE 8, 351–357), for further discussion.

81 Einstein's astronomer friend Erwin Freundlich was planning an expedition to the Crimea for this purpose.

82 "erfahren Ihre geniale Untersuchungen über die Grundlagen der Mechanik […] eine glänzende Bestätigung. Denn es ergibt sich mit notwendigkeit, dass die *Trägheit* in einer Art *Wechselwirkung* der Körper ihren Ursprung hat, ganz im Sinne Ihrer Überlegungen zum Newton'sche Eimer-Versuch." Einstein to Ernst Mach, 25 June 1913 (CPAE 5, Doc. 448).

Einstein went on to describe two concrete examples of effects illustrating the relativity of inertia, and thereby the Machian character of his theory. I already discussed the second example, which is that of a rotating shell producing a Coriolis field. These same examples are mentioned in the first of the two letters to Lorentz of August 1913 discussed above. In both letters, Einstein emphasized that the effects will be very small. The relativity of inertia is also mentioned prominently in the two lectures of fall 1913, the Frauenfeld lecture and the Vienna lecture (see Einstein 1913a, sec. 9; 1913b, p. 138; and 1914d, p. 290). In the Vienna lecture, though not in the Frauenfeld lecture, Einstein once again emphasized that the effects will be small:

> unfortunately, the effect one expects is so small that we cannot hope to detect it in terrestrial experiments or in astronomy.[83]

My conjecture is that Einstein accepted in late 1913 that the relativity of inertia effects predicted by the *Entwurf* theory, for all their importance from a conceptual point of view, were too small to produce a full Machian account of the bucket experiment. I want to suggest that he could accept this *because* of the argument from energy-momentum conservation of August 1913. That argument, or so Einstein thought, explains why the frame in which the bucket is rotating is privileged over the frame in which the bucket is at rest.

This may sound like wild speculation but surprisingly strong evidence for this conjecture comes from a second letter from Einstein to Mach of December 1913. Einstein begins this letter in much the same way as he began his letter half a year earlier:

> It pleases me enormously that the development of the theory reveals the depth and the importance of your studies about the foundation of classical mechanics.[84]

Gone, however, are the references to the relativity of inertia "in the sense of [Mach's] considerations about Newton's bucket experiment." Einstein's identification of what makes his theory Machian has changed drastically:

> For me it is an absurdity to ascribe physical properties to "space." The totality of masses generates a $g_{\mu\nu}$-field (gravitational field), which in turn governs the unfolding of all events, including the propagation of light rays and the behavior of measuring rods and clocks. Everything that happens is initially described in terms of four *completely arbitrary* spatio-temporal variables. If the conservation laws for momentum and energy are to be satisfied, these variables then need to be specialized in such a way that only (fully) [Einstein probably meant 'arbitrary'; MJ] *linear* substitutions connect one justified frame of reference to another. The frame of reference is, in a manner of speaking, tailored to the existing world with the help of the energy law and loses its nebulous a priori existence.[85]

The important point is no longer that inertia comes out as an interaction between masses and that Newton's bucket experiment can be accounted for without invoking

83 "leider ist der zu erwartende Effekt so gering, daß wir nicht hoffen dürfen, ihn durch terrestrische Versuche oder in der Astronomie zu konstatieren" (Einstein 1913a, 1261–1262).

84 "Es freut mich ausserordentlich, dass bei der Entwickelung der Theorie die Tiefe und die Wichtigkeit Ihrer Untersuchungen über das Fundament der klassischen Mechanik offenkundig wird." Einstein to Ernst Mach, second half of December 1913 (CPAE 5, Doc. 495).

absolute motion. Rather it is that the law of energy-momentum conservation now explains why certain frames of reference are privileged. In other words, the argument from energy-momentum conservation of 15 August 1913 not only made it possible for Einstein to give up the Machian requirement that the rotation metric be a solution of the gravitational field equations, it also supplied what Einstein saw as a perfectly good alternative Machian feature of his theory!

I confess that it is not clear to me why Einstein ever felt that this was a satisfactory solution to the problem of absolute space.[86] Einstein's answer to the question why certain frames of reference are privileged—if I understand the passage quoted above correctly—is that in those frames the law of energy-momentum conservation has a particularly simple form. Is this really an answer or is it just a way of restating the question? How does Einstein's answer differ from the following "answer"? Inertial frames are privileged because in those frames Newton's second law takes the form $F = ma$. That just side-steps the question what it is about those frames that is responsible for Newton's second law taking this form. In the end, of course, none of Einstein's attempts to make his theory Machian ever panned out, but in the case of the other attempts it is at least clear how they could in principle have met the challenge of Newton's bucket experiment. In this case, not even that much is clear, at least not to me.

The important point, however, in this context is that Einstein believed that with his simple argument from energy-momentum conservation he had somehow solved the thorny problem of absolute space. And this removes what seemed to be the one strong objection to the scenario in which Einstein accepted in late 1913 that the rotation metric is not a solution of the *Entwurf* equations.

Einstein's satisfaction with this state of affairs was relatively short-lived. The simple argument from energy-momentum conservation of August 1913 was retracted in print in (Einstein and Grossmann 1914b, 218, footnote). This paper was not published until May 1914, but it was almost certainly completed by the time Einstein left Zurich for Berlin in March 1914.[87] As I pointed out in sec. 2, Einstein briefly outlined the new treatment of the covariance properties of the *Entwurf* field equations of (Einstein

---

85 "Für mich ist es absurd, dem "Raum" physikalische Eigenschaften zuzuschreiben. Die Gesamtheit der Massen erzeugt ein $g_{\mu\nu}$-Feld (Gravitationsfeld), das seinerseits den Ablauf aller Vorgänge, auch die Ausbreitung der Lichtstrahlen und das Verhalten der Massstäbe und Uhren regiert. Das Geschehen wird zunächst auf vier *ganz willkürliche* raum-zeitliche Variable[n] bezogen. Die müssen dann, wenn den Erhaltungssätzen des Impulses und der Energie Genüge geleistet werden soll, derart spezialisiert werden, dass nur (ganz) *lineare* Substitutionen von einem berechtigten Bezugssystem zu einem andern führen. Das Bezugssystem ist der bestehenden Welt mit Hilfe des Energiesatzes sozusagen angemessen und verliert seine nebulose apriorische Existenz." Ibid. One might be tempted to read the second sentence of this passage as an early statement of what later became "Mach's principle" (Einstein 1918), the requirement that the metric field be fully determined by matter. However, since the Minkowski metric in its standard diagonal form is a vacuum solution of the *Entwurf* field equations, the *Entwurf* theory certainly does not qualify as Machian by this criterion.

86 Einstein, like everybody else at the time, did not systematically make the distinction, at the heart of the modern analysis of these issues (see Earman 1989), between the problem of motion (absolute versus relative) and the problem of space (substantival versus relational).

and Grossmann 1914b) in a letter to Besso of early March 1914.[88] In particular, Einstein claimed that the rotation metric satisfies the condition formulated in that paper for "adapted" coordinates. As a matter of fact, it does not (see Janssen 1999, fn. 47). If Einstein explicitly checked this, he must have botched this calculation too. It is possible, however, that he reached his conclusion on the basis of more general considerations. Such considerations can be found in a letter to Lorentz at the beginning of the following year, January 1915. In this letter, Einstein claimed that the condition for "adapted" coordinates puts no restrictions whatsoever on the state of motion of allowed coordinate systems. Referring to secs. 12–14 of (Einstein 1914e), published in November 1914, he explained how the condition for "adapted" coordinates uniquely determines the coordinates inside some matter-free spacetime region Σ once the coordinates on the region's borders are specified. The letter then continues:

> From what has been said it is then also clear that linear transformations belong to the "justified" transformations. It is also clear that the *state of motion* of justified systems can be chosen arbitrarily since the coordinates at the regions' borders can be freely chosen; one can easily verify this for special cases.[89]

Unfortunately, I do not understand Einstein's argument, so I cannot pinpoint where it fails. *That* it fails is clear from the fact that the rotation metric does not satisfy the condition for "adapted" coordinates. The results in (Einstein 1914e) on which this argument of January 1915 turns are a natural extension of the results reported in (Einstein and Grossmann 1914b). So Einstein may well have hit upon this argument in early 1914. Regardless, however, of how exactly Einstein convinced himself in early 1914 that the rotation metric is a vacuum solution of the *Entwurf* field equations after all, it is clear that in doing so he essentially reverted to the position of the first of the two letters to Lorentz of August 1913 discussed above. He believed that the *Entwurf* field equations were invariant under a broad enough class of *non-autonomous* transformations to satisfy the demands of the equivalence principle and the generalized relativity principle.

At this juncture, an assumption I made earlier becomes crucial, viz. that Einstein accepted the claim about rotation in the Besso memo *without carefully checking it*. When in early 1914 his new approach indicated that the rotation metric is a vacuum solution of the *Entwurf* field equations, Einstein either had forgotten about Besso's

87 In June 1914, referring to (Einstein and Grossmann 1914b), Einstein wrote: "While still in Zurich I found the proof of the covariance of the gravitational [field] equations. Now the relativity theory has really been extended to arbitrarily moving systems" ("In Zürich fand ich noch den Nachweis der Kovarianz der Gravitationsgleichungen. Nun ist die Relat[ivitäts]theorie wirklich auf beliebig bewegte Systeme ausgedehnt." Einstein to Wilhelm Wien, 15 June 1914 [CPAE 8, Doc. 14]).

88 The uncharacteristically lucid part of the draft of Besso's reply is quoted on p. 805; the more typical muddle-headed part on p. 796.

89 "Aus dem Gesagten ist dann auch klar, dass die linearen T[ra]nsformationen zu den "berechtigten" gehören. Ebenso ist klar, dass der *Bewegungszustand* berechtigter Systeme willkürlich wählbar ist, da die Koordinatenwahl an den Gebietsgrenzen frei ist; man kann sich dies an Spezialfällen leicht vergegenwärtigen." Einstein to H. A. Lorentz, 23 January 1915 (CPAE 8, Doc. 47).

earlier calculations or assumed they must have been in error. In his letter to Besso of March 1914, he did not refer to these calculations at all. Besso accepted the verdict implied by this omission. In the draft of his reply, he modestly inquired whether the new treatment gives the right answer for the centrifugal force.[90] Theirs was not a partnership of equals.

By convincing himself that the *Entwurf* field equations allow non-autonomous transformations to rotating coordinates in Minkowski spacetime, Einstein also convinced himself that the *Entwurf* theory vindicates the Machian account of Newton's bucket experiment. The latter claim is featured prominently in what was clearly meant to be the definitive exposition of the *Entwurf* theory submitted to the Prussian Academy on 29 October 1914. In the introduction, Einstein wrote:

> Let … K be a justified coordinate system in the Galilean-Newtonian sense, and let K' be a coordinate system rotating uniformly with respect K. In that case there will be centrifugal forces acting on masses at rest with respect to K', whereas there will be no such forces on masses at rest with respect to K. Newton already considered this proof that one has to look upon the rotation of K' as an "absolute" rotation, and that one is not equally justified in treating K' as being "at rest" as one is with K. This argument, however—as has been shown in particular by E. Mach—is not valid. We do not necessarily have to attribute the existence of centrifugal forces to the motion of K'; we can just as well attribute them to the average rotational motion of the ponderable distant masses of the surroundings with respect to K', where we treat K' as being "at rest."[91]

So, by the end of 1914, any doubts Einstein might have had concerning rotation had completely evaporated.[92]

In March 1915, the Italian mathematician Tullio Levi-Civita produced a coordinate transformation that turned the Minkowski metric in its standard diagonal form into a metric field that is no longer a vacuum solution of the *Entwurf* field equations, even though the transformation was specifically constructed in such a way that it was "justified" ("berechtigt") according to Einstein's own criterion for "adapted" ("angepasste") coordinate systems.[93] Einstein had claimed that this condition is both necessary and sufficient for coordinates to be adapted to a given metric field. Einstein tried to get around Levi-Civita's counter-example, but Levi-Civita remained uncon-

---

90 See the quotation on p. 796 from Besso to Einstein, draft, 20 March 1914.

91 "Es sei … K ein im Galilei-Newtonschen Sinne berechtigtes Koordinatensystem, K' ein relativ zu K gleichförmig rotierendes Koordinatensystem. Dann wirken auf relativ zu K' ruhende Massen Zentrifugalkräfte, während auf relativ zu K ruhende Massen solche nicht wirken. Hierin sah bereits Newton einen Beweis dafür, daß man die Rotation von K' als eine »absolute« aufzufassen habe, daß man also K' nicht mit demselben Rechte wie K als »ruhend« behandeln könne. Dies Argument ist aber—wie insbesondere E. Mach ausgeführt hat—nicht stichhaltig. Die Existenz jener Zentrifugalkräfte brauchen wir nämlich nicht notwendig auf eine Bewegung von K' zurückzuführen; wir können sie vielmehr ebensogut zurückführen auf die durchschnittliche Rotationsbewegung der ponderablen fernen Massen der Umgebung in bezug auf K', wobei wir K' als »ruhend« behandeln" (Einstein 1914e, p. 1031).

92 It is very telling that the title of (Einstein 1914e) proudly announces a "general" ("allgemeinen") theory of relativity, whereas the titles of (Einstein and Grossmann 1913; 1914b; and Einstein 1914c) had more modestly announced only a "generalized" ("verallgemeinerten") theory of relativity.

vinced, and the exchange between the two men about the covariance properties of the *Entwurf* field equations ended in a stalemate (see Einstein to Tullio Levi-Civita, 5 May 1915 [CPAE 8, Doc. 80]). It appears that Einstein remained supremely confident of his theory, but perhaps Levi-Civita's criticism got under his skin more than he cared to admit. There is no indication, however, that Einstein expressed any doubts about his theory in his Wolfskehl lectures in Göttingen in the summer of 1915. And although he preferred not to include any papers on the *Entwurf* theory in a proposed new edition of the Teubner anthology on the principle of relativity, this does not seem to have been because of any doubts concerning the theory (see Einstein to Arnold Sommerfeld, 15 July 1915 [CPAE 8, Doc. 96]).

Still, at some point during the late summer of 1915, Einstein must have gotten sufficiently worried about his theory to subject it to a test the outcome of which, be it positive or negative, he had essentially taken for granted for two years: is the rotation metric a vacuum solution of the *Entwurf* field equations or not? It could very well be, as Jürgen Renn has suggested to me, that Besso brought up the problem of rotation again during Einstein's visit to Zurich in September 1915 and that this is what finally made Einstein decide to repeat the calculation carefully. Despite the early warning signs recorded in the Besso memo two years earlier, one can understand the shock that comes through in the letter to Freundlich in which Einstein reported that the rotation metric is definitely *not* a solution.

This is the most convincing reconstruction of Einstein's struggles with rotation in the period 1913–1915 that I can come up with given all available source material. In (Janssen 1999), I argued that Einstein probably believed throughout the life span of the *Entwurf* theory that the rotation metric is a vacuum solution of its field equations. I now believe that there is strong evidence that there was a period in late 1913–early 1914 when Einstein believed that the rotation metric is actually *not* a solution. The comments about rotation in the Besso memo constitute the most important part of this evidence, but striking corroborating evidence comes from the comparison of Einstein's letters to Mach of June and December 1913.

In the reconstruction given in this section, one feature of the reconstruction I gave in (Janssen 1999) gets strongly amplified. One clearly sees a certain opportunistic streak in Einstein's *modus operandi*. In (Janssen 1999), I argued that Einstein on at least two occasions[94] missed the problem of rotation in his *Entwurf* theory because he was too convinced that his calculations would bear out his *stable* expectation that the rotation metric would be a vacuum solution of the *Entwurf* field equations. In the new reconstruction, things get worse in two (rather different) ways.

First, Einstein repeatedly failed to check carefully whether his theory fulfilled his expectations even though these expectations *changed* over time. In June 1913 and in

93 Tullio Levi-Civita to Einstein, 28 March 1915 (CPAE 8, Doc. 67). For a discussion of this exchange between Einstein and Levi-Civita, see (Cattani and De Maria 1989). This specific result is discussed on pp. 189–190.

94 In June 1913, when he did the calculations on pp. 41–42 of the Einstein-Besso manuscript, and in March 1914, when he checked whether the rotation metric satisfies the condition for adapted coordinates.

March 1914 he expected the rotation metric to be a vacuum solution of the *Entwurf* field equations, but in August 1913 he expected it not to be. Yet, in none of these cases did he take the trouble to do a relatively simple calculation to establish once and for all whether the rotation metric is a solution or not.

Secondly, Einstein drastically changed the formulation of what would make his theory Machian according to what he thought the *Entwurf* theory could deliver. When he was under the impression that the rotation metric was a vacuum solution of the field equations, he claimed that rotating and non-rotating frames of reference are equivalent in his theory. When he was under the impression that it was not, he claimed that the theory explained why rotating and non-rotating frames of reference are not equivalent. I am not saying that this was an unreasonable thing to do. On the contrary, it would have been foolish for Einstein to hold on stubbornly to the letter of his heuristic requirements if he felt that an otherwise attractive theory simply lacked the resources to meet this or that requirement. Creative scientists may need a healthy dose of opportunism. We shall see more manifestations of this trait of Einstein when we turn to the hole argument in the next section.[95]

4. THE BESSO MEMO AND THE HOLE ARGUMENT

We now finally get to the most intriguing passage of the Besso memo, the bottom half of the second page, where in three short paragraphs we find, first, the earliest extant version of the hole argument, second, a promising proposal for an escape from the argument, and, third, a brusque rejection of this escape. A facsimile reproduction of this passage can be found in Fig. 2. The first of the three paragraphs reads:

> The requirement of ⟨general⟩ covariance of the gravitational equations under arbitrary transformations cannot be imposed: if all matter ⟨is given⟩ were contained in one part of space and for this part of space a coordinate system [is given], then outside of it the coordinate system could still ⟨essentially⟩ except for boundary conditions be chosen arbitrarily, ⟨through which the g arbitrarily⟩ so that a unique determinability of the g's cannot be obtained.[96]

In essence, this is (a qualitative description of) the hole argument: if the field equations for the metric field are generally covariant, then a given matter distribution does not uniquely determine the metric field in matter-free regions. It is not essential to the

95 The two opportunistic moves distinguished above nicely illustrate an insightful distinction introduced in (Earman and Eisenstaedt 1999, 230) and amplified in (Kennefick 2005, 119–120). There are (at least) two kinds of opportunism: the garden variety—what Earman and Eisenstaedt call "unscrupulous opportunism"—and a much rarer form, which they call, using a beautiful oxymoron, "principled opportunism." Einstein, they argue and Kennefick concurs, was the master of the latter. Opportunism comes into play when there is a conflict between a principle (e.g., relativity of motion) and some concrete result (e.g., the rotation metric is not a solution of the vacuum *Entwurf* field equations). Faced with such a conflict, the unscrupulous opportunist changes the principle (as Einstein did when he redefined what makes a theory Machian), whereas the principled opportunist finds ways to ignore the result (as Einstein did with the troublesome rotation metric). I am grateful to Dan Kennefick for making me appreciate this point.

argument which regions contain matter and which regions do not. It is also not essential whether the argument is phrased in terms of regions of four-dimensional spacetime or in terms of regions of three-dimensional space. In the published versions of the hole argument, there is a finite matter-free region of spacetime—the "hole" from which the argument derives its name[97]—while there can be matter everywhere else.[98] In the version of the Besso memo it is just the other way around. There is a finite region of space in which all matter is concentrated while there is no matter anywhere else. This, of course, also divides spacetime into regions with and without matter. So, what Besso describes could be called an inverted hole argument or a hole argument without a hole. It should not be surprising that the hole argument is not yet stated in its canonical form given that Einstein only found it somewhere between 16 August 1913, when he reported the argument against general covariance from energy-momentum conservation to Lorentz, and 28 August 1913, the date of the Besso memo.

The formulation of the hole argument in the Besso memo suggests that the argument originated in concerns about the uniqueness of the metric field of the sun, which Einstein and Besso calculated in their attempt to account for the perihelion anomaly on the basis of the *Entwurf* theory. In his summary of the iterative approximation procedure used to find the static spherically symmetric solution of the *Entwurf* field equations to represent the metric field of the sun, Besso explicitly raised the issue of the solution's uniqueness: "Is the static gravitational field [. . .] a particular solution? Or is it the general solution expressed in particular coordinates?" (CPAE 4, Doc. 14, [p. 16]).[99]

The second paragraph of the passage from the Besso memo is the one quoted in the introduction. It proposes an escape from the hole argument:

> It is, however, not necessary that the g themselves are determined uniquely, only the observable phenomena in the gravitation space, e.g., the motion of a material point, must be.[100]

The more cryptic third paragraph, appended to the second, purports to show why the escape fails:

---

96 "Die Anforderung der ⟨allgemeinen⟩ Covarianz der Gravitationsgleichungen für beliebige Transformationen kann nicht aufgestellt werden: wenn in einem Teile des Raumes alle Materie ⟨gegeben ist⟩ enthalten wäre und für diesen Teil ein Coordinatensystem, so könnte doch ausserhalb desselben das Coordinatensystem noch, ⟨im wesentlichen⟩ abgesehen von den Grenzbedingungen, beliebig gewählt werden, ⟨wodurch die g beliebig eine⟩ so dass eine eindeutige Bestimmbarkeit der g s nicht eintreten könne."

97 I know of only one place where Einstein explicitly used the phrase "hole argument" ("Lochbetrachtung") in writing and that is in his letter to Besso of 3 January 1916 (CPAE 8, Doc. 178). In the first two published versions of the argument, the letter '*L*,' which presumably stands for "Loch" (Stachel 1989, 71), is used to designate the matter-free region (Einstein and Grossmann 1914a, 260; 1914b, 217–218). In the last two published versions, the matter-free region is designated by 'Φ' (Einstein 1914c, 178) and by 'Σ' (Einstein 1914e, 1067), respectively.

> Of no use, since with ⟨the⟩ a solution a motion is also fully given. If in coordinate system 1, there is a solution K_1, then this same construct is also a solution in 2, K_2; K_2, however, also a solution in 1.[101]

As I explained in sec. 2 (see p. 803–805), I am assuming that the Besso memo is the record of discussions between Einstein and Besso during a visit by the latter to Zurich in late August 1913. On this assumption, the first of the three paragraphs is most naturally understood as Besso's formulation of an embryonic version of the hole argument that Einstein had just told him about; the second as giving Besso's own proposal for an escape from the argument; and the third as giving (Besso's recollection of) Einstein's negative response to this proposal. As I pointed out in the introduction, Besso's proposal does not seem to be all that different from the point-coincidence argument with which Einstein himself explained the failure of the hole argument over two years later in letters to Ehrenfest *and Besso*. The main task of this section therefore will be to make it plausible that Einstein was aware of the escape proposed by Besso as early as August 1913 and nonetheless continued to trot out the hole argument for the next two years.

Before I get to this task, I want to point out that the passage on the hole argument in the Besso memo, like the passage on rotation discussed in sec. 3, supports the existing reconstruction of events in at least one important respect even though it may undermine it in others.[102] The last sentence of the third paragraph provides strong support for the interpretation of the first three published versions of the hole argument as cryptic statements of the fourth[103] (Norton 1984, 131).[104]

---

98 Einstein's hole argument is not quite the same as the argument advanced under the same name in (Earman and Norton 1987). Discussions of the latter account for a disproportionate fraction of the recent literature in philosophy of space and time. In one of the more interesting early contributions to this debate, Tim Maudlin gave a concise statement of how Einstein's argument differs from Earman and Norton's: "the question [in Einstein's case] is not whether the entire state of the universe outside the hole determines the state inside [as in Earman and Norton's case]. Rather the question is whether the stress-energy tensor […] defined everywhere determines the metric […] everywhere" (Maudlin 1990, 556). Maudlin goes on to suggest that Einstein was not so much worried about a conflict between general covariance and determinism (which is the focus of Norton and Earman's hole argument), but rather about a conflict between general covariance and Mach's principle, the requirement that matter fully determines the metric field. What militates against Maudlin's suggestion is that this requirement was not formulated until three and a half years later in Einstein to Willem de Sitter, 24 March 1917 (CPAE 8, Doc. 317) and was only published in (Einstein 1918). In late 1913, as we saw in sec. 3, Einstein still articulated his Machian intuitions in terms of the relativity of inertia. Einstein moreover explicitly introduced the final version of the hole argument in terms of a conflict between general covariance and the "law of causality" ("Kausalgesetz," Einstein 1914e, 1066). It is true that Maudlin only proposed his Machian interpretation for the first three published versions of the hole argument, which he sharply distinguished from the fourth, but the Besso memo, as we shall see, strongly suggests that there is no such distinction and that the first three versions are just cryptic formulations of the fourth. Despite these reservations, I find it an appealing suggestion that the worries about determinism and causality that are behind Einstein's hole argument have strong Machian overtones. This same suggestion was made in (Hoefer 1994).

99 "Ist das stat Schwerefeld [. . .] ein spezielles? Oder ist es das allgemeine, auf spec. Coordinaten zurück geführtes?" I owe this observation about the origin of the hole argument to Jürgen Renn.

To make good on this claim, I need to remind the reader of some of the fine print of the argument. It will be convenient to do so for the canonical form of the argument, rather than for the "inverted" form in the Besso memo. Consider two coordinate systems—one with coordinates x^μ, the other with coordinates x'^μ—that differ only in some finite matter-free region of spacetime ("the hole"). It follows that the components of the energy-momentum tensor, which describe the matter distribution, are given by the exact same functions of the coordinates in these two coordinate systems: $T_{\mu\nu}(x) = T'_{\mu\nu}(x')$.[105] Suppose we have some local field equations setting some differential operator acting on the metric tensor equal to the energy-momentum tensor.[106] Suppose $g_{\mu\nu}(x)$ is a solution of these field equations in the unprimed coordinate system for the matter distribution $T_{\mu\nu}(x)$. If the field equations are invariant under the transformation from x^μ to x'^μ, as would be case for generally-covariant field equations, then $g'_{\mu\nu}(x')$ will be a solution for $T'_{\mu\nu}(x')$ in the primed coordinate system. Inside the hole, $g_{\mu\nu}(x) \neq g'_{\mu\nu}(x')$[107] even though $T_{\mu\nu}(x) = T'_{\mu\nu}(x')$ everywhere.

The standard interpretation of the hole argument before the work of John Stachel and John Norton in the 1980s, was that Einstein thought that the inequality $g_{\mu\nu}(x) \neq g'_{\mu\nu}(x')$ amounted to indeterminism and that because of this the field equations could not be allowed to be invariant under such transformations as the one from x^μ to x'^μ (see, e.g., Pais 1982, 222). Needless to say, this interpretation is not very

---

100 "Es ist nun allerdings nicht nötig, dass die g selbst eindeutig bestimmt sind, sondern nur die im Gravitationsraum beobachtbaren Erscheinungen, z.B. die Bewegung des materiellen Punktes, müssen es sein."

101 "Nützt nichts, denn durch ⟨der⟩ eine Lösung ist auch eine Bewegung voll gegeben. Ist im Coordinatensystem 1 eine Lösung K_1, so ist dieses selbe Gebilde auch eine Lösung in 2, K_2; K_2 aber auch eine Lösung in 1." The deleted fragment at the bottom of the page ("⟨*Es h*⟩") is the beginning of the (deleted) first sentence of the third page: "⟨After all, it is only called *co*variance, not *in*variance of the gravitational [field] equations!?⟩" ("⟨Es heisst aber auch bloss *Co*varianz, nicht *In*varianz, der Grav. gl.!?⟩").

102 In the case of rotation, the Besso memo provided strong support for my earlier conjecture that Einstein used his iterative approximation procedure to check whether the rotation metric is a vacuum solution of the *Entwurf* field equations in order to interpret the inertial forces of rotation as gravitational forces due to distant rotating masses. At the same time, it seriously undermined my earlier assumption that from June 1913 till the end of September 1915 Einstein never wavered in his belief that the rotation metric to be a vacuum solution of the *Entwurf* field equations.

103 See note 97 for detailed references to all four versions.

104 Even in (Stachel 1989), the possibility is left open that the fourth version "may represent a significant evolution in Einstein's thinking about the "hole" argument" (ibid., 72).

105 Let me state this equality somewhat more precisely with the help of some modern terminology. At every point p of the manifold covered by two maps—one with coordinates x^μ, the other with coordinates x'^μ—the components $T_{\mu\nu}$ at p in x^μ-coordinates are equal to the components of $T'_{\mu\nu}$ at p in x'^μ-coordinates. A more explicit form of the equality would be $T_{\mu\nu}(x^\rho_p) = T'_{\mu\nu}(x'^\rho_p)$. For points p outside and on the edge of the hole, the equality holds because $x^\rho_p = x'^\rho_p$. For points p inside the hole, the equality holds, even though $x^\rho_p \neq x'^\rho_p$, simply because $T_{\mu\nu}(x^\rho_p) = T'_{\mu\nu}(x'^\rho_p) = 0$.

106 It is important for the hole argument to go through that the equations always set quantities evaluated *at the same point* equal to one another: hence the restriction to *local* field equations.

flattering to Einstein. It accuses him of mistaking different coordinate representations of one and the same field configuration for physically distinct field configurations. Only the last of the four published versions of the hole argument, however, unambiguously rules out this unkind reading.

In the fourth version, Einstein explicitly added an extra step, making the argument much more interesting. If $g'_{\mu\nu}(x')$ is a solution for $T'_{\mu\nu}(x')$ in the primed coordinates, then $g'_{\mu\nu}(x)$ is a solution for $T'_{\mu\nu}(x) = T_{\mu\nu}(x)$ in the unprimed coordinates. After all, the functions $g'_{\mu\nu}(x')$ will be a solution of the local field equations no matter whether we read its arguments as primed or as unprimed coordinates. Notice that Einstein has now generated two metric fields, $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$, expressed in the same coordinates, that differ inside the hole, even though they are both solutions of the field equations for the same matter distribution $T_{\mu\nu}(x)$.[108] In other words, the fourth version of the hole argument explicitly involves an active point transformation rather than just a passive coordinate transformation. It was in order to avoid the kind of indeterminism that seems to come out of these active point transformations—and *not* to avoid the completely innocuous non-uniqueness of the metric field's coordinate representation—that Einstein wanted to rule out field equations that are invariant under transformations such as the one from x^μ to x'^μ used in the hole construction.

The last sentence of the passage on the hole argument in the Besso memo shows that the crucial extra step of the fourth published version of the argument was there from the very beginning. Let me quote this sentence again, this time adding some of the notation introduced above (but suppressing all indices) to bring out the point more clearly:

> If in coordinate system 1 [with coordinates x], there is a solution K_1 [i.e., $g(x)$], then this same construct [modulo a coordinate transformation] is also a solution in [coordinate system] 2 [with coordinates x'], K_2 [i.e., $g'(x')$]; K_2, however, [is] also a solution in 1 [i.e., $g'(x)$]

So already in August 1913, Einstein went through the full sequence "$g(x) \rightarrow g'(x') \rightarrow g'(x)$," which only makes sense if he wanted to argue against generally-covariant field equations on the basis of the indeterminism lurking in the inequality $g(x) \neq g'(x)$. This makes it extremely unlikely that when he subsequently published the argument he would stop at $g'(x')$ and base his argument on the trivial inequality $g(x) \neq g'(x')$. The Besso memo therefore strongly suggests that the first three published versions of the hole argument are no different from the fourth, except that they were stated much more cryptically.

I now turn to the central question of this section. Why did Einstein reject Besso's escape from the hole argument in August 1913? Given the reconstruction in sec. 3 of

107 More explicitly, for points p in the overlap of the x^μ-map and the x'^μ-map, $g_{\mu\nu}(x^\rho_p) \neq g'_{\mu\nu}(x'^\rho_p)$ (cf. note 105).

108 It is helpful to think in somewhat more intuitive terms of how Einstein's two-step procedure changes the situation inside the hole. First, the values $g_{\mu\nu}$ are transformed to new values $g'_{\mu\nu}$ for every point inside the hole. Then these new values are redistributed over the points in the hole.

Einstein's struggles with rotation during this same period, an easy answer to this question readily suggests itself. We could simply invoke Einstein's opportunistic streak again. The story would then go something like this.

In the fall of 1913, about the last thing Einstein wanted was an escape from the hole argument. His letters to Lorentz of 14 August and 16 August 1913, discussed on pp. 810–813 above, show how in two short days he went from grave concern, thinking that any acceptable field equations had to be of broad covariance, to great relief, thinking that energy-momentum conservation restricts the covariance of the field equations to general linear transformations. The hole argument dovetailed very nicely with this argument from energy-momentum conservation.[109] As a result, Einstein was probably, shall we say, less than receptive to Besso's suggestion shortly afterwards that the hole argument might not rule out generally-covariant field equations after all.[110]

Two years later, the story continues, the situation was very different. In November 1915, Einstein replaced the *Entwurf* field equations by generally-covariant ones. Yet, in the relevant publications one searches in vain for an explanation of what is wrong with the hole argument. Einstein only offered such an explanation about a month later when pressed on the issue in correspondence with Ehrenfest and Besso. Given that Einstein at this point wanted to dispose of the hole argument, one can understand why he now endorsed essentially the same escape that he had rejected two years earlier, when the conclusion of the hole argument had been more congenial to him.

The basic presumption in this reconstruction, in which expediency is the sole determining factor, is that the escape proposed in the Besso memo is very close to the escape based on the point-coincidence argument. Besso argued that only wordlines need to be determined uniquely. Einstein's minor emendation was to replace 'worldlines' by 'intersections of worldlines.' The step from one to the other, however, is perhaps not as trivial as it may appear to be at first sight. Taking my inspiration from the debate over the hole argument in the recent philosophy of space and time literature (see note 98), I will argue that it may in fact have been a very significant step. The "Of no use"-comment with which Besso's escape is rejected in the memo can then be seen as a serious objection, which can be answered only when point coincidences, i.e., intersections of wordlines, are substituted for worldlines. There is strong evidence that Einstein got the notion of point coincidences from (Kretschmann 1915), which he probably read shortly after it appeared in late 1915 (Howard and Norton 1993, 52–55). On this reconstruction then, Einstein did not have the resources in August 1913 to overcome what in the unkind glare of hindsight looks like a lame objection to a perfectly viable escape from the hole argument. Pursuing this line of thought, one arrives at an answer to the question why Einstein rejected Besso's escape from the hole argument in 1913 that does not involve any opportunism at all.

---

109 Cf., e.g., the passage from a letter to Ehrenfest of November 1913 quoted on p. 801.

110 It would not be the last time that Einstein overhastily rejected a viable escape from the hole argument. The same thing happened in the fall of 1915 in correspondence with the Göttingen mathematician Paul Hertz. For a detailed reconstruction of this episode, see (Howard and Norton 1993).

Using the language of modern differential geometry,[111] one can say that a metric field, by assigning metrical properties to all points of the manifold, "dresses up" the "bare" manifold to become a spacetime. Before the manifold acquires it spatio-temporal properties from geometrical object fields such as the metric or the affine connection, it is not really a spacetime at all. Now two solutions, $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$, of some generally-covariant field equations—where $g'_{\mu\nu}(x)$ is generated from $g_{\mu\nu}(x)$ through Einstein's hole construction—dress up the bare manifold differently. Suppose $g_{\mu\nu}(x)$ dresses up the bare manifold points *p* and *q* inside the hole to become the spacetime points *P* and *Q* connected by a timelike geodesic. The metric field $g'_{\mu\nu}(x)$ will (in general) dress up *p* and *q* to become two different spacetime points that (in general) will not be connected by a timelike geodesic. So, if bare manifold points can be individuated independently of the metric field, $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ give different geodesics.[112] The antecedent of this conditional expresses a strong form of spacetime substantivalism. Given his Leibnizian-Machian relationist leanings, Einstein would of course have rejected such substantivalism, had he recognized it. But that recognition did not come until late 1915. So the above does provide us with a way to make sense of his comment in 1913 that Besso's escape fails "since with a solution a motion is also fully given." Since, on the tacit substantivalist assumption spelled out above, $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ give different geodesics, generally-covariant field equations do not seem to determine particle trajectories uniquely, just as they do not seem to determine the metric field uniquely.

The problem disappears the moment we accept that bare manifold points cannot be individuated independently of the metric field. Both $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ then turn the bare manifold into the same spacetime. It does not matter that $g_{\mu\nu}(x)$ dresses up the bare manifold points *p* and *q* to become the spacetime points *P* and *Q* connected by a timelike geodesic, whereas $g'_{\mu\nu}(x)$ will dress up some other bare manifold points *r* and *s* to become those same spacetime points *P* and *Q*. The bare manifold points *p, q, r,* and *s* only get their identity by becoming the spacetime points *P* and *Q*. The last time I checked, it was still an open question among philosophers of space and time whether this is a philosophically coherent account of identity and individuation.[113] But philosophical qualms aside, the above does seem to capture Einstein's response to the hole argument in his letters to Ehrenfest and Besso in December 1915–January 1916.[114]

111 I will phrase the argument using the kind of language that is used in discussions of the hole argument in modern philosophy of space and time. I am relying in particular on chap. 9 of (Earman 1989) on the hole argument, and on—various incarnations of—(Stachel 1993).

112 For example, $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ may have a timelike geodesic that is the same in both solutions outside the hole but then splits into two different ones inside the hole.

113 See, e.g., (Earman 1989, 196–199; Butterfield 1989, 21; and Maudlin 1990, 539). The basic problem is how to strike a balance between "thisness" and "suchness" in one's philosophical account of identity. In this area, Maudlin argued, Einstein could have learned a thing or two from Aristotle. Both Earman and Butterfield turn to more recent work, viz. (Adams 1979), for help with this difficult philosophical problem.

The point-coincidence argument plays an important role in these letters. It is easy to see why. Curves in the x^μ-coordinate system representing geodesics will be different inside the hole, depending on whether one uses $g_{\mu\nu}(x)$ or $g'_{\mu\nu}(x)$ to dress up the manifold with its spatio-temporal properties. By focusing on intersections of these geodesics (i.e., on point coincidences), however, one easily sees that there will be no observable differences. There is a one-one correspondence between the curves representing the geodesics in the picture based on $g_{\mu\nu}(x)$ and the curves representing the geodesics in the picture based on $g'_{\mu\nu}(x)$. One picture can be obtained from the other by a process of continuous deformation that preserves all point coincidences. Such point coincidences, Einstein suggested, exhaust the empirical content of the theory.[115] In an often reproduced diagram in his letter to Ehrenfest of 5 January 1916, Einstein illustrated this state of affairs with an example of null-geodesics originating from a star, going through an aperture, and then hitting a photographic plate. These considerations show that the metric fields $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ are empirically fully equivalent. Ontologically one still has indeterminism, but of an epistemologically totally harmless variety. If one rejects the tacit assumption from which the hole argument ultimately derives its apparent force (i.e., the assumption that bare manifold points have their identities independently of the geometrical object fields responsible for their spatio-temporal properties), the ontological indeterminism also disappears.

Given that Einstein did not have the notion of point coincidences in August 1913, one can understand why it would not have been easy for him to answer his own objection to Besso's proposed escape from the hole argument, even if he had tried. Given that the conclusion of the hole argument suited him just fine at the time, he probably did not try very hard. I therefore believe that the "Of no use"-comment in the Besso memo reflects both a genuine difficulty that Einstein saw in Besso's proposal and a certain impatience with Besso's criticism of a new and promising way to justify the limited covariance of the *Entwurf* field equations. In other words, I believe that the most plausible reconstruction of Einstein's dismissal of Besso's proposed escape from the hole argument is obtained by recognizing both the opportunistic element and the important conceptual gap between Besso's suggestion of 1913 and Einstein's resolution of the hole argument in late 1915.

For the record, I note that the notion of point coincidences is completely absent from the 1913–1914 portion of the new Besso material, whereas it is mentioned prominently on one of the pages from 1916. On the third page of the draft of his essay "The Relativity Principle in an Epistemological Formulation" (cf. pp. 790–791), Besso wrote in the margin:

---

114 See note 13 for exact references. These letters are quoted and commented on *at length* in (Stachel 1989, 86–88; Norton 1987, 168–184; and Howard 1999, 467–471). There is no need to quote them again here. It suffices to say that I subscribe to the view, shared by these three authors, that the point-coincidence argument should be seen not as signalling a retreat on Einstein's part to crude verificationism but as a vehicle for individuating spacetime points.

115 The proper length of the sections of geodesics between corresponding point coincidences will, of course, also be the same in the two pictures.

> What happens at the same place and at the same time—the spatiotemporal coincidence⟨s⟩—is the basic element of this kinematical world. 'at the same time and place' has absolute meaning; 'at the same time' or 'at the same place' alone do not.[116]

The reconstruction given above suggests that the notion of point coincidences was crucial to Einstein's resolution of the hole argument in late 1915. Kretschmann's paper, from which he presumably got this notion, must have come as a godsend. As was pointed out in (Howard and Norton 1993, 54): "What is extremely suggestive is that Kretschmann's paper appeared in an issue of the *Annalen der Physik* that was distributed on December 21, 1915, five days before the earliest of the surviving letters in which Einstein articulates the point-coincidence argument, his letter to Ehrenfest of December 26." It is true that Einstein had already made statements, both in print and in correspondence, about how his new generally-covariant theory robbed space and time of the last remnant of objective reality.[117] I think it is a mistake though to read the denial of the sort of spacetime substantivalism that gives the hole argument its apparent force into these statements.[118] They are much more naturally understood, I believe, in the light of Einstein's Machian commitments. Einstein thought that general covariance automatically meant full relativity of motion, an illusion he was disabused of sometime in 1916.[119] As late as July 1916, he still believed, for instance, that general relativity, simply by virtue of its generally-covariant field equations, finally provided the Machian account of rotation that had eluded him in the end with the *Entwurf* theory.[120] In November 1915 Einstein may have had some vague ideas about how to resolve the hole argument, but I very much doubt that he had articulated these ideas before Ehrenfest and Besso started pressing him on the issue or that he would have been able to articulate them had not Kretschmann's paper fallen into his lap at exactly the right time. If Einstein already had a fully worked-out escape from the hole argument when he replaced the *Entwurf* field equations by generally-covariant ones, it becomes hard to understand why he did not even mention the existence of such an escape in his papers of November 1915.

So Einstein published generally-covariant field equation without knowing exactly what was wrong with an argument that he had meanwhile published four times and

---

116 "Was am gleichen Orte und zur gleichen Zeit eintrifft—⟨die⟩ der zeiträumliche Coinzidenz⟨en⟩—ist das Grundelement dieser kinematischen Welt. Gleichzeitortlich hat absoluten Sinn; gleichzeitig allein, oder gleichortig allein hat keinen"

117 In the introduction of the paper on the perihelion motion presented on 18 November 1915, Einstein wrote about the assumption of general covariance "by which time and space are robbed of the last trace of objective reality" ("durch welche Zeit und Raum der letzten Spur objektiver Realität beraubt werden," Einstein 1915b, 831). In a letter to Schlick, he again wrote about general covariance that "[t]hereby time and space lose the last vestige of physical reality" ("Dadurch verlieren Zeit & Raum den letzter Rest von physikalischer Realität." Einstein to Moritz Schlick, 14 December 1915 [CPAE 8, Doc. 165]).

118 This interpretation is implied in (Stachel 1989, sec. 6).

119 See the editorial note, "The Einstein–De Sitter–Weyl–Klein Debate" (CPAE 8, 351–357), for further discussion. Cf. also note 86 above.

120 See the letter cited in note 66.

according to which generally-covariant field equations are physically unacceptable. On the face of it, this looks like another blatantly opportunistic move. Given that Einstein knew that Hilbert was hot on his trail, such opportunism would even be understandable. As in the case of his response to Besso's proposed escape in 1913, however, opportunism is not the whole story. Einstein may in fact have had good reason to believe that the hole argument had to be wrong by the time he published (Einstein 1915a), even if he could not quite put his finger yet on exactly where it went wrong.

This possibility is suggested by the close connection between the hole argument and so-called "coordinate restrictions."[121] This connection was first made by John Norton, who conjectures that the same sort of spacetime substantivalism that Einstein tacitly assumed in the hole argument was also responsible for Einstein's use of coordinate restrictions rather than coordinate conditions in the Zurich Notebook.[122] It is my belief that Einstein used coordinate restrictions in the Zurich Notebook simply because he did not yet have the modern understanding of coordinate conditions. No further explanation is needed. Consequently, I am skeptical about Norton's conjecture. It does suggest, however, that Einstein may well have realized something had to be wrong with the hole argument once he made the transition from coordinate restrictions to coordinate conditions.

A coordinate condition in the modern sense picks out (at least) one representative of each equivalence class of metric field configurations. Two metric field configurations are equivalent if they are merely different coordinate representations of what physically is one and the same field configuration. I want to emphasize two features of such coordinate conditions. First, a good coordinate condition picks a representative of each equivalence class of metric field configurations, no matter whether that field configuration is allowed by the field equations or not. It is not the job of the coordinate condition to decide which field configurations are allowed and which ones are not. That is the job of the field equations. Secondly, different coordinate conditions can be used for different problems. For example, the coordinate condition we use to show that the field equations have a sensible Newtonian limit need not be the same as the coordinate condition we use in deriving the exact solution for the case of a point mass.

The Zurich Notebook contains many examples of conditions that, at first sight, look like coordinate conditions. The role of these "coordinate conditions," however, is not clearly separated from the role of the field equations. Moreover, the freedom to apply different coordinate conditions in different contexts is not recognized. In several cases, Einstein rejected some candidate field equations because the "coordinate condition" used in showing that the equations had a sensible Newtonian limit ruled out, for example, the rotation metric. As these two observations illustrate, Einstein

121 For discussion of the difference between such coordinate restrictions and coordinate conditions in the modern sense, see also "Commentary …" (in this volume), e.g., the conclusion of sec. 5.5.4.

122 See "What was Einstein's fateful prejudice?" (in this volume).

treated these conditions as integral parts of the theories he was examining, on a par with the field equations, and not simply as a way of choosing a representation of the theory that would be convenient in a given context. The term "coordinate restrictions" was therefore introduced to distinguish these conditions from coordinate conditions in the modern sense.

In November 1915, Einstein's understanding of the role of coordinate conditions had become much closer to the modern understanding.[123] On the last page of (Einstein 1915a), Einstein first imposed the condition $\partial g^{\alpha\beta}/\partial x_\beta = 0$ to show that his new field equations had a sensible Newtonian limit and then, in the next paragraph, wrote that the theory allows transformations to rotating coordinate systems because rotations are part of the covariance group of the field equations. This is no longer true after the condition above is imposed. As Einstein presumably came to realize in the course of the research documented in the Zurich Notebook, $\partial g^{\alpha\beta}/\partial x_\beta \neq 0$ for the rotation metric. By November 1915, Einstein had apparently understood that this is not a problem at all. This suggests that he had essentially arrived at the modern understanding of coordinate conditions.

If Einstein did indeed have the modern understanding of coordinate conditions in November 1915, then he faced a very serious difficulty for the hole argument. Remember that a good coordinate condition picks out a representative of *every* equivalence class of metric field configurations. Hence, if the hole argument is valid, a good coordinate condition should *not* be selective between representations of *different* field configurations in the *same* coordinate system (such as $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x)$ related to one another through the hole construction); but it should be selective between representations of the *same* field in *different* coordinate systems (such as $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x')$). There is, however, a one-one correspondence between $g'_{\mu\nu}(x)$ and $g'_{\mu\nu}(x')$. So, if the hole argument is valid, coordinate conditions must do the impossible. Despite the one-one correspondence between $g'_{\mu\nu}(x)$ and $g'_{\mu\nu}(x')$, it must be selective between $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x')$, but not between $g_{\mu\nu}(x)$ and $g'_{\mu\nu}(x')$! Einstein may have sensed this absurdity[124] and may have concluded from it that the hole argument had to be wrong. A month or so later, he read (Kretschmann 1915) and was able to articulate exactly why the hole argument failed.

In the meantime, he had charged ahead and had published generally-covariant field equations, making it clear by doing so that he no longer believed in the hole argument but not explaining why not. There still is an element of opportunism in this. But it would have been foolish on Einstein's part to wait until he had found a fully satisfactory resolution of the hole argument. Just how tricky the hole argument is was illustrated forcefully a few years ago by the discovery of page proofs of Hilbert's first paper on general relativity (Corry et al. 1997). These page proofs suggest that even the

---

123 See "Untying the Knot" (in this volume), sec. 1.5 and sec. 5, for a reconstruction of how Einstein went from using coordinate restrictions to using coordinate conditions.

124 In the Berlin group analyzing the Zurich Notebook, we used to refer to this absurdity as "the Norton elephant" and we had lengthy discussions about whether or not Einstein swallowed the elephant.

great Göttingen mathematician originally fell hook, line, and sinker for the hole argument. There is still no consensus among philosophers of space and time exactly what the resolution of the hole argument is supposed to be. Einstein had more pressing business to take care of. He recognized that the *Entwurf* field equations were unacceptable and had to find new ones, preferably before Hilbert would. Pondering the niceties of the hole argument could be left for another occasion. Physics is not philosophy.

The upshot of this section then is that both in the 1913 chapter and in the 1915 chapter of the hole story we see a mixture of grappling with serious difficulties and a certain opportunism, the overhasty rejection of the escape from the hole argument proposed in the Besso memo in 1913, and the overhasty rejection of the hole argument itself in 1915. It is fair to say, however, that opportunism played a much smaller part in the hole story than in the rotation saga examined in sec. 3. I argued that there is an important difference between worldlines and intersections of worldlines and that the escape from the hole argument in the Besso memo of 1913 is therefore significantly different from the escape based on the point-coincidence argument of 1915. I also argued that Einstein may have recognized that the hole argument had to be wrong once he had reached the modern understanding of coordinate conditions in the fall of 1915 even though this did not tell him exactly where the argument went wrong.

5. EINSTEIN'S OPPORTUNISTIC STREAK AND THE CHARITY PRINCIPLE

In closing, I want to draw attention one more time to what I consider to be the most important feature of the story told in this paper. The story of Einstein's struggle with the problem of rotation and with the hole argument highlights what I have called, for lack of a better term, Einstein's opportunistic streak. This element is missing from current accounts of the genesis of general relativity.

In attempts to reconstruct Einstein's route to general relativity following the pathbreaking papers of John Stachel and John Norton in the 1980s (especially Stachel 1989 and Norton 1984), there has been a tendency to adopt a strong form of the so-called "charity principle." In practice, what this means is that one tries to reconstruct the development of Einstein's work starting from the strong presumption that he had good reasons for every move he made. So, to put it somewhat bluntly, whenever one encounters a passage containing what on the face of it looks like an error on Einstein's part, the strategy is to look for an interpretation in which the apparent error is the manifestation of some deep conceptual difficulty that had to be overcome before general relativity as we know it could be formulated.[125]

The two most impressive results of this approach were new much more satisfactory answers to two questions central to any reconstruction of Einstein's search for

125 In his classic 1984 paper, John Norton, for instance, explicitly stated that one of his major goals was to show that "Einstein's difficulties were based on nontrivial misconceptions and that the path he followed was a thoroughly reasonable one" (Norton 1984, 102). Certainly not all authors writing on Einstein these days adopt the charity principle. In fact, some are quite uncharitable. See, for instance, (Earman and Eisenstaedt 1999).

field equations for the metric field. The results are well known (Norton 1984, 101–102), but I nonetheless want to describe them briefly in order to bring out both the appeal and the danger of adopting the charity principle in this context. The two (pairs of) questions are the following. First, why did Einstein originally reject field equations based on the Ricci tensor and what made him eventually change his mind? Second, what exactly was Einstein's hole argument against general covariance and how did he overcome this argument in the end? In the older literature (see, e.g., Pais 1982, 221–223, 244, 251–252), the answers to these questions essentially turn on ascribing an elementary blunder to Einstein. The big stumbling block, the story went, was that Einstein did not fully appreciate that one and the same metric field can be represented in different coordinates. He initially believed that such different coordinate representations correspond to physically different field configurations. This, the story continued, had two dire consequences. First, Einstein did not recognize the freedom to apply coordinate conditions and had to reject the Ricci tensor because it apparently did not reduce to the Laplace equation of Newtonian theory in the special case of weak static fields. Secondly, it led Einstein to believe that a generally-covariant theory would be indeterministic, as illustrated in the hole argument. After the big stumbling block was removed, the story concluded, Einstein realized that the Ricci tensor was acceptable after all and that the indeterminism in the hole argument was completely illusory.

Might there not be more charitable answers to the questions under consideration? Of course, we now know there are.[126] As John Stachel first suggested, Einstein did not mistake the existence of different coordinate representations of the same metric field configuration for indeterminism, he only used these different coordinate representations to construct what look like genuinely different field configurations in one and the same coordinate system (cf. the discussion on p. 822 above). Consequently, Stachel argued, Einstein had to make an important conceptual leap to remove the apparent indeterminism revealed in the argument: he had to recognize that spacetime points cannot be individuated independently of the metric field. Similarly, we now know that Einstein's rejection of and eventual return to the Ricci tensor can be given a much more charitable interpretation. As John Norton argued, following another suggestion of John Stachel, the problem with the Ricci tensor and the Newtonian limit was not that Einstein did not know about coordinate conditions; the problem was that the relevant coordinate condition ruled out the simple form that Einstein mistakenly but quite naturally expected the metric field to take in the case of weak static fields. Once the calculations on the perihelion motion of Mercury in November 1915 made it clear that this expectation was not warranted, Einstein promptly returned to the Ricci tensor.

Both Stachel and Norton made extensive use of textual evidence, both published and unpublished, to argue for their new answers and against the old answers to the various questions at issue. A close reading of the various published versions of the

---

126 The great virtue of these new answers that is emphasized in the introductions of both (Norton 1984) and (Stachel 1989) is, in fact, that one no longer has to attribute trivial errors to Einstein.

hole argument, for instance, shows that the final version is compatible only with Stachel's more charitable interpretation of Einstein's reasoning. In more spectacular fashion, John Norton conclusively disproved the old interpretation of Einstein's problem with the Ricci tensor and the Newtonian limit by producing a page of the Zurich Notebook (p. 19L) containing a calculation formally identical to the application of a coordinate condition reducing the Ricci tensor to the Laplace equation for weak static fields. When one adds to this the enormous impact that the historical work on the hole argument has had in the philosophy of space and time literature, one readily understands why several historians of relativity, myself included, adopted the charity principle without too much critical reflection in further work on this fascinating episode.

Why have I nonetheless grown suspicious of the charity principle? For two reasons. The first is that there is a real danger that, in searching for charitable interpretations of Einstein's writings, one reads modern results back into these texts. John Norton's use of p. 19L of the Zurich Notebook to demonstrate that Einstein knew perfectly well about coordinate conditions provides a case in point, a case all the more instructive for its subtlety. The further analysis of the Zurich Notebook reported in this volume strongly suggests that Einstein did not yet have the modern understanding of coordinate conditions when he did the calculation on p. 19L after all. It now seems plausible that this lack of understanding played a much more important a role in Einstein's rejection of the Ricci tensor than his preconceptions concerning the form of the metric for weak static fields.[127]

The story told in this paper brings out a second and, at least to my mind, more serious danger of adopting the charity principle in reconstructing Einstein's route to general relativity. When one is not careful, one easily ends up with a seriously distorted view of Einstein's *modus operandi*. It is fair to say, I think, that the charity principle, as used in the tradition of Stachel and Norton, rests in part on the conviction that scientists like Einstein working on fundamentally new theories proceed in accordance with very strict standards of rationality, the kind one would expect, for instance, of a modern philosopher of science. Obviously I am in no position to spell out these standards. Fortunately I do not have to. What I hope to have shown in this paper is that at various points on his path to general relativity, Einstein made moves that can clearly and noncontroversially be recognized as blatant violations of such standards. Einstein's handling of the problem of rotation probably provides the most clear-cut example. For most of the life-span of the *Entwurf* theory, it was crucial for Einstein's goal of giving a Machian account of rotation that the rotation metric be a vacuum solution of the *Entwurf* field equations. Yet, for about two years, he never bothered to do a simple calculation with sufficient care to determine once and for all whether this was the case or not. Instead, his beliefs on this score appear to have been guided by wishful thinking, strong enough to ignore warning signs that something was wrong. In a historically accurate and well-balanced picture of how Einstein arrived at general relativity, these aspects of Einstein's work cannot be ignored.

---

127 See "Untying the Knot" (in this volume), sec. 1.1.

What is at stake here is not just a matter of historical accuracy in this particular case. Presumably, an important motivation for studying the case of Einstein and general relativity is that it may tell us something more general about the way in which new scientific theories are produced. One of the morals of this paper then is that the model that implicitly underlies the charity principle of scientists having logically cogent reasons for every move they make needs to be modified. As I suggested at the end of sec. 3, creative science may need a healthy dose of opportunism.

Even those readers who share my worries about the charity principle may feel, given the impressive results achieved with the help of it, that the dangers do not outweigh the benefits. I therefore want to make one final observation, namely that the charity principle deserves only part of the credit for these results. The most important factor behind the successes of Stachel and Norton was undoubtedly their ability and willingness to examine in unprecedented detail all relevant source material available to them. Their findings confirmed their strong suspicions that earlier historians had been too quick to attribute basic errors to Einstein. A new picture emerged in which the development of general relativity became predominantly a matter of Einstein struggling with subtle conceptual issues. Further evaluation of the source material augmented by important new archival findings such as the Besso memo discussed in this paper have modified that picture. The charity principle has become somewhat of a hindrance at this stage of the game, and we can easily do without it. That way we shall be better prepared to recognize aspects of Einstein's *modus operandi* that do not fit the model of scientific theorizing it presupposes.

NOTE ADDED IN PROOF

Since I wrote this paper, one more document that bears on the problem of rotation has come to light. A. J. Kox has alerted me to a letter that Paul Ehrenfest wrote to H. A. Lorentz in August 1913, shortly before the Besso Memo discussed in this paper.[128] The letter contains the following intriguing passage:

> It would also be nice at some point to check the calculation of the gravitational effects connected to rotational motion (constant angular velocity around a fixed axis). Five or six times Einstein has done this now—calculational errors have produced a different result almost every time: the Coriolis force came out correctly, but not the centrifugal force. To this day he still does not know whether this is merely the result of a calculational error or of a fundamental impossibility.[129]

The problem alluded to by Ehrenfest is basically the same as that recorded in the Besso Memo: the rotation metric—the Minkowski metric in rotating coordinates—is

128 Ehrenfest dated this letter 10 August 1913. The letter, however, is in response to a letter from Lorentz of 14 August 1913. Lorentz, in turn, responded to Ehrenfest's letter on 24 August 1913. Hence, the letter must have been written sometime between the 15th and the 23rd. I am grateful to A. J. Kox for alerting me to this letter, for providing me with a transcription, and for the information about its dating.

not a vacuum solution of the *Entwurf* field equations (for a more detailed exegesis, see the beginning of sec. 3).

How does the Ehrenfest letter affect the argument of my paper? First of all, it provides further evidence that the date on the Besso Memo was not just a slip on Besso's part. The possible dates for the letter, 15–23 August 1913, are remarkably close to the date on the memo, 28 August 1913. Second, the letter shows that by the middle of August Einstein was already aware of the trouble with rotation. In the paper I suggested that it was Besso who alerted him to the problem. In view of this letter, however, it is a definite possibility that Besso simply recorded the problem as explained to him by Einstein, as I conjectured he did in the case of the hole argument (see sec. 4). Third, since the letter makes it clear that Einstein had spent considerable time and effort on the problem of rotation, the question arises what, if anything, he might have been doing besides performing "five or six times" the relatively simple calculation mentioned in the Besso memo and found both in the 1913 portion of the Einstein-Besso manuscript (CPAE 4, Doc. 14, [pp. 41–42]) and on the 1915 Naumann draft (CPAE 8, Doc. 124)? The only two items I am aware of that may contain clues to answer this question are the calculation on [pp. 43–44] of the Einstein-Besso manuscript (the purpose of which remains unclear) and the calculation on the verso of the Naumann draft (see note 69). Both calculations break off before Einstein reached any definite conclusions. There is thus no evidence of a concerted effort on Einstein's part to find an escape from the problem of rotation. This then leads me to the fourth, and for the purposes of this paper, most important conclusion. If, as Ehrenfest's remarks suggest, by August 1913 Einstein had checked "five or six times" whether the rotation metric is a vacuum solution of the *Entwurf* field equations, finding "a different result almost every time," it becomes all the more astonishing that he was able to convince himself in early 1914 that the rotation metric is a solution and that it took him until September 1915 to establish that it is not. The Ehrenfest letter thus provides striking additional evidence for the opportunistic streak in Einstein's *modus operandi*.

ACKNOWLEDGMENTS

First of all, I want to express my gratitude to the Besso family for granting me permission to quote from the pages in the Besso *Nachlass* that form the basis for this paper and to reproduce two of these pages in facsimile. I am indebted to Robert Schulmann, who alerted me to the existence of this material in the late summer of 1998, and to Urs Schoepflin, for his tireless efforts to make the material available.

---

129 "Schön wäre auch noch gelegentlich die Gravitationierung der rotierenden Bewegung (constante Winkelgeschw. um feste Axe) nachzurechnen. Fünf oder sechsmal hat es Einstein gemacht — Rechenfehler haben fast jedesmal ein anderes Resultat ergeben: die Corioliskraft kam gut heraus, nicht aber die Centrifugalkraft. Er weiss noch bis heute nicht ob ein blosser Rechenfehler vorliegt oder eine wesentliche Unmöglichkeit." Paul Ehrenfest to H. A. Lorentz, before 24 August 1913 (Kox Forthcoming, Letter 278).

John Norton is largely responsible for the format of my paper by relentlessly pressing me for answers to various questions raised by accepting the date on the Besso memo. I would not have had answers to these questions, had not Robert Schulmann opened my eyes to Einstein's opportunistic streak. I also benefited from numerous discussions over the years with my co-authors of this volume, John Norton, Jürgen Renn, Tilman Sauer, and John Stachel, especially about the relation between "coordinate restrictions" and the hole argument and about the notion of "non-autonomous transformations." I would like to thank Matthias Schemmel for making me see the importance of Einstein's letter to Mach of December 1913. My former colleagues at the Einstein Papers Project, Christoph Lehner and Robert Schulmann, patiently answered requests to check this or that document, and offered many helpful suggestions. An embryonic version of this paper was presented at the Fifth International Conference on the History and Foundations of General Relativity (HGR5) held at the University of Notre Dame in June 1999. Further work on it was supported by the Max Planck Institute for the History of Science in Berlin. *Dea mea invita, opus conficere non poteram.*

UNTYING THE KNOT: HOW EINSTEIN FOUND HIS WAY BACK TO FIELD EQUATIONS DISCARDED IN THE ZURICH NOTEBOOK

"She bent down to tie the laces of my shoes. Tangled up in blue."
—Bob Dylan

1. INTRODUCTION: NEW ANSWERS TO OLD QUESTIONS

Sometimes the most obvious questions are the most fruitful ones. The Zurich Notebook is a case in point. The notebook shows that Einstein already considered the field equations of general relativity about three years before he published them in November 1915. In the spring of 1913 he settled on different equations, known as the "*Entwurf*" field equations after the title of the paper in which they were first published (Einstein and Grossmann 1913). By Einstein's own lights, this move compromised one of the fundamental principles of his theory, the extension of the principle of relativity from uniform to arbitrary motion. Einstein had sought to implement this principle by constructing field equations out of generally-covariant expressions.[1] The *Entwurf* field equations are not generally covariant. When Einstein published the equations, only their covariance under general linear transformations was assured. This raises two obvious questions. Why did Einstein reject equations of much broader covariance in 1912-1913? And why did he return to them in November 1915?

1 Throughout the period covered by this paper, Einstein thought that general covariance automatically extends the principle of relativity from uniform to arbitrary motion. In part, this was because he did not distinguish carefully, for reasons laid out in (Norton 1999), between the roles of Lorentz invariance in special relativity and of general covariance in general relativity. In part, as is argued in (Janssen 2005), it was just a matter of misleading terminology. Einstein chose to describe a key feature of his new theory—i.e., observers in arbitrary motion with respect to one another can both maintain to be at rest as long as they agree to disagree about whether or not there is a gravitational field—in terms of general relativity of motion, whereas what is relative is not so much the motion but the split of inertio-gravitational effects into inertial and gravitational components. As Einstein put it in 1920: "Like an induced electric field, the gravitational field at a particular point only has a relative existence" ("Das Gravitationsfeld hat an einem betrachteten [Punkte] in ähnlicher Weise nur eine relative Existenz wie das durch magnetelektrische Induktion erzeugte elektrische Feld." CPAE 7, Doc. 31, [p. 21]).

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 2
Einstein's Zurich Notebook: Commentary and Essays.

A new answer to the first question has emerged from the analysis of the Zurich Notebook presented in this volume. This calls for a reassessment of Einstein's subsequent elaboration of the *Entwurf* theory and of the transition to the theory of November 1915. On the basis of a reexamination of Einstein's papers and correspondence of this period, we propose a new answer to the second question.

For the discussion of these matters, it is important to distinguish between two strategies for finding suitable gravitational field equations, a 'physical strategy' and a 'mathematical strategy'. Following the physical strategy, one constructs field equations in analogy with Maxwell's equations, making sure from the start that energy-momentum conservation is satisfied and that the Poisson equation of Newtonian theory is recovered in the case of weak static fields. This is the approach that originally led Einstein to the *Entwurf* field equations. Following the mathematical strategy, one picks candidate field equations based largely on considerations of mathematical elegance and then investigates whether they make sense from a physical point of view.[2] With hindsight, one easily recognizes that the latter approach provides a royal road to the generally-covariant field equations of November 1915. Einstein himself used a combination of the two strategies. In the Zurich Notebook, he tried the mathematical strategy first, ran into what appeared to be insurmountable difficulties, switched to the physical strategy, and ended up with the *Entwurf* field equations. On that much all scholars working in this area agree. The question is what Einstein did in late 1915. The currently standard answer is that he abandoned the physical strategy, went back to the mathematical strategy prematurely abandoned in the Zurich Notebook, and in short order produced the happy results of November 1915.[3] With very few exceptions, Einstein's pronouncements—both at the time and in retrospect years later—fit very well with this answer.

As the title of our paper suggests, however, we see no abrupt change of strategy in 1915. Our metaphor is not "cutting the knot" but "untying the knot." We argue that Einstein found the field equations of general relativity by changing one element in a formalism he had developed in 1914 encoding the various physical considerations that had gone into the derivation of the *Entwurf* field equations. He picked a new mathematical object, known as the Christoffel symbols, to represent the gravitational field. This one modification, it turned out, untangled the knot of conditions and definitions that his theory had become in 1914–1915. We thus argue that the field equations of general relativity were the fruit of Einstein's relentless pursuit of the physical strategy. That is not to say that the mathematical strategy did not play any role at all. Without it Einstein would not have recognized that his new definition of the gravitational field was the key to the solution of his problem of finding suitable field equations. What happened in 1915 was that the physical strategy led Einstein back to field

2 For more careful discussion of the distinction between the 'mathematical strategy' and the 'physical strategy', see secs. 1.1 and 5.1 of "Commentary …" (in this volume).

3 See, e.g., (Norton 1984, 142), (Janssen 1999, 151), (Van Dongen 2002, 30). The most explicit version of this account is given in (Norton 2000). We shall have occasion to quote some typical passages from this paper in sec. 10.

equations to which the mathematical strategy had already led him in the Zurich Notebook but which he had then been forced to reject since he could not find a satisfactory physical interpretation for them. With two routes to the same field equations, Einstein had the luxury of a choice in how to present them to the Berlin Academy. He went with the mathematical considerations, which he turned into a simple and effective argument for his new field equations. It would have been much more complicated and less persuasive to opt for an exposition faithful to the arduous journey he himself had been forced to undertake only to discover in the end that equations he had considered very early on were the right ones after all.[4] In the context of discovery, the physical argument had been primary and the role of the mathematical argument had been to reinforce that argument. In the context of justification, it was just the other way around. Einstein gave pride of place to the mathematical argument and used elements from his physical argument only to show that his new field equations were perfectly acceptable on physical grounds. Once the mathematical route to the field equations had been reified in his first communication to the Berlin Academy of November 1915, the physical route rapidly faded from memory. The streamlined argument of the context of justification quickly supplanted the messy reasoning of the context of discovery. Einstein succumbed to a typical case of selective amnesia. Before long he had eyes only for the mathematical strand in his reasoning and had lost sight of the physical strand altogether.[5]

In the remainder of this introduction, we give an outline, as non-technical as possible, of our new understanding of the path that took Einstein away from generally-covariant field equations and back again in the period 1912–1915. The emphasis will be on the second part of this fascinating tale. The case for our new reconstruction is strong but largely circumstantial. We shall highlight the most important pieces of evidence in the introduction, so that the reader can judge for him- or herself how well our reconstruction is supported by the documents without having to go through the detailed calculations that make up the balance of the paper.[6]

1.1 Tying the Knot: Coordinate Restrictions

The central problem frustrating Einstein's search for generally-covariant field equations in the Zurich Notebook was his peculiar use of what a modern relativist would immediately recognize as coordinate conditions. One needs to impose such conditions, which the metric tensor has to satisfy in addition to the field equations, if one wants to compare equations of general relativity, which are valid in arbitrary coordinates, to equations in Newtonian gravitational theory, which in their standard form

4 A paper written by one of us (JR) which we have cannibalized for this paper was therefore called "Progress in a Loop."

5 Jeroen van Dongen (2002, 46–47) has emphasized that Einstein's selective memory only served him all too well in his later years in his defense of relying on a purely mathematical strategy in the search for a unified field theory.

6 For a short version of our account, see (Janssen 2005, 75–82).

are valid only in inertial frames. In particular, one needs a coordinate condition to show that the relevant component of the generally-covariant field equations of general relativity reduces to the Poisson equation of Newtonian theory in the case of weak static fields (see, e.g., Wald 1984, 75–77).[7] Such conditions are not essential to the theory. One can pick whatever coordinate condition is most convenient for the problem at hand. From a modern point of view this is trivial and there would be no point in spelling it out, if it were not for the fact that Einstein's use of such additional conditions both in the Zurich Notebook and in his subsequent elaboration of the *Entwurf* theory deviated sharply from our modern use.

As Einstein was examining various generally-covariant expressions in 1912-1913 to determine whether physically acceptable field equations could be extracted from them, he assumed that he needed additional conditions not just to recover the Poisson equation for weak static fields but also to guarantee that the equations be compatible with the law of energy-momentum conservation.[8] In general relativity energy-momentum conservation is a direct consequence of the general covariance of the Einstein field equations (see Einstein 1916c and sec. 9). This result is an instantiation of one of Emmy Noether's celebrated theorems connecting symmetries and conservation laws (Noether 1918).[9] In 1912–1913, however, Einstein thought that energy-momentum conservation required that the covariance of the field equations be restricted. In the Zurich Notebook he did not make a clear distinction between conditions imposed to guarantee energy-momentum conservation and conditions imposed to recover the Poisson equation for weak static fields. On the contrary, once he had found a condition that accomplished the latter, he would investigate what further conditions, if any, were needed for the former.[10]

Einstein used these conditions to eliminate various terms from equations of broad covariance and looked upon the truncated equations of severely restricted covariance rather than upon the equations of broad covariance he started from as candidates for the fundamental field equations of his theory. Since coordinate conditions used in this manner are ubiquitous in the Zurich Notebook we introduced a special name for them. We call them *coordinate restrictions*.[11]

---

7 Einstein originally imposed the stronger requirement that this would be the only non-trivial component of the field equations in the case of weak static fields. This was because he assumed that the metric for a weak static field must be spatially flat. It was only in November 1915 that he came to realize that this is not necessary (see p. 891 below).

8 This is a lesson Einstein had learned the hard way earlier in 1912 when he had been forced to modify the field equations of his theory for static gravitational fields because the original equations violated energy-momentum conservation (Einstein 1912, sec. 4). For further discussion, see "Pathways out of Classical Physics …" (in vol. 1 of this series).

9 For careful discussion of Noether's theorems and some simple but informative applications of them, see (Brading 2002); for a discussion of how they emerged from the discussion of general relativity in Göttingen, see (Rowe 1999), (Sauer 1999), and "Hilbert's Foundation of Physics …" (in vol. 4 of this series). For a concise discussion of Einstein's ideas about energy-momentum conservation in the period 1912–1918, see sec. VIII of the introduction to CPAE 8.

10 This approach is clearly in evidence on pp. 19L–20L of the Zurich Notebook.

This notion is the key to understanding why Einstein did not publish field equations based on the Riemann tensor in 1913. He recognized that the Riemann tensor—or rather the Ricci tensor, a direct descendant of it—was the natural starting point for finding field equations, but he had great difficulty finding coordinate restrictions that would guarantee compatibility with energy-momentum conservation even in first approximation. Moreover, none of the coordinate restrictions with which he could recover the Poisson equation for weak static fields left him enough covariance to implement the equivalence principle and the generalized principle of relativity.[12]

So towards the end of the notes on gravity in the Zurich Notebook, Einstein switched from the mathematical to the physical strategy. Instead of starting from a mathematical object such as the Ricci tensor with well-defined covariance properties, he now started from the physical requirements that the Poisson equation be recovered for weak static fields and that energy-momentum conservation be satisfied. Instead of demanding broad covariance, he only demanded covariance under general linear transformations.[13] From these requirements he derived the equations that would serve as the fundamental field equations of his theory without bothering to find the generally-covariant equations of which these equations would be the truncated version or the coordinate restriction with which to do the truncating. Einstein convinced himself that this procedure led to a unique result: the *Entwurf* field equations.

---

11 See secs. 4.1 of "Commentary …" (in this volume). There is no agreement among the authors of this volume as to why Einstein used coordinate restrictions. The majority view is that Einstein at the time did not yet have the modern understanding of coordinate conditions. John Norton, however, argues that Einstein did have the modern understanding all along and offers a different explanation for why he nonetheless chose to use coordinate restrictions instead (see "What was Einstein's 'Fateful Prejudice'?" [in this volume]). The story we tell in this paper is compatible with both views. This is an indication of how difficult it is to decide between them. John Norton argues that it boils down to one's view of Einstein's *modus operandi*. For the record, we share the view presented in "What Did Einstein Know …" (in this volume).

12 John Norton (1984, 102, 111–112, 142-143) argued that the incompatibility of the harmonic coordinate condition with the spatially flat metric that Einstein thought should describe weak static fields plays a crucial role both in Einstein's rejection of field equations based on the Ricci tensor in 1912–1913 and in his choice of new field equations in the first paper of November 1915 (Einstein 1915a). We seriously doubt whether Einstein was even aware of this incompatibility either at the time of the Zurich Notebook or in November 1915. We see no evidence that this incompatibility played any role in Einstein's search for gravitational field equations (cf. sec. 5.4 of "Commentary …" [in this volume] and the conclusion of sec. 5 below). Einstein's prejudice about the form of the metric for weak static field, for which there is abundant textual evidence, did play a role—as Norton (1984, 146–148) also emphasized—in that it was incompatible with field equations containing a term with the trace of the energy-momentum tensor of matter. Aside from general covariance, this trace term is the most important feature distinguishing the Einstein field equations from their *Entwurf* counterpart (see sec. 7 and the appendix).

13 Einstein's hope was that the equations would also be invariant under what he later called "non-autonomous" transformations to accelerating frames of reference. See sec. 3.3 below for discussion of the concept of non-autonomous transformations.

1.2 Tightening the Noose: Covariance Properties of the Entwurf Field Equations

Einstein's further elaboration of the *Entwurf* theory in 1913–1914 centered on clarifying the covariance properties of the *Entwurf* field equations. In August 1913, he produced an argument purporting to show that because of energy-momentum conservation the equations' covariance group had to be limited to general linear transformations. This argument was published in an addendum to the journal version of the *Entwurf* paper (Einstein and Grossmann 1914a). Within a few months, Einstein realized that it was based on a faulty premise.[14] The idea that energy-momentum conservation circumscribes the covariance of the field equations nonetheless survived. In the same paper in which he retracted his fallacious argument (Einstein and Grossmann 1914b), he and Grossmann presented a new argument tying the covariance of the *Entwurf* field equations to energy-momentum conservation. With Noether's theorems still four years into the future, Einstein's intuition that energy-momentum conservation is closely related to the covariance of the field equations is quite remarkable. It will play a crucial role in our story.

Einstein and Grossmann (1914b) found four conditions, compactly written as $B_\mu = 0$, that in conjunction with the *Entwurf* field equations imply energy-momentum conservation. They then used a variational formalism to show that these same conditions determine the covariance properties of the *Entwurf* field equations. Einstein thought that these conditions were the coordinate restriction with which the *Entwurf* field equations could be extracted from generally-covariant equations.[15] He had no interest in finding the latter, since his infamous 'hole argument' had meanwhile convinced him that the field equations could not possibly be generally covariant.[16] In fact, Einstein and Grossmann claimed that the four conditions they had found gave the field equations the maximum covariance allowed by the hole argument. With these results, the theory appeared to have reached its definitive form.

In the spring of 1914, Einstein left Zurich and Grossmann and moved to Berlin. In October 1914, nearly three months into the Great War, he completed a lengthy review article on his new theory, no longer called "a general*ized* theory of relativity" (Einstein and Grossmann 1913) but "the *general* theory of relativity" (Einstein 1914c). In this article, he reiterated and tried to improve on the results of his second paper with Grossmann. He now used the variational formalism to deal both with the covariance properties of the field equations and with energy-momentum conservation. And he did so without specifying the Lagrangian ahead of time as he had done in the paper with Grossmann. He only assumed that the Lagrangian transforms as a scalar under

---

14 For discussion of this episode, see (Norton 1984, sec. 5), "Pathways out of Classical Physics …" (in vol. 1 of this series), and sec. 2 of "What Did Einstein Know …" (in this volume).

15 Einstein (1914b, 178) believed that there is a corresponding generally-covariant equation for any physically meaningful equation that is not. See note 57 below for the relevant passage.

16 For a discussion of (the origin of) the hole argument, see sec. 4 of "What Did Einstein Know …" (in this volume).

general linear transformations. He found that a generic version of the set of conditions he had found with Grossmann, still written as $B_{\mu} = 0$, is necessary both for the covariance of the field equations and for their compatibility with energy-momentum conservation. Energy-momentum conservation, however, called for an additional set of conditions, compactly written as $S_{\sigma}^{\nu} = 0$. Einstein believed that these extra conditions uniquely picked out the Lagrangian giving the *Entwurf* field equations. As a matter of fact they do no such thing.

1.3 At the End of His Rope: The Demise of the Entwurf Field Equations

In early 1915, the Italian mathematician Tullio Levi-Civita contested some of the results of Einstein's review article but Einstein did not give ground.[17] Curiously, Levi-Civita did not take aim at Einstein's uniqueness argument, even though his interest in Einstein's article had been triggered by a letter from Max Abraham complaining about the arbitrariness of Einstein's choice of the Lagrangian (Cattani and De Maria 1989, 185). It was not until October 1915 that Einstein himself realized that his uniqueness argument was illusory. This setback came hard on the heels of another one. He had discovered that the *Entwurf* field equations are incompatible with one of the guiding ideas of the theory—the idea that the inertial forces of rotation can be conceived of as gravitational forces. Michele Besso had already put his finger on this problem two years earlier, but Einstein had ignored his friend's warnings.[18] He finally faced up to the problem in September 1915.

In a letter to H. A. Lorentz of October 12, 1915 (CPAE 8, Doc. 129), Einstein explained where his uniqueness argument went wrong. The extra conditions $S_{\sigma}^{\nu} = 0$ that he had used to determine the Lagrangian are trivially satisfied by any Lagrangian invariant under general linear transformations. So both sets of conditions—$B_{\mu} = 0$ and $S_{\sigma}^{\nu} = 0$—needed for energy-momentum conservation also emerge from the analysis of the theory's covariance properties. From a modern point of view, this is just an instance of one of Noether's theorems. If one sets the Lagrangian in Einstein's variational formalism equal to the Riemann curvature scalar, as Einstein (1916c) himself would do the following year, the four conditions $B_{\mu} = 0$ become the contracted Bianchi identities.

1.4 Pulling a Thread: from the Entwurf Field Equations to the November Tensor and the Einstein Field Equations

Despite the problem of rotation and the evaporation of the uniqueness argument, Einstein was not ready to part with the *Entwurf* field equations just yet. He told Lorentz that they are still the only equations that allow one to recover the Poisson equation for weak static fields. Just a few weeks later, however, on November 4, 1915, he submit-

17 See the correspondence between Einstein and Levi-Civita in March–May 1915 in (CPAE 8).

18 For discussion of Einstein's struggles with the problem of rotation in 1913–1915, see sec. 3 of "What Did Einstein Know …" (in this volume) and (Janssen 2005, 68–71).

ted a short paper to the Berlin Academy in which he replaced the *Entwurf* field equations by equations based on the Riemann tensor. He had examined and rejected these exact same equations three years earlier in the Zurich Notebook. Three more short communications to the academy followed in rapid succession, two of them with further modifications of the field equations (Einstein 1915b, d) and one on the perihelion motion of Mercury (Einstein 1915c). By the end of November, Einstein had thus arrived at the generally-covariant field equations that still bear his name and he had solved an outstanding puzzle in planetary astronomy.

What happened those last few weeks of October? Einstein has left us some tantalizing clues. In the first November paper, he singled out one element and called it "a fateful prejudice."[19] In a letter written later that month, shortly after the dust had settled, he wrote that changing that one element had been "the key to [the] solution."[20] The element in question is the definition of the components of the gravitational field. In the *Entwurf* theory, they are essentially just the derivatives of components of the metric field. This is the straightforward generalization of the definition of the gravitational field in Newtonian theory as the gradient of the gravitational potential. In Einstein's theory the components of the metric field play the role of the gravitational potentials. In the final version of the theory, the gravitational field is represented by the so-called Christoffel symbols. The Christoffel symbols consist of a sum of three terms with derivatives of the metric. These objects play an important role in Riemannian geometry. They also occur in the geodesic equation, which makes them the natural candidates for representing the gravitational field. Surprisingly from a modern point of view, the first November paper is the first place where Einstein actually makes this observation. Why did he put so much emphasis all of a sudden on the definition of the gravitational field?[21]

In the *Entwurf* theory, both the field equations and the equation for energy-momentum conservation were originally formulated in terms of the metric, the quantity representing the gravitational potentials, not in terms of the quantity representing the gravitational field.[22] Einstein, however, also tried to write both equations in terms of the field. In this form, the analogy between the *Entwurf* theory and electrodynam-

19 "ein verhängnisvolles Vorurteil" (Einstein 1915a, 782). Cf. note 38 below.

20 "Den Schlüssel zu dieser Lösung …" Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153). Cf. note 39 below.

21 Without the analysis of the Zurich Notebook presented in this volume, Einstein's remarks about the definition of the gravitational field have, as John Norton (1984, 145) put it, "all the flavor of an after-the-fact rationalization." Norton was also right in that these comments do not help us understand why Einstein turned his back on equations extracted from the Riemann tensor in 1913.

22 As John Stachel points out in "The Story of Newstein …" (in vol. 4 of this series), this is in part because Einstein had to make do with the mathematics available to him. Far from providing all the tools he needed, differential geometry at the time still lacked the concept of an affine connection, which is a much more natural object than the metric to describe the inertio-gravitational field of general relativity. The absence of the notion of parallel displacement and the concept of an affine connection also tripped up H. A. Lorentz in 1916 when he tried to give a coordinate-free formulation of general relativity (Janssen 1992).

ics, which Einstein had consciously pursued in constructing the theory,[23] was brought out more clearly. This in turn made the physical meaning of the equations more perspicuous.

In August 1913, Einstein had found that the *Entwurf* field equations can be written in the form of Maxwell's equations, with the four-divergence of the field on the left-hand side and the field's sources—the sum of the energy-momentum densities of matter and gravitational field[24]—on the right-hand side (Einstein 1913, 1258, eq. 7b). He had written the equations in this form ever since.[25] In the Zurich Notebook he had already noticed that the term representing the gravitational force density in the energy-momentum balance equation can be interpreted as an inner product of the field and its sources, just like the Lorentz force that some extended charge distribution experiences from its self-field. Most importantly, in his review article of 1914, Einstein wrote the Lagrangian for the *Entwurf* field equations in terms of the components of the gravitational field (Einstein 1914c, 1076, note 1). The *Entwurf* Lagrangian is the same quadratic expression in the field as the Lagrangian for the free Maxwell field. These structural similarities to electrodynamics—in the field equations and in the expressions for the force density and the Lagrangian—carry over from the *Entwurf* theory to the theory of the November 1915 papers if the components of the gravitational field are redefined as the Christoffel symbols.[26]

In view of this continuity, Einstein's remark that the new definition of the gravitational field was "the key to the solution" suggests a natural pathway along which, sometime during the second half of October 1915, Einstein found his way back to field equations of broad covariance discarded three years earlier in the Zurich Notebook.

Not long after his letter to Lorentz of October 12, Einstein must have come to accept that the problem of rotation was the nemesis of the *Entwurf* field equations (Janssen 1999). He needed new field equations or rather a new Lagrangian from which such new equations could be derived. His variational formalism would give him the conditions to guarantee compatibility with energy-momentum conservation.

---

23 For further discussion of the role of this analogy, see "Pathways out of Classical Physics …" (in vol. 1 of this series).

24 Because of the equivalence of energy and mass (inertial and gravitational) it is clear that the gravitational field contributes to its own source. This, of course, is a major disanalogy between the gravitational field equations and Maxwell's equations. For one thing, unlike Maxwell's equations, the gravitational field equations will not be linear in the components of the field.

25 See, e.g., (Einstein 1914a, 289, eq. 5), (Einstein 1914b, 179, eq. 6), (Einstein and Grossmann 1914b, 217, eq. II), and (Einstein 1914c, 1077, eq. 81). For the original form of the *Entwurf* field equations, see (Einstein and Grossmann 1913, 15–17, eqs. 13–16, 18, and 21).

26 Both in the *Entwurf* theory and in the theory of the first November paper, the Lagrangian has the form $g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}$, where $\Gamma^{\beta}_{\alpha\nu}$ are the components of the gravitational field. In the *Entwurf* theory, $\Gamma^{\beta}_{\alpha\nu} \equiv \frac{1}{2}g^{\beta\tau}g_{\tau\alpha,\nu}$, in the first November paper, $\Gamma^{\beta}_{\alpha\nu} \equiv -\begin{Bmatrix} \beta \\ \alpha\nu \end{Bmatrix} \equiv -\frac{1}{2}g^{\beta\tau}(g_{\tau\alpha,\nu} + g_{\tau\nu,\alpha} - g_{\alpha\nu,\tau})$. The Lagrangian is modelled on the Lagrangian for the free Maxwell field, $-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}$, where $F_{\mu\nu}$ and $F^{\mu\nu}$ are the covariant and contravariant components of the electromagnetic field, respectively.

The analogy with electrodynamics could be used to narrow the range of plausible candidates for the new Lagrangian. Replacing the derivatives of the metric field by the Christoffel symbols as components of the gravitational field in the *Entwurf* Lagrangian may well have been one of the first things he tried.

The expression for the left-hand side of the field equations that one finds upon feeding this new Lagrangian into the variational formalism bears a striking resemblance to the left-hand side of field equations that Einstein had extracted from the Ricci tensor in the Zurich Notebook by imposing the (relatively weak) restriction to unimodular transformations. These are transformations with a Jacobian equal to one, or, equivalently, transformations under which the determinant g of the metric transforms as a scalar. Imposing the restriction to unimodular transformations on the general variational formalism, which allows one to omit a factor of $\sqrt{-g}$ in the action, and feeding the new Lagrangian into this version of the formalism, one finds that the left-hand side of the resulting field equations is exactly the same as the left-hand side of field equations discarded in the Zurich Notebook. Because of its reappearance in November 1915, we call this expression the *November tensor*.[27]

By adjusting the physical reasoning that had gone into the derivation of the *Entwurf* field equations, Einstein had thus found new field equations that could also be derived along the lines of the mathematical strategy. This was exactly the sort of convergence of physical and mathematical considerations that had eluded Einstein in the Zurich Notebook and in his work on the *Entwurf* theory. The best he had been able to do was to convince himself in 1914 that the *Entwurf* field equations can at least in principle be extracted from generally-covariant ones with the help of the coordinate restriction $B_\mu = 0$. Now physical and mathematical considerations both pointed to the November tensor. He set the November tensor equal to the energy-momentum tensor for matter, and confidently replaced the *Entwurf* field equations by these new equations in his first communication to the Berlin Academy of November 1915.

In the Zurich Notebook, Einstein had not been able to prove compatibility of field equations based on the November tensor with energy-momentum conservation. His variational formalism, even though it had to be used with caution because of the restriction to unimodular transformations, now provided all the guidance he needed to solve that problem. This unexpected windfall, however, brought a new puzzle. Having caught on to the connection between covariance and conservation laws, Einstein had come to expect that the covariance of the field equations was determined by the four conditions $B_\mu = 0$ in his variational formalism that at the same time guarantee energy-momentum conservation. The covariance of the November tensor, however, is much broader than these conditions would seem to allow. What did Einstein make of this apparent mismatch between covariance and conservation laws? The November 1915 papers again provide some important clues.

In the first of these papers (Einstein 1915a, 785), Einstein rewrote the four conditions $B_\mu = 0$ in such a way that they can be replaced by one stronger condition. He

27 See sec. 5.5 of "Commentary …" (in this volume).

then showed that this stronger condition can be replaced by the requirement that the determinant of the metric not be a constant. In the second and in the fourth paper, Einstein proposed ways to circumvent this requirement. These moves become readily understandable if we assume that they were made in response to the discrepancy between covariance and conservation laws mentioned above. Given that the November tensor is invariant under arbitrary unimodular transformations, Einstein expected that energy-momentum conservation would not require any further restrictions. As we mentioned above, g, the determinant of the metric, transforms as a scalar under unimodular transformations. This explains why Einstein tried to rewrite the standard four conditions $B_\mu = 0$ giving energy-momentum conservation as one condition on g. It also explains why he was not satisfied with the requirement that g not be a constant. The restriction to unimodular *transformations* only requires g to transform as a scalar, not that it be either a constant or a variable. In fact, it turns out to be advantageous to impose the stronger restriction to unimodular *coordinates*, i.e., coordinates in which $g = -1$. It is thus perfectly understandable that Einstein tried to replace the condition that g not be a constant by the condition that $g = -1$. This was the driving force behind the transition from the field equations of the first November paper to those of the fourth one. In this last paper of November 1915, Einstein showed that one arrives at the desired condition $g = -1$ if a term involving the trace of the energy-momentum tensor is added to the field equations of the first November paper. These equations can be looked upon as generally-covariant equations expressed in terms of unimodular coordinates. The generally-covariant equations are the Einstein field equations.

1.5 Untying the Knot: Coordinate Conditions

Two problems that had defeated the November tensor in the Zurich Notebook still need to be addressed. How did Einstein recover the Poisson equation for weak static fields and how did he show that his new field equations allow Minkowski spacetime in rotating coordinates? These are two separate problems and they are easily solved separately, but in the Zurich Notebook they had become entangled with one another and with the problem of energy-momentum conservation. The entanglement was the result of Einstein's use of coordinate restrictions. One and the same restriction had to reduce the relevant component of the field equations to the Poisson equation in the case of weak static fields, guarantee energy-momentum conservation, and allow the metric for Minkowski spacetime in rotating coordinates. Coordinate conditions only have to do the first of these three things. The three problems can thus be disentangled by switching from coordinate restrictions to coordinate conditions.

Einstein, we believe, made this switch when he saw that field equations based on the November tensor can be made compatible with energy-momentum conservation by imposing just one weak coordinate restriction. Recovering the Poisson equation for weak static fields still required the usual four restrictions. This discrepancy of one restriction versus four opened up the possibility to handle recovery of the Poisson equation with a coordinate condition in the modern sense and impose a coordinate restriction only for energy-momentum conservation. It is impossible to say whether Einstein had arrived at the modern understanding of coordinate conditions earlier or whether he only reached this point when faced with this unexpected discrepancy. Only the separation of the two sets of conditions, however, made it possible to put the modern understanding of coordinate conditions to good use. Not only could Einstein now decouple the problem of energy-momentum conservation from the problem of recovering the Poisson equation, he could also decouple the latter from the problem of rotation. It is this disentanglement of various conditions and requirements that we tried to capture in the title of our paper: "Untying the knot."

The first November paper contains the first unambiguous instance of Einstein applying a coordinate condition in the modern sense to show that the relevant component of the field equations reduces to the Poisson equation for weak static fields (Einstein 1915a, 786). In the Zurich Notebook Einstein had used what we call the *Hertz restriction*[28] for this purpose. One of the problems with this restriction was that it does not allow the Minkowski metric in rotating coordinates. In the first November paper, Einstein used the exact same mathematical formula, but now interpreted as a coordinate condition rather than a coordinate restriction. As Einstein clearly recognized, it then no longer is a problem that the condition is not satisfied by the Minkowski metric in rotating coordinates. Right after he applied the Hertz condition, he pointed out that the class of unimodular transformations under which the field equations are invariant allow transformations to rotating coordinates. The obvious implication is that the new theory steers clear of the problem of rotation that had defeated the old one.

Einstein had untied the knot. The definition of the components of the gravitational field had been the thread he had pulled to do so. No wonder that he called the old definition "a fateful prejudice" and the new one "the key to the solution."

1.6 Tug of War: Physics or Mathematics?

How well does the text of the November 1915 papers support our reconstruction of how Einstein found his way back to generally-covariant field equations? As a matter of fact, Einstein does *not* introduce the new field equations by pointing out that they can be obtained simply by changing the definition of the gravitational field in the expression for the Lagrangian from which he had earlier derived the *Entwurf* equations. Instead, he uses that the new field equations are closely related to the generally-covariant Riemann tensor, rehearsing the argument that had led him to the November tensor in the Zurich Notebook. At first glance, this looks like a strike against us. On closer examination, it is not such a clear call. In his paper, Einstein was presumably concerned with making the strongest possible case for his new field equations. No matter how Einstein had arrived at these new field equations, it clearly was more con-

28 The only reason for this name is that the condition is discussed in Einstein to Paul Hertz, August 22, 1915 (CPAE 8, Doc. 111). See sec. 5.5.2 of "Commentary …" (in this volume).

vincing to show that these equations can easily be extracted from the Ricci tensor than to show that they can be obtained by a natural adjustment of the formalism that Einstein had used the year before in his failed attempt to prove the uniqueness of the *Entwurf* field equations. Emphasizing the former argument and suppressing the latter would have been the obvious preemptive strike against skeptical readers who might want to remind him of that fiasco. But it need not even have been a calculated rhetorical move on Einstein's part. He himself probably saw the connection to the Riemann tensor as the most convincing evidence in favor of his new field equations. It thus makes perfect sense that this is what he emphasized in his presentation and that he only availed himself of the variational formalism to do the one thing he did not know how to do any other way, namely proving compatibility with energy-momentum conservation.

If we are right, Einstein's papers of November 1915 not only gave his contemporaries and a host of later commentators a misleading picture of how he found the field equations of general relativity, they also and most importantly fooled their own author. Einstein would soon forget that he had arrived at the new field equations pursuing the physical strategy and that the complementary mathematical strategy had served mainly to give him the confidence that he was finally on the right track. In his later years, Einstein extolled the virtues of a purely mathematical approach to theory construction. As John Norton (2000) and, in much greater detail, Jeroen van Dongen (2002, 2004) have shown, the older Einstein routinely claimed that this was the lesson he had drawn from the way in which he had found general relativity. The way Einstein remembered it, physics had led him astray; it was only after he had decided to throw in his fate with mathematics that he had found the right theory. In our reconstruction, however, Einstein found his way back to generally-covariant field equations by making one important adjustment to the *Entwurf* theory, a theory born almost entirely out of physical considerations. He saw that he could redefine the components of the gravitational field without losing any of the structural similarities to electrodynamics that made the *Entwurf* theory so attractive from a physical point of view. After a few more twists and turns, this path led him to the Einstein field equations. That mathematical considerations pointed in the same direction undoubtedly inspired confidence that this was the right direction, but guiding him along this path were physical not mathematical considerations.

1.7 The Red Thread: Einstein's Variational Formalism

In the rest of this paper, we fill in the details of our new reconstruction of the transition from the *Entwurf* theory to general relativity. For those who do not want to go through the derivations, we give short summaries at the beginning of all (sub-)sections of the results derived in them. In sec. 2, we review the one result we need from the Zurich Notebook, namely the extraction of the November tensor from the Ricci tensor. In sec. 3, we give a self-contained exposition of the variational formalism of (Einstein 1914c) that plays a pivotal role in our account. In sec. 4, we show how Einstein used this formalism to make what he considered his most compelling case for the *Entwurf* theory. In secs. 5–7, we analyze how Einstein used the formalism in his papers of November 1915 (Einstein 1915a, b, d). In secs. 8 and 9, we turn to two papers (Einstein 1916a, 1916c) in which the results of November 1915 were consolidated, again with the help of the formalism of 1914. In sec. 10, we address the discrepancy noted above between how Einstein presented and remembered his discovery of general relativity and how he actually discovered it. Finally, in the appendix, drawing on calculations scattered throughout the body of the paper, we present a concise and sanitized version of the transition from the *Entwurf* field equations to the Einstein field equations, which makes the relation between these two sets of equations more perspicuous.

2. THE NOVEMBER TENSOR IN THE ZURICH NOTEBOOK

We review how the field equations based on the November tensor in (Einstein 1915a) made their first appearance in the Zurich Notebook. Einstein extracted the November tensor from the Ricci tensor by imposing a restriction to unimodular transformations. He then showed how the Hertz restriction reduces the November tensor to the d'Alembertian acting on the metric in the case of weak fields.

On p. 22R of the Zurich Notebook—at the instigation, it seems, of his friend and collaborator Marcel Grossmann whose name appears at the top of the page—Einstein wrote down the Ricci tensor in the form

$$T_{il} = \frac{\partial}{\partial x^l}\begin{Bmatrix} k \\ ik \end{Bmatrix} - \frac{\partial}{\partial x^k}\begin{Bmatrix} k \\ il \end{Bmatrix} + \begin{Bmatrix} \lambda \\ ik \end{Bmatrix}\begin{Bmatrix} k \\ \lambda l \end{Bmatrix} - \begin{Bmatrix} \lambda \\ il \end{Bmatrix}\begin{Bmatrix} k \\ \lambda k \end{Bmatrix}, \tag{1}$$

where

$$\begin{Bmatrix} k \\ il \end{Bmatrix} \equiv \frac{1}{2}g^{k\alpha}(g_{i\alpha,l} + g_{l\alpha,i} - g_{il,\alpha}) \tag{2}$$

are the Christoffel symbols.[29] Einstein extracted an expression from the Ricci tensor that transforms as a tensor under unimodular transformations. Under such transformations, the quantity

$$T_i \equiv \begin{Bmatrix} k \\ ik \end{Bmatrix} = (\lg\sqrt{-g})_{,i} \tag{3}$$

(with g the determinant of $g_{\mu\nu}$), transforms as a vector, and its covariant derivative,

$$\frac{\partial T_i}{\partial x^l} - \begin{Bmatrix} \lambda \\ il \end{Bmatrix}T_\lambda = \frac{\partial}{\partial x^l}\begin{Bmatrix} k \\ ik \end{Bmatrix} - \begin{Bmatrix} \lambda \\ il \end{Bmatrix}\begin{Bmatrix} k \\ \lambda k \end{Bmatrix}, \tag{4}$$

transforms as a tensor. It follows that the quantity

$$T_{il}^{x} \equiv \frac{\partial}{\partial x^k}\begin{Bmatrix} k \\ il \end{Bmatrix} - \begin{Bmatrix} \lambda \\ ik \end{Bmatrix}\begin{Bmatrix} k \\ \lambda l \end{Bmatrix}, \tag{5}$$

which is (minus) the difference between the generally-covariant Ricci tensor in eq. (1) and the expression in eq. (4), also transforms as a tensor under unimodular transformations. This is the quantity we call the *November tensor.*

Setting the November tensor equal to the energy-momentum tensor, $T_{\mu\nu}$, multiplied by the gravitational constant κ, one arrives at the field equations of Einstein's first paper of November 1915 (Einstein 1915a, 783, eq. 16a):

$$\frac{\partial}{\partial x^\alpha}\begin{Bmatrix} \alpha \\ \mu\nu \end{Bmatrix} - \begin{Bmatrix} \alpha \\ \mu\beta \end{Bmatrix}\begin{Bmatrix} \beta \\ \alpha\nu \end{Bmatrix} = \kappa T_{\mu\nu}, \tag{6}$$

The first term on the left-hand side does not reduce to the d'Alembertian acting on the metric in the weak-field case. There are additional terms with unwanted second-order derivatives of the metric. At the time of the Zurich Notebook, this made the November tensor itself unacceptable as a candidate for the left-hand side of the field equations. Einstein, however, extracted a candidate for the left-hand side of the field equations from the November tensor by imposing what we call the *Hertz restriction*,

$$g_k^{k\alpha} \equiv \frac{\partial g^{k\alpha}}{\partial x^k} = 0. \tag{7}$$

Expanding the Christoffel symbols in the first term of the November tensor, one finds

$$\frac{\partial}{\partial x^k}\begin{Bmatrix} k \\ il \end{Bmatrix} = \frac{1}{2}(g^{k\alpha}(g_{i\alpha,l} + g_{l\alpha,i} - g_{il,\alpha}))_k.$$

Using the Hertz restriction and the relation

29 We have adopted a notation that lies somewhere between slavishly following the original text and translating everything into modern language. Our guiding principle has been to use a notation that makes the equations both easy to follow for those familiar with the standard notation of modern general relativity and easy to compare with the original sources for those who want to check our claims against Einstein's own writings. On this basis, we have adopted the following rules. We typically follow Einstein's choice of letters for quantities and indices in the document under discussion. E.g., the Ricci tensor is not written as $R_{\mu\nu}$, as it is in most modern texts, but as T_{il} in our discussion of the Zurich Notebook in this section and as G_{im} in our discussion of (Einstein 1915b) in sec. 7. As in Einstein's writings of this period, all indices, Greek and Latin, run from 1 through 4. However, we do not follow Einstein's idiosyncratic convention before (Einstein 1914c) of writing nearly all indices downstairs and distinguishing between covariant and contravariant components (e.g., the components $g_{\mu\nu}$ and $g^{\mu\nu}$ of the metric) by using a Latin letter for one ($g_{\mu\nu}$) and a Greek letter for the other ($\gamma_{\mu\nu}$). We use Latin letters for all quantities and write all covariant indices downstairs and all contravariant indices upstairs. Following Einstein, we use Fraktur for tensor densities (e.g., $\mathfrak{T}_\nu^\mu = \sqrt{-g}T_\nu^\mu$). Deviating from Einstein, we occasionally use commas and semi-colons for ordinary and covariant differentiation, respectively. We consistently use the summation convention (introduced in Einstein 1916a, 788).

$$g^{k\alpha}(g_{i\alpha,l} + g_{l\alpha,i}) = -g_l^{k\alpha}g_{i\alpha} - g_i^{k\alpha}g_{l\alpha}$$

(where $g_l^{\kappa\alpha} \equiv g^{\kappa\alpha}{}_{,l}$), one can rewrite this expression as:

$$\frac{\partial}{\partial x^k}\begin{Bmatrix} k \\ il \end{Bmatrix} = -\frac{1}{2}(g^{k\alpha}g_{il,k\alpha} + g_l^{k\alpha}g_{i\alpha,k} + g_i^{k\alpha}g_{l\alpha,k}). \tag{8}$$

The first term in parentheses reduces to $-\Box g_{il}$ for weak fields. The other two terms are quadratic in first-order derivatives of the metric like the contribution coming from the term in the November tensor quadratic in the Christoffel symbols. All these terms can be neglected for weak fields.

On p. 23L of the notebook, Einstein tried to bring down the number of terms quadratic in first-order derivatives of the metric in his field equations by introducing yet another coordinate restriction in addition to the Hertz restriction and the restriction to unimodular transformations. We call this new restriction the ϑ-restriction.[30] Einstein discovered that this new coordinate restriction could be used to eliminate the unwanted terms with second-order derivatives as well, so that there was no longer any need for the Hertz restriction. Einstein eventually abandoned the ϑ-restriction because the ϑ-restriction—like the Hertz restriction for that matter—ruled out transformations to rotating frames in Minkowski spacetime. After a few more twists and turns, Einstein settled on the *Entwurf* field equations. The November tensor and the Hertz restriction—used now as a coordinate condition—only reappeared in November 1915.

3. EINSTEIN'S VARIATIONAL FORMALISM: FIELD EQUATIONS, ENERGY-MOMENTUM CONSERVATION, AND COVARIANCE PROPERTIES

We cover various aspects of the variational formalism that Einstein used both in his review article on the Entwurf theory of October 1914 and in a number of papers on general relativity in 1915–1918. The Lagrangian is left unspecified, so all results hold both in the Entwurf theory and in modern general relativity. The main point of the section is to show how two very different lines of reasoning—one aimed at finding conditions to ensure energy-momentum conservation, the other aimed at finding coordinate transformations leaving the action invariant—lead to the exact same conditions on the Lagrangian, written as $S_\sigma^\nu = 0$ and $B_\mu = 0$. The convergence of these two lines of reasoning confirmed what Einstein had come to suspect in the fall of 1913, namely that energy-momentum conservation is directly related to the covariance of the gravitational field equations.

30 For discussion of the ϑ-restriction, see note 69 below and secs. 5.5.4–5.5.10 in "Commentary …" (in this volume).

In early November 1915, Einstein (1915a) replaced the *Entwurf* field equations of severely limited covariance by field equations just a few tweaks away from the generally-covariant Einstein field equations of (Einstein 1915d). The way Einstein initially described it, it was a wholesale replacement:

> After all confidence in *the result and the method* of the earlier theory had thus given way, I saw clearly that a satisfactory solution could only be found in a connection to the general theory of covariants, i.e., to Riemann's covariant (our emphasis).[31]

About six weeks later, he recognized that the old had not been all bad:

> The series of my papers on gravitation is a chain of erroneous paths, which nonetheless gradually brought me closer to my goal.[32]

It is true that Einstein discarded some of his earlier *results*, but he retained the *method* that he had used to obtain those results. This method is the variational formalism first presented in (Einstein and Grossmann 1914b) and further developed in the definitive exposition of the *Entwurf* theory (Einstein 1914c, part D). In the latter paper, he used this formalism to produce an elegant derivation of the *Entwurf* field equations, to investigate their covariance properties, and to prove their compatibility with energy-momentum conservation. We argue that he used this same formalism to find the successor to the *Entwurf* field equations, published in the first of his four communications to the Prussian Academy in November 1915 (Einstein 1915a).

What complicates the use of the formalism both in the four November papers (Einstein 1915a, b, c, d) and in the first systematic exposition of the new theory (Einstein 1916a) is a restriction to unimodular transformations in the first paper and the choice of unimodular coordinates[33] in the other four. In all these papers, Einstein nonetheless relied heavily on the formalism to guide him in his analysis of the relation between field equations and energy-momentum conservation.

---

31 "Nachdem so jedes Vertrauen im Resultate und Methode der früheren Theorie gewichen war, sah ich klar, dass nur durch einen Anschluss an die allgemeine Kovariantentheorie, d.h. an Riemanns Kovariante, eine befriedigende Lösung gefunden werden konnte." Einstein to Arnold Sommerfeld, November 28, 1915 (CPAE 8, Doc. 153; our emphasis). Unless otherwise noted, all translations are based on those in the companion volumes to the Einstein edition. This letter to Sommerfeld provides the most detailed account of the developments of November 1915 that culminated in the publication of the Einstein field equations and the explanation of the anomalous motion of Mercury's perihelion. This document, however, needs to be treated with care. It was a calculated move on Einstein's part to tell Sommerfeld the whole story rather than, say, Lorentz, with whom he had corresponded much more intensively on matters general relativistic. In the fall of 1915, Sommerfeld was kept apprised of developments not only by Einstein but also by Hilbert. Writing to Sommerfeld, Einstein probably first and foremost wanted to make sure that Sommerfeld knew that he had put his house in order without any help from Hilbert.

32 "Die Serie meiner Gravitationsarbeiten ist eine Kette von Irrwegen, die aber doch allmählich dem Ziele näher führten." Einstein to H. A. Lorentz, January 17, 1916 (CPAE 8, Doc. 183). The mixing of metaphors ("Kette von Irrwegen") is Einstein's, not ours.

33 Recall the discussion of the difference between coordinate restrictions and coordinate conditions in the introduction.

It was only in (Einstein 1916c), written in October 1916, that Einstein first presented the new theory entirely in arbitrary rather than in unimodular coordinates. This paper follows the exposition of the variational formalism in (Einstein 1914c) almost to the letter (as already emphasized in Norton 1984, 141). In early 1918, Einstein used the formalism again to defend his approach to energy-momentum conservation in general relativity against objections from Levi-Civita, Lorentz, Klein, and others (Einstein 1918d). The formalism can also be found in Einstein's lecture notes for a course on general relativity in Berlin in 1919 (CPAE 7, Doc. 19, [pp. 13–17]).

Einstein's reliance on this variational formalism thus provides an important element of continuity in the transition from the *Entwurf* theory to general relativity and puts the lie to Einstein's remark to Sommerfeld that he had lost all confidence in both "the result and the method" of the old theory.

In this section, we cover various aspects of Einstein's formalism: the derivation of the field equations (sec. 3.1), the treatment of energy-momentum conservation (sec. 3.2), and the investigation of covariance properties (sec. 3.3). In subsequent sections, we discuss the applications of the formalism in the period 1914–1916. In sec. 4, we examine the relevant portion of (Einstein 1914c) published in November 1914. In secs. 5–7, we turn to the papers of November 1915 documenting the transition from the *Entwurf* theory to general relativity (Einstein 1915a, b, d). In sec. 8, we present the streamlined version of the argument of November 1915 given in the review article completed in March 1916 (Einstein 1916a, part C). In sec. 9, we cover what is probably the most elegant application of the formalism, the demonstration that energy-momentum conservation in general relativity is a direct consequence of the general covariance of the field equations. This argument was made in (Einstein 1916c), presented to the Prussian Academy in November 1916. Our story thus covers a timespan of two years, from November 1914 to November 1916. Our main focus will be on the tumultuous developments of one month in the middle of this period, November 1915.

3.1 Field Equations

With the appropriate definition of the gravitational energy-momentum pseudo-tensor, the field equations can be written in a form resembling Maxwell's equations, with the divergence of the gravitational field on the left-hand side and the sum of the energy-momentum densities of matter and gravitational field on the right-hand side.

Consider the gravitational part of the action

$$J = \int Q d\tau, \tag{9}$$

where $Q = H\sqrt{-g}$ is the gravitational part of the Lagrangian,[34] H is some as yet completely undetermined function of $g^{\mu\nu}$ and its first derivatives $g^{\mu\nu}_{\alpha}$, and $d\tau = d^4x$ is a four-dimensional volume element. The condition that J be an extremum, $\delta J = 0$, leads to the Euler-Lagrange equations

$$\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial Q}{\partial g^{\mu\nu}} = 0. \tag{10}$$

Although his proof did not satisfy Levi-Civita, Einstein thought he could show that the expression on the left-hand side transforms as a tensor density under all transformations under which H transforms as a scalar.

He generalized the vacuum field equations (10) to

$$\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial Q}{\partial g^{\mu\nu}} = -\kappa\sqrt{-g}T_{\mu\nu} \tag{11}$$

in the presence of matter described by the energy-momentum tensor $T_{\mu\nu}$. This equation can be written in a form analogous to Maxwell's equations, with the divergence of the gravitational field on the left-hand side and the sources of the field, the energy-momentum densities of matter and gravitational field, on the right-hand side. Contraction with $g^{\nu\lambda}$ of the left-hand side of eq. (11) gives:

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) - g^{\nu\lambda}_{\alpha}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}} - g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}};$$

contraction with $g^{\nu\lambda}$ of the right-hand $-\kappa\sqrt{-g}T^{\lambda}_{\mu}$. If the gravitational energy-momentum pseudo-tensor t^{λ}_{μ} is defined as

$$\kappa\sqrt{-g}t^{\lambda}_{\mu} \equiv -g^{\nu\lambda}_{\alpha}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}} - g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}}, \tag{12}$$

then eq. (11) can be rewritten as

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) = -\kappa(\mathfrak{T}^{\lambda}_{\mu} + \mathfrak{t}^{\lambda}_{\mu}), \tag{13}$$

where $\mathfrak{T}^{\lambda}_{\mu} \equiv \sqrt{-g}T^{\lambda}_{\mu}$ and $\mathfrak{t}^{\lambda}_{\mu} \equiv \sqrt{-g}t^{\lambda}_{\mu}$ are mixed tensor densities. These field equations fulfill an important requirement: the energy-momentum of the gravitational field enters the source term in the same way as the energy-momentum of matter.

If the quantity in parentheses on the left-hand side of eq. (13) is identified as the gravitational field, the equations have the same structure as Maxwell's equations, $\partial_{\mu}F^{\mu\nu} = \mu_0 j^{\nu}$, where $F^{\mu\nu}$ is the electromagnetic field tensor, μ_0 is a constant, and j^{ν} is the charge-current density, the source of the electromagnetic field.

34 Strictly speaking, Q is the Lagrangian density (for detailed discussion, see Wald 1984, Appendix E).

3.2 Energy-Momentum Conservation

In addition to the field equations, it is assumed that the covariant divergence of the energy-momentum tensor of matter vanishes. This equation can be rewritten as the vanishing of the ordinary divergence of the sum of the energy-momentum tensor densities for matter and gravitational field, provided that the gravitational energy-momentum pseudo-tensor is defined appropriately. Compatibility of this definition and the definition in the preceding subsection leads to the conditions $S_\sigma^\nu = 0$ *on the Lagrangian. In 1914, Einstein (erroneously) thought that these conditions uniquely pick out the Entwurf Lagrangian. Einstein imposed four more conditions, written as* $B_\mu = 0$*. Taken together with the field equations, the conditions* $B_\mu = 0$ *imply energy-momentum conservation. In general relativity, these conditions turn into the contracted Bianchi identities.*

The energy-momentum balance for matter in a gravitational field can be written as[35]

$$\mathfrak{T}^\alpha_{\mu,\alpha} = \begin{Bmatrix}\beta \\ \mu\alpha\end{Bmatrix}\mathfrak{T}^\alpha_\beta. \tag{14}$$

This equation is equivalent to (cf. Einstein 1914c, 1056, eq. 42a):[36]
$\mathfrak{T}^\alpha_{\mu,\alpha} = \frac{1}{2}g^{\beta\rho}g_{\rho\alpha,\mu}\mathfrak{T}^\alpha_\beta$. four-momentum density of matter at any given point can only change in two ways: it can flow to or from neighboring points and it can be transferred to or from the gravitational field at that point. The left-hand sides of eqs. (14)–() describe the former process, the right-hand sides the latter. The right-hand sides give the rate at which four-momentum density is transferred from gravitational field to matter. This term thus represents the gravitational force density. The analogy with the Lorentz force density $f_\mu = F_{\mu\nu}j^\nu$ —the contraction of the electromagnetic field $F_{\mu\nu}$ and its source, the charge-current density j^ν —suggests that this quantity should be equal to minus the contraction of the gravitational field and its source, the energy-momentum tensor of matter. The minus sign reflects that the gravitational force

---

35 Eq. (14) is equivalent to $T^\alpha_{\mu;\alpha} = 0$:

$$\sqrt{-g}T^\alpha_{\mu;\alpha} = \sqrt{-g}\left(T^\alpha_{\mu,\alpha} + \begin{Bmatrix}\alpha \\ \beta\alpha\end{Bmatrix}T^\beta_\mu - \begin{Bmatrix}\beta \\ \mu\alpha\end{Bmatrix}T^\alpha_\beta\right) = 0$$

Upon substitution of $\begin{Bmatrix}\alpha \\ \beta\alpha\end{Bmatrix} = (\sqrt{-g})_{,\beta}/\sqrt{-g}$, this equation turns into

$$\sqrt{-g}T^\alpha_{\mu,\alpha} + (\sqrt{-g})_{,\alpha}T^\alpha_\mu - \begin{Bmatrix}\beta \\ \mu\alpha\end{Bmatrix}\sqrt{-g}T^\alpha_\beta = 0,$$

which can be rewritten as eq. (14).

36 Using definition (2) of the Christoffel symbols, one can rewrite the right-hand side of eq. (14) as

$$\begin{Bmatrix}\beta \\ \mu\alpha\end{Bmatrix}\mathfrak{T}^\alpha_\beta = \frac{1}{2}g^{\beta\rho}(g_{\rho\mu,\alpha} + g_{\rho\alpha,\mu} - g_{\mu\alpha,\rho})\mathfrak{T}^\alpha_\beta = \frac{1}{2}\mathfrak{T}^{\alpha\rho}(g_{\rho\mu,\alpha} - g_{\mu\alpha,\rho}) + \frac{1}{2}g^{\beta\rho}g_{\rho\alpha,\mu}\mathfrak{T}^\alpha_\beta.$$

The first term of this last expression vanishes since it is the contraction of a quantity symmetric in the indices α and ρ and a quantity anti-symmetric in those same indices.

between two masses is attractive whereas the electric force between two like charges is repulsive. In the *Entwurf* theory, Einstein read off the expression for the gravitational field from the right-hand side of eq. ().[37] In the November 1915 theory, he used the right-hand side of eq. (14) instead. Commenting on this switch in his first paper of November 1915, Einstein wrote:

> This conservation law [essentially eq. ()] has led me in the past to look upon the quantities $[(1/2)g^{\tau\mu}g_{\mu\nu,\sigma}]$ as the natural expressions of the components of the gravitational field, even though the formulas of the absolute differential calculus suggest the Christoffel symbols […] instead. *This was a fateful prejudice*.[38]

After the fourth paper of November 1915, he told Sommerfeld:

> *The key to this solution* was my realization that not $[g^{l\alpha}g_{\alpha i,m}]$ but the related Christoffel symbols […] are to be regarded as the natural expression for the "components" of the gravitational field.[39]

To appreciate the full significance of these comments, one needs to see how the November tensor drops out of Einstein's variational formalism (see sec. 5 below). For now, we shall follow the treatment in (Einstein 1914c) and work with eq. () rather than with eq. (14).

In relativistic continuum mechanics, which is carefully tailored to electrodynamics, the theory for which it was first developed, a four-force density can be written as the four-divergence of a suitably chosen energy-momentum tensor.[40] So Einstein tried to write the gravitational force density in eq. () as the four-divergence of a suitably chosen gravitational energy-momentum (pseudo-)tensor density $\mathfrak{t}^{\alpha}_{\mu}$. If this can be done, energy-momentum conservation can be written as the vanishing of an ordinary divergence:

$$(\mathfrak{T}^{\lambda}_{\mu}+\mathfrak{t}^{\lambda}_{\mu})_{,\lambda} = 0. \tag{15}$$

Eq. () can indeed be written in this form, but the resulting expression for $\mathfrak{t}^{\alpha}_{\mu}$ differs from expression (12) for $\mathfrak{t}^{\alpha}_{\mu}$ found earlier. Einstein therefore had to add an extra condition to his theory that sets these two expressions equal to one another. As he discovered in October 1915, this same condition pops up in the analysis of the covariance properties of the theory.

---

37 In doing so, Einstein omitted a minus sign. The motivation for using eq. () rather than eq. (14) to identify the components of the gravitational field is explained in (Einstein 1914c, 1060, note 1). See also Einstein to Hans Thirring, 7 December 1917 (CPAE 8, Doc. 405, note 4).

38 "Diese Erhaltungsgleichung hat mich früher dazu verleitet, die Größen […] als den natürlichen Ausdruck für die Komponenten des Gravitationsfeldes anzusehen, obwohl es im Hinblick auf die Formeln des absoluten Differentialkalküls näher liegt, die Christoffelschen Symbole statt jener Größen einzuführen. Dies war ein verhängnisvolles Vorurteil" (Einstein 1915a, 782; our emphasis).

39 "Den Schlüssel zu dieser Lösung lieferte mir die Erkenntnis, dass nicht […] sondern die damit verwandten Christoffel'schen Symbole […] als natürlichen Ausdruck für die "Komponente" des Gravitationsfeldes anzusehen ist." Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153). Our emphasis.

40 See, e.g., sec. 20 of Einstein's "Manuscript on the Special Theory of Relativity" (CPAE 4, Doc. 1).

Since $g^{\beta\rho}g_{\rho\alpha,\mu} = -g^{\beta\rho}_{\mu}g_{\rho\alpha}$, eq. () can also be written as:

$$\mathfrak{T}^{\alpha}_{\mu,\alpha} + \frac{1}{2}g^{\alpha\beta}_{\mu}\mathfrak{T}_{\alpha\beta} = 0. \tag{16}$$

The second term has to be written in the form of $t^{\lambda}_{\mu,\lambda}$. To this end, the field equations (11) are used to replace $\mathfrak{T}_{\alpha\beta}$ by an expression in terms of the metric field and its derivatives:[41]

$$\frac{1}{2}g^{\alpha\beta}_{\mu}\mathfrak{T}_{\alpha\beta} = \frac{1}{2\kappa}g^{\alpha\beta}_{\mu}\left(\frac{\partial Q}{\partial g^{\alpha\beta}} - \frac{\partial}{\partial x^{\lambda}}\left(\frac{\partial Q}{\partial g^{\alpha\beta}_{\lambda}}\right)\right). \tag{17}$$

The right-hand side of this expression can indeed be written in the form $t^{\lambda}_{\mu,\lambda}$ with:[42]

$$t^{\lambda}_{\mu} \equiv \frac{1}{2\kappa}\left(\delta^{\lambda}_{\mu}Q - g^{\alpha\beta}_{\mu}\frac{\partial Q}{\partial g^{\alpha\beta}_{\lambda}}\right). \tag{18}$$

We introduce the more explicit notations $t^{\lambda}_{\mu}(Q, \text{cons})$ for t^{λ}_{μ} as defined in eq. (18) and $t^{\lambda}_{\mu}(Q, \text{source})$ for t^{λ}_{μ} as defined in eq. (12).[43]

Compatibility between these two definitions is assured if the quantity S^{ν}_{σ}, defined as (Einstein 1914c, 1075, eq. 76a),[44]

$$S^{\nu}_{\sigma} \equiv g^{\beta\nu}_{\alpha}\frac{\partial Q}{\partial g^{\beta\sigma}_{\alpha}} + g^{\alpha\nu}\frac{\partial Q}{\partial g^{\alpha\sigma}} + \frac{1}{2}\delta^{\nu}_{\sigma}Q - \frac{1}{2}g^{\alpha\beta}_{\sigma}\frac{\partial Q}{\partial g^{\alpha\beta}_{\nu}}, \tag{19}$$

41 This method for identifying the expression for the gravitational energy-momentum pseudo-tensor can already be found at several places in the Zurich Notebook (see, e.g., p. 19R and p. 24R, discussed in secs. 5.4.2 and 5.6.1, respectively, of "Commentary …" [in this volume]). It was also used in (Einstein and Grossmann 1913, 15). Einstein had used a completely analogous method in his earlier theory for static fields (Einstein 1912, 456).

42 Using that

$$\frac{\partial Q}{\partial x^{\mu}} = \frac{\partial Q}{\partial g^{\alpha\beta}}g^{\alpha\beta}_{\mu} + \frac{\partial Q}{\partial g^{\nu\sigma}_{\lambda}}g^{\alpha\beta}_{\lambda\mu},$$

with $g^{\alpha\beta}_{\lambda\mu} \equiv g^{\alpha\beta}{}_{,\lambda\mu}$, one can rewrite the first term on the right-hand side of eq. (17) as

$$g^{\alpha\beta}_{\mu}\frac{\partial Q}{\partial g^{\alpha\beta}} = \frac{\partial Q}{\partial x^{\mu}} - \frac{\partial Q}{\partial g^{\nu\sigma}_{\lambda}}g^{\alpha\beta}_{\lambda\mu}.$$

One thus arrives at

$$\frac{\partial Q}{\partial x^{\mu}} - g^{\alpha\beta}_{\mu\lambda}\frac{\partial Q}{\partial g^{\nu\sigma}_{\lambda}} - g^{\alpha\beta}_{\mu}\frac{\partial}{\partial x^{\lambda}}\left(\frac{\partial Q}{\partial g^{\alpha\beta}_{\lambda}}\right) = \frac{\partial}{\partial x^{\lambda}}\left(\delta^{\lambda}_{\mu}Q - g^{\alpha\beta}_{\mu}\frac{\partial Q}{\partial g^{\alpha\beta}_{\lambda}}\right),$$

from which eq. (18) follows.

43 The designations "source" and "cons[ervation]" refer to the fact that these two definitions are found from considerations of the source term of the field equations and considerations of energy-momentum conservation, respectively.

44 Our derivation of eq. (19) follows Einstein to H. A. Lorentz, 12 October 1915 (CPAE 8, Doc. 129). In his 1914 review article, Einstein derived this equation by substituting the left-hand side of eq. (11) for $\mathfrak{T}_{\mu\nu}$ in both terms on the left-hand side of eq. (16).

vanishes. This quantity is equal to (κ times) the difference between the two definitions of t^{λ}_{μ}:

$$S^{\nu}_{\sigma}(Q) = \kappa t^{\nu}_{\sigma}(Q, \text{cons}) - \kappa t^{\nu}_{\sigma}(Q, \text{source}). \tag{20}$$

At the time of his review article on the *Entwurf* theory, Einstein thought that this condition uniquely determined $Q = \sqrt{-g}H$ to be the Lagrangian for the *Entwurf* field equations. As it turns out, S^{ν}_{σ} vanishes for *any* H that transforms as a scalar under general linear transformations (see eqs. (30)–(31) below).

Einstein imposed another set of conditions on the Lagrangian density Q which guarantee energy-momentum conservation. Taking the divergence of both sides of the field equations (13), one arrives at

$$-\frac{\partial^2}{\partial x^{\lambda}\partial x^{\alpha}}\left(g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) = \kappa(\mathfrak{T}^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda}. \tag{21}$$

The field equations thus imply energy-momentum conservation, if Q satisfies the condition (Einstein 1914c, 1077):

$$B_{\mu} \equiv \frac{\partial^2}{\partial x^{\rho}\partial x^{\sigma}}\left(g^{\rho\tau}\frac{\partial Q}{\partial g^{\mu\tau}_{\sigma}}\right) = 0.. \tag{22}$$

Energy-momentum thus calls for two sets of conditions:

$$S^{\nu}_{\sigma} = 0,\ B_{\mu} = 0, \tag{23}$$

These same conditions, it turns out, also express the covariance properties of the field equations (see eq. (33) below).

3.3 Covariance Properties

The conditions the Lagrangian has to satisfy for the action to be invariant under a given coordinate transformation are determined. The assumption that the action is at least invariant under general linear transformations leads to the conditions $S^{\nu}_{\sigma} = 0$. Einstein did not explicitly write down these conditions in 1914, which explains why he thought that these conditions, which he did encounter in the context of energy-momentum conservation, could be used to determine the Lagrangian. The conditions for additional non-linear transformations leaving the action invariant are $B_{\mu} = 0$, which, as Einstein did recognize, were also the conditions guaranteeing energy-momentum conservation. In the Entwurf theory, these four conditions determine the class of what Einstein called "adapted coordinates." In general relativity, they turn into the generally-covariant contracted Bianchi identities.

What are the transformations that leave the action $J = \int H\sqrt{-g}d\tau$ (with H an arbitrary function of $g^{\mu\nu}$ and $g^{\mu\nu}_{\alpha}$) invariant?[45] Consider an arbitrary infinitesimal coordinate transformation $x'^{\mu} = x^{\mu} + \Delta x^{\mu}$. The changes in $g^{\mu\nu}$ and $g^{\mu\nu}_{\alpha}$ under this transformation are given by[46,47]

$$\Delta g^{\mu\nu} \equiv g'^{\mu\nu}(x') - g^{\mu\nu}(x) = g^{\mu\alpha}\frac{\partial \Delta x^{\nu}}{\partial x^{\alpha}} + g^{\nu\alpha}\frac{\partial \Delta x^{\mu}}{\partial x^{\alpha}}, \tag{24}$$

$$\Delta g^{\mu\nu}_{\alpha} \equiv g'^{\mu\nu}_{\alpha}(x') - g^{\mu\nu}_{\alpha}(x) = \frac{\partial}{\partial x^{\alpha}}(\Delta g^{\mu\nu}) - \frac{\partial \Delta x^{\beta}}{\partial x^{\alpha}} g^{\mu\nu}_{\beta}. \tag{25}$$

The change in J is given by

$$\Delta J = J' - J = \int Q' d\tau' - \int Q d\tau. \tag{26}$$

The Jacobian $|\partial x'/\partial x|$ can be written as $1 + \partial\Delta x^{\mu}/\partial x^{\mu}$.[48] ΔJ can then be rewritten as

$$\Delta J = \int Q'\left(1 + \frac{\partial \Delta x^{\mu}}{\partial x^{\mu}}\right) d\tau - \int Q d\tau = \int Q \delta^{\nu}_{\sigma}\frac{\partial \Delta x^{\sigma}}{\partial x^{\nu}} d\tau + \int \Delta Q d\tau. \tag{27}$$

Since Q is a function of $g^{\mu\nu}$ and $g^{\mu\nu}_{\alpha}$, $\Delta Q \equiv Q' - Q$ is given by

$$\Delta Q = \frac{\partial Q}{\partial g^{\mu\nu}}\Delta g^{\mu\nu} + \frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\Delta g^{\mu\nu}_{\alpha}.$$

Inserting eqs. (24)–(25) for $\Delta g^{\mu\nu}$ and $\Delta g^{\mu\nu}_{\alpha}$, one finds[49]

$$\Delta Q = \left\{2g^{\alpha\nu}\frac{\partial Q}{\partial g^{\alpha\sigma}} + 2g^{\beta\nu}_{\alpha}\frac{\partial Q}{\partial g^{\beta\sigma}_{\alpha}} - g^{\alpha\beta}_{\sigma}\frac{\partial Q}{\partial g^{\alpha\beta}_{\nu}}\right\}\frac{\partial \Delta x^{\sigma}}{\partial x^{\nu}} + 2\frac{\partial Q}{\partial g^{\mu\tau}_{\sigma}} g^{\rho\tau}\frac{\partial^2 \Delta x^{\mu}}{\partial x^{\sigma}\partial x^{\rho}}. \tag{28}$$

Inserting this expression for ΔQ into expression (27) for ΔJ, one finds:

$$\begin{aligned}\frac{1}{2}\Delta J = \int\left\{g^{\beta\nu}_{\alpha}\frac{\partial Q}{\partial g^{\beta\sigma}_{\alpha}} + g^{\alpha\nu}\frac{\partial Q}{\partial g^{\alpha\sigma}} + \frac{1}{2}\delta^{\nu}_{\sigma}Q - \frac{1}{2}g^{\alpha\beta}_{\sigma}\frac{\partial Q}{\partial g^{\alpha\beta}_{\nu}}\right\}\frac{\partial \Delta x^{\sigma}}{\partial x^{\nu}} d\tau \\ + \int g^{\rho\tau}\frac{\partial Q}{\partial g^{\mu\tau}_{\sigma}}\frac{\partial^2 \Delta x^{\mu}}{\partial x^{\rho}\partial x^{\sigma}} d\tau\cdot\end{aligned} \tag{29}$$

The expression in curly brackets in the first integral is just the quantity S^{ν}_{σ} defined in eq. (19) in the course of the discussion of energy-momentum conservation. Eq. (29) can thus be written more compactly as

45 Ultimately, the question is under which transformations the field equations are invariant. Both in (Einstein and Grossmann 1914b) and in (Einstein 1914c, 1069–1071), Einstein argued that these are just the transformations under which the action is invariant. Levi-Civita's criticism was aimed at this part of Einstein's argument, which for our purposes is not important. Einstein and Grossmann (1914b, 219, note 2) credit Paul Bernays with the suggestion to use a variational formalism to investigate the covariance properties of the *Entwurf* field equations.

$$\frac{1}{2}\Delta J = \int S_\sigma^\nu \frac{\partial \Delta x^\sigma}{\partial x^\nu} d\tau + \int g^{\rho\tau} \frac{\partial Q}{\partial g_\sigma^{\mu\tau}} \frac{\partial^2 \Delta x^\mu}{\partial x^\rho \partial x^\sigma} d\tau. \tag{30}$$

Einstein now focused his attention on functions H that transform as scalars under arbitrary linear transformations. This implies that the action J is invariant under linear transformations ($\sqrt{-g}d\tau$ is an invariant volume element). For linear transformations the second-order derivatives of Δx^μ all vanish, so the second integral in eq. (30) does not contribute to ΔJ. This means that the first integral must vanish identically for arbitrary values of the first-order derivatives of Δx^μ, i.e., that:

$$S_\sigma^\nu = 0. \tag{31}$$

Through partial integration, the second integral in eq. (30) can be rewritten as

$$\int \frac{\partial^2}{\partial x^\rho \partial x^\sigma}\left(g^{\rho\tau} \frac{\partial Q}{\partial g_\sigma^{\mu\tau}}\right) \Delta x^\mu d\tau$$

plus surface terms that can all be assumed to vanish. The integrand is the contraction of Δx^μ and an expression which is exactly equal to the quantity B_μ defined in eq. (22) in the context of the discussion of energy-momentum conservation:

$$B_\mu \equiv \frac{\partial^2}{\partial x^\rho \partial x^\sigma}\left(g^{\rho\tau} \frac{\partial Q}{\partial g_\sigma^{\mu\tau}}\right).$$

Assuming that condition (31) holds, one can thus rewrite eq. (30) as

46 Einstein had an idiosyncratic way of computing the variations induced by coordinate transformations. Felix Klein, David Hilbert, Emmy Noether, and other mathematicians in or closely affiliated with Göttingen (such as Hermann Weyl in Zurich) used what is called the "Lie variation" of the metric tensor, defined as $\delta g_{\mu\nu} \equiv g'_{\mu\nu}(x) - g_{\mu\nu}(x)$. Commenting on (Weyl 1918), which he was reading in proof, Einstein wrote: "He [Weyl] derives the energy law for matter with the same variational trick that you used in the note that recently appeared [Klein 1917]" ("Den Energiesatz der Materie leitet er mit demselben Variations-Kunstgriff ab wie Sie in Ihrer neulich erschienenen Note," Einstein to Felix Klein, 24 March 1918 [CPAE 8, Doc. 492]). Two years earlier he had already noted that Lie variation and differentiation commute (Einstein to David Hilbert, 30 March 1916 [CPAE 8, Doc. 207]). This is not the case if one does the variation the way Einstein does (see eq. (25)). One would have expected Einstein to pick up on this quickly. After all, the crucial distinction between $g'_{\mu\nu}(x')$ and $g'_{\mu\nu}(x)$ was very familiar to him from the hole argument (see, e.g., sec. 4 in "What Did Einstein Know …". [in this volume]). In fact, Einstein still had not fully assimilated the notion of Lie variation in late 1918, as can be inferred from his comments on (Klein 1918a): "At first I had some trouble understanding your equation (6) [involving Lie variation]. The point is that with your preferred way of doing variations $\delta(\partial g^{\mu\nu}/\partial x_\sigma) = \partial/\partial x_\sigma(\delta g^{\mu\nu})$" ("Anfänglich hatte ich etwas Mühe, Ihre Gleichung (6) zu begreifen. Der Witz ist eben, dass bei der von Ihnen bevorzugten Art zu varieren […] ist," Einstein to Felix Klein, 22 October 1918 [CPAE 8, Doc. 638]). Old habits die hard. In his lectures on general relativity in Berlin in 1919, Einstein still vacillated between his own way of doing the variations and that of Weyl and Klein (CPAE 7, Doc. 19, [pp. 13–17]). For discussion of different types of variation that played a role in the early years of general relativity, see (Kichenassamy 1993), sec. 3.

$$\frac{1}{2}\Delta J = \int B_\mu \Delta x^\mu d\tau. \tag{32}$$

The upshot then is that the following two sets of conditions have to be satisfied for the action to be invariant under some coordinate transformation $x'^\mu = x^\mu + \Delta x^\mu$:

$$S_\sigma^\nu = 0, \; B_\mu = 0. \tag{33}$$

These conditions are the same as the conditions guaranteeing energy-momentum conservation that we found in eq. (23).

In the case of the four conditions $B_\mu = 0$, Einstein clearly recognized in his 1914 review article that they play this dual role (Einstein 1914c, 1076–1077). In the case of the conditions $S_\sigma^\nu = 0$, however, he did not. He only encountered these conditions in the context of energy-momentum conservation. He did not encounter them in his analysis of the covariance of the action J. Einstein started from

$$\Delta J = \int \Delta H \sqrt{-g}\, d\tau \tag{34}$$

rather than from eq. (26). He did not bother to write down the coefficients of $\partial \Delta x^\sigma / \partial x^\nu$ in ΔH as we did for ΔQ (see eq. (28)). He wrote:

> We now assume that H is invariant under linear transformations, i.e., that ΔH should vanish if the [$\partial^2 \Delta x^\mu / \partial x^\alpha \partial x^\sigma$] vanish. On this assumption we arrive at

---

47 Eq, (24) for $\Delta g^{\mu\nu}$ follows from

$$\Delta g^{\mu\nu} = g'^{\mu\nu} - g^{\mu\nu} = \frac{\partial x'^\mu}{\partial x^\alpha}\frac{\partial x'^\nu}{\partial x^\beta} g^{\alpha\beta} - g^{\mu\nu} = \left(\delta_\alpha^\mu + \frac{\partial \Delta x^\mu}{\partial x^\alpha}\right)\left(\delta_\beta^\nu + \frac{\partial \Delta x^\nu}{\partial x^\beta}\right) g^{\alpha\beta} - g^{\mu\nu};$$

eq. (25) for $\Delta g_\sigma^{\mu\nu}$ from:

$$\begin{aligned}\Delta g_\sigma^{\mu\nu} &= g'^{\mu\nu}_\sigma - g_\sigma^{\mu\nu} = \frac{\partial x^\rho}{\partial x'^\sigma}\frac{\partial}{\partial x^\rho}\left(\frac{\partial x'^\mu}{\partial x^\alpha}\frac{\partial x'^\nu}{\partial x^\beta} g^{\alpha\beta}\right) - g_\sigma^{\mu\nu} \\ &= \left(\delta_\sigma^\rho - \frac{\partial \Delta x^\rho}{\partial x^\sigma}\right)\frac{\partial}{\partial x^\rho}\left(\left(\delta_\alpha^\mu + \frac{\partial \Delta x^\mu}{\partial x^\alpha}\right)\left(\delta_\beta^\nu + \frac{\partial \Delta x^\nu}{\partial x^\beta}\right) g^{\alpha\beta}\right) - g_\sigma^{\mu\nu}.\end{aligned}$$

48 The Jacobian can be computed as follows:

$$\left|\frac{\partial x'}{\partial x}\right| = \varepsilon_{\mu..\nu}\frac{\partial x'^\mu}{\partial x^1}..\frac{\partial x'^\nu}{\partial x^4} = \varepsilon_{\mu..\nu}\delta_1^\mu..\delta_4^\nu + \varepsilon_{\mu..\nu}\frac{\partial x'^\mu}{\partial x^1}..\delta_4^\nu + \ldots + \ldots + \varepsilon_{\mu..\nu}\delta_1^\mu..\frac{\partial x'^\nu}{\partial x^4} = 1 + \frac{\partial \Delta x^\mu}{\partial x^\mu}.$$

49 Eq. (28) is found as follows:

$$\begin{aligned}\Delta Q &= \frac{\partial Q}{\partial g^{\mu\nu}}\left(g^{\mu\alpha}\frac{\partial \Delta x^\nu}{\partial x^\alpha} + g^{\nu\alpha}\frac{\partial \Delta x^\mu}{\partial x^\alpha}\right) + \frac{\partial Q}{\partial g_\alpha^{\mu\nu}}\left(\frac{\partial}{\partial x^\alpha}(\Delta g^{\mu\nu}) - \frac{\partial \Delta x^\beta}{\partial x^\alpha} g_\beta^{\mu\nu}\right) \\ &= 2\frac{\partial Q}{\partial g^{\mu\nu}} g^{\mu\alpha}\frac{\partial \Delta x^\nu}{\partial x^\alpha} + \frac{\partial Q}{\partial g_\alpha^{\mu\nu}}\left(\frac{\partial}{\partial x^\alpha}\left(2 g^{\mu\beta}\frac{\partial \Delta x^\nu}{\partial x^\beta}\right) - \frac{\partial \Delta x^\beta}{\partial x^\alpha} g_\beta^{\mu\nu}\right) \\ &= 2\frac{\partial Q}{\partial g^{\mu\nu}} g^{\mu\alpha}\frac{\partial \Delta x^\nu}{\partial x^\alpha} + 2\frac{\partial Q}{\partial g_\alpha^{\mu\nu}} g_\alpha^{\mu\beta}\frac{\partial \Delta x^\nu}{\partial x^\beta} + 2\frac{\partial Q}{\partial g_\alpha^{\mu\nu}} g^{\mu\beta}\frac{\partial^2 \Delta x^\nu}{\partial x^\alpha \partial x^\beta} - \frac{\partial Q}{\partial g_\alpha^{\mu\nu}} g_\beta^{\mu\nu}\frac{\partial \Delta x^\beta}{\partial x^\alpha}.\end{aligned}$$

Grouping terms in $\partial \Delta x^\nu / \partial x^\alpha$ and in $\partial^2 \Delta x^\nu / \partial x^\alpha \partial x^\beta$ and relabeling indices, one arrives at eq. (28).

$$\left[\frac{1}{2}\Delta H = g^{\nu\alpha}\frac{\partial H}{\partial g^{\mu\nu}_{\sigma}}\frac{\partial^2\Delta x^{\mu}}{\partial x^{\alpha}\partial x^{\sigma}}\right]$$

With the help of [this equation and $\Delta(\sqrt{-g}d\tau) = 0$] one arrives at

$$\left[\frac{1}{2}\Delta J = \int d\tau g^{\nu\alpha}\frac{\partial H\sqrt{-g}}{\partial g^{\mu\nu}_{\sigma}}\frac{\partial^2\Delta x^{\mu}}{\partial x^{\alpha}\partial x^{\sigma}}\right]$$

and from this through partial integration at

$$\left[\frac{1}{2}\Delta J = \int d\tau(\Delta x^{\mu}B_{\mu}) + \text{surface terms}\right]^{50}$$

Using eq. (28) with H instead of Q and the invariance of $\sqrt{-g}d\tau$, one arrives at

$$\frac{1}{2}\Delta J = \int\left\{g^{\alpha\nu}\frac{\partial H}{\partial g^{\alpha\sigma}} + g^{\beta\nu}_{\alpha}\frac{\partial H}{\partial g^{\beta\sigma}_{\alpha}} - \frac{1}{2}g^{\alpha\beta}_{\sigma}\frac{\partial H}{\partial g^{\alpha\beta}_{\nu}}\right\}\frac{\partial\Delta x^{\sigma}}{\partial x^{\nu}}\sqrt{-g}d\tau$$
$$+\int g^{\rho\tau}\frac{\partial H}{\partial g^{\mu\tau}_{\sigma}}\frac{\partial^2\Delta x^{\mu}}{\partial x^{\rho}\partial x^{\sigma}}\sqrt{-g}d\tau.$$

The condition that the expression in curly brackets vanish guarantees that $\Delta J = 0$ for linear transformations. Comparing this expression to S^{ν}_{σ}, the coefficients of $\partial\Delta x^{\sigma}/\partial x^{\nu}$ in eq. (29), one sees that the condition read off of the expression for ΔJ above is equivalent but not identical to the conditions $S^{\nu}_{\sigma} = 0$. So even if Einstein actually did calculate the coefficients of $\partial\Delta x^{\sigma}/\partial x^{\nu}$ in ΔH and ΔJ, he would not have arrived at the conditions $S^{\nu}_{\sigma} = 0$ found in the context of energy-momentum conservation. Consequently, he would still not have realized that $S^{\nu}_{\sigma} = 0$ for any function that transforms as a scalar under general linear transformations and that these conditions therefore cannot be used to determine the Lagrangian.[51]

Almost a year went by before Einstein discovered his error. As he wrote to Lorentz in early October 1915:

> The invariant-theoretical method actually does not tell us more than the Hamiltonian principle when it comes to the determination of your function Q $(= H\sqrt{-g})$ [see Lorentz 1915, 763]. That I did not realize this last year is because I nonchalantly introduced the assumption on p. 1069 of my paper [Einstein 1914c] that H be an invariant under *linear* transformations.[52]

The conditions on Q coming from the “Hamiltonian principle” are presumably the ones coming from the requirement that expressions (13) and (19) for t^{μ}_{ν} are equal to one another. This is how Einstein derives the conditions $S^{\nu}_{\sigma} = 0$ in his letter to

50 “Wir nehmen nun an daß H bezüglich linearer Transformationen eine Invariante sei; d. h. ΔH soll verschwinden, falls die […] verschwinden. Unter dieser Voraussetzung enthalten wir […]. Mit hilfe von […] erhält man […] und hieraus durch partielle Integration […]” (Einstein 1914c, 1069–1070).

51 In (Einstein 1916c, 1113–1115), the conditions $S^{\nu}_{\sigma} = 0$ and $B_{\mu} = 0$ are derived in yet another way (see sec. 9, eqs. (117)–(122)).

Lorentz. He then adds: “This is also the condition for $[Q d\tau]$ being an invariant under linear transformations” (ibid.).[53]

We now turn from the conditions $S_\sigma^\nu = 0$ to the conditions $B_\mu = 0$. These are the conditions for “coordinates adapted to the gravitational field.”[54] or “adapted coordinates” for short. If some metric field $g^{\mu\nu}$ expressed in coordinates x^μ satisfies these conditions, the coordinates are called adapted to that field. Transformations from one adapted coordinate system to another are called “justified.”[55] Such transformations are not mappings of the form $x^\mu \rightarrow x'^\mu$, like ordinary coordinate transformations, but mappings of the form $(x^\mu, g^{\mu\nu}(x)) \rightarrow (x'^\mu, g'^{\mu\nu}(x'))$. Because of their dependence on the metric, Einstein, at Ehrenfest’s suggestion, called them “non-autonomous” transformations at one point.[56]

Einstein looked upon the conditions $B_\mu = 0$ for adapted coordinates as the coordinate restriction with which the *Entwurf* field equations could be extracted from unknown generally-covariant equations.[57] He must have been pleased to see that these coordinate restrictions follow from energy-momentum conservation. In March 1914, Einstein wrote a letter to Besso reporting on the results that would be published a few months later in (Einstein and Grossmann 1914b). He showed how the conditions $B_\mu = 0$ follow from the field equations and energy-momentum conservation (cf. eqs. (21)–(22)). The *Entwurf* field equations, he told Besso, “*hold in every frame of reference adapted to this condition*.”[58] Einstein claimed that this class of reference frames included all sorts of accelerated frames, including the important case of a rotating frame.[59] This is not true,[60] but that does not matter for our purposes. What is interesting for our story is the following passage from the draft of Besso’s reply:

> You already had the fundamental insight that the conservation laws represent the condition for positing an admissible coordinate system; but it did not appear to be ruled out that a restriction to Lorentz transformations was thereby essentially already given, so that nothing particularly interesting epistemologically comes out of it. Now everything is fundamentally completely satisfactory.[61]

---

52 “Thatsächlich liefert die invariantentheoretische Methode nicht mehr als das Hamilton’sche Prinzip wenn es sich um die Bestimmung der Ihrer Funktion Q $(= H\sqrt{-g})$ handelt. Dass ich dies letztes Jahr nicht merkte liegt daran, dass ich auf Seite 1069 meiner Abhandlung leichtsinnig die Voraussetzung einführte, H sei eine Invariante bezüglich linearer Transformationen.” Einstein to H. A. Lorentz, October 12, 1915 (CPAE 8, Doc. 129). The function Q was introduced in (Lorentz 1915, 763).

53 “Dies ist gleichzeitig die Bedingung dafür, dass $[Q d\tau]$ eine Invariante bezüglich linearer Substitutionen ist.”

54 “dem Gravitationsfeld angepaßte Koordinatensysteme” (Einstein 1914c, 1070). In (Einstein and Grossmann 1914b, 221), such coordinates are called “‘adapted’ to the manifold” (“der Mannigfaltigkeit „*angepaßte*“”).

55 “„*berechtigte*“” (Einstein and Grossmann 1914b, 221).

56 “„unselbständige“.” Einstein to H. A. Lorentz, 14 August 1913 (CPAE 5, Doc. 467). Non-autonomous transformations play an important role in the Zurich Notebook (see sec. 4.3 of “Commentary …” [in this volume]).

In the first sentence Besso is referring to Einstein's argument of late 1913 which seemed to show that energy-momentum conservation limits the covariance of the *Entwurf* field equations to linear transformations. Einstein had touted this specious result in several places. To Paul Ehrenfest, for instance, he wrote in November 1913, referring both to the argument from energy-momentum conservation and to the 'hole argument':

> The gravitation affair has been resolved to my *full satisfaction* (namely the circumstance that the equations of the gravitational field are only invariant under linear transformations[)]. It turns out that one can prove that *generally-covariant* equations that *fully* determine the field on the basis of the matter [energy-momentum] tensor cannot exist at all. What can be more beautiful than that the necessary specialization follows from the conservation laws?[62]

The argument that energy-momentum conservation restricts the covariance of the field equations to linear transformations evaporated early in 1914. But the triumphant rhetorical question in the passage above can also be applied to the argument leading to the condition $B_\mu = 0$ that took its place: "What can be more beautiful than that the necessary specialization follows from the conservation laws?"

Neither in (Einstein and Grossmann 1914b) nor in (Einstein 1914c) do we find statements drawing attention to the close connection between covariance of the field equations and energy-momentum conservation. Einstein probably did emphasize this connection though in his Wolfskehl lectures in Göttingen in the summer of 1915.[63] Afterwards, in two letters to his friend Heinrich Zangger,[64] Einstein expressed his satisfaction that he had been able to convince the Göttingen mathematicians, and David Hilbert in particular, of his *Entwurf* theory. In November 1915, Einstein found himself in a race against Hilbert to find field equations to replace the discarded *Entwurf* equa-

57 This fits with Einstein's general attitude towards general covariance at the time. In (Einstein 1914b, 177–178), he wrote: "When one has equations relating certain quantities that only hold in certain coordinate systems, one has to distinguish between two cases: 1. There are generally-covariant equations corresponding to the equations […]; 2. There are no generally-covariant equations that can be found on the basis of the equations given for a particular choice of reference frame. In case 2, the equations do not tell us anything about the things represented by these quantities; they only restrict the choice of reference frame. If the equations tell us anything at all about the things represented by these quantities, we are always dealing with case 1" ("Wenn Gleichungen zwischen irgendwelchen Größen gegeben sind, die nur bei spezieller Wahl des Koordinatensystems gültig sind, so sind zwei Fälle zu unterscheiden: 1. Es entsprechen den Gleichungen allgemein kovariante Gleichungen […]; 2. es gibt keine allgemein kovarianten Gleichungen, die aus den für spezielle Wahl des Bezugssystems gegebenen Gleichungen gefolgert werden können. Im Falle 2 sagen die Gleichungen über die durch die Größen dargestellten Dinge gar nichts aus; sie beschränken nur die Wahl des Bezugssystems. Sagen die Gleichungen über die durch die Größen dargestellten Dinge überhaupt etwas aus, so liegt stets der Fall 1 vor […]."). Similarly, he told Ehrenfest: "Grossmann wrote to me that he has now also been able to derive the gravitational [field] equations from the theory of general covariants. That would be a neat addition to our investigation [i.e., Einstein and Grossmann 1914b]" ("Grossmann schrieb mir, dass es ihm nun auch gelinge, die Gravitationsgleichungen aus der allgemeinen Kovariantentheorie abzuleiten. Es wäre dies eine hübsche Ergänzung zu unserer Untersuchung," Einstein to Paul Ehrenfest, before 10 April 1914 [CPAE 8, Doc. 2]).

tions. Page proofs of (Hilbert 1915),[65] the final version of which would not be published until late March 1916, show that the theory originally proposed by Hilbert has a structure that is remarkably similar to that of the *Entwurf* theory as presented in (Einstein and Grossmann 1914b) and (Einstein 1914c). In these page proofs, Hilbert introduces field equations that are invariant under arbitrary transformations of the coordinates—or, as Hilbert calls them, "world parameters" ("Weltparameter"). He then rehearses what is essentially Einstein's 'hole argument' to argue that these "world parameters" need to be restricted to what he calls "spacetime coordinates" ("Raum-Zeitkoordinaten"). Such spacetime coordinates are defined as those world parameters for which a condition called the "energy theorem" ("Energiesatz") holds.[66] It is probably because of these similarities between Hilbert's original theory and the *Entwurf* theory, that Einstein accused Hilbert of "nostrification" ("Nostrifikation") in another letter to Zangger.[67] This episode is interesting for our purposes since it provides circumstantial evidence for our conjecture that Einstein did mention in his Wolfskehl lectures that it should be possible to extract the *Entwurf* field equations from (unknown) generally-covariant equations by imposing the coordinate restriction $B_\mu = 0$ given by the demands of energy-momentum conservation.

---

58 "… *für jedes Bezugssystem gelten, welches dieser Bedingung angepasst ist*." Einstein to Michele Besso, ca. 10 March 1914 (CPAE 5, Doc. 514). Levi-Civita constructed a counter-example to Einstein's claim, Tullio Levi-Civita to Einstein, 28 March 1915 (CPAE 8, Doc. 67). In our notation, Levi-Civita found a non-autonomous transformation $(x^\mu, g^{\mu\nu}(x)) \rightarrow (x'^\mu, g'^{\mu\nu}(x'))$ satisfying the condition for justified transformations between adapted coordinates (i.e., $B_\mu(g^{\mu\nu}(x)) = B_\mu(g'^{\mu\nu}(x')) = 0$), under which the *Entwurf* field equations were nonetheless *not* invariant (i.e., $g^{\mu\nu}(x)$ is a solution but $g'^{\mu\nu}(x')$ is not). In Levi-Civita's example, $g^{\mu\nu}(x) = \eta^{\mu\nu} = \mathrm{diag}(-1, -1, -1, 1)$.

59 This claim was based on a general argument given in Einstein to H.A. Lorentz, 23 January 1915 (CPAE 8, Doc. 47).

60 For the Minkowski metric in rotating coordinates, $B_\mu \neq 0$ (Janssen 1999, 150–151, note 47)

61 "Du hattest schon principiell eingesehen, dass die Erhaltungssätze die Bedingung für die Aufstellung eines zulässigen Coordinatensystems darstellen; aber es schien nicht ausgeschlossen, dass schon dadurch, im Wesentlichen, die Beschränkung auf die Lorentztransformationen gegeben sei, so dass nichts erkenntnistheoretisch besonders interessantes herauskam. Nun ist alles principiell vollkommen befriedigend." Michele Besso to Einstein, draft, 20 March 1914 (CPAE 5, Doc. 516). For further discussion of this letter, see sec. 2.2 of "What Did Einstein Know …" (in this volume).

62 "Die Gravitationsaffäre hat sich zu meiner *vollen Befriedigung* aufgeklärt (der Umstand nämlich, dass die Gleichungen des Gr. Feldes nur linearen Transformationen gegenüber kovariant sind. Es lässt sich nämlich beweisen, dass *allgemein kovariante* Gleichungen, die das Feld aus dem materiellen Tensor vollständig bestimmen, überhaupt nicht existieren können. Was kann es schöneres geben, als dies, dass jene nötige Spezialisierung aus den Erhaltungssätzen fliesst?" Einstein to Paul Ehrenfest, before 7 November 1913 (CPAE 5, Doc. 481).

63 Notes taken by an unknown auditor present at (some of) these lectures were found by Leo Corry and are published in Appendix B of CPAE 6. These notes, however, do not touch on the field equations, nor on energy-momentum conservation.

4. THE MAXWELLIAN *ENTWURF* LAGRANGIAN

We feed the gravitational part of the Lagrangian for the Entwurf field equations, modelled on the Lagrangian for the free Maxwell field, into the general formalism of (Einstein 1914c) and derive the field equations, the expression for the gravitational energy-momentum pseudo-tensor, and the condition for "adapted coordinates" that determines for each solution what other coordinate representations of the solution are allowed by the Entwurf field equations.

One arrives at the gravitational part of the Lagrangian $Q = H\sqrt{-g}$ for the *Entwurf* field equations through the following choice for the function H (Einstein 1914c, 1076, note 1):[68]

$$H = -g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}, \tag{35}$$

where $\Gamma^{\alpha}_{\beta\mu}$ are the components of the gravitational field, defined as (Einstein 1914, p. 1077, eq. 81a):

$$\Gamma^{\alpha}_{\beta\mu} \equiv \frac{1}{2}g^{\alpha\rho}g_{\rho\beta,\mu}. \tag{36}$$

The Lagrangian is modelled on the Lagrangian $-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}$ for the free Maxwell field. Since H is a scalar under linear transformations, the conditions $S^{\nu}_{\sigma} = 0$ are satisfied (see eqs. (30)–(31)).

---

64 Einstein to Heinrich Zangger, 7 July 1915 (CPAE 8, Doc. 94) and between 24 July and 7 August 1915 (CPAE 8, Doc. 101).

65 These page proofs are located at the Niedersächsische Staats- und Universitätsbibliothek in Göttingen (Cod. Ms. D. Hilbert 634), where they were discovered by Leo Corry. For discussion, see (Corry et al. 1997), (Sauer 1999), and "Hilbert's Foundation of Physics …" (in vol. 4 of this series).

66 This restriction is stated in "Axiom III (Axiom of space and time)" ("Axiom III (Axiom von Raum und Zeit")) in the page proofs. This axiom is also mentioned in David Hilbert to Einstein, 13 November 1915 (CPAE 8, Doc. 140). It no longer occurs in (Hilbert 1915).

67 Einstein to Heinrich Zangger, 26 November 1915 (CPAE 8, Doc. 152). From Einstein to David Hilbert, 18 November 1915 (CPAE 8, Doc. 148) it can be inferred that Einstein saw a manuscript with an early version of the theory that would eventually be published in (Hilbert 1915).

68 The expression for H actually differs by a factor $1/2$ from the one that leads to the *Entwurf* field equations as given in Einstein's publications prior to (Einstein 1914c). Substituting eq. (36) for $\Gamma^{\rho}_{\mu\tau}$ into eq. (35), one can rewrite the function H as:

$$H = -g^{\mu\nu}\left(\frac{1}{2}g^{\alpha\sigma}g_{\sigma\beta,\mu}\right)\left(\frac{1}{2}g^{\beta\tau}g_{\tau\alpha,\nu}\right).$$

Since $g^{\alpha\sigma}g^{\beta\tau}g_{\tau\alpha,\nu} = -g^{\sigma\beta}_{\nu}$, this expression can also be written as (Einstein 1914, 1076, eq. 78):

$$H = \frac{1}{4}g^{\mu\nu}g_{\sigma\beta,\mu}g^{\sigma\beta}_{\nu}.$$

To recover the *Entwurf* field equations, the factor $1/4$ should be replaced by $1/2$ (see Einstein and Grossmann 1914, 219, eq.Va, and note 72 below). In other words, the function H should be defined as $H = -2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}$.

The definition of the components of the gravitational field is suggested by the energy-momentum balance equation, written in the form of eq. (), which with the help of eq. (36) can be rewritten as

$$\mathfrak{T}^{\alpha}_{\mu,\alpha} - \Gamma^{\beta}_{\alpha\mu}\mathfrak{T}^{\alpha}_{\beta} = 0.$$

The second term represents the gravitational force density and has the same form as the Lorentz force density, $f_\mu = F_{\mu\nu}j^\nu$. It is the contraction of the field $\Gamma^{\alpha}_{\beta\mu}$ and its source $\mathfrak{T}^{\alpha}_{\beta}$.

The quantities $\Gamma^{\alpha}_{\beta\mu}$ in eq. (36) are truncated versions of the Christoffel symbols[69]

$$\left\{\begin{matrix}\alpha\\ \beta\mu\end{matrix}\right\} = \frac{1}{2}g^{\alpha\rho}(g_{\rho\beta,\mu} + g_{\rho\mu,\beta} - g_{\beta\mu,\rho}).$$

Note that, unlike the Christoffel symbols, the $\Gamma^{\alpha}_{\beta\mu}$-s are not symmetric in their lower indices.

We derive the left-hand side of the *Entwurf* field equations from the action principle $\delta J = 0$. The gravitational part of the action is (see eq. (9))

$$J = \int Q d\tau,$$

with $Q = \sqrt{-g}H$. There are two contributions to δQ:

$$\delta Q = \sqrt{-g}\delta H + (\delta\sqrt{-g})H. \tag{37}$$

---

69 On p. 23L of the Zurich Notebook, Einstein had tried to extract field equations from the November tensor by truncating the Christoffel symbols in a similar fashion. Introducing the quantities

$$\vartheta_{il\alpha} \equiv \frac{1}{2}(g_{il,\alpha} + g_{l\alpha,i} + g_{\alpha i,l})$$

Einstein could write the Christoffel symbols as

$$\left\{\begin{matrix}k\\ il\end{matrix}\right\} = g^{k\alpha}(\vartheta_{il\alpha} - g_{il,\alpha}).$$

Inserting this expression into the November tensor,

$$T^x_{il} = \frac{\partial}{\partial x^k}\left\{\begin{matrix}k\\ il\end{matrix}\right\} - \left\{\begin{matrix}\lambda\\ ik\end{matrix}\right\}\left\{\begin{matrix}k\\ \lambda l\end{matrix}\right\}$$

(see eq. (5)), and eliminating all terms involving $\vartheta_{il\alpha}$ with the help of the appropriate coordinate restriction, Einstein arrived at the following candidate for the left-hand side of the field equations

$$-\frac{\partial}{\partial x^k}(g^{k\alpha}g_{il,\alpha}) - (g^{\lambda\alpha}g_{ik,\alpha})(g^{k\beta}g_{\lambda l,\beta}).$$

As Einstein realized, this expression can be obtained in one fell swoop by setting $\vartheta_{il\alpha} = 0$ and substituting $-g^{k\alpha}g_{il,\alpha}$ for the Christoffel symbols in the November tensor. Like all other candidates extracted from the Riemann tensor in the Zurich Notebook, this candidate was rejected because the necessary coordinate restriction turned out to be too restrictive. For a more detailed analysis, see sec. 5.5.4 of "Commentary …" (in this volume).

Since $\delta g = -g g_{\alpha\beta}\delta g^{\alpha\beta}$ (see Einstein 1914c, 1051, eqs. 32–34; Einstein 1916a, 796, eq. 29),

$$\delta\sqrt{-g} = -\frac{1}{2}\sqrt{-g}\,g_{\mu\nu}\delta g^{\mu\nu}. \tag{38}$$

Inserting this expression and eq. (35) for H into the second contribution to δQ in eq. (37), one arrives at:

$$(\delta\sqrt{-g})H = \left(\frac{1}{2}\sqrt{-g}\,g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\right)\delta g^{\mu\nu}. \tag{39}$$

Variation of H in the first contribution to δQ in eq. (37) gives:

$$\delta H = \delta(-g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}) = -\delta g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} - 2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\delta\Gamma^{\beta}_{\alpha\nu}.$$

For $\delta\Gamma^{\beta}_{\alpha\nu}$ one finds:[70]

$$\delta\Gamma^{\beta}_{\alpha\nu} = -\frac{1}{2}g_{\alpha\lambda}\delta g^{\beta\lambda}_{\nu} - g_{\alpha\rho}\Gamma^{\beta}_{\sigma\nu}\delta g^{\rho\sigma}.$$

It follows that:[71]

$$-2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\delta\Gamma^{\beta}_{\alpha\nu} = g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta}\delta g^{\mu\nu}_{\alpha} + 2g^{\rho\tau}g_{\alpha\mu}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\nu\tau}\delta g^{\mu\nu}.$$

Substituting this into the expression for δH above and collecting terms with $\delta g^{\mu\nu}$ and $\delta g^{\mu\nu}_{\alpha}$, one finds:

$$\delta H = (2g^{\rho\tau}g_{\alpha\mu}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\nu\tau} - \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu})\delta g^{\mu\nu} + (g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta})\delta g^{\mu\nu}_{\alpha}. \tag{40}$$

Inserting eqs. (39) and (40) into eq. (37), one finds:

$$\delta Q = \sqrt{-g}\Big[\Big(2g^{\rho\tau}g_{\alpha\mu}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\nu\tau} - \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\Big)\delta g^{\mu\nu} + (g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta})\delta g^{\mu\nu}_{\alpha}\Big].$$

Comparison of this expression with $\delta Q = \dfrac{\partial Q}{\partial g^{\mu\nu}}\delta g^{\mu\nu} + \dfrac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\delta g^{\mu\nu}_{\alpha}$ gives

---

70 Using eq. (36) for $\Gamma^{\beta}_{\alpha\nu}$, one finds:

$$\delta\Gamma^{\beta}_{\alpha\nu} = \frac{1}{2}\delta(g^{\beta\lambda}g_{\lambda\alpha,\nu}) = -\frac{1}{2}\delta(g^{\beta\lambda}_{\nu}g_{\lambda\alpha}) = -\frac{1}{2}\delta g^{\beta\lambda}_{\nu}g_{\lambda\alpha} - \frac{1}{2}g^{\beta\lambda}_{\nu}\delta g_{\lambda\alpha}.$$

Since $\delta g_{\alpha\lambda} = -g_{\alpha\rho}g_{\lambda\sigma}\delta g^{\rho\sigma}$, the last term can be rewritten as:

$$-\frac{1}{2}g^{\beta\lambda}_{\nu}\delta g_{\alpha\lambda} = \frac{1}{2}g^{\beta\lambda}_{\nu}g_{\alpha\rho}g_{\lambda\sigma}\delta g^{\rho\sigma} = -\frac{1}{2}g^{\beta\lambda}g_{\lambda\sigma,\nu}g_{\alpha\rho}\delta g^{\rho\sigma} = -g_{\alpha\rho}\Gamma^{\beta}_{\sigma\nu}\delta g^{\rho\sigma}.$$

71 This follows from

$$-2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\delta\Gamma^{\beta}_{\alpha\nu} = g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}(g_{\alpha\lambda}\delta g^{\beta\lambda}_{\nu}) + 2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}(g_{\alpha\rho}\Gamma^{\beta}_{\sigma\nu}\delta g^{\rho\sigma})$$

after relabeling indices.

$$\frac{\partial Q}{\partial g^{\mu\nu}} = \sqrt{-g}\Big(2g^{\rho\tau}g_{\alpha\mu}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\nu\tau} - \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\Big), \tag{41}$$

$$\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}} = \sqrt{-g}g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta}. \tag{42}$$

Inserting equations (41)–(42) into the general form of the field equations,

$$\frac{\partial}{\partial x^{\alpha}}\Big(\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\Big) - \frac{\partial Q}{\partial g^{\mu\nu}} = -\kappa\mathfrak{T}_{\mu\nu} \tag{43}$$

(see eq. (11)), one can write the *Entwurf* field equations as:[72]

$$\begin{aligned}\frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta}) - \sqrt{-g}\Big(2g^{\rho\tau}g_{\alpha\mu}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\nu\tau} - \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}\\ + \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\Big) = -\kappa\mathfrak{T}_{\mu\nu}.\end{aligned} \tag{44}$$

The *Entwurf* field equations can be written in a more compact form (Einstein 1914c, 1077). Instead of using eq. (43), one can use the field equations in the general form

72 Expressing $\Gamma^{\alpha}_{\mu\nu}$ in terms of $g_{\mu\nu}$ and multiplying the left-hand side of eq. (44) by 2 to correct for the error in eq. (35) for H (see note 68), one recovers the *Entwurf* field equation as originally given in (Einstein and Grossmann 1913). The first two terms on the left-hand side of eq. (44) can be written as:

$$\frac{\partial}{\partial x^{\alpha}}\Big(\sqrt{-g}g^{\alpha\beta}g_{\rho\nu}\Big[\frac{1}{2}g^{\rho\lambda}g_{\lambda\mu,\beta}\Big]\Big) - 2\sqrt{-g}g^{\rho\tau}g_{\alpha\mu}\Big(\frac{1}{2}g^{\alpha\sigma}g_{\sigma\beta,\rho}\Big)\Big(\frac{1}{2}g^{\beta\lambda}g_{\lambda\nu,\tau}\Big)$$
$$= \frac{1}{2}\sqrt{-g}\Big\{\frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}g^{\alpha\beta}g_{\mu\nu,\beta}) - g^{\alpha\beta}g^{\tau\rho}g_{\mu\tau,\alpha}g_{\nu\rho,\beta}\Big\}.$$

The expression in curly brackets is the quantity $D_{\mu\nu}(g)$ defined in (Einstein and Grossmann 1913, 16, eq. 16). The last two terms on the left-hand side eq. (44) can likewise be written as:

$$\sqrt{-g}\Big(\Big[\frac{1}{2}g^{\alpha\rho}g_{\rho\beta,\mu}\Big]\Big[\frac{1}{2}g^{\beta\sigma}g_{\sigma\alpha,\nu}\Big] - \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Big[\frac{1}{2}g^{\alpha\tau}g_{\tau\beta,\rho}\Big]\Big[\frac{1}{2}g^{\beta\lambda}g_{\lambda\alpha,\sigma}\Big]\Big)$$
$$= -\frac{1}{2}\sqrt{-g}\Big\{\frac{1}{2}\Big[g^{\alpha\beta}_{\mu}g_{\alpha\beta,\nu} - \frac{1}{2}g_{\mu\nu}g^{\alpha\beta}g^{\tau\rho}_{\alpha}g_{\tau\rho,\beta}\Big]\Big\}.$$

The expression in square brackets is the quantity $-2\kappa t_{\mu\nu}$ in (Einstein and Grossmann 1913, 16, eq. 14). The left-hand side of eq. (44) can thus be rewritten as:

$$\frac{1}{2}\sqrt{-g}\{D_{\mu\nu}(g) + \kappa t_{\mu\nu}\}.$$

Omitting the erroneous factor $1/2$ and dividing by $\sqrt{-g}$, one sees that eq. (44) can be rewritten as

$$-D_{\mu\nu}(g) = \kappa(t_{\mu\nu} + T_{\mu\nu}),$$

which is just (Einstein and Grossmann 1913, 17, eq. 21).

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\nu\lambda}\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}}\right) = -\kappa(\mathfrak{T}^{\lambda}_{\mu} + t^{\lambda}_{\mu}) \tag{45}$$

(see eq. (13)), along with eq. (18) for the gravitational energy-momentum tensor[73]

$$\kappa t^{\lambda}_{\mu} = \frac{1}{2}\left(\delta^{\lambda}_{\mu}Q - g^{\alpha\beta}_{\mu}\frac{\partial Q}{\partial g^{\alpha\beta}_{\lambda}}\right). \tag{46}$$

Using expression (35) for H in $Q = H\sqrt{-g}$, one recovers the *Entwurf* field equations as given by Einstein. From eq. (42) it follows that eq. (45) in this case is:[74]

$$\frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}g^{\alpha\beta}\Gamma^{\lambda}_{\mu\beta}) = -\kappa(\mathfrak{T}^{\lambda}_{\mu} + t^{\lambda}_{\mu}). \tag{47}$$

From eqs. (35) and (42) it follows that eq. (46) in this case is:

$$\kappa t^{\lambda}_{\mu} = \frac{1}{2}(\delta^{\lambda}_{\mu}\sqrt{-g}[-g^{\rho\tau}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\tau}] - g^{\alpha\beta}_{\mu}[\sqrt{-g}g^{\lambda\rho}g_{\tau\beta}\Gamma^{\tau}_{\alpha\rho}]). \tag{48}$$

Simplifying this expression, one finds[75]

$$\kappa t^{\lambda}_{\mu} = \sqrt{-g}\left(g^{\lambda\rho}\Gamma^{\alpha}_{\tau\mu}\Gamma^{\tau}_{\alpha\rho} - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\tau}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\tau}\right). \tag{49}$$

This is indeed the expression for the gravitational energy-momentum pseudo-tensor as given in (Einstein 1914c, 1077, eq. 81b). And with this expression for t^{λ}_{μ}, the field equations (47) are indeed the *Entwurf* field equations as given in (Einstein 1914c, 1077, eq. 81).[76]

From eq. (47) it follows that the conditions $B_{\mu} = 0$ —playing the dual role of restricting the coordinates (see eq. (32)) and guaranteeing the vanishing of the divergence of $t^{\lambda}_{\mu} + \mathfrak{T}^{\lambda}_{\mu}$ (see eqs. (21)–(22))—take on the specific form:

$$B_{\mu} = \frac{\partial^2}{\partial x^{\alpha}\partial x^{\lambda}}(\sqrt{-g}g^{\alpha\beta}\Gamma^{\lambda}_{\mu\beta}) = 0. \tag{50}$$

---

73 This expression is simpler than expression (12), which depends both on $\partial Q/\partial g^{\alpha\beta}_{\lambda}$ and on $\partial Q/(\partial g^{\mu\nu}.)$ Since $S^{\nu}_{\sigma} = 0$, expressions (12) and (18) are equivalent (see eq. (18)–(20)).

74 In detail: $\frac{\partial}{\partial x^{\alpha}}(g^{\nu\lambda}[\sqrt{-g}g^{\alpha\beta}g_{\rho\nu}\Gamma^{\rho}_{\mu\beta}]) = \frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}g^{\alpha\beta}\delta^{\lambda}_{\rho}\Gamma^{\rho}_{\mu\beta}) = \frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}g^{\alpha\beta}\Gamma^{\lambda}_{\mu\beta})$

75 The last term in eq. (48) can be rewritten as:

$$-\frac{1}{2}\sqrt{-g}g^{\alpha\beta}_{\mu}g^{\lambda\rho}g_{\tau\beta}\Gamma^{\tau}_{\alpha\rho} = \frac{1}{2}\sqrt{-g}g^{\alpha\beta}g^{\lambda\rho}g_{\tau\beta,\mu}\Gamma^{\tau}_{\alpha\rho} = \sqrt{-g}g^{\lambda\rho}\Gamma^{\alpha}_{\tau\mu}(\Gamma_{\alpha\rho},)^{\tau}$$

where in the last step eq. (36) was used.

76 To obtain the *Entwurf* field equations of Einstein's earlier publications, one needs to multiply both the left-hand side of eq. (47) and the right-hand sides of eqs. (48)–(49) by 2 (see notes 68 and 72).

Commenting on eq. (36) for the gravitational field, eq. (47), the *Entwurf* field equations, and eq. (49) for the gravitational energy-momentum pseudo-tensor, Einstein wrote

> Despite its complexity, the system of equations admits of a simple physical interpretation. The left-hand side [of eq. (47)] expresses a kind of divergence of the gravitational field [eq. (36)]. This [divergence] is—as the right-hand side shows—determined by the components of the total energy tensor. What is very important is the result that the energy tensor of the gravitational field [eq. (49)] acts as a source of the field in the same way as the energy tensor of matter.[77]

On the preceding page, Einstein boasted that his new derivation of the *Entwurf* field equations is essentially free from physical considerations. After showing that the expression for H in eq. (35) satisfies the conditions $S_\sigma^\nu = 0$ —as would any other expression transforming as a scalar under linear transformations—he wrote:

> We have now in a completely formal manner, i.e., without direct use of our physical knowledge about gravity, arrived at very definite field equations.[78]

Even if we forget for a moment that the uniqueness argument immediately preceding it is hogwash, this statement is patently false. The derivation of the *Entwurf* field equations in (Einstein 1914c, part D) may be more formal than earlier derivations, but it still relies heavily on physical considerations. The function H giving the Lagrangian is modelled on the Lagrangian for the free Maxwell field. It is assumed to depend only on first-order derivatives of the metric because the Poisson equation of Newtonian theory suggests that the gravitational field equations do not contain anything higher than second-order derivatives of the metric (Einstein and Grossmann 1913, 11). The conditions $S_\sigma^\nu = 0$ that supposedly determine H uniquely are derived from the energy-momentum balance law of matter in a gravitational field (see

77 "Das Gleichungssystem […] läßt trotz seiner Kompliziertheit eine einfache physikalische Interpretation zu. Die linke Seite drückt eine Art Divergenz des Gravitationsfeldes aus. Diese wird—wie die rechte Seite zeigt—bedingt durch die Komponente des totalen Energietensors. Sehr wichtig ist dabei das Ergebnis, daß der Energietensor des Gravitationsfeldes selbst in gleicher Weise felderregend wirksam ist wie der Energietensor der Materie" (Einstein 1914c, 1077).

78 "Wir sind nun auf rein formalem Wege, d. h. ohne direkte Heranziehung unserer physikalischen Kenntnisse von der Gravitation, zu ganz bestimmten Feldgleichungen gelangt" (Einstein 1914c, 1076). Einstein had already announced this proudly in the introduction of the paper: "In particular, it was possible to obtain the equations for the gravitational field in a purely covariant-theoretical way" ("Es gelang insbesondere, die Gleichungen des Gravitationsfeldes auf einem rein kovarianten-theoretischen Wege zu gewinnen;" ibid., 1030). Earlier in 1914, in a paper co-authored with Adriaan D. Fokker, Einstein had made a similar claim for his reformulation of the Nordström theory in terms of Riemannian geometry. In the conclusion of their paper, the authors wrote: "In the foregoing it was possible to show that, if one bases oneself on the principle of the constancy of the velocity of light, one can arrive at Nordström's theory by purely formal considerations, i.e., without recourse to additional physical hypotheses" ("Im vorstehenden konnte gezeigt werden, daß man bei Zugrundelegung des Prinzips von der Konstanz der Lichtgeschwindigkeit durch rein formale Erwägungen, d.h. ohne Zuhilfenahme weiterer physikalischen Hypothesen zur Nordströmschen Theorie gelangen kann;" Einstein and Fokker 1914, 328).

sec. 3.2). Moreover, H only gives the gravitational part of the field equations. The matter part, $\mathfrak{T}_{\mu}^{\lambda}$, is inserted on the basis of physical considerations. The same is true for the way in which the gravitational part of the field equations is split into a term with the divergence of the gravitational field and a term with the gravitational energy-momentum pseudo-tensor. All this is hard to reconcile with Einstein's claim to have derived the equations "in a completely formal manner."[79]

The claim, we suggest, should be understood against the backdrop of Einstein's obvious satisfaction that physical and mathematical considerations now seemed to point to the same field equations. Material in the Zurich Notebook shows that when Einstein began to generate field equations from their weak-field form by imposing energy-momentum conservation—the method that originally gave him the *Entwurf* field equations—he also tried to recover the resulting equations from the November tensor.[80] Such an alternative derivation of the field equations would have thrown light on their covariance properties. What Einstein presents in the review article of 1914 amounts to the same thing. Although he still had not found any connection between the *Entwurf* field equations and the Ricci tensor or the November tensor, he did supplement the physical considerations in the derivation of the *Entwurf* field equations by mathematical considerations that clarify—or so Einstein thought—their covariance properties. It therefore need not surprise us that Einstein overrated the importance of mathematical considerations in his new derivation of the *Entwurf* field equations.

5. A 'FATEFUL PREJUDICE' AND THE 'KEY TO THE SOLUTION': FROM THE *ENTWURF* LAGRANGIAN TO THE NOVEMBER LAGRANGIAN

When in the Entwurf Lagrangian the gravitational field is redefined as minus the Christoffel symbols, we find new field equations that bear a striking resemblance to field equations based on the November tensor found in the Zurich Notebook. When a factor $\sqrt{-g}$ is omitted in the action with the new definition of the gravitational field, the field equations are exactly the same as these equations in the Zurich Notebook. Einstein called the old definition of the gravitational field a "fateful prejudice" and the new definition "the key to the solution." This strongly suggests that the way in which Einstein found his way back to these discarded field equations of the Zurich Notebook shortly before he published them in (Einstein 1915a) was essentially the same as the way in which they are recovered in this section.

What are the field equations if one retains the form of (the gravitational part of) the *Entwurf* Lagrangian $Q = H\sqrt{-g}$, with

79 Einstein likewise overestimated the importance of purely mathematical considerations in deriving the field equations of the Nordström theory in (Einstein and Fokker 1914).

80 See pp. 24R–25R of the Zurich Notebook and sec. 5.6 of "Commentary …" (in this volume) for detailed analysis.

$$H = -g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} \tag{51}$$

(see eq. (35)), but changes the definition of the components of the gravitational field from

$$\Gamma^{\alpha}_{\beta\mu} \equiv \frac{1}{2}g^{\alpha\rho}g_{\rho\beta,\mu} \tag{52}$$

(see eq. (36)) to

$$\Gamma^{\alpha}_{\beta\mu} \equiv -\begin{Bmatrix}\alpha\\ \beta\mu\end{Bmatrix} = -\frac{1}{2}g^{\alpha\rho}(g_{\rho\beta,\mu} + g_{\rho\mu,\beta} - g_{\beta\mu,\rho}), \tag{53}$$

as Einstein did in his first November 1915 paper?

As before (see eqs. (35)-(44)), the left-hand side of the field equations follows from $\delta J = 0$, where

$$J = \int Q d\tau = \int H\sqrt{-g}d\tau. \tag{54}$$

Variation of Q gives two contributions (see eq. (37)):

$$\delta Q = \sqrt{-g}\delta H + (\delta\sqrt{-g})H. \tag{55}$$

The second contribution is the same as before (see eq. (39)):

$$(\delta\sqrt{-g})H = \left(\frac{1}{2}\sqrt{-g}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\right)\delta g^{\mu\nu}. \tag{56}$$

Likewise, δH can once again be written as

$$\delta H = -\delta g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} - 2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\delta(\Gamma_{\alpha\nu\cdot})^{\beta}$$

However, since $\Gamma^{\alpha}_{\beta\mu}$ in eq. (53) is symmetric in its lower indices whereas $\Gamma^{\alpha}_{\beta\mu}$ in eq. (52) is not, the expression for δH ends up being much simpler than before (cf. eq. (40)). The expression for δH above can be rewritten as

$$\delta H = \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}\delta g^{\mu\nu} - 2\Gamma^{\alpha}_{\beta\mu}\delta(g^{\mu\nu}\Gamma^{\beta}_{\alpha\nu}),$$

which reduces to:[81]

$$\delta H = \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}\delta g^{\mu\nu} - \Gamma^{\alpha}_{\mu\nu}\delta g^{\mu\nu}_{\alpha}. \tag{57}$$

---

81 Using the definition of $\Gamma^{\beta}_{\alpha\nu}$ in eq. (53), one can rewrite the last term of the expression above as

$$-\Gamma^{\alpha}_{\beta\mu}\delta(g^{\mu\nu}g^{\beta\lambda}(g_{\lambda\alpha,\nu} + g_{\lambda\nu,\alpha} - g_{\alpha\nu,\lambda}))$$

Since $\Gamma^{\alpha}_{\beta\mu}g^{\mu\nu}g^{\beta\lambda}$ is symmetric in λ and ν and $g_{\lambda\alpha,\nu} - g_{\nu\alpha,\lambda}$ is anti-symmetric in λ and ν, their contraction vanishes and the expression above reduces to:

$$-\Gamma^{\alpha}_{\beta\mu}\delta(g^{\mu\nu}g^{\beta\lambda}g_{\lambda\nu,\alpha}).$$

Using that $g^{\mu\nu}g^{\beta\lambda}g_{\lambda\nu,\alpha} = -g^{\mu\beta}_{\alpha}$, one can rewrite this as $\Gamma^{\alpha}_{\mu\nu}\delta g^{\mu\nu}_{\alpha}$.

Inserting eqs. (56) and (57) into eq. (55), one finds:

$$\delta Q = \sqrt{-g}\Big[\Big(\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\Big)\delta g^{\mu\nu} - \Gamma^{\alpha}_{\mu\nu}\delta g^{\mu\nu}_{\alpha}\Big]. \tag{58}$$

It follows that

$$\frac{\partial Q}{\partial g^{\mu\nu}} = \sqrt{-g}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{1}{2}\sqrt{-g}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}, \tag{59}$$

$$\frac{\partial Q}{\partial g^{\mu\nu}_{\alpha}} = -\sqrt{-g}\Gamma^{\alpha}_{\mu\nu}. \tag{60}$$

Inserting equations (59)–(60) into eq. (43), one finds the field equations:

$$\frac{\partial}{\partial x^{\alpha}}(\sqrt{-g}\Gamma^{\alpha}_{\mu\nu}) + \sqrt{-g}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{1}{2}\sqrt{-g}g_{\mu\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma} = \kappa\mathfrak{T}_{\mu\nu}. \tag{61}$$

If one omits the factors $\sqrt{-g}$ in the first two terms and uses eq. (53) for the components of the gravitational field, these two terms become:

$$-\frac{\partial}{\partial x^{\alpha}}\begin{Bmatrix}\alpha\\ \mu\nu\end{Bmatrix} + \begin{Bmatrix}\alpha\\ \beta\mu\end{Bmatrix}\begin{Bmatrix}\beta\\ \nu\alpha\end{Bmatrix}.$$

This is just minus the November tensor which Einstein had extracted from the Ricci tensor in the Zurich Notebook by imposing the restriction to unimodular transformations. It is not hard to see how the calculation in eqs. (54)–(61) needs to be modified in order to recover the field equations (6) based on the November tensor without any of the additional extra terms and factors in eq. (61). First, one only requires J to transform as a scalar under unimodular transformations whenever H does. One can then start from

$$J \equiv -\int H d\tau. \tag{62}$$

Before (see eq. (54)) a factor $\sqrt{-g}$ was needed because only the combination $\sqrt{-g}d\tau$ is an invariant volume element under arbitrary transformations. Under unimodular transformations, however, $d\tau$ by itself is invariant.

It turns out (see sec. 6) that omission of a factor $\sqrt{-g}$ in the action seriously complicates the use of the formalism of (Einstein 1914c). It would have been easier to work with the field equations (61) retaining all factors of $\sqrt{-g}$. The covariance properties of these equations, however, look as intractable as those of the *Entwurf* equations. Omission of a factor $\sqrt{-g}$ was a small price to pay for field equations with a broad well-defined covariance group closely connected to the Riemann tensor.[82] This was the connection Einstein had been looking for in vain in the days of the Zurich Notebook. In (Einstein 1914c) he thought that such a connection was no longer needed, that instead he could supplement the physical considerations going into the derivation of the *Entwurf* field equations with mathematical ones establishing, or so it seemed, that their covariance was broad enough for the generalization of the relativity principle he envisioned. That approach had ultimately failed. The action (62) now promised to resurrect the old ideal of the Zurich Notebook in which physical and mathematical considerations would point to the same field equations. Complications coming from omitting a factor $\sqrt{-g}$ could be dealt with later.

Eq. (62) is indeed the action from which the field equations are derived in (Einstein 1915a, 784, eq. 17). Einstein used the notation $\mathfrak{L}$ for $-H$. $\mathfrak{L}$ is given by (see eq. (51)):

$$\mathfrak{L} = -H = g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}, \tag{63}$$

The field equations are:

$$\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial\mathfrak{L}}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial\mathfrak{L}}{\partial g^{\mu\nu}} = -\kappa T_{\mu\nu} \tag{64}$$

(Einstein 1915a, 784, eq. 18). The variation $\delta\mathfrak{L} = -\delta H$ can be read off of eq. (57). It follows that (Einstein 1915a, 784, eqs. 19–19a):[83]

$$\frac{\partial\mathfrak{L}}{\partial g^{\mu\nu}} = -\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}, \tag{65}$$

$$\frac{\partial\mathfrak{L}}{\partial g^{\mu\nu}_{\alpha}} = \Gamma^{\alpha}_{\mu\nu}. \tag{66}$$

Inserting eqs. (65)–(66) into eq. (64), one finds the field equations (Einstein 1915a, 783, eq. 16a):

$$\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} = -\kappa T_{\mu\nu}. \tag{67}$$

When minus the Christoffel symbols are substituted for the quantities $\Gamma^{\alpha}_{\beta\mu}$, eq. (67) turns into eq. (6) based on the "November" tensor familiar from the Zurich Notebook. These field equations replace the *Entwurf* equations in (Einstein 1915a).

By changing the definition of the gravitational field in the *Entwurf* Lagrangian and by restricting the variational formalism of sec. 3 to unimodular transformations,

82 Another advantage was that unimodular transformations are autonomous. Einstein had been greatly relieved when, in August 1913, he hit upon the (fallacious) argument that energy-momentum conservation limited the covariance of the *Entwurf* equations to linear transformations. That meant that he could stop searching for non-linear non-autonomous transformation leaving the equations invariant. He had been unable to find a single one up to that point (Einstein to Lorentz, 14 and 16 August 1913 [CPAE 5, Docs. 467 and 470]; for further discussion, see sec. 3 of "What Did Einstein Know …" [in this volume]). After the argument had evaporated, Einstein had been forced to reconsider non-autonomous transformations. He eventually concluded that the condition $B_{\mu} = 0$ for the *Entwurf* theory (see eq. (50)) allows non-autonomous transformations to arbitrarily moving systems. The simple case of rotation in Minkowski spacetime proved him wrong. With field equations invariant under unimodular transformations, Einstein could avoid these problematic non-autonomous transformations altogether.

we have thus arrived at field equations with a clearly defined covariance group. Einstein's comments that the old definition (52) of the gravitational field was a "fateful prejudice" (cf. note 38) and that the new definition (53) was "the key to the solution" (cf. note 39) provide strong textual evidence that he found his way back to the field equations (67) in essentially the same way in which they were derived in this section.

This provides a remarkably simple solution to one of the central puzzles in reconstructing Einstein's path to the Einstein field equations. As John Norton (1984, 142) put it: "Why Einstein should choose [the November tensor, i.e., the left-hand side of eq. (67)] as his gravitation tensor rather than a generally-covariant tensor, such as the Ricci tensor or even the Einstein tensor itself, has hitherto been a puzzle." Norton conjectured that it was Einstein's prejudice about the form of the metric for weak static fields that prevented him from choosing the Ricci tensor. To reduce the Ricci tensor to the d'Alembertian acting on the metric in the case of weak fields, the argument went, one needs the harmonic coordinate condition, which is not satisfied by Einstein's metric for weak static fields. In the case of the November tensor, one can use the Hertz condition for this purpose (see eqs. (7)-(8)), which is satisfied by Einstein's metric for weak static fields. Aside from solving Norton's puzzle, there is no evidence that the incompatibility between the harmonic condition and Einstein's prejudice about the form of the metric for weak static fields played a role at this juncture. Our alternative solution to the puzzle removes the need for invoking this incompatibility.[84] Why did Einstein choose the November tensor rather than the Ricci tensor? Because both the mathematical and the physical strategy he employed in his search for suitable field equations pointed to the November tensor, not to the Ricci tensor.

---

83 The operations 'doing the variations' and 'setting $\sqrt{-g} = 1$' do not commute. Setting $\sqrt{-g} = 1$ in eqs. (59)–(60)—i.e., *after* doing the variations in eqs. (54)–(58)—does not reduce these equations to eqs. (65)-(66), which are obtained by setting $\sqrt{-g} = 1$ in eq. (54)—i.e., *before* doing the variations. If the condition $\sqrt{-g} = 1$ is imposed first, the variation is done under a constraint (Kichenassamy 1993, 197). This is the analogue in functional analysis of the problem in ordinary calculus of finding the extrema of a function under a constraint. Such problems can be replaced by the problem of finding the extrema of a related function(al) without constraints through the well-known technique of Lagrange multipliers. Einstein was familiar with these techniques for functionals from his work in statistical mechanics. To derive various ensembles in statistical mechanics (micro-canonical, canonical, or grand canonical), one maximizes the entropy under two constraints, one on the total energy and one on the total particle number. The difference with the case of varying the action for the metric field is that the constraint $\sqrt{-g(x)} = 1$ has to be imposed at every point x, so that there is an infinite number of constraints. The Lagrange multipliers thus become a new field. Techniques for doing this have been worked out in the context of what has come to be known as unimodular gravity, a theory first proposed in (Einstein 1919) and first cast in Lagrangian form in (Anderson and Finkelstein 1971).

84 Norton (1984, 102) invoked this same incompatibility to explain why Einstein abandoned field equations based on the Ricci tensor in the Zurich Notebook. As we mentioned earlier (see note 12), we see no evidence that it played any role there either.

6. THE FIRST NOVEMBER PAPER: THE KNOT UNTIED

In the Zurich Notebook Einstein had not been able to show that field equations based on the November tensor are compatible with energy-momentum conservation. In 1915 the variational formalism of (Einstein 1914c) showed him how to solve this problem. He essentially just had to find the conditions $B_\mu = 0$ *for this specific Lagrangian. As we saw in sec. 3, such conditions also determine the covariance properties of the field equations. Because of the way in which the November tensor can be extracted from the Ricci tensor, it is clear that the field equations based on the November tensor are invariant under unimodular transformations. One would therefore expect that in this case the four conditions* $B_\mu = 0$ *reduce to one condition expressing the restriction to unimodular transformations. The four conditions can indeed be replaced by one, but this one condition says that* $\sqrt{-g}$ *can not be a constant. This is more restrictive than the condition that* $\sqrt{-g}$ *transform as a scalar. It was nonetheless an important result that the compatibility of the field equations with energy-momentum conservation only called for one additional condition. It still takes four conditions to show that the relevant component of the field equations reduces to the Poisson equation for weak static fields. We suggest that this made it clear to Einstein that he could use coordinate conditions in the modern sense to recover the Poisson equation and that a coordinate restriction was needed only for energy-momentum conservation.*

According to the general formalism of (Einstein 1914c), the gravitational field equations are compatible with energy-momentum conservation if the conditions $S_\sigma^\nu = 0$ and $B_\mu = 0$ are satisfied (see eqs. (19)–(23)). These conditions, however, were derived for an action of the form $\int \sqrt{-g} H d\tau$. The field equations of (Einstein 1915a) were derived from an action of the form $\int \mathfrak{L} d\tau$ without the factor $\sqrt{-g}$ (see eqs. (62)–(63)). This seriously complicates matters (see notes 83 and 88) and in his papers of November 1915, as Einstein realized, he could not simply apply the formalism. He nonetheless relied heavily on the formalism to guide him in his analysis of the new theory. In (Einstein 1915a, 784–785), for instance, he went through a calculation closely analogous to the one in the general formalism (see sec. 3.2, eqs. (16)–(22)) to establish that the field equations derived from $\int \mathfrak{K} d\tau$ are compatible with energy-momentum conservation under the restriction to unimodular transformations.

Einstein (1915a, sec. 1–2) first exploited the restriction to unimodular transformations to replace the energy-momentum balance equation, $T^\lambda_{\sigma;\lambda} = 0$, by a simpler equation. The covariant divergence of $T_{\mu\nu}$, the energy-momentum tensor of matter, is given by (see note 35):

$$T^\lambda_{\sigma;\lambda} = T^\lambda_{\sigma,\lambda} + \begin{Bmatrix} \lambda \\ \mu\lambda \end{Bmatrix} T^\mu_\sigma - \begin{Bmatrix} \mu \\ \sigma\lambda \end{Bmatrix} T^\lambda_\mu. \tag{68}$$

The second term on the right-hand side can be rewritten as (see note 35):

$$\begin{Bmatrix} \lambda \\ \mu\lambda \end{Bmatrix} T^{\mu}_{\sigma} = (\log\sqrt{-g})_{,\mu} T^{\mu}_{\sigma};$$

the third term as (see note 36):

$$\begin{Bmatrix} \mu \\ \sigma\lambda \end{Bmatrix} T^{\lambda}_{\mu} = \frac{1}{2} g^{\mu\nu} g_{\nu\lambda,\sigma} T^{\lambda}_{\mu} = -\frac{1}{2} g^{\mu\nu}_{\sigma} T_{\mu\nu}.$$

Inserting both expressions into eq. (68) and regrouping terms, one finds

$$T^{\lambda}_{\sigma;\lambda} = \left[T^{\lambda}_{\sigma,\lambda} + \frac{1}{2} g^{\mu\nu}_{\sigma} T_{\mu\nu} \right] + (\log\sqrt{-g})_{,\mu} T^{\mu}_{\sigma}. \tag{69}$$

The left-hand side of eq. (69) is a generally-covariant vector. The last term on the right-hand side transforms as a vector under unimodular transformations. It follows that the expression in square brackets must also transform as a vector under unimodular transformations. In (Einstein 1915a) the vanishing of this expression is used as the energy-momentum balance law:

$$T^{\lambda}_{\sigma,\lambda} = -\frac{1}{2} g^{\mu\nu}_{\sigma} T_{\mu\nu}. \tag{70}$$

Note that eq. (70) is *not* equivalent to $T^{\lambda}_{\sigma;\lambda} = 0$, unless the last term of eq. (69) vanishes, as it does when the restriction to unimodular transformations is strengthened by setting $\sqrt{-g} = 1$.[85]

Einstein (1915a, 784–785) investigated whether any restrictions over and above the restriction to unimodular transformations would be needed to make sure that the field equations (67) are compatible with energy-momentum conservation as expressed in eq. (70). Using the field equations (64) on the right-hand side of eq. (70), one finds (cf. eq. (17)):

---

85 Einstein explicitly acknowledged that eq. (70) is not equivalent to $T^{\lambda}_{\sigma;\lambda} = 0$. The restriction to unimodular transformations, Einstein (1915a, 780) conceded, cannot be used to simplify the basic formulae for covariant differentiation given in his systematic exposition of the *Entwurf* theory (Einstein 1914c, 1050, eqs. (29) and (30)). But, he added, the "defining definition" ("Definitionsgleichung") of the covariant divergence can be simplified. He then went through the argument following eq. (69) to redefine the covariant divergence of an arbitrary symmetric tensor $A^{\mu\nu}$ (Einstein 1915a, 780, eq. 9) as: $\partial A^{\nu}_{\sigma}/\partial x^{\nu} - (1/2) g^{\tau\mu} g_{\mu\nu,\sigma} A^{\nu}_{\tau}$. He noted (ibid., 781) that this equation has the same form as the covariant divergence of the tensor density $\mathfrak{A}^{\mu\nu} \equiv \sqrt{-g} A^{\mu\nu}$ as defined in (Einstein 1914c, 1054, eq. 41b). This illustrates the general remark he made at the beginning of sec. 1 of (Einstein 1915a): "Because of the scalar character of $\sqrt{-g}$ a simplification of the basic formulae for the formation of invariant objects is possible … which in short comes down to this, that the factors $\sqrt{-g}$ and $1/\sqrt{-g}$ no longer occur in the basic formulae and that the difference between tensors and tensor densities disappears" ("Vermöge des Skalarscharakters von $\sqrt{-g}$ lassen die Grundformeln der Kovariantenbildung … eine Vereinfachung zu, die kurz gesagt darin beruht, daß in den Grundformeln die Faktoren $\sqrt{-g}$ und $1/\sqrt{-g}$ nicht mehr auftreten und der Unterschied zwischen Tensoren und V-Tensoren wegfällt.").

$$T^{\lambda}_{\sigma,\lambda} = \frac{1}{2\kappa} g^{\mu\nu}_{\sigma}\left(\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial \mathfrak{L}}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial \mathfrak{L}}{\partial g^{\mu\nu}}\right). \tag{71}$$

This can be rewritten as (Einstein 1915a, eq. 20)

$$(T^{\lambda}_{\sigma} + t^{\lambda}_{\sigma})_{,\lambda} = 0,$$

by introducing a gravitational energy-momentum pseudo-tensor defined as (ibid., eq. 20a):[86]

$$t^{\lambda}_{\sigma} = \frac{1}{2\kappa}\left(\delta^{\lambda}_{\sigma}\mathfrak{L} - g^{\mu\nu}_{\sigma}\frac{\partial \mathfrak{L}}{\partial g^{\mu\nu}_{\lambda}}\right). \tag{72}$$

Inserting eq. (63) for $\mathfrak{L}$ and eq. (66) for its derivative with respect to $g^{\mu\nu}_{\lambda}$, one finds

$$\kappa t^{\lambda}_{\sigma} = \frac{1}{2}(\delta^{\lambda}_{\sigma}[g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}] - g^{\mu\nu}_{\sigma}\Gamma^{\lambda}_{\mu\nu}),$$

which can be rewritten as (ibid, eq. 20b)[87]

$$\kappa t^{\lambda}_{\sigma} = \frac{1}{2}\delta^{\lambda}_{\sigma} g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} - g^{\mu\nu}\Gamma^{\alpha}_{\mu\sigma}\Gamma^{\lambda}_{\alpha\nu}. \tag{73}$$

Einstein now rewrote (the mixed form of) the field equations in such a way that they have $T^{\lambda}_{\mu} + t^{\lambda}_{\mu}$ on the right-hand side. The divergence of the left-hand side then gives the quantity B_{μ} in the new theory. The vanishing of B_{μ} in conjunction with the field equations guarantees energy-momentum conservation, i.e., the vanishing of the ordinary divergence of $T^{\lambda}_{\mu} + t^{\lambda}_{\mu}$.[88]

Contraction of the field equations (67) with $g^{\nu\lambda}$ gives:

$$g^{\nu\lambda}(\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}) = -\kappa T^{\lambda}_{\mu}.$$

---

86 The derivation of eq. (72) is fully analogous to the derivation of eq. (18) in the general formalism (replace Q by $\mathfrak{L}$ in the calculation in note 31).

87 Since the covariant derivative of the metric vanishes,

$$0 = g^{\mu\nu}{}_{;\sigma} = g^{\mu\nu}_{\sigma} + \begin{Bmatrix}\mu\\ \alpha\sigma\end{Bmatrix} g^{\alpha\nu} + \begin{Bmatrix}\nu\\ \alpha\sigma\end{Bmatrix} g^{\mu\alpha} = g^{\mu\nu}_{\sigma} - \Gamma^{\mu}_{\alpha\sigma}g^{\alpha\nu} - \Gamma^{\nu}_{\alpha\sigma}g^{\mu\alpha},$$

it follows that $g^{\mu\nu}_{\sigma}\Gamma^{\lambda}_{\mu\nu} = (\Gamma^{\mu}_{\alpha\sigma}g^{\alpha\nu} + \Gamma^{\nu}_{\alpha\sigma}g^{\mu\alpha})\Gamma^{\lambda}_{\mu\nu} = 2g^{\alpha\nu}\Gamma^{\mu}_{\alpha\sigma}\Gamma^{\lambda}_{\mu\nu} = 2g^{\mu\nu}\Gamma^{\alpha}_{\mu\sigma}\Gamma^{\lambda}_{\alpha\nu}$.

88 Einstein could not just replace Q by $H = -\mathfrak{L}$ in the field equations in the form of eq. (13) and read off B_{μ} from the resulting equations. Recall that there are two definitions of the gravitational energy-momentum tensor, designated earlier as $t^{\lambda}_{\mu}(Q, \text{source})$ and $t^{\lambda}_{\mu}(Q, \text{cons})$ (cf. eqs. (19)–(20)). The condition $S^{\nu}_{\sigma}(Q) = 0$ guarantees that these two quantities are equal to one another. The corresponding quantities $t^{\lambda}_{\mu}(\mathfrak{L}, \text{source})$ and $t^{\lambda}_{\mu}(\mathfrak{L}, \text{cons})$, however, are not equal to one another, since $S^{\nu}_{\sigma}(\mathfrak{L}) \neq 0$ (cf. the discussion following eq. (34)).The analogue of eq. (13) in this case would be:

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\nu\lambda}\frac{\partial \mathfrak{L}}{\partial g^{\mu\nu}_{\alpha}}\right) = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}(\mathfrak{L}, \text{source}))$$

The gravitational energy-momentum pseudo-tensor in eq. (73) corresponds to $t^{\lambda}_{\mu}(\mathfrak{L}, \text{cons})$ (as will be clear from comparing eq. (72) to eq. (18)). This quantity cannot be used interchangeably with $t^{\lambda}_{\mu}(\mathfrak{L}, \text{source})$.

This can be rewritten as:[89]

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - g^{\nu\rho}\Gamma^{\lambda}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} = -\kappa T^{\lambda}_{\mu}.$$

The second term on the left-hand side is equal to the last term of eq. (73). Hence:

$$-g^{\nu\rho}\Gamma^{\lambda}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} = \kappa t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}.$$

The field equations can thus be written as:[90]

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma} = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}). \tag{74}$$

The quantity B_{μ} in this case is thus given by (cf. eqs. (21)–(22)):

$$B_{\mu} = \frac{\partial}{\partial x^{\lambda}}\left(\frac{\partial}{\partial x^{\alpha}}(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu}) - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}\right). \tag{75}$$

The condition $B_{\mu} = 0$ guarantees that $(T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda} = 0$.

Given his analysis of the covariance properties of the *Entwurf* field equations in 1914, Einstein had come to expect that this same condition $B_{\mu} = 0$ circumscribes the covariance of the field equations. In the case of field equations (67), he knew that their covariance group is that of arbitrary unimodular transformations, i.e., transformations under which the determinant g of the metric transforms as a scalar. This only gives one condition, not four as in eq. (75). In view of this mismatch, it is understandable that Einstein tried to replace these four conditions by one condition on g.[91]

His first step was to rewrite B_{μ} in the form $\partial A/\partial x_{\mu}$ and make B_{μ} vanish by imposing the stronger condition $A = 0$. Eq. (75) can be rewritten as

$$B_{\mu} = \frac{\partial^2}{\partial x^{\lambda}\partial x^{\alpha}}(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu}) - \frac{1}{2}\frac{\partial}{\partial x^{\mu}}(g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}).$$

The first term works out to be $\frac{1}{2}g^{\alpha\beta}_{\alpha\beta\mu}$,[92] so this equation becomes (Einstein 1915a, 785, eq. 22[93])

89 The left-hand side can be written as

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - g^{\nu\lambda}_{\alpha}\Gamma^{\alpha}_{\mu\nu} + g^{\nu\lambda}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}.$$

Substituting $\Gamma^{\nu}_{\alpha\rho}g^{\rho\lambda} + \Gamma^{\lambda}_{\alpha\rho}g^{\nu\rho}$ for $g^{\nu\lambda}_{\alpha}$ in the second term (see note 87), one finds:

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - g^{\rho\lambda}\Gamma^{\nu}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} - g^{\nu\rho}\Gamma^{\lambda}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} + g^{\nu\lambda}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}$$

The second term cancels against the fourth and the two remaining terms form the left-hand side of the equation below.

90 Einstein omitted the manipulations to get to eq. (74). He simply wrote: "after simple rearrangement" ("nach einfacher Umformung," Einstein 1915a, 785). The second term on the left-hand side of eq. (74) is, as we shall see later (see eq. (85)), equal to $-(1/2)\delta^{\lambda}_{\mu}t$, where t is the trace of t^{λ}_{μ}.

91 As we see no other plausible explanation for this move, this provides strong evidence for our claim that Einstein relied heavily on the formalism of (Einstein 1914c) to guide him in the analysis presented in the papers of November 1915.

$$B_\mu = \frac{1}{2}\frac{\partial}{\partial x^\mu}[g^{\alpha\beta}_{\alpha\beta} - g^{\rho\sigma}\Gamma^\alpha_{\beta\rho}\Gamma^\beta_{\alpha\sigma}]. \tag{76}$$

Einstein now replaced the four conditions $B_\mu = 0$ by a single stronger condition (ibid., eq. 22a):

$$g^{\alpha\beta}_{\alpha\beta} - g^{\rho\sigma}\Gamma^\alpha_{\beta\rho}\Gamma^\beta_{\alpha\sigma} = 0. \tag{77}$$

The next step was to replace this condition by a condition on g. To this end, Einstein fully contracted the field equations and compared the resulting condition to condition (77). Contraction of the field equations (67) with $g^{\mu\nu}$ gives:

$$g^{\mu\nu}(\Gamma^\alpha_{\mu\nu,\alpha} + \Gamma^\alpha_{\beta\mu}\Gamma^\beta_{\alpha\nu}) = -\kappa T. \tag{78}$$

This equation can be rewritten as

$$(g^{\mu\nu}\Gamma^\alpha_{\mu\nu})_{,\alpha} - g^{\mu\nu}_\alpha\Gamma^\alpha_{\mu\nu} + g^{\mu\nu}\Gamma^\alpha_{\beta\mu}\Gamma^\beta_{\alpha\nu} = -\kappa T. \tag{79}$$

The first term on the left-hand side is equal to:[94]

$$g^{\alpha\beta}_{\alpha\beta} + \frac{\partial}{\partial x^\alpha}\left(g^{\alpha\beta}\frac{\partial}{\partial x^\beta}\log\sqrt{-g}\right);$$

the second to minus twice the third:[95]

$$-2g^{\mu\nu}\Gamma^\alpha_{\beta\mu}\Gamma^\beta_{\alpha\nu}.$$

Inserting these last two expressions into eq. (79), one finds (Einstein 1915a, 785, eq. 21[96]):

92 Inserting eq. (53) for $\Gamma^\alpha_{\mu\nu}$, one finds

$$\frac{\partial^2}{\partial x^\lambda \partial x^\alpha}(g^{\nu\lambda}\Gamma^\alpha_{\mu\nu}) = -\frac{1}{2}\frac{\partial^2}{\partial x^\lambda\partial x^\alpha}(g^{\nu\lambda}g^{\alpha\rho}(g_{\rho\mu,\nu} + g_{\rho\nu,\mu} - g_{\mu\nu,\rho}))$$

Using that $g^{\mu\alpha}g_{\alpha\nu,\lambda} = -g^{\mu\alpha}_\lambda g_{\alpha\nu}$, one can rewrite this as:

$$-\frac{1}{2}\frac{\partial^2}{\partial x^\lambda\partial x^\alpha}(-g^{\nu\lambda}g^{\alpha\rho}_\nu g_{\rho\mu} - g^{\nu\lambda}g^{\alpha\rho}_\mu g_{\rho\nu} + g^{\nu\lambda}_\rho g^{\alpha\rho}g_{\mu\nu}).$$

The first and the third term in parentheses can be grouped together to form a quantity anti-symmetric in λ and α and thus vanish upon contraction with $\partial^2/\partial x^\lambda\partial x^\alpha$; the second term can be rewritten as $\delta^\lambda_\rho g^{\alpha\rho}_\mu = g^{\alpha\lambda}_\mu$. Finally, $(g^{\alpha\lambda}_\mu)_{,\lambda\alpha} = g^{\alpha\lambda}_{\alpha\lambda\mu}$.

93 Einstein did not use the designation B_μ for this quantity, thereby obscuring its origin in the variational formalism of (Einstein 1914c).

94 Inserting eq. (53) for $\Gamma^\alpha_{\mu\nu}$, one finds (cf. note 92):

$$(g^{\mu\nu}\Gamma^\alpha_{\mu\nu})_{,\alpha} = -\frac{1}{2}\frac{\partial}{\partial x^\alpha}(g^{\mu\nu}g^{\alpha\rho}(2g_{\rho\mu,\nu} - g_{\mu\nu,\rho})).$$

The first term on the right-hand side can be rewritten as $(g^{\mu\nu}g^{\alpha\rho}_\nu g_{\rho\mu})_{,\alpha} = g^{\alpha\nu}_{\nu\alpha}$; the second term as

$$\frac{1}{2}\frac{\partial}{\partial x^\alpha}(g^{\alpha\rho}[g^{\mu\nu}g_{\mu\nu,\rho}]) = \frac{1}{2}\frac{\partial}{\partial x^\alpha}\left(g^{\alpha\rho}\left[2\frac{\partial}{\partial x^\rho}\log\sqrt{-g}\right]\right)$$

(see, e.g., Einstein 1914c, 1051, eq. 32). The sum of these two terms gives the expression below.

95 Substituting $\Gamma^\mu_{\alpha\rho}g^{\rho\nu} + \Gamma^\nu_{\alpha\rho}g^{\mu\rho}$ for $g^{\mu\nu}_\alpha$ in $-g^{\mu\nu}_\alpha\Gamma^\alpha_{\mu\nu}$ (cf. note 87), one finds $-2g^{\rho\nu}\Gamma^\mu_{\alpha\rho}\Gamma^\alpha_{\mu\nu}$. Relabeling of the summation indices gives the expression below.

$$g^{\alpha\beta}_{\alpha\beta} - g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = -\kappa T. \tag{80}$$

The first two terms on the left-hand side of this equation are equal to the two terms on the left-hand side of eq. (77). Given that eq. (80) follows from the field equations (67), it suffices to demand that

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = -\kappa T \tag{81}$$

(ibid., 785, eq. 21a) to make sure that condition (77) is also satisfied. Through eq. (76) this guarantees that $B_{\mu} = 0$. This in turn guarantees that $(T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda} = 0$ (see eqs. (74)–(75)). One condition on the determinant of the metric thus suffices to guarantee compatibility of the field equations (67) with energy-momentum conservation. The condition is an odd one though. The energy-momentum tensor phenomenologically representing ordinary matter has a non-vanishing trace. Eq. (81) thus says that g cannot be a constant. This means that there still is a residual discrepancy between the covariance of the field equations and the coordinate restriction needed to guarantee compatibility with energy-momentum conservation. The restriction to unimodular transformations only demands g to transform as a scalar, it does not say that it cannot be a constant. Within a few weeks, Einstein published two modifications of his field equations to change this condition to the more congenial condition $\sqrt{-g} = 1$ for unimodular coordinates (see sec. 7).

It was nonetheless an extremely important result that the four conditions $B_{\mu} = 0$ can be reduced to one condition in this case. Up to this point, Einstein had not made a distinction between coordinate restrictions needed to recover the Poisson equation for weak static fields and those needed to ensure compatibility with energy-momentum conservation. It now turned out that the latter demand could be satisfied by one condition whereas the former continued to call for four. We conjecture that this drove home the point that the two requirements should be dealt with separately.

In fact, immediately after eq. (81) in (Einstein 1915a), we find the very first unambiguous instance in both Einstein's published papers and extant manuscripts and correspondence of a coordinate condition used in the modern sense. Einstein (1915a, 786, eqs. 22 and 16b) showed how the conditions $g^{\alpha\beta}_{\beta} = 0$, which we have called the Hertz condition/restriction (see eq. (7)), reduce the November tensor to the d'Alembertian acting on the metric in the case of weak fields. Einstein had done the same calculation in the Zurich Notebook (see eqs. (7)–(8)). There he had used $g^{\alpha\beta}_{\beta} = 0$ as a coordinate restriction. As such it was unacceptable because it was not satisfied, for instance, by the Minkowski metric in rotating coordinates.[97] The return of $g^{\alpha\beta}_{\beta} = 0$ in (Einstein 1915a) makes it clear that Einstein did not see this as a problem anymore in 1915. Einstein had come to realize that the conditions $g^{\alpha\beta}_{\beta} = 0$ are

96 Einstein omitted the manipulations to get from eq. (78) to eq. (80), again writing simply "after simple rearrangement" (cf. note 90)

not an integral part of the theory and only serve to facilitate comparison of the field equations to the Poisson equation of Newtonian theory in the case of weak static fields. In other words, Einstein now saw that $g^{\alpha\beta}_{\beta} = 0$ is not a coordinate restriction but a coordinate condition in the modern sense.

The theory of (Einstein 1915a) was thus of broad covariance. The only restrictions were that the determinant of the metric transform as a scalar and that it not be a constant. The way Einstein saw it, this was all that was needed to solve the problem of rotation that had brought down the *Entwurf* theory.[98] In the concluding paragraphs of (Einstein 1915a), he pointed out that transformations to rotating coordinates belong to the class of unimodular coordinates under which the new field equations are invariant.[99]

Looking back on secs. 5 and 6, we can clearly see how redefining the components of the gravitational field untied the tight knot of conditions and definitions that had been the *Entwurf* theory and retied it in a slightly different way to become a theory within hailing distance of general relativity as we know it today. First and foremost, the redefinition of the gravitational field led to the replacement of the *Entwurf* field equations and their intractable covariance properties by field equations invariant under arbitrary unimodular transformations. But that was not all. In the new theory, instead of the four additional restrictions $B_{\mu} = 0$ familiar from the *Entwurf* theory, it took only a minimal strengthening of the restriction to unimodular transformations (namely that the determinant of the metric not be a constant) to ensure that these new field equations yield energy-momentum conservation. Finally, because energy-momentum conservation only called for one extra condition whereas recovery of the Poisson equation continued to call for four, it became clear that these two types of conditions have a different status. Taking advantage of this insight, Einstein used a coordinate condition in the modern sense to show that the relevant component of the new field equations reduces to the Poisson equation for weak static fields and only used a coordinate restriction to satisfy the demands of energy-momentum conservation. There was thus enough covariance left in the new theory to meet the demands of Einstein's relativity and equivalence principles.

---

97 John Norton (1984, 119 and 143) already suggested that Einstein rejected the combination of the November tensor and the conditions $g^{\alpha\beta}_{\beta} = 0$ in the Zurich Notebook because $g^{\alpha\beta}_{\beta} \neq 0$ for the Minkowski metric in rotating coordinates. We agree. Note, however, that Einstein's argument is cogent only if the conditions $g^{\alpha\beta}_{\beta} = 0$ are seen as a coordinate restriction rather than a coordinate condition. In fact, it was in an attempt to make sense of these remarks in (Norton 1984) that one of us (JR) first hit upon the distinction between coordinate conditions and what we have come to call coordinate restrictions.

98 In fact, the problem of rotation persisted even in the final version of general relativity. General covariance does not make rotation—or *any* non-geodesic motion for that matter—relative (see Janssen 2005, 68–72).

99 On the face of it, it may seem that the theory still does not allow the Minkowski metric in rotating coordinates because its determinant equals one. Since the Minkowski metric is a vacuum solution of the field equations, however, it does not matter in this case that through eq. (81) $\sqrt{-g} = 1$ implies that $T = 0$ as well.

7. FROM THE NOVEMBER TENSOR TO THE EINSTEIN FIELD EQUATIONS

Einstein soon found ways of replacing the condition of (Einstein 1915a) that $\sqrt{-g}$ cannot be a constant by the more congenial condition $\sqrt{-g} = 1$ for unimodular coordinates. In (Einstein 1915b), he achieved this through the assumption that the trace T of the energy-momentum tensor of matter vanishes. He justified this assumption by adopting the view, promoted by Gustav Mie and others, that all matter is electromagnetic. Energy-momentum conservation now followed from the field equations in unimodular coordinates without any additional coordinate restrictions. And the field equations themselves could be looked upon as generally-covariant field equations in unimodular coordinates. So Einstein had found generally-covariant field equations at last: $R_{\mu\nu} = -\kappa T_{\mu\nu}$ (with $R_{\mu\nu}$ the Ricci tensor). In his calculations, both in November 1915 and in (Einstein 1916a), however, he continued to use unimodular coordinates. And he soon had second thoughts about paying for general covariance by committing himself to the electromagnetic view of nature. In (Einstein 1915d), he changed the condition that $\sqrt{-g}$ cannot be a constant to the condition $\sqrt{-g} = 1$ without imposing any restrictions on T. This he achieved by adding a term with T to the right-hand side of the field equations based on the November tensor. He realized that this trace term was needed anyway to ensure that the energy-momentum tensor for matter enters the field equations in the exact same way as the gravitational energy-momentum pseudo-tensor. This told Einstein that these were the equations he had been looking for. As before, they could be looked upon as generally-covariant equations expressed in unimodular coordinates. Einstein had thus found the Einstein field equations: $R_{\mu\nu} = -\kappa(T_{\mu\nu} - (1/2)g_{\mu\nu}T)$.

In the second and fourth of his communications to the Berlin Academy in November 1915, Einstein (1915b, 1915d) proposed two different ways to avoid the requirement that $\sqrt{-g}$ cannot be a constant found in the first communication (Einstein 1915a). In the second November paper, a three-page "Addendum" ("Nachtrag") to the first, he assumed that all matter is electromagnetic, in which case $T = 0$ (Einstein 1915b). Condition (81) can then be satisfied by setting $\sqrt{-g} = 1$, the condition for unimodular coordinates. This has three advantages. First, by looking upon the field equations as holding only in unimodular coordinates (rather than in coordinates related to one another by unimodular transformations) he removed the residual discrepancy between the covariance of the field equations and the restriction needed to guarantee energy-momentum conservation. Second, with $\sqrt{-g} = 1$, the energy-momentum balance equation, $T^{\mu}_{\nu;\mu} = 0$, reduces to $T^{\mu}_{\nu,\mu} + (1/2)g^{\alpha\beta}_{\nu}T_{\alpha\beta} = 0$ (see eq. (70)), the equations used in the analysis of energy-momentum conservation in (Einstein 1915a). The third and most important advantage is that the field equations (67) could now be looked upon as generally-covariant field equations expressed in unimodular coordinates. Setting $\sqrt{-g} = 1$ also has one disadvantage. It rules out a metric of the form $g_{\mu\nu} = \mathrm{diag}(-1, -1, -1, f(x, y, z))$, which Einstein still assumed was the general form of the metric for weak static fields. Either Einstein did not think of this disadvantage at this point (though we shall see that he had thought of it a week later), or it was outweighed, at least for the time being, by the advantages.

Einstein (1915b, 800, eq. 16b) wrote these generally-covariant field equations as

$$G_{\mu\nu} = -\kappa T_{\mu\nu}, \tag{82}$$

where $G_{\mu\nu}$ is the Ricci tensor. As in (Einstein 1915a), he wrote the Ricci tensor as the sum of two terms,[100]

$$G_{im} = R_{im} + S_{im}.$$

The first term is defined as minus what we called the November tensor (i.e., T_{il}^{x} in eq. (5)):

$$R_{im} \equiv -\frac{\partial}{\partial x^l}\begin{Bmatrix} l \\ im \end{Bmatrix} + \begin{Bmatrix} \rho \\ il \end{Bmatrix}\begin{Bmatrix} l \\ \rho m \end{Bmatrix}.$$

The second term is defined as:

$$S_{im} \equiv \frac{\partial}{\partial x^m}\begin{Bmatrix} l \\ il \end{Bmatrix} - \begin{Bmatrix} \rho \\ im \end{Bmatrix}\begin{Bmatrix} l \\ \rho l \end{Bmatrix}.$$

Since the first and the third Christoffel symbol in this expression are equal to the gradient of $\lg\sqrt{-g}$ it follows that $S_{im} = 0$ in unimodular coordinates. In the Zurich Notebook and in his first November paper, Einstein used the decomposition of the Ricci tensor only to show that the November tensor transforms as a tensor under unimodular *transformations*. In unimodular *coordinates*, the Ricci tensor actually reduces to the November tensor and the field equations (82) reduce to the field equations (67) of (Einstein 1915a):

$$R_{\mu\nu} = -\kappa T_{\mu\nu} \tag{83}$$

(Einstein 1915b, 801, eq. 16).

Einstein had thus finally found generally-covariant field equations. His calculations in (Einstein 1915a) show that *in unimodular coordinates* these field equations guarantee energy-momentum conservation (see eqs. (70)–(85)). Although Einstein did not explicitly show this, it was reasonable to assume that the corresponding generally-covariant equations $G_{\mu\nu} = -\kappa T_{\mu\nu}$ guarantee energy-momentum conservation in arbitrary coordinates.

Most of the "Addendum" (Einstein 1915b) is taken up by a defense of the assumption $T = 0$. The results reported in the "Addendum" all depend on this assumption. The assumption holds for electromagnetic fields in Maxwell's theory and might continue to hold in the non-linear generalizations of Maxwell's theory pursued by Gustav Mie and other proponents of the electromagnetic view of nature.[101] It does not hold for the energy-momentum tensor routinely used to give a phenomeno-

100 See (Einstein 1915a, 782; 1915b, 800; 1915d, 844).

logical description of ordinary matter. To get around this problem, Einstein assumed that gravitational fields play an important role in the constitution of matter. In that case the energy-momentum tensor phenomenologically describing matter should not be identified with $T^{\mu\nu}$ but with $T^{\mu\nu} + t^{\mu\nu}$ and the non-vanishing trace might come from $t^{\mu\nu}$ rather than $T^{\mu\nu}$. Einstein's flirtation with the electromagnetic world picture was short-lived, but three and a half years later he resurrected the idea that gravity plays a role in the structure of matter in a theory that makes the cosmological constant of (Einstein 1917) responsible both for the stability of the cosmos and the stability of elementary particles (Einstein 1919).[102]

At first Einstein was very enthusiastic about the electromagnetic turn his theory had taken. In an abstract for his third paper of November 1915 (Einstein 1915c)—the one in which he used the field equations of (Einstein 1915b) in unimodular coordinates to explain the anomalous advance of the perihelion of Mercury—Einstein wrote that this result "confirms the hypothesis of the vanishing of the scalar of the energy tensor of "matter" [i.e., $T = 0$]."[103] His enthusiasm, however, waned quickly. In a footnote to the perihelion paper itself, he announced:

> In a communication that will follow shortly it will be shown that this hypothesis [i.e., $T = 0$] is dispensable. Essential is only that a choice of reference frame is possible such that the determinant $|g_{\mu\nu}|$ takes on the value -1.[104]

As we shall see, the calculation of the perihelion advance of Mercury played an important role in showing Einstein that one can set $\sqrt{-g} = 1$ without setting $T = 0$.

In (Einstein 1915d), the fourth and final paper of November 1915 and the communication announced in the footnote quoted above, Einstein changed the field equations in such a way that condition (81) changes to

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = 0. \tag{84}$$

This makes it possible to choose unimodular coordinates (i.e., set $\sqrt{-g} = 1$) without putting any condition on the trace T of the energy-momentum tensor.

How did Einstein arrive at this new condition (84)? Recall that the original condi-

---

101 Einstein knew about Hilbert's work along these lines. See (Sauer 1999) and "Hilbert's Foundation of Physics …" (in vol. 4 of this series).

102 This theory is enjoying renewed interest. It now goes by the name of "unimodular gravity" (see Anderson and Finkelstein 1971); for a more recent discussion and further references, see (Finkelstein et al. 2002, Earman 2003).

103 "Dadurch wird die Hypothese vom Verschwinden des Skalars des Energietensors der "Materie" bestätigt." *Königlich Preußische Akademie der Wissenschaften* (Berlin). *Sitzungsberichte* (1915): 803. For further discussion, see "Hilbert's Foundation of Physics …" (in vol. 4 of this series) and "Pathways out of Classical Physics …" (in vol. 1 of this series).

104 "In einer bald folgenden Mitteilung wird gezeigt werden, daß jene Hypothese entbehrlich ist. Wesentlich ist nur, daß eine solche Wahl des Bezugssystems möglich ist, daß die Determinante $|g_{\mu\nu}|$ den Wert -1 annimmt" (Einstein 1915c, 831, note 1).

tion (81) followed from combining two equations. The first is eq. (77) which comes from the condition $B_\mu = 0$ for the field equations (67) of (Einstein 1915a). The second is eq. (80) which comes from fully contracting those field equations. These two equations can be written more compactly by introducing the trace of the gravitational energy-momentum pseudo-tensor (73) as Einstein first did in (Einstein 1915d, 846):[105]

$$\kappa t = g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}. \tag{85}$$

Inserting κt in the second terms of both eq. (77) and eq. (80), one finds:

$$g^{\alpha\beta}_{\alpha\beta} - \kappa t = 0, \tag{86}$$

$$g^{\alpha\beta}_{\alpha\beta} - \kappa t + \frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = -\kappa T. \tag{87}$$

The combination of these two equations gives the problematic condition (81). Upon inspection of eqs. (86)–(87), one sees that condition (81) would change to condition (84) if, instead of eqs. (86)–(87), one had (cf. Einstein 1915d, eqs. 10 and 9, respectively):

$$g^{\alpha\beta}_{\alpha\beta} - \kappa(t+T) = 0, \tag{88}$$

$$g^{\alpha\beta}_{\alpha\beta} - \kappa(t+T) + \frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = 0. \tag{89}$$

The difference between eq. (87) and eq. (89) is the sign of the term κT. Recall that eq. (87) was obtained by fully contracting the field equations (67). One can change the sign of the term κT in eq. (87) by adding a trace term to the right-hand side of eq. (67):[106]

$$\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} = -\kappa\left(T_{\mu\nu} - \frac{1}{2}g_{\mu\nu}T\right). \tag{90}$$

Fully contracting these new field equations and rewriting the resulting equations, one arrives at (cf. eqs. (78)–(80))

$$g^{\alpha\beta}_{\alpha\beta} - g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} + \frac{\partial}{\partial x^{\alpha}}\left(g^{\alpha\beta}\frac{\partial}{\partial x^{\beta}}\log\sqrt{-g}\right) = \kappa T.$$

Using eq. (85) to substitute $-\kappa t$ for the second term on the left-hand side, one arrives at eq. (89).

The new field equations (90) contracted with $g^{\nu\lambda}$ are

$$g^{\nu\lambda}(\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}) = -\kappa\left(T^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}T\right),$$

105 This follows from $\kappa t \equiv \kappa t^{\lambda}_{\lambda} = 2g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} - g^{\mu\nu}\Gamma^{\alpha}_{\mu\lambda}\Gamma^{\lambda}_{\alpha\nu}$.

106 Contracting $-\kappa(T_{\mu\nu} - (1/2)g_{\mu\nu}T)$ with $g^{\mu\nu}$, one finds κT.

which can be rewritten as (cf. eq. (74)):

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma} = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}) + \frac{1}{2}\delta^{\lambda}_{\mu}T.$$

Using eq. (85) to substitute κt for $g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma}$, one arrives at:

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa(t+T) = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}). \tag{91}$$

Energy-momentum is guaranteed—i.e., $(T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda} = 0$ —if the divergence of the left-hand side vanishes:

$$\frac{\partial}{\partial x_{\lambda}}\left[(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa(t+T)\right] = 0.$$

This can be rewritten (cf. eqs. (75)–(76)) as

$$\frac{\partial}{\partial x^{\mu}}[g^{\alpha\beta}_{\alpha\beta} - \kappa(t+T)] = 0.$$

In other words, energy-momentum conservation is guaranteed if the expression in square brackets vanishes, which is just eq. (88). As we noted above, combining eqs. (88) and (89) gives condition (84) which makes it possible to set $\sqrt{-g} = 1$ without any consequences for the value of T. Eq. (89) is a direct consequence of the field equations. Eq. (88), which guarantees energy-momentum conservation, is therefore a consequence of the field equations plus the condition $\sqrt{-g} = 1$. There is no need anymore for the highly speculative assumption that all matter is electromagnetic.

As Norton (1984, 146–147) has emphasized, the addition of the trace term $(1/2)\kappa g_{\mu\nu}T$ to the field equations was not an option for Einstein before the perihelion paper (Einstein 1915c). In the Zurich Notebook, Einstein had briefly considered adding a trace term to field equations based on the Ricci tensor in a weak-field approximation. He had rejected such modified weak-field equations because they do not allow the spatially flat metric, $g_{\mu\nu} = \mathrm{diag}(-1, -1, -1, f(x, y, z))$, which Einstein expected to describe weak static fields.[107] The derivation of the perihelion motion of Mercury freed Einstein from this prejudice. It showed that weak static

107 These considerations can be found on pp. 20L–21R of the Zurich Notebook. See “Commentary …” (in this volume), secs. 5.4.3–5.4.4 for a detailed analysis and sec. 5.4.6 for a concise summary. The problem is this. For weak static fields, the field equations with trace term reduce to:

$$\Delta g_{\mu\nu} = \kappa\left(T_{\mu\nu} - \frac{1}{2}\eta_{\mu\nu}T\right)$$

(with $\eta_{\mu\nu} \equiv \mathrm{diag}(-1, -1, -1, 1)$). For a static mass distribution described by $T_{\mu\nu} = \mathrm{diag}(0, 0, 0, \rho)$ ($T = \rho$), the non-trivial components of these equations are:

$$\Delta g_{11} = \Delta g_{22} = \Delta g_{33} = \Delta g_{44} = \frac{1}{2}\kappa\rho.$$

The spatially flat metric $\mathrm{diag}(-1, -1, -1, f)$ is not a solution of these equations.

fields do not have to be spatially flat. This insight was directly related to his use of unimodular coordinates in this calculation (Earman and Janssen 1993, 144–145). If $\sqrt{-g} = 1$ and g_{44} is non-constant, then at least some of the spatial components g_{ij} ($i, j = 1, 2, 3$) must be non-constant as well ($g_{4i} = g_{i4} = 0$ for a static field). This removes the objection against adding a trace term. Einstein could now set $\sqrt{-g} = 1$ without committing himself to the electromagnetic worldview.

The field equations (90) with the trace term have another feature that strongly recommends them. Compare the field equations (90) in the form of eq. (91) to the field equations (67) of (Einstein 1915a) in the form of eq. (74). Using eq. (85) to substitute κt in the second term on the left-hand side, one can write eq. (74) as:

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa t = -\kappa(T^{\lambda}_{\mu} + t^{\lambda}_{\mu}). \tag{92}$$

The crucial difference between eq. (91) and eq. (92) is that in eq. (91) the energy-momentum tensor of matter enters the field equations in the exact same way as the energy-momentum pseudo-tensor for the gravitational field, whereas in eq. (92) it does not. In eq. (92) there is a term $-(1/2)\delta^{\lambda}_{\mu}\kappa T$ missing on the left-hand side. Einstein made this same observation comparing eq. (89) (after setting $\sqrt{-g} = 1$) to its counterpart eq. (87) for the field equations (67) without the trace term:

> Note that our additional [trace] term brings with it that in [eq. 9 of (Einstein 1915d), $g^{\alpha\beta}_{\alpha\beta} - \kappa(t + T) = 0$] the energy tensor of the gravitational field occurs alongside the one for matter in the same way, which is not the case in [the corresponding eq. 21 of (Einstein 1915a), $g^{\alpha\beta}_{\alpha\beta} - \kappa t + \ldots = -\kappa T$].[108]

In the general formalism of (Einstein 1914c), the conditions $B_{\mu} = 0$ guarantee the vanishing of $(T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda}$ and the conditions $S^{\nu}_{\sigma} = 0$ guarantee that $T_{\mu\nu}$ enters the field equations in the same way as $t_{\mu\nu}$ (see secs. 3.1 and 3.2). The conditions $S^{\nu}_{\sigma} = 0$, however, do not hold if the restriction to unimodular transformations or unimodular coordinates is made (see note 88). In his first November paper, Einstein made sure that $(T^{\lambda}_{\mu} + t^{\lambda}_{\mu})_{,\lambda} = 0$ holds, but he did not check whether $T_{\mu\nu}$ and $t_{\mu\nu}$ enter the field equations in the same way. If he had, he would have recognized the need for the trace term right away.[109]

---

108 “Man beachte, daß es unser Zusatzglied mit sich bringt daß in (9) der Energietensor des Gravitationsfeldes neben dem der Materie in gleicher Weise auftritt, was in Gleichung (21) a. a. O. nicht der Fall ist” (Einstein 1915d, 846).

109 Einstein concisely summarized this part of his struggle to come up with satisfactory field equations in a letter to Besso a little over a month later: “The first paper [Einstein 1915a] along with the addendum [Einstein 1915b] still suffers from the problem that the term $(1/2)\kappa g_{\mu\nu}T$ is missing on the right-hand side; hence the postulate $T = 0$. Obviously, things have to be done as in the last paper [Einstein 1915d], in which case there is no condition anymore on the structure of matter” (“Die erste Abhandlung samt dem Nachtrag krankt noch daran dass auf der rechten Seite das Glied $(1/2)\kappa g_{\mu\nu}T$ fehlt; daher das Postulat $T = 0$. Natürlich muss die Sache gemäss der letzten Arbeit gemacht werden, wobei sich über die Struktur der Materie keine Bedingung mehr ergibt.”) Einstein to Michele Besso, 3 January 1916 (CPAE 8, Doc. 178).

Einstein needed to check one more thing in his fourth November paper to make sure that the new field equations (90) with trace term do indeed give energy-momentum conservation in unimodular coordinates. He had to show that $(T_{\mu}^{\lambda} + t_{\mu}^{\lambda})_{,\lambda} = 0$ is equivalent to the energy-momentum balance equation in unimodular coordinates,

$$T_{\sigma,\lambda}^{\lambda} + \frac{1}{2}g_{\sigma}^{\mu\nu}T_{\mu\nu} = 0. \tag{93}$$

(cf. eqs. (68)–(70)). The question is whether the second term on the left-hand side of this equation can be rewritten as $t_{\sigma,\lambda}^{\lambda}$? The standard procedure for doing this is to replace $T_{\mu\nu}$ in this term by the left-hand side of the field equations (see note 41, eqs. (16)–(18) and eqs. (71)–(72)). In this case, however, the field equations have $T_{\mu\nu} - (1/2)g_{\mu\nu}T$ on the right-hand side rather than simply $T_{\mu\nu}$. It turns out that this does not lead to any complications. In unimodular coordinates, as Einstein (1915d, 846) noted,

$$g_{\sigma}^{\mu\nu}g_{\mu\nu} = -(\log\sqrt{-g})_{,\sigma} = 0.$$

It follows that the second term of eq. (93) can be written as:

$$\frac{1}{2}g_{\sigma}^{\mu\nu}\left(T_{\mu\nu} - \frac{1}{2}g_{\mu\nu}T\right).$$

With the help of the field equations (90) this turns into

$$-\frac{1}{2\kappa}g_{\sigma}^{\mu\nu}(\Gamma_{\mu\nu,\alpha}^{\alpha} + \Gamma_{\beta\mu}^{\alpha}\Gamma_{\alpha\nu}^{\beta}).$$

As Einstein had already shown in his first November paper (see eqs. (71)–(73)), this expression is equal to the divergence of the gravitational energy-momentum pseudotensor in unimodular coordinates (Einstein 1915d, 846, eq. 8a; 1915a, 785, eq. 20b)

$$\kappa t_{\sigma}^{\lambda} \equiv \frac{1}{2}\delta_{\sigma}^{\lambda}g^{\mu\nu}\Gamma_{\beta\mu}^{\alpha}\Gamma_{\alpha\nu}^{\beta} - g^{\mu\nu}\Gamma_{\mu\sigma}^{\alpha}\Gamma_{\alpha\nu}^{\lambda},$$

defined in eq. (73) and used throughout this section and sec. 6. In unimodular coordinates, the field equations (90) of (Einstein 1915d) thus satisfy all requirements needed for energy-momentum conservation:

(1) $T_{\mu\nu}$ and $t_{\mu\nu}$ enter the field equations in the exact same way;

(2) The field equations guarantee the vanishing of the divergence of $T_{\mu\nu} + t_{\mu\nu}$;

(3) The divergence of $t_{\mu\nu}$ is equal to the gravitational force density.

As with the field equations (83) of the "Addendum" (Einstein 1915b), Einstein looked upon the field equations (90),

$$R_{im} = -\kappa\left(T_{im} - \frac{1}{2}g_{im}T\right),$$

where R_{im} is the November tensor (Einstein 1915d, 845, eq. 6), as generally-covariant field equations expressed in unimodular coordinates. The corresponding generally-covariant equations are the Einstein field equations,

$$G_{im} = -\kappa\left(T_{im} - \frac{1}{2}g_{im}T\right), \tag{94}$$

where G_{im} is the full Ricci tensor (ibid., eq. 2a). As in (Einstein 1915b), he tacitly assumed that these equations would guarantee energy-momentum conservation in arbitrary coordinates.

To conclude our analysis of Einstein's four papers of November 1915, we summarize what we see as the four key steps in the transition from the *Entwurf* field equations to the Einstein field equations.[110] The first step was the redefinition of the components of the gravitational field which led Einstein back to field equations invariant under unimodular transformations that he had considered but rejected three years earlier in the Zurich Notebook. The second step was to rewrite the four conditions that in conjunction with the field equations guarantee energy-momentum conservation as one condition on g, the determinant of the metric, to reflect the connection between energy-momentum conservation and the covariance of the field equations. This made it possible for Einstein to start using coordinate conditions in the modern sense. The third step was to recognize that the theory could be tweaked to turn the one condition on g into the condition $\sqrt{-g} = 1$ for unimodular coordinates. This made it possible to look upon the new field equations as generally-covariant equations expressed in unimodular coordinates. This is what Einstein had to show for his brief dalliance with the electromagnetic worldview. The fourth and final step was to recognize that energy-momentum conservation dictates that such tweaking be done in a specific way, namely through adding a term with the trace of the energy-momentum tensor for matter to the field equations. The perihelion paper (Einstein 1915c) was important in this context in that it freed Einstein from his prejudice about the form of the metric for weak static fields which he had found to be incompatible with such a trace term in the Zurich Notebook. We reiterate that this whole chain of reasoning was set in motion by replacing definition (52) of the components of the gravitational field, the "fateful prejudice," by definition (53), "the key to the solution." In all of this Einstein relied heavily on the general variational formalism of (Einstein 1914c). The exact expressions, relations, and conditions given by this formalism could not be used because of the restriction to unimodular transformations and unimodular coordinates in the papers of November 1915, but the insights encoded in the formalism were Einstein's main guide in taking steps one, two, and four.

110 The first two steps were made in (Einstein 1915a) and are discussed in secs. 5 and 6, respectively; the last two were made in (Einstein 1915b) and (Einstein 1915d), respectively, and are both discussed in this section, sec. 7.

8. THE 1916 REVIEW ARTICLE: THE ARGUMENT OF NOVEMBER 1915 STREAMLINED

Einstein's argument in (Einstein 1915d) for adding a trace term on the right-side of the field equations proved difficult to follow even for those most supportive of his efforts, such as his Leyden colleagues Paul Ehrenfest and H. A. Lorentz. Although Einstein claimed in the introduction of (Einstein 1915d) that the paper was self-contained, it in fact relied heavily on (Einstein 1915a) in its justification of the trace term. The relevant part of (Einstein 1915a) in turn relied heavily on the exposition of the Entwurf theory in (Einstein 1914c). In early 1916, in a letter to Ehrenfest, Einstein produced a self-contained version of the argument leading to the trace term and the Einstein field equations of the fourth November communication without the detour through the various discarded field equations preceding them. This letter became the blueprint for the part on field equations and energy-momentum conservation in (Einstein 1916a), the first systematic self-contained exposition of the new theory.

It was clear to Einstein that the field equations of his last communication of November 1915 met all requirements that he had imposed on such equations and that no further changes would be needed. Given the rapid succession of different field equations during that one month, however, it is understandable that this was not so clear to his readers. Even those most supportive of Einstein's efforts, such as the Leyden physicists Paul Ehrenfest and H. A. Lorentz, had difficulties following the argument.

Einstein himself best described the impression that the flurry of papers of November 1915 must have made on his colleagues. Knowing that the final result was correct and fully aware of the monumental character of his achievement, Einstein could afford to poke fun at the chaotic way in which victory had at long last been achieved. "It's convenient with that fellow Einstein," he wrote to Ehrenfest, "every year he retracts what he wrote the year before."[111] With similar self-deprecation, he told Sommerfeld: "Unfortunately I have immortalized my final errors in this battle in the academy-papers [Einstein 1915a, b] that I can soon send you."[112] When he did send the papers a week and a half later, he urged Sommerfeld to study them carefully despite the fact "that, as you are reading, the final part of the battle for the field equations unfolds right in front of your eyes."[113]

111 "Es ist bequem mit dem Einstein. Jedes Jahr widerruft er, was er das vorige Jahr geschrieben hat." Einstein to Paul Ehrenfest, 26 December 1915 (CPAE 8, Doc. 173). With this comment, Einstein prefaced his retraction of the hole argument (see sec. 4 of "What Did Einstein Know …" [in this volume]).

112 "Die letzten Irrtümer in diesem Kampfe habe ich leider in den Akademie-Arbeiten, die ich Ihnen bald senden kann, verevigt [sic]." Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153).

113 "… dass sich beim Lesen der letzte Teil des Kampfes um die Feldgleichungen vor Ihren Augen abspielt." Einstein to Arnold Sommerfeld, 9 December 1915 (CPAE 8, Doc. 161).

As was his habit, Ehrenfest pestered his friend Einstein with questions about the new theory.[114] Lorentz, who had already filled an uncounted number of pages with calculations on the *Entwurf* theory and had cast the theory in Lagrangian form (Lorentz 1915), immediately went to work on the new theory and sent Einstein three letters with comments and queries.[115] One topic of discussion was the hole argument, which Einstein had silently and unceremoniously dropped upon his return to general covariance in November 1915.[116] For our purposes in this paper, the interesting part of the discussion concerns the relation between the field equations and energy-momentum conservation and the necessity of the trace term. At one point in his correspondence with Ehrenfest, Einstein refers to "the warrant demanded by you for the inevitability of the additional term $-(1/2)g_{im}T$."[117]

Ehrenfest's obstinacy paid off. Einstein finally broke down and sent him a lengthy self-contained version of the argument that before had to be pieced together from the papers of November 1915. As Einstein promised at the beginning of the letter: "I shall not rely on the [November 1915] papers at all but show you all the calculations."[118] After delivering on this promise, Einstein closed the letter saying:

> I assume you will have no further difficulty. Show the thing to Lorentz too, who also has not yet appreciated the necessity of the structure of the right-hand side of the field equations. Could you do me a favor and send these sheets back to me as I do not have these things so neatly in one place anywhere else.[119]

Ehrenfest presumably obliged. The letter reads like the blueprint for the sections on the field equations and energy-momentum conservation in (Einstein 1916a), the first systematic exposition of general relativity, sent to Willy Wien, the editor of *Annalen der Physik*, in March 1916[120] and published in May of that year.

As in his papers of November 1915 and in the letter to Ehrenfest, Einstein used unimodular coordinates in this paper. He started with the November Lagrangian

114 For discussion of the relationship between Einstein and Ehrenfest, see (Klein 1970, chap. 12).

115 This can be inferred from Einstein to H. A. Lorentz, 17 January 1916 (CPAE 8, Doc. 183). Unfortunately, none of the letters from Ehrenfest and Lorentz to Einstein of this period (late 1915–early 1916) seem to have been preserved. For a discussion of the three-way correspondence between Einstein, Lorentz and Ehrenfest in this period, see (Kox 1988).

116 For discussion of the hole argument and its replacement, the point-coincidence argument, and references to the extensive literature on these topics, see sec. 4 of "What Did Einstein Know …" (in this volume) and (Janssen 2005, 73–74).

117 "die von Dir verlangte Gewähr der "Zwangläufigkeit" für das Zusatzglied $-(1/2)g_{im}T$." Einstein to Paul Ehrenfest, 17 January 1916 (CPAE 8, Doc. 182).

118 "Ich stütze mich gar nicht auf die Arbeiten, sondern rechne Dir alles vor." Einstein to Paul Ehrenfest, 24 January 1916 or later (CPAE 8, Doc. 185).

119 "Du wirst nun wohl keine Schwierigkeit mehr finden. Zeige die Sache auch Lorentz, der die Notwendigkeit der Struktur der rechten Seite der Feldgleichungen auch noch nicht empfindet. Es wäre mir lieb, wenn Du mir diese Blätter dann wieder zurückgäbest, weil ich die Sachen sonst nirgends so hübsch beisammen habe." Ibid.

120 Einstein to Wilhelm Wien, 18 March 1916 (CPAE 8, Doc. 203). Einstein had told Wien in February that he was in the process of writing this paper, Einstein to Wilhelm Wien, 28 February 1916 (CPAE 8, Doc. 196).

$$H = g^{\mu\nu}\Gamma^{\alpha}_{\mu\beta}\Gamma^{\beta}_{\nu\alpha} \tag{95}$$

(Einstein 1916a, 804, eq. 47a; see eq. (63) above with $\mathfrak{L} = H$ rather than $-H$). The Euler-Lagrange equations,

$$\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial H}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial H}{\partial g^{\mu\nu}} = 0 \tag{96}$$

(ibid., 805, eq. 47b), for this Lagrangian are:

$$\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\mu\beta}\Gamma^{\beta}_{\nu\alpha} = 0 \tag{97}$$

(ibid., 803, eq. 47; see eqs. (63)–(67) with $T_{\mu\nu} = 0$). These are the vacuum field equations. The question is how to generalize these equations in the presence of matter. To this end, Einstein rewrote the vacuum field equations in terms of the gravitational energy-momentum pseudo-tensor $t_{\mu\nu}$. He then added the energy-momentum tensor for matter $T_{\mu\nu}$ in such a way that it enters the field equations in the exact same way as $t_{\mu\nu}$. This strategy originated in the letter to Ehrenfest. After writing down the field equations in the form of eq. (91) (eq. 8 in the letter), Einstein wrote: "This equation is interesting because it shows that the origin of the gravitational [field] lines is determined solely by the sum $T^{\nu}_{\sigma} + t^{\nu}_{\sigma}$, as one has to expect."[121]

To find $t_{\mu\nu}$, Einstein contracted the left-hand side of the eq. (96) with $g^{\mu\nu}_{\sigma}$

$$g^{\mu\nu}_{\sigma}\left(\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial H}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial H}{\partial g^{\mu\nu}}\right) = 0. \tag{98}$$

Since he did not have the field equations in the presence of matter yet, Einstein could not give the usual rationale for this move. Using eq. (90), the Einstein field equations in the presence of matter in unimodular coordinates, one can rewrite the left-hand side of eq. (98) as $\kappa g^{\mu\nu}_{\sigma}(T_{\mu\nu} - (1/2)g_{\mu\nu}T)$. As we saw in sec. 7, in unimodular coordinates $g^{\mu\nu}_{\sigma}g_{\mu\nu} = 0$, so this is equal to $\kappa g^{\mu\nu}_{\sigma}T_{\mu\nu}$, which is 2κ times the gravitational force density. By writing the left hand side of eq. (98) as a divergence, Einstein could thus express the gravitational force density as the divergence of gravitational energy-momentum density. As we have seen, this was Einstein's standard procedure for introducing $t_{\mu\nu}$ (see note 41, eqs. (16)–(18), eqs. (71)–(72), and the derivation following eq. (93)).

Eq. (98) can be rewritten as $t^{\alpha}_{\sigma,\alpha} = 0$, if t^{α}_{σ} is defined as[122]

---

121 "Diese Gleichung ist interessant, weil sie zeigt, dass das Entspringen der Gravitationslinien allein durch die Summe $T^{\nu}_{\sigma} + t^{\nu}_{\sigma}$ bestimmt ist, wie man ja auch erwarten muss." Einstein to Paul Ehrenfest, 24 January 1916 or later (CPAE 8, Doc. 185).

122 Einstein (1916a, 805) added a footnote saying: "The reason for the introduction of the factor -2κ will become clear later" ("Der Grund der Einführung des Faktors -2κ wird später deutlich werden."). He is referring to the generalization of the vacuum field equations (102) to the field equations (103) in the presence of matter in sec. 16 and to the discussion of energy-momentum conservation in secs. 17–18 of his paper (ibid., 807–810).

$$-2\kappa t_{\sigma}^{\alpha} = g_{\sigma}^{\mu\nu}\frac{\partial H}{\partial g_{\alpha}^{\mu\nu}} - \delta_{\sigma}^{\alpha}H \tag{99}$$

(Einstein 1916a, 805, eq. 49). Substituting eq. (66) (with $\mathfrak{L} = H$) and eq. (95) into eq. (99), one finds (cf. eq. (73))

$$\kappa t_{\sigma}^{\alpha} = \frac{1}{2}\delta_{\sigma}^{\alpha}g^{\mu\nu}\Gamma_{\beta\mu}^{\rho}\Gamma_{\rho\nu}^{\beta} - g^{\mu\nu}\Gamma_{\mu\beta}^{\alpha}\Gamma_{\nu\sigma}^{\beta} \tag{100}$$

(ibid., 806, eq. 50).

Einstein now used t_{ν}^{μ} to rewrite the field equations (97). The trace of the pseudo-tensor is (see eq. (85)):

$$\kappa t = g^{\mu\nu}\Gamma_{\mu\beta}^{\alpha}\Gamma_{\nu\alpha}^{\beta}.$$

Eq. (100) can thus be rewritten as

$$\kappa\Big(t_{\sigma}^{\alpha} - \frac{1}{2}\delta_{\sigma}^{\alpha}t\Big) = -g^{\mu\nu}\Gamma_{\mu\beta}^{\alpha}\Gamma_{\nu\sigma}^{\beta}. \tag{101}$$

The contraction of the vacuum field equations (97) with $g^{\nu\sigma}$,

$$g^{\nu\sigma}(\Gamma_{\mu\nu,\alpha}^{\alpha} + \Gamma_{\mu\beta}^{\alpha}\Gamma_{\nu\alpha}^{\beta}) = 0,$$

can be rewritten as (see footnote 89):

$$(g^{\nu\sigma}\Gamma_{\mu\nu}^{\alpha})_{,\alpha} - g^{\rho\tau}\Gamma_{\rho\beta}^{\sigma}\Gamma_{\tau\mu}^{\beta} = 0.$$

Using eq. (101) for the second term, one can thus write the vacuum field equations in unimodular coordinates as

$$(g^{\nu\sigma}\Gamma_{\mu\nu}^{\alpha})_{,\alpha} = -\kappa\Big(t_{\mu}^{\sigma} - \frac{1}{2}\delta_{\mu}^{\sigma}t\Big) \tag{102}$$

(ibid., 806, eq. 51).

On the argument that $T_{\mu\nu}$ should enter the field equations in the exact same way as $t_{\mu\nu}$, Einstein generalized the vacuum equations to

$$(g^{\nu\sigma}\Gamma_{\mu\nu}^{\alpha})_{,\alpha} = -\kappa\Big([t_{\mu}^{\sigma} + T_{\mu}^{\sigma}] - \frac{1}{2}\delta_{\mu}^{\sigma}[t + T]\Big) \tag{103}$$

in the presence of matter (ibid., 807, eq. 52). Since eq. (102) is just an alternative way of writing the vacuum field equations contracted with $g^{\nu\sigma}$, eq. (103) is equivalent to

$$\Gamma_{\mu\nu,\alpha}^{\alpha} + \Gamma_{\mu\beta}^{\alpha}\Gamma_{\nu\alpha}^{\beta} = -\kappa\Big(T_{\mu\nu} - \frac{1}{2}g_{\mu\nu}T\Big)$$

(ibid., 808, eq. 53; cf. eqs. (90)). These equations are more easily recognized as the generally-covariant Einstein field equations (94) in unimodular coordinates.

In the next section of his paper, Einstein (1916a, sec. 17) showed that energy-momentum conservation in the form $(T_\sigma^\alpha + t_\sigma^\alpha)_{,\alpha} = 0$ is a direct consequence of the field equations (103). Fully contracting eq. (103), one finds

$$(g^{\nu\sigma}\Gamma^\alpha_{\sigma\nu})_{,\alpha} = \kappa(t+T), \tag{104}$$

with the help of which eq. (103) itself can be rewritten as

$$\frac{\partial}{\partial x^\alpha}\Big(g^{\nu\sigma}\Gamma^\alpha_{\mu\nu} - \frac{1}{2}\delta^\sigma_\mu[g^{\lambda\beta}\Gamma^\alpha_{\lambda\beta}]\Big) = -\kappa(t^\sigma_\mu + T^\sigma_\mu).$$

The field equations thus guarantee energy-momentum conservation if

$$B_\mu \equiv \frac{\partial^2}{\partial x^\sigma \partial x^\alpha}\Big(g^{\nu\sigma}\Gamma^\alpha_{\mu\nu} - \frac{1}{2}\delta^\sigma_\mu[g^{\lambda\beta}\Gamma^\alpha_{\lambda\beta}]\Big) = 0. \tag{105}$$

This equation, it turns out, is an identity. The first term can be rewritten as[123]

$$(g^{\nu\sigma}\Gamma^\alpha_{\mu\nu})_{,\alpha\sigma} = \frac{1}{2}g^{\alpha\beta}_{\alpha\beta\mu};$$

the second as minus this same expression.[124] Eq. (106) gives the contracted Bianchi identities $(R^{\mu\nu} - (1/2)g^{\mu\nu}R)_{;\nu} = 0$ in unimodular coordinates.

Einstein (1916a, 809) finally showed that energy-momentum conservation in the form $(T^\alpha_\sigma + t^\alpha_\sigma)_{,\alpha} = 0$ is equivalent to the energy-momentum balance equation $T^\alpha_{\sigma,\alpha} + (1/2)g^{\mu\nu}_\sigma T_{\mu\nu} = 0$ (see the derivation following eq. (93)).

Three short sections of the review paper (Einstein 1916a, part C, secs. 15–18, pp. 804–810) thus provided a streamlined version of an argument that had been hard to piece together from the four papers of November 1915 even for the likes of Lorentz and Ehrenfest.

---

123 Using the definition (53) of $\Gamma^\alpha_{\mu\nu}$ as minus the Christoffel symbols, one can write

$$(g^{\nu\sigma}\Gamma^\alpha_{\mu\nu})_{,\alpha\sigma} = -\frac{1}{2}(g^{\sigma\beta}g^{\alpha\lambda}(g_{\lambda\mu,\beta} + g_{\lambda\beta,\mu} - g_{\mu\beta,\lambda}))_{,\alpha\sigma}$$

The combination of the first and the third term in the innermost parentheses are anti-symmetric in λ and β. They are contracted with a quantity symmetric in these same indices (cf. footnote 92 above).

$$(g^{\sigma\beta}g^{\alpha\lambda}(\ldots))_{,\alpha\sigma} = (g^{\alpha\beta}g^{\sigma\lambda}(\ldots))_{,\sigma\alpha} = (g^{\sigma\lambda}g^{\alpha\beta}(\ldots))_{,\alpha\sigma}$$

The expression above thus reduces to

$$(g^{\nu\sigma}\Gamma^\alpha_{\mu\nu})_{,\alpha\sigma} = -\frac{1}{2}(g^{\sigma\beta}g^{\alpha\lambda}g_{\lambda\beta,\mu})_{,\alpha\sigma} = \frac{1}{2}g^{\alpha\sigma}_{\mu\alpha\sigma}.$$

124 Using eq. (53), one can write

$$-\frac{1}{2}(\delta^\sigma_\mu g^{\lambda\beta}\Gamma^\alpha_{\lambda\beta})_{,\alpha\sigma} = -\frac{1}{2}(g^{\lambda\beta}\Gamma^\alpha_{\lambda\beta})_{,\alpha\mu} = \frac{1}{4}(g^{\lambda\beta}g^{\alpha\delta}(g_{\delta\lambda,\beta} + g_{\delta\beta,\lambda} - g_{\lambda\beta,\delta}))_{,\alpha\mu}.$$

Since $g^{\lambda\beta}g_{\lambda\beta,\delta} = (\log\sqrt{-g})_{,\delta}$ (Einstein 1916a, 796, eq. 29) vanishes for unimodular coordinates, the expression above reduces to

$$-\frac{1}{2}(\delta^\sigma_\mu g^{\lambda\beta}\Gamma^\alpha_{\lambda\beta})_{,\alpha\sigma} = \frac{1}{2}(g^{\lambda\beta}g^{\alpha\delta}g_{\delta\lambda,\beta})_{,\alpha\mu} = -\frac{1}{2}g^{\alpha\beta}_{\beta\alpha\mu}.$$

9. FROM THE NOVEMBER LAGRANGIAN TO THE RIEMANN SCALAR: GENERAL COVARIANCE AND ENERGY-MOMENTUM CONSERVATION

Both in the papers of November 1915 and in the review article that following March (Einstein 1916a), Einstein used the November Lagrangian—i.e., the Entwurf Lagrangian with the components of the gravitational field redefined as minus the Christoffel symbols—to derive the gravitational part of the Einstein field equations in unimodular coordinates. The use of unimodular coordinates clearly brings out the relation between the old and the new field equations (see the appendix), but complicates the use of the general formalism of (Einstein 1914c). Most seriously affected is the discussion of energy-momentum conservation. It was only in unimodular coordinates that Einstein was able to show that the field equations guarantee energy-momentum conservation in unimodular coordinates. He also did not make the connection between energy-momentum conservation and covariance of the field equations. In (Einstein 1916c) the November Lagrangian is replaced by a Lagrangian based on the Riemann scalar. Applying the formalism of (Einstein 1914c), Einstein now showed that the general covariance of the Einstein field equations guarantees that energy-momentum conservation holds in arbitrary coordinates. This is expressed in the conditions $S_\sigma^\nu = 0$ *and* $B_\mu = 0$ *. The latter are just the contracted Bianchi identities.*

Shortly after the triumphs of November 1915, Einstein acknowledged the desirability of deriving (the gravitational part of) the generally-covariant form of the field equations from a variational principle. In the November 1915 papers, as we have seen, he had only done so in unimodular coordinates (Einstein 1915a, 784). He realized that the generally-covariant Lagrangian would have to come from the Riemann curvature scalar. He also realized that terms with second-order derivatives of the metric in the Riemann scalar, which would lead to terms with third-order derivatives in the field equations, could be eliminated from the action through partial integration. He concluded that the effective Lagrangian had to be

$$L = \sqrt{-g}[g^{\sigma\tau}\Gamma^\beta_{\sigma\alpha}\Gamma^\alpha_{\tau\beta} - g^{\alpha\beta}\Gamma^\sigma_{\alpha\beta}\Gamma^\rho_{\sigma\rho}].$$

All this can be found in a letter to Lorentz of January 17, 1916. Einstein wrote that he had only gone through the calculation once, but the expression above is actually correct. He also told Lorentz that he had not attempted to derive the corresponding Euler-Lagrange equations: "The calculation of $\partial L/\partial g^{\mu\nu}$ and $(\partial L/\partial g_\sigma^{\mu\nu})$, however, is rather cumbersome, at least with my limited proficiency in calculating."[125]

When he wrote the review article (Einstein 1916a) less than two months later, he apparently still did not have the stomach for this cumbersome though straightforward

125 "Die Berechnung von $\partial L/\partial g^{\mu\nu}$ und $\partial L/\partial g_\sigma^{\mu\nu}$ ist aber ziemlich beschwerlich, wenigstens bei meiner geringen Sicherheit im Rechnen." Einstein to H. A. Lorentz, 17 January 1916 (CPAE 8, Doc. 183). He explicitly said he had not done the calculation in another letter to Lorentz two days later (Einstein to H. A. Lorentz, 19 January 1916 [CPAE 8, Doc. 184]).

calculation. As we have seen in sec. 8, both the presentation of the field equations and the discussion of energy-momentum conservation in secs. 14–18 of (Einstein 1916a) are in terms of unimodular coordinates.

Einstein may originally have planned to cover this material in arbitrary coordinates. This is suggested by a manuscript for an ultimately discarded five-page appendix to the review article (CPAE 6, Doc. 31). At the top of the first page of the manuscript, we find "§14" which was subsequently deleted and replaced by "Appendix: Formulation of the theory based on a variational principle."[126] Sec. 14 is the first of the five sections in (Einstein 1916a) on the field equations and energy-momentum conservation. In the manuscript under consideration here, Einstein gave a variational derivation of the field equations in arbitrary coordinates along the lines sketched in the letter to Lorentz discussed above. He still did not explicitly evaluate the Euler-Lagrange equations. But he did write down the quantities S_σ^ν and B_σ of the general formalism of (Einstein 1914c) for the effective Lagrangian of the new theory (now denoted by $\mathfrak{G}$). He pointed out that the general covariance of the Riemann scalar guarantees that these quantities vanish identically. He did not mention that this automatically implies energy-momentum conservation (see sec. 3.2 and 3.3). This might simply be because Einstein did not bother to finish this manuscript once he had decided to rewrite sec. 14 and the remainder of part C of his review article in unimodular coordinates. The original generally-covariant treatment was relegated to an appendix, which ultimately did not make it into the published paper. Einstein returned to it a few months later, revised and completed the manuscript, and submitted it to the Prussian Academy on October 26, 1916. This paper, (Einstein 1916c), will be the main focus of this section. But first we discuss some of Einstein's pronouncements on the topic in the intervening months.

Ehrenfest must have taken Einstein to task for using unimodular coordinates in the crucial sections of the review article (Einstein 1916a). In May 1916, shortly after the article was published, Einstein wrote to his friend in Leyden defensively: "My specialization of the coordinate system is not *just* based on laziness."[127] Did Einstein have some reason to believe that the choice of unimodular coordinates was not just convenient but physically meaningful?[128] At the time of this letter to Ehrenfest, it may not have been more than an inkling, but a month later Einstein actually published an argument purporting to show that unimodular coordinates are indeed physically privileged (Einstein 1916b).

Given that general relativity had been developed in analogy with electrodynamics (see sec. 3.1 and 3.2), it was only natural for Einstein to explore the possibility of

126 "Anhang: Darstellung der Theorie ausgehend von einem Variationsprinzip." (CPAE 6, Doc. 31, [p. 1]).

127 "Meine Spezialisierung des Bezugssystems beruht nicht *nur* auf Faulheit." Einstein to Paul Ehrenfest, 24 May 1916 (CPAE 8, Doc. 220).

128 In December 1915, Einstein had called the choice of unimodular coordinates "epistemologically meaningless" ("erkenntnistheoretisch ohne Bedeutung," Einstein to Moritz Schlick, 14 December 1915 [CPAE 8, Doc. 165]).

gravitational waves in his theory. This is what he did in (Einstein 1916b). He found three types of waves, two of which curiously do not transport energy (Einstein 1916b, 693). In an addendum to the paper, Einstein noted that these spurious waves can be eliminated by choosing unimodular coordinates. This, he concluded, shows that the choice of unimodular coordinates has "a deep physical justification."[129] He also rehearsed this argument in a letter to De Sitter, another member of the Leyden group around Lorentz and Ehrenfest working on relativity.[130]

Two letters from Leyden to Berlin the following year suggest that, in late 1917, Einstein still believed that unimodular coordinates have a special status. The author of these letters was Gunnar Nordström, who was in Leyden on a three-year fellowship (CPAE 8, Doc. 112, note 3). Nordström had a hard time convincing Einstein that in unimodular coordinates the gravitational field of the sun carries no energy.[131] Nordström also caught an error in (Einstein 1916b), which prompted Einstein to publish a corrected version of his 1916 paper on gravitational waves (Einstein 1918a). He now used a different argument to eliminate the spurious gravitational waves, one that makes no mention of unimodular coordinates (ibid., 160–161). By the time Gustav Mie, in his efforts to convince Einstein of the need for special coordinates, reminded him of the original argument, Einstein had abandoned the notion of privileged coordinates, unimodular or otherwise, altogether.[132]

Immediately following the defensive passage from the letter to Ehrenfest of May 1916 quoted above (see footnote 127), Einstein promised: "At some point I may present the matter without such specialization [of the coordinates], along the lines of [Lorentz 1915]."[133] Given Einstein's views at the time that unimodular coordinates were special, such a fully generally-covariant presentation of the theory was probably not a matter of great urgency to him. He was nonetheless forced to keep thinking about the issue, not by Ehrenfest this time but by a new correspondent.

In June 1916, Théophile de Donder, professor of mathematical physics in Brussels, respectfully informed Einstein that the latter's expression for the gravitational energy-momentum pseudo-tensor was wrong (Théophile de Donder to Einstein, 27 June 1916 [CPAE 8, Doc. 228]). An exchange of letters across enemy lines ensued, mercifully cut short a little over a month later by exhaustion on the Belgian side. De Donder began what would turn out to be the last letter of this testy correspondence with the announcement of a truce of sorts: "the extensive research and innumerable calculations that I have devoted to your theory have forced me to take some rest for a few weeks."[134] Einstein probably read this with a sigh of relief. Even though De

129 "eine tiefe physikalische Berechtigung" (Einstein 1916b, 696).

130 Einstein to Willem de Sitter, 22 June 1916 (CPAE 6, Doc. 32). The work of the Leyden group is described in (Kox 1992).

131 Gunnar Nordström to Einstein, 22–28 September 1917, 23 October 1917 (CPAE 8, Docs. 382, 393).

132 Gustav Mie to Einstein, 6 May 1918 (CPAE 8, Doc. 532). For brief discussions of the episode described in the last two paragraphs, see (CPAE 8, li-lii, and CPAE 7, xxv).

133 "Vielleicht werde ich die Sache auch einmal ohne die Spezialisierung darstellen, so wie Lorentz in seiner Arbeit."

Donder's missives were ostensibly about clarifying the relation of his own work to Einstein's, it is hard not to get the impression that De Donder's ulterior motive was to have Einstein concede priority for at least part of general relativity to his Belgian colleague.[135] If this was indeed De Donder's hidden agenda, he must have been bitterly disappointed by the letters from Berlin. The way Einstein saw it, De Donder had simply overlooked that the expressions whose correctness he was contesting only held in unimodular coordinates. In Einstein's last contribution to the debate, he showed how one would obtain the expression for the gravitational energy-momentum pseudo-tensor without choosing unimodular coordinates. The formula that Einstein gives is

$$\mathrm{t}_\sigma^\nu = -\frac{1}{2\kappa}\left(\frac{\partial L^*}{\partial g_\nu^{\alpha\beta}} g_\sigma^{\alpha\beta} - \delta_\sigma^\nu L^*\right).$$

L^* is Einstein's notation in this letter for the effective Lagrangian extracted from the Riemann scalar.[136] The letter shows that Einstein had no trouble with the continuation of the argument of the appendix to (Einstein 1916a) discussed above.

In the fall of 1916, Einstein finally finished what he had begun in this appendix and published a generally-covariant discussion of the field equations and energy-momentum conservation. The paper, (Einstein 1916c), brings together in a systematic fashion the various elements of this discussion that we encountered piecemeal in the letter to Lorentz, the discarded appendix, and the letter to De Donder. As is acknowledged in the introduction of (Einstein 1916c), both Hilbert (1915) and Lorentz (1916a) had already shown how to derive the Einstein field equations from a variational principle without choosing special coordinates.[137] Einstein's own paper owes little or nothing to this earlier work.[138] It follows the relevant sections of (Einstein 1914c) virtually step by step.

Einstein starts from the action

$$\int \mathfrak{H} d\tau = \int (\mathfrak{G} + \mathfrak{M}) d\tau,$$

134 "Les longues recherches et les innombrables calculs que j'ai consacré à vos théories m'obligent à prendre quelques semaines de repos." Théophile de Donder to Einstein, 8 August 1916 (CPAE 8, Doc. 249)

135 The following year, De Donder (1917) claimed priority for the field equations with cosmological constant of (Einstein 1917b). This prompted Einstein to write to Lorentz who had communicated De Donder's paper to the Amsterdam Academy. Clearly embarrassed to bother Lorentz with this matter, Einstein emphasized that it was because of a serious error in De Donder's paper not because of the priority claim that he urged his Dutch colleague to have De Donder publish a correction. Einstein to H. A. Lorentz, 18 December 1917 (CPAE 8, Doc. 413). We do not know whether Lorentz took up this matter with De Donder. We do know that no correction ever appeared.

136 In terms of the more explicit notation introduced in our discussion of the general formalism of (Einstein 1914c) in sec. 3, t_σ^ν would be written as $\mathrm{t}_\sigma^\nu(L^*, \text{cons})$ (cf. eq. (18)).

137 See (Sauer 1999) and "Hilbert's Foundation of Physics …" (in vol. 4 of this series) for discussion of Hilbert's work; and (Janssen 1992) for discussion of Lorentz's work.

138 See footnote 46 for discussion of how Einstein's variational techniques deviated from the standard techniques of the Göttingen crowd.

where $\mathfrak{G}$, the gravitational part of the Lagrangian, is the Riemann scalar and $\mathfrak{M}$, the Lagrangian for the material part of the system, is left unspecified (Einstein 1916c, 1111–1112).[139] Through partial integration, all terms involving second-order derivatives of the metric can be removed from the integral over $\mathfrak{G}$. The gravitational part of the field equations thus follows from the variational principle

$$\delta\int\mathfrak{G}^* d\tau = 0, \tag{106}$$

where $\mathfrak{G}^*$ is the effective Lagrangian we encountered at the beginning of this section

$$\mathfrak{G}^* = \sqrt{-g}g^{\mu\nu}\left[\begin{Bmatrix}\beta\\\mu\alpha\end{Bmatrix}\begin{Bmatrix}\alpha\\\nu\beta\end{Bmatrix}-\begin{Bmatrix}\alpha\\\mu\nu\end{Bmatrix}\begin{Bmatrix}\beta\\\alpha\beta\end{Bmatrix}\right] \tag{107}$$

(Ibid., 1113, note 2). For $\sqrt{-g} = 1$, this expression for $\mathfrak{G}^*$ reduces to expression (95) for the Lagrangian L in unimodular coordinates used in (Einstein 1916a).[140]

The field equations are the Euler-Lagrange equations

$$\frac{\partial}{\partial x^\alpha}\left(\frac{\partial\mathfrak{G}^*}{\partial g^{\mu\nu}_\alpha}\right) - \frac{\partial\mathfrak{G}^*}{\partial g^{\mu\nu}} = \frac{\partial\mathfrak{M}}{\partial g^{\mu\nu}} \tag{108}$$

(Einstein 1916c, 1113, eq. 7). Einstein still did not bother to evaluate the functional derivatives $\partial\mathfrak{G}^*/\partial g^{\mu\nu}_\alpha$ and $\partial\mathfrak{G}^*/\partial g^{\mu\nu}$ to show that the left-hand side reproduces the Einstein tensor (or rather, the corresponding tensor density). The right-hand side gives minus the energy-momentum tensor density for matter:[141]

---

139 As Einstein writes in the introduction: "In particular, specific assumptions about the constitution of matter should be kept to a minimum, in contrast especially to Hilbert's presentation" ("Insbesondere sollen über die Konstitution der Materie möglichst wenig spezialisierende Annahmen gemacht werden, im Gegensatz besonders zur Hilbertschen Darstellung." Einstein 1916c, 1111). Following Mie, Hilbert (1915) had endorsed the electromagnetic worldview, according to which the matter Lagrangian is a function only of $g^{\mu\nu}$ and of the components A_μ of the electromagnetic four-vector potential and their first-order derivatives. Einstein had tired of this electromagnetic program almost as fast as he had become enamored of it in November 1915. In a footnote to the discarded appendix to (Einstein 1916a), he characterized Hilbert's approach as "not very promising" ("wenig aussichtsvoll"). This phrase was meant for public consumption. He was much more dismissive of Hilbert's work in the letter to Ehrenfest from which we already quoted in footnotes 127 and 133 (see also footnote 152 below). And reporting on (Einstein 1916c) to Weyl, Einstein bluntly wrote: "Hilbert's assumption about matter seems infantile to me, in the sense of a child innocent of the deceit of the outside world" ("Der Hilbertsche Ansatz für die Materie erscheint mir kindlich, im Sinne des Kindes, das keine Tükken der Aussenwelt kennt," Einstein to Hermann Weyl, 23 November 1916 [CPAE 8, Doc. 278]).

140 The second term in square brackets in eq. (107) vanishes since $\begin{Bmatrix}\alpha\\\alpha\beta\end{Bmatrix} = (\lg\sqrt{-g})_{,\beta}$.

141 Factors of κ, the gravitational constant, are not to be found in (Einstein 1916c). Presumably, they are absorbed into the Lagrangians $\mathfrak{G}^*$ and $\mathfrak{M}$ for matter and gravitational field.

$$\mathfrak{T}_{\mu\nu} \equiv -\frac{\partial \mathfrak{M}}{\partial g^{\mu\nu}} \tag{109}$$

(Einstein 1916c, 1115, eq. 19).

Substituting this definition into eq. (108) and contracting the resulting equations with $g^{\mu\sigma}$, one arrives at:

$$g^{\mu\sigma}\left(\frac{\partial}{\partial x^{\alpha}}\left(\frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}_{\alpha}}\right) - \frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}}\right) = -\mathfrak{T}^{\sigma}_{\nu}.$$

As we have seen in sec. 3.1 (eqs. (11)–(13)), this equation can be rewritten as

$$\frac{\partial}{\partial x^{\alpha}}\left(g^{\mu\sigma}\frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}_{\alpha}}\right) = -(\mathfrak{T}^{\sigma}_{\nu} + \mathfrak{t}^{\sigma}_{\nu}) \tag{110}$$

(ibid., eq. 18), if $\mathfrak{t}^{\sigma}_{\nu}$, the gravitational energy-momentum pseudo-tensor, is defined as:

$$\mathfrak{t}^{\sigma}_{\nu} \equiv - g^{\mu\sigma}_{\alpha}\frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}_{\alpha}} - g^{\mu\sigma}\frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}} \tag{111}$$

(ibid., eq. 20, first part).

Energy-momentum conservation in the form

$$(\mathfrak{T}^{\sigma}_{\nu} + \mathfrak{t}^{\sigma}_{\nu})_{,\sigma} = 0 \tag{112}$$

(ibid., eq. 21) is guaranteed through eq. (110) if

$$B_{\nu} \equiv \frac{\partial^2}{\partial x^{\sigma}\partial x^{\alpha}}\left(g^{\mu\sigma}\frac{\partial \mathfrak{G}^*}{\partial g^{\mu\nu}_{\alpha}}\right) = 0 \tag{113}$$

(ibid., eq. 17; Einstein does not use the notation B_{μ} in this paper).

Eq. (112) is equivalent to energy-momentum conservation in the form $T^{\mu\nu}{}_{;\nu} = 0$, or, equivalently (see eqs. (14)–(16) and footnote 35),

$$\mathfrak{T}^{\sigma}_{\nu,\sigma} + \frac{1}{2}g^{\alpha\beta}_{\nu}\mathfrak{T}_{\alpha\beta} = 0$$

(ibid., 1116, eq. 22), if

$$\mathfrak{t}^{\sigma}_{\nu,\sigma} = \frac{1}{2}g^{\alpha\beta}_{\nu}\mathfrak{T}_{\alpha\beta}.$$

Using definition (109) of $\mathfrak{T}_{\alpha\beta}$ and the field eqs. (108), one can rewrite this as

$$\mathfrak{t}^{\sigma}_{\nu,\sigma} = -\frac{1}{2}g^{\alpha\beta}_{\nu}\left(\frac{\partial}{\partial x^{\lambda}}\left(\frac{\partial \mathfrak{G}^*}{\partial g^{\alpha\beta}_{\lambda}}\right) - \frac{\partial \mathfrak{G}^*}{\partial g^{\alpha\beta}}\right).$$

As we have seen in sec. 3.2 (eqs. (17)–(18)), this equation holds, if $\mathfrak{t}^{\sigma}_{\nu}$ is defined as

$$\mathfrak{t}_\nu^\sigma \equiv \frac{1}{2}\left(\delta_\nu^\sigma \mathfrak{G}^* - g_\nu^{\alpha\beta}\frac{\partial \mathfrak{G}^*}{\partial g_\sigma^{\alpha\beta}}\right) \tag{114}$$

(ibid., 1115, eq. 20, second part).

Compatibility of the definitions (111) and (114) of $\mathfrak{t}_\nu^\sigma$ requires that[142]

$$S_\sigma^\nu \equiv 2g_\alpha^{\beta\nu}\frac{\partial \mathfrak{G}^*}{\partial g_\alpha^{\beta\sigma}} + 2g^{\alpha\nu}\frac{\partial \mathfrak{G}^*}{\partial g^{\alpha\sigma}} + \delta_\sigma^\nu \mathfrak{G}^* - g_\sigma^{\alpha\beta}\frac{\partial \mathfrak{G}^*}{\partial g_\nu^{\alpha\beta}} = 0. \tag{115}$$

Energy-momentum conservation thus requires both eq. (113) and eq. (115):

$$B_\sigma = 0, \quad S_\sigma^\nu = 0 \tag{116}$$

(see sec. 3.2, eq. (23)).

Before these considerations of energy-momentum conservation Einstein (1916c, 1114–1115) has already shown that both equations are satisfied identically for $\mathfrak{G}^*$ as a consequence of the general covariance of the action in eq. (106).[143] Consider a coordinate transformation $x'^\mu = x^\mu + \Delta x^\mu$, where the Δx^μ are chosen such that they vanish outside of some arbitrarily chosen region of spacetime. Since the integral over $\mathfrak{G}^*$ only differs by surface terms from the integral over the Riemann scalar $\mathfrak{G}$, the invariance of the latter under coordinate transformations $x'^\mu = x^\mu + \Delta x^\mu$ implies that the former is invariant under such transformations as well. Hence,

$$0 = \Delta\int \mathfrak{G}^* d\tau = \int \Delta\left(\frac{\mathfrak{G}^*}{\sqrt{-g}}\right)\sqrt{-g}\,d\tau \tag{117}$$

(the second step is justified because $\sqrt{-g}\,d\tau$ is an invariant volume element). The integrand is the sum of two terms:

$$\sqrt{-g}\,\Delta\left(\frac{\mathfrak{G}^*}{\sqrt{-g}}\right) = \Delta\mathfrak{G}^* + \sqrt{-g}\,\Delta\left(\frac{1}{\sqrt{-g}}\right)\mathfrak{G}^*. \tag{118}$$

The first term can be written as (see sec. 3.3, eq. (28))

$$\Delta\mathfrak{G}^* = \left\{2g^{\alpha\nu}\frac{\partial \mathfrak{G}^*}{\partial g^{\alpha\sigma}} + 2g_\alpha^{\beta\nu}\frac{\partial \mathfrak{G}^*}{\partial g_\alpha^{\beta\sigma}} - g_\sigma^{\alpha\beta}\frac{\partial \mathfrak{G}^*}{\partial g_\nu^{\alpha\beta}}\right\}\frac{\partial \Delta x^\sigma}{\partial x^\nu} + 2\frac{\partial \mathfrak{G}^*}{\partial g_\alpha^{\mu\sigma}}g^{\mu\nu}\frac{\partial^2 \Delta x^\sigma}{\partial x^\nu \partial x^\alpha};$$

the second term as[144]

142 In the more explicit notation of sec. 3, eq. (111) defines $\mathfrak{t}_\nu^\sigma(\mathfrak{G}^*, \text{source})$ and eq. (114) defines $\mathfrak{t}_\nu^\sigma(\mathfrak{G}^*, \text{cons})$. Compatibility requires that $S_\nu^\sigma(\mathfrak{G}^*) = 2\mathfrak{t}_\nu^\sigma(\mathfrak{G}^*, \text{cons}) - 2\mathfrak{t}_\nu^\sigma(\mathfrak{G}^*, \text{source}) = 0$. Note that definition (115) of S_ν^σ, which is the one given in (Einstein 1916c, 1114, eq. 14), differs by a factor 2 from definition (19), which is the one given in (Einstein 1914c, 1075, eq. 76a).

143 In the discarded appendix to (Einstein 1916a), the covariance properties are also discussed first. Einstein never gets to energy-momentum conservation in that document (CPAE 6, Doc. 31).

$$\sqrt{-g}\Delta\left(\frac{1}{\sqrt{-g}}\right)\mathfrak{G}^* = \mathfrak{G}^*\delta^\nu_\sigma\frac{\partial\Delta x^\sigma}{\partial x^\nu}.$$

Inserting these expressions into eq. (118), one finds

$$\sqrt{-g}\Delta\left(\frac{\mathfrak{G}^*}{\sqrt{-g}}\right) = \left\{2g^{\beta\nu}_\alpha\frac{\partial\mathfrak{G}^*}{\partial g^{\beta\sigma}_\alpha} + 2g^{\alpha\nu}\frac{\partial\mathfrak{G}^*}{\partial g^{\alpha\sigma}} + \delta^\nu_\sigma\mathfrak{G}^* - g^{\alpha\beta}_\sigma\frac{\partial\mathfrak{G}^*}{\partial g^{\alpha\beta}_\nu}\right\}\frac{\partial\Delta x^\sigma}{\partial x^\nu} + 2\frac{\partial\mathfrak{G}^*}{\partial g^{\mu\sigma}_\alpha}g^{\mu\nu}\frac{\partial^2\Delta x^\sigma}{\partial x^\nu\partial x^\alpha}. \tag{119}$$

The expression in curly brackets is just S^ν_σ as defined in eq. (115). Eq. (119) can thus be written more compactly as

$$\sqrt{-g}\Delta\left(\frac{\mathfrak{G}^*}{\sqrt{-g}}\right) = S^\nu_\sigma\frac{\partial\Delta x^\sigma}{\partial x^\nu} + 2\frac{\partial\mathfrak{G}^*}{\partial g^{\mu\sigma}_\alpha}g^{\mu\nu}\frac{\partial^2\Delta x^\sigma}{\partial x^\nu\partial x^\alpha} \tag{120}$$

(Einstein 1916c, 1114, eq. 13). Since $\mathfrak{G}^*$ transforms as a scalar under arbitrary linear transformations,

$$S^\nu_\sigma = 0 \tag{121}$$

(ibid., eq. 15). The only contribution to the action comes from the second term on the right-hand side of eq. (120). Through partial integration this contribution can be rewritten as

$$\int 2\frac{\partial^2}{\partial x^\nu\partial x^\alpha}\left(\frac{\partial\mathfrak{G}^*}{\partial g^{\mu\sigma}_\alpha}g^{\mu\nu}\right)\Delta x^\sigma d\tau$$

plus surface terms that will vanish. The invariance of $\int\mathfrak{G}^* d\tau$ thus implies that

$$B_\sigma = \frac{\partial^2}{\partial x^\nu\partial x^\alpha}\left(\frac{\partial\mathfrak{G}^*}{\partial g^{\mu\sigma}_\alpha}g^{\mu\nu}\right) = 0. \tag{122}$$

These are the contracted Bianchi identities. The general covariance of (the Lagrangian for) the Einstein field equations thus results in two identities—$S^\nu_\sigma = 0$ and $B_\sigma = 0$—that guarantee energy-momentum conservation (see eq. (116)).

144 Using that $\Delta\sqrt{-g} = -\frac{1}{2}\sqrt{-g}g_{\mu\nu}\Delta g^{\mu\nu}$ (eq. (38)), one can write

$$\Delta\left(\frac{1}{\sqrt{-g}}\right) = \frac{1}{g}\Delta\sqrt{-g} = \frac{1}{2\sqrt{-g}}g_{\mu\nu}\Delta g^{\mu\nu}.$$

Using that $\Delta g^{\mu\nu} = g^{\mu\alpha}\frac{\partial\Delta x^\nu}{\partial x^\alpha} + g^{\nu\alpha}\frac{\partial\Delta x^\mu}{\partial x^\alpha}$ (eq. (24) and Einstein 1916c, 1114, eq. 11), one finds:

$$\sqrt{-g}\Delta\left(\frac{1}{\sqrt{-g}}\right) = \frac{1}{2}\left(2g_{\mu\nu}g^{\mu\alpha}\frac{\partial\Delta x^\nu}{\partial x^\alpha}\right) = \delta^\alpha_\nu\frac{\partial\Delta x^\nu}{\partial x^\alpha},$$

from which the equation below follows.

For Einstein this was the central point of the paper. Writing to Ehrenfest, he summed up the paper as follows: "I have now given a Hamiltonian [read: variational] treatment of the essential points of general relativity as well, in order *to bring out the connection between relativity and the energy principle*" (our emphasis).[145] He told four other correspondents the same thing. Shortly after he had submitted the paper, he wrote to Besso: "You will soon receive a short paper of mine about the foundations of general relativity, in which it is shown how the requirement of relativity is connected with the energy principle. It is very amusing."[146] Similarly, he wrote to De Sitter a few days later: "Take a look at the page proofs [of (Einstein 1916c)] that I sent to Ehrenfest. There the connection between relativity postulate and energy law is brought out very clearly."[147] A little over a week later, he sent Lorentz an offprint of the paper describing it as "a short paper, in which I explained how in my opinion the relation of the conservation laws to the relativity postulate is to be understood."[148] He emphasized that the conservation laws are satisfied for any choice of the Lagrangian $\mathfrak{M}$ for matter, adding: "So the choice [of $\mathfrak{M}$] made by Hilbert appears to have no justification."[149] He made the same point in a letter to Weyl in which he once more reiterated the key point of (Einstein 1916c), namely that "[t]he connection between the requirement of general covariance and the conservation laws is also made clearer."[150]

Two years earlier Einstein had already made the connection between covariance and energy-momentum conservation in the context of the *Entwurf* theory (Einstein 1914c). He had shown that the conditions $B_\mu = 0$ and $S_\sigma^\nu = 0$ that in conjunction with the *Entwurf* field equations guarantee energy-momentum conservation also determine the class of "justified transformations" between "adapted coordinates" (see sec. 3.3). In the review article (Einstein 1916a), he had not connected the conditions guaranteeing energy-momentum conservation in unimodular coordinates to the corresponding covariance of the field equations. Instead, he had shown by direct calculation that these conditions are identically satisfied as long as unimodular coordinates

145 "Ich habe nun das Prinzipielle an der allgemeinen Relativitätstheorie auch hamiltonisch dargestellt, um den Zusammenhang zwischen Relativität und Energieprinzip zu zeigen." Einstein to Paul Ehrenfest, 24 October 1916 (CPAE 8, Doc. 269).

146 "Du erhältst bald eine kleine Arbeit von mir über die Basis der allgemeinen Relativitätstheorie, in der gezeigt wird, wie die Rel-Forderung mit dem Energieprinzip zusammenhängt. Es ist sehr amusant." Einstein to Michele Besso, 31 October 1916 (CPAE 8, Doc. 270).

147 "Sehen Sie sich die Druckbogen an, die ich Ehrenfest geschickt habe. Es kommt dort der Zusammenhang zwischen Relat. Postulat und Energiesatz besonders klar heraus." Einstein to Willem de Sitter, 4 November 1916 (CPAE 8, Doc. 273).

148 "eine kleine Arbeit, in der ich dargestellt habe, wie nach meiner Ansicht die Beziehung der Erhaltungssätze zum Relativitätspostulat aufgefasst werden soll." Einstein to H. A. Lorentz, 13 November 1916 (CPAE 8, Doc. 276).

149 "Die von Hilbert getroffene Wahl erscheint daher durch nichts gerechtfertigt." Ibid.

150 "Auch wird der Zusammenhang zwischen allgemeiner Kovarianz-Forderung und Erhaltungssätzen deutlicher." Einstein to Hermann Weyl, 23 November 1916 (CPAE 8, Doc. 278). This is the same letter in which Einstein sharply criticizes Hilbert's adherence to the electromagnetic program (see footnote 139).

are used (Einstein 1916a, sec. 17, eq. 55; cf. eq. (105) and footnotes 123 and 124). As he wrote to Ehrenfest: "In my earlier presentation [in Einstein 1916a] with $\sqrt{-g} = 1$, direct calculation establishes the identity that is here [in Einstein 1916c] presented as a consequence of the invariance [of the action]."[151] The variational treatment in arbitrary coordinates in (Einstein 1916c) thus fills two important gaps. The paper explicitly shows that energy-momentum conservation holds in arbitrary and not just in unimodular coordinates. More importantly, it establishes for the new theory what Einstein had already found for the old one, namely that there is an intimate connection between covariance and conservation laws.

It is no coincidence that the generalization of Einstein's insight—the celebrated Noether theorems—was formulated only two years later. Energy-momentum conservation in general relativity was hotly debated in Göttingen following the abstruse treatment of the topic in (Hilbert 1915).[152] In the course of his first attempt to make sense of this part of Hilbert's paper, Felix Klein (1917) claimed that energy-momentum conservation is an identity in Einstein's theory. Klein claimed—or, to be more charitable to Klein, Einstein took him to claim—that eq. (112) holds as a direct consequence of the invariance of the action (106), *independently of the field equations*. In fact, only eq. (113) is an identity (see eq. (122)). And it is only in conjunction with the field equations (110), that this identity implies energy-momentum conservation as expressed in eq. (112). Einstein immediately set Klein straight on this score.[153] This was the start of a correspondence between the two men about energy-momentum conservation in general relativity.[154]

The debate quickly shifted from the status of the identities flowing from the general covariance of the action to the (related) issue of whether or not it was acceptable in a generally-covariant theory to have a non-generally-covariant gravitational energy-momentum tensor. Unaware that Lorentz (1916b, c) and Levi-Civita (1917) had already made the same proposal, Klein suggested to define the left-hand side of the gravitational field equations as the generally-covariant gravitational energy-momentum tensor. Like Lorentz and Levi-Civita before him, Klein even wrote a paper on this proposal, which Einstein convinced him not to publish.[155]

---

151 "In meiner früheren Darstellung mit $\sqrt{-g} = 1$ wird die Identität direkt durch Ausrechnen konstatiert, welche hier als Folge der Invarianz dargestellt wird." Einstein to Paul Ehrenfest, 7 November 1916 (CPAE 8, Doc. 275).

152 In the letter to Ehrenfest from which we already quoted in footnotes 127 and 133, Einstein vented his irritation with (Hilbert 1915): "I do not care for Hilbert's presentation. It is [...] unnecessarily complicated, not honest (= Gaussian) in its structure (creating the impression of being an *übermensch* by obfuscating one's methods)" ("Hilberts Darstellung gefällt mir nicht. Sie ist [...] unnötig kompliziert, nicht ehrlich (= Gaussisch) im Aufbau (Vorspiegelung des Übermenschen durch Verschleierung der Methoden)."). Our assessment of Hilbert's paper follows "Hilbert's Foundation of Physics ..." (in vol. 4 of this series). For a more positive assessment, see (Sauer 1999).

153 See the first paragraph of Einstein to Felix Klein, 13 March 1918 (CPAE 8, Docs. 480).

154 The most interesting letters are the first three, all written in March 1918: (1) the letter cited in footnote 153; (2) Felix Klein to Einstein, 20 March 1918 (CPAE 8, Doc. 487); (3) Einstein to Felix Klein, 24 March 1918 (CPAE 8, Doc. 492).

Einstein was virtually alone at this point in his defense of the pseudo-tensor. As he stated with his usual flair for high drama in the first sentence of (Einstein 1918d): "While the general theory of relativity has met with the approval of most physicists and mathematicians, almost all my colleagues object to my formulation of the energy-momentum law."[156] Einstein was unfazed by the opposition. Drawing heavily on (Einstein 1916c), (Einstein 1918d) provides a sustained defense of the views on energy-momentum conservation that had guided Einstein in finding and consolidating the *Entwurf* theory in 1913–1914 and that had guided him again in finding and consolidating its successor theory in 1915–1916. Subsequent developments would prove Einstein right. We now know that gravitational energy-momentum is represented by a pseudo-tensor and not by a tensor because gravitational energy-momentum cannot be localized.

Klein meanwhile continued to discuss the problem of energy-momentum conservation with other Göttingen mathematicians, notably with Carl Runge and Emmy Noether—one of the wrong sex, the other too old to be sent to the front. With Runge he undertook a systematic survey of the relevant literature. These efforts resulted in two important papers on the topic (Klein 1918a, 1918b). Noether's work on the problem resulted in her seminal paper on symmetries and conservation laws (Noether 1918).[157]

The importance of (Einstein 1916c) for our story is not so much its role in the run-up to Noether's theorems, but the evidence it provides for the continuity of Einstein's reliance on the variational formalism of (Einstein 1914c) in the transition from the *Entwurf* theory to general relativity. There was no abrupt break, no sudden switch from physical to mathematical strategy. Instead, the transition was brought about by changing one key element in the formalism encoding much of the physical knowledge that went into the *Entwurf* theory and then modifying other parts of the formalism (if necessary) to accommodate the new version of this one element. Einstein himself pinpointed this one element for us. It was the definition of the components of the gravitational field. Not all modifications necessitated by changing this definition were in place by the time he published the first of his four communications of November 1915 to the Prussian Academy (Einstein 1915a). Most of them were in place by the time he published the fourth (Einstein 1915d). This Einstein made clear in his systematic exposition of the theory in (Einstein 1916a). Even this paper, how-

155 Two drafts of this paper can be found in the Klein *Nachlass* in the Niedersächsische Staats- und Universitätsbibliothek in Göttingen (see CPAE 7, Doc. 9, note 5, for more details).

156 "Während die allgemeine Relativitätstheorie bei den meisten theoretischen Physikern und Mathematikern Zustimmung gefunden hat, erheben doch fast alle Fachgenossen gegen meine Formulierung des Impuls-Energiesatzes Einspruch" (Einstein 1918d, 448). This paper pulls together and amplifies earlier comments in (Einstein 1918a, sec. 6), written in response to Levi-Civita, and (Einstein 1918b), written in response to one of two short, little-known, and inconsequential excursions into general relativity by Erwin Schrödinger (1918). For discussion of the debate over energy-momentum conservation between Einstein and Levi-Civita, see (Cattani and De Maria 1993).

157 In broad outline this story can be found in (Rowe 1999). For a particularly illuminating analysis of Noether's theorems and their applications in physics, see (Brading 2002).

ever, left at least one important question unanswered (viz., do the field equations guarantee energy-momentum conservation in arbitrary coordinates) and failed to transfer at least one important insight from the *Entwurf* theory to the new theory (viz., the relation between covariance and energy-momentum conservation). These issues were settled only with (Einstein 1916c), a paper that can be seen as the end of the consolidation phase of the theory, although one can argue that this phase was not brought to a conclusion until the publication of (Einstein 1918a, c, d).

10. HOW EINSTEIN REMEMBERED HE FOUND HIS FIELD EQUATIONS

In his papers of November 1915, Einstein introduced his new field equations by arguing that they were the natural choice given the central role of the Riemann tensor in differential geometry. The field equations are thus presented as a product of what we have called the mathematical strategy. The continuity with the Entwurf field equations, a product of the physical strategy, is lost in Einstein's presentation and the reader is left with the impression that Einstein abruptly switched from the physical to the mathematical strategy in the fall of 1915. This is exactly how Einstein himself came to remember the breakthrough of November 1915. The physics, he felt, had been nothing but a hindrance; he had been saved at the eleventh hour by the mathematics. In his later years Einstein routinely used this version of events to justify the purely mathematical approach in his work in unified field theory.

The way Einstein presented his new field equations in the first of his four papers of November 1915 (Einstein 1915a) is very different from the way we claim he found them. The paper opens with the retraction of the uniqueness argument of (Einstein 1914c) for the *Entwurf* field equations. After explaining what is wrong with this argument, Einstein writes in the third paragraph:

> For these reasons I completely lost confidence in the field equations I had constructed and looked for a way that would constrain the possibilities in a natural manner. I was thus led back to the demand of a more general covariance of the field equations, which I had abandoned with a heavy heart three years ago when I was collaborating with my friend Grossmann. In fact, back then we already came very close to the solution of the problem given below.[158]

The fourth paragraph announces a new theory in which all equations, including the field equations, are covariant under arbitrary unimodular transformations. Einstein does not explain, neither in this paragraph nor anywhere else in the paper, what made him forgo *general* covariance at this point. Our explanation is that the physical strategy pointed not to the generally-covariant Ricci tensor but to the November tensor, which only transforms as a tensor under unimodular transformations. We showed how changing the definition of the gravitational field set in motion a chain of reasoning that led from the *Entwurf* field equations to field equations based on the November tensor. Reading the passage quoted above, one would not have suspected such continuity. In fact, Einstein's revelations that he has "completely lost confidence" in the *Entwurf* field equations and that he had already come "very close to the [new] solution" three years earlier suggest a dramatic about-face. The fifth and final paragraph of Einstein's introduction confirms this impression and suggests an abrupt switch from the physical to the mathematical strategy:

> Hardly anybody who has truly understood the theory will be able to avoid coming under its spell. It is a real triumph of the method of the general differential calculus developed by Gauss, Riemann, Christoffel, Ricci, and Levi-Civita.[159]

This impression is further reinforced by the way in which the field equations are introduced in the paper. In sec. 2, on the construction of quantities transforming as tensors under unimodular transformations, Einstein shows how to extract the November tensor R_{ij} from the Ricci tensor $G_{ij} = R_{ij} + S_{ij}$ (Einstein 1915a, 782, eqs. (13), (13a), (13b)) just as he had done in the Zurich Notebook.[160] At the beginning of sec. 3, he then writes:

> After what has been said so far, it is natural to posit field equations of the form $R_{\mu\nu} = -\kappa T_{\mu\nu}$, because we already know that these equations are covariant under arbitrary transformations of determinant 1.[161]

It is only at this point that Einstein gives the Lagrangian formulation of these field equations (Einstein 1915a, 784, eq. (17)) and goes through the argument demonstrating that they are compatible with energy-momentum conservation (see sec. 6).[162]

Not surprisingly in light of the above, some of the best modern commentators on (Einstein 1915a) have concluded that its author had abruptly switched strategies in the fall of 1915. The clearest, most concise and most explicit version of this account

---

158 "Aus diesen Gründen verlor ich das Vertrauen zu den von mir aufgestellten Feldgleichungen vollständig und suchte nach einem Wege, der die Möglichkeiten in einer natürlichen Weise einschränkte. So gelangte ich zu der Forderung einer allgemeineren Kovarianz der Feldgleichungen zurück, von der ich vor drei Jahren, als ich zusammen mit meinem Freunde Grossmann arbeitete, nur mit schwerem Herzen abgegangen war. In der Tat waren wir damals der im nachfolgenden gegebenen Lösung des Problems bereits ganz nahe gekommen" (Einstein 1915a, p. 778). The Zurich Notebook shows that Einstein and Grossmann did indeed consider field equations based on the November tensor three years earlier (see sec. 2). Norton (2000, 150) inaccurately translates "gelangte … zurück" as "went back" rather than as "was led back." The difference is not unimportant. Norton's "went back" conveys discontinuity: Einstein abandoned one approach and adopted another, characterized by "the demand of a more general covariance." On this reading "a more general covariance" sounds odd. One would have expected "general covariance." Our "was led back" conveys continuity: staying the course Einstein ended up with "the demand of a more general covariance." On our reading "demand" sounds odd. One would have expected "property" or "feature" instead. Our reading, however, does fit with Einstein's remark quoted at the beginning of sec. 3 (see footnote 32): "The series of my papers on gravitation is a chain of erroneous paths, which nonetheless gradually brought me closer to my goal." Einstein to H.A. Lorentz, 17 January 1916 (CPAE 8, Doc. 183)

159 "Dem Zauber dieser Theorie wird sich kaum jemand entziehen können, der sie wirklich erfaßt hat; sie bedeutet einen wahren Triumph der durch Gauss, Riemann, Christoffel, Ricci, und Levi-Civita begründeten Methode des allgemeinen Differentialkalküls" (Einstein 1915a, p. 779).

160 See eqs. (1)–(5) in sec. 2; G_{ij}, R_{ij}, and S_{ij} are defined in the equations following eq. (82).

161 "Nach dem bisher Gesagten liegt es nahe, die Feldgleichungen in der Form $R_{\mu\nu} = -\kappa T_{\mu\nu}$ anzusetzen, da wir bereits wissen, daß diese Gleichungen gegenüber beliebigen Transformationen von der Determinante 1 kovariant sind" (Einstein 1915a, p. 783).

can be found in (Norton 2000).[163] At the beginning of sec. 5, "Reversal at the Eleventh Hour," Norton gives the following summary of the developments of fall 1915:

> *… aware of the flaws in his Entwurf theory, Einstein decided he could only find the correct theory through the expressions naturally suggested by the mathematics. He proceeded rapidly to the completion of the theory and the greatest triumph of his life […]. Einstein now saw the magic in mathematics*. (Norton 2000, 148)

He elaborates:

> In effect, [Einstein's] new tactic [in the fall of 1915] was to reverse his decision of 1913. When the physical requirements appeared to contradict the formal mathematical requirements, he had then chosen in favour of the former. He now chose the latter and, writing down the mathematically natural equations, found himself rapidly propelled towards a theory that satisfied all the requirements and fulfilled his 'wildest dreams'[164] […] Einstein's reversal was his Moses that parted the waters and led him from bondage into the promised land of his general theory of relativity—and not a moment too soon. Had he delayed, the promised land might well have been Hilbert's.[165] (Einstein 1933b, 289) recalled how he 'ruefully returned to the Riemann curvature'. He now saw just how directly the mathematical route had delivered the correct equations in 1913 and, by contrast, how treacherous was his passage if he used physical requirements as his principal compass (Norton 2000, 151–152)

There is an amusing pair of quotations from letters to Besso that can be used as evidence for 'Einstein's reversal' (cf. Norton 2000, 152). In March 1914, reporting results that seemed to solidify the *Entwurf* theory (see sec. 3), Einstein told Besso:

> The general theory of invariants only proved to be an obstacle. The direct route proved to be the only feasible one. The only thing that is incomprehensible is that I had to feel my way around for so long before I found *the obvious* [our emphasis].[166]

In December 1915, Einstein used the same term to tell Besso the exact opposite: "the obvious" ("das Nächstliegende") now refers to the mathematically rather than the physically obvious:

> This time *the obvious* was correct; however Grossmann and I believed that the conservation laws would not be satisfied and that Newton's law would not come out in first approximation [our emphasis].[167]

---

162 The same pattern can be found in the review article. Einstein (1916a, 803–804) introduces the field equations by connecting them to the Riemann tensor and then proceeds to discuss them using the variational formalism. In the letter to Ehrenfest, however, that (as we argued in sec. 8) formed the blueprint for the discussion of the gravitational field equations in the review article, Einstein writes down the Lagrangian right a way and does not say a word about the connection between the field equations and the Riemann tensor. Einstein to Paul Ehrenfest, 24 January 1916 or later (CPAE 8, Doc. 185). Of course, he could simply have omitted that part because that was not what Ehrenfest had trouble with.

163 In a recent paper, Jeroen van Dongen (2004, sec. 2) fully endorses Norton's account. He is more careful in his dissertation (Van Dongen 2002).

164 See Einstein to Michele Besso, 10 December 1915 (CPAE 8, Doc. 162).

165 See (Corry et al. 1997) for conclusive evidence of Einstein's priority (cf. footnote 65 above)

166 "Die allgemeine Invariantentheorie wirkte nur als Hemmnis. Der direkte Weg erwies sich als der einzig gangbare. Unbegreiflich ist nur, dass ich so lange tasten musste, bevor ich das Nächstliegende fand." Einstein to Michele Besso, ca. 10 March 1914 (CPAE 5, Doc. 514).

These twin quotations seem to provide strong, if anecdotal, evidence for Einstein changing horses in the fall of 1915.

Even in late 1915, however, as the last quotation illustrates, Einstein mentioned physical as well as mathematical considerations. The same thing he told Besso he told Sommerfeld and Hilbert too:

> It is easy, of course, to write down these generally-covariant field equations but difficult to see that they are a generalization of the Poisson equation and not easy to see that they satisfy the conservation laws.[168]
>
> The difficulty did not lie in finding generally-covariant equations for the $g_{\mu\nu}$; this is easily done with the help of the Riemannian tensor. Rather it was difficult to recognize that these equations formed a generalization of Newton's laws and indeed a simple and natural generalization.[169]

To be sure, these references to physical considerations fit with the alleged 'reversal' from physics to mathematics. First, we have to keep in mind that Einstein had ulterior motives in emphasizing that the mathematics was easy and that getting the physics straight was the hard part. He wanted to downplay the importance of Hilbert's work. Einstein felt that Hilbert had only worked on the theory's mathematical formalism and had not wrestled with the physical interpretation of the formalism the way he had. Second, Einstein's comments on the difficulty of the physical interpretation of the field equations still suggest that the decisive breakthrough occurred in the mathematics and that the physics then fell into place. We have argued that it was just the other way around.

Why did Einstein nonetheless choose to present the new theory as a product of his mathematical strategy? Undoubtedly, part of the answer is that the key mathematical consideration pointing to the new field equations—the November tensor's pedigree in the Riemann tensor—is much simpler than the physical reasoning that had led Einstein to these equations in the first place. But even had the physical considerations been less forbidding, they would in all likelihood not have made for an effective and

167 "Diesmal ist das Nächstliegende das Richtige gewesen; Grossmann und ich glaubten, dass die Erhaltungssätze nicht erfüllt seien, und das Newton'sche Gesetz in erster Näherung nicht herauskomme." Einstein to Michele Besso, 10 December 1915 (CPAE 8, Doc. 162).

168 "Es ist natürlich leicht, diese allgemein kovariante Gleichungen hinzusetzen, schwer aber, einzusehen, dass sie Verallgemeinerungen von Poissons Gleichungen sind, und nicht leicht, einzusehen, dass sie den Erhaltungssätzen Genüge leisten." Einstein to Arnold Sommerfeld, 28 November 1915 (CPAE 8, Doc. 153; see footnote 31 for a discussion of the context in which this letter was written). It is very telling that recovering the Poisson equation is presented as a problem that is harder than proving energy-momentum conservation. This is indeed the case—it requires overcoming the notion of coordinate restrictions and the prejudice about the form of the static metric—but one would never have guessed this from the November 1915 paper where the Poisson equation is recovered simply by applying the Hertz condition.

169 "Die Schwierigkeit bestand nicht darin allgemein kovariante Gleichungen für die $g_{\mu\nu}$ zu finden; denn dies gelingt leicht mit Hilfe des Riemann'schen Tensors. Sondern schwer war es, zu erkennen, dass diese Gleichungen eine Verallgemeinerung, und zwar eine einfache und natürliche Verallgemeinerung des Newton'schen Gesetzes bilden." Einstein to David Hilbert, 18 November 1915 (CPAE 8, Doc. 148).

convincing argument for the new field equations. After all, Einstein had essentially drawn on these same considerations a year earlier for his fallacious argument for the uniqueness of the *Entwurf* field equations. That debacle was bound to come back and haunt a new argument along similar lines.

The math envy Einstein developed in the course of his work on general relativity may also have been a factor. As he confessed to Sommerfeld early on in his collaboration with Grossmann: "One thing for sure though is that I have never before in my life exerted myself even remotely as much and that I have been infused with great respect for mathematics, the subtler parts of which I until now, in my innocence, considered pure luxury. Compared to this problem, the original theory of relativity is child's play."[170] In 1917 he told Levi-Civita that "[i]t must be a pleasure to ride through these fields on the steed of real mathematics, while the likes of us must trudge through on foot."[171]

We suspect, however, that Einstein's main reason for going with the mathematical argument was simply that he felt that this was by far the most persuasive argument in favor of the new field equations. Recall Einstein's satisfaction in October 1914 with the physical and mathematical lines of reasoning apparently converging on the *Entwurf* field equations, thereby finally rendering their covariance properties tractable (see our discussion at the end of sec. 4). If anything, the convergence of mathematical and physical lines of reasoning in late 1915 was more striking than it had been the year before. The concomitant clarification of the equations' covariance properties was accordingly more complete and more perspicuous. In the case of the *Entwurf* field equations, the clarification had taken the form of a complicated condition for non-autonomous transformations. In the case of the November tensor, the connection to the Riemann tensor immediately told Einstein that his new field equations were invariant under arbitrary unimodular transformations. Given how pleased Einstein had been with his much more modest result in 1914, this new result cannot have failed to impress him. As we saw at the end of sec. 4, Einstein got carried away by the earlier result, claiming that he had found definite field equations "in a completely formal manner, i.e., without direct use of our physical knowledge about gravity" (Einstein 1914c, 1076; cf. footnotes 78 and 79). The same happened in November 1915. In arguing for his new field equations, Einstein emphasized the covariance considerations to the exclusion of (at least) equally important considerations concerning energy-momentum conservation and the relation to Newtonian gravitational theory.

---

170 "Aber das eine ist sicher, dass ich mich im Leben noch nicht annäherend so geplag[t] habe, und dass ich grosse Hochachtung für die Mathematik eingeflösst bekommen habe, die ich bis jetzt in ihren subtileren Teilen in meiner Einfalt für puren Luxus ansah! Gegen dies Problem ist die ursprüngliche Relativitätstheorie eine Kinderei." Einstein to Arnold Sommerfeld, 29 October 1912 (CPAE 5, Doc. 421).

171 "Es muss hübsch sein, auf dem Gaul der eigentlichen Mathematik durch diese Gefilde zu reiten, während unsereiner sich zu Fuss durchhelfen muss." Einstein to Tullio Levi-Civita, 2 August 1917 (CPAE 8, Doc. 368).

These physical considerations rapidly faded from memory. The way Einstein came to remember it, the general theory of relativity—the crowning achievement of his scientific career—was the result of a purely mathematical approach to physics. Sometimes he knew better than that. In 1918, for instance, he wrote to Besso:

> Re-reading your last letter I find something that almost makes me angry: that speculation has proved itself to be superior to empiricism. You are thinking here about the development of relativity theory. I find that this development teaches something else, which is almost the opposite, namely that a theory, to deserve our trust, must be built upon generalizable *facts* [… In the case of g]eneral relativity: *equality of inertial and gravitational mass* […] Never has a truly useful and profound theory really been found purely speculatively.[172]

Statements like this, however, are the exception. Much more typical is what he wrote to Cornelius Lanczos in 1938: "the problem of gravitation has made me into a believing rationalist, i.e., one who looks for the only reliable source of truth in mathematical simplicity."[173] This distorted memory of how he had found general relativity served an important purpose in his subsequent career. Whenever the need arose to justify the speculative mathematical approach that never got him anywhere in his work on unified field theory, Einstein reminded his audience that he could boast of at least one impressive successful application of his preferred methodology.

The emblematic text documenting the later Einstein's extreme rationalist stance on scientific methodology is his Herbert Spencer lecture, held in Oxford on June 10, 1933.[174] This is where Einstein famously enthused that "[o]ur experience hitherto justifies us in believing that nature is the realization of the simplest conceivable mathematical ideas" (Einstein 1933a, 274[175]). Einstein routinely claimed that this was the lesson he had drawn from the way in which he had found general relativity. The passage in the letter to Lanczos that we just quoted is a good example. A few more exam-

---

172 "In Deinem letzten Brief finde ich beim nochmaligen Lesen etwas, das mich geradezu erbost: die Spekulation habe sich als der Empirie überlegen gezeigt. Du denkst dabei an die Entwicklung der Relativitätstheorie. Aber ich finde, dass diese Entwicklung etwas anderes lehrt, das fast das Gegenteil davon ist, nämlich, dass eine Theorie, um Vertrauen zu verdienen, auf verallgemeinerungsfähige *Thatsachen* aufgebaut sein muss […] Algemeine Relativität: *Gleichheit der trägen und schweren Masse* […] Niemals ist eine wirklich brauchbare und tiefgehende Theorie wirklich rein spekulativ gefunden worden." Einstein to Michele Besso, 28 August 1918 (CPAE 8, Doc. 607). Quoted and discussed in (Holton 1968, 246–247).

173 "… hat das Gravitationsproblem mich zu einem gläubigen Rationalisten gemacht, d.h. zu einem, der die einzige zuverlässige Quelle der Wahrheit in der mathematischen Einfachheit sucht." Einstein to Cornel Lanczos, 24 January 1938 (EA 15 267). Quoted and discussed in (Holton 1968, 259) and (Van Dongen 2002, 48).

174 For discussion, see, e.g., (Holton 1968, 251–252), (Norton 2000), and (Van Dongen 2002).

175 The German manuscript (EA 1 114) has: "Nach unserer bisherigen Erfahrung sind wir nämlich zu dem Vertrauen darin berechtigt, dass die Natur die Realisierung des mathematisch denkbar Einfachsten ist."

ples must suffice here.[176] In a letter to Louis de Broglie the year before he died Einstein wrote that he arrived at the position expounded in his Spencer lecture

> through the experiences with the gravitational theory. The gravitational [field] equations could only be found on the basis of a purely formal principle (general covariance), i.e., on the basis of trust in the largest imaginable simplicity of the laws of nature.[177]

In his autobiographical notes of 1949, he similarly wrote that

> I have learned something else from the theory of gravitation: no collection of empirical facts however comprehensive can ever lead to the formulation of such complicated equations […] Equations of such complexity as are the equations of the gravitational field can be found only through the discovery of a logically simple mathematical condition that determines the equations completely or [at least] almost completely. Once one has those sufficiently strong formal conditions, one requires only little knowledge of facts for the setting up of a theory; in the case of the equations of gravitation it is the four-dimensionality and the symmetric tensor as expression for the structure of space which together with the invariance concerning the continuous transformation group, determine the equations almost completely.[178]

Discussing this passage, Jeroen van Dongen (2002, 30) notes that this is hardly a historically balanced account and that it reads more "like a unified field theory manifesto." As we have shown in this paper, the Einstein field equations were found not, as the later Einstein would have it, by extracting the mathematically simplest equations from the Riemann tensor, but by pursuing the analogy with Maxwell's equations for the electromagnetic field, making sure that they be compatible with Newtonian gravitational theory and energy-momentum conservation. Considerations of mathematical elegance played a role at various junctures but were always subordinate to physical considerations.

---

176 For more examples, see, e.g., (Holton 1968, 259–260), (Norton 2000), and (Van Dongen 2002).

177 "durch die Erfahrungen bei der Gravitationstheorie. Die Gravitations-gleichungen waren nur auffindbar auf Grund eines rein formalen Prinzipes (allgemeine Kovarianz), d.h. auf Grund des Vertrauens auf die denkbar grösste logische Einfachheit der Naturgesetze" Einstein to Louis de Broglie, 8 February 1954. This letter is quoted and discussed in (Van Dongen 2002, 8)

178 "Noch etwas anderes habe ich aus der Gravitationstheorie gelernt: Eine noch so umfangreiche Sammlung empirischer Fakten kann nicht zur Aufstellung so verwickelter Gleichungen führen […] Gleichungen von solcher Kompliziertheit wie die Gleichungen des Gravitationsfeldes können nur dadurch gefunden werden, dass eine logisch einfache mathematische Bedingung gefunden wird, welche die Gleichungen völlig oder nahezu determiniert. Hat man aber jene hinreichend starken formalen Bedingungen, so braucht man nur wenig Tatsachen-Wissen für die Aufstellung der Theorie; bei den Gravitationsgleichungen ist es die Vierdimensionalität und der symmetrische Tensor als Ausdruck für die Raumstruktur, welche zusammen mit der Invarianz der kontinuierlichen Transformationsgruppe die Gleichungen praktisch vollkommen determinieren" (Einstein 1949, 88–89).

APPENDIX: THE TRANSITION FROM THE *ENTWURF* FIELD EQUATIONS TO THE EINSTEIN FIELD EQUATIONS SANITIZED

Drawing on calculations scattered throughout this paper and with the benefit of hindsight, we present a sanitized version of the path that took Einstein from the *Entwurf* field equations to the Einstein field equations. We start from the vacuum field equations in unimodular coordinates. In the form in which they were originally presented (Einstein and Grossmann 1913, 16-17, eqs. 15 and 18) the *Entwurf* equations look nothing like the Einstein field equations. In unimodular coordinates they can be written in a form that clearly brings out the relation to their successor.

Comparing Vacuum Field Equations. Both in the *Entwurf* theory and in general relativity, the vacuum field equations in unimodular coordinates can be derived from the action principle $\delta\int\sqrt{-g}L d\tau$. In both cases the Lagrangian is given by:

$$L = g^{\mu\nu}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu} \tag{A.1}$$

(see eq. (63) with $L \equiv \mathfrak{L}$ for general relativity and eq. (35) with $L \equiv -H$ for the *Entwurf* theory). In general relativity the gravitational field is defined as (see eq. (53))

$$\Gamma^{\alpha}_{\beta\mu} \equiv -\begin{Bmatrix}\alpha\\ \beta\mu\end{Bmatrix} = -\frac{1}{2}g^{\alpha\rho}(g_{\rho\beta,\mu} + g_{\rho\mu,\beta} - g_{\beta\mu,\rho}); \tag{A.2}$$

in the *Entwurf* theory as (see eq. (52) with a minus sign)

$$\tilde{\Gamma}^{\alpha}_{\beta\mu} \equiv -\frac{1}{2}g^{\alpha\rho}g_{\rho\beta,\mu}. \tag{A.3}$$

To distinguish between corresponding quantities in the two theories, we shall write the *Entwurf* quantities with a tilde, as in eq. (A.3). Note that $\tilde{\Gamma}^{\alpha}_{\beta\mu}$ in eq. (A.3) is nothing but a truncated version of $\Gamma^{\alpha}_{\beta\mu}$ in eq. (A.2). Also note that the Lagrangian in eq. (A.1) is modelled on the Lagrangian for the free Maxwell field, $-\frac{1}{4}F^{\mu\nu}F_{\mu\nu}$.

The structural identity of the Lagrangians in the two theories does not carry over to the Euler-Lagrange equations. This is because of two complications. (1) The operations 'setting $\sqrt{-g} = 1$' and 'doing the variations' do not commute (see footnote 83). In the *Entwurf* theory we do the variations first. In general relativity we set $\sqrt{-g} = 1$ first. (2) The quantities $\Gamma^{\alpha}_{\beta\mu}$ are symmetric in their lower indices, whereas their counterparts, $\tilde{\Gamma}^{\alpha}_{\beta\mu}$, in the *Entwurf* theory are not.

In unimodular coordinates, the vacuum Einstein field equations can be written as (see footnote 89)[179]

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - g^{\nu\rho}\Gamma^{\lambda}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} = 0, \tag{A.4}$$

and the vacuum *Entwurf* field equations as (see eqs. (47) and (49)):

$$(g^{\alpha\beta}\tilde{\Gamma}^{\lambda}_{\mu\beta})_{,\alpha} - g^{\lambda\rho}\tilde{\Gamma}^{\alpha}_{\tau\mu}\tilde{\Gamma}^{\tau}_{\alpha\rho} + \frac{1}{2}\delta^{\lambda}_{\mu}g^{\rho\tau}\tilde{\Gamma}^{\alpha}_{\beta\rho}\tilde{\Gamma}^{\beta}_{\alpha\tau} = 0. \tag{A.5}$$

We can get these equations to resemble each other even more closely by defining

$$\Gamma_{\alpha}^{\mu\nu} \equiv g^{\mu\beta}\Gamma_{\alpha\beta}^{\nu} \qquad \text{(A.6)}$$

in general relativity and the corresponding quantities

$$\tilde{\Gamma}_{\alpha}^{\mu\nu} \equiv g^{\nu\beta}\tilde{\Gamma}_{\alpha\beta}^{\mu} \qquad \text{(A.7)}$$

in the *Entwurf* theory. Note that the order of the indices μ and ν is different in eqs. (A.6) and (A.7).[180] Inserting these quantities into eqs. (A.4) and (A.5), we find:

$$(\Gamma_{\mu}^{\lambda\alpha})_{,\alpha} - \Gamma_{\alpha}^{\nu\lambda}\Gamma_{\nu\mu}^{\alpha} = 0, \qquad \text{(A.8)}$$

$$(\tilde{\Gamma}_{\mu}^{\lambda\alpha})_{,\alpha} - \tilde{\Gamma}_{\alpha}^{\tau\lambda}\tilde{\Gamma}_{\tau\mu}^{\alpha} + \frac{1}{2}\delta_{\mu}^{\lambda}\tilde{\Gamma}_{\beta}^{\alpha\tau}\tilde{\Gamma}_{\alpha\tau}^{\beta} = 0. \qquad \text{(A.9)}$$

The first two terms in these two equation have the exact same form.

Expressed in unimodular coordinates and in terms of $\{\Gamma_{\alpha\beta}^{\mu}, \Gamma_{\mu}^{\alpha\beta}\}$ and $\{\tilde{\Gamma}_{\alpha\beta}^{\mu}, \tilde{\Gamma}_{\mu}^{\alpha\beta}\}$, respectively, the gravitational energy-momentum pseudo-tensors of the two theories also take on the exact same form. With the help of eq. (A.6) the pseudo-tensor of general relativity in unimodular coordinates (see eq. (73)) can be written as

$$\kappa t_{\sigma}^{\lambda} = \frac{1}{2}\delta_{\sigma}^{\lambda}\Gamma_{\mu\beta}^{\alpha}\Gamma_{\alpha}^{\mu\beta} - \Gamma_{\mu\sigma}^{\alpha}\Gamma_{\alpha}^{\mu\lambda}. \qquad \text{(A.10)}$$

With the help of eq. (A.7) the pseudo-tensor of the *Entwurf* theory in unimodular coordinates, with an overall minus sign because of the switch from H to $L = -H$ (see minus eq. (49) for $\sqrt{-g} = 1$) can be written as

$$\kappa\tilde{t}_{\mu}^{\lambda} = \frac{1}{2}\delta_{\mu}^{\lambda}\tilde{\Gamma}_{\beta\rho}^{\alpha}\tilde{\Gamma}_{\alpha}^{\beta\rho} - \tilde{\Gamma}_{\tau\mu}^{\alpha}\tilde{\Gamma}_{\alpha}^{\tau\lambda}. \qquad \text{(A.11)}$$

Eqs. (A.10) and (A.11) have the exact same form. The first term in both expressions contains the trace of the pseudo-tensor:

$$\kappa t = \Gamma_{\mu\beta}^{\alpha}\Gamma_{\alpha}^{\mu\beta}, \qquad \kappa\tilde{t} = \tilde{\Gamma}_{\beta\rho}^{\alpha}\tilde{\Gamma}_{\alpha}^{\beta\rho}. \qquad \text{(A.12)}$$

Using the expressions for the gravitational energy-momentum pseudo-tensors and their trace, we can write the field equations (A.8) and (A.9) in a form that brings out

---

179 When the variation $\delta\int\sqrt{-g}Ld\tau$ for L in eq. (A.1) is done *before* setting $\sqrt{-g} = 1$, one finds

$$\Gamma_{\mu\nu,\alpha}^{\alpha} + \Gamma_{\beta\mu}^{\alpha}\Gamma_{\alpha\nu}^{\beta} + \frac{1}{2}g_{\mu\nu}g^{\rho\sigma}\Gamma_{\beta\rho}^{\alpha}\Gamma_{\alpha\sigma}^{\beta} = 0$$

(see eq. (61) with $\mathfrak{T}_{\mu\nu} = 0$). Contracting this equation with $g^{\nu\lambda}$, one finds

$$(g^{\nu\lambda}\Gamma_{\mu\nu}^{\alpha})_{,\alpha} - g^{\nu\rho}\Gamma_{\alpha\rho}^{\lambda}\Gamma_{\mu\nu}^{\alpha} + \frac{1}{2}\delta_{\nu}^{\lambda}g^{\rho\sigma}\Gamma_{\beta\rho}^{\alpha}\Gamma_{\alpha\sigma}^{\beta} = 0$$

Not surprisingly, this last equation resembles eq. (A.5) in the *Entwurf* theory more closely than eq. (A.4), obtained when the variation is done *after* setting $\sqrt{-g} = 1$.

180 Expressed in terms of the new quantities $\Gamma_{\alpha}^{\mu\nu}$ and $\tilde{\Gamma}_{\alpha}^{\mu\nu}$, the Lagrangians for the two theories retain their structural identity: $L = g^{\mu\nu}\Gamma_{\beta\mu}^{\alpha}\Gamma_{\alpha\nu}^{\beta} = \Gamma_{\mu\beta}^{\alpha}\Gamma_{\alpha}^{\mu\beta}$ and $\tilde{L} = g^{\mu\nu}\tilde{\Gamma}_{\beta\mu}^{\alpha}\tilde{\Gamma}_{\alpha\nu}^{\beta} = \tilde{\Gamma}_{\beta\mu}^{\alpha}\tilde{\Gamma}_{\alpha}^{\beta\mu}$.

the physical interpretation of the various terms more clearly. Using eq. (A.12), we can rewrite eq. (A.10) as:

$$-\Gamma^{\nu\lambda}_{\alpha}\Gamma^{\alpha}_{\nu\mu} = \kappa t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa t.$$

Substituting this equation into the field equations (A.8), we find[181]

$$(\Gamma^{\lambda\alpha}_{\mu})_{,\alpha} + \kappa t^{\lambda}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa t = 0. \tag{A.13}$$

Substituting eq. (A.11) into the field equations (A.9), we find

$$(\tilde{\Gamma}^{\lambda\alpha}_{\mu})_{,\alpha} + \kappa \tilde{t}^{\lambda}_{\mu} = 0. \tag{A.14}$$

The crucial difference between these last two equations is the trace term on the left-hand side of eq. (A.13).

From the Entwurf Field Equations to the Einstein Field Equations. Eqs. (A.13)–(A.14) suggest a short-cut for getting from the *Entwurf* field equations in unimodular coordinates to the Einstein field equations, first in unimodular coordinates and then in their generally-covariant form. Comparison of eq. (A.14) to eq. (A.13) shows that changing the definition of the gravitational field from $\tilde{\Gamma}^{\alpha}_{\beta\mu}$ in eq. (A.3) to $\Gamma^{\alpha}_{\beta\mu}$ in eq. (A.2) changes the way in which the gravitational energy-momentum pseudo-tensor occurs in the gravitational part of the field equations in unimodular coordinates. Since the energy-momentum of matter should enter the field equations in the same way as the energy-momentum of the gravitational field itself, this also affects the matter part of the field equations. In the presence of matter described by an energy-momentum tensor $T_{\mu\nu}$, the vacuum equations (A.14)—based on definition (A.3) of the gravitational field, Einstein's "fateful prejudice"—should be generalized to

$$(\tilde{\Gamma}^{\lambda\alpha}_{\mu})_{,\alpha} = -\kappa(\tilde{t}^{\lambda}_{\mu} + T^{\lambda}_{\mu}). \tag{A.15}$$

These are the *Entwurf* field equations in unimodular coordinates. By the same token, eq. (A.13)—based on definition (A.2) of the gravitational field, Einstein's "key to the solution"—should be generalized to:[182]

181 If eq. (A.4) obtained by doing the variations *after* setting $\sqrt{-g} = 1$ are replaced by the equations

$$(g^{\nu\lambda}\Gamma^{\alpha}_{\mu\nu})_{,\alpha} - g^{\nu\rho}\Gamma^{\lambda}_{\alpha\rho}\Gamma^{\alpha}_{\mu\nu} + \frac{1}{2}\delta^{\lambda}_{\nu}g^{\rho\sigma}\Gamma^{\alpha}_{\beta\rho}\Gamma^{\beta}_{\alpha\sigma} = 0,$$

obtained by doing the variations *before* setting $\sqrt{-g} = 1$ (see footnote 179), then eq. (A.13) gets replaced by $(\Gamma^{\lambda\alpha}_{\mu})_{,\alpha} + \kappa t^{\lambda}_{\mu} = 0$ which has the exact same form as eq. (A.14) in the *Entwurf* theory.

182 In his first November paper, Einstein (1915a) chose field equations in the presence of matter that set the left-hand side of eq. (A.13) equal to $-\kappa T^{\lambda}_{\mu}$. In the fourth November paper, Einstein (1915d) replaced the right-hand side by $-\kappa(T^{\lambda}_{\mu} - (1/2)\delta^{\lambda}_{\mu}T)$.

$$(\Gamma^{\lambda\alpha}_{\mu})_{,\alpha} = -\kappa\Big([t^{\lambda}_{\mu} + T^{\lambda}_{\mu}] - \frac{1}{2}\delta^{\lambda}_{\mu}[t + T]\Big). \tag{A.16}$$

These are the proper field equations for the successor theory to the *Entwurf* theory.

Eq. (A.15) guarantees energy-momentum conservation, $(\tilde{t}^{\lambda}_{\mu} + T^{\lambda}_{\mu})_{,\lambda} = 0$, in the *Entwurf* theory, if—in addition to $\sqrt{-g} = 1$ —the condition

$$\tilde{B}_{\mu} \equiv (\tilde{\Gamma}^{\lambda\alpha}_{\mu})_{,\alpha\lambda} = 0 \tag{A.17}$$

holds (cf. eq. (50)).

Eq. (A.16) guarantees energy-momentum conservation, $(t^{\lambda}_{\mu} + T^{\lambda}_{\mu})_{,\lambda} = 0$, in the new theory if—in addition to $\sqrt{-g} = 1$ —the condition

$$\Big[(\Gamma^{\lambda\alpha}_{\mu})_{,\alpha} - \frac{1}{2}\delta^{\lambda}_{\mu}\kappa(t + T)\Big]_{,\lambda} = 0 \tag{A.18}$$

holds. Contracting eq. (A.16), one finds that

$$(\Gamma^{\rho\alpha}_{\rho})_{,\alpha} = \kappa(t + T)$$

(see eq. (104)). Using this equation to eliminate T from eq. (A.18), one arrives at the condition $B_{\mu} = 0$ in the new theory

$$B_{\mu} \equiv \Big[\Gamma^{\lambda\alpha}_{\mu} - \frac{1}{2}\delta^{\lambda}_{\mu}\Gamma^{\rho\alpha}_{\rho}\Big]_{,\alpha\lambda} = 0 \tag{A.19}$$

(see eq. (105)). Eq. (A.19), it turns out, is an identity (see eq. (105) and footnotes 123–124). Eq. (A.17) in the *Entwurf* theory imposes a coordinate restriction over and above unimodularity. Eq. (A.19), its counterpart in the new theory, imposes no additional restriction.

The gravitational part of the field equations (A.16), i.e., the left-hand side of eq. (A.13), is nothing but an alternative expression for the November tensor $\Gamma^{\alpha}_{\mu\nu,\alpha} + \Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\alpha\nu}$ (see eq. (67)), which itself is nothing but the Ricci tensor in unimodular coordinates (see eqs. (82)–(83)). It follows that the field equations (A.16) are (the mixed form of) the generally-covariant Einstein field equations,

$$R_{\mu\nu} = -\kappa\Big(T_{\mu\nu} - \frac{1}{2}g_{\mu\nu}T\Big), \tag{A.20}$$

in unimodular coordinates (where $R_{\mu\nu}$ is the Ricci tensor). Eq. (A.19) gives the contracted Bianchi identities in unimodular coordinates.

The generally-covariant form of the Einstein field equations can be derived from the action principle, $\delta\int\sqrt{-g}R\,d\tau = 0$, where R is the Riemann curvature scalar. All terms involving second-order derivatives of the metric can be eliminated from the action through partial integration. One then arrives at an action of the form

$$\int \mathfrak{G}^{*} d\tau, \tag{A.21}$$

where

$$\mathfrak{G}^* \equiv \sqrt{-g}\,g^{\mu\nu}\left[\begin{Bmatrix}\beta\\ \mu\alpha\end{Bmatrix}\begin{Bmatrix}\alpha\\ \nu\beta\end{Bmatrix} - \begin{Bmatrix}\alpha\\ \mu\nu\end{Bmatrix}\begin{Bmatrix}\beta\\ \alpha\beta\end{Bmatrix}\right]. \tag{A.22}$$

In unimodular coordinates $\mathfrak{G}^*$ reduces to

$$\mathfrak{G}^*(\sqrt{-g} = 1) = g^{\mu\nu}\begin{Bmatrix}\beta\\ \mu\alpha\end{Bmatrix}\begin{Bmatrix}\alpha\\ \nu\beta\end{Bmatrix}. \tag{A.23}$$

This is just the Lagrangian given in eq. (A.1) with the gravitational field defined as minus the Christoffel symbols (see eq. (A.2)).[183]

ACKNOWLEDGMENTS

This paper grew out of joint work with John Norton, Tilman Sauer, and John Stachel. All along, we have had John Norton's seminal paper, "How did Einstein find his field equations?" (Norton 1984), in the cross hairs. Our deepest gratitude is therefore to John Norton for providing us with such a worthy target. We are also indebted to John Stachel for alerting us to the non-commutativity of (partial) gauge fixing and (unconstrained) variation of the action and to Serge Rudaz for further discussion of this issue. We thank Katherine Brading, David Rowe, and Tilman Sauer for discussion of (the history of) Noether's theorems and Dan Kennefick for discussion of the gravitational energy-momentum pseudo-tensor. For additional comments and stimulating discussion, we thank Paul Brinkman, Peter Damerow, Jeroen van Dongen, Tony Duncan, Joska Illy, Martin J. Klein, A. J. Kox, Christoph Lehner, Matthias Schemmel, Robert Schulmann, Bernard Schutz, and Bill Unruh. Part of this paper was written at the *Max-Planck-Institut für Gravitationsphysik* (*Albert Einstein Institut*) in Golm outside Berlin; another part at the Outing Lodge near Stillwater, Minnesota. We thank Bernard Schutz (*Albert Einstein Institut*) and Lee Gohlike (Outing Lodge) for their hospitality and support. Swetlana Freifrau von dem Bottlenberg-Minkow could have hosted us at *Gut Schloß Golm* but chose not to. Finally, we want to thank our families—Fiorenza, Suzy, Leonardo, Eleonora, and Luc—for putting up with the vicissitudes of our transatlantic cooperation.

183 This once again illustrates that 'doing the variations' does not commute with 'choosing unimodular coordinates' (cf. footnotes 83 and 179). The Lagrangian (A.23)—i.e., setting $\sqrt{-g} = 1$ first—leads to Euler-Lagrange equations that set the Ricci tensor, $R_{\mu\nu}$, in unimodular coordinates equal to zero. The Lagrangian (A.22)—i.e., doing the variations first—leads to Euler-Lagrange equations that set the Einstein tensor, $R_{\mu\nu} - (1/2)g_{\mu\nu}R$, equal to zero.

GRAVITATION IN THE TWILIGHT OF CLASSICAL PHYSICS: AN INTRODUCTION

AIM AND STRUCTURE OF THIS BOOK

More than is the case for any other theory of modern physics, general relativity is usually seen as the work of one man, Albert Einstein. In taking this point of view, however, one tends to overlook the fact that gravitation has been the subject of controversial discussion since the time of Newton. That Newton's theory of gravitation assumes action at a distance, i.e., action without an intervening mechanism or medium, was perceived from its earliest days as being problematical. Around the turn of the last century, in the twilight of classical physics, the problems of Newtonian gravitation theory had become more acute. Consequently, there was a proliferation of alternative theories of gravitation which were quickly forgotten after the triumph of general relativity. In order to understand this triumph, it is necessary to compare general relativity to its contemporary competitors. As we shall see, general relativity owes much to this competition. A historical analysis of the struggle between alternative theories of gravitation and the different approaches to the problem of gravitation thus complements the analysis of Einstein's efforts. An account of the genesis of general relativity that does not discuss these competitors remains incomplete and biased. At the same time, this wider perspective on the emergence of general relativity provides an exemplary case of alternatives in the history of science, presenting a whole array of alternative theories of gravitation and the eventual emergence of a clear winner. It is thus an ideal topic for addressing long-standing questions in the philosophy of science on the basis of detailed historical evidence.

The present book, comprising volumes 3 and 4 of the series, discusses alternative theories of gravitation that were relevant to the genesis of general relativity and thus constitute its immediate scientific context. Many of these theories figured in the discussions of Einstein and his contemporaries. The set of theories covered here is not complete as far as gravitation theories in the late nineteenth and early twentieth centuries are concerned. But even a comprehensive treatment of this narrower set of theories represents a considerable challenge for the history of science. Unlike Einstein's work, many of the theories dealt with here are known only to a few specialists. This situation has only just begun to improve through recent work on the genesis of general relativity and much remains to be done in the future.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

What is presented in these volumes are two types of texts, sources and interpretations. The sources are key documents relevant to the history of general relativity. Many of these texts were originally written in German and are presented here for the first time in English translation. The interpretative texts are essays, most of them specially written for these volumes. They provide historical context and analysis of the theories presented in the sources. The book is divided into sections reflecting a classification of approaches to the problem of gravitation. Different subdisciplines of classical physics generated different ways of approaching the problem of gravitation. The emergence of special relativity further raised the number of possible approaches while creating new requirements that all approaches had to come to terms with. Each section of this book is dedicated to one of these approaches and, as a rule, consists of an historical essay and several sources.

THE UNFOLDING OF ALTERNATIVE THEORIES OF GRAVITATION

From the perspective of an epistemologically oriented history of science, the unfolding of alternative theories of gravitation in the twilight of classical physics can be interpreted as the realization of the potential embodied in the knowledge system of classical physics to address the problem of gravitation, this knowledge system eventually being transformed by the special-relativistic revolution. The dynamics of this unfolding was largely governed by internal tensions of the knowledge system rather than by new empirical knowledge, which at best played only a minor role. A central problem of the Newtonian theory of gravitation was, as already mentioned, that it assumed the action between two attracting bodies to be instantaneous and that it did not provide any explanation for the instantaneous transport of action along arbitrary distances. This characteristic feature of the gravitational force, called action at a distance, became even more dubious after the mid-nineteenth century when it was recognized that electromagnetic forces did not comply with the idea of action at a distance. This internal tension of the knowledge system of classical physics was intensified, but not created, by the advent of the theory of special relativity, according to which the notion of an instantaneous distance between two bodies as it appears in Newton's force law can no longer be accepted.

The attempts to resolve these kinds of tensions typically crystallized around mental models representing the gravitational interaction on the basis of other familiar physical processes and phenomena. A mental model is conceived here as an internal knowledge representation structure serving to simulate or anticipate the behavior of objects or processes, like imagining electricity as a fluid. Mental models are flexible structures of thinking that are suitable for grasping situations about which no complete information is available. They do so by relying on default assumptions that result from prior experiences and can be changed if additional knowledge becomes available without having to give up the model itself.

Thus, in what may be called the *gas model*, gravitation could be conceived as resulting from pressure differences in a gaseous aether. Or, in what may be called the *umbrella model*, the attraction of two bodies could be imagined to result from the mutual shielding of the two bodies immersed in an aether whose particles rush in random directions and, in collisions with matter atoms, push them in the direction of the particles' motions. Or one could think of gravitation in analogy to the successful description of electromagnetism by the *Lorentz model*, accepting a dichotomy of gravitational field on the one hand and charged particles—masses—that act as sources of the field on the other. The elaboration of these approaches, with the help of mathematical formalism, led typically to a further proliferation of alternative approaches and, at the same time, provided the tools to explore these alternatives to a depth that allowed new tensions to be revealed. The history of these alternative approaches can thus be read, in a way similar to Einstein's work, as an interaction between the physical meaning embodied in various models and the mathematical formalism used to articulate them.

THE POTENTIAL OF CLASSICAL PHYSICS

The history of treatments of gravitation in the nineteenth century reflects the transition from an era in which mechanics constituted the undisputed fundamental discipline of physics to an era in which mechanics became a subdiscipline alongside electrodynamics and thermodynamics.

From the time of its inception, the action-at-a-distance conception of Newtonian gravitation theory was alien to the rest of mechanics, according to which interaction always involved contact. This explains the early occurrence of attempts to interpret the gravitational force by means of collisions, for instance, by invoking the umbrella model described above. During these early days the comparison of the gravitational force to electric and magnetic forces had already been suggested as well. However, the analogy with electricity and magnetism became viable only after theories on these subjects had been sufficiently elaborated. There were even attempts at thermal theories of gravitation after thermodynamics had developed into an independent subdiscipline of physics. Besides providing new foundational resources for approaching the problem of gravitation, the establishment of independent subdisciplines and the questioning of the primacy of mechanics that resulted from it affected the development of the theoretical treatment of gravitation in yet another way, namely through the emergence of revisionist formulations of mechanics. This *heretical mechanics*, as we shall call it, consisted in attempts to revise the traditional formulation given to mechanics by Newton, Euler and others, and often amounted to questioning its very foundations.

Approaches to the problem of gravitation in the context of these developments of classical physics are covered by the first and last sections of the first volume of this book, *The Gravitational Force between Mechanics and Electrodynamics*, and *From Heretical Mechanics to a New Theory of Relativity.* Further stimuli for rethinking gravitation came from the development of astronomy and mathematics. This approach is addressed by the second section, *An Astronomical Road to a New Theory of Gravitation*.

The Mechanization of Gravitation

Before the advent of the special theory of relativity, the validity of Newton's law of gravitation was essentially undisputed in mainstream physics. Alternative laws of gravitation were, of course, conceivable but Newton's law proved to be valid to a high degree of precision. While the minute discrepancies between the observed celestial motions and those predicted by Newtonian theory, most prominently the advance of Mercury's perihelion, could be resolved by one of these alternatives, they could also be resolved by adjusting lower-level hypotheses such as those regarding the distribution of matter in the solar system. In any case, the empirical knowledge at that time did not force a revision of Newtonian gravitation theory. The more pressing problem of this theory was that it did not provide a convincing model for the propagation of the gravitational force.

The most elaborate theories to address this problem made use of the umbrella model. These theories start from the idea of an impact of aether particles on matter, as formulated by Le Sage in the late eighteenth century. The gravitational aether is imagined to consist of particles that move randomly in all directions. Whenever such an aether atom hits a material body it pushes the body in the direction of its movement. A single body remains at rest since the net impact of aether particles from all sides adds up to zero. However, if two bodies are present, they partly shield each other from the stream of aether particles. As a result, the impact of aether particles on their far sides outweighs that on their near sides and the two bodies are driven towards each other.

Caspar Isenkrahe, Sir William Thomson (Lord Kelvin), and others developed different theories based on this idea in the late nineteenth century. But regardless of the details, this approach suffers from a fundamental problem related to the empirical knowledge about the proportionality of the force of gravity with mass. In order to take this into account one needs to allow the aether particles to penetrate a material body in such a way that they can interact equally with all of its parts. This requirement is better fulfilled the more transparent matter is to the aether particles. But, the more transparent matter is, the less shielding it provides from the aether particles on which the very mechanism for explaining gravity is based. Hence, without shielding there is no gravitational effect; without penetration there is no proportionality of the gravitational effect to the total mass. Furthermore, in theories explaining gravitation by the mechanical action of a medium, the problem of heat exchange between the medium and ordinary matter arises (in analogy to electromagnetic heat radiation), in most approaches leading to an extreme heating of matter.

From a broader perspective, such attempts at providing a mechanical explanation of gravity had lost their appeal by the end of the nineteenth century after the successful establishment of branches of physics that could not be reduced to mechanics, such as Maxwell's electrodynamics and Clausius' thermodynamics. Nevertheless, this development led indirectly to a contribution of the mechanical tradition to solving the problem of gravitation by provoking the emergence of revised formulations of mechanics, referred to here as heretical mechanics.

Heretical Mechanics

A critical revision of mechanics, pursued in different ways by Carl Neumann, Ludwig Lange, and Ernst Mach among others, had raised the question of the definition and origin of inertial systems and inertial forces, as well as their possible relations to the distribution of masses in the universe. Through the latter issue, this revision of mechanics was also important for the problem of gravitation. It also gave rise to attempts at formulating mechanics in purely relational terms, that is, exclusively in terms of the mutual distances of the particles and derivatives of these distances. Such attempts are documented, for instance, in the texts presented in this book of Immanuel and Benedict Friedlaender and of August Föppl. As becomes clear from these texts, heretical mechanics contributed to understanding the relation between gravitational and inertial forces as both are due to the interaction of masses. According to Föppl there must be velocity-dependent forces between masses although he did not think of these forces as being gravitational. The Friedlaender brothers also conceived of inertia as resulting from an interaction between masses and did speculate on its possible relation to gravitation. In spite of such promising hints, heretical mechanics remained marginal within classical physics, in part because it lacked a framework with which one could explore the relation between gravitation and inertia. This relation was established by Einstein within the framework of field theory, first in 1907 through his principle of equivalence, and more fully with the formulation of general relativity.

Einstein's successful heuristic use of Machian ideas in his relativistic theory of gravitation encouraged the mechanical tradition to continue working toward a purely relational mechanics in the spirit of Mach. Attempts in this direction were made by Hans Reissner, Erwin Schrödinger, and, more recently, Julian Barbour and Bruno Bertotti. The success of general relativity provided a touchstone for the viability of these endeavors. At the same time, the question to which extent the issues raised by heretical mechanics, such as a relational understanding of inertia, have been settled by general relativity is still being discussed today.

From Peripheral Mathematics to a New Theory of Gravitation

The success or failure of a physical idea hinges to a large extent on the mathematical tools available for expressing it. In view of the crucial role of the mathematical concept of affine connection at a later state in the development of the general theory of relativity, it is interesting to consider the impact this tool might have had on the formulation of physical theories had it been part of mathematics by the latter half of the nineteenth century. That this counter-factual assumption is actually not that far-fetched can be seen from the work of Hermann Grassmann, Heinrich Hertz, Tullio Levi-Civita, and Elie Cartan, in part reproduced in this book. Such a fictive development might have given rise to a kind of heretical gravitation theory driven by peripheral mathematics and formulated by some "Newstein" long before the advent of special relativity. Perhaps the search for a different conceptualization of mechanics in which gravitation and inertia are treated alike, as is the case according to Einstein's equivalence principle, could have provided a physical motivation for such an alternative formulation of classical mechanics with the help of affine connections. Perhaps Heinrich Hertz's attempt to exclude forces from mechanics, replacing them by geometrical constraints, might have served as a starting point for such a development, triggering a geometrization of physics, had it not been so marginal to the mainstream of late nineteenth-century physics.

As with ordinary classical mechanics, Newstein's theory would have eventually conflicted with the tradition of electrodynamics and its implication of a finite propagation speed for physical interactions, which ultimately leads to the metrical structure of special relativity with its constraints on physical interactions. Then the problem that arose from this conflict could be—in contrast to the actual course of history—formulated directly in terms of the compatibility of two well-defined mathematical structures, the affine connection expressing the equality in essence of gravitation and inertia, and the metric tensor expressing the causal structure of spacetime. This formulation of the problem would have smoothed the pathway to general relativity considerably since the heretical aspect of Einstein's work—the incorporation of the equality in essence of gravitation and inertia—would have already been implemented in Newstein's predecessor theory. General relativity might thus have been the outcome of mainstream research.

The Potential of Astronomy

Another field of classical science that might have contributed more than it actually did to the emergence of general relativity is astronomy. This is made evident by the sporadic interventions by astronomers such as Hugo von Seeliger, who questioned the seemingly self-evident foundations of the understanding of the universe in classical science. Their work was stimulated by new mathematical developments such as the emergence of non-Euclidean geometries or by heretical mechanics insofar as it raised questions relevant to astronomy, for instance, concerning the definition of inertial systems. It was further stimulated by the recognition of astronomical deviations from the predictions of Newton's law (such as the perihelion advance of Mercury), or by the paradoxes resulting from applying classical physics to the universe-at-large when this is assumed to be infinite (such as the lack of definiteness in the expression of the gravitational force, or Olbers' paradox of the failure of the night sky to be as bright as the Sun).

Although the full extent to which these problems were connected became clear only after the establishment of general relativity, the astronomer Karl Schwarzschild, who was exceptional in his interdisciplinary outlook, addressed many of them and was even able to relate them to one another. He explored, for instance, the cosmological implications of non-Euclidean geometry and considered the possibility of an anisotropic large-scale structure of the universe in which interial frames can only be defined locally. With less entrenched disciplinary boundaries of late nineteenth-century classical science, such considerations could have had wider repercussions on the foundations of physics, perhaps giving rise to the emergence of a non-classical cosmology.

A Thermodynamic Analogy

In rejecting the assumption of an instantaneous propagation of gravitational interactions, it makes sense to modify classical gravitation theory by drawing upon analogies with other physical processes that have a finite propagation speed, such as the propagation of electromagnetic effects or the transport of heat in matter. Such analogies obviously come with additional conceptual baggage. A gravitational theory built according to the model of electrodynamic field theory, for instance, was confronted with the question of whether the gravitational analogue of electromagnetic waves really exist, or the question of why there is only one kind of charge (gravitational mass) in gravitation theory as opposed to two in electromagnetism (positive and negative charge). To avoid such complications, one could also consider amending Newtonian theory by extending the classical Poisson equation for the gravitational potential into a diffusion equation by adding a term with a first-order time derivative term, exploiting the analogy with heat transport in thermodynamics. In 1911, such a theory was proposed by Gustav Jaumann without, however, taking into account the spacetime framework of special relativity. As a consequence, it had little impact.

Electromagnetism as a Paradigm for Gravitation

Since early modern times magnetism served as a model for action at a distance as it apparently occurs between the constituents of the solar system. However, as long as there was no mathematical formulation describing magnetic forces, no quantitative description of gravitation could be obtained from this analogy. After Newton had established a quantitative description of gravitation, this could now conversely be used as a model for describing magnetic and electric forces, as realized in the laws of Coulomb, Ampère, and Biot-Savart. With the further development of electromagnetic theory as represented by velocity-dependent force laws and Maxwellian field theory, it regained its paradigmatic potential for understanding gravitation. After the striking success of Einstein's field theory of gravitation, which describes the gravitational force in terms of the geometry of spacetime, gravitation took the lead again as attempts were made that aimed at a geometrical description of electromagnetism and the other fundamental interactions with a view toward the unification of all natural forces. Such attempts are still being made today.

The motive of unification also underlay nineteenth-century attempts to reduce gravitation to electricity, such as those of Ottaviano Fabrizio Mossotti and Karl Friedrich Zöllner, who interpreted gravity as a residual effect of electric forces. They assumed that the attractive electric force slightly outweighs the repulsive one, resulting in a universal attraction of all masses built up from charged particles. Ultimately, however, this interpretation amounts to little more than the statement that there is a close analogy between the fundamental force laws of electrostatics and Newtonian gravitation.

The paradigmatic role of electromagnetism for gravitation theory was boosted dramatically when electrodynamics emerged as the first field theory of physics. A field-theoretic reformulation of Newtonian gravity modelled on electrostatics was provided by the Poisson equation for the Newtonian gravitational potential. Even though the Poisson equation was merely a mathematical reformulation of Newton's law, it had profound implications for the physical interpretation of gravitation and introduced new possibilities for the modification of Newtonian gravitation theory. The analogy with electromagnetism raised the question of whether gravitational effects propagate with a finite speed like electromagnetic effects. A finite speed of propagation further suggested the existence of velocity-dependent forces among gravitating bodies, amounting to a gravitational analogue to magnetic forces. It also suggested the possibility of gravitational waves. In short, a field theory of gravitation opened up a whole new world of phenomena that might or might not be realized in nature.

The uncertainty of the existence of such phenomena was in any case not the most severe problem that a field theory of gravitation was confronted with. If gravitation is conceived of as a field with energy content, the fact that like "charges" always attract has a number of problematic consequences. First and foremost, ascribing energy to the gravitational field itself leads to a dilemma that does not occur in the electromagnetic case. In the latter case, the work performed by two attracting charges as they approach each other can be understood to be extracted from the field, and the field energy disappears when they meet at one point. In contrast, while work can also be performed by two approaching gravitating masses, the field energy is enhanced, rather than diminished, as they come together at one point. (Accordingly no equivalent of a black hole is known in electrodynamics.) As Gustav Mie explains in his paper on the gravitational potential presented in this book, the gravitational field is peculiar in that it becomes stronger when work is released. While a similar effect occurs with the magnetic field of two current-bearing conductors, the source of the energy is obvious in this case. The energy comes from an external energy supply such as a battery. Such an external supply is missing in the case of gravitation. A plausible escape strategy was to assume that the energy of the gravitational field is negative so that, when the field becomes stronger, positive energy is released, which can be exploited as work. For the plausible option of formulating a theory of gravitation in strict analogy to electrodynamics by simply postulating Maxwell's equations with appropriately changed signs for the gravitational field, this negative energy assumption has dramatic consequences when considering dynamic gravitational fields. A minute deviation of a gravitating system from equilibrium will cause the field to release more and more energy, while the system deviates further and further from its original state of equilibrium. In fact, due to the reversed sign, gravitational induction, if conceived in analogy to electromagnetic induction, becomes a self-accelerating process. This will be referred to here as the *negative energy problem*.

Despite this problem, Hendrik Antoon Lorentz took up the thread of Mossotti and others and proposed to treat gravitation as a residual force resulting from electromagnetism. While the electromagnetic approach to gravitation offered, in principle, the possibility to account for observed deviations from Newtonian gravitation theory, the field theories actually elaborated by Lorentz and others failed to yield the correct value for the perihelion advance of Mercury, a commonly used touchstone.

All in all, the analogy of gravitation with electromagnetism, promising as it must have appeared, could not be as complete as advocated by its proponents. The considerable potential of the tradition of field theory for formulating a new theory of gravitation still needed to be explored and the key to disclosing its riches had yet to be discovered.

The attempts to subsume gravitation under the familiar framework of electromagnetism were later followed by approaches that aimed at a unification of physics on a more fundamental level, still focusing, however, on gravitation and electromagnetism. The most prominent attempts along these lines, contemporary to the genesis of general relativity, were those of Gustav Mie and David Hilbert. Their works are covered in the sections *From an Electromagnetic Theory of Matter to a New Theory of Gravitation* and *Including Gravitation in a Unified Theory of Physics*. These attempts, however, only led to a formal integration of the two forces without offering any new insights into the nature of gravity.

The key to successfully exploiting the resources of field theory for a new theory of gravitation was only found when the challenge of formulating a gravitational field theory was combined with insights from heretical mechanics. Instead of attempting a formal unification of two physical laws, Einstein combined the field theoretic approach with the idea of an equality in essence of gravitation and inertia, and eventually achieved an integration of two knowledge traditions hitherto separated due to the high degree of specialization of nineteenth-century physics.

THE CHALLENGE OF SPECIAL RELATIVITY FOR GRAVITATION

The advent of special relativity in 1905 made the need for a revision of Newtonian gravitation theory more urgent since an instantaneous propagation of gravitation was incompatible with the new spacetime framework in which no physical effect can propagate faster than the speed of light. A revision of this kind could be achieved in various ways. One could formulate an action-at-a-distance law involving a finite time of propagation as had been developed in electromagnetism, e.g. by Wilhelm Weber. Or one could formulate a genuine field theory of gravitation. The four-dimensional formulation of special relativity emerging from the work of Henri Poincaré, Hermann Minkowski, and Arnold Sommerfeld brought about a set of clearly distinguished alternative approaches for realizing such a field theory of gravitation. Eventually, however, due to the implications of special relativity not only for the kinematic concepts of space and time but also for the dynamic concept of mass, gravitation was bursting out of the framework of special relativity.

A New Law of Gravitation Enforced by Special Relativity

The simplest way to make gravitation theory consistent with special relativity was to formulate a new direct particle interaction law of gravitation in accordance with the conditions imposed by special relativity, e.g., that the speed of propagation of the gravitational force be limited by the speed of light. This kind of approach, which was pursued by Poincaré in 1906 and by Minkowski in 1909, and which is presented here in the section *A New Law of Gravitation Enforced by Special Relativity*, could rely on the earlier attempts to introduce laws of gravitation with a finite speed of propagation. However, the stricter condition of Lorentz invariance now had to be satisfied.

While the formulation of a relativistic law of gravitation could solve the particular problem of consolidating gravitation theory with the new theory of special relativity, it disregarded older concerns about Newtonian gravitation, such as those relating to action at a distance. Furthermore, questions concerning fundamental principles of physics such as that of the equality of action and reaction emerged in these formulations. It remained, in any case, unclear to which extent the modified laws of gravitation could be integrated into the larger body of physical knowledge.

Towards a Field Theory of Gravitation

More important and more ambitious than the attempts at a new direct-particle interaction law of gravitation was the program of formulating a new field theory of gravitation. As pointed out above, if gravitation—in analogy to electromagnetism—is transmitted by a field with energy content, the fact that in the gravitational case like "charges" (masses) attract has problematic consequences, such as the negative energy problem. A promising approach to the negative energy problem was the assumption that masses also have energy content defined in such a way that the energy content of two attracting masses decreases when the masses approach each other. This effect can in turn be ascribed to a direct contribution of the gravitational potential to the energy content of the masses. Hence, there is a way to infer a relation between mass and energy content by considering the negative energy problem of a gravitational field theory.

The above considerations on the negative energy problem of gravitational field theory suggest that the potential plays a greater role in such a theory than it does in classical electromagnetic field theory. How to represent the gravitational potential is further directly connected with the question of how to represent the gravitational mass, or, more generally, the source of the gravitational field, since both are related through the field equation. The following three mathematical types of potentials were considered before the establishment of general relativity with the corresponding implications on the field strengths and the sources.

- *Scalar theories*. Potential and source are Lorentz scalars and the field strength is a (Lorentz) four-vector.
- *Vector theories*. Potential and source are four-vectors and the field is what was then called a "six-vector" (an antisymmetric second-rank tensor).
- *Tensor theories*. Potential and source are symmetric second-rank tensors and the field is represented by some combination of derivatives of the potential.

From what has been said above about a theory of gravitation construed in analogy with electrodynamics, the problems of a vector theory become apparent. In contrast to the electromagnetic case, where the charge density is one component of the four-current, the gravitational mass density is not one component of a four-vector. From this it follows in particular that no expression involving the mass is available to solve the negative energy problem by forming a scalar product of source and potential in order to adjust the energy expression.

Having thus ruled out vector theories, only scalar theories and tensor theories remain. Einstein's theories, in particular the *Entwurf* theory and his final theory of general relativity, belong to the latter class. Further alternative tensor theories of gravitation were proposed, but only after the success of general relativity, which is why they are not discussed here. As concerns scalar theories, a further branching of alternatives occurs as shall be explained in the following.

Every attempt to embed the classical theory of gravitation into the framework of special relativity had to cope not only with its kinematic implications, that is, the new spacetime structure which required physical laws be formulated in a Lorentz covariant manner, but also with its dynamical implications, in particular, the equivalence of energy and mass expressed by the formula $E = mc^2$. Since, in a gravitational field, the energy of a particle depends on the value of the gravitational potential at the position of the particle, the equivalence of energy and mass suggests that either the particle's mass or the speed of light (or both) must also be a function of the potential. Choosing the speed of light as a function of the potential immediately exits the framework of special relativity, which demands a constant speed of light. It thus may seem that choosing the inertial mass to vary with the gravitational potential is preferable since it allows one to stay within that framework.

According to contemporary evidence and later recollections, Einstein in 1907 explored both possibilities, a variable speed of light and a variable mass. He quickly came to the conclusion that the attempt to treat gravitation within the framework of special relativity leads to the violation of a fundamental tenet of classical physics, which may be called *Galileo's principle*. It states that in a gravitational field all bodies fall with the same acceleration and that hence two bodies dropped from the same height with the same initial vertical velocity reach the ground simultaneously. The latter formulation generalizes easily to special relativity. If the inertial mass increases with the energy content of a physical system, as is implied by special relativity, a body with a horizontal component of motion will have a greater inertial mass than the same body without such a motion, and hence fall more slowly than the latter.

The same conclusion can be drawn by purely kinematic reasoning in the framework of special relativity. Consider two observers, one at rest, the other in uniform horizontal motion. When the two observers meet, they both drop identical bodies and watch them fall to the ground. From the viewpoint of the stationary observer, the body he has dropped will fall vertically, while the body the moving observer has dropped will fall along a parabolic trajectory. From the viewpoint of the moving observer, the roles of the two bodies are interchanged: the first body will fall along a parabolic trajectory while the second will fall vertically.

If one now assumes that, in the reference frame of the stationary observer, the bodies will touch the ground simultaneously, as is required by Galileo's principle in the above formulation, the same cannot hold true in the moving system due to the relativity of simultaneity. In other words, Galileo's principle cannot hold for both observers. Thus, the assumption of Galileo's principle leads to a violation of the principle of relativity. On the other hand, if one assumes, in accordance with the principle of relativity, that the two observers both measure the same time of fall for the body falling vertically in their respective frame of reference, the time needed for the body to fall along a parabolic path can be determined from this time by taking time dilation into account. It thus follows that the time needed for the fall along a parabolic path is longer than the time needed for the vertical fall, in accordance with the conclusion drawn from the dynamical assumption of a growth of inertial mass with energy content.

Both of the possibilities considered by Einstein, a dependence on the gravitational potential either of the speed of light or of the inertial mass, were later explored by Max Abraham and Gunnar Nordström respectively. These theories, which represented the main competitors of Einstein's theories of gravitation, are discussed in the sections *The Problem of Gravitation as a Challenge for the Minkowski Formalism* and *A Field Theory of Gravitation in the Framework of Special Relativity*, to which the remainder of this introduction is devoted.

The Problem of Gravitation as a Challenge for the Minkowski Formalism

The assumption of a dependence of the speed of light on the gravitational potential made it necessary to generalize the Minkowski formalism, although the full consequences of this generalization became clear only gradually. It was Max Abraham who took the first steps in this direction by implementing Einstein's 1907 suggestion of a variable speed of light related to the gravitational potential within this formalism. Questioned by Einstein about the consistency of the modified formalism with

Minkowski's framework, he introduced the variable line element of a non-flat four-dimensional geometry.

Abraham's theory stimulated Einstein in 1912 to resume work on a theory of gravitation. Apart from developing his own theory, Abraham also made perceptive observations on alternative options for developing a relativistic theory of gravity, on internal difficulties as well as on physical and astronomical consequences such as energy conservation in radioactive decay or the stability of the solar system.

A Field Theory of Gravitation in the Framework of Special Relativity?

While Abraham explored the implications of a variable speed of light, Nordström pursued the alternative option of a variable mass. Nordström thus remained within the kinematic framework of special relativity. As in all such approaches, however, he did so at the price of violating to some extent Galileo's principle.

More importantly, Nordström also faced the problem that in a special relativistic theory of gravitation the dynamical implications of special relativity need to be taken into account as well. These dynamical consequences suggested, for example, ascribing to energy not only an inertial but also a gravitational mass, which immediately implies that light rays are curved in a gravitational field. This conclusion, however, is incompatible with special relativistic electrodynamics in which the speed of light is constant.

Another implication of the dynamic aspects of special relativity concerns the source of the gravitational field. If any quantity other than the energy-momentum tensor of matter is chosen as a source-term in the gravitational field equation, as is the case in all scalar theories including Nordström's, gravitational mass cannot be fully equivalent to inertial mass, whose role has been taken in special relativistic physics by the energy-momentum tensor. However, while such conceptual considerations cast doubt on the viability of special relativistic theories of gravitation, they were not insurmountable hurdles for such theories. In fact, Nordström's final version of his theory remained physically viable as long as no counter-evidence was known. Einstein's successful calculation of Mercury's perihelion advance on the basis of general relativity in late 1915 undermined Nordström's theory, which did not yield the correct value. This, however, did not constitute a fatal blow as long as other astrophysical explanations of Mercury's anomalous motion remained conceivable. The fatal blow only came when the bending of light in a gravitational field was observed in 1919. Nordström's theory did not predict such an effect. For the final version of his theory this can easily be seen by observing that the trace of the energy-momentum tensor, which acts as the source of the gravitational field in that theory, vanishes for electromagnetic fields. Another way of seeing this makes use of the work of Einstein and Adriaan Fokker, who showed that Nordström's theory can be viewed as a special case of a metric theory of gravitation with the additional condition that the speed of light is a constant, thus excluding a dispersion of light waves that gives rise to the bending of light rays.

Before Nordström's theory matured to its final version, which constitutes a fairly satisfactory special relativistic theory of gravitation, several steps were necessary in which the original idea was elaborated, in particular regarding the choice of an appropriate source expression. The most obvious choice and the first considered by Nordström is the rest mass density. The problem with this quantity is, however, that it is not a Lorentz scalar. Nordström's second choice was the Lagrangian of a particle. This, however, leads to a violation of the equality of gravitational and inertial mass. While according to special relativity, kinetic energy, (e.g. the thermal motion of the particles composing a body), adds to the body's inertial mass, it is subtracted from the potential energy in the Lagrangian. If that Lagrangian hence describes the gravitational mass, the difference between the two masses increases as more kinetic energy is involved. In his final theory Nordström chose, at Einstein's suggestion, the trace of the energy-momentum tensor, the Laue scalar, thus extending the validity of the equivalence principle from mass points at rest to "complete static systems." A complete static system is a system for which there exists a reference frame in which it is in static equilibrium. In such a frame, the mechanical behavior of the system is essentially determined by a single scalar quantity. In fact, since in special relativity the inertial behavior of matter is determined by the energy-momentum tensor, the requirement of equality of inertial and gravitational mass implies that a scalar responsible for the coupling of matter to the gravitational field must be derived from the energy-momentum tensor.

The problem in choosing the Laue-scalar as a source expression is how deal with the transport of stresses in a gravitational field while maintaining energy conservation. Einstein argued that such stresses may be used—unless appropriate provisions are taken—to construct a *perpetuum mobile*, since—by creating or removing stresses—one can, so to speak, apparently switch gravitational mass on and off. In other words, while the work required for creating a stress can simply be recovered by removing it, the gravitational mass created by the stress can meanwhile be used to perform work in the presence of a gravitational field. Given that stresses depend on the geometry of the falling object under consideration, a solution can be found by appropriately adjusting the geometry, as Nordström showed. In other words, the assumption that gravitational mass can be generated by stresses led, in conjunction with the requirement of energy-momentum conservation, to the conclusion that the geometry has to vary with the gravitational potential.

According to Einstein's assessment of Nordström's final theory in his Vienna lecture, the theory satisfies all one can require from a theory of gravitation based on contemporary knowledge, which did not yet include the observation of light deflection in a gravitational field. At that time no known gravitation theory was able to explain Mercury's perihelion advance. Einstein's only remaining objection concerned the fact that what he considered to be Mach's principle—the assumption that inertia is caused by the interaction of masses—appears not to be satisfied in Nordström's theory.

But as we have seen, because of the role of stresses for gravitational mass, Nordström had to assume that the behavior of rods and clocks also depends on the gravitational potential. Indeed, as becomes clear from the hindsight of general relativity, it is arguable whether his theory really fits the special relativistic framework, corresponding as it does to a spacetime theory that is only conformally flat, i.e., based on a metric that is flat besides a scalar factor. The way that Nordström's theory stands to general relativity in that it attributes transformations to material bodies, which in the later theory are understood as transformations of spacetime, is reminiscent of the way that Lorentz's theory of the aether stands to special relativity.

ACKNOWLEDGEMENTS

For their careful reading of this text, extensive discussions, and helpful commentaries, we would like to thank Michel Janssen, Domenico Giulini, Christopher Smeenk, and John Stachel. We would also like to thank Lindy Divarci, Christoph Lehner, Carmen Hammer, Miriam Gabriel, Yoonsuhn Chung, and Dieter Hoffmann for their considerable effort and stamina during the preparation of the index.

NOTES ON THE TRANSLATIONS

The translation of sources in these volumes, if not indicated otherwise, were produced through a collective effort. The majority of the texts were first translated by Dieter Brill. Werner Heinrich also contributed considerably to the initial translations. Other texts were translated by June Inderthal and Barbara Stepansky. The translations were further reworked by Dieter Brill, Lindy Divarci, Christopher Martin, Matthias Schemmel, and Christopher Smeenk. We would also like to thank Don Salisbury for helping us to improve the translation of Max Abraham's *Eine neue Gravitationstheorie* and Erhard Scholz for helping to improve the translation of Weyl's text.

For clarification of terminology, certain words are given in the original language. The occurrence of page breaks in the original texts are marked and page numbers are given in the margin.

SOURCES

The following list contains the literature referred to in this introduction. It further contains references to a selection of the numerous contributions to the understanding of gravitation that were published in the period between the end of the nineteenth century and the advent of general relativity, without claiming to be complete. Further references as well as historical commentaries on the development of gravitational theories are found, e.g., in N. T. Roseveare *Mercury's Perihelion from Le Verrier to Einstein* (Clarendon Press, 1982); Matthew R. Edward (ed.) *Pushing Gravity: New Perspectives on Le Sage's Theory of Gravitation* (Apeiron, 2002); G. J. Whitrow and G. E. THE GRAVITATIONAL FORCE BETWEEN MECHANICS AND ELECTRODYNAMICS

JÜRGEN RENN

THE THIRD WAY TO GENERAL RELATIVITY: EINSTEIN AND MACH IN CONTEXT

1. INTRODUCTION

The relationship between Einstein and Mach is often discussed as a prototypical case of the influence of philosophy on physics.[1] It is, on the other hand, notoriously difficult to accurately pinpoint such influences of philosophy on science, in particular with regard to modern physics. To a working scientist, such influences must seem to belong to a past era. There seems to be little room left for philosophy in the practice of today's physics. It plays virtually no part in the physics curriculum, and scholars who are both active physicists and philosophers are rare exceptions. In view of this situation it may be appropriate to reexamine the mythical role that philosophy played for one of the founding heroes of modern physics, Albert Einstein. It is conceivable that the disjointed remarks on philosophy that are dispersed throughout his œuvre can be integrated into a coherent image of what may then rightly be called "his philosophy." But even if such a reconstruction should be successful and yield more than an eclectic collection of occasional reflections, the more decisive question of the utility of philosophy for his science would be left unanswered. In fact, Einstein as a philosopher may have been a rather different *persona* from Einstein the physicist, and having two souls in one breast would not be an atypical state of affairs for a German intellectual. This contribution will therefore not undertake a systematic attempt at reconstructing his philosophy, but rather be limited to a case study of the interaction between philosophy and physics, reexamining the impact of Mach's philosophical critique of classical mechanics on Einstein's discovery of general relativity.[2] This reexamination is made possible by newly discovered documentary evidence concerning Einstein's research as well as by the achievements of recent studies in the history of general relativity.[3] Both factors contribute to an historical understanding of the

---

1 The literature on this subject is considerable; for more or less comprehensive accounts, see among others, (Blackmore 1992; Boniolo 1988; Borzeszkowski and Wahsner 1989, in particular, pp. 49–64; Goenner 1981; Hoefer 1994; Holton 1986, chap. 7; Norton 1993; Pais 1982, 282–288; Reichenbach 1958; Sciama 1959; Sewell 1975; Stein 1977; Torretti 1978, 1983, 194–202; Wolters 1987), as well as other literature quoted below. An earlier version of the present paper has been widely circulated in preprint form since 1994, an Italian version of this can be found in (Pisent and Renn 1994). Its themes have been taken up in various subsequent publications, see, e.g., (Barbour and Pfister 1995; CPAE 8).

2 For Mach's critique, see (Mach 1883: translated in Mach 1960).

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

relation between Mach's philosophy and Einstein's physics that is not only richer in detail, but also in context, and hence able to reveal the alternatives available to the historical actors in the search for a new theory of gravitation.

The main result of the analysis presented below is that the theory of general relativity can be seen to have emerged as the result of one among several possible strategies dealing with conceptual problems of classical physics, strategies which were worked out to different degrees in the course of the historical development. Since this development was, in other words, not completely determined by the intrinsic features of the scientific problems which the historical actors confronted, it is now possible to evaluate more clearly the external factors affecting the choice between different strategies.[4] The approach pursued by Einstein can be characterized as a combination of field theoretical and mechanistic approaches shaped by his philosophical outlook on foundational problems of physics. In the following, two conclusions are drawn in particular:

i) The heuristics under the guidance of which Einstein elaborated general relativity was rooted in the heterogeneous conceptual traditions of classical physics. At least in its intermediate stages of development, the conceptual framework of Einstein's theory resembled the peculiar combination of field theoretic and mechanistic elements in Lorentz's electron theory, rather than the coherent and self-contained conceptual framework of special relativity, which had superseded the conceptual patchwork of Lorentz's theory.[5] Mach's ideas were one element in this mixture of traditional conceptual frameworks; their interpretation by Einstein depended on the context provided by the other elements. In particular, the heuristic role of Mach's ideas has to be seen in the wider context of the role that classical mechanics played for the emergence of general relativity. As with the other heuristic elements, Mach's ideas were eventually superseded by the conceptual consequences of general relativity, as Einstein saw them. In particular, Mach's concept of inertia as a property not of space but of the interaction between physical masses played a role comparable to that of the aether in Lorentz's theory of electrodynamics: it introduced a helpful heuristics that led to its own elimination, since the conceptual preconditions of the development of general relativity turned out to be incompatible with its outcome.

ii) What distinguished Einstein's early approach to the problem of gravitation from that of his contemporaries was his refusal to accept that a mechanistic and a field theoretic outlook on physics were mutually exclusive alternatives. It was his philosophical perspective on foundational problems of physics that allowed him to conceive of field theory and mechanics as complementary resources for the formulation of a new theory of gravitation. Contrary to most contemporary physicists dealing

---

3 For new evidence, see in particular, the various volumes of *The Collected Papers of Albert Einstein*. For recent historical studies of the development of general relativity, see the contributions to vols. 1 and 2 of this series and the references given therein.

4 For a similar kind of argumentation, see (Freudenthal 1986).

5 See the extensive discussion in "Classical Physics in Disarray …" and "Pathways out of Classical Physics …" (both in vol. 1 of this series).

with the problem of gravitation, he attempted to incorporate in his new theory both foundational assumptions of classical mechanics and their critical revision by Mach; and contrary to most physicists searching for a physical implementation of Mach's analysis of the foundations of mechanics, he took into account the antimechanistic philosophical intentions of this critique. Einstein's philosophical perspective is, however, not only characterized by his interest in and understanding of such philosophical intentions, but even more by his integrative outlook on the conceptual foundations of physics. His peculiar approach to the specific problem of gravitation can only be understood if one acknowledges that for him the problem of a new theory of gravitation was simultaneously the problem of developing new conceptual foundations for the entire body of physics. Although it may not be common to label such an integrative perspective as "philosophical"—in view of the predominantly metatheoretical concerns of the philosophy of science—it was also no longer a self-evident preoccupation of science at the beginning of this century, let alone of science today. Nevertheless, the fruitfulness of Einstein's approach argues for its reconsideration by both philosophy and science.

In the following, it will first be discussed how Einstein's project of generalizing the principle of relativity emerged in the context of his own research as well as in that of other contemporary approaches to the problem of gravitation (section 2). Some of the historical presuppositions of the conceptual innovation represented by general relativity will then be examined, paying particular attention to the contributions of mechanics and field theory to its development. The aim is to describe the horizon of possibilities open to the historical actors (section 3).[6] Next, the influence of Mach's critique of classical mechanics on the creation and interpretation of general relativity by Einstein (section 4) will be traced in some detail. Finally, the question of Einstein's philosophical perspective on the foundational problems of physics and its role in the emergence of general relativity (section 5) will be addressed once again.

2. A NEW THEORY OF GRAVITATION IN THE CONTEXT OF COMPETING WORLDVIEWS

2.1 A Relativistic Theory of Gravitation as a Problem of "Normal Science"

In 1907, when Einstein first dealt with the problem of a relativistic theory of gravitation, philosophical interests seemed to be far from his main concerns. Although he was employed by the Swiss patent office at that time, he was no longer an outsider to academic physics. By way of his publications, correspondence, and personal relationships, he was already becoming a well-respected member of the physics establishment. The times had passed when philosophical readings in the mock "Olympia" academy, which Einstein had founded some years earlier together with other bohemian friends, formed one of the centers of his intellectual life. Einstein was first con-

6 For the concept of horizon, see (Damerow and Lefèvre 1981).

fronted with the task of revising Newton's theory of gravitation in light of the relativity theory of 1905 when he was asked to write a review on relativity theory that would also cover its implications for various areas of physics not directly related to the field from which it originated, namely the electrodynamics of moving bodies.[7] Hence, the revision of Newton's theory of gravitation entered Einstein's intellectual horizon, not as the consequence of a philosophically minded ambition to go beyond the original special theory towards a more general theory of relativity, but as a necessary part of the usual "mopping up operation" whereby new results are integrated with the traditional body of knowledge. The necessity to modify the classical theory of gravitation appeared to Einstein and his contemporaries all the more pressing, as within the conceptual framework of classical physics an asymmetry could already be observed between the instantaneous propagation of the gravitational force and the propagation of the electromagnetic field with the finite speed of light. It therefore comes as no surprise that not only Einstein but also several of his contemporaries addressed the problem of formulating a field theory of gravitation that was to be in agreement with the principles suggested by the theory of the electromagnetic field and, most importantly, with the new kinematics of relativity theory.[8]

2.2 The Proliferation of Alternative Approaches to the Problem of Gravitation

It appears to be a phenomenon characteristic of the development of science that in a situation of conceptual conflict of this kind, alternative approaches to the solution of the conflict begin to proliferate. Among the factors accounting for this proliferation are the diverse resources upon which the alternative approaches can draw. Even after the establishment of special relativity, the instruments available for a revision of Newton's theory of gravitation had to be taken essentially from the arsenal of classical physics, in particular from classical mechanics and classical electrodynamics. As these two branches of classical physics were founded on different conceptual structures—on the one hand the direct interaction between point particles, and on the other hand, the propagation of continuous fields in time—the use of resources from one or the other branch to solve the same problem could present itself as a choice between conceptual alternatives. In this way, the problem of a new theory of gravitation assumed right from the beginning the character of a borderline problem of classical physics.[9] The choice among alternative approaches to the problem of gravitation was

7 See (Einstein 1907b, sec. V). See also Einstein's later recollections, e.g. those reported in (Wheeler 1979, 188). For a historical discussion of this paper, see (Miller 1992).

8 See, among others, the source papers in this and in vol. 4 of this series (Lorentz 1910; Minkowski 1908; Poincaré 1906), as well as the various papers by Abraham, Nordström, and Mie. See also (Abraham 1912a, 1912b; Lorentz 1910; Mie 1914; Minkowski 1911a [1908], in particular, pp. 401–404; Minkowski 1911b [1909], in particular, pp. 443–444; Nordström 1912; Poincaré 1905, in particular, pp. 1507–1508; 1906, in particular, pp. 166–175; Ritz 1909).

9 For the concept of borderline problem, see "Classical Physics in Disarray …" (in vol. 1 of this series).

therefore also related to the way in which such borderline problems were handled at that time.

Even before the turn of the century, that is, long before the great conceptual revolutions of early twentieth century physics, many physicists saw themselves at a crossroads, forced to decide between alternative conceptual foundations for their field.[10] Mechanics had long played the dual role of a subdiscipline and of an ontological foundation of physics, and at the threshold to the twentieth century, there were still physicists who adhered to the ontological primacy of mechanics, and who were therefore convinced that the entire body of physics should be built on conceptual foundations drawn from mechanics. With the formulation of classical electrodynamics by Maxwell, Hertz, and Lorentz, the difficulty of achieving such a reduction of physics to the conceptual apparatus of mechanics became increasingly evident. Although field theory itself was initially formulated in a mechanical language, towards the end of the century it came to represent an autonomous conceptual framework largely independent of that of mechanics. To some physicists, such as Wien and Lorentz, field theory even appeared to offer an alternative conceptual foundation for all of physics; they speculated about an electrodynamic worldview in which mechanics would have to be reformulated as a field theory rather than the other way around. Finally, with the development of classical thermodynamics in the mid-nineteenth century, including the formulation of the principle of conservation of energy, a third alternative conceptual foundation of physics (discussed under the name of "energetics") seemed to volunteer itself.[11] Hence, the mechanistic conception of physics, the electromagnetic worldview, and energetics distinguished themselves by the choice of the subdiscipline of classical physics to which they granted a foundational role for the entire field.

The formulation of a field theory of gravitation in analogy with, or even on the basis of, the Maxwell-Lorentz theory of the electromagnetic field was thus not a farfetched thought in the context of the electrodynamic world picture and had been approached by several authors.[12] In such a theory, gravitation, like electrodynamical interactions, would have to propagate with a finite speed. The establishment of the theory of relativity in 1905 did not make attempts in this direction obsolete; on the contrary, the issue of formulating a theory of gravity became even more urgent, since Newton's theory clearly violated one of the fundamental principles of the relativity theory—the requirement that no physical action propagates with a velocity greater than that of light. The primary task was to reformulate the experimentally well-con-

---

10 For further discussion of the conceptual foundations of classical physics at the turn of the century, see "Classical Physics in Disarray …" (in vol. 1 of this series). For a brief account of the different approaches prevalent at the turn of the century, see also (Jungnickel and McCormach 1986, chap. 24).

11 For a comprehensive historical analysis of energetics, see (Deltete 2000).

12 For contemporary reviews, see "Gravitation" (Zenneck 1903); "Recent Theories of Gravitation" (Abraham 1915), (both in this volume). For the heuristic role of electrodynamics for Einstein's formulation of a field theory of gravitation, see "Pathways out of Classical Physics …" (in vol. 1 of this series).

firmed Newtonian law of gravitation in accordance with the principles of the new kinematics, in particular with the Lorentz transformations of space and time coordinates, under which the classical law does not remain invariant. It is in fact not difficult to formulate a Lorentz covariant field equation which can be interpreted as a direct generalization of Newton's law. Around 1907 Einstein apparently pursued this line of research without, however, achieving satisfying results. Indeed, if such a Lorentz covariant generalization of Newton's theory could have been formulated without problems, there would have been no reason for Einstein to look beyond the special theory of relativity of 1905 and choose the thorny path that was to lead him to the formulation of the general theory of relativity in 1915.

One of the difficulties encountered by Einstein concerns the concept of mass, or more precisely the relation between the *two* concepts of mass in classical mechanics: gravitational and inertial. According to the special theory of relativity the inertial mass of a body depends on its energy content.[13] On the other hand, it was empirically known in the context of classical mechanics that the inertial mass is always exactly equal to the gravitational mass. In a relativistic theory of gravitation, the gravitational mass of a physical system should therefore also depend on its total energy. In a later recollection, Einstein summarized his view of this implication of classical mechanics and the special theory of relativity for a relativistic theory of gravitation:

> If the theory did not accomplish this or could not do it naturally, it was to be rejected. The condition is most naturally expressed as follows: the acceleration of a system falling freely in a given gravitational field is independent of the nature of the falling system (specially therefore also of its energy content).[14]

It was precisely this requirement, however, which turned out not to be fulfilled in the early attempts at a special relativistic theory of gravitation.[15]

In other words, a straightforward relativistic generalization of Newton's gravitational law seemed to be in conflict with "Galileo's principle," i.e., with the principle that the accelerations of bodies falling in a gravitational field are equal.[16] Quantitatively, however, the failure of the Galileo's principle may have been negligibly small, as Mie, for instance, claimed for his later special relativistic theory of gravitation.[17] Researchers such as Mie, whose outlook on this issue was shaped by the electrody-

---

13 See (Einstein 1907a), in which this conclusion is rederived in a general way, possibly with the problems of a relativistic theory of gravitation already in mind.

14 "Wenn die Theorie dies nicht oder nicht in natürlicher Weise leistete, so war sie zu verwerfen. Die Bedingung lässt sich am natürlichsten so aussprechen: die Fall-Beschleunigung eines Systems in einem gegebenen Schwerefelde ist von der Natur des fallenden Systems (speziell also auch von seinem Energie-Inhalte) unabhängig." (Einstein 1992, 64, 65)

15 For a reconstruction of Einstein's failed attempt to incorporate gravitation within the relativity theory of 1905, see "Classical Physics in Disarray …" sec. 2.9 (in vol. 1 of this series), see also "Einstein, Nordström, and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in this volume). For Einstein's later recollections, see (Einstein 1992, 58–63).

16 Galileo's name is usually (but incorrectly) associated with the introduction of the principle of inertia, while the principle which is named after him here can indeed be found in his work; for historical discussion, see (Damerow et al. 2004, chap. 3).

namic worldview, were all the more willing to give up the Galileo's principle as they did not feel obliged to consider the implications of classical mechanics as foundational for physics, unless they perceived an unavoidable conflict with experimental evidence. Einstein, however, somewhat prematurely gave up this line of research. In the years 1912 to 1914, Nordström, with the help of contributions from von Laue and Einstein himself, attempted to formulate a consistent special relativistic field theory of gravitation and eventually succeeded to some extent in including the equality of gravitational and inertial mass.[18] This theory even triggered insights—e.g., that clocks and rods are affected by the gravitational field—upon which its further development in the direction of general relativity could have been based. Hence, it constituted at least the beginning of an independent road towards a theory similar to general relativity, "the route of field theory."

2.3 Mach's Critique of Mechanics and the Three Routes to General Relativity

From the conflict between classical mechanics and the special theory of relativity, which Einstein perceived in 1907, he drew a conclusion that was diametrically opposed to that of the followers of an electromagnetic worldview. For him the equality of inertial and gravitational mass was not just an empirically confirmed but otherwise marginal result of classical mechanics; he held onto it as a principle upon which a new theory of gravitation was to be based. He was therefore ready to accept that this theory would no longer fit into the framework of special relativity.[19] Hence Einstein's

---

17 See (Mie 1913, 50). Similar views are also found in other authors pursuing a special relativistic field theory of gravitation, see e.g. (Nordström 1912, 1129): "From a letter from Herr Prof. Dr. A. Einstein I learn that earlier he had already concerned himself with the possibility I used above for treating gravitational phenomena in a simple way. However, he became convinced that the consequences of such a theory cannot correspond with reality. In a simple example he shows that, according to this theory, a rotating system in a gravitational field will acquire a smaller acceleration than a non-rotating system. I do not find this result dubious in itself, for the difference is too small to yield a contradiction with experience." ("Aus einer brieflichen Mitteilung von Herrn Prof. Dr. A. Einstein erfahre ich, daß er sich bereits früher mit der von mir oben benutzten Möglichkeit befaßt hat, die Gravitationserscheinungen in einfacher Weise zu behandeln, daß er aber zu der Überzeugung gekommen ist, daß die Konsequenzen einer solchen Theorie der Wirklichkeit nicht entsprechen können. Er zeigt an einem einfachen Beispiel, daß nach dieser Theorie ein rotierendes System im Schwerkraftfelde eine kleinere Beschleunigung erhalten wird als ein nichtrotierendes. Diese Folgerung finde ich an sich nicht bedenklich, da der Unterschied zu klein ist, um einen Widerspruch mit der Erfahrung zu geben.")

18 For Nordström's work, see the section "A Field Theory of Gravitation in the Framework of Special Relativity," in particular "Einstein, Nordström and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation" (in this volume).

19 Einstein remarked with regard to the violation of Galileo's principle in Abraham's and Mie's theories of gravitation (Einstein 1914, 343): "Due to their smallness, these effects are certainly not accessible to experiments. But it seems to me that there is much to be said for taking the connection between inertial and gravitational mass to be warranted *in principle*, regardless of what forms of energy are taken into account." ("Diese Wirkungen wären zwar wegen ihrer Kleinheit dem Experiment nicht zugänglich. Aber es scheint mir viel dafür zu sprechen, dass der Zusammenhang zwischen der trägen und schweren Masse *prinzipiell* gewahrt ist, abgesehen von der Art der auftretenden Energieformen.")

further considerations did not lead him away from mechanics, but rather brought him into contact with its foundational questions, in particular with the role of inertial systems in classical mechanics.

Mach's philosophical critique of the foundations of classical mechanics suggested to Einstein that the problem of a new theory of gravitation had to be resolved in connection with a generalization of the relativity principle of classical mechanics and special relativity. Quite apart from the specific problem of gravitation, some of Mach's contemporary readers, as well as researchers who had independently arrived at similar views, had drawn the conclusion that one should look for a new, generally relativistic formulation of mechanics.[20] Their conceptual and technical resources were mostly confined to those of classical mechanics, and their chances of making contact with the more advanced results of physics at the turn of the century, which to a large extent were based on field theory (in particular, classical electrodynamics), were, at least at that time, slender. Nevertheless, the line of research that extends from the work of these early followers of Mach (discussed in more detail in the next section) to the recent work of Julian Barbour and Bruno Bertotti, Fred Hoyle and Jayant Narlikar, André Assis and others demonstrates that the project of formulating a generally relativistic theory of mechanics, including a treatment of gravitation, could be as successfully pursued as the project of a purely field theoretic approach to the problem of gravitation, as represented in particular by the work of Nordström.[21] In the following, this approach will be called "the mechanistic generalization of the relativity principle."

In view of this historical context, the heuristics that guided Einstein's formulation of the general theory of relativity can now be identified as a "third way," a peculiar mixture of field theoretical and mechanical elements. This affirmation suggests several questions, which are addressed in the following: What are the advantages and the disadvantages of the different strategies? What exactly are the contributions of the field theoretical and of the mechanical tradition to Einstein's heuristic strategy? What is the relation between the conceptual structures guiding Einstein's research and those that were newly established by it? As the development of the general theory of relativity was apparently not uniquely determined by the intrinsic nature of the problem to be solved, what then were the external factors that shaped Einstein's perspective and what role did philosophical positions play among them?

20 See, for example, the source texts in the first part of this volume "The Gravitational Force between Mechanics and Electrodynamics." For a survey of the interpretation of Mach's critique by contemporary readers, see also (Norton 1995).

21 For historical overviews of attempts to incorporate Mach's critique in physical theories, see (Assis 1995; Barbour 1993, Barbour and Pfister 1995; Goenner 1970, 1981).

3. ROOTS OF GENERAL RELATIVITY IN CLASSICAL PHYSICS

3.1 Resources and Stumbling Blocks Presented by the Tradition of Field Theory

The conceptual roots of general relativity in the tradition of field theory are more familiar than those in the tradition of mechanics. As mentioned above, not only special relativity but even the classical theory of the electromagnetic field made it plausible to conceive of gravitation as a field propagated with finite velocity. But there were also other contributions from this tradition which sooner or later found their way into the development of general relativity. Notably, field theory endows space with physical properties and thus contributes to blurring the distinction between matter and space. That this tendency (even taken by itself) could suggest the introduction of non-Euclidean geometry as a physical property of space is illustrated by the work of Georg Friedrich Bernhard Riemann and William Clifford in the nineteenth century.[22] In any case, field theory enriched the limited ontology of classical mechanics by introducing the field as a reality in its own right, an apparently trivial consequence, which, as we shall see, took considerable time to achieve a firm standing even within the development of general relativity. Field theory also suggested the existence of forces more general than the two-particle interactions usually considered in point mechanics, as is illustrated, for instance, by the transition from Coulomb forces between point charges to electrodynamic interactions such as induction; and it offered a mechanism for unifying separate forces as aspects of one more general field, as can again be illustrated by the example of electrodynamics conceived of as a unification of electric and magnetic interactions. It was therefore natural for those who pursued the program of formulating a field theory of gravitation either on the basis of, or in analogy to electrodynamics to search for the dynamic aspects of the gravitational field, considering Newton's law (in analogy to Coulomb's) as a description of the field's static aspects only. But the knowledge of the Newtonian special case could, and also did serve as a touchstone for any attempt at a more general theory—including Einstein's general theory of relativity, in whose development the question of the "Newtonian limit" was to play a crucial role.[23] The mature formulation of electrodynamic field theory by H. A. Lorentz also suggested a model for the essential elements of a field theory of gravitation and for their interplay: a field equation was needed to describe the effect of sources on the field, and an equation of motion was needed to describe the motion of bodies in the field.[24] Finally, those who looked for an "electromagnetic" theory of gravitation were also very clear about the

---

22 See (Clifford 1976 [1889]; Riemann 1868). On p. 149 of his paper, Riemann claims that non-Euclidean geometry could be important in physics if the concept of body should turn out not to be independent of that of space. He expected this consideration to be of relevance for a future microphysics.

23 See (Norton 1989b) and "Pathways out of Classical Physics …" (in vol. 1 of this series).

24 For a discussion of the historical continuity between Lorentz's electron theory and Einstein's theory of general relativity, see (McCormmach 1970) and "Pathways out of Classical Physics…" (in vol. 1 of this series).

experimental evidence to be accounted for by the new theory: the explanation of the perihelion shift of Mercury was in fact mentioned as an empirical check in almost all discussions of electromagnetic theories of gravitation, which, in this sense, can be said to have left a very tangible patrimony to general relativity in pointing to one of its classical tests.[25]

But as much as the tradition of field theory was able to contribute to the conceptual development of general relativity, it did not determine a heuristic strategy that clearly outlined the way to a satisfactory solution of the problem of gravitation. What is more, in hindsight, from the perspective of the completed theory of general relativity, it becomes evident that the tradition of classical field theory also included conceptual components that must be considered as stumbling blocks on the way to such a solution. In first turning to the problem of the heuristic ambiguity of field theory, as mentioned above, there were indeed several different lines to follow in formulating a field theory of gravitation within this tradition.[26] One of the factors accounting for this proliferation of alternatives lay in the uncertainty as to which principles of mechanics were to be maintained in a field theory of gravitation, given the necessity of revising at least some of them. The electromagnetic approach to the problem of gravitation tended, in any case, to ignore the foundational problems of mechanics, as long as this seemed experimentally acceptable. An early example of this tendency, characteristic of the electromagnetic world picture, is provided by the stepmotherly way in which, before the advent of special relativity, the principle of relativity and the principle of the equality of action and reaction was treated in Lorentz's electron theory. The same attitude characterized his later attempts to integrate gravitation into the conceptual framework of field theory. For instance, in a 1910 review paper (Lorentz 1910) Lorentz seemed unperturbed by the fact that the relativistic law of gravitation he proposed violated the principle of the equality of action and reaction. This difficulty is just one representative example of the problems associated with the task of reconstructing the shared knowledge accumulated in mechanics on the basis of purely field theoretic foundations. In addition to these problems, there was little experimental guidance in how to proceed in building the new theory of gravitation—apart from the speculations about the perihelion shift of Mercury mentioned above. To use a metaphor employed by Einstein (1913, 1250): the task of constructing a field theory of gravitation was similar to finding Maxwell's equations exclusively on the basis of Coulomb's law of electrostatic forces, that is, without any empirical knowledge of non-static gravitational phenomena.

Let us now address the problem of the conceptual stumbling blocks. Their evaluation naturally depends on the point of view one takes. In view of the conceptual framework of the finished general theory of relativity, classical field theory must have been misleading in several respects. One obvious aspect is the linearity of the classi-

---

26 See note 8 above.

cal theory in contrast to the non-linearity of the field equations of general relativity. A related aspect is the independence of the field equation and the equation of motion from each other in the classical theory, as opposed to their interdependence in general relativity. Closely associated with these more structural aspects—and perhaps even more important—are the conceptual changes with respect to classical physics brought about by general relativity. These changes include the introduction of new concepts of space and time, the new role of the gravitational field acting as its own source, and the changes of the concepts of energy and force manifested, for instance, by the absence of a gravitational stress-energy tensor in general relativity, in contrast to the existence of such a stress-energy tensor for the electromagnetic field in classical field theory. These changes could not have been anticipated on the basis of classical field theory; furthermore, in the search for a new theory of gravitation, classical field theory necessarily engendered expectations which were flatly contradicted by the outcome of that search.

3.2 The Foundational Critique of Mechanics and the Mechanistic Generalization of the Relativity Principle

The heuristic contributions of classical physics to the development of general relativity as well as the conceptual stumbling blocks it presented for this development obviously require a more detailed treatment and should be discussed in particular in the context of the concrete theories which are subsumed here under the rather general heading of "classical physics." For the purposes of the present contribution, an examination of this kind will be attempted only for the tradition of mechanics, for which one particular strand was of primary influence on the development of general relativity—both directly and as an alternative to Einstein's theory. This strand was represented by a reevaluation of mechanics, which was the outcome of a debate on its foundations in the second half of the nineteenth century. In this period some basic concepts of classical mechanics had ceased to be as self-evident as they had once appeared in the Newtonian tradition.

A central example is Newton's claim that even a single body in an otherwise empty universe possesses inertia, a claim which—in spite of its metaphysical character—played a crucial role in his argument in favor of the existence of absolute space.[27] This argument involves a bucket filled with water, which is considered first in a state in which the bucket rotates but the water is at rest and its surface flat, and second in a state in which both the bucket and the water rotate, producing a curved surface. According to Newton's interpretation of this experiment, the second case represents an absolute rotation, whereas the first case represents only a relative motion between water and bucket that does not cause physical effects. The conclusion that this argument provides evidence for the existence of absolute space is, however, only legitimate if other physical causes of the curvature of the water in the

27 This has been shown in detail in (Freudenthal 1986), on which also the following remarks are based.

second case can be excluded; in other words, the argument is convincing only under the physically unrealizable assumption that a rotational motion of the water in an otherwise empty universe would also give rise to the same effect. This assumption in turn is based on the metaphysical premise that a system is composed of parts which carry their essential properties (such as inertia in the case of a material system) even when they exist in isolation in empty space. It was also on this premise that Newton considered gravitation—in contrast to inertia—to be a universal but not an essential property of a material body.[28]

In the middle of the nineteenth century, a motivation for revisiting such metaphysical foundations of mechanics was provided by the establishment of non-mechanical theories such as electrodynamics and thermodynamics as mature subdisciplines of classical physics.[29] As a consequence of this development, mechanics not only lost its privileged status as the only conceivable candidate providing a conceptual basis for the entire building of physics, a status which was often associated with a claim to *a priori* truth, but also the conceptual foundation of mechanics itself could now be critically reexamined, including, for instance, the concept of absolute space and its justification by Newton. This revision of the status of the fundamental concepts of mechanics alone helped to prepare the conditions for a change of these concepts, should such a change become necessary in view of the growing body of knowledge.[30]

In any case, the critical reevaluation of the conceptual presuppositions of mechanics led to a proliferation of alternative approaches to the problem of gravitation, much as with the proliferation of alternative approaches within the framework of field theory. It was possible to elaborate more clearly the presuppositions upon which classical Newtonian mechanics was built, to revise the theory by attempting to eliminate those assumptions, which now appeared to be no longer acceptable (without any other substantial changes), or to formulate a new theory altogether. Carl Neumann's paper "On the Principles of the Galilean-Newtonian Theory" of 1869 provides an example of the first alternative: in order to replace Newton's concept of absolute space, he introduced the "body alpha" as the material embodiment of an absolute reference frame, comparing it with the luminiferous aether of electrodynamics as a like-

28 See the explanation of *Regula* III in (Newton 1972 [1726], 389).

29 Compare also the sequence in which Einstein, in his *Autobiographical Notes* (Einstein 1992), treats the *external* criticism of mechanics (the critique of mechanics as the basis of physics, pp. 22–23) and the "internal," conceptual criticism (pp. 24–31).

30 Compare e.g. the remark by Carl Neumann in 1869 (Neumann 1993 [1870], 367): "Finally, just as the present theory of electrical phenomena may perhaps one day be replaced by *another* theory, and the notion of an electric fluid could be removed, it is also the case that it is not an absolute impossibility that the Galilean-Newtonian theory will be supplanted one day by another theory, by some other picture, and the body alpha be made superfluous." ("Ebenso endlich, wie die gegenwärtige Theorie der elektrischen Erscheinungen vielleicht dereinst durch eine *andere* Theorie ersetzt, und die Vorstellung des elektrischen Fluidums beseitigt werden könnte; ebenso ist es wohl auch kein Ding der absoluten Unmöglichkeit, dass die Galilei-Newton'sche Theorie dereinst durch eine andere Theorie, durch ein anderes Bild verdrängt, und jener Körper Alpha überflüssig gemacht werde.") For the "body alpha" see below.

wise hypothetical, yet legitimate, conceptual element of the theory.[31] Nevertheless, by this reformulation Neumann did not intend to change the substance of Newton's theory, in particular not with respect to the question of relative and absolute motion, as the following passage illustrates:

> This seems to be the right place for an observation which forces itself upon us and from which it clearly follows how unbearable are the contradictions that arise when motion is conceived as something relative rather than something absolute.
>
> Let us assume that among the stars there is one which is composed of fluid matter and is somewhat similar to our terrestrial globe and that it is rotating around an axis that passes through its center. As a result of such a motion, and due to the resulting centrifugal forces, this star would take on the shape of a flattened ellipsoid. We now ask: *What shape will this star assume if all remaining heavenly bodies are suddenly annihilated (turned into nothing)?*
>
> These centrifugal forces are dependent only on the state of the star itself; they are totally independent of the remaining heavenly bodies. Consequently, this is our answer: These centrifugal forces and the spherical ellipsoidal form dependent on them will persist regardless of whether the remaining heavenly bodies continue to exist or suddenly disappear.[32]

The critical examinations of the foundations of classical mechanics in (Lange 1886) and (Mach 1960) correspond to the second alternative mentioned above, since both authors were guided by the intention to revise mechanics by eliminating problematic assumptions. They may be considered as attempts to provide a conceptual reinterpretation of the existing formalism of classical mechanics (possibly even including

---

31 "But a further question arises, whether this body exists—really, concretely, as the earth, the sun, and the remaining heavenly bodies do. We may answer this question, as I see it, by saying that its existence can be stated with the same right, with the same certainty, as the existence of the luminiferous ether or the electrical fluid." ("Aber es erhebt sich die weitere Frage, ob jener Körper denn eine wirkliche, concrete Existenz besitze gleich der Erde, der Sonne und den übrigen Himmelskörpern. Wir könnten, wie mir scheint, hierauf antworten, dass seine Existenz mit demselben Recht, mit derselben Sicherheit behauptet werden kann wie etwa die Existenz des Licht-Aethers oder die des elektrischen Fluidums.") (Neumann 1993 [1870], 365).

32 "Es mag hier eine Betrachtung ihre Stelle finden, welche sich leicht aufdrängt, und aus welcher deutlich hervorgeht, wie unerträglich die Widersprüche sind, welche sich einstellen, sobald man die Bewegung nicht als etwas Absolutes, sondern nur als etwas Relatives auffasst.
Nehmen wir an, dass unter den Sternen sich einer befinde, der aus *flüssiger* Materie besteht, und der—ebenso etwa wie unsere Erdkugel—in rotirender Bewegung begriffen ist um eine durch seinen Mittelpunkt gehende Axe. In Folge einer solchen Bewegung, infolge der durch sie entstehenden Centrifugal kräfte wird alsdann jener Stern die Form eines abgeplateten Ellipsoids besitzen. *Welche Form wird*—fragen wir nun—*der Stern annehmen, falls plötzlich alle übrigen Himmelskörper vernichtet (in Nichts verwandelt) würden?*
Jene Centrifugalkräfte hängen nur ab von dem Zustande des Sternes selber; sie sind völlig unabhängig von den übrigen Himmelskörpern. Folglich werden—so lautet unsere Antwort—jene Centrifugalkräfte und die durch sie bedingte ellipsoidische Gestalt ungeändert *fortbestehen*, völlig gleichgültig ob die übrigen Himmelskörper fortexistiren oder plötzlich verschwinden.") (Neumann 1993 [1870], 366, n. 8)

minor adjustments of this formalism), with no ambition to formulate a new theory or to cover new empirical ground. Lange's approach is today the less well known, precisely because his contribution was the introduction of the concept of an inertial system, a contribution that was successful in becoming part of the generally accepted conceptual interpretation of classical mechanics. Mach's widely discussed critique of the foundations of classical mechanics, on the other hand, is characterized by vacillation between more or less successful attempts to reformulate Newtonian mechanics on a clearer and leaner conceptual basis and suggestions to create a new theory. It seems plausible to assume that this ambiguity was actually not in conflict with Mach's intentions, as the principal aim of his reformulation of elements of classical mechanics was to stress and clarify the dependence of this theory on experience, and hence to open up the possibility of revising the theory if required by new empirical evidence.[33]

One of the principal targets of Mach's critique was Newton's interpretation of the bucket experiment as evidence in favor of the existence of absolute space.[34] To Newton's argument, according to which the curvature of the surface of the rotating water is a physical effect of the rotation with respect to absolute space, he objected that in our actual experience this rotation can be considered as a relative rotation, namely with respect to the fixed stars:

> Try to fix Newton's bucket and rotate the heaven of fixed stars and then prove the absence of centrifugal forces. (Mach 1960, 279)

Thus, Mach questioned the fundamental metaphysical presupposition of Newton's conclusion that physical effects of absolute space would also occur if the rotation took place in an otherwise empty universe, i.e. the presupposition that all elements of a system retain their essential properties independently of their relation to the composite system:

> Nature does not begin with elements, as we are obliged to begin with them. (Mach 1960, 287–288)

On the grounds of his different philosophical view, Mach demanded that the entire corpus of mechanics should be reformulated in terms of the motion of material bodies relative to each other. For instance, he introduced a new definition of the concept of mass based on the mutual accelerations of bodies with respect to each other. He also suggested that inertial frames of reference should be determined on the basis of the observable relative motions of bodies in the universe, e.g. by determining a frame of reference in which the average acceleration of a mass with respect to other—ide-

---

33 This seems to be the most natural explanation for Mach's rather indifferent reaction to the controversy about the purpose of his critique as observed in (Norton 1995). Compare Mach's remarks on his revised principle of inertia: "It is impossible to say whether the new expression would still represent the true condition of things if the stars were to perform rapid movements among one another. The general experience cannot be constructed from the particular case given us. We must, on the contrary, *wait* until such an experience presents itself." (Mach 1960, 289)

34 See (Mach 1960, chap. 2, sec. 6), in particular, pp. 279–284.

ally all—bodies in the universe vanishes. On the one hand, Mach's proposals for a reformulation of classical mechanics clearly presuppose the validity of classical mechanics: both his new definition of mass by mutual accelerations and his idea of introducing increasingly improved inertial frames of reference by taking into account more and more bodies, over whose relative motion an average can be taken, assume that the concept of an inertial frame makes sense exactly as understood in classical mechanics. In other words, his proposal presupposes that there is indeed such a privileged class of reference frames and that they can be realized physically with sufficient approximation.[35] However, Mach's analysis also indicated the limits of the validity of classical mechanics, in particular by explicitly relating the concept of inertial frame to the motion of cosmic masses. Thus, without changing the substance of classical mechanics, he succeeded nevertheless in making clear—by proposing an alternative formulation based on different philosophical presuppositions—that the range of application of classical mechanics may be more limited than hitherto assumed, and that the theory might have to be changed eventually, for instance, in light of growing astronomical knowledge. Only on the basis of such an increased knowledge could it then be decided whether Mach's suggestion to reformulate classical mechanics in terms of relative motions would actually amount to proposing a new theory, substantially different from Newton's.

Attempts to formulate such a new theory, even in the absence of new empirical evidence, form a third alternative reaction to the critical reevaluation of the foundations of mechanics in the second half of the nineteenth century. Whether these attempts were stimulated by Mach or not, their common starting point was the rejection of Newton's philosophical presupposition that the properties of the elements of a physical system could be ascribed to each one of them even if they existed alone in empty space. It was this presupposition that enabled Newton to infer from the nature of the inertial effects present in the bucket experiment to that of the inertial behavior of a single particle in empty space, and from there, to the physical reality of empty space. Only by introducing an entity such as "absolute space" did Newton succeed in distinguishing between the kinematical and dynamical aspects of motion. Hence, if now this presupposition had become questionable, so had the entire relation between dynamics and kinematics. In particular, the distinction between force-free motions and those explained by the action of forces had to be given a new grounding in terms of relative motions between ponderable bodies. While Mach had essentially presupposed the validity of classical mechanics and attempted to reconstruct its achievements on this new basis, it was also conceivable to start from first principles and reformulate dynamics from the beginning in terms of relative motions between ponderable bodies, possibly even without using the concept of an inertial frame in the sense of classical mechanics. Attempts in this direction of a *mechanistic generalization of the relativity principle* were first undertaken around the turn of the century by Benedict and Imman-

35 See the penetrating analysis in (Wahsner and von Borzeszkowski 1992, 324–328).

uel Friedlaender, August Föppl, and Wenzel Hofmann, then decades later by Reissner and Schrödinger, and in our days by Barbour, Bertotti and others.[36]

Physicists of at least the first generation in this genealogy were confronted with the difficulty of taking up once again many of the foundational questions of mechanics discussed centuries earlier by Galileo Galilei, René Descartes, Isaac Newton, Gottfried Wilhelm Leibniz, and Christiaan Huyghens, and they attempted to recreate mechanics essentially from scratch. Indeed, apart from the foundational role given to the concept of relative motion even in dynamics and the known laws of classical mechanics, this approach of a mechanistic generalization of the relativity principle had few heuristic clues to go on. One of these clues was directly related to the criticism of Newton's interpretation of the bucket experiment: if it is indeed true that the curvature of the rotating water in the bucket is due to an interaction between the water and the distant cosmic masses, then a similar but smaller effect should be observable if large but still manipulable terrestrial masses are brought into rotation with respect to a test body. Experiments along these lines were suggested by several of these researchers and conducted by, among others, the Friedlaender brothers and Föppl—all with a negative result.[37] Nevertheless, the theoretical efforts continued—even though they remained marginal—and eventually found additional resources and inspiration in the theory of general relativity formulated in 1915 by Einstein.

3.3 Resources and Stumbling Blocks Presented by the Tradition of Mechanics

After this discussion of the historical roots of the mechanistic generalization of the relativity principle, we can now summarize some of the principal heuristic contributions and obstacles which the tradition of mechanics presented to the development of general relativity, as in the beginning of this section for field theory. First and foremost it was the idea of abolishing the privileged status of the inertial frame, which emerged from the foundational critique of mechanics in the nineteenth century, that proved to be an essential component of both Einstein's early research concerning generalized relativity, and of the considerations surrounding the competing traditions to provide a mechanistic generalization of the relativity principle. In fact, if separable material bodies are to be the ultimate basis of reality, as they are in the approach of a mechanistic generalization of the relativity principle, each material body should be equally well suited to defining a reference frame, and therefore should enter into the laws of physics on the same level with all other bodies. The idea of abolishing the privileged status of inertial frames was associated with the interpretation of the so-called inertial forces—such as those acting on the rotating water in Newton's bucket—as aspects of a new, yet to be discovered, velocity-dependent physical interaction between masses in relative motion with respect to each other. Under the desig-

36 See, e.g., (Friedlaender and Friedlaender 1896; Föppl 1905a, 1905b; Hofmann 1904; Reissner 1914, 1915; Schrödinger 1925, Barbour and Bertotti 1977).

37 See (Friedlaender and Friedlaender 1896; Föppl 1905a).

nation of “dragging effects,” such interactions became an important theme of the later general theory of relativity; there they can be understood as a new aspect of the gravitational interaction between masses, which was unknown in Newtonian mechanics. Finally, Mach’s definition of inertial mass in terms of the accelerations that two bodies induce in each other brought the concept of inertial mass even closer to the concept of gravitational mass than their quantitative identity in classical mechanics had so far. It follows from this definition that, contrary to Newtonian mechanics, inertial mass, in contrast to gravitational mass, can no longer be considered as a property that bodies possess independently of their interaction with each other. The search for effects of the presence of other bodies on the inertial mass of a test body became a component of the heuristics guiding Einstein’s research on a generalized theory of relativity.

While these were the specific and crucial contributions of the foundational critique of mechanics, other aspects of mechanics in the nineteenth century also contained important heuristic hints and conceptual resources for the development of general relativity; these resources, however, cannot be dealt with here systematically. In particular, the introduction of laws of motion expressed in generalized coordinates, the formulation of mechanics for non-Euclidean geometry, and the attempts at an elimination of the concept of force all represent resources which could be, and in part were, exploited in the development of general relativity.[38] The study of motion constrained to curved surfaces in classical mechanics provided, for instance, the blueprints for the formulation of the geodesic law of motion as a generalization of the principle of inertia in general relativity: in both cases the essential assertion is that motion not subject to external forces follows a geodesic line.

But unlike the foundational critique of mechanics, these other aspects of the development of classical mechanics did not themselves constitute another independent research program for formulating a substantially new mechanics that could lead to a theory comparable to general relativity. Rather their heuristic contribution to formulating such a new theory became relevant only in the context of Einstein’s later attempt to solve the problem of gravitation, and only on the basis of results that lay outside their scope. For instance, Hertz’s mechanics (Hertz 1894) is a reformulation of classical mechanics in which the elimination of the concept of force requires the introduction of hypothetical invisible masses acting as constraints for the visible motions. Not only does its formalism and, in particular, its generalized geodesic law of motion bear a number of similarities with the formalism of general relativity, but also the general approach of replacing the concept of force by geometrical concepts is common to both theories.[39] Although, even in the context of classical mechanics, the concept of force can be eliminated in the specific case of the gravitational interaction without introducing Hertz’s speculative entities—merely on the basis of Galileo’s principle, that is, by realizing that all bodies move with equal speeds in a gravitational

---

38 For a historical account of these developments, see (Lützen 1993).

39 The geometrical interpretation of general relativity is, however, a largely post-1915 development.

field—a systematic exploitation of formal results such as Hertz's required not only a restriction of mechanics to the special case of gravitational interaction, but also the introduction of Minkowski's reformulation of special relativity uniting the time with the space-coordinates into one spacetime continuum. Only under these presuppositions did the formal achievements of nineteenth-century mechanics become a resource for the insight that force-free motion in a gravitational field can also be understood as geodesic motion in a non-Euclidean spacetime continuum.

Considered in hindsight, however, these contributions to the development of general relativity that were rooted in the tradition of classical mechanics also presented conceptual obstacles to its development. First of all, as in the case of field theory discussed above, there was much ambiguity in the research program of a mechanistic generalization of the relativity principle. It is impossible to assess the direction that this program would have taken by itself without the guidance of Einstein's achievement, since the general theory of relativity was formulated in 1915—long before an elaborate and more or less successful realization of this program emerged. Around 1915 it was far less advanced than the attempts to solve the problem of gravitation in the context of field theory. The papers proposing a mechanistic generalization of the relativity principle are mostly in the form of programmatic treatises. They contain few technical details, and show, even by their style, that they deal with foundational problems of mechanics as commonly discussed by Galileo and his contemporaries in early modern times. In particular, in exploring the postulated velocity-dependent interaction, the mechanistic approach had few tools comparable to the powerful methods developed in the field-theoretic context: of particular interest were the tools for coping with the interaction of electrically charged masses in motion with respect to each other. Also on the experimental level, the mechanistic generalization of the relativity principle failed to identify evidence in favor of this new interaction between moving masses. It is therefore not surprising that the followers of a mechanistic generalization of the relativity principle were few and played only a marginal role in contemporary discussions. In addition to its weaknesses as an independent program of research, the idea of a mechanistic generalization of the relativity principle included aspects that, if judged from the perspective of the accomplished theory of general relativity, were both stimulating and misleading: while the ideal of a theory in which all physical aspects of space are derived from the relations between separable material bodies was an essential motivation for the search for a general theory of relativity, it turned out to be incompatible with its outcome since in general relativity the gravitational field has an existence in its own right, which cannot be reduced to the effects of matter in motion.

3.4 The Example of Benedict and Immanuel Friedlaender

The opportunities and difficulties presented by a mechanistic generalization of the relativity principle are best illustrated by the contribution of the Friedlaender brothers. Their philosophical starting point is the critique of the concept of motion of a single body in an otherwise empty space, on which, as we have seen, Newton's argument for absolute space was founded:

> Now think (if you can) of a progressive motion of a *single* body in a universal space that is otherwise imagined to be totally empty; how can the motion be detected, i.e. distinguished from rest? *By nothing* we should think; indeed the whole idea of such an absolute, progressive motion is meaningless.[40]

Like other critics of Newtonian mechanics, Immanuel and Benedict Friedlaender question the meaning of inertial frames and postulate a new velocity-dependent interaction between moving masses. But unlike other representatives of a mechanistic generalization of the relativity principle, they explicitly link this new interaction to gravitation:

> If this phenomenon was verifiable, this would be the incentive for a reformulation of mechanics and at the same time a further insight would have been gained into the nature of gravity, since these phenomena must be due to the actions at a distance of masses, and here in particular to the dependence of these actions at a distance on relative rotations.[41]

How far they went in anticipating the relation between gravitation and inertia as understood in general relativity becomes clear from speculations presented towards the end of their paper:

> It is also apparent that according to our conception the motions of the bodies of the solar system could be seen as pure *inertial motions*, whereas according to the usual view the inertial motion, or rather its permanent gravitationally modified tendency, would strive to produce a rectilinear-tangential motion.[42]

And, in another suggestive passage:

> But it seems to me that the correct formulation of the law of inertia will be found only when *relative inertia* as an effect of masses on each other, and gravity, which is after all also an effect of masses on each other, are reduced to a *unified law*.[43]

At a first glance, the insight formulated by the Friedlaenders into the relation between velocity-dependent inertial forces and gravitation seems to contradict the claim that a

---

40 "Nun denke man sich aber, (wenn man kann,) eine fortschreitende Bewegung eines *einzigen* Körpers in dem als sonst völlig leer gedachten Weltenraume; woran wäre die Bewegung bemerklich, d.h. von Ruhe unterscheidbar? An *Nichts* sollten wir meine; ja, die ganze Vorstellung einer solchen absoluten, fortschreitenden Bewegung ist sinnleer." The first part of their jointly published booklet, pp. 5–17, is by Immanuel Friedlaender and the second part, pp. 18–35, by Benedict Friedlaender. (Friedlaender and Friedlaender 1896, 20)

41 "War diese Erscheinung nachzuweisen, so war der Anstoß zu einer Umformung der Mechanik gegeben und zugleich ein weiterer Ausblick in das Wesen der Gravitation gewonnen, da es sich ja dabei nur um Fernwirkungen von Massen und zwar hier der Abhängigkeit dieser Fernwirkungen von relativen Rotationen handeln kann." (Friedlaender and Friedlaender 1896, 15)

42 "Es ist auch leicht ersichtlich, daß nach unsrer Auffassung die Bewegungen der Körper des Sonnensystems als reine *Beharrungsbewegungen* angesehen werden könnten; während nach der üblichen Anschauung die Beharrungsbewegung, oder vielmehr deren fortwährend durch die Gravitation abgeänderte Tendenz eine geradlinig-tangentiale Bewegung hervorzurufen bestrebt wäre." (Friedlaender and Friedlaender 1896, 33)

mechanistic generalization of the relativity principle did not possess tools comparable to those used in the electromagnetic tradition to treat the interaction of charged masses in motion with respect to one another. However, a footnote to the same passage makes it clear that the source of this insight into a possible relation between gravity and inertia actually is the *combination* of the introduction of velocity-dependent forces by the mechanistic generalization of the relativity principle and of the treatment of velocity-dependent forces in the electromagnetic tradition:

> For this it would be very desirable to resolve the question whether Weber's law applies to gravity, as well as the question concerning gravity's speed of propagation.[44]

The reference is to Wilhelm Weber's fundamental law for the force between electric point charges, which is a generalization of Coulomb's law for the electrostatic force, taking into account also the motion of the charges. By including velocity-dependent terms, Weber's law represents an attempt to cover electrodynamic interactions too, while maintaining the form of an action-at-a-distance law, that is, of a direct interaction between the point charges without an intervening medium. In other words, the Friedlaenders established a connection between their foundational critique of mechanics and the contemporary discussions about an electromagnetic theory of gravitation.[45]

By the time their paper was published, however, action-at-a-distance laws such as Weber's had been largely superseded by the field-theoretic approach to electromagnetism taken by Maxwell, Hertz, and others, who assumed a propagation of the electromagnetic force by an intervening medium, the aether.[46] The Friedlaenders themselves seem to have entertained considerations along these lines, without, however, drawing any technical consequences from them:

> No mind thinking scientifically could ever have permanently and seriously believed in unmediated action at a distance; the apparent action at a distance can be nothing other than the result of the action of forces that are transmitted in some way by the medium being situated between the two gravitating bodies.[47]

---

43 "Mir will aber scheinen, daß die richtige Fassung des Gesetzes der Trägheit erst dann gefunden ist, wenn die *relative Trägheit* als eine Wirkung von Massen auf einander und die Gravitation, die ja auch eine Wirkung von Massen auf einander ist, auf ein *einheitliches Gesetz* zurückgeführt sein werden." (Friedlaender and Friedlaender 1896, 17)

44 "Es wäre dazu sehr zu wünschen, daß die Frage, ob das Webersche Gesetz auf die Gravitation anzuwenden ist, sowie die nach der Fortpflanzungsgeschwindigkeit der Schwerkraft gelöst würden." (Friedlaender and Friedlaender 1896, 17)

45 Hints to such a connection are also found in other authors, even if they are less explicit; see, e.g., (Föppl 1905b, 386–394; Mach 1960, 296), with reference to the Friedlaender brothers and Föppl. For a discussion of Mach's position, see (Wolters 1987), in particular, pp. 37–70.

46 For the role of Weber's law in the later tradition of generally relativistic mechanics, see (Assis 1989, 1995; see also Barbour 1992, 145).

47 "An die unvermittelte *Fernwirkung* kann kein naturwissenschaftlich denkender Kopf jemals andauernd und ernstlich geglaubt haben; die scheinbare *Fernkraft* kann nichts anderes sein, als das Resultat von Kraftwirkungen, die durch das zwischen beiden gravitirenden Körpern befindliche Medium in irgend einer Art vermittelt werden." (Friedlaender and Friedlaender 1896, 19)

But whether in the field-theoretic or in the action-at-a-distance form, it was the tools of the electromagnetic tradition of classical physics which allowed the Friedlaenders to establish the link between the new understanding of inertia and gravitation. It is therefore not surprising that they treat the dragging effects of masses in relative motion to each other in analogy with electromagnetic induction:

> ... only in order to indicate the extent to which the problem of motion that we have raised and hypothetically solved here is related to that of the nature of gravity, but at the same time that comes rather close to the known effects of electric forces, will the following parallel be pointed out: a body that approaches a second one or moves away from it would be without influence on the latter as long as the velocity of approach (to be taken either with a positive or a negative sign) remains unchanged; any change of this velocity would entail the above-demonstrated [dragging] effect.
>
> As is well known, the presence of a current in a conductor is not sufficient for the generation of induction effects, either the magnitude of the current or the distance must vary; in our case the change of distance, i.e. the motion, would not suffice for the generation of the attractive or repulsive effects, but rather the velocity itself has to change.[48]

3.5 The Historical Horizon Before Einstein's Contribution

In summary, we have identified and discussed two entirely different strategies—both pursued at the time when Einstein began to work seriously on a relativistic theory of gravitation—for dealing with important conceptual issues at the foundations of mechanics and gravitation theory. The field theoretic approach to the problem of gravitation was, around this time, mainly stimulated by the incompatibility between Newton's theory of gravitation and the special theory of relativity, while the starting point of the mechanistic generalization of the relativity principle was a philosophical critique of the foundations of Newtonian mechanics based on newly established branches of classical physics. Their relation can be understood in the context of the two principal competing worldviews of classical physics around the turn of the century, the electromagnetic worldview and the mechanical worldview. In particular, these worldviews determined the different conceptual resources from which the two strategies drew rather exclusively, those of field theory and of classical mechanics respectively. Whereas the mechanistic generalization of the relativity principle

---

48 "… und nur, um anzudeuten, in wie fern das hier angeregte und hypothetisch gelöste Bewegungsproblem mit demjenigen des Wesens der Gravitation zusammenhängt, sich zu gleicher Zeit aber den bekannten Wirkungsweisen elektrischer Kräfte einigermaßen nähert, sei auf folgende Parallele hingewiesen: Ein Körper, der sich einem zweiten nähert oder von ihm entfernt, würde ohne Einfluß auf diesen sein, solange die positiv oder negativ zu nehmende Annäherungsgeschwindigkeit unverändert bleibt; jede Aenderung der Geschwindigkeit hingegen würde die vorher gezeigte Wirkung ausüben.
Das Vorhandensein eines Stromes in einem Leiter genügt bekanntlich zur Erzeugung von Induktionswirkungen nicht, es muß entweder die Stromstärke oder die Entfernung wechseln; in unserem Falle würde nun zur Erzeugung der anziehenden oder abstoßenden Wirkungen auch die Entfernungsänderung, d.h. die Bewegung nicht ausreichen, es muß vielmehr die Geschwindigkeit selbst sich ändern." (Friedlaender and Friedlaender 1896, 30)

remained in the margin of contemporary physics, the field theoretic approach to gravitation, at least for a while, played a larger part in contemporary discussions, and both strategies were pursued in ignorance of one another.

The two strategies encountered problems which, in hindsight, can be recognized as being closely related to each other. On a general level, the difficulties of the two strategies were in an inverse relation to each other: those following the field theoretic approach were confronted with the problem of reconstructing on a new conceptual basis the shared knowledge accumulated in classical mechanics, e.g. the insight into the equality of gravitational and inertial mass. The followers of a mechanistic generalization of the relativity principle, on the other hand, had to face the task of keeping up in their terms with the immense contribution of field theory to the progress of physics in the nineteenth century, a formidable challenge even for current attempts to pursue the tradition of the mechanistic generalization of the relativity principle. But on the specific level of the gravitational and inertial interactions of masses, the problems faced by the two approaches are better characterized as being complementary to each other: on the basis of concise theoretical considerations, the electromagnetic approach to the problem of gravitation required the existence of a velocity-dependent gravitational interaction in analogy to electromagnetic induction, for which there was, however, little, if any, experimental evidence; the mechanistic generalization of the relativity principle, on the other hand, postulated a new velocity-dependent interaction between inertial masses in order to explain well-known observations such as the curvature of the water's surface in Newton's bucket experiment, but failed to develop a theoretical framework for its systematic treatment. Since the two traditions remained isolated from each other—with the remarkable but inconsequential exception of the Friedlaender brothers—their complementary strengths were not exploited before Einstein's contribution.

4. MACH'S PRINCIPLE: BETWEEN A MECHANISTIC GENERALIZATION OF THE RELATIVITY PRINCIPLE AND A FIELD THEORY OF GRAVITATION

4.1 The Emergence of a Link Between Einstein's Research on Gravitation and Mach's Critique of Mechanics in 1907

The problems of a field theory of gravitation, from which Einstein had started in 1907, pointed in two ways to Mach's critique of Newton's mechanics, namely, to his redefinition of the concept of mass and to his rejection of absolute space as a foundation for the understanding of inertial motion. As discussed in the previous section, the concept of inertial mass and the concept of absolute space were in fact connected through Newton's assumption that the essential properties of the elements of a system are independent of these elements' part in the larger (composite) system. The rejection of this assumption shattered both Newton's distinction between inertial and gravitational mass as essential and non-essential properties of a body respectively, and his demonstration of absolute space. Einstein had been familiar with Mach's critique of Newton's mechanics since his student days[49] and probably reread the corresponding chapters of the *Mechanik* after his first attack on the problem of gravitation in 1907.[50]

The physical asymmetry between inertial and gravitational mass, which, as perceived by Einstein in 1907, was at the heart of the conflict between a special relativistic theory of gravitation and classical mechanics, may have directed his attention to their more general asymmetry in Newtonian mechanics. According to Newtonian mechanics, inertial mass is a property that can also be ascribed to a single body in an otherwise empty universe, whereas gravitational mass can only be conceived as a property of a system of bodies. Mach's analysis of the concept of inertial mass can be considered as an attempt to remove just this asymmetry, at least on the level of an operational definition of inertial mass. According to this definition, inertial mass is determined, as we have seen, on the basis of the mutual accelerations within a system of bodies, i.e. not as the independent property of a single body. Although Mach's intention was probably only to give a more concise account of classical mechanics without changing its content, nevertheless his definition makes it clear that, in principle, the interaction between two masses, and hence their magnitude, may depend on the presence of other masses in the world (recall that the inertial frame within which the accelerations are measured is, according to Mach's critique of absolute space, determined by the distribution of masses in the universe). In any case, according to Mach, inertial mass and gravitational mass both depend upon interactions between bodies. This lends additional strength to Einstein's conclusion that the equivalence of inertial and gravitational mass in classical mechanics points to a deeper conceptual unity that is to be preserved also in a new theory of gravitation.

Einstein's introduction of the principle of equivalence, which expresses the equality of inertial and gravitational mass independent of the specific laws of motion of classical mechanics, indicated a connection to Mach's critical discussion of Newton's purported demonstration of absolute space. The successful use of a uniformly accelerated frame of reference to describe the behavior of bodies falling in a constant gravitational field must naturally have raised questions about the relation between arbitrarily accelerated reference frames and more general gravitational fields. For Einstein, such questions pointed in particular to the problem of the privileged role of inertial frames in classical mechanics, as he confirms in the recollection already quoted in the first section:

---

49 For an early reference to Mach, see Einstein to Mileva Marić, 10 September 1899 (CPAE 1, Doc. 54; Renn and Schulmann 1992, 14, 85). For later recollections mentioning Mach, see (Einstein 1933, 1954b, 1992).

50 For contemporary evidence of Einstein's rereading, see p. 58 of Einstein's Scratch Notebook 1910–1914? (CPAE 3, 592, app. A), where Einstein wrote the title of the crucial sec. 6 of chap. 2 of Mach's *Mechanics* (Mach 1960); pp. 7–8 of Einstein's *Lecture Notes for an Introductory Course on Mechanics* at the University of Zurich, Winter semester 1909/1910, (CPAE 3, 15–16, discussed in more detail below); and the discussion of Mach's ideas in a notebook on Einstein's Course on Analytical Mechanics, Winter semester 1912/13, by Walter Dällenbach, (for a brief description, see (CPAE 4, app. A).

> So, if one considers pervasive gravitational fields, not *a priori* restricted by spatial boundary conditions, physically possible, then the concept of 'inertial system' becomes completely empty. The concept of 'acceleration relative to space' then loses all meaning and with it the principle of inertia along with the paradox of Mach.[51]

In other words, the appearance of accelerated frames of reference in an argument concerning gravitation made it possible to relate to each other two theoretical traditions which had until then led essentially separate existences, the tradition of a field theory of gravitation in the sense of electrodynamics and the tradition of foundational critique of mechanics in the sense of what is called here "mechanistic generalization of the relativity principle." In the previous section, we have seen that the idea of including accelerated frames of reference on an equal footing with inertial systems was as alien to the tradition of field theory as the idea of a field theory of gravitation was to the tradition of the mechanistic generalization of the relativity principle.

Now, however, Mach's critical examination of the privileged role of inertial frames in classical mechanics provided Einstein with the context for considering his introduction of an accelerated frame of reference in the equivalence principle argument, not only as a technical trick to deal with a specific aspect of the problem of formulating a field theory of gravitation, but as a hint to the solution of a foundational problem of classical mechanics. But while Mach's critique justified the consideration of arbitrary frames of reference as a basis for the description of physical processes, and hence the extension of the equivalence principle argument to include more general accelerated frames, such as the rotating frame of Newton's bucket,[52] it did not provide Einstein with the conceptual tools for dealing with the strange effects encountered in such frames. The tradition of field theory, in the context of which he had first approached the problem of gravitation, offered him, on the other hand, just the conceptual tools that allowed him to interpret the inertial forces in accelerated frames of reference as aspects of a more general notion of a gravito-inertial field, in the same sense that electromagnetic field theory makes it possible to conceive induction as an aspect of a more general notion of an electric field.

In other words, instead of attempting to resolve Mach's paradox of the privileged role of inertial frames in the context of a revised version of classical mechanics, as did the adherents of a mechanistic generalization of the relativity principle, Einstein was now able to address this foundational problem of mechanics in the context of a field theory of gravitation in which inertial forces could be understood as an aspect of

---

51 "Wenn man also das Verhalten der Körper inbezug auf das letztere Bezugssystem als durch ein "wirkliches" (nicht nur scheinbares) Gravitationsfelder als möglich betrachtet, so wird der Begriff des Inertialsystems völlig leer. Der Begriff "Beschleunigung gegenüber dem Raume" verliert dann jede Bedeutung und damit auch das Trägheitsprinzip samt dem Mach'schen Paradoxon." (Einstein 1992, 62–63)

52 For the particular role of rotating frames in motivating this generalization, compare Einstein's later remark concerning an objection against the privileged role of inertial frames in classical mechanics and in special relativity: "The objection is of importance more especially when the state of motion of the reference-body is of such a nature that it does not require any external agency for its maintenance, e.g. in the case when the reference body is rotating uniformly." (Einstein 1961, 72)

a unified gravito-inertial field. By establishing a "missing link" between the traditions of a mechanistic generalization of the relativity principle and field theory, he had found the key to the problems which appeared to be unsolvable within each of the two traditions taken separately. Where the followers of a field theory of gravitation searched in vain for an empirical clue which could have guided them beyond "Coulomb's law" of static gravitation (i.e. Newton's law) to a gravitational dynamics, Einstein succeeded with the help of Mach's critique in recognizing in the inertial effects of a rotating system, such as Newton's bucket, the case of a stationary gravitational field caused by moving masses. He interpreted this case as a gravitational analogue to a magnetostatic field in electrodynamics which can also be conceived as being caused by moving (in this case: electrical) masses.[53] And vice versa, where the adherents of a mechanistic generalization of the relativity principle searched in vain for new effects that could reveal more about the mysterious interaction between distant masses in relative motion with respect to each other, which in the only case known to them was responsible for the curvature of the water's surface in Newton's bucket, Einstein had no qualms about identifying this force as a dynamical aspect of universal gravitation and thus relating the unknown force to a well-explored domain of classical physics. In summary, Einstein's experiences with a field theory of gravitation and his familiarity with the foundational problems of mechanics had set the stage for his reception of whatever these two traditions had to offer for his program to build a relativistic theory of gravity that was also to be a theory of general relativity. What had previously seemed to be mutually exclusive approaches, to some extent now became, from his perspective, complementary.

4.2 Hints at a Machian Theory of Mechanics in Einstein's Research on Gravitation Between 1907 and 1912

The following is a brief account of those features of Einstein's heuristics that reflect the complementary influence of the two traditions in the sense outlined above. While there is no direct contemporary evidence for the role of Mach's critique of mechanics on Einstein's 1907 formulation of what later became known as the equivalence principle, such an influence very likely forms the background for Einstein's reaction to the problems of a relativistic theory of gravitation.[54] Beyond shaping this reaction and opening the perspective towards a generalization of relativity theory, Mach's influence on the further development of this theory remained secondary, even when Einstein began to elaborate his original insight into the equivalence principle in papers published in 1911 and 1912.[55] The principal reason for this secondary status is that, in

53 See Einstein to Paul Ehrenfest, 20 June 1912 (CPAE 5, Doc. 409), discussed below.

54 See, in particular, (Einstein 1954b) for evidence that Einstein's perspective was indeed shaped at a very early stage by Mach's critique of mechanics. For a discussion of the relation between equivalence principle and Mach's interpretation of the bucket experiment, see "Classical Physics in Disarray …" (in vol. 1 of this series).

55 See, in particular, (Einstein 1911, 1912a, 1912b, 1912c).

this period, he drew mainly on the resources of field theory with the aim of constructing a field equation—analogous to the classical field equation for Newton's gravitational field—for the static gravitational field of his elevator thought experiment.[56]

Nevertheless, between 1907 and 1912 Einstein seems also to have collected hints pointing at a Machian theory of mechanics. For instance, he made use of Mach's analysis of the conceptual foundations of mechanics in preparing a course on classical mechanics at the University of Zurich for the winter semester 1909/1910[57] and referred to it in connection with his research on gravitation in correspondence to Ernst Mach of the same period.[58] At about the same time, he wrote the following in a letter to a friend:

> I am just now lecturing on the foundations of that poor, dead mechanics, which is so beautiful. What will its successor look like? With that question I torment myself ceaselessly.[59]

In the notes Einstein prepared for his lecture course he introduces Mach's definition of mass.[60] He emphasized the close relation between gravitational and inertial mass, following from the independence of gravity from material properties:

> The fact that the force of gravity is independent of the material demonstrates a close kinship between inertial mass on the one hand and gravitational action on the other hand.[61]

The dependence of inertial mass on the entire system of bodies in the universe implicit in Mach's definition of mass made it conceivable for Einstein that the inertial mass of a given body may also be a function of the system of other bodies, which varies with their distribution around the given body.[62] In (Einstein 1912c), he partially confirmed this conclusion by calculating the effect on the inertial mass of a body due to the presence of a massive spherical shell around it; the paper also deals with the effect on this body by an accelerated motion of the spherical shell. This paper, dedicated to Einstein's theory of the static gravitational field, is not only the first paper in

62 This is in disagreement with the claim expressed in (Barbour 1992, 135), that Einstein was not justified in maintaining that he was a following a stimulation by Mach in considering a dependence of inertial mass on the presence of other masses in the universe.

which he publicly mentions Mach's critique as a heuristic motivation behind his search for a generalized theory of relativity, but it also carries a title expressing the translation of this heuristics into the language of field theory: "Is there a gravitational effect which is analogous to electrodynamic induction?"

In 1912 Mach's critique gained a new importance for Einstein's work on gravitation for yet another reason. After convincing himself that he had found a more or less satisfactory theory of the static gravitational field, he turned to what he considered to be the next simple case, the stationary field represented by the inertial forces in a rotating frame. In other words, after exhausting, at least for the time being, the heuristic potential of the "elevator," he now turned to that of the "bucket." His contemporary correspondence confirms that he considered this case both from the perspective of field theory and from that of the mechanistic generalization of the relativity principle. In a letter to Ehrenfest from 20 June 1912, with reference to his theory of the static gravitational field and to the generalization necessary to cope with situations such as that of a rotating ring, he wrote:

> In the theory of electricity my case corresponds to the electrostatic field, while the more general static case would further include the analogue of the static magnetic field. I am not yet that far.[63]

In a letter to Besso dated 26 March 1912, Einstein remarked—probably referring to the same topic, i.e., the treatment of the inertial forces in a rotating frame as generalized gravitational effects in a frame at rest—in the spirit of Mach's remark on Newton's bucket: "You see that I am still far from being able to conceive rotation as rest!".[64] Not only Einstein's publications and correspondence but also his private research notes document the influence of both traditions—electrodynamics and mechanics—on the terminology in which he expressed the heuristics of his theory. Thus, we can exclude the possibility that his choice of words was merely a matter of making himself understood by his audience.[65]

4.3 Einstein's Machian Heuristics in his Research on a Relativistic Theory of Gravitation between 1912 and 1915

Einstein found it difficult to accomplish the transition from his treatment of the static special case to a more general theory that included the dynamical aspects of the gravitational field. In the summer of 1912, however, he attained the insight into the crucial role of non-Euclidean geometry for formulating the gravitational field theory he

63 "Mein Fall entspricht in der Elektrizitätstheorie dem elektrostatischen Felde, wogegen der allgemeine[r]e statische Fall noch das Analogon des statischen Magnetfeldes mit einschliessen würde." Einstein to Paul Ehrenfest, 20 June 1912, (CPAE 5, Doc. 409, 486).

64 "Du siehst, dass ich noch weit davon entfernt bin, die Drehung als Ruhe auffassen zu können." Einstein to Michele Besso, 26 March 1912, (CPAE 5, Doc. 377, 436).

65 See, in particular, Einstein's comments on his calculation of the effect of rotation and linear acceleration of a massive shell on a test particle in his and Michele Besso's May 1913 "Manuscript on the Motion of the Perihelion of Mercury" in (CPAE 4, Doc. 14).

searched for, an insight which, in spite of the many difficulties still to be resolved, paved the way for the final theory of general relativity published in 1915. This insight provides an important example of the fruitfulness of the combined heuristics of "elevator" (i.e., Einstein's equivalence principle) and "bucket" (i.e., Newton and Mach's bucket in Einstein's interpretation).[66] The heuristics of the bucket, i.e. the Machian idea to consider water in a bucket as constituting a frame at rest, first provided the qualitative insight into a possible role of non-Euclidean geometry in a rotating frame of reference.[67] The heuristics of the elevator, i.e. the elaboration of the theory of the static gravitational field, then prepared, in combination with Minkowski's four-dimensional formalism, the technical environment for the concrete application of this insight to the problem of gravitation. The crucial link between the general idea and this technical environment was provided by Gaussian surface theory, which made it possible to interpret the equation of motion suggested by the formalism of the static theory as the geodesic equation of a non-Euclidean geometry. It was only possible, however, to exploit the formal similarity between the two equations because of the deeper conceptual similarity between the problem of motion in a gravitational field and the problem of inertial motion in an accelerated frame of reference, as suggested by Einstein's Machian interpretation of inertia. This conceptual similarity may have helped Einstein to think of Gaussian surface theory in the first place, as he had been familiar since his student days with the relation in classical mechanics between motion constrained to a surface without external forces—which also can be conceived of as generalized inertial motion—and the geodesic equation in Gaussian surface theory.[68]

But even after Einstein recognized that the gravitational potential of his static theory could be interpreted as a component of the metric tensor in four-dimensional geometry, he would nevertheless have been, at least in principle, in the same situation as those searching for a dynamic theory of the gravitational field starting from Newton's theory as the only known special case. It was his "Machian" insight that the inertial effects in accelerated frames can be considered as an aspect of a more general gravito-inertial field that provided him with an entire class of examples supporting the relation between the equation of motion, metric tensor, and gravito-inertial field, which emerged from the generalization of the static theory. In fact, Einstein could

66 Compare also Einstein's Kyoto Lecture (Ishiwara 1971, 78–88).

67 This was first stressed in (Stachel 1989). For a more extensive reconstruction, see "Classical Physics in Disarray …" and "The First Two Acts" (both in vol. 1 of this series).

68 This is suggested by the similarity between a page in the Zurich Notebook by Einstein (p. 41R of "Research Notes on a Generalized Theory of Relativity," dated ca. August 1912, in (CPAE 4, Doc. 10) and p. 88 of the student notes on Geiser's lecture course on infinitesimal geometry, taken by Einstein's friend Marcel Grossmann in 1898 (Eidgenössische Technische Hochschule, Zürich, Bibliothek, Hs 421: 16); for Einstein's attendance of this course in the summer semester 1898, see (CPAE 1, 366); for his later recollections on the significance of this course for his work on general relativity, see (Ishiwara 1971, 78–88). The connection between Einstein's research notes and Grossmann's student notes was identified by Tilman Sauer; see also (Castagnetti et al. 1994) and "Commentary" (in vol. 2 of this series).

easily show that the inertial motion of a particle in an arbitrarily accelerated frame of reference can be described by the same type of equation as that published in May 1912 for a static gravitational field,[69] involving not just one variable but indeed a 4-by-4 metric tensor.

The introduction of the metric tensor provided Einstein with the framework for capturing the resources of the two traditions, field theory and the mechanistic generalization of the relativity principle, as well as those of the mathematical tradition established, among others, by Riemann and Christoffel. The tradition of field theory suggested, for instance, that—following the model of Poisson's equation for the gravitational potential in classical physics—some second-order differential operator was to be applied to the metric tensor in order to yield the left-hand-side of a gravitational field equation.[70] It therefore comes as no surprise to find that the first entries in the Zurich Notebook, in which Einstein tackled the problem of gravitation, reflect his attempt to translate the field equation of the theory for the static field into a second order differential equation for the metric tensor.[71] However, the construction of a satisfactory field equation for the gravitational field was an incredibly difficult task that would demand Einstein's attention for the following three years. In his search, he could rely on the tradition of the mechanistic generalization of the relativity principle which offered him concrete examples for metric tensors to be covered by the new theory, such as the metric tensor for Minkowski space described from the perspective of a rotating frame of coordinates. The inertial forces arising in such a rotating frame are well known from classical physics and could hence serve as criteria for the theory to be constructed.

In the course of Einstein's long search for a gravitational field equation, he continued to exploit the heuristics of the "elevator" and "bucket" in particular, and the traditions of field theory and mechanics in general, in order to build up a considerable "machinery" of formalisms, mathematical techniques, and conceptual insights. This machinery eventually developed a dynamics of its own and led to a "conceptual drift"; i.e., to results that were not always compatible with Einstein's heuristic starting points, whether they were rooted in field theory or in the mechanistic generalization of the relativity principle.[72]

One of the first indications of such a conceptual drift was a revision published in 1912 of the theory of the static gravitational field, which conflicted with the "heuristics of the elevator," and also with an expectation raised by traditional field theory.[73]

69 See (Einstein 1912b).

70 For more extensive discussion, see "Pathways out of Classical Physics …" (in vol. 1 of this series).

71 See p. 39L of "Research Notes on a Generalized Theory of Relativity" (dated ca. August 1912) in (CPAE 4, Doc. 10). See also "Facsimile and Transcription of the Zurich Notebook" (in vol. 1 of this series).

72 See (Elkana 1970).

73 For Einstein's first theory, see (Einstein 1912a), for his second, revised theory, see (Einstein 1912b). For historical discussion, see "The First Two Acts" and "Pathways out of Classical Physics …" (both in vol. 1 of this series).

The revision of Einstein's static theory became necessary after he found out that his theory violated the principle of the equality of action and reaction. The non-linearity of the revised field equation turned out to be incompatible with the equivalence principle as formulated by Einstein in 1907. The homogeneous static gravitational field which he replaced by a uniformly accelerated frame of reference was simply no longer a solution of the revised, non-linear field equation.[74] In other words, after the revision, the theory of the static gravitational field contradicted its own heuristic starting point. Consequently, Einstein had to restrict the principle of equivalence. But from the perspective of our present discussion, the most significant implication of this episode was that the gravitational field had entered the scene in its own right, on a par with the material bodies acting as its source. Hence it became, at least in principle, conceivable that non-trivial gravito-inertial fields could exist without being caused by material bodies. Einstein, however, remained hesitant to accept this conclusion—which is in obvious contradiction with the Machian requirement that all inertial effects are due to ponderable masses—even after he had formulated the final theory of general relativity.

During Einstein's work on his generalized theory of relativity in the years 1912 and 1913, the "heuristics of the bucket" did not fare much better. In Einstein's research notes from this period, one encounters again and again the metric tensor representing the Minkowski space as seen from a rotating frame of reference.[75] However, it remained unclear for some time whether or not the field equation of the preliminary theory of gravitation, which Einstein published in 1913 with his mathematician friend Marcel Grossmann (Einstein and Grossmann 1913), satisfied this requirement of incorporating the Machian bucket. Einstein's eventual discovery that the "*Entwurf*" theory conflicted with this expectation was an important motive for discarding this theory and for beginning anew the search for a theory that promised to fulfill his original goals.[76] In this way, the "heuristics of the bucket" once more played a crucial role in the genesis of the general theory of relativity.

4.4 Attempts at a Machian Interpretation of General Relativity in the Period 1915–1917

After Einstein had formulated his theory in 1915, the tension between his original heuristics and the implications of the new theory remained unresolved; this tension continued to characterize the further development of the theory until at least 1930. Initially, one motive behind Einstein's emphasis on epistemological arguments based

74 For an extensive evaluation of Einstein's principle of equivalence, see (Norton 1989a), and, in particular, for the present discussion, p. 18.

75 See, e.g., pp. 42R, 43L, 11L, 12L, 12R, 24R, and 25R of "Research Notes on a Generalized Theory of Relativity" (dated ca. August 1912) in (CPAE 4, Doc. 10). See also "Facsimile and Transcription of the Zurich Notebook" (in vol. 1 of this series).

76 See, e.g., Einstein to Arnold Sommerfeld, 28 November 1915, (CPAE 8, Doc. 153). For historical discussion, see (Janssen 1999) and "What Did Einstein Know …" (in vol. 2 of this series).

on the relation between the new theory and its Machian heuristics may have been his desire to make his achievement acceptable to the scientific community. In fact, an important element of the empirical confirmation of the theory was only supplied when the eclipse expedition of 1919 confirmed the bending of light in a gravitational field. In 1913 Einstein had written to Mach that the agreement which he had found between the consequences of his then preliminary theory of gravitation and Mach's critique of Newtonian mechanics was practically the only argument he had in its favor.[77] Also in his early publications on the final theory he continued to insist on its epistemological advantages, which provided additional support for its claim of superiority with regard to competing theories.[78]

But Einstein's insistent pursuit of the Machian aspects of general relativity in the early years after its formulation was determined less by tactical motives than by the perceived need for a physical interpretation of the technical features of the new theory in light of his original heuristics. For instance, Einstein soon realized that, as a rule, the field equation determines the gravitational field only if, in addition to the matter distribution, boundary conditions are specified. This technical feature of the theory had to be brought together with his intention to realize a generally relativistic theory and his Machian hopes of explaining inertial behavior by material bodies only.[79] For some time in 1916 and early 1917, he attempted to formulate boundary conditions that would somehow comply with his original intentions.[80] He searched, for example, for boundary conditions in which the components of the metric tensor take on degenerate values since he assumed that a singular metric tensor would remain invariant under general coordinate transformations, and thus make it possible to maintain the requirement of general covariance even at the boundary region of spacetime. He also searched for a way to define a region outside the system of masses that constituted the physical universe in which a test body would possess no inertia, so that he might then be able to claim that inertia is indeed created by the physical system circumscribed by this empty boundary region.[81] In the course of these attempts, the expectation that general relativity was to provide a Machian explanation of inertia began to be silently transformed from a requirement concerning the nature of the theory to a criterion to be applied to specific solutions of the theory. Since Minkowski's flat spacetime, with inertial properties familiar from classical mechanics and special relativity, was a solution to the vacuum field equations of general rela-

tivity, it simply could not be true in general that in this theory inertial effects are explained by the presence of matter.

After Einstein's failure to find a satisfactory treatment of the supposed Machian properties of general relativity along the road of singular boundary conditions, in (Einstein 1917) he advanced a completely different proposal for dealing with the cosmological aspects of the theory. He introduced a spacetime that satisfied all his expectations concerning the constitution of the universe, including the explanation of its inertial properties by the masses acting as sources of the gravitational field, but at the price of modifying the field equations to which this spacetime was a solution. As Einstein's cosmological paper of 1917 has been discussed a number of times, it may suffice to briefly emphasize its place in the development of the tensions between Einstein's Machian heuristics and the implications of the new theory.[82] The solution to the field equations—modified by the introduction of a "cosmological constant"—which Einstein considered in 1917 describes a spatially closed, static universe with a uniform matter distribution. It therefore entirely avoided the problem of specifying appropriate boundary conditions and, at the same time, was believed by him to correspond to a more or less realistic picture of the universe as known at that time. In general, though, Einstein tended to neglect the relation between the new theory and astronomy, as well as the exploration of the properties of the solutions to its field equations. In contrast, Willem de Sitter—at the time Einstein's principal opponent in the discussion of the allegedly Machian features of general relativity— repeatedly emphasized the astronomical consequences of the various solutions to the field equations.[83] In any case, Einstein not only hoped that his radical step of modifying the field equations of general relativity allowed him to find at least one acceptable solution to the field equations, but he also assumed that he would succeed in excluding altogether empty space solutions in which inertial properties are present in spite of the absence of matter.[84] It was therefore an unpleasant surprise—which he found difficult to digest and at first attempted to refute—when de Sitter demonstrated shortly after the publication of Einstein's paper that even the modified field equations allow such an empty space solution.[85] In 1918 Einstein published a critical note on de Sitter's solution in which he wrote:

> If de Sitter's solution were valid everywhere, then it would be thereby shown that the purpose which I pursued with the introduction of the λ-term [the cosmological con-

> stant–J R.] has not been reached. In my opinion the general theory of relativity only forms a satisfactory system if according to it the physical qualities of space are *completely* determined by matter alone. Hence no $g_{\mu\nu}$ -field must be possible, i.e., no space-time-continuum, without matter that generates it.[86]

4.5 The Introduction of "Mach's principle" in 1918

The increasing tension between Einstein's original intentions and the ongoing exploration of the consequences of the new theory was accompanied by attempts to rephrase the criteria of what it meant to satisfy the philosophical requirements corresponding to the heuristics that had guided the discovery of the theory. Characteristically, Einstein (Einstein 1918a, 241–242) introduced and defined the very term "Mach's principle" in the context of a controversy over whether or not the general theory of relativity in fact represented a realization of his intention to implement a generalization of the relativity principle of classical mechanics and special relativity. His paper of 1918 was a response to the argument by Kretschmann that the general covariance of the field equations of general relativity does not imply such a generalization of the relativity principle, but can be considered as a mathematical property only. Einstein argued that he had so far not sufficiently distinguished between two principles, which he now introduced as the principle of relativity and Mach's principle.[87]

The first principle, as defined by Einstein, states that the only physically meaningful content of a relativistic theory are coincidences of physical events at points of space and time. Since the occurrence of these point coincidences is independent of whether they are described in one or the other coordinate frame, their most appropriate description is by a generally covariant theory. This principle had, of course, not been the starting point of Einstein's search for a generally relativistic theory of gravitation, but rather constitutes a result of his reflection on complications encountered in a long, but eventually successful, search for such a theory.[88] For our purposes here, it is particularly remarkable that this formulation of the principle of relativity no longer appeals to the intuition of a world of isolated bodies distributed in an otherwise empty space whose physical interactions should depend only on their relative distances, velocities, etc. As we have seen, this intuition was characteristic of the mechanistic generalization of the relativity principle, and was at the root of Einstein's search for a generalized theory of relativity.

---

86 "Bestände die De Sittersche Lösung überall zu Recht, so würde damit gezeigt sein, daß der durch die Einführung des "λ- Gleides" von mir beabsichtigte Zweck nicht erreicht wäre. Nach meiner Meinung bildet die allgemeine Relativitätstheorie nämlich nur dann ein befriedigendes System, wenn nach ihr die physikalischen Qualitäten des Raumes allein durch die Materie vollständig bestimmt werden. Es darf also kein $g_{\mu\nu}$ -Feld, d. h. dein Raum-Zeit-Kontinuum, möglich sein ohne Materie, welche es erzeugt." (Einstein 1918b, 271)

87 For historical discussions of this paper and its context, on which the following account is based, see (Norton 1992a, in particular, pp. 299–301, 1993, 806–809; Rynasiewicz 1999).

88 See the various discussions of Einstein's "hole argument" in the recent literature, e.g. in (Norton 1989b, sec. 5). See also the discussion in "Untying the Knot …" (in vol. 2 of this series).

This original intuition in fact included Mach's suggestion to conceive of inertial effects as the result of physical interactions between the bodies of such a world. Now, however, the causal link between inertial effects and matter suggested by Mach's critical analysis of the foundations of classical mechanics needed to be reinterpreted in light of the newly developed formalism of general relativity. According to this formalism, inertial effects are described by the metric tensor representing the gravito-inertial field, while matter is described by the energy-momentum tensor representing the source term of the field equations for the gravitational field. It was therefore natural for Einstein to translate the supposed causal nexus between inertial forces and matter into the requirement that the gravitational field be entirely determined by the energy-momentum tensor. It is this requirement which he chose in 1918 to call "Mach's principle."[89] Certainly, this was not a mathematically concise criterion to determine whether general relativity as a theory, or, as particular solutions of the theory, do or do not satisfy Mach's principle. Two aspects of this principle are nevertheless clear. First, the translation of Mach's original suggestion into the language of general relativity transferred it from the conceptual context of mechanics into that of field theory, as both terms in Einstein's 1918 definition of Mach's principle—the gravitational field and the energy-momentum tensor—are basically field theoretical concepts. Second, it is obvious from the context of this definition, discussed above, that whatever was precisely intended, Einstein considered empty space solutions of the gravitational field equations as a violation of this principle.

4.6 The Conceptual Drift from Mach's Principle to "Mach's Aether" (1918–1920)

Ironically, both these aspects of Einstein's first explicit definition of Mach's principle in his writings contributed to the preparation for its eventual rejection. As a first step towards this rejection, de Sitter established that not only Einstein's gravitational field equations of 1915, but even the equations modified by the introduction of the cosmological constant, admit empty space solutions. As a consequence, Mach's principle now definitely took on the role of a selection principle for solutions to the field equations. It seems that one interpretative reaction by Einstein to this serious defeat of his principle was to extend the field theoretical interpretation of general relativity at the expense of the emphasis on the mechanical roots of his original heuristics. By 1920, the 1918 attempt to define Mach's principle in terms of the conceptual building blocks of his theory had been complemented by the introduction of a "Machian aether" as a means of capturing its conceptual implications.[90] In a lecture given in Leiden, Einstein (1920) exploited the time-honored concept of an aether, to which

89 "Mach's principle: The *G*-field is *completely* determined by the masses of bodies. Since mass and energy are identical in accordance with the results of the special theory of relativity and the energy is described formally by means of the symmetric energy tensor ($T_{\mu\nu}$), the *G*-field is conditioned and determined (*bedingt und bestimmt*) by the energy tensor of the matter." See (Einstein 1918a, 241–242), quoted from (Barbour 1992, 138).

Lorentz had given the definitive form in the realm of electrodynamics, in order to explain the new concept of space which had emerged with general relativity. He now directly turned against Mach's interpretation of inertial effects as caused by cosmic masses, because this interpretation presupposed an action at a distance, a notion incompatible with both field theory and relativity theory. Instead, contrary to his original heuristics, Einstein (1920, 11–12) associated these inertial effects with the nature of space, which he now conceived as being equipped with physical qualities, and which he hence appropriately called aether. Contrary to Lorentz's aether, however, Mach's aether, which Einstein thought of as being represented by the metric tensor, was supposed not only to condition but also to be conditioned, at least in part, by matter. This capacity of being influenced by the presence of matter was, apparently, the last resort for the Machian idea of the generation of inertial effects by the interaction of material bodies in Einstein's conceptual framework.

For the time being, however, two aspects of the relation between matter and space remained open problems: with space—under the name Machian aether—taking on the role of an independent physical reality, the question presented itself of whether matter had not lost all claims to primacy in a causal nexus between space and matter. In his Leiden lecture, Einstein (1920, 14) noted that it was possible to imagine a space without an electromagnetic field, but not one without a gravitational field, as space is only constituted by the latter; he concluded that matter, which for him was represented by the electromagnetic field, appears to be only a secondary phenomenon of space. In (Einstein 1919), he had made an attempt at a derivation of the properties of matter from the gravitational and the electrodynamic field, an attempt which he considered as still being unsatisfactory but which, for him, constituted the beginning of a new line of research in the tradition of the electrodynamic—or field theoretical—worldview. This kind of research program held out the possibility not only of reintroducing the concept of an aether in order to represent the physical qualities of space, but also of providing a theoretical construction of matter as an aspect of this aether. The other outstanding question concerning the relation between matter and space, which was left unclarified even after Einstein's introduction of a Machian aether, was the astronomical problem of the distribution of masses and of the large-scale spatial structure of the universe. Both questions, the theoretical as well as the empirical, turned out to be significant, not only for Einstein's further exploration of general relativity, but indirectly for the fate of Mach's principle as well.

---

90 For historical discussions, see (Illy 1989; Kox 1989; Kostro 1992, 2000; Renn 2003). Probably under the influence of Lorentz, Einstein had begun to reconsider the concept of aether already in 1916. On 17 June of this year he had written to H. A. Lorentz: "I admit that the general theory of relativity is closer to the aether hypothesis than the special theory." ("Ich gebe Ihnen zu, dass die allgemeine Relativitätstheorie der Aetherhypothese näher liegt als die spezielle Relativitätstheorie." (CPAE 8, Doc 226; English translation in Kostro 1992, 262.) At that time, however, as the same letter suggests, Einstein took it for granted that the aether is entirely determined by material processes. The transition to the aether concept as explained in the following seems to be complete by the end of 1919, see Einstein to H. A. Lorentz, 15 November 1919, (CPAE 9, Doc. 165).

4.7 Mach's Principle: From the Back Burner to Lost in Space (1920–1932)

The program of interpreting general relativity along the lines of Mach's philosophical critique of classical mechanics ceased to play a significant role in Einstein's research after 1920. In addition to the difficulty of implementing Machian criteria in the elaboration of the theory, his exploration during the twenties of the heuristic potential that general relativity offered for the formulation of a unified theory of gravitation and electrodynamics was probably responsible for this shift of interest.[91] As this heuristic potential for a further unification of physics was associated with the field theoretic aspects of general relativity, the relation of the theory to the foundational problems of mechanics naturally faded into the background. Nevertheless, on several occasions during his ongoing research on a unified theory of gravitation and electromagnetism, Einstein hoped that he could link the program of a unified field theory with a satisfactory solution of the cosmological problem in the sense of his Machian heuristics. In 1919, for example, he emphasized that his new theory had the advantage that the cosmological constant appears in the fundamental equations as a constant of integration, and no longer as a universal constant peculiar to the fundamental law; he made a point of showing that again a spherical world results from his new equations (Einstein 1919, 353; 1923b, 36). An additional reason for not completely rejecting Mach's principle may have been Einstein's awareness, in a period which saw the triumph of quantum mechanics, that, after all, the corpuscular foundation of physics and not the field theoretic might prevail in the end; fields would then indeed have to be conceived as epiphenomena of matter, like the gravitational field according to Mach's principle.[92]

There was also a rather mundane reason why Mach's principle did not figure prominently in Einstein's publications of this period, while not being entirely dismissed by him. More than its definition in 1918, its association with the cosmological model of 1917 had brought the principle to an end point of its theoretical development, to a point where the question of whether or not Mach's principle could be implemented in general relativity had become a question of its confirmation or refutation by astronomical data. In 1921 Einstein remarked, with reference to the possibility of explaining inertia in the context of his cosmological model:

> Experience alone can finally decide which of the two possibilities is realized in nature. (Einstein 1922a, 42)[93]

In any case, for the time being, he remained convinced that astronomical research on the large systems of fixed stars would bear a model of the universe compatible with his Machian expectations. In 1921 he also wrote:

---

91 See (Pais 1982, 287–288); see also the extensive discussion in (Vizgin 1994).

92 See, in particular, Einstein's views expressed in connection with theoretical and experimental studies of radiation in this period, for example: "It is thus proven with certainty that the wave field has no real existence, and that the Bohr emission is an instantaneous process in the true sense." Einstein to Max Born, 30 December 1921, my translation; see also the discussion in (Vizgin 1994, 176).

93 The German original is (Einstein 1921a).

> A final question has reference to the cosmological problem. Is inertia to be traced to mutual action with distant masses? And connected with the latter: Is the spatial extent of the universe finite? It is here that my opinion differs from that of Eddington. With Mach, I feel that an affirmative answer is imperative, but for the time being nothing can be proved. (Einstein 1921b, 784)[94]

In other words, although in the period between 1920 and 1930 Einstein invested his hopes and his research efforts mainly in the creation of a unified field theory, he nevertheless kept Mach's principle on the back burner as long as it was not contradicted by astronomical data.

Einstein's firm conviction made him sceptical with respect to the possibility of alternative cosmological models. In 1922 he criticized, among other proposals, Friedmann's paper on solutions to the original field equations which correspond to a dynamical universe.[95] He mistakenly identified a calculational error in Friedmann's solution, which he had viewed with suspicion from the beginning. In another paper of the same year (Einstein 1922b, 437), he explicitly criticized a cosmological model for its incompatibility with "Mach's postulate." In 1923, however, Einstein recognized that he had committed an error in rejecting Friedmann's dynamical solutions. He published a retraction (Einstein 1923c) of his earlier criticism and henceforth no longer expected an astronomical confirmation of his Machian cosmology with the same certainty as before. The change of Einstein's attitude is apparent from a comparison between the published retraction of his criticism with a manuscript version that has been preserved. In the manuscript version Einstein wrote:

> It follows that the field equations, besides the static solution, permit dynamic (that is, varying with the time coordinate) spherically symmetric solutions for the spatial structure, to which a physical significance can hardly be ascribed.

In the published paper, on the other hand, Einstein omitted the last half-sentence.[96] In another paper of the same year, Einstein referred with scepticism to "Mach's postulate" and to the modification of the field equations that it required, because the introduction of the cosmological constant was not founded on experience. He concluded:

> For this reason the suggested solution of the 'cosmological problem' can, for the time being, not be entirely satisfactory.[97]

Nevertheless, until the end of the twenties Einstein did not give up hope that Mach's principle could be maintained as a feature of a cosmologically plausible solution of the field equations of general relativity. When he discussed the "aether" of general

---

94 Einstein's astronomical views in this period were strongly under the influence of his Machian belief, see, e.g., (Einstein 1922b, 436).

95 See (Einstein 1922d); for Einstein's criticism of other proposals, see (Einstein 1922b, 1922c).

96 This has been noted by John Stachel. For the translation of the passage, see also (Stachel 1986, 244).

97 "Aus diesem Grunde kann die angedeutete Lösung des kosmologischen Problems einstweilen nicht völlig befriedigen." (Einstein 1923a, 8; my translation.) He also modified an earlier version of an attempt to formulate a unified field theory by omitting the cosmological constant, see (Vizgin 1994, 192–193).

relativity in (Einstein 1924, 90), he added that it is determined by ponderable masses and that this determination is complete if the world is spatially finite and closed in itself. In the same paper, he dealt both with the possibility that a unification of gravitation and electrodynamics can be achieved by field theory and with the possibility that an understanding of the quantum problem can be achieved without field theoretical components.[98] As suggested above, it is conceivable that this ambivalence as to which of the foundational concepts—field or corpuscle—would eventually prevail may have reinforced the role of Mach's principle in Einstein's thinking. In 1926, he discussed the cosmological implications of general relativity in line with his earlier arguments in favor of a finite static universe.[99] In 1929 he wrote:

> Nothing certain is known of what the properties of the space-time continuum may be as a whole. Through the general theory of relativity, however, the view that the continuum is infinite in its time-like extent but finite in its space-like extent has gained in probability. (Einstein 1929, 107)

Around 1930, however, things began to change. Primarily driven by his strong intellectual engagement in the program to formulate a unified field theory, Einstein expressed himself even more definitely than earlier in favor of a causal primacy of space in relation to matter—in sharp contrast to his original Machian heuristics. He would still ask the question:

> If I imagine all bodies completely removed, does empty space still remain?

and suggest a negative answer. But now this question was not so much intended to refer to the constitution of the universe, but was rather an epistemological inquiry regarding the construction of the concept of space:

> But how is the concept of space itself constructed? If I imagine all bodies completely removed, does empty space still remain? Or is even this concept to be made dependent on the concept of body? Yes, certainly, I reply.[100]

While in the sequel of the paper, Einstein develops at length his reasons for suggesting a *cognitive* primacy of the concept of physical object with respect to the concept of space, he concludes his discussion of the state of research on the foundations of physics with the following remark:

> Space, brought to light by the corporeal object, made a physical reality by Newton, has in the last few decades swallowed ether and time and seems about to swallow also the field and the corpuscles, so that it remains as the sole medium of reality.[101]

---

98 See (Einstein 1924), in particular, pp. 92–93.

99 See (Einstein 1926–1927) and, for historical discussion, (Vizgin 1994, 212–213).

100 "Wie kommt aber der Raumbegriff selbst zustande? Wenn ich die Körper allesamt weggenommen denke, bleibt doch wohl der leere Raum über? Soll etwa auch dieser vom Körperbegriff abhängig gemacht werden? Nach meiner Überzeugung ganz gewiß!" (Einstein 1930a, 180)

101 "Der Raum, ans Licht gebracht durch das körperliche Objekt, zur physikalischen Realität erhoben durch Newton, hat in den letzten Jahrzehnten den Äther und die Zeit verschlungen und scheint im Begriffe zu sein, auch das Feld und die Korpuskeln zu verschlingen, so daß er als alleiniger Träger der Realität übrig bleibt." (Einstein 1930a, 184)

In a lecture given in 1930 Einstein formulated his view even more drastically:

> The strange conclusion to which we have come is this—that now it appears that space will have to be regarded as a primary thing and that matter is derived from it, so to speak, as a secondary result. Space is now turning around and eating up matter. We have always regarded matter as a primary thing and space as a secondary result. Space is now having its revenge, so to speak, and is eating up matter. (Einstein 1930b, 610)

In the course of his work on unified field theory, assisted by his epistemological reflections, Einstein had come a long way from believing that a successful implementation of Mach's principle would entail a synthesis of physics in which the concept of matter would play a primary and the concept of space a secondary role. Nevertheless, as the development of Mach's principle in his thinking had become so closely associated with his cosmological ideas, the question of Mach's principle remained open precisely to the extent that the decision about Einstein's static universe was left open by observational cosmology. In the period between 1917 and 1930, a prevailing problem debated by researchers in this field was whether de Sitter's or Einstein's static universe is a better model of reality, while the question of expanding universes, raised by Friedmann in 1922 and by Lemaître in 1927, largely remained outside the horizon of observational cosmology.[102] The range of theoretical alternatives taken into account by contemporary researchers testifies to the persistent role of Einstein's Machian interpretation of general relativity for cosmology, even if this interpretation gradually became a mere connotation of one of the cosmological alternatives rather than being the primary issue.

With the stage thus set for an observational decision on Mach's principle, a definitive blow to Einstein's belief in it came with the accumulation of astronomical evidence in favor of an expanding universe, the decisive contribution being Hubble's work published in 1929.[103] Einstein became familiar with these results early in 1931 during a stay at the California Institute of Technology. As is suggested by an entry in his travel diary from 3 January 1931, Richard Tolman convinced Einstein that his doubts about the correctness of Tolman's arguments in favor of the role of nonstatic models for a solution of the cosmological problem were not justified.[104] In March of the same year Einstein wrote to his friend Michele Besso:

> The Mount Wilson Observatory people are excellent. They have recently found that the spiral nebulae are spatially approximately uniformly distributed and show a strong Doppler effect proportional to their distance, which follows without constraint from the theory of relativity (without cosmological constant).[105]

---

102 See (Ellis 1989, 379–380).

103 For historical discussion, see (Ellis 1989, 376–378).

104 "Doubts about correctness of Tolman's work on cosmological problem. Tolman, however, was in the right." Quoted from (Stachel 1986, n. 53, 249); for a discussion of Tolman's contribution, see (Ellis 1989, 379–380).

105 Einstein to Michele Besso, 1 March 1931, quoted from (Stachel 1986, 245).

Almost immediately after his return to Berlin, Einstein published a paper (Einstein 1931b) on the cosmological problem in which he stated that the results of Hubble had made his assumption of a static universe untenable. As it was even easier for general relativity to account for Hubble's results than for a static universe—because no modification of the field equations by the introduction of a cosmological constant was required—his earlier static solution now appeared unlikely to Einstein, given the empirical evidence (Einstein 1931b, 5).

In a lecture given in October of 1931, he still mentioned his static solution in connection with the implementation of Mach's ideas in general relativity, but, in spite of the numerous remaining difficulties of the dynamical conception of the universe, he now had definitely given up his belief in a Machian world (Einstein 1932). In 1932, in a joint paper with de Sitter—his main antagonist in the earlier controversy about a Machian explanation of inertia—Einstein himself presented an expanding universe solution to the unmodified field equations. In this paper, the original Machian motivation for Einstein's static universe solution is no longer even mentioned:

> Historically the term containing the "cosmological constant" λ was introduced into the field equations in order to enable us to account theoretically for the existence of a finite mean density in a static universe. It now appears that in the dynamical case this end can be reached without the introduction of λ. (Einstein and de Sitter 1932, 213)

In other words, in the course of the evolution of Einstein's cosmological views, from his adherence to a static world to his acceptance of an expanding universe, Mach's principle had simply disappeared.

4.8 Reflections in the Aftermath of Mach's Principle

Although Einstein continued to acknowledge the role of Mach's critique of classical mechanics for the emergence of general relativity even after 1930, one can nevertheless notice a tendency to reinterpret even the heuristics which had originally guided his formulation of the theory. In his later accounts of the conceptual foundations of general relativity, he appealed to the field concepts in order to point out those weaknesses of classical physics that he had discussed earlier in the spirit of Mach's critique of mechanics. He emphasized, for instance, that it was due to the introduction of the field concept that the standpoint of considering space and time as independent realities had been surmounted.[106] Or he argued (Einstein 1961, app. V, 153) that the principle of equivalence, which had originally motivated the extension of the relativity principle beyond the special theory of relativity, already demonstrated the existence of the field as a reality in its own right, that is, independent of matter, since for the field experienced by an observer in an accelerated frame of reference the question of sources does not arise.

When the occasion presented itself, Einstein also became quite explicit about his rejection of his earlier Machian heuristics. In a letter to Felix Pirani, for instance, he

106 See, e.g., (Einstein 1961, app. V, 144).

explains with reference to Mach's principle, as he himself had earlier defined it, that he no longer finds it plausible that matter represented by the energy-momentum tensor could completely determine the gravitational field, since the specification of the energy-momentum tensor itself already presupposes knowledge of the metric field. In the same letter Einstein explicitly revokes Mach's principle:

> In my view one should no longer speak of Mach's principle at all. It dates back to the time in which one thought that the "ponderable bodies" are the only physically real entities and that all elements of the theory which are not completely determined by them should be avoided. (I am well aware of the fact that I myself was long influenced by this *idée fixe*.)[107]

He similarly explains in his *Autobiographical Notes*:

> Mach conjectures that in a truly reasonable theory inertia would have to depend upon the interaction of the masses, precisely as was true for Newton's other forces, a conception that for a long time I considered in principle the correct one. It presupposes implicitly, however, that the basic theory should be of the general type of Newton's mechanics: masses and their interaction as the original concepts. Such an attempt at a resolution does not fit into a consistent field theory, as will be immediately recognized. (Einstein 1992, 27)

In summary, this section has shown that Mach's critique of classical mechanics was a crucial element in the heuristics guiding Einstein's way to the formulation of the general theory of relativity. It played this role as one among several aspects of the tradition of classical physics and was, just as many of these other elements, eventually superseded by the development of general relativity. At the outset, it opened up Einstein's perspective towards a generalization of the relativity principle and towards an explanation of inertial effects, and hence of the physical properties of space, by material bodies. By conceptualizing inertial forces as an interaction of bodies in motion, it provided a decisive complement to the prospect of a dynamical theory of gravitation, which was suggested by the conceptual tradition of field theory, but lacked an empirical substantiation that could offer orientation among a variety of possible research directions. The results which Einstein accumulated in the course of his search for a general theory of relativity enforced several adjustments and reformulations of his original heuristics. Eventually, it became impossible for him to bring the progress of general relativity into agreement with these heuristics.[108] Here we have seen that this is the case for those aspects of his heuristics which were founded on the stimulation received from Mach's critique of mechanics. It turns out, however, that the incompatibility between the conceptual framework that shaped Einstein's original heuristics and that which emerged from the final theory can be demonstrated more generally.[109]

5. EINSTEIN'S PHILOSOPHICAL PERSPECTIVE ON THE FOUNDATIONAL PROBLEMS OF PHYSICS

5.1 Einstein's Route to General Relativity: Between Physics and Philosophy

The account given in the previous section of the impact of Mach's critique on the development of general relativity seems to provide a strong case in point for an influence of philosophy on physics. Einstein himself confirms in many contemporary comments as well as in later recollections that he conceived the emergence of general relativity at least in part as a response to Mach's analysis of the foundations of classical mechanics.[110] He indeed continued his search for such a response even when more simple alternative approaches to the problem of gravitation seemed to be available and when only epistemological arguments could motivate the continuation of his search for a generalization of the relativity principle.[111] The fact that also the followers of a mechanistic generalization of the relativity principle could refer to Mach's analysis as the philosophical background of their enterprise, however, raises some doubts as to how significant the contribution of philosophy to Einstein's particular approach actually was. The starting point of Einstein's revision of the foundations of mechanics was in fact, as we have seen, in contrast to that of these "Machians," not a general philosophical concern but a concrete problem which he encountered in the course of his research. It was not that the principle of equivalence had been formulated as a consequence of Einstein's search for a generalization of the principle of relativity, but vice versa, that the introduction of the equivalence principle in the context of a problem of "normal science" had opened up the perspective towards the foundational questions of mechanics. In a recollection from 1919 Einstein laconically states with reference to the emergence of general relativity:

> The epistemological urge begins only in 1907.[112]

There is, however, a crucial distinction between the reaction of Einstein and that of the adherents of a mechanistic generalization of the relativity principle to Mach's critique of the foundations of mechanics. In Einstein's view, the primary philosophical force of Mach's critique was directed against precisely what seemed to be for the "Machian relativists"—at least within the context of this particular research problem—an undisputed presupposition of their thinking, namely the mechanistic ontol-

---

110 For contemporary evidence, see, e.g., Einstein's correspondence with Mach quoted above, for a later recollection, see, e.g., (Einstein 1954a, 133–134). The significance of Mach's philosophical critique of mechanics for Einstein is exhaustively treated in (Wolters 1987, chap. 1).

111 See (Einstein 1914, 344), where Einstein comments on Nordström's competing theory.

112 "Das erkenntnistheoretische Bedürfnis beginnt erst 1907." Einstein to Paul Ehrenfest, 4 December 1919 (CPAE 9, Doc. 189 - my translation). See also (Wheeler 1979, 188), for a later recollection by Einstein, according to which he recognized the significance of the equality of inertial and gravitational mass only as a consequence of his failure to formulate a special relativistic theory of gravitation. For a different interpretation, see (Barbour 1992, 130, 133).

ogy on the basis of which they attempted a generalization of the relativity principle. Einstein himself later remembered that questioning the self-evident character of the concepts of mechanics was one of the principal effects that Mach's philosophy had upon him:

> We must not be surprised, therefore, that, so to speak, all physicists of the last century saw in classical mechanics a firm and definitive foundation for all physics, yes, indeed, for all natural science, and that they never grew tired in their attempts to base Maxwell's theory of electromagnetism, which, in the meantime, was slowly beginning to win out, upon mechanics as well. ... It was Ernst Mach who, in his *History of Mechanics*, shook this dogmatic faith; this book exercised a profound influence upon me in this regard while I was a student.[113]

In other words, in contrast to those physicists whose reception of Mach's critique of mechanics was shaped only by the perspective of this one subdiscipline of physics, Einstein read Mach as a philosopher and understood the central philosophical intention behind Mach's historical and critical account of mechanics, which was directed against the special status which mechanics had had for a long time among the subdisciplines of physics.

We may therefore ask whether it was this philosophical sensibility with regard to the epistemological character of some of the foundational problems of classical physics which protected Einstein from the temptation to seek a solution to these problems within one of the subdisciplines of classical physics, as for instance, the adherents of a mechanistic generalization of the relativity principle. Indeed, there can be little doubt that Einstein's thinking was characterized by such a sensibility, which was heightened by his reading of philosophical authors such as Kant, Hume, Helmholtz, Mach, and Poincaré.[114] But it seems doubtful, on the other hand, whether philosophical scepticism with regard to false pretensions of a conceptual system is sufficient to overcome its limitations. At the turn of the century, philosophical critics of the privileged status of classical mechanics, often associated as it was with the pretension of an *a priori* character, may themselves serve as counter examples. Neither Mach nor Poincaré built the foundations of a new mechanics upon the basis of their respective epistemological critiques, let alone the foundations of a new conceptual framework for all of physics. As late as 1910, Poincaré—who had emphasized the conventional character of scientific concepts—was nevertheless of the opinion that the principles of mechanics may turn out to be victorious in their struggle with the new theory of relativity, and

113 "Wir dürfen uns daher nicht wundern, dass sozusagen alle Physiker des letzten Jahrhunderts in der klassischen Mechanik eine feste und endgültige Grundlage der ganzen Physik, ja der ganzen Naturwissenschaft sahen, und dass sie nicht müde wurden zu versuchen, auch die indessen langsam sich durchsetzende Maxwell'sche Theorie des Elektromagnetismus auf die Mechanik zu gründen. […] Ernst Mach war es, der in seiner *Geschichte der Mechanik* an diesem dogmatischen Glauben rüttelte; dies Buch hat gerade in dieser Beziehung einen tiefen Einfluss auf mich als Student ausgeübt." (Einstein 1992, 20–21) See also (Holton 1986, chap. 7, 237–277, in particular, p. 241; 1988, chap. 4, 77–104; Wolters 1987, chap. 1, 20–36).

114 For a list of some of Einstein's philosophical readings, see the introduction to (CPAE 2).

that it was hence unjustified to prematurely abandon these principles.[115] Mach (1960, 295–296) had left it open, as we have seen, that new empirical evidence may require a modification of the principles of mechanics. Contrary to Einstein, he speculated that an electromagnetic worldview may provide a new universal conceptual framework for the entire body of physics, while his own contributions to such a unity remained rather on the level of a metatheoretical reflection on science.[116] Einstein, in any case, was convinced that one should not attempt to identify Mach's crucial contribution in what can also be found in the works of Bacon, Hume, Mill, Kirchhoff, Hertz, or Helmholtz, but rather in his concrete analysis of scientific content.[117]

In addition, it can be historically documented that Einstein's scepticism, with respect to the competing worldviews based on mechanics, electrodynamics, or thermodynamics, was rooted in his precise knowledge of their respective scientific failings and not only in his epistemological awareness.[118] Shortly after the turn of the century, when the electromagnetic worldview still appealed to many physicists as the most promising starting point for a new conceptual foundation of physics, Einstein had already recognized the devastating consequences which the discovery by Planck of the law of heat radiation had for classical electrodynamics and hence for the conceptual backbone of a worldview based on traditional field theory. But does this observation not imply that Einstein's philosophical perspective on the foundational problems of physics simply dissolves, in the end, into technical competence in physics? This conclusion would only be justified if one accepted the conceptual distinction between philosophy of physics and physics as accepted today, that is, as a distinction between a methodological, epistemological, or metaphysical—in any case, a metatheoretical—study of physics and the concrete occupation with its scientific problems. In order to respond to the question of the philosophical character of Einstein's perspective, we therefore have to examine briefly the historical situation of the relation between physics and philosophy in Einstein's time.

5.2 The Historical Context of Einstein's Philosophical Perspective on Physics

At the turn of the century, the separation between philosophy of science and science in the sense accepted today had long been complete. The more recent history of this separation can be understood as a consequence of the failure of traditional philosophy to integrate the natural sciences into its reflective enterprise. This failure is partly due to the explosive growth of the shared knowledge of the various disciplines, and partly

---

115 See (Poincaré 1911); see also (Cuvaj 1970, 108) for a historical discussion.

116 For an extensive discussion of Mach's attitude with respect to the electromagnetic worldview, see (Wolters 1987, 29–36). For Mach's attempt to integrate mechanics into the body of physics on the level of methodological reflections, see (Mach 1960, chap. 5).

117 See his remarks to this effect in his obituary for Mach, (Einstein 1916b, 154–155).

118 See, in particular, Einstein's own account in his *Autobiographical Notes* (Einstein 1992), in particular, pp. 42–45, which is confirmed by contemporary evidence such as Einstein's letters to Mileva Marić, see (Renn and Schulmann 1992; CPAE 1).

to the change of the cultural and political role which philosophy, and philosophy of science in particular, underwent in the nineteenth century. In German academic philosophy of the second half of the nineteenth century, for instance, neo-Kantianism, which saw itself as a critical reaction to the philosophy of German idealism, played a weighty role.[119] Its stance was that of a politically neutral epistemology which—in contrast to the natural philosophy of German idealism—often anything but politically neutral—no longer issued any prescriptions for science but just attempted to capture the epistemological and methodological structures that made scientific progress possible. Although neo-Kantianism and the tradition in philosophy of science that pursued its metatheoretical concerns took the natural sciences as their guidepost, they did not, however, offer a theoretical framework that enabled scientists to reflect upon the body of scientific knowledge in its totality, let alone to discuss the social and cultural conditions and implications of science.

On the other hand, since the middle of the nineteenth century, the intrinsic necessity of dealing with science as a social and cultural phenomenon had been approached primarily on a pragmatic level, as is witnessed by the increasing role in the development of the large-scale structure of science played by state science and education policy and the creation of funding agencies and scientific organizations (such as the Kaiser-Wilhelm-Gesellschaft in Germany). Attempts to achieve an intellectual integration of scientific knowledge, for instance in the form of a scientific worldview, remained in the shadow of this development towards a practical control of the sciences as a social system, and was only later supplemented by theoretical studies of science policy and the sociology of science.[120] As a consequence of this complex dynamics of the social and the intellectual development of science, the transfer of knowledge beyond disciplinary boundaries, and the establishment of connections between disparate branches of the body of knowledge, remained a process largely left to chance and to the initiative of the individual researcher. Only to a small degree was this process systematically furthered by the requirements of the intellectual integration of science for the purposes of education, to mention one extreme, and in the context of a few, themselves highly specialized interdisciplinary research projects, to mention the other extreme. The lack of a global intellectual synthesis of scientific knowledge was, on the other hand, only poorly compensated for by a popular scientific literature whose aim was often less the distribution and mediation of scientific knowledge than its mystification.

The lack of a systematic place in the social system of the sciences and of academic philosophy for reflection on the contents of science beyond the narrow requirements of disciplinary specialization lent a particular importance to the philosophical efforts by scientists themselves. For Einstein's intellectual development it is in fact clear that the writings of scientists such as Mach, Duhem, Poincaré, and Helmholtz

119 For this and the following, see the detailed study, (Köhnke 1986).

120 For an attempt to assess this historical situation from the point of view of a systematic historical epistemology, see (Damerow and Lefèvre 1994).

had a greater impact on his philosophical reflection on science than the works of contemporary academic philosophers, precisely because they often dealt with the philosophical implications of concrete problems at the forefront of research. Nevertheless, it would be misleading to consider Einstein's own philosophical contribution only as a continuation of the tradition of epistemological and methodological reflections by nineteenth-century philosopher-scientists. Although this view is naturally suggested by the separation of physics and philosophy as understood today, it is too restrictive to capture the peculiar way in which research in physics and philosophical reflection are intertwined in Einstein's work. In fact, Einstein's scientific contributions to many branches of physics, from thermodynamics to statistical mechanics, from the theory of relativity to quantum physics, cannot be understood without assuming the background of a scientific world picture holding together otherwise disparate chunks of knowledge. As student, Einstein already possessed an extraordinary overview of the state of physics of his time. This enabled him to recognize foundational questions of physics in problems which others preferred to see only from the point of view of their area of specialization.[121] In comparison to Einstein's perception of the entire body of physics and its conceptual incongruences, the claim of those who undertook the construction of, say, an electromagnetic world picture almost appears to be an attempt to conceal the limitations of a specialists' outlook. In any case, Einstein's perspective distinguished itself profoundly—and with significant consequences—from the mutual ignorance that characterized the field theoretical approach to the problem of gravitation and the approach of a mechanistic generalization of the relativity principle, as we have seen earlier.

5.3 Einstein and the Culture of Science

From this sketch of the historical relation between physics and philosophy, it should be clear that the roots of the scientific worldview, which shaped Einstein's perception of physics at the beginning of his career, could only have been of a highly eclectic and backward character. From what is known of his early biography, it is clear that his reading of popular scientific books, together with his exposure to the technical culture associated with the business activities of his family, played a crucial role in the early development of his scientific worldview.[122] The popular scientific books that he devoured as an adolescent combined an easily accessible and conceptually organized overview of scientific knowledge with the claim that the enterprise of science also serves as a model for the development of moral and political standards.[123] These works represented an attempt to transmit the values of democracy and of political and technological progress (which had been defeated on the political scene with

121 For a reconstruction of Einstein's discoveries of 1905 along these lines, see (Renn 1993). See also (Holton 1988, chap. 4).

122 For evidence, see (Einstein 1992), as well as the documents collected in (CPAE 1); for historical discussion, see (Damerow and Lefèvre 1994; Gregory 2000; Pyenson 1985; Renn 1993).

123 See, in particular, (Bernstein 1867–1869).

the failure of the revolution of 1848) in the medium of popular science.[124] Einstein's scientific worldview, which apparently had some of its roots in his early fascination with these popular scientific books, has indeed much in common with their image of science as a substitute for religion, with their appeal to the moral and also political ideals of science, and with their effort to achieve a conceptual unification of scientific knowledge beyond its disciplinary boundaries.[125]

The conceptual framework that formed the basis of this effort was a rather primitive combination of remnants of the old natural philosophy from the beginning of the nineteenth century, and of scientific results roughly on the level of the state of knowledge at the middle of the century. It was, however, apparently sufficient to provide the young Einstein with a global perspective on science to which he could then assimilate a broad array of detailed knowledge without committing himself to a premature specialization. In any case, during his entire scientific career he pursued the idea of a conceptual unity of physics, whose first primitive image he may have encountered in his early reading of popular scientific literature. The history of Einstein's formulation of the special theory of relativity, for instance, illustrates not only that he saw, even at the start of his career, in the conceptual diversity of mechanics and field theory a challenge to this unity of physics, but also that he was aware that neither of the two subdisciplines alone could provide the basis for a solution of this conflict. The foundation of the special theory of relativity—the principle of relativity being rooted in classical mechanics, and the principle of constancy of the speed of light in the tradition of field theory—makes it clear that the conceptual innovation represented by this theory presupposed an integration of the knowledge accumulated in these two branches of classical physics.[126]

In Einstein's reaction to the clash between classical mechanics and field theory in the case of gravitation it is now possible to recognize an intellectual attitude that was deeply rooted in his scientific worldview and shaped by his experience with the creation of the special theory of relativity.[127] The approach of a mechanistic generalization of the relativity principle had a function for the emergence of general relativity which is similar to the function mechanics had for the development of special relativity: it supported the principle of relativity with a network of arguments that went beyond the narrow scope of the specific questions under examination, whether these concerned the electrodynamics of moving bodies or the integration of Newton's theory of gravitation into a relativistic field theory. Although Einstein's perspective on the foundational problems of physics encompassed the entire range of classical phys-

---

124 The biographical background of Bernstein, the author of the book which apparently played a key role for Einstein's early intellectual development, is discussed in (Gregory 2000). For more on the relation between popular scientific literature and political developments in the nineteenth century, see (Gregory 1977); see also (Lefèvre 1990).

125 For a systematic analysis of the role of "images of science" as a mediator between science and its external influences, see (Elkana 1981). For a discussion of the religious dimensions of Einstein's scientific worldview, see (Renn 2005).

126 For further discussion, see "Classical Physics in Disarray …" (in vol. 1 of this series).

ics, there can be no doubt that it was dominated by the tension between its two major conceptual strands, field theory and mechanics. In 1931, for instance, he wrote:

> In a special branch of theoretical physics the continuous field appeared side by side with the material particle as the representative of physical reality. This dualism, though disturbing to any systematic mind, has today not yet disappeared.

He then added with specific reference to Lorentz's theory of electrons, as well as with respect to the special and general theories of relativity:

> The successful physical systems that have been set up since then represent rather a compromise between these two programmes, and it is precisely this character of compromise that stamps them as temporary and logically incomplete, even though in their separate domains they have led to great advances. (Einstein 1931a, 69–70, 72)

For Einstein, the insight into the need to overcome the dualism of matter and field was not just paying lip service to the conceptual unity of physics, but one of the principal determinants of his research program. While his perspective was broader than that of many contemporary physicists, it was also limited by this same program. The extent to which Einstein's intellectual horizon was actually circumscribed by the problem of reconciling the fundamental, conceptual conflict he perceived at the heart of classical physics can be seen in his role, up to the twenties, in the exploration of the consequences of the theory of general relativity. Contrary to other researchers who took part in this research, Einstein's interest focused almost exclusively on what might be called the "philosophical closure" of the new theory. Whether concerning boundary conditions for the gravitational field, or the exact solutions to the field equations, his interest in these emerging research topics was not guided by a program of exploring new features of the theoretical structures he had created, nor by comparing these structures with the empirical results of astronomy, but rather by the question of whether or not a deeper understanding of general relativity would reveal its agreement with the heuristics that had guided its discovery. This interest merely reflects the perspective which had accompanied Einstein's work on general relativity since its inception: he had not searched for a theoretical foundation of cosmology, but rather for a contribution to the conceptual unification of classical physics and, in particular, a synthesis of the field theoretical and mechanical aspects of gravitation.

---

127 Einstein himself compared the heuristics which motivated his search for a general theory of relativity with that guiding his formulation of special relativity: "The theory has to account for the equality of the inertial and the gravitational mass of bodies. This is only achieved if a similar relation is established between inertia and gravitation as that [which is established] by the original theory of relativity between Lorentz's electromotive force and the action of electrical field strength on an electrical mass. (Depending on the choice of the frame of reference, one is dealing with one or the other.)" ("Die Theorie muss Rechenschaft geben von der Gleichheit der trägen und schweren Masse der Körper. Dies wird nur erzeilt, wenn zwischen Trägheit und Schwerkraft eine ähnliche Beziehung hergestellt wird, wie durch die urprüngl. Relativitätstheorie zwischen Lorentz'scher elektromotorischer Kraft und Wirkung elektrischer Feldstärke auf eine elektrische Masse. (Je nach der Wahl des Bezugssystems liegt das eine oder das andere vor.)") Einstein to H. A. Lorentz, 23 January 1915 (CPAE 8, Doc. 47 - my translation).

In spite of these limitations of Einstein's perspective, and in spite of the conflict between his heuristic expectations and the conceptual implications of what he had found, it is remarkable that in the course of his work on general relativity he was nevertheless gradually able to overcome his own preconceived expectations and to adapt the interpretation of his theory to new results. This contrasts with many other cases of conceptual innovation in science, in which the crucial step of conceptual innovation takes place at a generational transition, in the transmission of knowledge from "master" to "disciple" so to speak, as was actually the case in the transformation of Lorentz's electrodynamics into Einstein's special theory of relativity.[128] Einstein's own significant contribution to the conceptual understanding of general relativity is related to the fact that, from his earliest efforts to formulate such a theory until the end of his life, he expounded unceasingly the conceptual presuppositions and consequences of his research in accounts accessible also to the non-specialist. Einstein was himself one of the great authors of popular scientific literature. With only minimal technical content, his writings made the intellectual core of his scientific problems accessible to readers. That Einstein's general accounts of the theory of relativity functioned not only to disseminate expert knowledge to the layman, and that they also formed a medium for his own reflection on the conceptual aspects of scientific problems, are facts often overlooked by philosophers of science. But the gradual adaptation of Einstein's Machian heuristics to the implications of general relativity, and its eventual definitive abandonment in the light of these implications, provide a vivid illustration of the impact these reflective accounts had on Einstein's own understanding of general relativity.

In general, it is hardly possible to overlook the significance that the effort to explain scientific knowledge to laymen had for Einstein's intellectual biography, in particular his capacity to address foundational questions beyond the limits imposed by disciplinary specialization. In Bern, as well as in Zurich, he shared his ideas with a group of friends, most of whom were not physicists. We know with certainty that Einstein was indebted to Michele Besso for a decisive inspiration which made possible the breakthrough in the formulation of the special theory of relativity.[129] Einstein also belonged to amateur science societies in Bern and in Zurich that offered an institutional framework for an exchange of ideas which transgressed the usual academic and social boundaries. Even before studying physics in Zurich, he attended an unusual high school in Aarau whose intellectual atmosphere presented no sharp demarcation between research and education, and in which he could experience the spirit of a *res publica litterarum*. Teachers, who were also scientists, such as the physicists Conrad Wüest and August Tuchschmid, or the linguist Jost Winteler, must have confirmed Einstein's conviction that science could offer the foundation for making a life, and not just an intellectual life.[130]

128 See (Damerow et al. 2004; Renn 1993).
129 See the acknowledgement in (Einstein 1905) as well as the recollection in (Ishiwara1971).

To conclude: a culture of science which includes the effort of explanation as well as the search for conceptual unity in the diversity of scientific knowledge, that is, a "culture of scientific mediation," forms an essential background for Einstein's philosophical perspective on the foundational problems of physics. The historical preconditions that made this perspective possible were already fragile at the time: evidently, neither popular scientific literature nor amateur science societies could halt the disciplinary fragmentation of scientific knowledge and the loss of possibilities for a single individual to achieve a comprehensive overview. Despite the claim by many physicists of Einstein's generation of the proximity of their field to philosophy, Einstein was in fact already part of a small minority who continually attempted to reflect upon the whole of physics and to search for its conceptual unity. The isolation in which he worked on his later attempts to create a unified field theory testify to his failure to achieve a unity of physics along these lines. But considering how much a single individual could accomplish, even on the basis of inadequate presuppositions, we can read the history of Einstein's achievements as the challenge and the encouragement to work on a culture of science that responds to the needs of today.

ACKNOWLEDGEMENTS

For permission to quote from unpublished Einstein documents I am grateful to Ze'ev Rosenkranz, former curator of the Albert Einstein Archives of the Hebrew University, Jerusalem. I would like to thank my colleagues from the Eidgenössische Technische Hochschule in Zurich—where part of the research for this paper was done—for their hospitality and friendly support, in particular Elmar Holenstein. For their careful reading of earlier versions of this text, as well as for helpful suggestions I am grateful to Met Bothner, Leo Corry, Peter Damerow, Yehuda Elkana, Gideon Freudenthal, Hubert Goenner, John Norton, Wolfgang Lefèvre, Peter McLaughlin, Fiorenza Renn, Ted Richards, Tilman Sauer, and Gereon Wolters. To Frederick Gregory, Michel Janssen, and Tilman Sauer I am particularly indebted for making preliminary versions of their papers accessible to me.

GRAVITATION

Originally published as the entry "Gravitation" in the Encyklopädie der mathematischen Wissenschaften, 5th Volume: Physics, A. Sommerfeld, ed. B. G. Teubner, Leipzig 1903–1921, pp. 25–67. Finished in August, 1901, as noted by the author.

TABLE OF CONTENTS

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

Comprehensive Literature

can be found at the beginning of each section in notes 1, 2, 36, 47, 48, 77, 82, 107.

Introductory Note

In this paper astronomical questions, which are not dealt with in detail until Volume VI, must be mentioned several times. The present paper does not aspire to completeness in this regard, but only draws upon as much astronomical material as is unavoidable for treating the subject.

1. Newton's Law

As is well known, the fundamental gravitational law was first[1] conceived clearly by Newton, and formulated in the third book of his *Philosophiae naturalis principia mathematica*, propositions I–VII. |

It states: If at a certain instant of time two mass elements with masses m_1 and m_2 [27] are at distance r from each other, then at the same instant a force acts on each of the two elements in the direction of the other with a magnitude

$$G\frac{m_1 m_2}{r^2}.$$

In this expression, G is a universal—i.e., only dependent on the system of units—constant, the so-called gravitational constant.

1. DETERMINATION OF THE GRAVITATIONAL CONSTANT[2]

2. Significance of this Determination

The inherent significance of the absolute determination of any physical constant is enhanced in the case of the gravitational constant for two additional reasons:

1. If the gravitational constant is known, the acceleration due to gravity g and the dimensions of the Earth yield the mass and the mean density of the Earth.[3] The latter

---

1 About Newton's forerunners cf. F. Rosenberger, *Isaac Newton und seine physikalischen Prinzipien*, Leipzig 1895. A compilation of nearly all papers (up to 1869) which are in some way related to the *mathematical* implementation of the law of attraction can be found in I. Todhunter, *History of the mathematical theories of attraction and the figure of the Earth*, 2 Vols., London 1873.

2 Principal review literature about absolute determinations: J.H. Poynting, *The Mean Density of the Earth*, London 1894; F. Richarz and O. Krigar-Menzel, *Berl. Abh.* 1898, Appendix; C.V. Boys, *Rapp. congrès internat. phys.* 3, Paris 1900, p. 306–349. Then there are Gehler's *Physikalisches Handwörterbuch*, Leipzig 1825, articles: *Anziehung, Drehwage, Erde, Materie*; S. Günther, *Lehrbuch der Geophysik* 1, 2nd ed., Stuttgart 1879; F. Richarz, Leipzig, *Vierteljahrschr. astr. Ges.* 24 (1887), p. 18–32 and 184–186.

3 If Δ is the mean density of the Earth and R its radius, to first approximation we get

$$g = \frac{4}{3}R\pi\Delta G.$$

Considering the corrections which are caused by flattening, centrifugal force and their differences within various latitudes, then one arrives at the relation explained in detail by F. Richarz and O. Krigar-Menzel[2]

$$9.7800\frac{\mathrm{m}}{\mathrm{sec}^2} = \frac{4}{3}\cdot R_P\pi\Delta G\left(1+\mathfrak{a}-\frac{3}{2}\mathfrak{c}\right),$$

where

R_P = earth radius at the pole = 6356079m,

$\mathfrak{a}$ = flattening = 0.0033416,

$\mathfrak{c}$ = relation between centrifugal force and gravity at the equator = 0.0034672.

was the ultimate aim of most determinations; therefore, they are usually known as *determinations of the mean density of the Earth*.

[28] 2. If the Earth's mass is known, the masses of the | other planets and of the Sun follow, since the proportion of these masses to the Earth's mass is supplied by astronomical observation.[4]

3. Survey of Various Methods

The various methods chosen to gain the value for the gravitational constant G in absolute terms can be divided essentially into three main classes:

1. The force that masses of known magnitudes at known distances exert on each other, was determined directly: determinations with the torsion balance, the double pendulum, and the ordinary balance.[5]

2. Changes in the direction or magnitude of the acceleration due to gravity g caused by masses of known magnitudes were measured: deflection of the plumbline, pendulum observations.

3. It was attempted to calculate the Earth's mean density and thereby the gravitational constant from the density at the surface, based on a more or less hypothetical law about the increase of density towards the center of the Earth.

4. Determinations with the Torsion Balance

a. Static method. The weights attached to the balance beam are attracted by masses *next to* the beam. The resulting rotation of the beam is a measure of the attractive force's magnitude.

This method, which was probably first suggested by Reverend J. Michell,[6] was used by H. Cavendish,[7] F. Reich,[8] F. Baily,[9] A. Cornu and J. Baille,[10] C.V. Boys,[11] and finally by C. Braun.[12]

Reich's advance over Cavendish lies primarily in his use of a mirror arrangement to make measurements. Baily's measurements are particularly valuable because they were extended to a large number of materials, and were varied in other, manifold
[29] ways. Cornu and Baille have shown that the same | accuracy (the same deflection angle) can be achieved despite any reduction of scale, if only a suitable choice in sus-

---

4 But cf. section 11.

5 In the latter method, g enters into the result.

6 Quoted from Cavendish, *Lond. Trans.* 88 (1798).

9 *Lond. Astr. Soc. Mem.* 14 (1843).

10 Paris, *C. R.* 76 (1873), p. 954–58.

11 *Lond. Trans.* 186 (1889), p. 1–72.

12 *Wien. Denkschr.* 64 (1897), p. 187–285. Report on this: F. Richarz, *Leipzig Vierteljahrsschr. astr. Ges.* 33 (1898), p. 33–44.

pension provides equal oscillation periods of the torsion balance. Consequently, they used much smaller dimensions for their apparatus and so avoided a number of disturbances. Boys[13] extended this reduction to a smaller scale and made it possible to replace the metal suspension wires with much more favorable quartz fibers. Braun uses a torsion balance in a vacuum to avoid totally the worst disturbance while measuring with the torsion balance, namely the air currents.

Boys partly evaded the deficiency of the extremely small dimensions he used by skillful arrangement of his torsion balance; however, the disadvantage remains that with small dimensions, apart from the strong damping of the oscillations, errors in length determination and deficient homogeneity of the material can easily spoil the result's accuracy.[14] To avoid this deficiency of small dimensions and nevertheless reach high sensitivity, F. R. Burgess[15] suggested that arranging the weights to float on mercury would enable the use of large masses and thin suspension wires. In a pre-experiment with weights of 10×2 kg on both sides, he found a 12° deflection, but has not yet carried out his determinations.

b. Dynamical method. The attracting masses are placed *in line* with the balance beam. Their attraction serves to reinforce the restoring torque of the suspension. The resulting decrease of the oscillation period gives a measure of the attractive force's magnitude.

With this method, C. Braun obtained a value of G that agrees very well with results of his measurements via the static method. R. von Eötvös[16] suggested modifying this | method but has not yet published final results. [30]

5. Determinations with the Double Pendulum

J. Wilsing's vertical double pendulum[17]—a vertical balance beam with a weight at each end, attracted by horizontally displaced masses—does not work by torsion of wires, but uses gravity as the restoring force. The torque is reduced to a minimum by placing the double pendulum's center of gravity only ca. $0,01\,\mathrm{mm}$ beneath the edge. Such an arrangement combines high sensitivity[18] with significant stability, and moreover, in contrast to the torsion balance, has the advantage of being influenced to a lesser degree by air currents.

---

13 At length 2.3 cm of the balance beam, loaded on both sides with 1.3 to 3.98 g and deflected at each side by 7.4 kg, Boys received a deflection of ca. 370 scale sections. For Cavendish the quantities concerned were 196 cm, 730 g, 158 kg; he received a deflection of 6–14 scale sections.

14 Cf. F. Richarz's report cited in note 12.

15 Paris, *C.R.* 129 (1899), p. 407–409. Poynting[2] had already performed a similarly arranged experiment, but abandoned this arrangement due to interfering currents in the fluid.

16 *Ann. Phys. Chem.* 59 (1896), p. 354–400.

17 *Potsdam. Astr.-physik. Obs.* 6 (1887), No. 22 and 23.

18 At 325×0.54 kg, 1 to $10'$ deflection.

6. Determinations with the Ordinary Balance

The principle of this method, seemingly already presented by Descartes,[19] is as follows. Two equal weights m are placed on the scales of a balance. Underneath one of the two scales—possibly simultaneously above the other one—a mass M is brought in. The weight difference now observed provides a measure of the attraction M has on m.

For the purpose of absolute determination of the gravitational constant this method was probably first used by Ph. von Jolly,[20] later by J.H. Poynting,[2] and then by F. Richarz and O. Krigar-Menzel.[2]

Jolly's arrangement, which was already used in Newton's time by Hooke[21] in a quite similar way to determine a decrease of g with height, has the disadvantage that vertical air currents caused by temperature differences can disturb the weighing process by friction on the long suspending wires. Poynting avoided this shortcoming; furthermore, he saw to it that the angle by which the balance beam rotates can be read precisely, and that the attracting weights can be removed or brought closer without having to lock the balance or to expose it to vibration. Richarz's and Krigar-Menzel's
[31] method has the advantage of tolerating extraordinarily large attracting | masses (100,000 kg lead) without excessive difficulties, and moreover of allowing an effective four-fold attraction of this mass. However, the method suffers from the drawback that relieving and locking the balance becomes necessary in the course of determination.

7. Determinations with Plumbline and Pendulum

a. Static method (*plumbline deflection*). Deflecting masses were always mountains, and their deflection of the plumbline was determined by measuring the difference of geographical latitude between two points, if possible taken to the north and south of the deflecting mountain, once astronomically—where the direction of the plumbline enters—and then trigonometrically. The difference between the two determinations is twice the deflection caused by the mountain. The dimensions and the specific weight of the rocks determine the mass of the mountain.

Determinations of this kind were carried out by Bouguer[22] at Chimborazo, by N. Maskelyne and C. Hutton,[23] later by James[24] and Clarke at mountains in the Scottish highlands, by E. Pechmann[25] in the Alps and under particularly favorable conditions by E.D. Preston[26] on the Hawaiian islands.

It has been suggested to use the sea at low and high tide[27] or a drainable lake[28] instead of a mountain, but a determination never seems to have been performed this way, though it would have significant advantages over using a mountain.

b. Dynamical method (*pendulum observation*). The scheme of such determinations is the following. Either at the foot and the top of a mountain or on the Earth's surface and in the depth of a mine, the oscillation period of the same pendulum is observed. The measured difference in oscillation period and hence in the acceleration due to gravity at the two points | yields the attraction of the mountain or the layer of Earth [32] above the mine, respectively.[29]

Determinations of the first kind are due to Bouguer[22] (Cordills), Carlini[30] (and Plana) (Mont Cenis), under particularly favorable conditions from Mendenhall[31] (Fujiyama, Japan) and E.D. Preston[26] (Hawaiian islands).

Determinations of the second kind were first suggested by Drobisch,[32] later carried out by G.B. Airy[33] and in large number by R.v. Sterneck.[34]

A third method, in principle definitely more favorable, was attempted by A. Berget:[35] artificial alteration of g due to a difference in the water level of a drainable lake. However, his determination was spoiled by an unsuitable measurement of this change in g.

8. Calculation of the Gravitational Constant[36]

1. Laplace[37] based his calculations on the following conditions, as did Clairaut and Legendre:

a. The Earth consists of separate ellipsoidal layers. The density within each layer is constant.

b. The rotation is so slow that the deviation from the spherical shape becomes small, as well as the influence of the centrifugal force on g.

c. The Earth's substance shall be regarded as fluid.

Under these circumstances Laplace calculates the conditions of equilibrium, into
[33] which, besides the Earth's elliptical property, the | law expressing the density of an Earth layer as a function of its distance from the center enters. Laplace makes two assumptions for this law:

$$\rho = \rho_0[1 + e(1 - a)], \tag{1}$$

$$\rho = \frac{A}{a}\sin(an), \tag{2}$$

where ρ stands for the density, a for the distance of a layer to the Earth's center (Earth radius = 1), and ρ_0, e as well as A, n are constants. These constants are determined on the one hand by the value of ρ on the Earth's surface, and on the other hand by the derived equilibrium conditions. One then obtains a relation between the mean density of the Earth (and hence of the gravitational constant) and the Earth's surface density ρ_0; that is, from the first assumption regarding increasing density towards the center of the Earth, it follows that

$$\Delta_1 = 1.587 \cdot \rho_0,$$

and from the second assumption, that

$$\Delta_2 = 2.4225 \cdot \rho_0,$$

if the Earth's ellipticity is assumed to equal 0,00326.

2. On essentially the same basis, using Laplace's second assumption regarding increasing density towards the center of the Earth, Clairant's formula for the equilibrium of the rotating Earth, taken to be a fluid, and the value 0.00346 for the ellipticity of the Earth, J. Ivory[38] arrives at the relation:[39]

$$\Delta = 1.901 \cdot \rho_0.$$

3. The recent extensive literature on this question (Lipschitz, Stieltjes, Tisserand, Roche, Maurice Lévy, Saigey, Callandreau, Radau, Poincaré, Tumlirz) can not be discussed here; therefore we refer to the previously cited chapters in Tisserand[40] or to Vol. VI of the Encyclopedia.

9. The Result of the Determinations

Regarding the question of what should be taken as the most probable value for the gravitational constant, the results of the methods discussed in sections 7 and 8 must immediately be excluded. |

38 *Phil. Mag.* 66 (1825), p. 321 f.

39 Taking for the mean density all over the Earth surface S. Haughton's[33] value $\rho_0 = 2.059$, one would obtain according to Laplace: $\Delta_1 = 3.268$, $\Delta_2 = 4.962$, and according to Ivory: $\Delta = 3.914$.

40 Cf. note 36.[1]

Indeed, the terrestrial methods (section 7) actually carried out have the advantage [34] over laboratory methods (sections 4–6) in that the attracting masses and hence the differences to be observed have a relatively significant magnitude. But this advantage is more than outweighed by the fact that dimensions and density of the attracting masses are known only incompletely, and that the inadequately observed mass distribution below the place of observation plays an essential, but entirely uncontrollable, part.[41]

Those terrestrial methods, however, that could have had prospects for success, because not only do they allow for using very large masses, but also because the magnitude of the attracting masses could be determined with sufficient accuracy, and because the influence of the environment—such as change of magnitude or direction of g by a lake or the sea at different levels—would drop out, have not been carried out at all or were carried out only in a flawed manner.

The attempts to calculate the gravitational constant (section 8) can not provide a reasonably reliable result, either. Apart from other uncertainties, the mean surface density of the Earth enters this calculation, and this is far from being known with as much accuracy as the gravitational constant itself when obtained by laboratory determination.

Thus only the results of laboratory determinations remain (sections 4–6). Considering the two most recent determinations from each method only, we get the following compilation:

		Δ	G
Torsion balance	*Boys*	5.527	$6.658 \cdot 10^{-8}\ \mathrm{cm}^3\ \mathrm{s}^{-2}\ \mathrm{g}^{-1}$
	Braun	5.5270[a]	
(Double pendulum	*Wilsing*	5.577	$6.596 \cdot 10^{-8}\ \mathrm{cm}^3\ \mathrm{s}^{-2}\ \mathrm{g}^{-1}$)
Balance	*Poynting*	5.4934	$6.698 \cdot 10^{-8}\ \mathrm{cm}^3\ \mathrm{s}^{-2}\ \mathrm{g}^{-1}$
	Richarz and *Krigar-Menzel*	5.5050	$6.685 \cdot 10^{-8}\ \mathrm{cm}^3\ \mathrm{s}^{-2}\ \mathrm{g}^{-1}$
Mean value of these determinations		5.513[b]	$6.675 \cdot 10^{-8}\ \mathrm{cm}^3\ \mathrm{s}^{-2}\ \mathrm{g}^{-1}$

a. In copies issued later, Braun assumed the most probable result of his observations to be $\Delta = 5{,}52725$ (communicated by Prof. F. Richarz).

b. As we know, Newton (*Principia lib. III, prop. X*) estimated the Earth's mean density to be 5–6. The mean 5.5 thus agrees with the mean value from the most recent measurements to $1/4$ %.

41 Cf. W.S. Jacob, *Phil. Mag.* (4) 13 (1857), p. 525–528. Conversely, such determinations can be significant because they allow for a conclusion about mass distribution close to the place of observation. Cf. R. v. Sterneck's *Messungen*.[34]

[35] | The good agreement[42] between the values obtained by the same method on the one hand, and the relatively significant disagreements among results of different methods[43] on the other, show that these disagreements can only be due to deficiencies in principle of the methods. As long as these have not been cleared up, none of the results can be given more weight than another. It is a pity that Wilsing's method has not yet been employed by a second observer to check Wilsing's result, and that the influence of magnetic permeability of the double pendulum has not yet been examined.[44] Therefore, we did not take Wilsing's result into consideration in the calculation of the mean value above.

2. ASTRONOMICAL AND EXPERIMENTAL TESTS OF NEWTON'S LAW

10. General

Two independent fields insure that Newton's law, even if not absolutely accurate, represents real conditions with a far-reaching accuracy unmatched by hardly any other law.

In the *astronomical*[45] domain, this law yields planetary motions not only to the first approximation (Kepler's laws); but even to the second approximation, the deviations of planetary motion due to pertubations by other planets follow from Newton's law so accurately that the observed perturbations led to the prediction of the orbit and relative mass of a hitherto unknown planet (Neptune).

[36] On the other hand there are a number of astronomical | observations that show deviations compared to calculations based on Newton's law. This deviation amounts to[46]

1. ca. 40″ per century in the perihelion motion of Mercury;
2. 5-fold probable error in the motion of the node of Venus' orbit;
3. 3-fold probable error in the perihelion motion of Mars; and
4. 2-fold probable error (uncertain!) in the eccentricity of Mercury's orbit.

In addition there are:

5. significant anomalies in the motion of Encke's comet; and

---

42 Between torsion balance determinations there is a difference ≤ 0.012 %, between balance determinations there is a difference of ca. 0.2%.

43 The largest difference between balance and double pendulum determinations is ca. 1.5%.

44 According to F. Richarz and O. Krigar-Menzel (*Bemerkungen zu dem ... von Herrn C.V. Boys über die Gravitationskonstante ... erstatteten Bericht*, Greifswald 1901) the deviation of Wilsing's result from others could be caused by such an influence.

45 Discussion of the validity of Newton's law in the astronomical domain in Tisserand, *Méc. cél*. 4 (1896), chap. 29 and S. Newcomb.[48]

46 S. Newcomb, *The elements of the four inner planets* etc., Washington 1895. On page 109 ff. is a discussion of possible explanations of these deviations.

6. small irregularities in the Moon's orbit.

Small corrections of Newton's law are therefore not excluded by the astronomical evidence,[47] even if it is not at all settled—particularly in the cases listed in 5) and 6) where conditions are more complicated and uncertain than for planetary orbits—that the above differences are due to an inaccuracy of the gravitational law.[46]

In the *experimental* area the best determinations of the gravitational constant, which all rest on the assumption of the validity of Newton's law, yield results in rather good agreement.[48] As these determinations were carried out with masses of a great variety of magnitudes, materials and distances, this agreement therefore excludes any considerable inaccuracy of | Newton's law, and allows at most for small [37]
corrections.

11. Dependence on Mass: Astronomical Test

Newton inferred that the force that two bodies exert on each other is proportional to the mass of each body as follows:

a. Observation shows Jupiter conferring *acceleration* to its satellites, the Sun to the planets, Earth to the Moon, and the Sun to Jupiter and its satellites, which is equal at equal distance. Hence, it follows that in these cases the *force* must be proportional to the mass of the *attracted* body.

47 Th. von Oppolzer (*Tagebl. d. 54. Vers. d. Naturf. u. Ärzte*, Salzburg, 1881) even draws quite an apodictic conclusion: "The theory of the Moon makes a conjecture quite probable, the theory of Mercury points at it firmly, Encke's comets lift it up to an irrefutable certainty that the theories built solely on Newton's law of attraction *in present form* are not sufficient for explaining the motion of heavenly bodies."

48 To compare the best terrestrial and laboratory methods:

	Observer	attracting mass	Δ
Laboratory methods	*Boys*	7.4 kg	5.527
	Braun	9.1 "	5.5270
	Poynting	154 "	5.4934
	Wilsing	325 "	5.577
	Richarz and *Krigar-Menzel*	100.000 "	5.5050

	Observer	attracting mass	Δ	
Terrestrial methods	*Mendenhall*	mountain of 3.800 m height	5.77	
	E. D. Preston	" 3.000 "	5.57	5.35
	"	" 4.000 "	5.13	
	von Sterneck	strata of various thickness	5.275	
	(Wien. Ber. 108)	"	5.56	
	"	"	5.3	
	"	"	5.35	

b. The principle of action and reaction then implies that the force must be proportional to the mass of the *attracting* body as well.

M.E. Vicaire[49] raised the following objection against this line of reasoning, which would however require discussion.[50] The examples presented represent a very special case: a very large body attracting a relatively very small body. But then the assumption that at equal distance the attraction can only be a function of the two masses already provides the result that the attractive force must be approximately proportional to the small body's mass.

This is because the function A_{Mm}, which expresses the attraction a large mass M has on small mass m, is certainly homogeneous in M and m. One can hence put: |

[38]

$$\begin{aligned} A_{Mm} &= M^k \cdot f(\frac{m}{M}) \\ &= M^k \Big[\frac{m}{M} \cdot f'(0) + \Big(\frac{m}{M}\Big)^2 \cdot \frac{f''(0)}{1 \cdot 2} + \ldots\Big] \\ &= M^{k-1} \cdot m \cdot f'(0) \qquad \text{approx.}, \end{aligned}$$

so the attraction is to first approximation proportional to m. Hence, from the fact that this proportionality is confirmed by observation, one must not conclude that the attraction is also proportional to the mass of the attracting large body. However, from this it would follow that calculations of planetary masses in relation to the Sun's mass based on Kepler's third law are in principle misguided.

Vicaire also objects to supporting these calculations by the usual calculations from the planetary perturbations. The *secular* perturbations of a planet m by another m', which are primarily observed and drawn upon in these calculations, do not at all result in the relative mass of planet m', but in the proportion $A_{mm'} : A_{Mm}$, which according to the above does not need to be identical to $m' : M$. Only the *periodic* perturbations could provide information about $m' : M$.

12. Dependence on Mass:
Experimental Test for Masses of the Same Material

The G-determinations of Poynting[2] and of Richarz and Krigar-Menzel[2] are of special value in relation to the question of how far the proportionality of the attractive force to the mass is guaranteed for masses of the same material. Both experimenters used unobjectionable laboratory methods carried out with the greatest care. Both

49 Paris, *C.R.* 78 (1874), p. 790–794.

50 This is opposed by the agreement within probable error between the mass of the planets determined from the perturbations which they exert on other planets, and the mass of the same planets determined from the motion of their moons, if they have any. For example, the mass of Mars from Jupiter's perturbations results in $= 1/2.812.526$, from the elongation motions of its moons $= 1/3.093.500$. Cf. as well F.W. Bessel, *Berl. Abh.* 1824 and *Ges. Werke* 1, p. 84.

determinations employed the same material (lead) and the same method of measurement, but masses of very different magnitudes (154 or 100.000 kg). Even though in one case the mass was 650 times greater than the other, the results agree to approximately 0.2%.

13. Dependence on Mass: Experimental Test for Masses of Various Chemical Compositions

Three different methods have been used to examine whether the proportionality of the attractive force to mass is also strictly valid for masses of different chemical compositions.

a. The gravitational constant was determined for masses of different materials.

F. Baily[9] carried out a large number of measurements of this kind. If his results are arranged according to the specific weight | of the mass which was suspended from [39]
the torsion balance,[51] and if we take for each material the mean value from all measurements, the following is revealed. The values of Δ increase—the values of G decrease accordingly—as the specific weight of the mass is decreased.[52] However, there is reason to assume that these disagreements are a matter of a basic error in his arrangement or calculation.[53]

In any case, the fact that the results of Boys[11] and Braun[12] agree to 0.01%, although they refer to different materials, counts against the assumption that these different results are due to a different value of the gravitational constant for different substances. Likewise, with the help of a particularly sensitive torsion balance, v. Eötvös[16] claims to have found that the difference of attraction of glass, antimony, and corkwood from that of brass is less than $1/2 \cdot 10^{-7}$ and of air from that of brass less than $1 \cdot 10^{-5}$ of the total attraction.

b. Pendulums were produced out of various materials to compare their periods of oscillation.

---

51 Same attracting substance everywhere = lead.

52

Substance	specific weight	Δ	
Platinum	21	5.609	
Lead	11.4	5.622	
Brass	8.4	5.638	
Zinc	7	5.691	
Glass	ca. 2.6	5.748	exception
Ivory	1.8	5.745	

53 Cf. also F. Reich in the paper cited in note 8, "*Neue Versuche* etc.", p. 190.

This method, already employed by Newton,[54] has been refined by F.W. Bessel,[55] in particular. While Newton could only conclude from his experiments that the difference of attraction which the Earth exerts on bodies of very different composition is smaller than $1 \cdot 10^{-3}$ of the total attraction, Bessel managed to squeeze this limit down to $1/6 \cdot 10^{-4}$.

c. A sealed vessel which contains two different chemical substances is weighed, then the substances combine, and after completion of the chemical reaction the vessel is weighed again. |

[40] The first experiments of this kind by D. Kreichgauer[56] with mercury and bromine, and with mercury and iodine gives the result "that with the bodies employed, a change of attraction by the Earth due to chemical forces should stay below 1/20,000,000 of the total attraction." But H. Landolt[57] found under conditions as simple as possible—except for reactions, where a change of weight could not be determined with certainty—the following:

1. For reduction of silver sulphate by ferrosulphate in three series of experiments, a weight decrease by 0.167, 0.131 and 0.130 mg.

2. For iodic acid and hydrogen iodide weight decreases in six experimental series, varying between 0.01 and 0.177 mg.

Not only do these decreases in weight exceed probable measurement errors, but some of them also exceed the largest deviation among single measurements. A. Heydweiller[58] resumed these measurements after M. Hänsel[59] established that the deviations observed by Landolt in the first example can not be explained by the influence of magnetic forces. He also obtains decreasing weight in a series of cases and reaches the conclusion: "one may regard a change in weight as ascertained: in the effect iron has on copper sulphate in acid or basic solution ... , regarding the dissolution of acid copper sulphate ... , and in the effect potassium hydroxide has on copper sulphate ... ."

The cases presented above are therefore *well established but for the time being completely unexplained deviations from the proportionality of the action of gravity to mass*.

57 *Zeitschr. physik. Chem.* 12 (1894), p. 11. He cites that in the synthesis of iodine and bromide silver J. S. Stas always obtained less than equivalent of the initial quantities. Indeed, the difference amounted on average in five experiments to $1/4 \cdot 10^{-4}$ of the total mass.

58 *Ann. Phys.* 5 (1901), p. 394–420.

59 Diss. Breslau 1899.

14. Dependence on Mass:
Experimental Test for Masses of Various Structures

The conjecture that attraction between two masses could depend on their structure is suggested by several theories explaining gravitation. This was examined experimentally in two directions. |

a. Kreichgauer[56] examined whether a body (acetic sodium) changes weight while crystallizing. He found, however, that any change of weight is below $1/2 \cdot 10^{-7}$ of the total attraction.[60] [41]

b. A. S. Mackenzie[61] as well as J. H. Poynting and P. L. Grey[62] deal with the question of whether the gravitational effect of a crystalline substance varies with different directions. Mackenzie tested calcite against lead, and also calcite against calcite, but he found the difference to be smaller than 1/200 of the total attraction. Poynting and Grey arrive at the result that the attraction of quartz to quartz at parallel and crossed axes differs less than 1/16500 of the total attraction, and that at parallel axes, when one of the crystals is rotated by 180°, the attraction changes by less than 1/2850 of the total.

15. Dependence on Distance: Astronomical Test (cf. Vol. VI)[2]

S. Newcomb[63] discussed the question of the extent to which the $1/r^2$ in Newton's law is fixed by astronomical data. He reaches the following result:

a. The agreement between the observed parallax of the Moon and that calculated from the magnitude of g on the Earth surface shows that for values of r that lie between Earth's radius and the radius of the Moon's orbit, the 2 in r^2 is guaranteed up to 1/5000 of its value.

b. The agreement between the observed perturbation of the Moon by the Sun and the calculation based on Newton's law proves (with about the same accuracy) the validity of r^2 up to distances of the order of magnitude of the Earth's orbit, i.e. approximately up to 24000 times the Earth's radius.

c. The validity of Newton's law up to the limits of the entire planetary system follows from the validity of Kepler's third law; that is, up to distances which amount to 20 times the Earth orbit's radius. Yet for this range the | accuracy with which $1/r^2$ [42] can be established from observation cannot be stated with certainty.

One more touchstone of the same question, as Newton[64] already emphasized, is related to the fact that *perihelion motion* of the planets would result from a deviation in the exponent of the distance from 2. While on the one hand such a deviation can

---

60 Earlier Bessel,[57] and more recently von Eötvös,[16] found no difference between crystalline and amorphous bodies in their experiments.

61 *Phys. Rev.* 2 (1895), p. 321–343.

62 *Lond. Trans.* A 192 (1899), p. 245–256.

63 In the paper cited in note 46.

64 *Principia lib. I, sec. IX.*

not be large, because otherwise this would result in perihelion motions which contradict observation, on the other hand the observed anomalous perihelion motions could be rooted in a minor inaccuracy of the gravitational law. Indeed, M. Hall[65] proved that the law previously examined by G. Green,[66] which replaces $1/r^2$ with $1/r^{2+\lambda}$, where λ stands for a small number, is sufficient to explain the anomalous perihelion motion of Mercury, if $\lambda = 16 \cdot 10^{-8}$. This figure for λ would also give the right result for the observed anomalous perihelion motion of Mars, though for Venus and Earth the consequence would be somewhat too large a perihelion motion.[67] However, Newcomb, after discussing the respective conditions, states that Hall's assumption seems to him "provisionally not inadmissible."

16. Dependence on Distance: Experimental Test

This question was examined directly by Mackenzie,[61] by measuring at various distances the attraction of the same bodies with the torsion balance. He found that the discrepancy between the observed result and that calculated from Newton's law is in any case smaller than 1/500 of the total attraction.

From a theoretical perspective, our confidence in the 2 in the exponent of Newton's law stems essentially from the fact that from the standpoint of field theory (section 34) this law alone is compatible with the assumption of a general, source-free distribution of field strength; i.e., the concept of lines of force of the gravitational field is meaningful only if this law is valid precisely.

17. Influence of the Medium on Gravitation

The analogy of electric and magnetic charges, whose effect depends to a large degree on the medium in which they are contained, makes it seem altogether possible that [43] such an influence is present in gravitation | as well, and that hence the gravitational constant is not universal, as Newton assumed, but rather depends on the medium. Just the relatively good agreement, in spite of the very different *form* of the employed masses, among G-determinations excludes a fairly considerable influence of bodies in the region between the attracting masses.[68] Furthermore, with a torsion balance L.W. Austin and C.B. Thwing[69] directly examined the question of whether a body with a different permeability for gravitation than air exists. Between two bodies attracting each other they inserted plates of various substances whose thickness was 1/3 the distance between the attracting masses. The result was that the difference would have to be smaller than 0.2% of the total attraction.

In another direction, Laplace[70] discussed the question of a possible influence of the medium. He assumes that bodies except air may possess a small absorption coef-

---

65 *Astr. Journ.* 14, p. 45.

66 *Cambr. Trans.* 1835, p. 403.

67 Cf. Newcomb in the paper cited in note 46, p. 109.

ficient α for gravitation so that the gravitational law for two mass elements m_1 and m_2 embedded in such a medium would be:

$$K = G\frac{m_1 \cdot m_2}{r^2} \cdot e^{-\alpha r}.$$

The application of this law to the Sun-Moon-Earth system, however, leads him to the conclusion that the value for Earth (radius R) would have to be:[71]

$$\alpha R < \frac{1}{10^6}.$$

18. Influence of Temperature

Some mechanical theories about the nature of gravitation[72] make it seem quite possible that the gravitational effect is modified by the temperature of | the medium. A [44]
direct examination of this question has not yet been carried out; however, von Jolly points out that in his absolute determinations, the temperature difference was maximally 29.6°, without any difference in the results exceeding the magnitude of experimental error.

19. Dependence on Time: Constancy

The tacit assumption of the gravitational effect's independence on time in Newton's law has been challenged in two respects:

a. Is the gravitational constant also a constant with respect to time, or does it change over the course of time?

b. Does gravitation need time to take effect—does it have a finite speed of propagation, or is the gravitational effect instantaneous?

---

68 Wilsing uses long cylinders, Boys and Braun use spheres, Richarz and Krigar-Menzel use cubes, nevertheless good agreement, namely:

Wilsing	$\Delta = 5.577$	Difference 0.9%
Boys and *Braun*	$\Delta = 5.527$	" 0.4%.

70 *Méc. Cél.* 5, book XVI, chap. IV, §6.

71 Poynting presents an indirect proof against the existence of a specific gravitational permeability: A deflection (refraction) of the gravitational effect has never been observed. However this question appears not to have been carefully examined to date.

72 Cf. part V of this article.

R. Pictet[73] discussed the first question based on the idea that gravitation is caused by impacts of aether particles.[72] His reasoning is the following: The total energy of the solar system consists of two parts: 1) the *vis viva* of planets and Sun; 2) the *vis viva* of aether particles. The *vis viva* of planets varies strongly depending on their momentary position with respect to the Sun. If the total energy of the solar system remains constant, then it follows that the *vis viva* of aether atoms and thereby the gravitational constant have to change with the course of time.

Experiments to prove such a temporal change of the gravitational constant would have a chance to succeed according to R. Pictet and P. Cellérier,[74] since the difference in the *vis viva* of the planets—the decisive ones are Jupiter and Saturn—e.g., between the minimum of year 1898–99 to the maximum of 1916–17, comes to about 18%.

20. Dependence on Time: Finite Speed of Propagation[75]

The second question, whether gravitation operates instantaneously or has a finite speed of propagation, was examined recently in terms of planetary motion by R. Lehmann-Filhès[76] and J. v. Hepperger.[77] |

[45] Both works introduce a finite propagation velocity in the same way. At the moment when the planet (mass m) is at distance r from the Sun (mass M), the force $G \cdot M \cdot m/r^2$ as per Newton's law is propagated from the Sun with a finite velocity. This force then takes effect on the planet at a time when its distance from the Sun is different from r in direction as well as in magnitude. The same holds for the force that the planet exerts on the Sun.

There is some difference between Lehmann-Filhès and von Hepperger in their equations of motion, as the former takes the Sun's velocity, the latter the velocity of the Sun's and the planet's center of gravity, to be constant.

Both arrive at the result that the most influential change of planetary motion would be a secular change of the mean radius. From this it follows: first, that the introduction of a finite speed propagation *while retaining Newton's law* does not contribute anything to remove the difficulties regarding planetary orbits as presented on p. 86 [p. 36]; and second that the hypothetical propagation velocity would have to be much larger than the velocity of light, because otherwise a secular change of the mean radius would result, by an amount that would contradict observation. If the velocity of the Sun's proper motion lies between 1 and 5 km/sec,[78] then the propaga-

tion velocity of gravitation would have to be at least 500 times larger than the velocity of light, according to v. Hepperger.

A stricter test of the assumption of a temporal propagation velocity is provided by its application to the Moon's motion, as carried out by R. Lehmann-Filhès.[79] He draws the conclusion that in order to keep the perturbations of the Moon's radius below an acceptable amount while retaining Newton's law, the propagation velocity of gravitation would have to be given an enormous value, perhaps a million times the velocity of light. Also the sign of the perturbation does not correspond to the discrepancy found between observation and theory for the Moon.

Th. v. Oppolzer[47] comes across similar difficulties when | applying the assumed [46]
finite propagation velocity to calculate orbits of comets.

3. EXTENSION OF NEWTON'S LAW TO MOVING BODIES[80]

21. Transferring Fundamental Electrodynamic Laws to Gravitation

The result of the attempts to introduce a finite propagation of gravitation while retaining Newton's law for moving bodies as well, and thereby to remove the existing disagreements between observation and calculation, must be characterized as rather unsatisfactory. It is therefore small wonder that attempts were made to question the validity of Newton's law for moving bodies, to regard it merely as a special case for bodies at rest, and to replace it with an extended law for moving bodies.

Above all it was examined whether the previously known electrodynamic fundamental laws were sufficient for this purpose.

C. Seegers[81] and G. Holzmüller[82] applied Weber's fundamental law, according to which the potential for two mass elements m_1 and m_2 at a distance r is

$$P = \frac{G \cdot m_1 \cdot m_2}{r^2}\left[1 - \frac{1}{c^2} \cdot \left(\frac{dr}{dt}\right)^2\right] \qquad (c = \text{velocity of light}),$$

which as is well known Zöllner thought to be the fundamental law of all action-at-a-distance forces, to planetary motion in general, and the planetary motions were calculated numerically by F. Tisserand[83] and H. Servus.[84] For Mercury, the application of Weber's law results in an anomalous secular perihelion motion of ca. 14''.

82 *Zeitschr. Math. Phys.* 1870, p. 69–91.

83 Paris, *C. R.* 75 (1872), p. 760 and 110 (1890), p. 313.

84 Diss. Halle 1885. F. Zöllner cites (based on correspondence) that W. Schreibner calculated a secular perihelion motion of 6.7″ for Mercury based on Weber's law. The reason for this figure's two-fold deviation from the figures cited in the text is that Schreibner equates the constant c in Weber's law with $\sqrt{2}$ times the velocity of light.

Transferring Gauss'[85] fundamental electrodynamic law to gravitation, in the sense that one introduces an attractive force K between two mass elements with co-ordinates x_1, y_1, z_1 and x_2, y_2, z_2, given by: |

[47]
$$K = \frac{G \cdot m_1 m_2}{r^2}\left\{1 + \frac{2}{c^2}\left[\left(\frac{d(x_1 - x_2)}{dt}\right)^2 + \left(\frac{d(y_1 - y_2)}{dt}\right)^2 + \left(\frac{d(z_1 - z_2)}{dt}\right)^2 - \frac{3}{2}\left(\frac{dr}{dt}\right)^2\right]\right\},$$

gives a secular perihelion motion of Mercury of only 28", according to F. Tisserand's[86] calculation.

Riemann's[87] fundamental law

$$P = \frac{G \cdot m_1 \cdot m_2}{r}\left\{1 - \frac{1}{c^2}\left[\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2\right]\right\}$$ (x, y, z are co-ordinates of m_1 relative to m_2),

would imply, according to M. Lévy,[88] twice the perihelion motion of Mercury that follows from Weber's law.

Therefore, Levy suggested a combination of Riemann's and Weber's laws in the form:

$$\begin{aligned} P &= P_{Weber} + \alpha(P_{Riemann} - P_{Weber}) \\ &= \frac{G \cdot m_1 \cdot m_2}{r}\left\{1 - \frac{1}{c^2}\left[(1-\alpha)\left(\frac{dr}{dt}\right)^2 + \alpha\left(\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2\right)\right]\right\} \end{aligned}$$

where α was then to be determined from the observed secular perihelion motion of Mercury. Assuming the perihelion motion of $38''$ as observed and $14.4''$ [89] as given by Weber's law, one finds $\alpha = 1.64 =$ approx. $5/3$. [88] On the basis of a perihelion motion of Mercury of $41.25''$, as given by other observers, and a motion given by Weber's law of $13.65''$,[89] α becomes $= 2.02$.

The law one obtains in this way has the decisive advantage of matching the achievement of Riemann's and Weber's laws in electrodynamics, and moreover it represents an extension of Newton's law to moving bodies that eliminates the worst disagreement between observation and calculation that has persisted until now.

22. Transferring Lorentz's Fundamental Electromagnetic Equations to Gravitation

H.A. Lorentz[90] has attempted to use Maxwell's equations,[91] as extended by him to moving bodies, for gravitation. His conception | of the constitution of gravitating [48] molecules is essentially in agreement with that of F. Zöllner, though in slightly modernized form. The foundation of Lorentz's approach is covered in section 36.

The additional forces Lorentz obtains, apart from the ones given by Newton's law, have a factor of either $(p/c)^2$ or $(p \cdot w)/c^2$, where p is the velocity of the central body taken to be constant, w is the velocity of the planet relative to the central body, and c is the velocity of light. These additional forces are so small that they will probably be beyond observation in all cases; in the case of Mercury they are certainly below what is observable, as shown by Lorentz's calculation. It follows that Lorentz's equations, combined with Zöllner's conception of the nature of gravitating molecules, can be applied to gravitation,[92] but they do not contribute to removing existing disagreements between observation and calculation.

23. Laplace's Assumption

Previously Laplace[93] envisaged an extension of Newton's law for moving bodies in quite a different way. He seems to imagine the force coming from an attracting body m_1 as a sort of wave, which exerts an attractive force on each body m_2 it encounters of magnitude $G \cdot m_1 m_2 / r^2$ in the direction in which it propagates. The effect such a wave has on a moving body m_2 depends only on the relative motion of wave and body. One can thus imagine body m_2 at rest in space, if one ascribes to the wave another velocity component apart from its velocity in the r-direction, equal and opposite to the velocity of m_2. If $v =$ velocity of m_2 and c indicates the propagation velocity of gravitation, then the body m_2 receives a force component opposite to its orbit's direction and of value $(m_1 m_2 / r^2) \cdot (v/c)$,[94] rather than receiving only a force component in the r-direction. |

Following through with this point of view gives little satisfaction with respect to [49] the planets: it does not result in a perihelion motion at all, but in a secular change of the mean radius; e.g., this change for the Moon has a value such that the lowest limit for c would have to be about 100,000,000 times the velocity of light. It is, however, not uninteresting that Laplace's conception achieves the same effect as a *resistance of the medium* proportional to the velocity of the planet.

---

90 *Amsterdam Versl.*, April 1900.

91 Harlem, *Arch. Néerl.* 25 (1892), p. 363.

92 This includes the possibility that *the propagation velocity of gravitation is equal to the velocity of light*.

93 *Méc. cél.* 4, book X, chap. VII, §19 and 22.

94 These conditions would therefore correspond completely with those for the aberration of light.

According to Encke[95] and v. Oppolzer,[96] a resistance of the medium—however, proportional to the square of the velocity—could perhaps explain the irregularities of Encke's comet presented on p. 36. The anomalies of Winnecke's comet, presupposed by Oppolzer and explained the very same way, have since been shown to be non-existent by E. v. Haerdtl's[97] calculations.

24. Gerber's Assumption

P. Gerber's[98] two premises are:

a. The potential P transmitted from a mass μ to a second one m is $\frac{\mu}{r}$, where r is the distance from μ to m *at the moment of transmitting* the potential. This potential propagates with finite velocity c.

b. A certain time is necessary for the potential "to reach m, to impart itself to the mass; i.e., to evoke in m the state of motion corresponding to the potential." "If the masses are at rest, the motion of the potential passes m with its own velocity; then its value transmitted to m is in inverse proportion to the distance. If the masses speed towards each other, the time of transmission as well as the transmitted potential decrease proportionally to the ratio of the characteristic velocity of the potential to the sum of its and the masses' velocity, as the potential has this total velocity relative to m."

Gerber arrives at the value that the potential must have under these assumptions in the following manner:

"The potential moves with the velocity of the attracting mass in addition to its
[50] own velocity c. The space $| r - \Delta r$[99] traversed in time Δt by the two motions, one of the potential and the other one of the attracted mass, is thus

$$\Delta t\left(c - \frac{\Delta r}{\Delta t}\right),$$

while $r = c\Delta t$. So for the distance where the potential starts developing and to which it is in inverse proportion, one obtains

$$r - \Delta r = r\left(1 - \frac{1}{c}\frac{\Delta r}{\Delta t}\right).$$

Since, moreover, the velocity with which the motions pass each other has the value

$$c - \frac{\Delta r}{\Delta t},$$

95 Cited by von Oppolzer.

97 *Wien. Denkschr.* 56 (1889), p. 179 f.
98 *Zeitschr. Math. Phys.* 43 (1898), p. 93–104.
99 $\Delta r > 0$ for increasing r.

the potential turns out also to be proportional to

$$\frac{c}{c - \frac{\Delta r}{\Delta t}}.$$

due to the time consumed to impart itself to m. Thus one finds:

$$P = \frac{\mu}{r\left(1 - \frac{1}{c}\frac{\Delta r}{\Delta t}\right)^2}.$$

As long as the distance Δr is short and therefore $\Delta r / \Delta t$ small compared to c, one may replace the latter by dr/dt. So it becomes

$$P = \frac{\mu}{r\left(1 - \frac{1}{c}\frac{dr}{dt}\right)^2},$$

from which it follows with help of the binomial law to the second power:

$$P = \frac{\mu}{r}\left[1 + \frac{2}{c}\frac{dr}{dt} + \frac{3}{c^2}\left(\frac{dr}{dt}\right)^2\right]."$$

The application of this equation to planetary motions yields the following remarkable result: If the propagation velocity c is determined from Mercury's observed perihelion motion, then one finds $c = 305.500$ km/sec, which is the velocity of light with surprising accuracy. In other words, *if in Gerber's equation the velocity of light replaces the propagation velocity of gravitation, then this equation yields exactly the observed anomalous perihelion motion of Mercury.*

No difficulties for the other planets follow from Gerber's assumption, | except for [51]
Venus, where Gerber's approach gives a slightly too large secular perihelion motion of $8''$.

Gerber's assumption thus shows, as does Lévy's, that a propagation velocity of gravitation of the same magnitude as the velocity of light is not only possible, but can also serve to eliminate the worst disagreement that has existed between astronomical observation and calculation so far. To be sure, this was achieved only by confining the validity of Newton's Law to bodies at rest and postulating an extended law for moving bodies.

4. EXTENSION OF NEWTON'S LAW TO INFINITELY LARGE MASSES

25. Difficulty with Newton's Law for Infinitely Large Masses

Doubts have been expressed concerning the universal validity of Newton's law leading in quite a different direction, and the necessity of an extension has been considered.

In case the universe contains infinitely many masses, to obtain the force acting at any point one would strictly speaking have to solve the problem: to specify the effect of infinitely many masses of finite size at one particular point.

C. Neumann[100] was probably the first to point out that in this case the forces resulting from Newton's law may become indefinite. H. Seeliger[101] examined this question in a more general way, and showed that for infinite masses Newton's law can produce infinitely large forces as well as leaving them completely indefinite.

26. Elimination of the Difficulty by Altering the Law of Attraction

Seeliger suggests a slight modification of Newton's law in order to eliminate this difficulty, and he discusses various possibilities.

The form already discussed by Laplace

$$K = \frac{G \cdot m_1 \cdot m_2}{r^2} \cdot e^{-\alpha r}$$

[52] | is physically expected to suffice for the above purpose, as it corresponds to the assumption of absorption by the medium. In fact, it does suffice, and would moreover have the advantage of giving planetary perihelion motion. Yet the value of $\alpha = 0.00000038$ taken from Mercury's observed perihelion motion gives perihelion motions for the other planets which are difficult to reconcile with observations.[102]

The laws discussed by C. Neumann, according to which the potential P takes the form

$$P = G \cdot m_1 m_2 \left(\frac{Ae^{-\alpha r}}{r} + \frac{Be^{-\beta r}}{r} + \ldots \right),$$

serve the same purpose, but the resulting perihelion motions of the planets stand in severe contradiction to observation.

In contrast, Green-Hall's law discussed earlier,

102 *Münchn. Ber.* 26 (1896), p. 388.

$$P = \frac{G \cdot m_1 m_2}{r^{1+\lambda}},$$

which would be suitable to account for the perihelion motions of the planets, retains the same problems as Newton's law with regards to infinite masses.

27. Elimination of the Difficulty by Introducing Negative Masses

A. Föppl[103] introduced the idea that the difficulty of Newton's law emphasized by Neumann and Seeliger is to be eliminated by introducing "negative masses" and maintaining the law, rather than by altering the form of the law. As with the gravitational force lines emitted by the familiar positive masses, there would be force lines flowing into negative masses. If the sum of the negative masses is taken to equal that of the positive ones, the total would be 0; as in the electric and the magnetic domain there would be the same number of sources and sinks.

With this assumption, the expression for field energy cannot be based upon the usual one,

$$\frac{1}{2} a |\mathfrak{R}|^2 dS,$$

where a is a constant of the medium, $\mathfrak{R}$ the vector of field strength defining the gravitational field, $|\mathfrak{R}|$ its | absolute value, and dS a volume element. Rather, as Maxwell [53]
already pointed out, one must replace this expression by

$$\left(C - \frac{1}{2} a |\mathfrak{R}|^2\right) dS \qquad (C = \text{constant})$$

to obtain an attraction between masses of the same sign. Cf. section 34 regarding the significance of the constant C.

Prior to Föppl, C. Pearson[122] had already suggested the mere introduction of negative masses of the same magnitude as the familiar positive masses. This suggestion is actually a consequence of his theory, which attempts to derive electrical, optical, chemical and gravitational phenomena from suitably chosen aether motions.

The introduction of negative masses hardly causes any problems. For the fact that repulsion between two masses has never been observed, i.e. a negative mass has never been noticed, points to the possibility—though not to the necessity—that such masses were driven to spaces no longer accessible to observation due to the repulsion from positive masses in our system. On the other hand, according to A. Schuster,[104] who had the same thought (though merely in a "holiday dream"), the introduction of negative masses could perhaps serve to shed completely new light upon several phenomena, such as comet tails.

5. ATTEMPTS TO EXPLAIN GRAVITATION THROUGH MECHANICS[105]

28. Pressure Differences and Currents in the Aether[106]

The conjecture that gravitation could be caused by *pressure differences* in the supposedly homogeneous aether surrounding gravitating | masses stems from Newton[107] himself. According to him the aether would become denser the further it is from masses. Since each body has the tendency—later on he speaks of an elastic force of the medium—to go from the denser parts of the medium to the less dense ones, each of the two bodies must move in the direction of the other.
[54]

Similar ideas have been worked out by Ph. Villemot,[108] L. Euler,[109] J. Herapath[110] and in a slightly different way by J. Odstrčil.[110]

A consequence of the assumption of pressure differences in the aether, combined with the idea that aether behaves like a fluid or a gas, is that *aether currents* must flow into the atoms.[3] According to J. Bernoulli,[108] B. Riemann,[111] and J. Yarkovski,[112] it is these aether currents which carry the body along and hence cause gravitation. G. Helm,[150] as well as C. Pearson,[113] arrived at a similar conception while trying "to explain gravitation with energy transfer in the aether."

Yarkovski pondered the question of the *cause* of the aether currents, but produced an explanation that is physically not tenable.

Among the many objections raised against these theories, there is also the question of what happens to the aether that flows into the atoms. There are only two possible answers: either the aether accumulates or it disappears inside them. Bernoulli, Helm, Yarkowski have decided for the former possibility; Riemann for the latter, who allows matter in ponderable bodies constantly to make a transition "from the physical world into the spiritual world."

29. Aether Vibrations

The idea that aether vibrations in the form of longitudinal waves may cause not only the phenomena of light and heat, but also gravitation, has been developed in two directions. |

1. According to the first view the attracting body, or its atoms, are supposed to [55]
vibrate themselves; these vibrations pass on to the aether, propagate to the attracted body and cause its approach.

Hooke,[114] Newton's inventive rival, already expressed this conception, which was taken up again by J. Guyot and F. Guthrie. The latter two seem to have arrived at this through the observation that light objects close to a vibrating body are pushed towards it. However, the fact that the approach takes place only under very particular conditions, and that under different conditions one observes an apparent repulsion—such was also included by F.A.E. and E. Keller[115] for explaining gravitation—proves that the assumption of an elastic aether and vibrating atoms does not suffice to explain gravitation. There must be at least one more assumption which produces conditions that guarantee an *attraction* under all circumstances.

To find these conditions, J. Callis[116] examined the following question analytically and in detail: What effect do longitudinal waves in a fluid whose pressure changes proportionally to changes in density, have on small inelastic, smooth spheres embedded in the elastic fluid medium? He reaches the conclusion that if the wave length is large compared to the spheres' radius, the spheres are then pushed towards the center of the spherical wave. For explaining gravitation, one would thus need to assume that there are vibrations whose wave lengths in the aether are large compared to the dimensions of the gravitating atoms.

A deficiency of this treatment is the requirement that only the attracting body emits waves. Such a principled differentiation between attracting and attracted body is incompatible with the nature of gravitation. The question must not be what effect do spherical waves have on bodies at rest, but rather what effect do they have on a body which is itself vibrating.

This complete problem was probably first handled mathematically by C.A. |
Bjerknes,[117] for the case of an incompressible aether and pure pulsation of the [56]
spheres (atoms). He proved that two pulsating spheres, whose radius is small compared to their separation, show an apparent attraction, and that this attraction is proportional to the intensity of pulsation and inversely proportional to the square of distance, if their pulsations agree in frequency and phase. If gravitation is to be attributed to pulsating atoms and molecules,[2] then at least the following additional assumptions are needed:

---

114 Cf. W.B. Taylor[105] and F. Rosenberger.[1]

115 Paris, *C. R.* 56 (1863), p. 530–533; also cf. Taylor.[105]

116 E.g. *Phil. Mag.* (4) 18 (1859), p. 321–334 and 442–451, cf. Taylor[105] about other work by Callis.

117 Cf. the compilation in V. Bjerknes, "Vorlesungen über hydrodynamische Fernkräfte nach C.A. Bjerknes' Theorie", Leipzig 1900.

a. The pulsations of all atoms or molecules must agree in frequency and phase.

b. The intensity of pulsation must be proportional to the mass.

There is one more thing. A.H. Lealy[118] pointed out that for the case of a *compressible* fluid, the effect of two spheres pulsating with equal phase and frequency reverses its sign if the distance between them exceeds half a wave length. So if one wants to use Bjerknes' results for gravitation, one would have to suppose either that the aether is *completely* incompressible (Bjerknes) or that it has such low compressibility that half the wave length of aether vibrations is larger than the distances for which observations have established the validity of Newton's law (A. Korn[119]). Only then is attraction always guaranteed, in agreement with observation.

Bjerknes' conception received further development by C. Pearson[120] and in the work by A. Korn just mentioned. The latter extended these ideas mainly to electromagnetic phenomena, the former to phenomena of optics and molecular physics, assuming complicated modes of vibration of the atoms. In his last paper, Pearson abandoned the assumption of oscillations for gravitation and only retained this
[57] assumption for optics and molecular physics, while replacing the | pulsating atoms by places in the incompressible aether at which aether continuously flows in and out in an oscillatory manner ("aether squirts"). For gravitation, he assumes that there is a constant flow in addition to the oscillating one at the locations concerned. With this requirement, the assumed incompressibility of the aether leads directly to the conclusion that apart from places of emission (source points, ordinary masses) there must be just as many places of absorption (sink points, "negative masses").[121]

Using Bjerknes' results for explaining gravitation suffers from the obvious deficiency that assumptions are required which would first have to be explained themselves. Attempts to supply real reasons have been made for only *one* of these assumptions, the synchronous pulsation of atoms. J.H. Weber[122] points out that in the attempt to demonstrate Bjerknes' results the synchronization of the two spheres happens quickly "on its own"; i.e., due to the forces which are caused by the vibrations in the fluid, even if the pulsations were not synchronous at first. From this he concludes that if atoms pulsate at all, the pulsations should become synchronous "on their own" (as specified above).

According to Korn, the assumption of synchronous pulsation can be replaced by another one, which is that the whole solar system is exposed to a periodic pressure. This assumption may be preferred due to its simplicity, but this is the only advantage over Bjerknes's assumption.

2. The second class of attempts to base an explanation of gravitation on aether vibrations assumes that the atoms are not themselves vibrating, but that their activity consists only in a kind of shielding or absorption of aether vibrations.

Representatives of this view include F. and E. Keller,[115] Lecoq de Boisbaudran,[123] and, in a slightly different way, N. von Dellinghausen.[124]

30. Aether Impacts: The Original Ideas of Le Sage

The starting point of all aether impact theories is an idea which | Le Sage[125] developed in a particularly clear and skillful way. According to him the gravitational aether surrounding the atoms of a body consists of discrete particles—"corpuscules ultramondains"—which zoom about in all directions with the same extraordinarily high velocity. No continuous motion is imparted to a single atom embedded in this aether due to the impacts of these aether particles, since the effect of aether impacts from all directions cancels out. But if two atoms A_1 and A_2 are brought into this aether, the conditions change in two respects: [58]

a. A_2 shields A_1 from a part of the aether atoms: The side of A_1 turned towards A_2 is hit by fewer aether particles than its side turned away from A_2. The consequence would have to be that A_1 is driven towards A_2 by the action of the aether impacts, and conversely A_2 is driven towards A_1.

If the atoms are assumed to be very large in comparison to the aether particles, it follows directly that this *shielding effect* of one atom of a body on another decreases with the square of distance. To make the shielding proportional to mass, Le Sage introduces the assumption that the gravitating masses are extraordinarily porous[126] to the aether particles so that the efficacy of the whole body becomes proportional to the number of atoms it contains.[127]

b. Due to the *reflection* of aether particles on A_2, a number of aether particles also hit the atom A_1 that would not have hit A_1 without the presence of A_2.[128] If these reflected aether atoms had the same velocity as those hitting A_1 directly, then they would cancel out the approach of A_1 towards A_2 caused by the shielding effect of A_2; thus, gravitation would not be produced.

124 "Die Schwere oder das Wirksamwerden der potentiellen Energie," *Kosmos* 1, Stuttgart 1884. Cf. C. Isenkrahe.[107]

125 *Berlin Mém*. 1782 and in P. Prévost, *Deux traîtés de Physique mécanique*, Paris 1818. In the last paper it is quoted that similar theories have been established before (by Nicolas Fatio and F. A. Redecker).

126 Strangely enough, Le Sage extends the assumption of very high porosity to every single atom of a body and therefore arrives at the conception of the peculiar "box atoms" [*Kastenatome*].

127 But cf. section 32, c).

128 In P. Drude[77] we find the note that Le Sage simply ignores reflection and thus his observation lacks rigor. This is probably a mistake: Le Sage devotes chapter IV to reflection in P. Prévost.

This is why Le Sage assumes furthermore that the aether particles are *absolutely*
[59] *inelastic*—"privé de toute élasticité"—and | states that under this assumption the average velocity of the reflected atoms = $2/3$ of the non-reflected ones.[129]

Thus the difference of effects a) and b) still results in both atoms approaching each other.

31. Aether Impacts: Further Development of Le Sage's Theory

Recently, Le Sage's theory was primarily defended by C. Isenkrahe, who emphasized in particular the assumption that collisions between the aether particles and atoms are subject to the laws of *inelastic* collision. Isenkrahe's progress beyond Le Sage consists of the following points:

a. He ascribes to gravitational aether the properties of a gas in the sense of kinetic gas theory. Hence he is giving up the assumption of *equal* velocity[130] of the aether atoms.

b. He does not explain the porosity of the body to aether particles by porosity of the atoms themselves, but by assuming that the distance between atoms[131] is large compared to their dimensions.

c. To achieve the proportionality between attraction and mass, which was guaranteed by Le Sage's assumption only for bodies of the same composition, he assumes that "the final components of matter are all of equal size; they may be the aether atoms themselves."

A. Rysáneck's[132] assumptions are very similar. His achievement consists of the precise implementation of the ideas of kinetic gas theory.[133] In his calculations he actually takes into consideration that the velocities of aether atoms are distributed according to Maxwell's law, whereas e.g. Isenkrahe does assume different velocities of aether atoms, but replaces them by *one* average velocity in all his derivations.

[60] Prior to Isenkrahe S.T. Preston[134] | already pointed out that Le Sage's conceptions could be suitably replaced by ideas of kinetic gas theory, if the mean free path of aether atoms is assumed to be of the order of planetary distances. He developed this idea in several papers, though without going into details as carefully as Isenkrahe and Rysáneck.

---

129 About justification and validity of this information cf. C. Isenkrahe[107] in paper b., p. 155 ff.

130 Which Le Sage also chose merely for simplicity, as he explicitly points out the *different* velocities in the reflections of aether particles and atoms.

131 Which are assigned a spherical form for simplicity.

32. Aether Impacts: Difficulties of these Theories

a. A necessary condition for a gravitational effect is that aether atoms lose translational velocity upon collision with atoms, which is achieved most easily by assuming inelastic collisions.

However, this assumption leads to the problem of where the energy lost at impact goes. P. Leray[135] and later P.A. Secchi,[136] W. Thomson,[137] S.T. Preston,[134] then A. Vaschy,[138] Isenkrahe himself and Rysáneck tried to avoid this problem in many different ways. None of these attempts, however, is itself unobjectionable.[139]

b. J. Croll[140] turns against the assumption made in most aether impact theories, which is that the distance between two molecules is very large compared to their dimensions, or rather compared to their spheres of action. He notes that this assumption grossly contradicts W. Thomson's estimates regarding the size of the molecules and their number per unit volume.

c. Objections can be raised from a different angle against the assumption of high porosity of the body for the aether atoms. If the porosity is presumed to be so large that the aether atoms that passed one layer of a body hit the next layer with completely undiminished velocity, then the proportionality between attraction and mass would be strictly preserved. At the same time, this requirement excludes any attraction at all. Hence, one must assume that the aether atoms forfeit a noticeable amount of their energy when passing a body layer. A.M. Bock[141] has shown that this assumption | is not incompatible with the required strict proportionality between attraction [61]
and mass.

d. Bock pointed out one more problem. If a third mass comes between two masses, then the attraction of the two masses is considerably modified, such that the third mass seems to have a larger permeability, as shown by a mathematical examination of this case based on aether impact theories. Because this case is not rare, e.g., for the Moon, Earth and Sun, there would have to be observable perturbations over the course of time. But in fact no perturbations of this type have ever been observed.

e. Le Sage already discussed another objection against aether impact theories. If any body, e.g. a planet, moves in an aether with the assumed properties, then it must experience resistance. But none has been observed for the planets.

The last question was examined more precisely by Rysáneck, Bock and W. Browne[142] on the basis of astronomical data.[143] Since the secular changes of

planetary orbits give an upper limit on this hypothetical resistance, the aether impact theories yield a lower limit on the velocity of the aether atoms, if their density is assumed to be known. By using a density of the same order of magnitude as has been estimated for the optical aether, one obtains enormous numbers as the lower limit on the mean velocity. Rysáneck, e.g. based on calculations on Neptune's orbit, obtained the number $5 \cdot 10^{19}$cm/sec.

f. Of all the objections that P. du Bois-Reymond[144] raised against the aether impact theories, one is particularly noteworthy.

Think of a ponderable truncated cone (cross-section $ABCD$) with a molecule α close to the top. According to the aether impact theories, the acceleration which α receives towards the cone is the difference between the effect the aether atoms with solid angle ω_1 and the effect the aether atoms with solid angle ω_2 have on the molecule. The first effect remains unaltered, but the second decreases if R, the distance
[62] between base CD and cone top O, increases. | Therefore, the total effect always remains smaller than the effect of the aether atoms of solid angle ω_1.

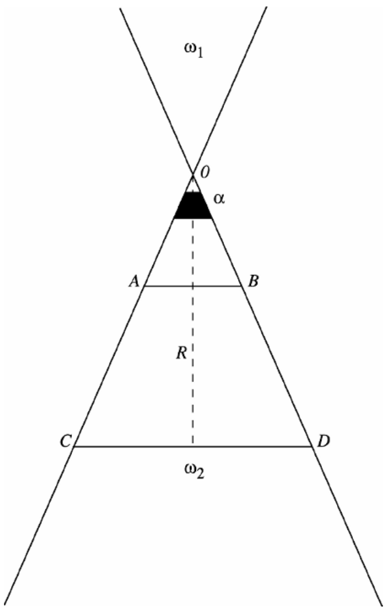

Figure 1

On the other hand, since according to Newton's law the attraction of the cone on α increases with R and exceeds any specifiable number, if the same is assumed about R, there are then only two possibilities: either to presume that the effect of

144 *Naturw. Rundschau* 3 (1888), p. 169–178.

aether atoms in space ω_1 on molecule α is infinitely large, or to assume that Newton's law no longer holds for infinitely extended masses.[145]

Isenkrahe[146] countered P. du Bois-Reymond's objection with the latter assumption. However, the difficulty persists, in that one must ascribe an enormous, if not infinite, magnitude to the aether atom's effect, which leads to shortcomings in other areas.[147]

33. Aether Impacts: Jarolimek's Objections and Theory

A. Jarolimek[148] emphasized a deficiency of all aether impact theories that suppose aether to be a gas in the sense of kinetic gas theory. The derivation of the law of gravity in these theories is based on a simple calculation with a certain mean free path of the aether atoms, which fails to take the variety of paths into account.

Regarding this point, Jarolimek notes that *in order to produce mutual attraction of two molecules, only those aether atoms whose actual path length is larger than the distance between the two molecules can be effective*. Thus it depends precisely upon the *absolute* |—*and not the average*—path length. But if one takes the variety of [63] absolute path lengths into account, under the usual conditions of aether impact theory one does not obtain Newton's law at all.

Referring to Isenkrahe's[149] assumption that the atoms of a body may themselves be an aggregate of the extremely fine aether atoms, Jarolimek points out one more difficulty: this assumption contradicts a shielding effect of two body elements that decreases with the square of the distance. If these elements are identical to aether atoms, then an element could shield another only from those aether atoms whose center lies exactly on the line connecting the two elements; the shielding effect would therefore not depend on the distance at all, if the distance is so large compared to the element's radius that the element could be regarded as devoid of size.

Jarolimek establishes the following theory based on such considerations. He keeps Isenkrahe's assumption—the ultimate elements of atoms are identical to gravitational aether atoms. This practically fully frees him from a shielding effect. He arrives at a decrease of the gravitational effect with the square of the distance in the following way: "One has to think of the infinite number of *swarming* aether atoms as uniformly distributed in space at every instant, and one has to imagine that atoms *bouncing off* from one point fly off in straight lines in all directions. Considering a cone bundle, whose vertex is the point of origin and whose cross-section accordingly increases in quadratic proportion with distance to the vertex and which therefore contains at increasing distance *more uniformly distributed aether atoms* in quadratic proportion, one must realize that for atoms that bounced off (of which a *definite* number

---

149 Cf. section 31.

passes the observed cone bundle from the vertex), the probability to hit another atom in space must increase in quadratic proportion to the distance between the two.

From this it follows directly that the number of freely and linearly moving atoms decreases with increasing distance in quadratic proportion, or in other words: *that the aether contains* n^2 *times as many atoms with free path* r *as with free path* nr." Con-
[64] sequently, "*the simplest explanation for the law of gravity | is provided by the inequality of the path lengths of the aether molecules*."

6. REDUCTION OF GRAVITATION TO ELECTROMAGNETIC PHENOMENA

34. Gravitation as a Field Effect

Before reporting on explanatory attempts based on electromagnetism, the empirical facts contained in Newton's law will be mathematically formulated by describing the "gravitational field" without reference to any particular conception of its nature.[150]

One is used to regarding Newton's law as the most distinguished example of an action at a distance. On the other hand, it must be emphasized that its content can be formulated by the following statement, which corresponds to the field theory standpoint: "*The field strength of gravitation is irrotational, and source-free in those regions of space where there are no masses. Where there are masses, the divergence of the field strength is proportional to the local mass density* ρ."

We understand by field strength the attractive force exerted on a *unit mass*; the force exerted on *mass* m_1 is m_1-times as large as the field strength. The proportionality factor for the divergence of the field strength is identical to $4\pi G$. In formulas,[151] the expression of our description of the gravitational field takes the following form, if $\mathfrak{R}$ stands for the vector of field strength:

$$\mathrm{curl}\,\mathfrak{R} = 0, \qquad \mathrm{div}\,\mathfrak{R} = 0 \quad \text{or} \quad = -4\pi G\rho.$$

This formulation and the classical formulation given in section 1 are mathematically exactly equivalent; in particular, it follows from the above differential equations according to the laws of potential theory that the field strength due to a single mass m_2 at distance r is calculated to be

$$\mathfrak{R} = \mathrm{grad}\frac{m_2 G}{r}.$$

This yields the following value of the field strength (or its magnitude in the r-direction) in agreement with Newton's law:

---

150 Field representations of particular kinds are given by G. Helm, *Ann. Phys. Chem.* 14 (1881), p. 149; O. Heaviside, *Electrician* 31 (1893), p. 281 and 359.

151 Because of the significance of vector symbols rot, div, grad, cf. the beginning of the 2nd semi-volume V of the encyclopedia.

$$|\mathfrak{R}| = \frac{d}{dr}\frac{m_2 G}{r}.$$

| So far the field interpretation of gravitation offers neither advantages nor disadvantages over the action-at-a-distance interpretation. An advantage of the former would arise if a finite propagation velocity of gravitational effects could be proven with certainty, especially if it turned out to be equal to the velocity of light. Then the above differential equations for stationary gravitational effects would have to be extended to the case of a time-varying gravitational effect, which could easily be patterned after the example of the electromagnetic equations. On the other hand, the field interpretation involves a serious problem which Maxwell[152] pointed out. Enquiring about the gravitational energy contained in a volume element dS of the field, one must, in order to get an *attraction* of masses of the same sign, assume the form [65]

$$\left(C - \frac{1}{2}a|\mathfrak{R}|^2\right)dS$$

for this energy, where the constant a is identical to $1/4\pi G$. The constant C would have to be larger than $(a/2)|\mathfrak{R}'|^2$, so that the gravitational energy has a positive value throughout, where $|\mathfrak{R}'|$ stands for the largest value of field strength at any point in space. However, it would follow from this that at points of vanishing field strength, e.g. between the Earth and Sun at the point where the Sun's and the Earth's attraction compensate each other, the energy content of space would have to have the enormous quantity C per unit volume. Maxwell adds that he can not possibly imagine a medium with such a property.

35. Electromagnetic Vibrations

The hypothesis that gravitation could be caused by aether vibrations, already discussed in section 29, was examined by H.A. Lorentz[92] under the following assumptions:

a. The gravitating molecules consist of ions possessing an electric charge.

b. The aether vibrations are electromagnetic vibrations whose wave length is small compared to all those distances over which Newton's law is still valid.

Lorentz arrives at this result: an attraction is possible under these conditions only if | electromagnetic energy flows continuously into the volume elements that contain [66]
gravitating molecules. If the assumptions are changed so that such a disappearance of electromagnetic energy is avoided, then no attractive forces are obtained. This is why Lorentz himself dismisses this theory and in the further course of his discussion joins Mossotti-Zöllner's conception (see below).

---

152 *Lond. Trans.* 155 (1865), p. 492 = *Scient. Papers* 1, p. 570, Cambridge 1890.

36. Mossotti's Assumption and its Modern Development

In a completely different direction, O.F. Mossotti[153] tried to reduce gravitation to electrical forces, apparently following Aepinus. He assumes that a repulsion takes place between two molecules and likewise between two "aether atoms," but that there is an attractive force between a molecule and an aether atom which exceeds the repulsion between two molecules or two aether atoms. This assumption provides an attraction between two molecules embedded in the aether, as required by Newton's law.

This idea was simplified by F. Zöllner.[154] He imagines that each gravitating molecule or atom consists of one negatively and one positively charged particle, and assumes that the repulsion between two equal charges is smaller than the attraction between two unequal ones of the same size.

Zöllner's assumption was examined mathematically by W. Weber[155] based on his electrodynamic fundamental law. This was applied to moving bodies only recently by H.A. Lorentz,[90] using his generalized Maxwell equations (cf. section 22). Lorentz's approach is continued in a paper by W. Wien.[156] Cf. the end of article 14 of this volume concerning this most recent phase of the gravitational problem.

As attractive as the explanatory attempts based on electromagnetism, in particular, may appear today, it behooves one to wait, since little of the subject has been worked
[67] out, to see if tangible advantages arise from it for understanding the | gravitational effect and for release from persistent problems. According to section 22, it seems that not much can be gained in this direction by the electromagnetic conception.

For the time being, one will have to summarize the above considerations as follows: all attempts to connect gravitation with other phenomena in a satisfying way are to be regarded as unsuccessful or as not yet adequately established. With this, however, one has, at the beginning of the 20th century, returned to the view of the 18th century, to the view that takes gravitation to be a fundamental property of all matter.

EDITORIAL NOTES

[1] In the original, Zenneck mistakenly refers to note 46 (44 according to our numbering), rather than 36.

HENDRIK A. LORENTZ

CONSIDERATIONS ON GRAVITATION

Originally published in Proceedings Royal Academy Amsterdam 2 (1900), pp. 559–574. A Dutch version appeared under the title "Beschouwingen over de zwaartekracht" in Verslag Koninklijke Akademie van Wetenschapen te Amsterdam 8 (1900), pp. 603–620. A French version appeared under the title "Considérations sur la Pesanteur" in Archives néerlandaises 7 (1902), pp. 325–338.

§1. After all we have learned in the last twenty or thirty years about the mechanism of electric and magnetic phenomena, it is natural to examine in how far it is possible to account for the force of gravitation by ascribing it to a certain state of the aether. A theory of universal attraction, founded on such an assumption, would take the simplest form if new hypotheses about the aether could be avoided, i. e. if the two states which exist in an electric and a magnetic field, and whose mutual connection is expressed by the well known electromagnetic equations were found sufficient for the purpose.

If further it be taken for granted that only electrically *charged* particles or ions, are directly acted on by the aether, one is led to the idea that every particle of ponderable matter might consist of two ions with equal opposite charges—or at least might contain two such ions—and that gravitation might be the result of the forces experienced by these ions. Now that so many phenomena have been explained by a theory of ions, this idea seems to be more admissible than it was ever before.

As to the electromagnetic disturbances in the aether which might possibly be the cause of gravitation, they must at all events be of such a nature, that they are capable of penetrating all ponderable bodies without appreciably diminishing in intensity. Now, electric vibrations of extremely small wave-length possess this property; hence the question arises what action there would be between two ions if the aether were traversed in all directions by trains of electric waves of small wave-length.

The above ideas are not new. Every physicist knows Le Sage's theory in which innumerable small corpuscula are supposed to move with great velocities, producing gravitation by their impact against the coarser particles of ordinary ponderable matter. I shall not here discuss this theory which is not in harmony with modern physical views. But, when it had been found that a pressure against a body may be produced as well by trains of electric waves, by rays of light e. g., as by moving projectiles and when the Röntgen-rays with their remarkable penetrating power had been discovered,

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

it was natural to replace Le Sage's corpuscula by vibratory motions. Why should there not exist radiations, far more penetrating than even the X-rays, and which might therefore serve to account for a force which as far as we know, is independent of all intervening ponderable matter?

[560] I have deemed it worthwhile to put this idea to the test. In | what follows, before passing to considerations of a different order (§5), I shall explain the reasons for which this theory of rapid vibrations as a cause of gravitation can not be accepted.

§2. Let an ion carrying a charge e and having a certain mass, be situated at the point $P(x,y,z)$; it may be subject or not to an elastic force, proportional to the displacement and driving it back to P, as soon as it has left this position. Next, let the aether be traversed by electromagnetic vibrations, the dielectric displacement being denoted by $\mathfrak{d}$, and the magnetic force by $\mathfrak{H}$, then the ion will be acted on by a force

$$4\pi V^2 e\mathfrak{d},$$

whose direction changes continually, and whose components are

$$X = 4\pi V^2 e\mathfrak{d}_x, \qquad Y = 4\pi V^2 e\mathfrak{d}_y, \qquad Z = 4\pi V^2 e\mathfrak{d}_z. \tag{1}$$

In these formulae V means the velocity of light.

By the action of the force (1) the ion will be made to vibrate about its original position P, the displacement (x, y, z) being determined by well known differential equations.

For the sake of simplicity we shall confine ourselves to simple harmonic vibrations with frequency n. All our formulae will then contain the factor, $\cos nt$ or $\sin nt$ and the forced vibrations of the ion may be represented by expressions of the form

$$\begin{aligned} x &= ae\mathfrak{d}_x - be\dot{\mathfrak{d}}_x, \\ x &= ae\mathfrak{d}_y - be\dot{\mathfrak{d}}_y, \\ x &= ae\mathfrak{d}_z - be\dot{\mathfrak{d}}_z, \end{aligned} \tag{2}$$

with certain constant coefficients a and b. The terms with $\dot{\mathfrak{d}}_x$, $\dot{\mathfrak{d}}_y$ and $\dot{\mathfrak{d}}_z$, have been introduced in order to indicate that the phase of the forced vibration differs from that of the force (X, Y, Z); this will be the case as soon as there is a resistance, proportional to the velocity, and the coefficient b may then be shown to be positive. One cause of a resistance lies in the reaction of the aether, called forth by the radiation of which the vibrating ion itself becomes the center, a reaction which determines at the same time an apparent increase of the mass of the particle. We shall suppose however that we have kept in view this reaction in establishing the equations of motion, and in
[561] assigning their values to the coefficients a and b. | Then, in what follows, we need only consider the forces due to the state of the aether, in so far as it not directly produced by the ion itself.

Since the formulae (2) contain e as a factor, the coefficients a and b will be independent of the charge; their sign will be the same for a negative ion and for a positive one.

Now, as soon as the ion has shifted from its position of equilibrium, new forces come into play. In the first place, the force $4\pi V^2 e\mathfrak{d}$ will have changed a little, because, for the new position, $\mathfrak{d}$ will be somewhat different from what it was at the point P. We may express this by saying that, in addition to the force (1), there will be a new one with the components

$$4\pi V^2 e\left(x\frac{\partial \mathfrak{d}_x}{\partial x} + y\frac{\partial \mathfrak{d}_x}{\partial y} + z\frac{\partial \mathfrak{d}_x}{\partial z}\right), \text{etc.} \tag{3}$$

In the second place, in consequence of the velocity of vibration, there will be an electromagnetic force with the components

$$e(\dot{y}\mathfrak{H}_z - \dot{z}\mathfrak{H}_y), \text{etc.} \tag{4}$$

If, as we shall suppose, the displacement of the ion be very small, compared with the wave-length, the forces (3) and (4) are much smaller than the force (1); since they are periodic—with the frequency $2n$, —they will give rise to now vibrations of the particle. We shall however omit the consideration of these slight vibrations, and examine only the mean values of the forces (3) and (4), calculated for a rather long lapse of time, or, what amounts to the same thing, for a full period $2\pi/n$.

§3. It is immediately clear that this mean force will be 0 if the ion is *alone* in a field in which the propagation of waves takes place equally in all directions. It will be otherwise, as soon as a second ion Q has been placed in the neighborhood of P; then, in consequence of the vibrations emitted by Q after it has been itself put in motion, there may be a force on P, of course in the direction of the line QP. In computing the value of this force, one finds a great number of terms, which depend in different ways on the distance r. We shall retain those which are inversely proportional to r or r^2, but we shall neglect all terms varying inversely as the higher powers of r; indeed, the influence of these, compared with that of the first mentioned terms will be of the order λ/r if λ is the | wave-length, and we shall suppose this to be a very [562] small fraction.

We shall also omit all terms containing such factors as $\cos 2\pi kr/\lambda$ or $\sin 2\pi kr/\lambda$ (k a moderate number). These reverse their signs by a very small change in r; they will therefore disappear from the resultant force, as soon as, instead of *single* particles P and Q, we come to consider systems of particles with dimensions many times greater than the wave-length.

From what has been said, we may deduce in the first place that, in applying the above formulae to the ion P, it is sufficient, to take for $\mathfrak{d}$ and $\mathfrak{H}$ the vectors that would exist if P were removed from the field. In each of these vectors two parts are to be distinguished. We shall denote by $\mathfrak{d}_1$, and $\mathfrak{H}_1$, the parts existing independently of Q and by $\mathfrak{d}_2$ and $\mathfrak{H}_2$ the parts due to the vibrations of this ion.

Let Q be taken as origin of coordinates, QP as axis of x, and let us begin with the terms in (2) having the coefficient a.

To these corresponds a force on P, whose first component is

$$4\pi V^2 e^2 a\left(\mathfrak{d}_x \frac{\partial \mathfrak{d}_x}{\partial x} + \mathfrak{d}_y \frac{\partial \mathfrak{d}_x}{\partial y} + \mathfrak{d}_z \frac{\partial \mathfrak{d}_x}{\partial z}\right) + e^2 a(\dot{\mathfrak{d}}_y \mathfrak{H}_z - \dot{\mathfrak{d}}_z \mathfrak{H}_y). \tag{5}$$

Since we have only to deal with the mean values for a full period, we may write for the last term

$$-e^2 a(\mathfrak{d}_y \dot{\mathfrak{H}}_z - \mathfrak{d}_z \dot{\mathfrak{H}}_y)$$

and if, in this expression, $\dot{\mathfrak{H}}_y$ and $\dot{\mathfrak{H}}_z$ be replaced by

$$4\pi V^2\left(\frac{\partial \mathfrak{d}_z}{\partial x} - \frac{\partial \mathfrak{d}_x}{\partial z}\right) \text{ and } 4\pi V^2\left(\frac{\partial \mathfrak{d}_x}{\partial y} - \frac{\partial \mathfrak{d}_y}{\partial x}\right)$$

becomes

$$2\pi V^2 e^2 a \frac{\partial(\mathfrak{d}^2)}{\partial x}, \tag{6}$$

where $\mathfrak{d}$ is the numerical value of the dielectric displacement.

Now, $\mathfrak{d}^2$ will consist of three parts, the first being $\mathfrak{d}_1^2$, the second $\mathfrak{d}_2^2$ and the third depending on the combination of $\mathfrak{d}_1$ and $\mathfrak{d}_2$.

Evidently, the value of (6), corresponding to the first part, will be 0.

As to the second part, it is to be remarked that the dielectric displacement, produced by Q, is a periodic function of the time. At distant points the amplitude takes
[563] the form c/r where c is independent | of r. The mean value of $\mathfrak{d}^2$ for a full period is $c^2/2r^2$ and by differentiating this with regard to x or to r, we should get r^3 in the denominator.

The terms in (6) which correspond to the part

$$2(\mathfrak{d}_{1x}\mathfrak{d}_{2x} + \mathfrak{d}_{1y}\mathfrak{d}_{2y} + \mathfrak{d}_{1z}\mathfrak{d}_{2z})$$

in $\mathfrak{d}^2$, may likewise be neglected. Indeed, if these terms contain no factors such as to $\cos 2\pi kr/\lambda$ or $\sin 2\pi kr/\lambda$ there must be between $\mathfrak{d}_1$ and $\mathfrak{d}_2$, either no phase-difference at all, or a difference which is independent of r. This condition can only be fulfilled, if a system of waves, proceeding in the direction of QP, is combined with the vibrations excited by Q, in so far as this ion is put in motion by that system itself. Then, the two vectors $\mathfrak{d}_1$ and $\mathfrak{d}_2$ will have a common direction perpendicular to QP, say that of the axis of y, and they will be of the form

$$\mathfrak{d}_{1y} = q\cos n\left(t - \frac{x}{V} + \varepsilon_1\right)$$

$$\mathfrak{d}_{2y} = \frac{c}{r}\cos n\left(t - \frac{x}{V} + \varepsilon_2\right).$$

The mean value of $\mathfrak{d}_{1y}\mathfrak{d}_{2y}$ is

$$\frac{1}{2}\frac{qc}{r}\cos n(\varepsilon_1 - \varepsilon_2),$$

and its differential coefficient with regard to x has r^2 in the denominator. It ought therefore to be retained, were it not for the extremely small intensity of the. systems of waves which give rise to such a result. In fact, by the restriction imposed on them as to their direction, these waves form no more then a very minute part of the whole motion.

§4. So, it is only the terms in (2), with the coefficient b, with which we are concerned.The corresponding forces are

$$-4\pi V^2 e^2 b\left(\dot{\mathfrak{d}}_x \frac{\partial \mathfrak{d}_x}{\partial x} + \dot{\mathfrak{d}}_y \frac{\partial \mathfrak{d}_x}{\partial y} + \dot{\mathfrak{d}}_z \frac{\partial \mathfrak{d}_x}{\partial z}\right) \tag{7}$$

and

$$-e^2 b(\ddot{\mathfrak{d}}_y \mathfrak{H}_z - \ddot{\mathfrak{d}}_z \mathfrak{H}_y). \tag{8}$$

| If Q were removed, these forces together would be 0, as has already been remarked. On the other hand, the force (8), taken by itself, would then likewise be 0. Indeed, its value is [564]

$$n^2 e^2 b(\mathfrak{d}_y \mathfrak{H}_z - \mathfrak{d}_z \mathfrak{H}_y) \tag{9}$$

or, by Poynting's theorem $(n^2 e^2 b S_x / V^2)$, if S_x be the flow of energy in a direction parallel to the axis of x. Now, it is clear that, in the absence of Q, any plane must be traversed in the two directions by equal amounts of energy.

In this way we come to the conclusion that the force (7), in so far as it depends on the part $(\mathfrak{d}_1)$, is 0, and from this it follows that the total value of (7) will vanish, because the part arising from the combination of $(\mathfrak{d}_1)$ and $(\mathfrak{d}_2)$, as well as that which is solely due to the vibrations of Q, are 0. As to the first part, this may be shown by a reasoning similar to that used at the end of the preceding section. For the second part, the proof is as follows.

The vibrations excited by Q in any point A of the surrounding aether are represented by expressions of the form

$$\frac{1}{r}\vartheta \cos n\left(t - \frac{r}{V} + \varepsilon\right),$$

where ϑ depends on the direction of the line QA, and r denotes the length of this line. If, in differentiating such expressions, we wish to avoid in the denominator powers of r, higher than the first—and this is necessary, in order that (7) may remain free from powers higher than the second– $1/r$ and ϑ have to be treated as constants. Moreover, the factors ϑ are such, that the vibrations are perpendicular to the line QA. If, now, A coincides with P, and QA with the axis of x, in the expression for d_x we shall have $\vartheta = 0$, and since this factor is not to be differentiated, all terms in (7) will vanish.

Thus, the question reduces itself to (8) or (9). If, in this last expression, we take for d and H their real values, modified as they are by the motion of Q, we may again write for the force

$$\frac{n^2e^2b}{V^2}S_x;$$

this time, however wo have to understand by S_x the flow of energy as it is in the actual case. |

[565] Now, it is clear that, by our assumptions, the flow of energy must be symmetrical all around Q; hence, if an amount E of energy traverses, in the outward direction, a spherical surface described around Q as center with radius r, we shall have

$$S_x = \frac{E}{4\pi r^2}$$

and the force on P will be

$$K = \frac{n^2e^2bE}{4\pi V^2r^2}.$$

It will have the direction of QP prolonged.

In the space surrounding Q the state of the aether will be stationary; hence, two spherical surfaces enclosing this particle must be traversed by equal quantities of energy. The quantity E will be independent of r, and the force K inversely proportional to the square of the distance.

If the vibrations of Q were opposed by no other resistance but that which results from radiation, the total amount of electromagnetic energy enclosed by a surface surrounding Q would remain constant; E and K would then both be 0. If, on the contrary, in addition to the just mentioned resistance, there were a resistance of a different kind, the vibrations of Q would be accompanied by a continual loss of electromagnetic energy; less energy would leave the space within one of the spherical surfaces than would enter that space. E would be negative, and, since b is positive, there would be attraction. It would be independent of the signs of the charges of P and Q.

The circumstance however, that this attraction could only exist, if in some way or other electromagnetic energy were continually disappearing, is so serious a difficulty, that what has been said cannot be considered as furnishing an explanation of gravitation. Nor is this the only objection that can be raised. If the mechanism of gravitation consisted in vibrations which cross the aether with the velocity of light, the attraction ought to be modified by the motion of the celestial bodies to a much larger extent than astronomical observations make it possible to admit.

§5. Though the states of the aether, the existence and the laws of which have been deduced from electromagnetic phenomena, are found insufficient to account for universal attraction, yet one may try to establish a theory which is not wholly different from that of | electricity, but has some features in common with it. In order to obtain a [566] theory of this kind, I shall start from an idea that has been suggested long ago by Mossotti and has been afterwards accepted by Wilhelm Weber and Zöllner.

According to these physicists, every particle of ponderable matter consists of two oppositely electrified particles. Thus, between two particles of matter, there will be four electric forces, two attractions between the charges of different, and two repulsions between those of equal signs. Mossotti supposes the attractions to be somewhat greater than the repulsions, the difference between the two being precisely what we call gravitation. It is easily seen that such a difference might exist in cases where an action of a specific electric nature is not exerted.

Now, if the form of this theory is to be brought into harmony with the present state of electrical science, we must regard the four forces of Mossotti as the effect of certain states in the aether which are called forth by the positive and negative ions.

A positive ion, as well as a negative one, is the center of a dielectric displacement, and, in treating of electrical phenomena, these two displacements are considered as being of the same nature, so that, if in opposite directions and of equal magnitude, they wholly destroy each other.

If gravitation is to be included in the theory, this view must be modified. Indeed, if the actions exerted by positive and negative ions depended on vector-quantities of the same kind, in such a way that all phenomena in the neighborhood of a pair of ions with opposite charges were determined by the resulting vector, then electric actions could only be absent, if this resulting vector were 0, but, if such were the case, no other actions could exist; a gravitation, i.e. a force in the absence of an electric field, would be impossible.

I shall therefore suppose that the two disturbances in the aether, produced by positive and negative ions, are of a somewhat different nature, so that, even if they are represented in a diagram by equal and opposite vectors, the state of the aether is not the natural one. This corresponds in a sense to Mossotti's idea that positive and negative charges differ from each other to a larger extent, than may be expressed by the signs $+$ and $-$.

After having attributed to each of the two states an independent and separate, existence, we may assume that, though both able to act on positive and negative ions, the one has more power over the positive particles and the other over the negative ones. This difference | will lead us to the same result that Mossotti attained by means [567] of the supposed inequality of the attractive and the repulsive forces.

§6. I shall suppose that each of the two disturbances of the aether is propagated with the velocity of light, and, taken by itself, obeys the ordinary laws of the electromagnetic field. These laws are expressed in the simplest form if, besides the dielectric displacement $\mathfrak{d}$, we consider the magnetic force $\mathfrak{H}$, both together determining, as we shall now say, *one* state of the aether or one field. In accordance with this, I shall introduce two pairs of vectors, the one $\mathfrak{d}$, $\mathfrak{H}$ belonging to the field that is produced by the positive ions, whereas the other pair $\mathfrak{d}'$, $\mathfrak{H}'$ serve to indicate the state of the aether which is called into existence by the negative ions. I shall write down two sets of equations, one for $\mathfrak{d}$, $\mathfrak{H}$, the other for $\mathfrak{d}'$, $\mathfrak{H}'$, and having the form which I have used in former papers[1] for the equations of the electromagnetic field, and which is founded on the assumption that the ions are perfectly permeable to the aether and that they can be displaced without dragging the aether along with them.

I shall immediately take this general case of moving particles.

Let us further suppose the charges to be distributed with finite volume-density, and let the units in which these are expressed be chosen in such a way that, in a body which exerts no electrical actions, the total amount of the positive charges has the same numerical value as that of the negative charges.

Let ρ be the density of the positive, and ρ' that of the negative charges, the first number being positive and the second negative.

Let $\mathfrak{v}$ (or $\mathfrak{v}'$) be the velocity of an ion.

Then the equations for the state $(\mathfrak{d}, \mathfrak{H})$ are[2]

$$\left.\begin{aligned} \mathrm{Div}\,\mathfrak{d} &= \rho \\ \mathrm{Div}\,\mathfrak{H} &= 0 \\ \mathrm{Curl}\,\mathfrak{H} &= 4\pi\rho\mathfrak{v} + 4\pi\dot{\mathfrak{d}} \\ 4\pi V^2\mathrm{Curl}\,\mathfrak{d} &= -\dot{\mathfrak{H}} \end{aligned}\right\} \qquad \text{(I)}$$

[568] | and those for the state (d',H')

$$\left.\begin{aligned} \mathrm{div}\,\mathfrak{d}' &= \rho' \\ \mathrm{div}\,\mathfrak{H}' &= 0 \\ \mathrm{Curl}\,\mathfrak{H}' &= 4\pi\rho'\mathfrak{v}' + 4\pi\dot{\mathfrak{d}}' \\ 4\pi V^2\mathrm{Curl}\,\mathfrak{d}' &= -\dot{\mathfrak{H}}' \end{aligned}\right\} \qquad \text{(II)}$$

1 Lorentz, La théorie électromagnétique de Maxwell at son application aux corps mouvants, *Arch. Néerl. XXV*, p. 363; Versuch einer Theorie der electrischen und optischen Erscheinungen in bewegten Körpern.

2 $\mathrm{Div}\,\mathfrak{d} = \frac{\partial\mathfrak{d}_x}{\partial x} + \frac{\partial\mathfrak{d}_y}{\partial y} + \frac{\partial\mathfrak{d}_z}{\partial z}$. $\mathrm{Curl}\,\mathfrak{d}$ is a vector, whose components are: $\frac{\partial\mathfrak{d}_z}{\partial y} - \frac{\partial\mathfrak{d}_y}{\partial z}$, etc.

In the ordinary theory of electromagnetism, the force acting on a particle, moving with velocity $\mathfrak{v}$, is

$$4\pi V^2\mathfrak{d} + [\mathfrak{v}.\mathfrak{H}],$$

per unit charge.[3]

In the modified theory: we shall suppose that a positively electrified particle with charge e experiences a force

$$k_1 = \alpha\{4\pi V^2\mathfrak{d} + [\mathfrak{v}.\mathfrak{H}]\}e \tag{10}$$

on account of the field $(\mathfrak{d}, \mathfrak{H})$, and a force

$$k_2 = \beta\{4\pi V^2\mathfrak{d}' + [\mathfrak{v}.\mathfrak{H}']\}e \tag{11}$$

on account of the field $(\mathfrak{d}', \mathfrak{H}')$, the positive coefficients α and β having slightly different values.

For the forces, exerted on a negatively charged particle I shall write,

$$k_3 = \beta\{4\pi V^2\mathfrak{d} + [\mathfrak{v}'.\mathfrak{H}]\}e' \tag{12}$$

and

$$k_4 = \alpha\{4\pi V^2\mathfrak{d}' + [\mathfrak{v}'.\mathfrak{H}']\}e', \tag{13}$$

expressing by these formulae that e is acted on by $(\mathfrak{d}, \mathfrak{H})$ in the same way as e' by $(\mathfrak{d}', \mathfrak{H}')$, and vice versa.

§7. Let us next consider the actions exerted by a *pair* of oppositely charged ions, placed close to each other, and remaining so during their motion, For convenience of mathematical treatment, we may even reason as if the two charges penetrated each other, so that, if they are equal, $\rho' = -\rho$. |

On the other hand $\mathfrak{v}' = \mathfrak{v}$, hence, by (I) and (11), [569]

$$\mathfrak{d}' = -\mathfrak{d} \qquad \text{and} \qquad \mathfrak{H}' = -\mathfrak{H}.$$

Now let us put in the field, produced by the pair of ions, a similar pair with charges e and $e' = -e$, and moving with the common velocity $\mathfrak{v}$. Then, by (10)–(13),

$$k_2 = -\frac{\beta}{\alpha}k_1, \qquad k_3 = -\frac{\beta}{\alpha}k_1, \qquad k_4 = k_1.$$

The total force on the positive particle will be

3 $[\mathfrak{v}\,.\,\mathfrak{H}]$ is the vector-product of $\mathfrak{v}$ and $\mathfrak{H}$.

$$k_1 + k_2 = k_1\left(1 - \frac{\beta}{\alpha}\right)$$

and that on the negative ion

$$k_3 + k_4 = k_1\left(1 - \frac{\beta}{\alpha}\right).$$

These forces being equal and having the same direction, there is no force tending to *separate* the two ions, as would be the case in an *electric field*. Nevertheless, the pair is acted on by a resultant force

$$2k_1\left(1 - \frac{\beta}{\alpha}\right).$$

If now β be somewhat larger than α the factor $2(1 - \beta/\alpha)$ will have a certain negative value $-\varepsilon$, and our result may be expressed as follows:

If we wish to determine the action between two ponderable bodies, we may first consider the forces existing between the positive ions in the one and the positive ions in the other. We then have to reverse the direction of these forces, and to multiply them by the factor ε. Of course, we are led in this way to Newton's law of gravitation.

The assumption that all ponderable matter is composed of positive and negative ions is no essential part of the above theory. We might have confined ourselves to the supposition that the state of the aether which is the cause of gravitation is propagated in a similar way as that which exists in the electromagnetic field. |

[570] Instead of introducing two pairs of vectors $(\mathfrak{d}, \mathfrak{H})$ and $(\mathfrak{d}', \mathfrak{H}')$, both of which come into play in the electromagnetic actions, as well as in the phenomenon of gravitation, we might have assumed one pair for the electromagnetic field and one for universal attraction.

For these latter vectors, say $\mathfrak{d}$, $\mathfrak{H}$, we should then have established the equations (I), ρ being the density of ponderable matter, and for the force acting on unit mass, we should have put

$$-\eta\{4\pi V^2\mathfrak{d} + [\mathfrak{v}.\mathfrak{H}]\},$$

where η is a certain positive coefficient,

§8. Every theory of gravitation has to deal with the problem of the influence, exerted on this force by the motion of the heavenly bodies. The solution is easily deduced from our equations; it takes the same form as the corresponding solution for the electromagnetic actions between charged particles.[4]

I shall only treat the case of a body A, revolving around a central body M, this latter having a given constant velocity p. Let r be the line MA, taken in the direc-

4 See the second of the obeys cited papers.

tion from M towards A, x,y,z the relative coordinates of A with respect to M, to the velocity of A's motion relatively to M, ϑ the angle between w to and p, finally p_r, the component of p in the direction of r.

Then, besides the attraction

$$\frac{k}{r^2}, \tag{14}$$

which would exist if the bodies were both at rest, A will be subject to the following actions.

1st. A force

$$k \cdot \frac{p^2}{2V^2} \cdot \frac{1}{r^2} \tag{15}$$

in the direction of r.

2nd. A force whose components are

$$-\frac{k}{2V^2}\frac{\partial}{\partial x}\left(\frac{p_r^2}{r}\right), -\frac{k}{2V^2}\frac{\partial}{\partial y}\left(\frac{p_r^2}{r}\right), -\frac{k}{2V^2}\frac{\partial}{\partial z}\left(\frac{p_r^2}{r}\right). \tag{16}$$

| 3rd. A force [571]

$$-\frac{k}{V^2}p \cdot \frac{1}{r^2}\frac{dr}{dt} \tag{17}$$

parallel to the velocity p.

4th. A force

$$\frac{k}{V^2}\frac{1}{r^2}pw\cos\vartheta \tag{18}$$

in the direction of r.

Of these, (15) and (16) depend only on the common velocity p, (17) and (18) on the contrary, on p and w to conjointly.

It is further to be remarked that the additional forces (15)-(18) are all of the second order with respect to the small quantities $\frac{p}{V}$ and $\frac{w}{V}$.

In so far, the law expressed by the above formulae presents a certain analogy with the laws proposed by Weber, Riemann and Clausius for the electromagnetic actions, and applied by some astronomers to the motions of the planets. Like the formulae of Clausius, our equations contain the absolute velocities, i. e. the velocities, relatively to the aether.

There is no doubt but that, in the present state of science, if we wish to try for gravitation a similar law as for electromagnetic forces, the law contained in (15)-(18) is to be preferred to the three other just mentioned laws.

§9. The forces (15)-(18) will give rise to small inequalities in the elements of a planetary orbit; in computing these, we have to take for p the velocity of the Sun's motion through space. I have calculated the *secular* variations, using the formulae communicated by Tisserand in his *Mécanique céleste*.

Let a be the mean distance to the Sun,
e the eccentricity,
φ the inclination to the ecliptic,
θ the longitude of the ascending node,
$\tilde{\omega}$ the longitude of perihelion,
[572] κ' the mean anomaly at time, $t = 0$, in this sense that, if n be the mean motion, as determined by a, the mean anomaly at time t is given by

$$\kappa' + \int_0^t n dt.$$

Further, let λ, μ and ν, be the direction-cosines of the velocity p with respect to: 1st. the radius vector of the perihelion, 2nd. a direction which is got by giving to that radius vector a rotation of $90°$, in the direction of the planet's revolution, 3rd. the normal to the plane of the orbit, drawn towards the side whence the planet is seen to revolve in the same direction as the hands of a watch.

Put $\omega = \tilde{\omega} - \theta$, $p/V = \delta$ and $na/V = \delta'$ (na is the velocity in a circular orbit of radius a).

Then I find for the variations *during one revolution*

$$\left.\begin{aligned}
\Delta a &= 0 \\
\Delta e &= 2\pi\sqrt{(1-e^2)}\left\{\lambda\mu\delta^2\frac{(2-e^2)-2\sqrt{(1-e^2)}}{e^3} - \lambda\delta\delta'\frac{1-\sqrt{(1-e^2)}}{e^2}\right\} \\
\Delta\varphi &= \frac{2\pi}{\sqrt{(1-e^2)}}\nu\left\{[-\lambda\delta^2\cos\omega + \delta(e\delta'-\mu\delta)\sin\omega]\frac{1-\sqrt{(1-e^2)}}{e^2} + \mu\delta^2\sin\omega\right\} \\
\Delta\theta &= -\frac{2\pi}{\sqrt{(1-e^2)}\sin\varphi}\nu\left\{[\lambda\delta^2\sin\omega + \delta(e\delta'-\mu\delta)\cos\omega]\frac{1-\sqrt{(1-e^2)}}{e^2} + \mu\delta^2\cos\omega\right\}
\end{aligned}\right\} \quad (19)$$

$$\Delta\tilde{\omega} = \pi(\mu^2 - \lambda^2)\delta^2\frac{(2-e^2) - 2\sqrt{(1-e^2)}}{e^4} + 2\pi\mu\delta\delta'\frac{\sqrt{(1-e^2)} - 1}{e^3}$$

$$-\frac{2\pi tg\frac{1}{2}\varphi}{\sqrt{(1-e^2)}}\nu\left\{[\lambda\delta^2\sin\omega + \delta(e\delta' - \mu\delta)\cos\omega]\frac{1-\sqrt{(1-e^2)}}{e^2} + \mu\delta^2\cos\omega\right\}$$

$$\Delta\kappa' = \pi(\lambda^2 - \mu^2)\delta^2\frac{(2+e^2)\sqrt{(1-e^2)} - 2}{e^4} - 2\pi\delta^2 - 2\pi\mu^2\delta^2$$

$$-2\pi\mu\delta\delta'\frac{(1-e^2) - \sqrt{(1-e^2)}}{e^3}$$

§10. I have worked out the case of the planet Mercury, taking $276°$ and $+34°$ for the right ascension and declination of the apex of the Sun's motion. I have got the following results: |

$$\Delta a = 0$$ [573]

$$\Delta e = 0.018\delta^2 + 1.38\delta\delta'$$

$$\Delta\varphi = 0.95\delta^2 + 0.28\delta\delta'$$

$$\Delta\theta = 7.60\delta^2 - 4.26\delta\delta'$$

$$\Delta\tilde{\omega} = -0.09\delta^2 + 1.95\delta\delta'$$

$$\Delta\kappa' = -6.82\delta^2 - 1.93\delta\delta'$$

Now, $\delta' = 1.6 \times 10^{-4}$ and, if we put $\delta = 5.3 \times 10^{-5}$, we get

$$\Delta e = 117 \times 10^{-10}$$

$$\Delta\varphi = 51 \times 10^{-10}$$

$$\Delta\theta = -137 \times 10^{-10}$$

$$\Delta\tilde{\omega} = 162 \times 10^{-10}$$

$$\Delta\kappa' = -355 \times 10^{-10}.$$

The changes that take place in a century are found from these numbers, if we multiply them by 415, and, if the variations of φ, θ, $\tilde{\omega}$ and κ' are to be expressed in seconds, we have to introduce the factor 2.06×10^5. The result is, that the changes in φ, θ, $\tilde{\omega}$ and κ' amount to a few seconds, and that in e to 0.000005.

Hence we conclude that our modification of Newton's law cannot account for the observed inequality in the longitude of the perihelion—as Weber's law can to some extent do—but that, if we do not pretend to explain this inequality by an alteration of the law of attraction, there is nothing against the proposed formulae. Of course it will be necessary to apply them to other heavenly bodies, though it seems scarcely probable that there will be found any case in which the additional terms have an appreciable influence.

The special form of these terms may perhaps be modified. Yet, what has been said is sufficient to show that gravitation may be attributed to actions which are propagated with no greater velocity than that of light.

As is well known, Laplace has been the first to discuss this question of the velocity of propagation of universal attraction, and later astronomers have often treated the same problem. Let a body B be attracted by a body A, moving with the. velocity p. Then, if the action is propagated with a finite velocity V, the influence which reaches B at time t, will have been emitted by A at an anterior moment, say $t-\tau$. Let A_1 be the position of the acting body at this moment, A_2 that at time t. It is an easy mat-
[574] ter to calculate the distance between those positions. Now, if the action at time | t is calculated, as if A had continued to occupy the position A_1, one is led to an influence on the astronomical motions of the order p/V if V were equal to the velocity of light, this influence would be much greater than observations permit us to suppose. If, on the contrary, the terms with p/V are to have admissible values, V ought to be many millions of times as great as the velocity of light.

From the considerations in this paper, it appears that this conclusion can be avoided. Changes of state in the aether, satisfying equations of the form (I), are propagated with the velocity V; yet, no quantities of the first order p/V or w/V (§8), but only terms containing p^2/V^2 and pw/V^2 appear in the results. This is brought about by the peculiar way—determined by the equations—in which moving matter changes the state of the aether; in the above mentioned case the condition of the aether will *not* be what it would have been, if the acting body were at rest in the position A_1.

ABSOLUTE OR RELATIVE MOTION?

Originally published in German as a pamphlet "Absolute oder relative Bewegung?" by Verlag von Leonhard Simion, Berlin 1896. 1: Immanuel Friedlaender; Berlin, Spring 1896. 2: Dr. Benedict Friedlaender; Berlin, January 1896.

1. The Question of the Reality of Absolute Motion and a Means for its *Experimental* Resolution.
2. On the Problem of Motion and the Invertibility of Centrifugal Phenomena on the *Basis of Relative Inertia*.

PREFACE

The question treated in the following is old; in addition to the cited writings there exists a rather extensive literature on it, about which we reserve comment to a later time. Our work was conceived without knowledge of that literature. It once more illuminates the uncertainty of the basis of our mechanics and of all exact science in general—wherein it must necessarily deal with long-known material—and points the way toward an attempt to solve the question, without any claim of already presenting the solution. If experiments now in progress lead to a result, they may silence the frequently raised objection that the limitations on our experience do not permit a decision. But if the experiments do not succeed, we may perhaps lead others to successful work in this direction by pointing out that the invertibility [*Umkehrbarkeit*] of the centrifugal force, considered already by Newton, urgently needs an experimental treatment as well as a theoretical investigation by reduction to a law of relative inertia. | [3]

1. THE QUESTION OF THE REALITY OF ABSOLUTE MOTION [5]

A body whose position in space changes is said to be in motion. This is one of two possible but fundamentally different definitions of motion. It presupposes that the process of change in position of a *single* body in space, quite independent of actual or possible relations to other bodies, has *content*, that is, that it differs from the state of rest by *recognizable effects*. When we apply this concept to any mechanical problems we have to refer observed motions to a coordinate system fixed in space in order to represent them properly; to do this we must know the true motion of our Earth—from

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

which all measurements originate—so that we can transform from its co-moving coordinates, which we have fixed in the Earth, to a system of coordinates at absolute rest in the universe.

This definition with its consequences forms the basis of our present-day mechanics, and the well-founded high regard for the achievements of this science often prevents critics from daring to examine the justification of this definition. Nevertheless many have already stated the suspicion that this definition of motion is wrong,
[6] because only the relative motions of two or several bodies have *reality*, and | because the motion of one body, apart from its relations to other bodies, does *not* differ from a state of rest. This notion corresponds to our laws of thought and powers of imagination, but, as we shall see, not to the world of phenomena as understood according to the principles of mechanics.

Two groups of phenomena are relevant:

1. The appearance of the centrifugal force,
2. The stability of the free axes and of the plane of a Foucault pendulum.

The question of whether an absolute motion possesses reality, or whether there can be only relative motion, can be answered in different ways; to be precise there are *three* views that we want to consider here.[1] We will totally neglect those who deny the reality of absolute motion at the beginning of textbooks, give only the definition of relative motion, and then as they go along introduce a coordinate system fixed in space without allowing it to be noticed (without noticing it themselves?), particularly for the phenomena of rotation. Others, Kirchhoff for example, introduce *ab initio* coordinates at absolute rest, and in that way at least avoid self-contradiction. Only rarely is the question posed and discussed before it is answered.

Newton was the first to encounter the difficulty; he opines that it should be solved by experiment, and on the basis of an admittedly totally inadequate experiment[2] he
[7] arrives at | the view that absolute motion is real (see Mach, *Geschichte der Mechanik*, p. 317).

Kant grasped the question in its full significance with perfect clarity. He arrives at a solution by construing a difference between purely mathematical, "phoronomical" motion and physical, "phenomenological" motion; about the first he states the following (*Metaphysische Anfangsgründe der Naturwissenschaft*, 1786, Phoronomie, Grundsatz 1):[1]

> Every motion, as object of a possible experience, can be viewed arbitrarily as motion of the body in a space at rest, or else as rest of the body, and, instead, as motion of the space in the opposite direction with the same speed.

By way of contrast, propositions 1 and 2 of the Phenomenology state:

---

1 In the following only the three main points of view will be briefly sketched, as seems necessary for understanding the experiment, without entering into the theoretical treatment of the question by numerous authors.

2 Cf. below, [p. 20 in the original].

> 1. The rectilinear motion of a matter with respect to an empirical space, as distinct from the opposite motion of the space, is a merely *possible* predicate. The same when thought in no relation at all to a matter external to it, that is *as absolute motion*, is *impossible*. [...]
>
> 2. The circular motion of a matter, as distinct from the opposite motion of the space, is an *actual* predicate of this matter; by contrast, the opposite motion of a relative space, assumed instead of the motion of the body, is no actual motion of the latter, but, if taken to be such, is mere semblance.

What Kant states here can be found in Budde's general mechanics[2] in a different form, which more nearly corresponds to the modern point of view and will therefore be more easily understood. He does admit (p. 6) that the determination of position is relative in nature, but after making the transition from *phoronomics to kinetics* he observes—presupposing the principle of inertia—that we are forced by the facts to assume an absolute coordinate system,

> a | fundamental system within which the center of the Sun lies, with an angular velocity [8] $-w$ relative to the Earth. The principle of inertia holds in this system F, and in every other system that is at rest or in uniform translation relative to it; but this principle is no longer valid in a different system that rotates with respect to F, as shown by our experience on Earth.

We can properly state this claim of Kant and Budde as follows: in the purely geometric phenomenon of motion, or in mathematical space, there are neither fixed directions nor a fixed system of coordinates, all motion here is only relative; but in the dynamical phenomena of motion, or in physical space, there is such a coordinate system, which however can be translated parallel to itself without resulting in any real change. In the following I will call this a *fixed system of directions*, and for purposes of visualization I wish to compare physical space with the interior of a crystal imagined to be infinite in extent, in which to a certain extent each rotation, but no translational motion, would have a physical meaning. Indeed, Budde concludes that space is filled with a *medium*, and that the principle of inertia is a property of matter relative to this medium.[3]

Finally, the third possible conception is taken by Mach (p. 322); namely, that only relative motion is real, that our present-day mechanics is incomplete, and that *"the mechanical principles can probably be put in such a form that centrifugal forces result also for relative rotation."*

In short, the three conceptions are:[4] |

1. There is absolute motion, translation as well as rotation; physical space, as [9] opposed to purely geometrical space, possesses a *fixed coordinate system*.

---

3 Earlier authors already expressed similar views.

4 The first point of view is taken by Newton, Euler, Laplace, Lagrange, Poinsot, Poisson, Narr, the second, however partially in a quite different formulation, by Maxwell, Thomson-Tait, Streintz, Lange and others; the third especially by Mach. Some of these authors vacillate in their view or try, like Lange, to unite views 2 and 3.

2. There is no absolute translation, but there is absolute rotation. Real space, as opposed to that corresponding to our conceptual ability [*Denkvermögen*], has an *absolute system of directions*.

3. There is nothing but relative motion; *physical* space does *not differ* from *mathematical* space; but our present-day mechanics explains the phenomena of rotation incorrectly, or at least incompletely.

In the following we wish to treat the special case of centrifugal force first, in order to test the validity of the three views

Imagine a rigid system, consisting of a weightless rigid rod of length $2r$, which has two equal spheres, each of mass m, attached to its ends.

If we allow this system to rotate about an axis perpendicular to the rod at its midpoint—motions being referred to the Earth or to the fixed stars, because in the following we want to assume that the motion of the Earth relative to the fixed stars can be neglected as rather minor compared to that of our system—then there occurs a tension in the rod that equals mv^2/r, according to the well-known formula, where v is the velocity of the mass m. Now we treat this system, which we take to be located on the Earth, based on the three possible assumptions concerning motion. If we first pro-
[10] ceed on the assumption that there is only relative motion, and that | our coordinate system can be fixed completely arbitrarily, then whenever we take the rod itself as a coordinate, for example, or choose any coordinate system rigidly connected to our system of bodies, there is no accounting for the occurrence of the centrifugal force, that is, the measurable stress in the rod. For the rotational motion would then be represented as a rotation of the Earth and the whole firmament of fixed stars about our rod with the two spheres.

However, the rotation of these external bodies cannot explain the existence of the stress in the rod according to any law of mechanics known to date.

Secondly, let us assume that space is constituted somewhat like an infinitely large crystal, that there is no fixed system of axes in it, but that it possesses a system of directions. In this case only the angular velocity and the direction of the rotational axis would be uniquely determined, and we would therefore be entitled to assume that our system is rotating about a fixed axis, perpendicular to the rod and at a distance $a \leq r$ from its midpoint. We then obtain on one side of the axis the stress

$$F_1 = \frac{mv^2(r-a)^2}{(r-a)r^2},$$

and on the other side,

$$F_2 = \frac{mv^2(r+a)^2}{(r+a)r^2},$$

where v denotes the *same* speed as in our earlier equation. Since the rotational axis just assumed—which is only imaginary—is actually free, the rod will take on a uniform stress along its entire extent, namely

$$F = \frac{F_1 m + F_2 m}{2m},$$

but this stress equals

$$\frac{F_1 + F_2}{2} = \frac{mv^2}{2r^2}(r - a + r + a) = \frac{mv^2}{r}.^5$$

| What we have shown in this special example is valid in general according to Budde's treatment: A system of directions in space, which suffices only to define the angular velocity of a system without yielding information on its translational motion, is enough to determine uniquely the centrifugal forces. [11]

In our case just mentioned the motion would consist not only in rotation of one sphere about the other, which is simultaneously rotating about its axis with the same angular velocity and in the same sense, but at the same time the Earth together with the system of the world considered as a whole would move in a circle of radius r about our axis of rotation. This rotation would take place with the same angular velocity as that of our system and in the same sense, but such that the Earth and system of the world would always be only parallely displaced, and every line placed through the Earth and the firmament of fixed stars would maintain a constant direction.

Let us finally go on to the third point of view, the one which admittedly appeals least to us. Let us assume that there is absolute motion—even translation—that is, a space with a fixed coordinate system. Then an absolute rotation can be determined by using systems of masses such as our rod with the two spheres. Thereby we are enabled to refer our motion to a coordinate system of which we can claim that relative to space—relative to an absolute coordinate system—it does not rotate, but it may execute an arbitrary translational motion, for whose determination we have no basis. The whole edifice of our mechanics is based on this view, and by taking this view no contradiction with experience has yet turned up, as far as I know. But until one is in a position to exhibit an absolute translation, the known facts | agree equally [12]
well with a space in which only a system of directions possesses reality. Experiments in this direction have been performed, but we do not want to go into that here.

So the phenomena of centrifugal force teach us—on the basis of the usual mechanical views, namely the formula mv^2/r —that there is an absolute space, or at least a system of directions, and that the motion of a rigid system in this space in certain cases *really* differs from rest in a perceptible way, that is, by the existence of the measurable centrifugal force. But this assumption means that there is a real and in certain circumstances mechanically effective space that significantly differs from the space of mathematics. The only attempt known to us to make this idea moderately

5 The tension in a thread at whose two ends the mass m_1 is being pulled under the influence of an acceleration g_1 by a force F_1, and m_2 with the acceleration g_2 and the force F_2, is given by

$$\frac{m_1 m_2 g_1 + m_1 m_2 g_2}{m_1 + m_2} = \frac{F_1 m_2 + F_2 m_1}{m_1 + m_2}.$$

understandable is Budde's above-mentioned attempt[6] to regard space as occupied, and to regard inertia as a consequence of relative motion with respect to the occupying medium.

The second group of phenomena mentioned above, namely the fact that free axes and the plane of the Foucault pendulum (at the pole) remain fixed with respect to the sky of fixed stars, can be treated more briefly here, since they behave in exactly the same way. Suppose we take the view that there is only relative motion. Then we cannot explain the phenomena mentioned above if we treat, say, the Earth as fixed. Why the Sun, Moon and stars should drag along the free axes or the plane of the pendulum upon their daily revolution about the Earth could not be explained by mechanics. If
[13] we take the second view—that space | has a system of directions—then the phenomena mentioned above prove that the Earth possesses its own absolute rotation. They are explained and calculable under this assumption.

Of course, the same follows on the basis of a space in which not only absolute rotations, but also absolute translational motions are real.

We briefly summarize again what we have stated so far: our way of thinking is in accordance with a space in which one position as such does not differ from another position, nor one direction from another direction. That a body or a rigid system moves in this space, or that it rotates about an interior or exterior point or stays at rest, would then be only different ways of stating the same set of facts, depending on whether it pleases us to fix our system of coordinates by an external body, with respect to which the corresponding relative motion takes place, or by the system in question itself.

But from this point of view we cannot—as shown above—explain the two groups of phenomena of centrifugal force and preservation of axes on the basis of an arbitrary coordinate system.

We can then ascribe to space a system of directions, or assume that space is fixed in a sense and that we can recognize absolute rotation by the appearance of centrifugal phenomena—on the Earth, for example, by a decrease in g toward the equator, etc.; whereas, at least for the time being, we lack evidence for the recognition of any absolute translational motion of the Earth.

To repeat, our intuition opposes this result; the proper reason for this opposition is
[14] that we see ourselves forced to admit a factual difference between mathematical | space and actual space, or differently put, between the space that corresponds to our conceptual ability and the space of phenomena perceived by our senses.

We can try to explain this result the way Budde did. Similar ideas are found already in Kant, who also tried to explain that the content of *vis viva* [*lebendige Kraft*] in a moving mass equals $mv^2/2$ by filling space with a medium.[7] But if we are not content with this, we must contest the result by disputing the premises; that is,

6 This idea was already formulated by Kant in the 1747 treatise regarding the true assessment of *vis viva* [*lebendige Kraft*] (which is in other respects full of obscurities), and it was later expressed by many others, in different forms.[3]

we must question the basis of the usual mechanical explanation of the rotational phenomena under discussion (namely, the law of inertia and the formula $mv^2/2$ for the *vis viva*).

Without knowing that Mach had already done this, I have for many years had doubts about the completeness of these foundations of mechanics, and in particular I have become convinced that the phenomenon of centrifugal force, properly mechanically understood, should also be explicable solely in terms of the relative motions of the system concerned without taking refuge in absolute motion. But I was well aware that the mere statement of these doubts does not amount to much, and that one must find either a new formulation of the expression for *vis viva* of a moving mass and thereby an improved version of the law of inertia, | or one must prove the inadequacy [15]
of the prevailing view experimentally. The phenomena of the centrifugal force in particular seemed to me suited for such an experimental resolution of the question: if the centrifugal force that appears in a flywheel can be explained solely from its relative motion, then it must be possible to derive it also under the assumption that the flywheel is at rest, but that the Earth is turning with the same angular speed about the flywheel axis in the opposite sense. Now, just as the centrifugal force appeared in the resting wheel as a consequence of the rotation of the massive Earth together with the universe, so there should appear, I reasoned, in correspondingly smaller measure an action of centrifugal force in resting bodies in the vicinity of massive moving flywheels. If this phenomenon was verifiable, this would be the incentive for a reformulation of mechanics, and at the same time further insight would have been gained into the nature of gravity, since these phenomena must be due to the actions at a distance[8] of masses, and here in particular to the dependence of these actions at a distance on relative rotations.

In light of the smallness of the masses available for our experiment, I had little hope of an experimental solution, until I thought of a promising experimental arrangement in the fall of 1894. This arrangement consists of putting the most sensitive of all physical instruments, a torsion balance, in the extension of the axis of a heavy mass that rotates as rapidly as possible, namely a large flywheel, for example in a rolling-mill. If the beam of the balance, bearing two small spheres at its ends, is not parallel to the (vertical) plane of the flywheel when the latter is at rest but inclined by an angle of about $45°$ to it, then according to our | theory tensile forces that tend [16]
to separate the spheres from the extension of the axis must appear, so as to make the balance parallel. However, a sensitive balance is a delicate instrument, and a rolling-

7 See footnote 6. Even if I think of space as filled, because otherwise action at a distance would remain inexplicable, I nevertheless strongly doubt that the phenomenon of inertia (respectively, of *vis viva*) derives from motion relative to the nearly massless aether, but I am of the opinion that motion relative to the aether as influenced by nearby gravitating masses, or equivalently motion relative to the gravitating masses themselves causes the inertia (respectively, the *vis viva*) of a moving mass through mediation by the aether.

8 Whether these actions are, as the writers believe, transmitted through a medium or not makes no difference to the matter.

mill is probably not the most comfortable and optimal location for precision measurements, and so due to the many sources of error my experiments, which I started already in November of 1894 at the rolling-mill in Peine—with the kindest support on the part of the management and engineers—have brought to light no incontestable results that I would want to transmit to the public, even though a deviation in the expected sense was established at the beginning and the end of the motion. But since the balance that was used also reacted to other influences, in particular being deviated by a burning candle at a distance of 4 meters in a room (the closer sphere being "attracted"), and since at the rolling-mill at Peine certain furnace doors are opened and closed in the same time intervals as the starting and stopping of the machines we used, I do not yet consider my results unobjectionable. Experiments with a torsion balance inside a double-walled box of copper with a layer of water about 14 mm thick between the two walls, have shown that even this precaution does not suffice to make the needle completely independent of external heat sources. Whether the heat perturbations are to be explained simply by the circulation of air in the interior of the box—which is always sealed airtight to the exterior—or whether effects as with a radiometer are to be considered, I do not dare to decide for the time being. A new instrument that is being prepared will, we hope, exclude all previous sources of error. Although reliable results are not yet available, the constant occupation with the matter and the frequent discussions with my brother Dr. Benedict Friedlaender have led
[17] us to the conclusion that the matter is of sufficient importance | to publish our thoughts already. My brother called my attention to Mach right at the start and in joint work we have drawn many of the consequences that would result from our view. The results of these considerations, as well as several opinions that I cannot fully share, were put together by my brother in the second part of this treatise, and there he has also attempted to state the law of inertia differently, so that one can derive from it the relativity, hence also the invertibility, of centrifugal forces. But it seems to me that the correct formulation of the law of inertia will be found only when the relative inertia, as an effect of masses on each other, and gravity, which is after all also an effect of masses on each other, are reduced to a unified law.[9] The challenge to theoreticians and calculators to attempt this will only be truly successful when the invertibility of centrifugal force has been successfully demonstrated. |

[18] 2. ON THE PROBLEM OF MOTION AND THE INVERTIBILITY OF CENTRIFUGAL PHENOMENA

We are accustomed to regard mechanics as the most perfect of all natural sciences, and efforts are made to reduce all other sciences to mechanics or, so to speak, to resolve

9 For this it would be very desirable to resolve the question of whether Weber's law applies to gravity, as well as the question concerning gravity's speed of propagation. Regarding the latter question, one might use an instrument that makes it possible to measure statically the diurnal variations of the Earth's gravity as it depends upon the position of the celestial bodies.

them in mechanics. Mechanics is the most concrete and nevertheless also the mathematically (that is, for quantitative calculations) finest, clearest and most exactly developed science. We have no cause to examine to what extent this evaluation of mechanics is justified, and we recalled the above statements only in order to indicate that all considerations or matters of fact related to the foundations of mechanics may claim more than the usual interest and importance. Our subject at present is such a consideration, which truly concerns the foundations of mechanics and thereby those of our whole scientific worldview; however, this is no new subject, but surely a nearly forgotten and at any rate not always sufficiently respected problem, *the problem of motion*. This problem is probably connected with another one, which has been discussed far more frequently in former and more recent times, but which is apparently still a long way from an even moderately satisfactory solution, *the problem of gravitation*. |

Concerning gravity we have nothing more than the knowledge of superficially [19] perceptible facts, along with a purely *mathematical* theory, which is in no way physical. No mind thinking scientifically could ever have permanently and seriously believed in unmediated action at a distance; the apparent force at a distance can be nothing other than the result of the effects of forces that are transmitted in some way by the medium being situated between two gravitating bodies. But our presentations refer primarily only to the problem indicated first, that of motion, as we may briefly denote it, and not directly to the latter problem. For the science of motion with all its derivations and consequences contains an image, or rather a formulation that can *not* be imagined, which must be a hint of a present flaw to all who are convinced *that something that cannot be imagined also cannot be actual, i.e. acting*. *Vis viva*, for example, is defined to be proportional to the velocity squared $(mv^2/2)$; and the velocity is defined as the measure of distance divided by that of time (l/t). Centrifugal phenomena are explained by the conflict between a constrained, curvilinear motion and inertia, which tends to maintain rectilinear motion. In both cases, and more generally, one thinks of motion—or let us say, rather, one defines motion—as *absolute* motion, as motion of a mass from one "absolute position" to another "absolute position"; for *thinking* about absolute motion is just what we can *not* do, and precisely this motivated the following considerations. The root of these considerations, as far as the author is concerned, lies in some difficulties and obscurities of none less than Newton, which | I came to know in the early 90's from quotes of Mach in his [20] *Geschichte der Mechanik*.

In themselves the arguments are as simple as they are unusual, which can easily lead to obscurity if one does not demonstrate and think through the matter step by step from the simplest case.

What we perceive of motion is always only relative motion, changes in position of masses *with respect to other masses*. Our hand moves against the rest of the body, considered as relatively motionless; we move on the deck of a ship, the ship moves on the surface of the Earth, it changes its distance from the continent, thought of as fixed. Our planet moves in the universe, namely with respect to a coordinate system that is considered fixed somewhere (in the Sun, for example), and so forth.

Now think (if you can) of a progressive motion of a *single* body in a universal space that is otherwise imagined to be totally empty; how can the motion be detected, i.e. distinguished from rest? By *nothing* we should think; indeed, the whole idea of such an absolute, progressive motion is meaningless. And still, in one case, namely when in motion, our absolutely moving body, thought of as isolated, is supposed to possess an amount of energy that is proportional to (half) the square of its (meaningless) velocity!

That this cannot be imagined is no new discovery; it is so apparent, and in connection with our astronomical knowledge the reasoning suggests itself so naturally, that many should have encountered it. (Cf., e.g., Wundt, *System der Philosophie* etc.)

More tenacious than the absurd idea of an absolute, so-called *translational* motion is that of the rotation of a sphere, for example, about an axis taken in its abso-
[21] lute sense. | To make the picture more concrete and impressive, let us immediately consider one of those well-known apparatuses used in schools for illustrating centrifugal effects. An approximately spherical framework of elastic brass blades can be rapidly rotated about its axis, so that all the blades are bent in such a way that this originally spherical frame suffers a polar flattening and an equatorial thickening. Here too, according to the usual interpretation, one thinks of the rotational motion as absolute and explains the whole phenomenon in the well-known way. Connected with this, or at least with an entirely equivalent example, is the difficulty that Newton already felt strongly, and which seduced that researcher into statements that seem to us more than merely risky. Newton had suspended a glass of water on two strings so that after twisting the strings about each other they put the glass into rapid rotation as they unwound. Since the friction between the glass and the water is rather small, and the inertia of the mass of water in the glass is quite considerable, at the beginning the glass turns nearly alone, whereas the water remains behind; only slowly does the mass of water take part in the rotation. One observes, as is well known, that no centrifugal effects whatever occur as long as the glass rotates alone (or almost alone); the surface of the water remains flat. But as the water takes part in the rotation more and more, it increasingly rises at the rim and falls at the center. Newton concludes from this that the centrifugal effects are a consequence of absolute—but not of relative—rotation; for in the beginning the glass turns compared to the objects "at rest" in the room, including also the mass of water in the glass; but afterwards, according to N., the water rotates "absolutely," and this absolute rotation brings centrifugal effects
[22] into play. It is not difficult to establish the | untenability or even the incorrectness of this Newtonian idea, as Mach did. In the beginning the glass turns with respect to the objects at rest in the room or with respect to the Earth, or more correctly the universe; whereas later the mass of water rotates with respect to the universe. In the first case there was relative rotation between *mass of water* (+ universe) and *glass*, in the second between *mass of water* (+ glass) and the *universe*; and only the latter, but not the former, produced the centrifugal effects. Mach justifiably points out that "absolute rotation" is a fiction, or more accurately, an unthinkable absurdity. The naive mind will immediately object that it is just not possible to hold the mass of water fixed and

now “let the universe rotate” about the same rotation axis; but the more acute mind will quickly agree that *both ideas are plainly identical, namely indistinguishable in any logical or practical way.* The true fact of the matter is just this, that the rotation of the glass with respect to the mass of water releases no centrifugal forces, but that the rotation of the universe with respect to the glass (or equivalently the rotation of the mass of water with respect to the universe) does do so. In the first case it is the very small mass of the glass’s wall that rotates with respect to the mass of water, in the second case it is the universe; we should not be surprised that the vanishingly small mass of the glass does not call forth any noticeable centrifugal forces, but no one could know, as Mach aptly remarked, how the experiment would turn out if the thickness of the glass were significantly increased and its walls ultimately became several leagues thick. Of course, this experiment cannot be executed in this form. But there is still the question of whether an experimental arrangement is possible in practice that would amount to the same thing, and allow us to establish the *invertibility* or *relativity* of centrifugal effects. |

Now it was my brother Immanuel who devised and tried to test an experimental [23]
arrangement of this type. Technical difficulties, some of them quite unexpected, have so far prevented the realization of a reliable result.

It is well known that the torsion balance is the most sensitive of all instruments. The large flywheels in rolling mills and other large factories are probably the largest rotating masses with which we can *experiment*. The centrifugal forces express themselves in a push causing recession from the axis of rotation. Thus, if we place a torsion balance at not too great a distance from a large flywheel, so that the point of suspension of the part of the torsion balance that can turn (the “needle”) lies exactly or approximately on the extension of the flywheel’s axis, then if the needle was not originally parallel to the plane of the flywheel it should tend to approach that position and show a corresponding deflection. Namely, the centrifugal force acts on each element of mass that is not on the rotation axis in a direction tending to move it away from the axis. It is immediately apparent that the greatest possible separation is reached when the needle becomes parallel. So far the difficulties opposing the experiment were that a sensitive torsion balance is also put into motion by perturbing influences —particularly effects of *heat*— as if, by the way, the warmer parts of the apparatus would have an *attractive* effect.

Now if we assume that the experiment were to work flawlessly, we would have thereby discovered a new mechanical-physical phenomenon, whose consequences would be extraordinarily far-reaching. Certainly the phenomenon would be explicable and predictable, as shall be shown immediately, if one were to recast motion and
all concepts connected with it, including | *inertia* in particular, in such a way that *rel-* [24]
ative motion would replace the present tacitly assumed concept of *absolute* motion. However, the predictability on the basis of this suggested recasting would be no objection to the claim that we would be dealing with a fundamentally new phenomenon; for precisely this recasting has not been carried out and tested by anyone. The law of inertia in the usual manner of representation can be transparently described by

saying that every body opposes any change of its velocity (conceived as absolute) with a resistance proportional to its mass in the corresponding direction. Here, the remaining bodies of the universe are completely ignored; in fact, a point that must be especially emphasized is that the concept of mass is, except for its derivation from gravity (mg), derived precisely from the facts of inertia. Every change in velocity, i.e., every acceleration (in the simplest case, for example, the imparting of motion to a body previously at rest until it reaches a certain velocity) is held to be opposed by a *resistance*, the overcoming of which requires the quantity of energy that is afterwards, when the body is in motion, supposed to be contained in that motion as "kinetic energy." It is here to be noted once more that translational motion of a single body in space otherwise regarded as empty is an absurdity, namely, it does not differ from its opposite, rest. Thus, the creation of such a chimera should not require any energy; therefore, if in contrast the actual world does agree with our prerequisites of thought [*Denknotwendigkeiten*], it should surely make a difference with respect to which other bodies motion is to be created, in a word, what *relative* motion of previously nonmoving bodies is to be created. Accordingly, inertia is to be grasped rela-
[25] tively; one could formulate the law of relative inertia as follows: All | masses strive to maintain their *mutual* state of motion with respect to speed and direction; every change requires positive or negative energy expenditure, that is, work is either required—in the case of an increase in velocity—or is released—in the case of a decrease in velocity. The resistance to changes in velocity would then, as soon as we regard all motions as relative, be expressed not only in the one body that, as we are accustomed to say, we "set in motion" (that is, set in motion relative to the Earth) but also in all the others that we regard as being at rest in accordance with the usual conception. According to the usual conception, inertia occurs on a railway train that is to be brought from rest to a certain velocity, but not on the Earth; according to our view it occurs also on the Earth, even though this is not noticeable due to the extraordinarily much larger mass. But when we put very large masses into motion, to the extent permitted by our technology, and we can observe the behavior of very easily moved masses in the vicinity, it is possible that the relativity of inertia can be shown directly. Precisely that experiment of my brother, namely to find the needle in parallel orientation, which has been unsuccessful so far, would be, as is easily demonstrated, not only the proof of the invertibility of the centrifugal force, but also of the relativity of inertia. In our view, both are the same.

The application of the thought indicated here is very simple but unusual to a high degree. For if we consider the resistance to acceleration that some body exhibits, we do not have the slightest thought of other masses that are nearby! But if we do so and hold firmly to the guiding thought that the masses strive to maintain their *relative*
[26] velocity, it turns out that (for motion on a | straight line of body A relative to body B as the simplest case):

$$\left.\begin{array}{l}\text{accelerated approach and}\\ \text{decelerated withdrawal}\end{array}\right\}\text{must have a repulsive effect}$$

$$\left.\begin{array}{l}\text{accelerated withdrawal and}\\ \text{decelerated approach}\end{array}\right\}\text{must have an attractive effect.}$$

In the first two cases a recession, and conversely in the last two cases an approach of the second body B would satisfy the striving to maintain the relative velocity, that is, the inertia considered as relative. But since the second body B has to be treated as inert with respect to the Earth as well, the motion induced in it in this way by body A, having changing velocities, will not annul the relative velocity, but only reduce it; and no matter how large we may choose the mass of body A, it will always be extremely small compared to the Earth's mass, so the motion of body B with respect to the Earth can only be very small, and if it be detectable at all, then only by a sensitive apparatus. As further illustration one can say that due to its inertia with respect to A, body B strives to set itself in motion with respect to the Earth, but because of its inertia with respect to the Earth it strives to move relative to A rather than relative to the Earth.

Let us now apply these considerations to our flywheel and the torsion balance placed before it.

Let the circle $AFCBDF'A$ [in Fig. 1] represent the rim of the flywheel and P a readily movable body or mass point within the rim of the flywheel, as close as possible to its plane, namely a part of the mass of the arm of the torsion balance. For simplicity, let us assume that the point P actually lies within the plane of the flywheel, which of course cannot be realized with strict accuracy | for common wheels whose [27]
spokes and rim lie in one plane.

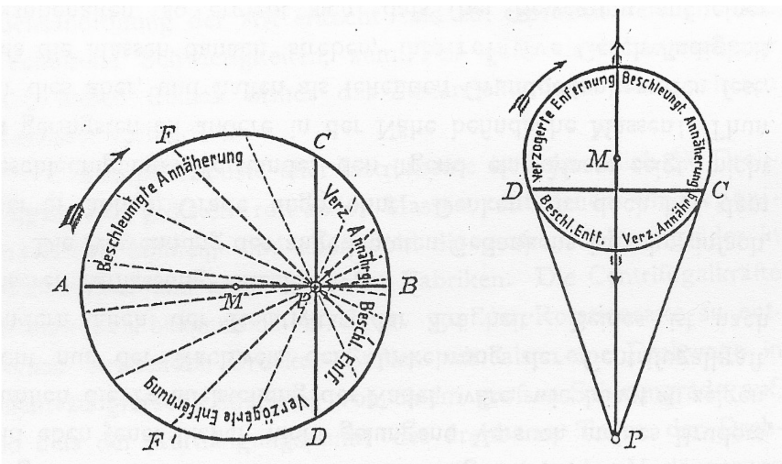

Fig. 1. Fig. 2.

[Beschleunigte Annäherung–accelerated approach; Verz. Annäherg–decelerated approach; Beschl. Entf.–accelerated withdrawal; Verzögerte Entfernung–decelerated withdrawal.]

Let us now join point P to the center of the flywheel M, rotating in the direction of the arrow, and extend this line until it meets the rim at A on the left, at B on the right and also erect the perpendicular on AB at P, cutting the rim above at C, below at D. Then it is clear that every mass point of the rim on its way from A over C to B approaches the point P and then on the way from B over D to A recedes from it. However, the approach on the semicircle AB is accelerated up to C and then decelerated to B; similarly, the withdrawal on the semicircle BA is accelerated to D and decelerated from D to A. In view of the simplicity of the situation we can dispense with an analytic proof. But since in accordance with what we have said accelerated approach and decelerated withdrawal act in the same sense, namely both repulsively, while decelerated approach and accelerated withdrawal both act attractively, we see
[28] that we can divide the rim into two parts that differ | in their effect, namely, the part left of CD, which repels, and that part right of CD, which attracts the point P. But it is also easily understood that only the force components acting along the line AB are effective. Namely, opposite to every point F on the rim there is another, F', whose force components along the line AB reinforce each other, whereas the perpendicular components cancel, being equal and opposite. All forces that push from the left of CD and all those that pull from the right of CD act together along the line AB in the direction from A to B. Therefore, on the basis of the conception of the relativity of inertia an acceleration *away from the axis* is imparted to the point P, as our conception of the invertibility of centrifugal force requires. The relative rotation between the wall of Newton's bucket and the water contained in it would indeed generate appreciable centrifugal forces in the water if the wall were sufficiently massive to be no longer practically non-existent compared with the mass of the Earth.[10]

If the ideas sketched here are correct, many consequences will follow, some of which will admittedly seem very strange. The same amount of gunpowder, acting on the same cannon ball in the same cannon, would impart to the projectile a greater velocity on, for example, the Moon than on the Earth. Naturally, however, the greater velocity would represent, rather than a greater amount, the same amount of energy as the smaller velocity that the projectile receives on our more massive planet. This
[29] would reveal itself in the fact that despite the greater velocity, | the penetration capacity on the Moon would not be greater than on the Earth. For the $mv^2/2$ as measure of the so-called kinetic energy would not be the complete formula, as it fails to take into account the surroundings with regards to mass and distance, that is, the specification of the masses for which the velocity "v" holds.

One should not be overly hasty in rejecting our ideas as obviously incorrect because of their actual or apparent consequences. For example, Foucault's pendulum should be explicable according to our ideas as well. According to the conception of relativity of all motion the fact that the plane of the pendulum is carried along not by the Earth, assumed to be rotating, but rather by the universe when it is assumed to be

10 We originally said "universe" but now the "Earth." It is to be assumed that the Earth will probably play a much larger role than the more distant masses of the universe.

rotating; the plane notoriously follows the latter, and *not* the Earth. To resolve the difficulty one only has to assume that the forces that turn the plane have their origin in the one-sided action of the masses of Sun and Moon, whereas the uniformly distributed mass of the Earth has no effect.

The phenomena of the tides would also have to have a treatment different from the usual one; namely, in our figure we merely need to take our point P outside the circle and draw tangents from it to C and D [Fig. 2]; the circle then represents the Earth, the point P the Moon or the Sun, and PC and PD the axial section of a cone tangent to the Earth from the Moon, treated as a point. One will then see that the Earth will be divided by the approximately circular plane CD, which appears in the figure as a line, into two parts that, on account of the distance, are very nearly equal; of these, the half below CD, i.e., the part turned toward the Moon, will be attracted, while the part above CD, away from the Moon, must be repelled; the mobile water follows these attractive and repulsive forces and excites both the tidal waves that circle the Earth in the time between two culminations | of the Moon. Incidentally, this [30]
explanation differs from the standard one essentially, rather than only in the point of view. Were it possible to connect the two objects rigidly, so that rotation but no approach or recession were possible, then a difference would result; according to the usual explanation the wave away from the Moon could *not* be realized; according to our explanation the occurrence of the tides would not be materially changed.

It is not our intention to dwell on the many other consequences, and likewise we forgo a more detailed interpretation of the analogies that suggest themselves. Still, let us mention the following parallels only in order to indicate the extent to which the problem of motion that we have raised and hypothetically solved here is related to that of the nature of gravity and at the same time comes rather close to the known effects of electric forces: a body that approaches a second one or moves away from it would be without influence on the latter as long as the velocity of approach (to be taken either with a positive or a negative sign) remains unchanged; any change of this velocity on the other hand would entail the above-demonstrated effect.

As is well known, the presence of a current in a conductor is not sufficient for the generation of induction effects, either the magnitude of the current or the distance must vary; in our case the *change* of distance, i.e. the motion, would not suffice for the generation of the attractive or repulsive effects, but rather the velocity itself has to change.

If we think of the effects in question as originating from some as yet unspecified waves, for example from longitudinal pressure waves (although most people would rather think first of transverse waves, due to the prevailing opinions!), then | the [31]
breaking of the waves with equal speed would have no effect, whereas acceleration of the rhythm would induce a repulsive force as long as it lasts, and deceleration an attractive force. It should be noted that these last considerations are only hints and not completed developments that could be understood by attentive reading only. They are also hypothetical to a high degree, as are our main statements, which of course can be regarded as facts only if the experiments described above (or equivalent experiments)

are successful. But let us finally emphasize that the success of the experiments would prove the presence of the type of action in question (even if not our interpretation), but its failure would not disprove this action. It remains questionable whether the effect is of an order of magnitude that would be reliably observable in the face of the experimental error sources. But if we deny the existence of the "inverse centrifugal force," for short, there would be consequences that would really be totally untenable. The incomprehensible would be deemed a fact, the logical absurdity of absolute motion would have to be regarded as having an effect, hence also as actual or real. To imagine and grasp this again in a concrete way, let the reader imagine being on a seat that is fixed on the axis of a rotational apparatus, freely rotating in otherwise empty space, in such a way that he must take part in the "rotation" of the apparatus. The "rotation" of the apparatus would then be accompanied by no change in position with respect to other heavenly bodies, it would not only be imperceptible *as such*, it would be totally unthinkable. It would be a logical monster. Nevertheless, according to the prevailing view that unthinkable "rotation," which cannot be differentiated from rest, is supposed to generate centrifugal forces so that the reader sitting on that seat can
[32] observe the phantom "rotation" by the | equatorial bulge of his little speck of matter, and can even *measure* the motion, not to say the ghost of the motion, by the amount of the deformation.

The world as a whole, we dare say, is not made in a way that would be in conflict with our prerequisites of thought. And therefore the idea of the relativity of all motion and also the origin of the centrifugal effects in *relative* acceleration resistance may have a priori probability on its side, and not against it, in spite of all its unaccustomed and seemingly alarming consequences.

On the basis of our conception it is naturally also necessary to modify the interpretation of the astronomical facts. The Ptolomaic and the Copernican system are both equally "*correct*" as far as they both describe the actual motions of the celestial bodies truthfully; but this description takes a much *simpler* form if one puts the coordinate system at the larger so-called central body, rather than at the Earth. In accordance with the conception of the relativity of all motions, including therefore central motions, a revolution of the Earth can be completely replaced by an axial rotation of the Sun *insofar as only these two bodies come into consideration*. The circumstance that the Earth, despite the "attraction," does not plunge into the Sun, or the Moon into the Earth, is of course explained on the basis of the usual conception by the motion of revolution of the smaller celestial body; while, for example, the axial rotation of the Sun with respect to the universe is taken to be negligible, and plays no role at all. If our conception is correct, the so-called axial rotations are not irrelevant to the equilibrium of the world systems but must be equally taken into account like all other factors. Incidentally, the assumption of an attraction of the Earth by the Sun is not a felicitous interpretation of the factual situation insofar as the so-called *attractive* |
[33] forces can only be adduced from the reduction of distance; naturally, this is not to say that the Sun would not attract the Earth if the relative motions of the two bodies were other than they actually are. However, as the facts stand, that true attraction does *not*

obtain; in accordance with everything we know, it would indeed occur in the case of relative rest of the bodies and bring about the fall of the Earth into the Sun. The attraction is compensated by the existing relative motions, and this would correspond to the usual conception if it would take into account the relative motions instead of operating with the phantom of absolute rotation and inertia treated correspondingly as absolute.

It is also apparent that according to our conception the motions of the bodies of the solar system could be seen as pure *inertial motions*, whereas according to the usual view the inertial motion, or rather its permanent gravitationally modified tendency, would strive to produce a rectilinear-tangential motion.

The central point upon which our view differs from the conventional one can also be expressed precisely as follows. The prevailing view refers all locations, hence all motions and derived concepts such as accelerations and inertia in particular, to a coordinate system considered *absolutely fixed in space*; the absolutely fixed point in space would accordingly be not only an idea, but would have a most real meaning; it would be actual because it could act. It would be such although no criterion can be given for its being fixed. A sympathetic devotee of Kant objected in a private communication that my law of inertia is | not well defined, whereas the usual is definite and moreover [34]
is merely an application of the law of causality to mechanics, with its (allegedly) *a priori* character. "No body changes its motion without cause." By no means do we acknowledge the *a priori* character of the law of causality; if so, the work of Galileo, to the extent that he discovered inertia, would then have been labor in vain and would have resulted only in trivialities, so to speak, which could have been obtained far more simply by deductively applying theorems that were certain *a priori*. To repeat, this we deem incorrect; yet our law of inertia may be given quite an analogous formulation, such as the statement that "no bodies change their *relative* motions without cause"; wherein the "old" law, you see, is only completed by the emphasized word "*relative*." That Kantian objection is surprising, since it, in particular, further supports the objectively real meaning of spatial relations. This is also the basis for the interest that our treatment may perhaps claim, even in the case that it would for some reasons turn out to be untenable. Namely, in that case we would have shown that it is *possible* to proceed from the relativity of all motions, that one *can* explain inertia and centrifugal motions on the basis of the relativity hypothesis; but that upon following this chain of thought further one hits upon factual contradictions, which make the assumption of absolute motion necessary and therefore make manifest the real significance of a coordinate system taken to be absolutely fixed in space, and thereby with even greater probability make manifest the reality of the spatial relations.

From private objections I gather incidentally that if *incorrectly*, that is incompletely, applied, our hypothesis seems to include a violation of the principle of conservation of energy; when considered more exactly, however,| namely when our point [35]
of view is completely implemented, this apparent contradiction disappears. It is true, as we already emphasized, that the formulas for the kinetic energy and everything

depending on it are in need of an appropriate completion by respecting the other masses in the vicinity.

AUGUST FÖPPL

ON ABSOLUTE AND RELATIVE MOTION

Originally published as "Über absolute und relative Bewegung" in Sitzungsberichte der Bayerischen Akademie der Wissenschaften, mathematisch-physikalische Klasse (1904) 34: 383–395 (submitted November 5, 1904). Excerpts already translated by Julian Barbour have been used. (Julian Barbour and Herbert Pfister (eds.)"Mach's Principle: From Newton's Bucket to Quantum Gravity.")

The most acute observations on the physical significance of the law of inertia and the related concept of absolute motion are due to Mach. According to him, in mechanics, just as in geometry, the assumption of an absolute space and, with it, an absolute motion in the strict sense is not permitted. Every motion is only comprehensible as a relative motion, and what one normally calls absolute motion is only motion relative to a reference system, a so-called inertial system, which is required by the law of inertia and has its orientation determined in accordance with some law by the masses of the universe.

Most authors are today in essential agreement with this point of view, as expressed most recently by Voss[1] and Poincaré[2] in particular. A different standpoint is adopted by Boltzmann,[3] who does not believe he can simply completely deny an absolute space and, with it, an absolute motion. Here, however, I shall proceed from Mach's view and attempt to add some further considerations to it. |

Mach summarizes his considerations in the following sentence:[4] "The natural [384] standpoint for the natural scientist is still that of regarding the law of inertia provisionally as an adequate approximation, relating it in the spatial part to the heaven of fixed stars and in the time part to the rotation of the Earth, and to await a correction or refinement of our knowledge from extended experience." Now it seems to me not entirely impossible that just such an extended experience could now be at hand. In a recent publication of K. R. Koch[5] on the variation in time of the strength of gravity we read: "Accordingly, the assumption of a genuine variation of gravity, or, more pre-

cisely, its difference between Stuttgart and Karlsruhe, seems to me appropriate." We shall naturally have to wait and see if this assertion stands up to further testing; at the least, we must now reckon with the real possibility that it is correct.

An explanation of such a phenomenon, if it is correct, would be very difficult on the basis of known causes. This circumstance encourages me to come forward now with a consideration that I have already developed earlier and long ago led me to the assumption that small periodic variations of gravity of measurable magnitude should be considered as a possibility.

Experience teaches us first that the inertial system required by the law of inertia can be taken to coincide with the heaven of the fixed stars to an accuracy adequate for practical purposes. It is also possible to choose a reference system differently, for example, fixed relative to the Earth, in order to describe the phenomena of motion. However, it is then necessary to apply to every material point the additional Coriolis
[385] forces of relative motion if one is to predict the motions correctly. One can therefore | say that the inertial system is distinguished from any other reference system by the fact that in it one can dispense with the adoption of the additional forces. Rectilinear uniform translation of the chosen reference system can be left out of consideration here as unimportant.

However, it is obvious that the fixing of the inertial system relative to the heaven of the fixed stars cannot be regarded as fortuitous. Rather, one must ascribe it to the influence, expressed in some manner, of the masses out of which it is composed. We can therefore pose the question of the law in accordance with which the orientation of the inertial system is determined when the instantaneous form and relative motion of the complete system of masses, i.e., the values of the individual masses, their separations, and the differential quotients of these separations with respect to the time, are regarded as given.

The logical need for such a formulation of the problem if one wishes to avoid the assumption of an absolute space was also felt by Boltzmann when he referred in passing to the possibility[6] that the three principal axes of inertia of the complete universe could provide the required orientation. If this rather natural supposition could be maintained, the conceptual difficulties would indeed be overcome. However, I believe that this supposition is not admissible. Let us imagine, for example, a universe that is otherwise arranged like ours but with the only difference that there are no forces at all between the individual bodies in the universe. Then for the inertial system valid for this universe, all the bodies in it would move along straight lines. However, a calculation that is readily made shows us that under this assumption the principal axes of inertia of the complete system would in general execute rotations relative to the inertial system. It is therefore necessary to look for a different condition that can enable us to understand the fixing of the inertial system. |

[386] If first we assume that all the bodies of the universe are at rest relative to each other except for a single mass point that I suppose is used to test the law of inertia,

6 Loc. cit., p. 333.

and which I will call the "test point," [*Aufpunkt*] then in accordance with the experiences we already have one could not doubt that the test point would, when no forces act on it, describe a straight path relative to a reference system rigidly fixed to the masses. In this case, the inertial system would be immediately fixed in space.

We can now imagine the case in which the bodies of the universe consist of two groups, one of which is "overwhelmingly" large compared to a smaller group and in which the masses within each group do not change their relative separations, whereas the smaller group, regarded in its totality, does carry out at the considered time a motion, say a rotation, relative to the larger group. If only one of the two groups were present, the inertial system would have to be fixed relative to it. Since the two work together, and one of the groups has been assumed to be much more "powerful" than the other, the inertial system will now be indeed very nearly at rest relative to the first group, but it will still execute a small motion relative to that group, which, of course, will be the consequence of the influence of the second, smaller group.

Given such a situation, what would be the most expedient way to proceed? I believe that one cannot be in doubt. One would fix the reference system exclusively using the first, overwhelming group and calculate as if this were the inertial system but take into account the influence of the second group by applying in this case to every test point the very weak additional forces of the relative motion that the chosen reference system executes relative to the true inertial system. If one makes such a decision, then these Coriolis forces no longer appear as mere computational quantities that arise from a coordinate transformation but as physically existing forces that are exerted by the masses of the smaller group | on every test point and arise because [387]
these masses have a motion relative to the chosen reference system.

To develop this idea further, one could start by investigating the case in which the second, smaller group that I just mentioned is represented by a single body. One then has the task of determining the magnitude and direction of the force, which will depend on the velocities of the single body and the test point relative to the reference system determined by the remaining bodies of the universe and on the separation between the single body and the test point. If we suppose that this problem has been solved for a single body, then, using the superposition law, we can also obtain the influence of a whole group of moving bodies.

The securely established observational results that are currently available are certainly not adequate to solve this fundamental problem; however, one does not therefore need to doubt that on the basis of further observations we could arrive at a solution.

After these preliminary considerations, I now turn to the case that corresponds to reality. Using the circumstance that the constellation of the fixed stars changes little in the course of several years or centuries, we can suppose that a reference system that more or less coincides with the inertial system is fixed relative to three suitably chosen stars. However, in order to take into account the small deviations that still remain, one must suppose that to each test point there are applied Coriolis forces, which, as we have just described, are to be interpreted as forces that depend on the velocities of the individual bodies in the universe and the velocity of the test point.

We are now in the position—and on this I put considerable value—to specify a condition meeting our requirement for causality that must be satisfied by the true inertial system required by the law of inertia. Namely, the true inertial system is the
[388] reference system for which all the | velocity-dependent forces that arise from the individual bodies of the universe are in balance at the test point. Even if in practice it is clear that we have not gained very much through this statement, it does appear to me that we have thereby obtained a very suitable basis for forming a clear concept of what is known as absolute motion in mechanics. There is at the least a prospect opened up of a way of determining the inertial system once the law that establishes the velocity-dependent forces has been found. In other words, it will be possible to construct the absolute space that appears in the law of inertia without having to sacrifice the notion that ultimately all motions are merely relative.

Besides, in all these considerations my main aim is to make it at least plausible that if one is to find a satisfactory solution to the questions that relate to the law of inertia it will be necessary to assume the existence of forces between the bodies in the universe that depend on their velocities relative to the inertial system. If this is accepted, then there follows the task of looking for possible phenomena whose relation to the expected general law of nature could be such that the law governing the velocity-dependent forces could be inferred. These forces, which for brevity I shall in what follows simply call "velocity forces," have nothing to do with gravitational forces, which arise concurrently with them, and specifically they can—and probably will— follow a quite different law than the gravitational forces with regard to distance dependence.

At this point I should like to make a remark in order to divide this communication into two quite separate sections. I believe that I can defend with complete definiteness and confidence what I have said up to now. However, I regard what follows as merely
[389] an attempt that could very | well fail; nevertheless, it is an attempt that at the least has a prospect of success and therefore must be brought forward at some time.

It seems to me that the most promising way of proving the existence of the postulated velocity forces and finding the law in accordance with which they act is to observe with the greatest possible accuracy phenomena associated with motions near the Earth that occur with great velocity. Just as the discovery of gravitation had as its starting point the observation of free fall, here too the first step to the solution of the puzzle could be obtained through observations of terrestrial motions and their correct interpretation. The immediate vicinity of the Earth's mass opens up some prospect of proving the existence of velocity forces more accurately than would be possible with the finest astronomical observations, which, as experience teaches, are certainly only very weak under normal circumstances.

This thought led me some time ago to make the gyroscope experiments that I reported to the Academy very nearly a year ago.[7] I expected then, as I explicitly said, to establish a behavior of the gyroscope that did not agree with the usual theory in the

hope that the observed deviation could be attributed to the velocity forces I seek and that these would therefore be made accessible to experimental research. Now certain indications of a deviation were indeed discernible, but as a careful and conscientious experimentalist I could not put any weight on them and I was forced, as I did, to declare a negative result of the experiment as regards the direction that it was intended to follow in the first place. In the meanwhile, I have made some further experiments with the same apparatus, though admittedly few, since they are very laborious and time consuming. However, the result could do nothing but | strengthen [390]
me in the view that the accuracy that can be achieved with this experimental arrangement is not sufficient to prove the existence of the velocity forces if they exist at all.

More promise of success probably lies in a further continuation of the free fall experiments, whose results to date can already be described as rather encouraging, after all. The ordinary theory, which does not take velocity forces into account, leads one to expect in the northern hemisphere, in addition to an easterly deviations of free fall motion from the vertical, a southerly deviation of such an extraordinarily small amount only that its experimental confirmation would be entirely out of the question. Nevertheless observers have time and again found southerly deviations of measurable magnitude, which are of a totally different order of magnitude (several hundred times larger and more) than those expected from theory. The newest observations in this area, due to the well-known American physicist E. H. Hall,[8] famous as an experimentalist and discoverer of "Hall's Phenomenon," have confirmed these experiences again. Indeed Hall considers further experiments on a larger scale (for greater heights of fall) necessary, and he holds out a prospect of such experiments. One may expect very valuable insights from them. Perhaps it will also serve to further the continued performance of such experiments if the hope for a positive result is strengthened by the theoretical considerations as I have offered here. For it takes indeed no small measure of courage to undertake painstaking and lengthy experiments, if the unanimous opinion of all theoreticians comes to this, that they cannot possibly lead to the expected result. This consideration has been for me the main motive to come forward with my views, although | I must admit that so far they are too deficient in an ade- [391]
quate experimental basis to be likely to meet with much approval.

Now I come to the admittedly most doubtful conjecture that I formed in connection with the above, and which is connected with the observation of Koch mentioned in the beginning. One can understand immediately that I must also expect velocity forces that arise from the motion of the Earth with respect to the Sun. The Sun is a fixed star like others and it contributes its part to the determination of the inertial system; or, in other words, it exerts velocity forces, if we account for the motion relative to a system of reference that is established without regard to the Sun. Even if nothing is known about the dependence of these forces on distance we may nonetheless

7 *Sitzungsberichte* 1904, p. 5.

8 Edwin H. Hall, *Physical Review,* 17, p. 179 and p. 245, 1903; further *Proceedings of the American Acad.* 39, No. 15, p. 399, 1904.

regard it as probable that the influence of a closer body is larger than that of a much more distant one. Therefore nothing is more natural than the assumption of velocity forces of such a kind that could cause a small periodic change of gravity with a diurnal as well as an annual period.

One difficulty, a very serious and possibly insurmountable one, arises only when one assumes that these velocity forces could be of such a magnitude that they would be measurable on the surface of the Earth and that the observations of Koch could be evaluated in this sense. Then one necessarily encounters the astronomers' objections, who have noticed nothing of the occurrence of such forces in spite of the great accuracy with which they can predict the phenomena of motion in the solar system.

This objection is so lucid that one would almost abandon the hope of being able to [392] silence it. To be sure, as long as nothing is conclusive about the | laws of action of the velocity forces in other ways, one could retreat to the view that a remote possibility exists that this contradiction could be cleared up later. And in this hope one could first quietly wait and see what consequences derive from such observational results as those found by Koch, temporarily neglecting the contradiction. If for example the original observation of Koch were not only confirmed, but if also the daily period of gravity fluctuations were really found as are expected on the basis of the views proposed here, then one could regard this as a certain confirmation of the suggested theory in spite of all objections.

However, I understand that such a position would be untenable. If it is not possible even now to make it reasonably credible that the interpretation of Koch's observations that I regard as possible does not necessarily have to be in contradiction with astronomical experience, then no one will pay heed to my interpretation, and the danger could arise that the same fate awaits Koch's observations as so far has befallen the southerly deviation of falling bodies, that is, that one does not take it seriously and immediately tends to assign it to errors in observation, because it does not fit with the accepted theory.

Only with this intention and by no means in order to represent the several possibilities I am about to discuss as somehow particularly probable, I still mention the following.

Consider a planet that circles its central body in agreement with the first two laws of Kepler. Let the law of the velocity forces be of the form that the planet is subject to an attraction by its sun that is proportional to the velocity component orthogonal to the radius vector and inversely proportional to the first power of the distance. One immediately recognizes that under these circumstances one would not need any grav- [393] itational force in addition to the velocity force in order to | explain the motion of the planet that is given by the observations. The astronomers of a solar system with only a single planet would have indeed no means to decide whether Newton's gravitational force or the velocity force adopted in the indicated manner were correct if they wished to restrict themselves to observation of the orbit alone. However, the difference would immediately be apparent when they took into account observations on their planet.

In accordance with Newton's gravitational law as well, there is, as is well known, a daily period of variation of the gravity force that gives rise to the contribution of the Sun to the motion of the tides but is too weak to be established by pendulum observations. However, if the astronomers of that solar system were to make the attempt to replace Newton's law of gravitation by the law of the velocity forces that we have mentioned, they would have to expect a much greater daily period, which, for the same relations between our Earth and the Sun, would be about 180 times greater than would be expected in the other case.

It should also be remarked here that the velocity law, which was chosen at random, is in fact only one of infinitely many that would all achieve the same, namely, the explanation of the motion of a single planet around its sun in agreement with Kepler's first two laws without having to invoke in addition Newton's gravitational force. All one needs to do is to allow the velocity component in the direction of the radius vector, which was hitherto assumed to be without influence, to participate as well in accordance with some arbitrary law and then arrange the law according to which the orthogonal velocity component acts on the force of attraction in such a way that the required motion results. There is also no need to make a restriction to the first power of the velocity; one could also consider the second or other powers. |

When a solar system has more than one planet, it is naturally much more difficult [394]
to explain all the planetary orbits merely with the help of velocity forces, since it is now necessary to satisfy Kepler's third law as well. So far as I can see, one would then be forced to make quite artificial assumptions. Even if one could achieve success in a simpler manner than it now appears to me, it would still be questionable if one could also explain the disturbances of the planetary orbits, the motions of the moons, etc.

However, one should not forget the aim of this discussion. It is in no way my intention to replace Newton's law by a law of velocity forces. I only want to make it plausible that under certain circumstances the velocity forces by themselves could have effects very similar to those of the gravitational forces. If this is then granted, it immediately follows that in such an event it would be very difficult to separate out from the astronomical observations the part due, on the one hand, to gravitational forces and, on the other, to the velocity forces.

On the basis of this consideration, I believe it is best not to be deflected by the admittedly very weighty objections of the astronomers from seeking phenomena that could be related to velocity forces. If it does prove possible, following this entirely independent research approach, to derive a law of the velocity forces, it will still be possible to make, as the best test of the admissibility of the result, an accurate comparison with the astronomical observations, taking into account the error limits that are relevant.

Naturally, I would not recommend such a procedure if I did not have great confidence in the very existence of the velocity forces, even though I must leave it as an
open question whether they have a magnitude such | that they are measurable in [395]
motions accessible to our perception. If one will admit an absolute space, then, of course, every reason for the assumption of velocity forces disappears. However, in

this point at least—that I do not recognize an absolute space—I am in agreement with the majority of natural scientists, and I therefore hope that I shall receive recognition among them, at least for the conclusions drawn in the first part of this communication.

AN ASTRONOMICAL ROAD TO
A NEW THEORY OF GRAVITATION

MATTHIAS SCHEMMEL

THE CONTINUITY BETWEEN CLASSICAL AND RELATIVISTIC COSMOLOGY IN THE WORK OF KARL SCHWARZSCHILD

1. KARL SCHWARZSCHILD: PIONEER OF RELATIVISTIC ASTRONOMY

Only a few weeks after Einstein had presented the successful calculation of Mercury's perihelion advance on the basis of his new theory of general relativity in late 1915, the German astronomer Karl Schwarzschild (1873–1916) published the first non-trivial exact solution of Einstein's field equations (Schwarzschild 1916a). The solution describes the spherically symmetric gravitational field in a vacuum and holds a central place in gravitation theory, comparable to that of the Coulomb potential in electrodynamics. It was not only an important point of departure for further theoretical research but also, up to recent times, the basis for all empirical tests of general relativity that proved not only the principle of equivalence but also the field equations themselves. Schwarzschild made a further substantial contribution to the theory when he found another exact solution describing the interior gravitational field of a sphere of fluid with uniform energy density (Schwarzschild 1916b). In this communication an important quantity makes its first appearance. It is the quantity that is later known as the *Schwarzschild radius*, which plays an important role in the theory of black holes many decades later.[1] But even long before the final theory of general relativity was established, Schwarzschild had already occupied himself with possible implications of its predecessors for astronomy; in 1913 he carried out observations of the solar spectrum in order to clarify if the gravitational redshift predicted by Einstein on the basis of the equivalence principle was detectable (Schwarzschild 1914).

In view of the fundamental role played by general relativity in astronomy, astrophysics, and cosmology today, it appears quite natural that an astronomer would engage in the study of this theory. Astronomical objects of all scales ranging from supermassive stars via galaxy nuclei and quasars to the universe as a whole are described on its basis. However, at the time when Schwarzschild made his contributions, the situation was quite different. None of the spectacular objects nowadays so successfully described by general relativity were in the focus of research, most of

1 For a thorough analysis of the early history of the interpretation of Schwarzschild's solutions and the Schwarzschild radius in particular, see (Eisenstaedt 1982; 1987; 1989). See also (Israel 1987), in particular sec. 7.7 on the *Schwarzschild 'Singularity'*.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

them not even known at all. Rather, the deviations from Newtonian theory that general relativity predicted were so small that in most cases they lay on the verge of detectability, even on astronomical scales. General relativity could thus easily be considered a physical theory—it was developed in the attempt to solve problems in physics such as the incompatibility of Newtonian gravitation theory and special relativity—with little implications on astronomy. And even as a physical theory it was still controversial, as is strikingly illustrated by the case of the physicist Max von Laue who as late as 1917 preferred Nordström's theory of gravitation to Einstein's.[2] Accordingly, at the time, astronomers showed little interest in general relativity. Einstein's plea to put the theory to an empirical test went unheard by most of them. In his attempts to provide empirical evidence for the theory, Erwin Freundlich, an outsider to the astronomical community, even met with hostility among Germany's most prominent astronomers.[3] Why was Schwarzschild an exception to this? What put him in the position to recognize so early the significance of general relativity?

The clue for answering these questions lies in the study of work Schwarzschild had done long before the rise of general relativity. In the course of the late 19th century, foundational questions surfaced in classical physics that had implicit consequences for astronomy: consequences that were often of a cosmological dimension. Mach's critique of Newton's absolute space, for example, immediately led to the question of an influence of distant stars on terrestrial physics. The deviation of the geometry of physical space from Euclidean geometry, to give another example, had become a possibility with the work of Gauss and Riemann and could be imagined to be measurable on cosmological scales. A further example is provided by the various attempts to modify Newton's law of gravitation. Such a modification would have consequences not only for planetary motion but also touches upon questions concerning the stability of the whole universe and the large-scale distribution of matter therein.[4] These foundational questions were, despite their astronomical implications, not on the agenda of contemporary astronomical research. Nevertheless, they were studied by a few individual scientists, among them Karl Schwarzschild.

In this paper it is argued that a continuity exists between Schwarzschild's prerelativistic work on foundational problems on the borderline of physics and astronomy and his occupation with general relativity. After a brief biographical introduction (sec. 2), Schwarzschild's prerelativistic considerations on the relativity of rotation (sec. 3) and on the non-Euclidean nature of physical space (sec. 4) are presented as they are documented in his publications as well as in his unpublished notes. On this background, Schwarzschild's reception of general relativity will then be shown to have been shaped to a large extent by his earlier experiences. In fact, what at first sight may appear to be a rather technical contribution to a physical theory—Schwarz-

2 See (Laue 1917).

3 For an account on Freundlich's work on empirical tests of general relativity and the astronomers' reaction to it, see (Hentschel 1997).

4 For a discussions of fundamental problems arising in Newtonian cosmology, see (Norton 1999).

schild's derivation of an exact solution of Einstein's field equations—turns out to have been motivated by Schwarzschild's concern for a consolidation of the connection between astronomy and the foundations of physics as established by Einstein's successful calculation of Mercury's perihelion motion (sec. 5). What is more, Schwarzschild was reexamining his prerelativistic cosmological considerations in the framework of the new theory of relativity as hitherto neglected manuscript evidence reveals for the case of the problem of rotation (sec. 6, a manuscript page from Schwarzschild's Nachlass is reproduced with annotations in the Appendix). Furthermore it turns out that, prepared by his earlier cosmological considerations, Schwarzschild was the first to consider a closed universe as a solution to Einstein's field equations (sec. 7). Summing up, Schwarzschild's road to general relativity may be called an astronomical one. Concluding this paper it will be argued that it was no coincidence that Schwarzschild of all astronomers took this road, but that this was the natural outcome of his interdisciplinary approach to the foundations of the exact sciences (sec. 8).

2. KARL SCHWARZSCHILD: ASTRONOMER, PHYSICIST AND ASTROPHYSICIST

Schwarzschild was born on October 9, 1873 in Frankfurt am Main, the eldest of seven children of a Jewish businessman.[5] He studied astronomy in Strasbourg and in Munich, where he obtained his doctoral degree in 1896 under Hugo von Seeliger (1849–1924), one of the most prominent German astronomers at the time. After having worked for three years at the Kuffner Observatory in Ottakring near Vienna, Schwarzschild obtained his post-doctoral degree (*Habilitation*) in Munich in 1899. On this occasion, Schwarzschild had to defend five theses, mostly concerned with foundational questions, that inspired him, as we will see, to much of the work relevant to our discussion. It is therefore interesting to question the extent to which Schwarzschild's teacher, von Seeliger, was involved in formulating these theses. While it may well be the case that Schwarzschild himself played some role in their creation, their exact wording makes it plausible that they were formulated by von Seeliger (see the discussion below). Thus this sheds some light on von Seeliger's ambivalent role in the early history of relativity. On one hand he was known to be very sceptical of relativity theory. For example, he severely criticized Erwin Freundlich's attempts to provide empirical evidence supporting general relativity. On the other hand he was interested in foundational questions of theoretical astronomy and apparently inspired Schwarzschild to much of the work discussed here.

In 1901, Schwarzschild was appointed professor of astronomy and director of the observatory of Göttingen University. He became closely associated with the circle of mathematicians and natural scientists around Felix Klein and furthered the integration of Göttingen astronomy with general scientific life.[6] Schwarzschild left Göttin-

5 For a short biographical account on Schwarzschild, see (Schwarzschild 1992, 1–25).

gen in 1909 and became director of the *Astrophysikalisches Institut* in Potsdam, but, for the short remainder of his life, he maintained the personal and scientific relationships established in Göttingen. Thus it was his Göttingen colleagues and acquaintances who, on several occasions, wrote him about the latest developments of Einstein's theory and pointed out the importance of its astronomical verification.[7] On May 11, 1916, Schwarzschild died an untimely death from a skin disease he contracted while serving at the Russian front.

Schwarzschild's scientific work is characterized by its rare breadth. The range of topics from physics and astronomy covered by his more than one hundred publications is hardly surpassed by any other single scientist of the twentieth century. Schwarzschild is further known to be one of the founders of astrophysics in Germany and was its most prominent exponent at the time. While disciplinary astrophysics itself was a rather specialized enterprise—using physical instruments for astronomical observation and applying physical theory to astronomical objects—Schwarzschild's interdisciplinary outlook on the foundations of science[8] enabled him to overcome the constraints imposed by specialization and deal with foundational problems on the borderline of physics and astronomy that were not in the focus of mainstream research.

3. SCHWARZSCHILD'S PRERELATIVISTIC CONSIDERATIONS ON THE RELATIVITY OF ROTATION

In 1897, while he was assistant at the Kuffner Observatory in Ottakring, Schwarzschild published a popular article entitled *Things at Rest in the Universe* (*Was in der Welt ruht,* Schwarzschild 1897). In this paper he discusses the relativity of motion and the problem of finding appropriate reference frames. In particular, he is concerned with the question of how fixed directions in space can be defined.

Schwarzschild's starting point is the observation that the motion of an object can only be perceived relative to other objects and that therefore any object may be considered at rest. The question of what thing is at rest in the universe should therefore be reformulated in a historical manner as "[w]hat things in the universe did one find useful to treat as being at rest, at different times [in history]?".[9] In the Copernican system, Schwarzschild explains, fixed directions in space were defined by reference

6 See (Blumenthal 1918).

7 See, in particular, Schwarzschild's correspondence with David Hilbert. On a postcard to Schwarzschild from October 1915, for example, Hilbert wrote: "The astronomers, I think, should now leave everything aside and only strive to confirm or refute Einstein's law of gravitation." ("Die Astronomen, meine ich, müssten nun Alles liegen lassen u. nur danach trachten, das Einsteinsche Gravitationsgesetz zu bestätigen oder widerlegen!") Hilbert to Schwarzschild, 23 October, 1915, N Briefe 331, 6r. (This and all following translations are my own, a few of them are based on the companion volumes to the Einstein edition.) Examples of this kind are also found in Schwarzschild's correspondence with Arnold Sommerfeld. A selection of Sommerfeld's scientific correspondence has recently been published (Sommerfeld 2000–2004).

8 See sec. 8.

to the system of fixed stars. Towards the end of the 17th century it became clear however that the Copernican stipulation is not unambiguous: the stars perform motions relative to one another, the so-called proper motions. Schwarzschild therefore next considers the electromagnetic aether as a candidate for a material reference of rest but comes to the conclusion that the aether too cannot serve such a purpose since it is affected by ponderable matter moving through it. Schwarzschild concludes that there are no material objects in the universe that one could reasonably consider at rest and that one can only take resort to "certain conceptually defined points and directions that may serve as a substitute to a certain extent".[10]

In order to explain how fixed directions in space may be defined on the basis of the law of inertia, Schwarzschild refers to Foucault's pendulum. By accurate observations of the rotation of the pendulum's plane of oscillation, Schwarzschild explains, one could calculate the speed of rotation of the Earth, and would then have to describe as fixed the direction with respect to which the Earth rotates with the calculated speed.

In following this idea further, Schwarzschild establishes an interesting connection between inertia and gravitation in the following way. In regarding the planets orbiting around the Sun as gigantic, diagonally pushed pendulums, he conceives an astronomical realization of the physical model of the pendulum. In analogy to Foucault's pendulum, fixed directions in space are then given by the aphelia (or perihelia) of the orbits of the different planets. However, Schwarzschild explains, astronomical observations since the middle of the 19th century reveal that the directions singled out by the orbits of the different planets rotate with respect to each other at a very slow rate, so that it is "impossible to consider all as fixed."[11] Although Schwarzschild was aware of possible astronomical explanations, such as interplanetary friction, he considered it more probable that an explanation of these small anomalies has to go further, requiring a revision of the classical law of gravitation.

In this way, Schwarzschild established a relation between the two physical phenomena, inertia and gravitation, the integration of which was later to lie at the basis of Einstein's theory of general relativity. Moreover, the observational fact by which Schwarzschild links the two phenomena—the perihelion shift of the inner planets—was later to play a crucial role in the establishment of general relativity, for some years being the only empirical fact suggesting a superiority of general relativity over the Newtonian theory.

There are, of course, fundamental aspects of general relativity that have no analogue in Schwarzschild's prerelativistic considerations. Most notably, Schwarzschild did not consider a field theory of gravitation that unifies gravitation and inertia in one

---

9 "[w]as in der Welt hat man zu verschiedenen Zeiten als ruhend zu betrachten für gut befunden?" (Schwarzschild 1897, 514). All page numbers cited for this text refer to vol. 3 of the *Collected Works* edition (Schwarzschild 1992).

10 "[...] gewisse begrifflich definierte Punkte und Richtungen, die einigermaßen als Ersatz eintreten können [...]" (Schwarzschild 1897, 516).

11 "[...] unmöglich alle als fest betrachtet werden können." (Schwarzschild 1897, 520.)

single field. In fact, in this text, Schwarzschild does not even question the origin of inertia. Unlike Mach and Einstein, he does not search for a physical cause of inertia but rather assumes inertia to be given and, on its basis, defines fixed directions in space. Most probably he therefore thought of modifications of the Newtonian law of gravitation that do not affect inertial frames. For example, it was well known at the time that the change of the exponent in Newton's inverse square law yields perihelion motions.[12] Such a motion could have easily been subtracted from the observed motions in order to obtain the "true" inertial directions in space given by the planets' orbits. There are however notes found in Schwarzschild's manuscripts that show that he was concerned with the question of the origin of inertia and that, in this context, he considered the possibility of local inertial frames rotating with respect to one another. These notes, in which Schwarzschild was again using orbits of celestial bodies in order to determine inertial directions, shall now be discussed.

As explained in sec. 2, Schwarzschild had to defend five theses, probably formulated by his teacher von Seeliger, in order to obtain his post-doctoral degree in 1899. One of these theses read: "The existence of centrifugal forces is comprehensible only under the assumption of a medium pervading all of space."[13] In a notebook of 1899 (N 11:17),[14] we find Schwarzschild's tentative defense of this thesis. In a thought experiment reminiscent of Einstein's later ones, attempting to clarify the nature of rotation, Schwarzschild imagines two planets of identical constitution rotating with different angular velocity and having atmospheres that are so dense that the outer world cannot be observed.[15] An inhabitant of one of the planets travelling to the other would have no way of understanding how the difference in the "gravitational conditions" (*Schwereverhältnisse*) arises, since he would not notice the rotation. This shows clearly, Schwarzschild explains,

12 Thus, Schwarzschild's teacher Hugo von Seeliger wrote in a letter to Arnold Sommerfeld: "that the law of attraction $1/r^n$ $(n \neq 2)$ [causes] perihelion shifts, that is known to any astronomer since time immemorial. [...] *Newton* already treated this case, or a quite similar one, in his 'Principia.'" ("[...] daß das Anziehungsgesetz $1/r^n$ $(n \neq 2)$ Perihelbewegungen [hervorruft], das ist jedem Astronomen seit jeher bekannt. [...] Schon *Newton* hat diesen oder einen ganz ähnlichen Fall in den 'Prinzipien' behandelt.") Hugo von Seeliger to Arnold Sommerfeld, May 25, 1902, Arnold Sommerfeld Nachlass, Deutsches Museum, Munich, HS 1977-28/A, 321, 1-1.

13 "Die Existenz von Centrifugalkräften ist nur unter der Annahme eines den ganzen Raum erfüllenden Mittels zu begreifen." A document naming the five theses can be found in N 21 (for an explanation of this notation see the next footnote).

14 Here and in the following, references to Karl Schwarzschild's Nachlass in the Niedersächsische Staats- und Universitätsbibliothek Göttingen are indicated by an archival number following an 'N' (e.g. N 11:17).

15 Consider, for example, Einstein's thought experiment involving two identical fluid bodies rotating with respect to one another (Einstein 1916, 771–772). Schwarzschild's thought experiment is further reminiscent of a later one by Poincaré, who also considered a planet covered by clouds so that its inhabitants cannot see the sun or stars. They therefore, Poincaré argued, would have to wait longer than we did until a "Copernicus" arrived, who could explain the centrifugal and Coriolis forces by assuming that the planet rotates (Poincaré 1902, chap. 7).

> that not only the internal relative circumstances but also the relations to the surrounding space have an influence on the processes in a system of bodies. Following Newton we could state that there is an absolute space and that the relation of motions to this absolute space has an influence on the forces appearing through this motion. Or, in other words: absolute space has an effect on the bodies. Now, we are used to thinking of anything having an effect as something real, namely something material, and from this it follows that, if we want to stick to the usual way of thinking, we have to imagine space, Newton's absolute space, filled with a substance.[16]

The hypothetical identification of space with a substance now puts Schwarzschild in a position to discuss the global validity of the locally distinguished directions:

> This substance does not have to be at absolute rest, but only in a state of motion that in some way distinguishes three fixed directions in space [...]. Then it is comprehensible that the centrifugal forces are based on a relation of the motion of the usual bodies to the motion of this substance.[17]

From the observation that the perihelia of double stars are at rest with respect to the directions that seem fixed inside the solar system, Schwarzschild concludes that the directions distinguished in their region of space have to be the same as in the solar system.

To sum up, while in the previous example, Schwarzschild had established a relation between inertia and gravitation, here he relates inertia to the structure of space, considering the possibility that the local inertial directions may vary on cosmological scales.

4. SCHWARZSCHILD'S PRERELATIVISTIC CONSIDERATIONS ON NON-EUCLIDEAN COSMOLOGY

A second example for Schwarzschild's prerelativistic treatment of foundational questions having cosmological implications is provided by his application of non-Euclidean geometry to physical space. Again, this work appears to have been inspired by one of the five theses Schwarzschild had to defend in order to attain his degree. This thesis reads: "The hypothesis that our space is curved should be rejected".[18] It is

---

16 "[...] daß auf die Vorgänge in einem Körpersystem nicht nur die inneren relativen Verhältnisse, sondern auch die Beziehungen zum Raum, der sie umgiebt, von Einfluß sind. Wir könnten mit Newton sagen, daß es einen absoluten Raum giebt und daß das Verhalten der Bewegungen zu diesem absoluten Raum auf die bei der Bewegung auftretenden Kräfte von Einfluß ist. Oder in anderen Worten: der absolute Raum hat eine Wirkung auf die Körper. Nun pflegen wir uns aber alles, was eine Wirkung hat, als etwas wirkliches, nämlich als etwas Materielles zu denken, und daraus folgt, daß wir, wenn wir überhaupt in der üblichen Denkweise bleiben wollen, uns den Raum, Newtons absoluten Raum durch einen Stoff erfüllt denken müssen." (N 11:17, 8v–9r.) There are no page numbers in this notebook. The page numbers given here refer to my pagination.

17 "Dieser Stoff muß nicht absolut ruhen, sondern nur eine Bewegungsform haben, welche auf irgend eine Weise drei besondre feste Richtungen auszeichnet [...]. Dann ist begreiflich, daß die Centrifugalkräfte auf einer Beziehung der Bewegung der gewöhnlichen Körper zur Bewegung dieses Stoffes beruhen." (N 11:17, 9r.)

18 "Die Hypothese einer Krümmung unseres Raumes ist zu verwerfen" (N 21).

plausible to assume that this thesis too was formulated by von Seeliger. In fact, the thesis seems to reflect von Seeliger's attitude toward the application of non-Euclidean geometry to physics and astronomy which was extremely sceptical as may be illustrated by the following passage from a talk by von Seeliger entitled *Remarks on the So-Called Absolute Motion, Space, and Time*:

> [...] the common and therefore very fatal misapprehension has emerged that one believed to be able to decide by measurement which geometry is the "true" one, or even, which space is the one in which we live. From the stand point taken here the latter formulation is by far the more dangerous one, since space in itself has no properties at all.[19]

In the above-mentioned notebook of Schwarzschild we find an entry in which the thesis is slightly reformulated as follows: "The assumption of a curvature of our space is without any advantage for the explanation of the structure of the system of fixed stars".[20] The note is accompanied by considerations and calculations in which Schwarzschild examines empirical consequences of a curvature of space, for example, on the parallaxes of stars. One year later, Schwarzschild published a more detailed account of these considerations, though now under a different perspective. While the notebook entries aimed at a rejection of the curvature of space—understandably so in view of their context, the defense of a thesis—the purpose of the published article is to estimate the degree of curvature that can be assumed without contradicting observation. The article bears the title *On the Permissible Scale of the Curvature of Space (Über das zulässige Krümmungsmaass des Raumes,* Schwarzschild 1900).[21]

In his article Schwarzschild mainly discusses two cases: hyperbolic space, having constant negative curvature, and spherical space, having constant positive curvature. He makes the assumption that light travels along geodesics.

As far as hyperbolic space is concerned, Schwarzschild is able to estimate a minimal radius of curvature with the help of the parallax. As is well known, the parallax of a star, for simplification assumed to be nearly perpendicular to the ecliptic, is defined as half the difference of the two angles under which the star is seen in an interval of half a year, $\pi = (\alpha - \beta)/2$ (see Fig. 1). (In Euclidean space this coincides with the angle under which the radius of the Earth's orbit is seen from that star.) In Euclidean space, therefore, a parallax of exactly zero implies that the star is infinitely far from the Earth, since parallel geodesics in Euclidean space intersect at infinity. In hyperbolic space, in contrast, neighboring geodesics diverge. Thus even stars infinitely remote from the Earth possess a certain parallax. This minimal paral-

19 "[Es] ist der verbreitete, aber gerade darum sehr verhängnisvolle Irrtum entstanden, daß man glaubte durch Messungen entscheiden zu können, welche Geometrie die "wahre" ist, oder gar, welcher Raum der ist, in dem wir leben. Von dem hier vertretenen Standpunkt aus ist die letztere Fassung die bei weitem gefährlichere, da der Raum an sich überhaupt keine Eigenschaften hat." (Seeliger 1913, 200–201.)

20 "Die Annahme einer Krümmung unseres Raumes ist ohne jeden Vorteil für die Erklärung des Baues des Fixsternsystems." (N 11:17, 4r.)

21 The article is based on a talk Schwarzschild held at the Heidelberg meeting of the *Astronomische Gesellschaft* in 1900.

lax decreases with an increase in the radius of curvature. Since for most stars no parallax can be observed, the minimal parallax is given by the accuracy of observation. This is given by Schwarzschild as 0.05″. From this he concludes that the curvature radius of hyperbolic space must be at least 4 million times the radius of the Earth's orbit.

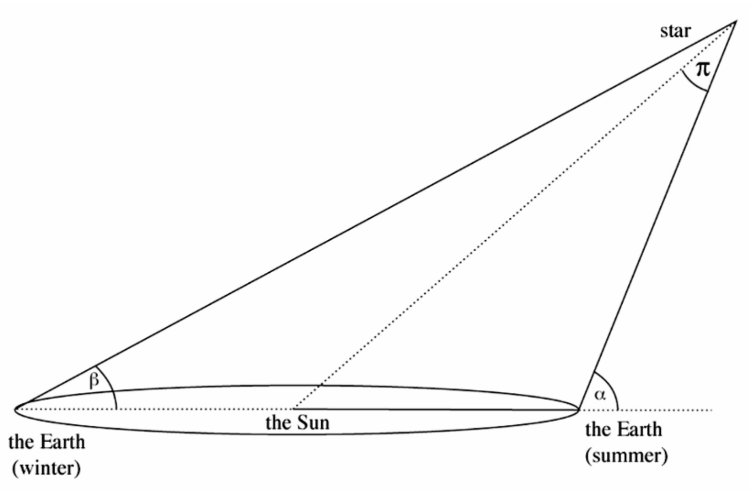

Figure 1: The annual parallax of a star nearly perpendicular to the ecliptic

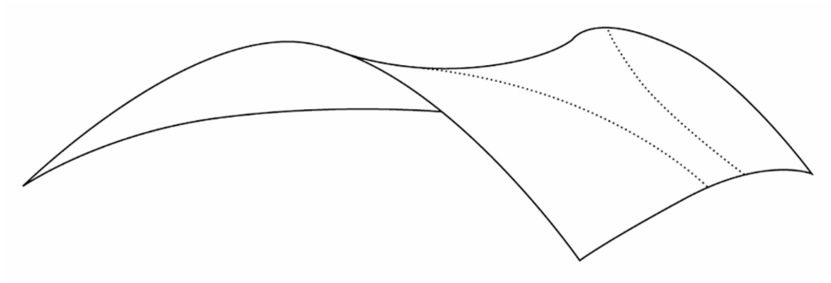

Figure 2: Two-dimensional hyperbolic space. Two geodesics are drawn as dotted lines

As concerns spherical space, Schwarzschild discusses the special case of an elliptic space. The latter can be obtained from usual spherical space by identifying antipodal points. As a consequence, two geodesics going around the world intersect at only one point. Schwarzschild's reason for preferring elliptic to spherical space is that, in the latter, light emitted at one point in space in different directions would converge on the antipodal point, a rather artificial-looking consequence which, according to Schwarzschild, one would not accept without being forced to.

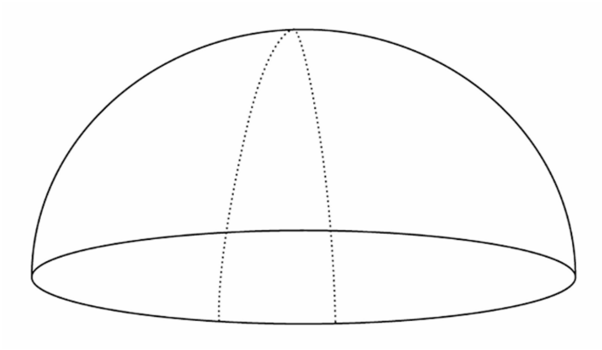

Figure 3: Two-dimensional elliptic space (the antipodal points on the circle c are to be identified). Two geodesics are drawn as dotted lines

In the case of elliptic space there is no minimal parallax and physical considerations are required in order to determine a minimal radius of curvature. Schwarzschild offers the following reasoning. In elliptic space neighboring geodesics converge and thus intersect already at a finite distance, namely at the distance $(\pi/2)R$, where R denotes the curvature radius. Stars having a parallax smaller than a certain given value, say $0.1''$, therefore have all to be located within a finite volume. Now, there are approximately 100 stars of parallax above $0.1''$. All other stars are thus to be found in this finite volume. If one assumes a uniform distribution of stars, one can determine a certain minimal radius of curvature. A weaker requirement, however, is that the stars with parallax less than $0.1''$ occupy a volume large enough so that they do not influence each other in a way that could not have escaped observation. Schwarzschild does, for instance, calculate that if the elliptic space had a curvature radius of about 30,000 times the radius of the Earth's orbit, stars at great distances from the Earth would be separated from one another by only about 40 times the radius of the Earth's orbit. The physical interactions between the stars resulting from this could hardly be concealed from observation. From these considerations Schwarzschild concludes that the minimal radius of curvature of elliptic space is of the order of 100 million times the radius of the Earth's orbit. Schwarzschild further argues that such a relatively small radius of curvature (roughly 1600 light years) is only a realistic possibility if one further assumes an absorption of the starlight of about 40 magnitudes in one circulation around the universe because it is only under this assumption that the appearance of a counter image of the Sun can be avoided.

In this article, as in a later one (Schwarzschild 1909), Schwarzschild expresses his preference for the elliptic space over the hyperbolic or even the Euclidean one, because its finiteness would make it possible in principle to investigate the macroscopic world exhaustively. This idea would have a soothing effect on the mind.

While the differences between Schwarzschild's application of non-Euclidean geometry to physical space on one side and modern cosmology on the other are obvious (application to three-dimensional space rather than to four-dimensional spacetime, no dynamics of geometry, consideration of scales that today are hardly considered cosmological), Schwarzschild's consideration also contains striking parallels to the modern treatment of the problem such as the idea that light proceeds along geodesics and, most notably, the possibility that the universe is spatially closed.[22]

5. THE PERIHELION BREAKTHROUGH

In sec. 3 we have seen how Schwarzschild put the perihelion anomalies of the inner planets into the context of the fundamental physical phenomena of inertia and gravitation. In view of this, Einstein's successful calculation of Mercury's perihelion motion on the basis of his new theory must have appeared to Schwarzschild as the realization of his earlier speculations on the relations between physics and astronomy. In this sec. it will be argued that it was indeed Einstein's perihelion result that instigated Schwarzschild's interest in general relativity. It turns out that even Schwarzschild's derivation of his first exact solution was motivated by his concern to consolidate Einstein's result.

As early as 1912 Schwarzschild had been confronted with the question of the observability of astronomical consequences of general relativity and its predecessors—in particular consequences of the principle of equivalence. Interestingly, in view of Schwarzschild's correspondence, it was not Einstein himself who first confronted Schwarzschild with the question of astronomical consequences of such a theory but rather one of his antagonists in the search for a new theory of gravitation: the theoretical physicist Max Abraham (1875–1922). Abraham, at that time holding a post as professor of rational mechanics at the University of Milan, was himself working on a new theory of gravitation on which he had already published.[23] Although Einstein and Abraham were in severe disagreement about the foundations the new theory of gravitation should build upon, some empirical consequences of Abraham's theory coincided with those Einstein had derived from his more general considerations. Thus, in his first publication on the matter, Abraham discusses the bending of light in a gravitational field that follows from Huygens' principle whenever the speed of light is assumed to be variable, and, in a footnote, points out that Einstein has drawn the astronomers' attention to the fact that the bending of star light in the gravitational field of the Sun may be observable (Abraham 1912, 2).

There are two remnants of Schwarzschild's correspondence with Abraham found in Schwarzschild's Nachlass. The first is a draft in Schwarzschild's hand of a letter most probably addressed to Abraham,[24] the second is a letter from Abraham to Schwarzschild, dated October 13, 1912 (N Briefe 5). From Schwarzschild's draft it

---

22 In an addendum to his article, Schwarzschild mentions a further possibility that later became a debated subject in relativity theory: the possible application of different topologies to physical space.

23 His first publication on that matter being (Abraham 1912).

becomes apparent that Abraham had previously raised the question whether there would be an effect recognizable through astronomical observation if the Sun's loss of inertial mass was proportional to the energy it radiates away, while the gravitational mass did not change in this proportion. In his letter from October 13, 1912, Abraham formulated another idea, arguing that the energy loss of the planets when cooling down in the process of the genesis of the solar system must have diminished the inertial and the gravitational mass in equal proportion, since otherwise Kepler's third law of planetary motion could not be valid. Finally, in their correspondence, the two discussed the possible shift of spectral lines in a gravitational field. Here, as elsewhere in his correspondence and writings prior to Einstein's perihelion result, Schwarzschild is very sceptical about the astronomical detectability of the predicted effects, although he appears to regard the nascent theory of relativity with openness. Thus, as concerns the redshift in the solar spectrum, Schwarzschild writes:

> The shift of the wavelengths on the Sun that Einstein demands, exists [...] due to a strange coincidence in exactly the right magnitude. There is, however, no doubt that it is to be blamed partly on pressure and partly on downwards motions in the solar atmosphere. To see more clearly in this respect, one has to study the lines at the different points of the solar disk. Until now, this has only been done in a really sufficient manner for the lines 3933 Å of calcium (St. John, Astrophysical J[ournal).] His results do in fact speak *against* the existence of the sought-after shift. Despite this, I do not want to claim that this is already an absolute veto against the theory. Before that, more lines would have to be equally well investigated.[25]

In 1913 Schwarzschild himself started an investigation of exactly the kind he had spoken of in his letter to Abraham, performing a series of observations of the band at 3883 Å in the solar spectrum. The continuation of these observations was foiled by the outbreak of war in 1914, but Schwarzschild reported on the results so far obtained in a communication that was presented to the Prussian Academy of Sciences by Einstein on November 5, 1914 (Schwarzschild 1914). In the introduction to this commu-

---

24 N Briefe 846. The draft is dated in another hand as "1912" and commented on as "possibly [to] W. Lorey." The contents however makes it most probable that it is the draft of a letter to Max Abraham. It may be dated September 29, 1912 (or a little earlier) on the basis of Abraham's letter to Schwarzschild from October 13, 1912, mentioning a letter from Schwarzschild from September 29: most probably the letter that was written on the basis of the draft.

25 "Die Verschiebung der Wellenlängen auf der Sonne, die Einstein fordert, besteht [...] durch einen merkwürdigen Zufall genau in der richtigen Größe. Es ist aber kein Zweifel, daß dieselbe zum Teil auf Druck, zum Teil auf absteigende Bewegungen in der Sonnenatmosphäre zu schieben sind. Um Klarheit darüber zu bekommen, muß man die Linien an den einzelnen Punkten der Sonnenscheibe studieren. Das ist in wirklich ausreichender Weise bisher nur für die Linien 3933 A. E. des Calciums geschehen (St. John, Astrophysical J. dessen Resultate sprechen durchaus *gegen* die Existenz der gesuchten Verschiebung. Trotzdem möchte ich nicht behaupten, daß hiermit schon ein absolutes Veto gegen die neue Theorie gegeben ist. Es müßten doch erst noch mehr Linien gleich gut untersucht werden." Draft of a letter from Schwarzschild to Abraham, probably September 29, 1912, N Briefe 846, 27v, 28r. St. John's publications in the *Astrophysical Journal* on the motion of calcium vapour in the solar atmosphere are (St. John 1910; 1910–11). For an account on St. John's later work on line shifts and its relation to general relativity, see (Hentschel 1993).

nication, Schwarzschild points out that the observation of the solar spectrum is of interest not only for the sake of solar physics, but "can, according to Mr. Einstein, inform us about the relativity of the world".[26] By referring to Einstein's article on the influence of gravitation on the propagation of light (Einstein 1911), Schwarzschild explicitly relates the gravitational redshift to the principle of equivalence. However, once more Schwarzschild does not conclude affirmatively, describing his preliminary results and other astronomers' observations he reports on as still being indecisive concerning the gravitational redshift.

In his correspondence with Max Planck in 1913, Schwarzschild even more clearly expresses his doubts concerning an astronomical verification of Einstein's theory. In a letter from January 31, 1913, Planck had asked Schwarzschild for an assessment of the feasibility and the expenses of the eclipse expedition that Erwin Freundlich was planning for the year 1914 and for which he was going to apply to the *Preussische Akademie der Wissenschaften* for funding (N Briefe 593, 2r, v). Freundlich intended to search for a deflection of starlight near the solar disk as predicted by Einstein. Schwarzschild commented on the observational side of the problem in the following way:

> In the problem itself I also have no particular confidence. The diminution of the frequency on the Sun and the shift to red of all spectral lines on the Sun that Einstein assumes can be regarded as refuted by the observations. The last word has not yet been spoken, but the shifts which for single lines are also to violet, can be too well interpreted as being due to pressure. Since this whole thing looks rather fishy, it won't be much different for the deflection of light rays by the Sun's gravitation.[27]

When Einstein succeeded in deriving the correct value for Mercury's perihelion shift from his theory,[28] Schwarzschild's appraisal of the new theory of relativity changed drastically. Einstein presented his calculation of Mercury's perihelion advance to the Prussian Academy of sciences on November 18, 1915. Schwarzschild was on leave from his military duties at the Russian front and attended the meeting.[29] Back in Russia, Schwarzschild wrote to Einstein:

> It is quite a wonderful thing that from such an abstract idea the Mercury anomaly emerges so stringently.[30]

---

26 "[...] kann nach Hrn. Einstein auch Auskunft über die Relativität der Welt geben." (Schwarzschild 1914, 1201.)

27 "Auch zum Probleme selbst habe ich kein besonderes Fiduz. Die Verminderung der Schwingungszahl auf der Sonne und die [...] Verschiebung aller Spektrallinien nach Rot auf der Sonne, die Einstein annimmt [...] kann als durch die Beobachtungen als widerlegt angesehn werden. Das letzte Wort ist noch nicht gesprochen, aber die [...] Verschiebungen, die [...] bei einzelnen Linien auch nach Violett gehen, lassen sich zu gut als Druckverschiebungen deuten. Da es hiermit ziemlich faul [?] steht, wird es mit der Ablenkung der Lichtstrahlen durch die Sonnengravitation auch nicht viel anders sein." Draft of a letter from Schwarzschild to Planck, after January 31, 1913, N Briefe 593, 6r. The passages omitted are crossed-out in Schwarzschild's manuscript.

28 On Einstein's derivation and its historical context, see (Earman and Janssen 1993).

29 See the minutes of the meeting on November 18, 1915, *Archiv der Berlin-Brandenburgischen Akademie der Wissenschaften* II–V, Vol. 91, 64–66.

In a letter of the same day to Arnold Sommerfeld, Schwarzschild even explicitly states that to him the perihelion result was much more convincing than the empirical consequences of Einstein's theory discussed earlier:

> Did you see Einstein's paper on the motion of Mercury's perihelion in which he obtains the observed value correctly from his last theory of gravitation? That is something much closer to the astronomers' heart than those minimal line shifts and ray bendings.[31]

It is a matter of course that the quantitatively appropriate explanation of an anomaly that had been detected by astronomers more than half a century earlier provided a stronger argument for the new theory than the hardly detectable effects that it also predicted. However, Einstein's successful calculation of the perihelion shift did not convince everybody to the same degree as Schwarzschild. More than one year after Einstein's calculation, Max von Laue still described the result as a "agreement of two single numbers"[32] which

> remarkable as it may be, does not seem to us to give sufficient reason to change the whole physical world picture in its foundations, as Einstein's theory does.[33]

In view of Schwarzschild's earlier contextualization of perihelion motions, it becomes understandable why, for him, Einstein's result signified much more than the "agreement of two single numbers." Furthermore, on the background of Schwarzschild's prerelativistic cosmological considerations that included the application of non-Euclidean geometry to physical space and the idea of mutually accelerated inertial systems, the changes brought about by Einstein's theory must have appeared less drastic to Schwarzschild than to most others, including von Laue.

Einstein's derivation of the perihelion advance which was based on an approximation had, however, one blemish: the uniqueness of the solution remained questionable. In order to consolidate Einstein's result, Schwarzschild tried to prove the uniqueness of the solution. In the above-mentioned letter to Sommerfeld, Schwarzschild reports:

> In Einstein's calculation the uniqueness of the solution remains doubtful. In the first approximation, which Einstein makes, the solution, when carried out completely, is even apparently ambiguous—one additionally gets the beginning of a divergent expansion. I have tried to derive an exact solution, and that was unexpectedly easy.[34]

---

30 "Es ist eine ganz wunderbare Sache, daß von so einer abstrakten Idee aus die Erklärung der Merkuranomalie so zwingend herauskommt." Schwarzschild to Einstein, December 22, 1915 (CPAE 8, Doc. 169).

31 "Haben Sie Einstein's Arbeit über die Bewegung des Merkurperihels gesehen, wo er den beobachteten Wert richtig aus seiner letzten Gravitationstheorie heraus bekommt? Das ist etwas, was den Astronomen viel tiefer zu Herzen geht, als die minimalen Linienverschiebungen und Strahlenkrümmungen." Schwarzschild to Sommerfeld, December 22, 1915, München, Deutsches Museum Archiv NL 89, 059, p. 1.

32 "Übereinstimmung zwischen zwei einzelnen Zahlen"

33 "[...] scheint uns, so bemerkenswert sie ist, doch kein hinreichender Grund, das gesamte physikalische Weltbild von Grund aus zu ändern, wie es die Einsteinsche Theorie tut." (Laue 1917, 269.)

And even in his publication that is today known for containing the first derivation of an exact non-trivial solution of Einstein's field equations, Schwarzschild emphasizes that, rather than the quest for an exact solution, it is the consolidation of Einstein's result which is of primary concern:

> It is always convenient to possess exact solutions of a simple form. More important is that the calculation yields, at the same time, the uniqueness of the solution about which Mr. Einstein's treatment remained doubtful and which arguably, in view of the way in which it emerges below, could hardly have been proven by such an approximative method.[35]

6. THE RELATIVITY OF ROTATION REVISITED

After his consolidation of the connection between general relativity and observational astronomy established by Einstein's perihelion calculation, Schwarzschild turned to other questions of theoretical astronomy for which general relativity appeared to provide the adequate framework. One of these questions concerned the relativity of rotation, a question we already encountered in Schwarzschild's prerelativistic work.

The major source documenting Schwarzschild's work on this question in the context of general relativity is a formerly unrecognized manuscript page in Schwarzschild's Nachlass in the University Library of Göttingen (N 2:2, 12r). A reproduction with explanations of the page is given in the Appendix. The page is full of calculations and contains hardly any text. It is found among a few similar pages, some of which contain notes on general relativity the purpose of which however is not obvious. The notes on the page under discussion are undated but obviously stem from the short period between Einstein's successful perihelion calculation in November 1915 and Schwarzschild's death in May 1916.

In these notes, Schwarzschild distinguishes an "inner" and an "outer" metric. The inner metric describes a Minkowski spacetime in a coordinate system rotating with constant angular velocity n. Using cylindrical coordinates, the outer metric can be written as

---

34 "Bei Einstein's Rechnung bleibt die Eindeutigkeit der Lösung noch zweifelhaft. In der ersten Annäherung, die Einstein macht, ist die Lösung sogar, wenn man sie vollständig macht, scheinbar mehrdeutig — man bekommt noch den Anfang einer divergenten Entwicklung herein. Ich habe versucht, eine strenge Lösung abzuleiten, und das ging unerwartet einfach." Schwarzschild to Sommerfeld, December 22, 1915, München, Deutsches Museum Archiv NL 89, 059, 1. In his letter to Einstein from December 22, 1915, Schwarzschild reports in even more detail about the motivation that led him to his exact solution, see (CPAE 8, Doc. 169).

35 "Es ist immer angenehm, über strenge Lösungen einfacher Form zu verfügen. Wichtiger ist, daß die Rechnung zugleich die eindeutige Bestimmtheit der Lösung ergibt, über die Hrn. Einsteins Behandlung noch Zweifel ließ, und die nach der Art, wie sie sich unten einstellt, wohl auch nur schwer durch ein solches Annäherungsverfahren erwiesen werden könnte." (Schwarzschild 1916a, 190.)

$$g_{\mu\nu_{\text{outer}}} = \begin{bmatrix} -f_1 & 0 & 0 & 0 \\ 0 & -f_2 & 0 & f \\ 0 & 0 & -1 & 0 \\ 0 & f & 0 & f_4 \end{bmatrix},$$

where x_1 is a radial coordinate, x_2 is an angle, x_3 is parallel to the symmetry axis of the cylinder, and x_4 is a time-like coordinate. f and f_i, $i = 1, 2, 4$, are functions of x_1 only. For the radial coordinate becoming infinitely large, Schwarzschild imposes the condition that the outer metric tends to the (non-rotating) Minkowski metric, rescaled in such a way that it satisfies the determinant condition, $|\det(g_{\mu\nu})| = 1$.[36] The spacetime Schwarzschild attempts to investigate thus consists of a cylindrical section of Minkowski space, the inner space, rotating with constant angular velocity n relative to an inertial frame at radius infinity and surrounded by an outer space, becoming Minkowskian for $x_1 \to \infty$.

Schwarzschild then obviously tries to find general expressions for the metric functions f and f_i, $i = 1, 2, 4$ (the g_{33}-component of the outer metric Schwarzschild had set to -1). In this he follows exactly the procedure he elaborated in his publication on the field of a point mass (Schwarzschild 1916a). First, he constructs the Lagrangian of a point particle

$$F = \frac{1}{2}\sum g_{\mu\nu}\frac{dx_\mu}{ds}\frac{dx_\nu}{ds}.$$

Next, he calculates $\partial F/\partial x_i$ and $\partial F/\partial \dot{x}_i$ for $i = 1, 2, 3, 4$ and puts the resulting terms into the Euler-Lagrange equation

$$\frac{\partial F}{\partial x_i} - \frac{d}{ds}\left(\frac{\partial F}{\partial \dot{x}_i}\right) = 0.$$

He then manipulates the resulting equations—further using the determinant condition $f_1(f_2 f_4 + f^2) = 1$—in such a way that he may read off the field strengths $\Gamma^\lambda_{\mu\nu}$ by a comparison of the coefficients with those appearing in the equations of motion of a point particle. He then puts the expressions for the field strengths into the field equations and manipulates them in order to determine the functions f and f_i by integra-

36 As in (Schwarzschild 1916a), Schwarzschild here employs the condition that the determinant of the metric tensor be unity. Einstein had introduced this condition in an addendum to his publication *Concerning the Theory of General Relativity* (*Zur allgemeinen Relativitätstheorie (Nachtrag)*, Einstein 1915a), and continued to use it in his paper on the perihelion motion of Mercury (Einstein 1915b). The field equations Einstein presented and used in these papers read $G_{\mu\nu} = -\kappa T_{\mu\nu}$, where $G_{\mu\nu}$ denotes the Ricci tensor and $T_{\mu\nu}$ denotes the energy-momentum tensor. These are not the field equations of the final theory, which contain a trace term on either the left or the right-hand side. However, since in vacuum the older field equations coincide with those of the final theory, Einstein and Schwarzschild's solutions still hold there.

tion. However, while in the case of the spherically symmetric vacuum field this procedure led to a simple result, in this case the differential equations become rather involved and no solution is obtained. The calculations on the page discussed end with a second order differential equation coupling f and f_1 (see the equation at the bottom right-hand side of Schwarzschild's manuscript page reproduced as Fig. 6 in the Appendix).

What is the purpose of Schwarzschild's notes? Clearly these notes are concerned with the problem of the relativity of rotation in general relativity. As was explained in sec. 3, Schwarzschild had, in his earlier work, considered the possibility of inertial reference frames rotating with respect to one another. The spacetime Schwarzschild considers here is a realization of such an arrangement in the framework of general relativity, one inertial system being given at radial infinity, the other within the rotating cylindrical section of spacetime. The difficulty in making any further-reaching statements about the physical situation Schwarzschild is trying to describe here arises from the fact that, in his notes, Schwarzschild does not specify the matter distribution he assumes.[37] It is, however, plausible to assume that the spacetime under consideration should function as a model for the spatially two-dimensional situation of a rotating disk of Minkowski space. Then Schwarzschild's calculations can be interpreted as the exploration of a simple model for the spacetime inside and outside the rotating system of fixed stars.[38] This would mean that Schwarzschild assumed the spacetime within the system to be approximately Minkowskian, an assumption that is consistent with his earlier observation that the perihelia of remote double stars do not rotate relative to the directions defined by the planetary orbits in the solar system and that therefore inertial frames inside the Galaxy do not rotate with respect to one another. At the same time, Schwarzschild must have assumed that in its rotational motion the matter content of the system of fixed stars—be it concentrated in a ring or distributed over an ellipsoidal volume—drags along the interior Minkowski space.[39]

37 A spacetime similar to the one Schwarzschild describes here is generated by an infinitely long, rotating, cylindrical shell of matter. The interior field of such a matter distribution is indeed Minkowskian; see (Davies et al. 1971). The exterior vacuum metric of such a matter distribution, including the dragging of inertial frames close to the shell, is discussed in (Frehland 1972). Non-local effects of such a matter distribution, corresponding to the Aharonov-Bohm effect in electrodynamics, are discussed in (Stachel 1983). The problem of the relativity of rotation was addressed in 1918 by Thirring who considered a rotating spherical mass shell rather than a cylindrical one (Thirring 1918, see also Lense and Thirring 1918).

38 In an earlier publication (Schwarzschild 1909, 41–42), Schwarzschild had described the solar system whose dynamics is dominated by a central mass as being of "monarchic constitution", and the Galaxy where every star is acted upon by all other stars as being of "republican constitution", and had speculated that the whole Universe might be built up from a hierarchical sequence of structures of these two basic types. While Schwarzschild's first exact solution to Einstein's field equations provides the basis for describing the monarchic constitution in the framework of general relativity, the notes considered here can be understood as an attempt to complement this with the description of the republican constitution within that framework.

39 The spacetime of an axially symmetric distribution of particles revolving with constant angular velocity was later derived by (Stockum 1937).

In fact, Schwarzschild could have hoped that, within general relativity, a problem concerning the rotation of the system of fixed stars could be resolved. On one hand, namely, Schwarzschild contended that, by analogy to other celestial motions, it must be assumed that the system of fixed stars as a whole rotates.[40] Yet, on the other hand, such a rotation had hardly been observed, as Schwarzschild explained in an earlier text:

> [...] it turns out that the average of those few thousand stars, whose proper motions are known, displays no evidence of rotation with respect to [the] directions [defined by the planetary orbits] [...].[41]

General relativity now provided a possible explanation of this phenomenon, if it was assumed that, together with the stars themselves, the global inertial system within the Galaxy was rotating. In searching for the functions f and f_i describing the outer metric, Schwarzschild would then have attempted to clarify in what sense one may speak in general relativity of a rotation of the system of fixed stars as a whole.

That Schwarzschild indeed considered the question of the rotation of the Galaxy in the context of general relativity is made evident by a letter from Einstein dated January 9, 1916.[42] In a preceding letter by Schwarzschild which is lost, Schwarzschild must have raised several questions, which Einstein answers one by one. Einstein's second point reads as follows:

> The statement that "the system of fixed stars" is free of rotation may retain a relative meaning, which is to be fixed by a comparison.
>
> The surface of the Earth is irregular, as long as I regard very small sections of it. However, it approaches the flat elementary shape when I regard larger sections of it, whose dimensions are still small in comparison to the length of the meridian. This elementary shape becomes a curved surface when I regard even larger sections of the Earth's surface.
>
> For the gravitational field things are similar. On a small scale the individual masses produce gravitational fields that, even with the most simplifying choice of the reference system, reflect the character of the quite irregular matter distribution on the small scale. If I consider larger regions, as astronomy presents them to us, the Galilean reference system provides me with the analogue to the flat elementary shape of the Earth's surface in the previous comparison. But if I consider even larger regions, there probably will be no continuation of the Galilean system to simplify the description of the universe to the same degree as on a small scale, that is, throughout which a mass point sufficiently remote from other masses moves uniformly in a straight line.[43]

Schwarzschild's response is consistent with the calculations as interpreted above:

> As concerns the inertial system, we are in agreement. You say that beyond the Milky Way system conditions may arise under which the Galilean system is no longer the simplest. I only hold that within the Milky Way system such conditions do not arise.[44]

---

40 See, for example, (Schwarzschild 1897, 519).

41 "[...] zeigt sich, dass der Durchschnitt aus jenen paar Tausend Sternen, deren Eigenbewegung man kennt, [...] keine Rotation gegen diese Richtungen aufweist." (Schwarzschild 1897, 520.)

42 Einstein to Schwarzschild, January 9, 1916, N 193, 3-5, see also (CPAE 8, Doc. 181).

In view of this exchange between Schwarzschild and Einstein, it appears obvious that Schwarzschild's calculations are related to the question he must have posed to Einstein: Does it make sense to speak of a rotation of the system of fixed stars? The calculations then document the attempt to explore the "even larger regions" outside the system of fixed stars, in which "there probably will be no continuation of the Galilean system."

7. A CLOSED UNIVERSE AS A SOLUTION OF EINSTEIN'S FIELD EQUATIONS

In his calculations, Schwarzschild had assumed the Universe to be asymptotically Minkowskian. In his correspondence with Einstein on the question of global frames of inertia, Schwarzschild mentions a further possibility. In direct continuation of the passage quoted above, he explicates:

> As concerns very large spaces, your theory has a quite similar position as Riemann's geometry, and you are certainly not unaware that one obtains an elliptic geometry from your theory, if one puts the entire universe under uniform pressure (energy tensor $-p, -p, -p, 0$).[45]

Thus, Schwarzschild was the first to entertain the possibility of a closed universe with an elliptic geometry as a solution to Einstein's field equations. Schwarzschild's remark that Einstein's theory had a similar position as Riemann's geometry thereby alludes to his prerelativistic application of elliptic geometry to the universe on the background of Riemannian geometry discussed in sec. 4.

Contrary to Schwarzschild's assumption, Einstein was, at the time, most probably unaware of such cosmological implications of his theory.[46] It was only through a debate with the Dutch astronomer Willem de Sitter (1872–1934) beginning in fall

---

43 "Die Aussage, dass "das Fixsternsystem" rotationsfrei sei, behält wohl einen relativen Sinn, der durch ein Gleichnis festgelegt sei.
Die Oberfläche der Erde ist, solange ich ganz kleine Teile derselben ins Auge fasse, unregelmässig. Sie nähert sich aber der ebenen Grundgestalt, wenn ich grössere Teile ins Auge fasse, deren Abmessungen aber immer noch klein sind gegen die Länge des Meridians. Diese Grundgestalt wird zu einer gekrümmten Fläche, wenn ich noch grössere Teile der Erdoberfläche ins Auge fasse.
So ähnlich ist es auch mit dem Gravitationsfeld. Im Kleinen liefern die einzelnen Massen Gravitationsfelder, welche auch bei möglichst vereinfachender Wahl des Bezugssystems den Charakter der ziemlich regellosen Verteilung der Materie im Kleinen widerspiegeln. Betrachte ich grössere Gebiete, wie sie uns die Astronomie bietet, so bietet mir das Galileische Bezugssystem das Analoge zu der ebenen Grundgestalt der Erdoberfläche beim vorigen Vergleich. Betrachte ich aber noch grössere Gebiete, so wird es wohl keine Fortsetzung des Galileischen Systems geben, welche in solchem Masse wie im Kleinen die Beschreibung der Welt einfach gestaltet d.h. in welchem überall der von anderen Massen hinlänglich entfernte Massenpunkt sich gradlinig gleichförmig bewegt." Einstein to Schwarzschild, January 9, 1916 (CPAE 8, Doc. 181).

44 "Was das Inertialsystem angeht, so sind wir einig. Sie sagen, daß jenseits des Milchstraßensystems sich Verhältnisse einstellen können, in denen das Galilei'sche System nicht mehr das einfachste ist. Ich behaupte nur, daß sich innerhalb des Milchstraßensystems solche Verhältnisse nicht einstellen." Schwarzschild to Einstein, February 6, 1916, N 193, 7–8, see also (CPAE 8, Doc. 188).

1916 that Einstein was led to consider a closed universe which he hesitantly proposed in 1917 (Einstein 1917).[47] The distinction between spherical and elliptic space had thereby remained obscure to him. De Sitter pointed the distinction out to Einstein, referring to Schwarzschild's 1900 paper on the curvature of space and the argument for preferring elliptic to spherical space given therein.[48]

In Einstein's debate with de Sitter, the question of the global geometry of the universe emerged from a discussion of the relativity of inertia. Strikingly, in Schwarzschild's correspondence with Einstein, the question of the global geometry of the Universe is brought up in exactly the same context.[49] It is therefore tempting to see here the commencement of an Einstein–Schwarzschild debate foreshadowing the later Einstein–de Sitter debate. Einstein appears, however, to have not yet been prepared to consider the cosmological implications of his theory at that time. And by the time he was slowly pushed into that direction in his exchange with the astronomer de Sitter, Schwarzschild had already died. Nevertheless, in view of Schwarzschild's deliberations discussed here, it seems safe to say that, had Schwarzschild lived longer, he could have made a substantial contribution to the cosmological debates emerging later.

8. SCHWARZSCHILD'S INTERDISCIPLINARY APPROACH TO THE FOUNDATIONS OF SCIENCE

Let us come back to the question raised at the beginning: Why did Schwarzschild recognize the significance of general relativity at such an early stage? Here it has been attempted to show that, already in his early astronomical work, Schwarzschild did not act as a specialist but attempted to meet the challenges resulting from the implica-

45 "Was die ganz großen Räume angeht, hat Ihre Theorie eine ganz ähnliche Stellung, wie Riemann's Geometrie, und es ist Ihnen gewiß nicht unbekannt, daß man die elliptische Geometrie aus Ihrer Theorie herausbekommt, wenn man die ganze Welt unter einem gleichförmigen Druck stehen läßt (Energietensor $-p, -p, -p, 0$). " Schwarzschild to Einstein, February 6, 1916, N 193, 7–8, see also (CPAE 8, Doc. 188). This energy tensor actually does not yield a spherical static universe. It does, however, yield the universe Schwarzschild is speaking of when the trace term in the field equations is neglected, i.e. in the context of the older field equations $G_{\mu\nu} = -\kappa T_{\mu\nu}$, where $G_{\mu\nu}$ denotes the Ricci tensor and $T_{\mu\nu}$ denotes the energy-momentum tensor (see footnote 36). It may be the case that Schwarzschild originally conceived of the tensor on the basis of these field equations and later did not modify it as the new field equations would have demanded. Schwarzschild continues his letter by explaining the solution inside a sphere of fluid with uniform energy density (energy tensor $-p, -p, -p, \rho_0$). Here, as well as in the corresponding publication (Schwarzschild 1916b, 431–432), Schwarzschild points out that inside the sphere spherical geometry applies.

46 In November 1916, Einstein still calls the question of the boundary conditions of the metric field "purely a matter of taste which will never attain a scientific meaning." ("eine reine Geschmacksfrage, die nie eine naturwissenschaftliche Bedeutung erlangen wird.") Einstein to de Sitter, November 4, 1916 (CPAE 8, Doc. 273).

47 On the Einstein–de Sitter debate, see (CPAE 8, 351–357) and the references given therein, in particular (Kerszberg 1989; 1989a).

48 De Sitter to Einstein, June 20, 1917 (CPAE 8, Doc. 355).

tions of foundational questions in physics on astronomy. Thus it comes as no surprise that Schwarzschild was also among the first to recognize that Einstein had—without being aware of it—provided the astronomers with the adequate framework for treating their questions. As a result, a clear continuity can be perceived in Schwarzschild's work on cosmology, prerelativistic and relativistic. In this context it is interesting to question the extent to which parallel cases are provided by the work of other pioneers of relativistic astronomy such as Willem de Sitter and Arthur Eddington (1882–1944). The study of this question, however, does not lie in the scope of this contribution. Here, in conclusion, it shall only be pointed out that it was no coincidence that Schwarzschild took an astronomical road to general relativity, but that this may rather be seen as the natural outcome of his interdisciplinary approach to the foundations of the exact sciences.

Indeed, not only is interdisciplinarity the hallmark of Schwarzschild's scientific work, but he also was quite aware of the general significance of interdisciplinarity for the progress of science. On many occasions Schwarzschild explained how he saw scientific progress emerging from the interplay of the different branches of science, for instance when, on the occasion of his inaugural lecture at the Prussian Academy of Sciences, he stated that "the greatest yet unsolved problem of celestial mechanics, the so-called many-body problem, most closely touches a problem of physics that concerns the foundations of its newest developments".[50] As a further example, consider the following passage from the same speech in which Schwarzschild describes the establishment of special relativity:

> [...] an important source for the electron and relativity theory lay in an astronomical problem. The astronomical aberration results from the finite propagation speed of light through the aether in combination with the Earth's motion in space. H.A. Lorentz occupied himself many times with the theory of aberration and searched for a satisfying picture of the aether's behavior when large masses, like the Earth, move through it, until he

49 In Einstein's letter to Schwarzschild from January 9, there is, in fact, a passage in which he expresses exactly the kind of strong Machian claims concerning his theory which later sparked off his debate with de Sitter. In direct continuation of the passage quoted above, Einstein explains: "According to my theory, inertia is an interaction between masses, in the end, not an effect in which, besides the mass under consideration, 'space' itself would be involved. The essence of my theory is precisely that no independent properties are attributed to space itself.
Jokingly one may put it this way. If I let all things in the world disappear, according to Newton the Galilean inertial space remains, according to my perception, however, *nothing* remains."
("Die Trägheit ist eben nach meiner Theorie im letzten Grunde eine Wechselwirkung der Massen, nicht eine Wirkung bei welcher ausser der ins Auge gefassten Masse der 'Raum' als solcher beteiligt ist. Das Wesentliche meiner Theorie ist gerade, dass dem Raum als solchem keine selbständigen Eigenschaften gegeben werden.
Man kann es scherzhaft so ausdrücken. Wenn ich alle Dinge aus der Welt verschwinden lasse, so bleibt nach Newton der Galileische Trägheitsraum, nach meiner Auffassung aber *nichts* übrig.") Einstein to Schwarzschild, January 9, 1916 (CPAE 8, Doc. 181).

50 "[...] berührt sich das höchste noch ungelöste Problem der Himmelsmechanik, das sogenannte Vielkörperproblem, aufs engste mit einem Problem der Physik, das an die Fundamente ihrer neuesten Entwicklung greift." (Schwarzschild 1913, 597.)

> finally cut the knot by consistently implementing Fresnel's assumption that the aether is absolutely rigid and cannot be brought to flow by any force acting on it. In this way the path was cleared for the electron theory. Furthermore, the completely rigid aether stepped out of the circle of the objects that can be influenced and thus can be more closely perceived, so much so that relativity theory became possible, in which the concept of the aether only appears as a spacetime concept deepened by new experience.
>
> Electron theory and relativity theory in turn have already posed various problems to astronomy as a consequence of the modifications of celestial mechanics they necessitate.[51]

Clearly Schwarzschild was equipped to take up these challenges posed to astronomy by its neighboring disciplines. He knew that scientific progress is not a matter of the advancement of isolated disciplines, as both the previous and the following quotations make clear:

> Mathematics, physics, chemistry, astronomy march in line. Whichever lags behind is pulled forward. Whichever hastens ahead pulls the others forward. The closest solidarity exists between astronomy and the whole circle of exact sciences.[52]

ACKNOWLEDGEMENTS

This paper was previously published in the journal *Science in Context* (Schemmel 2005). I am indebted to Jürgen Renn who inspired and supported my work from its inception up to its present state. For helpful discussions and comments I would also like to thank Dieter Brill, Giuseppe Castagnetti, Peter Damerow, Jürgen Ehlers, Hubert Goenner, Michel Janssen, John Norton, and John Stachel.

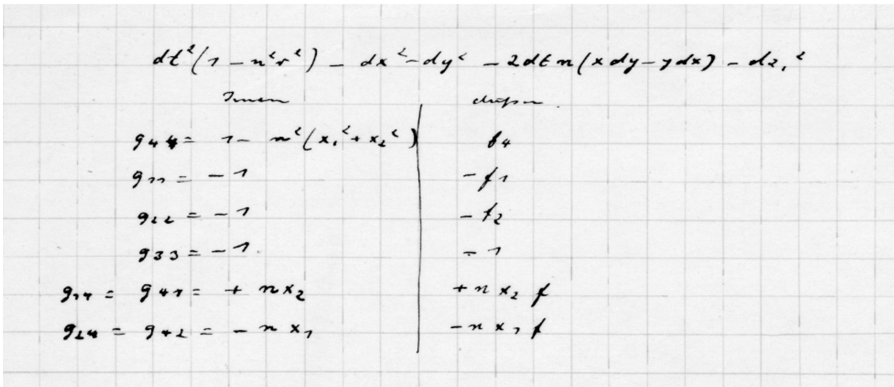
---

51 "[...] eine wichtige Quelle für die Elektronen- und Relativitätstheorie in einem astronomischen Probleme lag. Die astronomische Aberration ist eine Folge der endlichen Ausbreitungsgeschwindigkeit des Lichtes im Äther verbunden mit der Bewegung der Erde im Weltraum. H.A. Lorentz hat sich vielfach mit dem Problem der Aberration beschäftigt und nach einer befriedigenden Anschauung über das Verhalten des Äthers, wenn große Massen, wie die Erde, sich durch ihn hindurchbewegen, gesucht, bis er schließlich den Knoten zerhieb durch völlig konsequente Durchführung der alten Fresnelschen Annahme, daß der Äther absolut starr und durch keine auf ihn wirkende Kraft zum Fließen zu bringen sei. Dadurch war die Bahn frei geworden für die Elektronentheorie. Der völlig starre Äther trat ferner so sehr aus dem Kreis der beeinflußbaren und damit näher erkennbaren Objekte heraus, daß auch die Relativitätstheorie möglich wurde, bei welcher der Begriff des Äthers nur als ein durch neue Erfahrungen vertiefter Raum-Zeitbegriff erscheint.
Elektronentheorie und Relativitätstheorie haben auch Rückwärts der Astronomie schon wieder mancherlei Probleme gestellt infolge der Modifikationen der Himmelsmechanik, die sie notwendig machen." (Schwarzschild 1913, 598.)

52 "Mathematik, Physik, Chemie, Astronomie marschieren in einer Front. Wer zurückbleibt, wird nachgezogen. Wer vorauseilt, zieht die anderen nach. Es besteht die engste Solidarität der Astronomie mit dem ganzen Kreis der exakten Naturwissenschaften." (Schwarzschild 1913, 599.)

APPENDIX: ANNOTATED REPRODUCTION OF SCHWARZSCHILD'S RELATIVISTIC NOTES ON THE PROBLEM OF ROTATION

In this appendix, the manuscript page that documents Schwarzschild's relativistic calculations on the problem of rotation referred to in sec. 6 is reproduced with annotations. It is preserved as a part of Schwarzschild's Nachlass in the Niedersächsische Staats- und Universitätsbibliothek Göttingen as page 12r of folder 2:2. The page is found among a few similar pages, some of which contain further notes on general relativity. For technical reasons this reproduction is divided into three parts shown in figs. 4, 5, and 6, respectively. I am grateful to the Niedersächsische Staats- und Universitätsbibliothek Göttingen for their permission to reproduce this page.



$dt^2(1-n^2r^2) - dx^2 - dy^2 - 2dt\,n(x\,dy - y\,dx) - dz^2$

Innen	Außen
$g_{44} = 1 - n^2(x_1^2 + x_2^2)$	f_4
$g_{11} = -1$	$-f_1$
$g_{22} = -1$	$-f_2$
$g_{33} = -1$	-1
$g_{14} = g_{41} = +nx_2$	$+nx_2 f$
$g_{24} = g_{42} = -nx_1$	$-nx_1 f$

Figure 4: Schwarzschild N 2:2, 12r, upper part

Schwarzschild begins his considerations by writing down the metric for the "inner" and the "outer" spacetime in Cartesian coordinates,

$$g_{\mu\nu_{\text{inner}}} = \begin{bmatrix} -1 & 0 & 0 & nx_2 \\ 0 & -1 & 0 & -nx_1 \\ 0 & 0 & -1 & 0 \\ nx_2 & -nx_1 & 0 & 1-n^2(x_1^2+x_2^2) \end{bmatrix}; \quad g_{\mu\nu_{\text{outer}}} = \begin{bmatrix} -f_1 & 0 & 0 & nx_2 f \\ 0 & -f_2 & 0 & -nx_1 f \\ 0 & 0 & -1 & 0 \\ nx_2 f & -nx_1 f & 0 & f_4 \end{bmatrix}.$$

In the following calculation (figs. 5 and 6), he then shifts to cylindrical coordinates and absorbs the factors of n in the function f. The outer metric then reads

$$g_{\mu\nu_{\text{outer}}} = \begin{bmatrix} -f_1 & 0 & 0 & 0 \\ 0 & -f_2 & 0 & f \\ 0 & 0 & -1 & 0 \\ 0 & f & 0 & f_4 \end{bmatrix}.$$

KARL SCHWARZSCHILD

THINGS AT REST IN THE UNIVERSE

Originally published as "Was in der Welt ruht" in Die Zeit, Vienna, Vol. 11, No. 142, 19 June 1897, 181–183 (1897). Reprinted in Collected Works, vol. 3, H. H. Voigt, ed., Springer-Verlag, Berlin 1992, p. 514–521. Page numbers refer to reprinted version.

Is there anything in the universe that is at rest, around which or within which the rest of the universe is constructed, or is there no hold in the unending chain of motions in which everything seems to be caught up? It is worth considering the extent to which these questions are justified and how they can be answered.

On a clear evening a few weeks ago, many people claimed to have observed how the Moon rushed across the sky with most unusual speed. On that evening a light veil of mist seems to have been blown past the Moon by the wind, more subtly creating the same illusion one believes one observes every time broken clouds move quickly past it: one assumes that the clouds stand still and that the Moon rushes through them against the wind.

This phenomenon and other much more common ones, such as the apparent rotation of long furrows when one travels through a flat landscape by train, or the enchanted room at recent fairs which leads one to believe that one is upside down and walking on the ceiling, simply provide evidence to support the immediately comprehensible statement that all perceptible motion is relative, that one can say that an object moves relative to another one but never in absolute terms that an object moves or is at rest.

With this one can already see that neither of the original two questions has been properly formulated. Namely, if only the motion of different objects relative to each other can be perceived, then without actually contradicting experience one may ascribe a completely arbitrary motion to a particular object in the universe or, as a special case, declare it to be at rest. Thus, everything and nothing is at rest in the universe. Logically, there is nothing to stop someone from stipulating, for example, that the wing tips of a buzzing insect are still. In that case one would simply have to ascribe a buzzing motion in the opposite direction to one's own body, the Earth, and all celestial objects, in order to recover the directly observable relative motion of the insect's wings with respect to the rest of the universe.

Why, however, does one smile at he who would seriously wish to claim that the Moon really did rush across the sky, or that the fields rotated when one went through

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

them on the train? The reasons are of a purely practical and utilitarian nature. A clumsy assumption regarding things at rest in the universe would result in an unspeakable confusion of ideas. And for this reason, the above questions are to be replaced by the following: What things in the universe did one find it useful to treat as being at rest, at different times? Each time it becomes necessary to redefine what can be treated as being at rest, an important stage is passed in the process of development of human ideas concerning the universe. It has often been forgotten, or not even rec-
[515] ognized, that here we are | dealing with arbitrary assumptions, and at times the opinions have become doctrines which have even found their own martyrs.

When one talks of motion or rest in everyday life, one leaves out the object with respect to which motion or rest is ascribed, but one means: relative to the ground or to objects fixed with respect to the ground. It is useful to tacitly assume this particular completion of the concept of motion because most of what appears before our eyes during the course of the day is at rest relative to the ground, or at least we can name a special cause when something moves relative to the ground. However, since Copernicus science has begun to recognize other completions as useful, to ascribe motion to other objects, and to treat other things as "points at rest" in the universe.

Indeed, Copernicus suggested that all motion is relative to the center of the Sun and showed that all the complicated curves and ribbons traced by the planets in the sky found an explanation if one allows the planets to describe circles around the Sun, which is taken to be fixed.

But more precisely, Copernicus makes a further assumption, in that he stipulates that the fixed stars, located at a huge distance from our planetary system, should be considered to be at rest. In fact, the single assumption that the center of the Sun is fixed would not suffice as a definition of all motion. One could then recognize only changes in distance relative to this point but not rotations about it, just as one does not know whether a completely smooth ball, whose surface is the same all over, is stationary or rotating about its center.

Accordingly, in the Copernican system, one describes the motion of a body by giving its distance from the Sun, and direction in terms of a fixed star as seen from the Sun, at various times. The assumption that the fixed stars are at rest thereby forces one to attribute a daily rotation from west to east to the Earth, because relative to the Earth's surface the fixed stars apparently revolve from east to west within a 24 hour period. Consequently one must imagine that together with our surroundings we rush through space with the speed of a cannon ball, and that the direction of this motion continually changes. It cannot be said that at first such a way of thinking seems to be particularly in accordance with the principle of utility, which we must recognize as the single decisive principle for these questions. From this viewpoint, the reluctance of the Aristotelians at the time certainly does not seem to be as naive and ridiculous as it is generally made out to be. All the more worthy of admiration is a man such as Galileo, who, through his mechanical principles, made the adventurous elements of the new view as well as the presumed contradictions with everyday experience disappear, so that only its overwhelming advantages in the depiction of celestial motions remained. |

It was not until the end of the seventeenth century—when the use of the telescope and progress in the production of finely divided circles, used to read off the position of stars, had led to an unexpected improvement in observation skills—that the Copernican stipulation of motion was recognized as not being wholly exact and unambiguous. At that time it was noticed that the fixed stars do not actually deserve their name: they all shift in position relative to each other, and in the very distant past Cygnus and Orion once formed quite different constellations. However, these shifts in position progress extremely slowly. If Stephan's Tower would list so far in the course of one year that its top shifted by one centimeter, then this shift, as observed from Kahlenberg, would be conspicuous compared to the shift in position of the majority of the fixed stars visible to the naked eye.[1] But as soon as the shifts are at all perceptible, Copernicus' use of the fixed star system as a basis for motion is no longer possible. [516]

From those same observations concerning the change in position of the fixed stars relative to each other it has also emerged that the other Copernican point of reference, the center of the Sun, possesses no particular right to the privilege of being considered at rest. The "proper motions" of the fixed stars, such being the technical term, are indeed distributed irregularly so that neighboring stars in the sky move away in all possible directions, but on average out of several hundred stars one can see that when one looks into the sky in a certain direction, on the whole the constellations seem to spread, to get bigger, and in the opposite direction, to get smaller. From this it follows that the Sun and the former region of the sky come closer to each other. Although it would not be impossible to do, there would be no point in ascribing this motion wholly to the fixed stars and continuing to treat the Sun as being at rest, for we know that the Sun is a relatively subordinate member of the great family of stars.

Just realize into what insecurity the universe has fallen as a result, how imagination finds no place to drop anchor and no single rock in the world has a special right to be thought of as fixed and at rest.

Unfortunately we have still not reached the epoch of astronomy that will intervene offering a new fundamental definition. This will have come about when a pattern has been found in the seemingly so irregular proper motions. No effort is being spared in order to promote its appearance. Twenty observatories have joined together in order to produce a catalogue which details the position of 150,000 fixed stars relative to each other at the present time, and a major part of this huge task has already been completed. Just as many institutes have divided up the sky amongst themselves in order to establish the position of two million stars with even greater precision through photographic images. When this work is repeated | in a few decades time, [517]
such a huge number of proper motions will be known to us that a law, if it exists, must reveal itself, and that a new Copernicus, who admittedly would have no prejudice to overcome, can show from where and how these motions appear ordered. Admittedly, it could also turn out that no general order exists within the army of fixed stars. In this case, all these spheres in space are to be compared with gas molecules, which fly around completely irregularly, so irregularly that the irregularity itself

becomes a principle, according to which the effect of the gas mass as a whole can be derived through considerations of probabilities and averages.

But, for the time being, to what does the astronomer refer the heavenly motions?

Among the pieces of ponderable matter there is none, as we have seen, which can be reasonably distinguished as stationary. Thus among material things one's only chance is to look around for imponderables. As is well known, the universe is filled with an all-pervasive substance, which is weightless, neither solid nor fluid, neither visible nor invisible, and to which there is no physical description that really fits: this is the aether, the only imponderable of modern physics. Through the aether do the gentlest light waves shimmer, but the aether also mediates the mighty effects of electrical machinery. When the power of a distant waterfall is transferred to a central power station, then in a certain sense aether is the long rod impacted by the water over there and pushing the wheel of the machine here. The electrical cable is of only secondary importance; it simply maintains the energy flowing in the desired direction, rather than dispersing. Now, it would be very tempting from a philosophical standpoint to take the ever-present aether to be the basic stationary substance, and occasionally this has actually been done. But eventually, both optical and electrical phenomena have pressed upon us the conviction that the aether certainly cannot remain at rest where ponderable masses move through it, nor can it remain at rest in empty space, that rather it is traversed by internal currents. According to an investigation which Helmholtz carried out in the penultimate year of his life, the aether smoothly transfers energy from one particle to another without itself moving, as long as the energy is delivered to it evenly. Every build-up or acceleration in the energy supply, however, sets the aether into motion; and that will happen often enough.

Now that this hope has also come to naught, there remains no material object in the universe that one would have reason to consider at rest. There remain only certain conceptually defined points and directions that can serve as a substitute to a certain
[518] extent. For bringing these to its attention, astronomy owes thanks to a | science to which it is intimately related, namely mechanics. Thus we arrive at the path along which research is currently moving.

One of the basic laws of mechanics, the law of inertia, goes as follows: Each body moves in a straight line at an unchanging speed, as long as no forces act on it. This statement, however, contains more than a law based on experience; it contains at the same time a certain definition of what should be considered as being at rest in space. Since we can only identify relative motions, we can in theory ascribe any motion we choose to an individual body, even when it is unaffected by other forces. The law of inertia prescribes: Take any body (or to be more exact, so that rotations can also be recognized, any three bodies remaining at unchanging distances from each other) on which no forces act, and ascribe to these bodies a straight path and a uniform speed. The same will then apply for every other body on which no forces act. The system of inertia has so innumerably many important applications near and far that it is certainly fit and proper to make those arbitrary assumptions which lend it its simplest and only natural form.

So let us look at which ideas concerning celestial motions astronomy has to develop on the basis of this stipulation implicit in the law of inertia.

In a system comprising many mutually attracting bodies, naturally no single body describes a straight line in general, but when such a system is isolated from the effects of any forces from external, foreign bodies, still its center of gravity will describe a straight line, as shown by a simple conclusion from the law of inertia. If one treats all the bodies of the universe as constituents of one system, there would certainly be no external influence because nothing else exists beyond this system, and so its center of gravity must proceed along a straight line. Recall further an experience from mechanics, that in a train even at the highest speed, every activity can be carried out just as it can when all is at rest, provided that the speed does not alter and the train does not go around curves. This too is a special case of a general conclusion drawn from the law of inertia, which can be stated as follows: The internal processes within an isolated system of bodies are exactly the same whether its center of gravity is stationary or whether it is moving in a straight line at uniform speed. As far as the internal processes in the star system are concerned, it is therefore equally irrelevant whether its center of gravity is stationary or moving steadily. Since, furthermore, the only things we can learn about are internal processes in the star system, it is sensible to stipulate that the center of gravity of all masses in the universe and in the entire star system is the ideal point of rest.

It will, of course, look bad for the practical realization of this stipulation if, as is plausible, an infinite number of bodies of finite mass exist in the universe, all of which we then | cannot hope ever to know. However, the center of gravity of the larg- [519]
est possible system of masses is to be taken as an approximation to the definition of this ideal point of rest, especially when this system of masses is separate and remote from other such systems and as such experiences nearly no forces due to them. It is likely that the millions of stars that can be seen through a medium-sized telescope form a special system, which has been given the name "Milky Way System." The shimmering band of the Milky Way is in reality a huge ring comprised of a countless number of stars, which forms the largest mass in this system and characterizes its form. What remains of the brighter stars appear to be scattered inside this ring or to form small external appendages. Maybe other similar specimens existing in unimaginably distant regions of space are co-ordinated with our own Milky Way, but perhaps it is the only one of its kind and beyond it exist only chaotic nebular masses.

The center of gravity of the Milky Way System should then for the time being be seen as a point at rest. One will know more about its position when the great undertakings mentioned above are completed and have been sifted. However, this falls into the next phase of astronomy; for now, one makes do with a rather poor substitute. To date one knows only the proper motions of a few thousand stars, and for now one assumes that the center of gravity of these stars is at rest. As calculation shows, a speed of approximately twelve kilometres per second must then be ascribed to the Sun, a speed of similar magnitude to that with which the planets move in their orbits around the Sun.

Now there is still the matter of fixing certain directions with respect to which the rotations of each body can be reckoned. As far as the ring of the Milky Way is concerned, by analogy with all known celestial motions we must assume that it rotates in some way; therefore, from the outset it cannot be used for this purpose. However, here again new consequences of the law of inertia provide help.

Foucault's pendulum experiment is well known. If one hangs a heavy ball from a thread and causes this pendulum to oscillate from east to west, then in the course of a few hours one notices a rotation of the direction of oscillation, gradually moving in the north-south direction and, if only the pendulum swings long enough, it eventually completes a full revolution in over a day. This extremely remarkable process is usually considered to be the best proof of the Earth's rotation. For in theory, under the assumptions of the law of inertia, the 24-hour rotation of the Earth, and the Earth's gravitational pull, one finds just the amount of rotation of the oscillation direction shown by observations; whereas in the case of a stationary Earth, no rotation should take place at all. Strictly speaking, however, the Foucault pendulum experiment
[520] proves only | that a rotation of the Earth must be assumed whenever one wants to use the stipulations implicit in the law of inertia concerning that, to which motion is to be referred. Conversely, by accurate observations of the rotation of the pendulum, one could calculate the speed of rotation that has to be ascribed to the Earth according to the law of inertia, and one would then have to describe as fixed the direction with respect to which the Earth rotates with the calculated speed.

Because terrestrial pendulums are subject to too many disturbances due to air resistance and friction, one uses with a similar aim the larger pendulum experiments with which nature presents us. One can cause a pendulum to describe an elongated elliptical curve by pushing it at an angle, as in a well-known game of bowling. The planets are pendulum bobs of a similar kind. It is well known that the planets describe flattened curves, ellipses, around the Sun. The point in its path where a planet is furthest away from the Sun is called its aphelion. From the law of inertia and Newton's law of gravitation, it follows that for an isolated planet which revolves around the Sun, the direction of the aphelion is fixed in space. In reality, however, the planets are not isolated but exist in greater number, yet Newton's law allows the calculation of the small deviations from the elliptical path and the small rotations which the direction to the aphelion suffers as a result of the disturbing influences from other planets. Thus, after subtracting these disturbances from the observed aphelion directions, a direction fixed in space is obtained.

If one carries this out with the level of precision which was possible 50 years ago, then everything seems to fit together beautifully. The directions that, according to the theory, should turn out to be fixed for the different planets also appear to be fixed with respect to each other, and additionally it turns out that the average of those few thousand stars, whose proper motions we know, displays no evidence of rotation with respect to these directions within these limits of precision. According to this, the entire ring of the Milky Way can also rotate only extremely slowly. Today, however, things look different. With the level of precision which theory and observation have now achieved, one finds that the directions which one derives from the aphelions of the various planets and which one would expect to be fixed, actually perform minimal yet clearly recognizable shifts relative to each other, and thus it is impossible to treat them all as fixed. Our measure of time depends upon which directions one considers to be fixed. For we define a day to be the time it takes the Earth to revolve once around its axis and we must, of course, have a fixed direction within space in order to be able to judge when the Earth has completed a rotation. Two clocks, which agree at the beginning of a century, one tied to the direction of Jupiter's aphelion, the other to Mercury's aphelion, | would differ by three seconds at the end of it. One does not [521] really know how to explain this difference. It is possible that friction plays a role in the case of these heavenly pendulums as well, for they do not swing through an absolutely empty space. However, it is more likely that Newton's law does not describe the attractive forces of the Sun and the planets with absolute accuracy. However, there are still insufficient clues to know how a correction of Newton's law should actually read, and so one must renounce the wish to determine fixed directions with greater precision from the planetary motions using mechanical theorems. At present one prefers to hold on to the other result which, from these considerations, proved itself to be reasonably correct, and to treat those few thousand stars as being without rotation on average. That is the provisional stipulation that, in a roundabout way, one has to choose also as regards the definition of rotations in the universe.

Finally, a certain arbitrariness, with which each definition of fixed points and directions based on mechanical theorems is afflicted, is still to be pointed out. One can only base a conclusion on the law of inertia when all forces that act in a given case are known, or when it is known that no forces are present. Now there could always be forces acting in our surroundings, which spin us, together with all the neighboring stars, around arbitrarily in the universe, without however exerting any influence on the relative position of all these bodies. Such forces would, of course, completely elude our experience, and therefore the principle of utility, which alone guides us, commands us not to allow ourselves to become disconcerted by the thought of such a possibility when using theorems based on the law of inertia.

One senses a certain feeling of unease when one stops and thinks about all that is provisional, intermediate, undecided in present-day science concerning a point which is so important for a clear idea of the universe, as is the establishment of what is at rest in the universe. Yet, that is a characteristic of our times. The proud era of natural science, when it believed to have found absolute laws and to be able to give philosophy a real basis, is over. Similar instances of relativity as are found in the case of motion, exist everywhere, and with each broadening of experience, uncertainties turn up in previously accepted definitions. A profound scepticism has become fashionable, for one asks oneself even about the foundations of exact natural science, which are given the honorable name of "laws of nature": what can they be other than the most practical summary possible of what is most important for man within a limited field of experience?

A NEW LAW OF GRAVITATION ENFORCED
BY SPECIAL RELATIVITY

SCOTT WALTER

BREAKING IN THE 4-VECTORS: THE FOUR-DIMENSIONAL MOVEMENT IN GRAVITATION, 1905–1910

INTRODUCTION

In July, 1905, Henri Poincaré (1854–1912) proposed two laws of gravitational attraction compatible with the principle of relativity and all astronomical observations explained by Newton's law. Two years later, in the fall of 1907, Albert Einstein (1879–1955) began to investigate the consequences of the principle of equivalence for the behavior of light rays in a gravitational field. The following year, Hermann Minkowski (1864–1909), Einstein's former mathematics instructor, borrowed Poincaré's notion of a four-dimensional vector space for his new matrix calculus, in which he expressed a novel theory of the electrodynamics of moving media, a space-time mechanics, and two laws of gravitational attraction. Following another two-year hiatus, Arnold Sommerfeld (1868–1951) characterized the relationship between the laws proposed by Poincaré and Minkowski, calling for this purpose both on space-time diagrams and a new 4-vector formalism.

Of these four efforts to capture gravitation in a relativistic framework, Einstein's has attracted the lion's share of attention, and understandably so in hindsight, but at the expense of a full understanding of what is arguably the most significant innovation in contemporary mathematical physics: the four-dimensional approach to laws of physics. In virtue of the common appeal made by Poincaré, Minkowski, and Sommerfeld to four-dimensional vectors in their studies of gravitational attraction, their respective contributions track the evolving form of four-dimensional physics in the early days of relativity theory.[1] The objective of this paper is to describe in terms of theorists' intentions and peer readings the emergence of a four-dimensional language for physics, as applied to the geometric and symbolic expression of gravitational action.

The subject of gravitational action at the turn of the twentieth century is well-suited for an investigation of this sort. This is not to say that the reform of Newton's

---

1 In limiting the scope of this paper to the methods applied by their authors to the problem of gravitation, four contributions to four-dimensional physics are neglected: that of Richard Hargreaves, based on integral invariants (Hargreaves 1908), two 4-vector systems due to Max Abraham (Abraham 1910) and Gilbert Newton Lewis (Lewis 1910a), and Vladimir Varičak's hyperbolic-function based approach (Varičak 1910).

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

law was a burning issue for theorists. While several theories of gravitation claimed corroboration on a par with that of classical Newtonian theory, contemporary theoretical interest in gravitation as a research topic—including the Lorentz-invariant variety—was sharply curtailed by the absence of fresh empirical challenges to the inverse-square law. Rather, in virtue of the stability of the empirical knowledge base, and two centuries of research in celestial mechanics, the physics of gravitation was a well-worked, stable terrain, familiar to physicists, mathematicians and astronomers alike.[2]

The leading theory of gravitation in 1905 was the one discovered by Isaac Newton over two centuries earlier, based on instantaneous action at a distance. When Poincaré sought to bring gravitational attraction within the purview of the principle of relativity, he saw it had to propagate with a velocity no greater than that of light in empty space, such that a reformulation of Newton's law as a retarded action afforded a simple solution.

Newton's law was the principal model for Poincaré, but it was not the only one. With the success of Maxwell's theory in explaining electromagnetic phenomena (including the behavior of light) during the latter third of the nineteenth century, theories of contiguous action gained greater favor with physicists. In 1892, the Dutch theorist H. A. Lorentz produced a theory of mobile charged particles interacting in an immobile aether, that was an habile synthesis of Maxwell's field theory and Wilhelm Weber's particle theory of electrodynamics. After the discovery of the electron in 1897, and Lorentz's elegant explanation of the Zeeman effect, certain charged microscopic particles were understood to be electrons, and electrons the building-blocks of matter.[3]

In this new theoretical context of aether and electrons, Lorentz derived the force on an electron moving in microscopic versions of Maxwell's electric and magnetic fields. To determine the electromagnetic field of an electron in motion, Alfred Liénard and Emil Wiechert derived a formula for a potential propagating with finite velocity. In virtue of these two laws, both of which fell out of a Lagrangian from Karl Schwarzschild, the theory of electrons provided a means of calculating the force on a charged particle in motion due to the fields of a second charged particle in motion.[4]

An electron-based analogy to gravitational attraction of neutral mass points was then close at hand. Lorentz's electron theory was held in high esteem by early twenti-

2 For an overview of research on gravitation from 1850 to 1915, see (Roseveare 1982). On early 20th-century investigations of gravitational absorption, see de Andrade Martins (de Andrade Martins 1999). While only Lorentz-covariant theories are considered in this paper, the relative acceptance of the principle of relativity among theorists is understood as one parameter among several influencing the development of four-dimensional physics.

3 See (Buchwald 1985, 242; Darrigol 2000, 325; Buchwald and Warwick 2001).

4 Lorentz took the force per unit charge on a volume element of charged matter moving with velocity $\mathfrak{v}$ in the electric and magnetic fields $\mathfrak{d}$ and $\mathfrak{h}$ to be $\mathfrak{f} = \mathfrak{d} + \frac{1}{c}[\mathfrak{v} \cdot \mathfrak{h}]$, where the brackets indicate a vector product (Lorentz 1904c, 2:156–7). For a comparison of electrodynamic Lagrangians from Maxwell to Schwarzschild, see (Darrigol 2000, app. 9).

eth-century theorists, including both Poincaré and Minkowski, who naturally catered to the most promising research program of the moment. They each proposed two force laws: one based on retarded action at a distance, the other appealing directly to contiguous action propagated in a medium. All four particle laws were taken up in turn by Sommerfeld.[5]

Several other writers have discussed Poincaré's and Minkowski's work on gravitation. Of the first four substantial synoptic reviews of the two theories, none employed the notation of the original works, although this fact itself reflects the rapid evolution of formal approaches in physics. Early comparisons were carried out with either Sommerfeld's 4-vector formalism (Sommerfeld 1910b; Kretschmann 1914), a relative coordinate notation (de Sitter 1911), or a mix of ordinary vector algebra and tensor calculus (Kottler 1922). No further comparison studies were published after 1922, excepting one summary by North (North 1965, 49–50), although since the 1960s, the work of Poincaré and Minkowski has continued to incite historical interest.[6] Sommerfeld's contribution, while it inflected theoretical practice in general, and contemporary reception of Lorentz-covariant gravitation theory in particular, has been neglected by historians.

The present study has three sections, beginning with Poincaré's contribution, moving on in the second section to Minkowski's initial response to Poincaré's theory, and a review of his formalism and laws of gravitation. A third section is taken up by Sommerfeld's interpretation of the laws proposed by Poincaré and Minkowski. The period of study is thus bracketed on one end by the discovery of special relativity in 1905, and on the other end by Sommerfeld's paper. While the latter work did not spell the end of either 4-vector formalisms or Lorentz-covariant theories of gravitation, it was the first four-dimensional vector algebra, and represents a point of closure for a study of the emergence of a conceptual framework for four-dimensional physics.

1. HENRI POINCARÉ'S LORENTZ-INVARIANT LAWS OF GRAVITATION

Poincaré's memoir on the dynamics of the electron (Poincaré 1906), like Einstein's relativity paper of 1905, contains the fundamental insight of the physical significance of the group of Lorentz transformations, not only for electrodynamics, but for all natural phenomena. The law of gravitation, to no lesser extent than the laws of electrodynamics, fell presumably within the purview of Einstein's theory, but this is not a point that Einstein, then working full time as a patent examiner in Bern, chose to elaborate upon immediately. Poincaré, on the other hand, as Professor of Mathematical Astron-

5 On the Maxwellian approach to gravitation, see (North 1965, chap. 3; Roseveare 1982, 129–31; Norton 1992, 32). The distinction drawn here between retarded action at a distance and field representations reflects that of Lorentz (Lorentz 1904b), for whom this was largely a matter of convenience. On nineteenth-century conceptions of the electromagnetic field, see (Cantor and Hodge 1981).

6 On Poincaré's theory see (Cunningham 1914, 173; Whitrow and Morduch 1965, 20; Harvey 1965, 452; Cuvaj 1970, app. 5; Schwartz 1972; Zahar 1989, 192;Torretti 1996, 132). On Minkowski's theory see (Weinstein 1914, 61; Pyenson 1985, 88; Corry 1997, 287).

omy and Celestial Mechanics at the Sorbonne, could hardly finesse the question of gravitation. In particular, his address to the scientific congress at the St. Louis World's Fair, on 24 September, 1904, had pinpointed Laplace's calculation of the propagation velocity of gravitation as a potential spoiler for the principle of relativity.[7]

There may have been another reason for Poincaré to investigate a relativistic theory of gravitation. In the course of his study of Lorentz's contractile electron, Poincaré noted that the required relations between electromagnetic energy and momentum were not satisfied in general. Raised earlier by Max Abraham, the problem was considered by Lorentz to be a fundamental one for his electron theory.[8]

Solving the stability problem of Lorentz's contractile electron was a trivial matter for Poincaré, as it meant transposing to electron theory a special solution to a general problem he had treated earlier at some length: to find the equilibrium form of a rotating fluid mass.[9] He postulated a non-electromagnetic, Lorentz-invariant "supplementary" potential that exerts a binding (negative) pressure inside the electron, and reduces the total energy of the electron in an amount proportional to the volume decrease resulting from Lorentz contraction. When combined with the electromagnetic field Lagrangian, this binding potential yields a total Lagrangian invariant with respect to the Lorentz group, as Poincaré required.

In accordance with the electromagnetic world-picture and the results of Kaufmann's experiments, Poincaré supposed the inertia of matter to be exclusively of electromagnetic origin, and he set out, as he wrote in §6 of his paper,

> to determine the total energy due to electron motion, the corresponding action, and the quantity of electromagnetic momentum, in order to calculate the electromagnetic masses of the electron.

---

7 Laplace estimated the propagation velocity of gravitation to be 10^6 times that of light, and Poincaré noted that such a signal velocity would allow inertial observers to detect their motion with respect to the aether (Poincaré 1904, 312).

8 See (Poincaré 1906, 153–154; Miller 1973, 230–233). Following Abraham's account (Abraham 1905, 205), the problem may be presented in outline as follows (using modified notation and units). Consider a deformable massless sphere of radius a and uniformly distributed surface charge, and assume that this is a good model of the electron. The longitudinal mass $m_{||}$ of this sphere may be defined as the quotient of external force and acceleration, $m_{||} = d|\boldsymbol{G}|/d|\boldsymbol{v}|$, where $\boldsymbol{G}$ is the electromagnetic momentum resulting from the electron's self-fields, and $\boldsymbol{v}$ is electron velocity. Defining the electromagnetic momentum to be $\boldsymbol{G} = \int \boldsymbol{E} \times \boldsymbol{B}\, dV$, where $\boldsymbol{E}$ and $\boldsymbol{B}$ denote the electric and magnetic self-fields, and V is for volume, we let $c = 1$, and find the longitudinal mass for small velocities to be $m_{||} = \frac{e^2}{6\pi a}(1-v^2)^{-3/2}$. Longitudinal electron mass may also be defined in terms of the electromagnetic energy W of the electron's self-fields, assuming quasistationary motion: $m_{||} = \frac{1}{|\boldsymbol{v}|}\frac{dW}{d|\boldsymbol{v}|}$, where $W = \frac{e^2}{6\pi a}(1-v^2)^{-1/2} + \frac{e^2}{24\pi a}(1-v^2)^{1/2}$. This leads, however, to an expression for longitudinal mass different from the previous one: $m_{||} = \frac{e^2}{6\pi a}\left[(1-v^2)^{-3/2} + \frac{1}{4}(1-v^2)^{-1/2}\right]$. From the difference in these two expressions for longitudinal mass, Abraham concluded that the Lorentz electron required the postulation of a non-electromagnetic force and was thereby not compatible with a purely electromagnetic foundation of physics.

9 See (Poincaré 1885, 1902a, 1902b). In the limit of null angular velocity, gravitational attraction can be replaced by electrostatic repulsion, with a sign reversal in the pressure gradient.

Non-electromagnetic mass does not figure in this analysis, and consequently, one would not expect the non-electromagnetic binding potential to contribute to the tensorial electromagnetic mass of the electron, although Poincaré did not state this in so many words. Instead, immediately after obtaining an expression for the binding potential, he derived the small-velocity, "experimental" mass from the electromagnetic field Lagrangian alone, neglecting a contribution from the binding potential. The mass of the slowly-moving Lorentz electron was then equal to the electrostatic mass, just as one would want for an electromagnetic foundation of mechanics. This fortuitous result, which revised Lorentz's electron mass value downward by a quarter, was obtained independently by Einstein, using a method that did not constrain electron structure (Einstein 1905, 917).[10] Although the question of electron mass was far from resolved, Poincaré had shown that the stability problem represented no fundamental obstacle to the pursuit of a new mechanics based on the concept of a contractile electron.

With this obstacle out of the way, Poincaré proceeded as if the laws of mechanics were applicable to the experimental mass of the electron.[11] Noting that the negative pressure deriving from his binding potential is proportional to the fourth power of mass, and furthermore, that Newtonian attraction is itself proportional to mass, Poincaré conjectured that

> there is some relation between the cause giving rise to gravitation and that giving rise to the supplementary potential.

On the basis of a formal relation between experimental mass and the binding potential, in other words, Poincaré predicted the unification of his negative internal electron pressure with the gravitational force, in a future theory encompassing all three forces.[12]

On this hopeful note, Poincaré began his memoir's ninth and final section, entitled "Hypotheses concerning gravitation." Lorentz's theory, Poincaré explained, promised to account for the observed relativity of motion:

> In this way Lorentz's theory would fully explain the impossibility of detecting absolute motion, if all forces were of electromagnetic origin.[13]

---

10 Poincaré also neglected the mass contribution of the binding potential in his 1906–1907 Sorbonne lectures, according to student notes (Poincaré 1953, 233). For reviews of Poincaré's derivation of the binding potential, see (Cuvaj 1970, app. 11) and (Miller 1973). On post-Minkowskian interpretations of the binding potential (also known as Poincaré pressure), see (Cuvaj 1970, 203; Miller 1981, 382, n. 29; Yaghjian 1992).

11 In this paper Poincaré made no distinction between inertial and gravitational mass.

12 As Cuvaj points out (Cuvaj 1968, 1112), Poincaré may have found inspiration for this conjecture in Paul Langevin's remark that gravitation stabilized the electron against Coulomb repulsion. Unlike Langevin, Poincaré anticipated a unified theory of gravitation and electrons, in the spirit of theories pursued later by Gustav Mie, Gunnar Nordström, David Hilbert, Hans Reissner, Hermann Weyl and Einstein; for an overview see (Vizgin 1994).

13 "Ainsi la théorie de Lorentz expliquerait complètement l'impossibilité de mettre en évidence le mouvement absolu, si toutes les forces étaient d'origine électromagnétique" (Poincaré 1906, 166).

The hypothesis of an electromagnetic origin of gravitational force had been advanced by Lorentz at the turn of the century. On the assumption that the force between "ions" (later "electrons") of unlike sign was of greater magnitude at a given separation than that between ions of like sign (following Mossotti's conjecture), Lorentz represented gravitational attraction as a field-theoretical phenomenon analogous to electromagnetism, reducing to the Newtonian law for bodies at rest with respect to the aether. Lorentz's theory tacitly assumed negative energy density for the "gravitational" field, and a gravitational aether of huge intrinsic positive energy density, two well-known sticking-points for Maxwell. Another difficulty stemmed from the dependence of gravitational force on absolute velocities.[14]

Neither Lorentz's gravitation theory nor Maxwell's sticking-points were mentioned by Poincaré in the ninth section of his memoir. Instead, he recalled a well-known empirical fact: two bodies that generate identical electromagnetic fields need not exert the same attraction on electrically neutral masses. Although Lorentz's theory clearly accounts for this fact, Poincaré concluded that the gravitational field was distinct from the electromagnetic field. What this tells us is that Poincaré's attention was not focused on Lorentz's theory of gravitation.[15]

To Poincaré's way of thinking, it was the impossibility of an electromagnetic reduction of gravitation that had driven Lorentz to suppose that all forces transform like electromagnetic ones:

> The gravitational field is therefore distinct from the electromagnetic field. Lorentz was obliged thereby to extend his hypothesis with the assumption that *forces of any origin whatsoever, and gravitation in particular, are affected by a translation* (or, if one prefers, by the Lorentz transformation) *in the same manner as electromagnetic forces*. (Poincaré 1906, 166.)[16]

---

14 See (Lorentz 1900; Havas 1979, 83; Torretti 1996, 131). On Lorentz's precursors see (Whittaker 1951–1953, 2:149; Zenneck 1903). Lorentz's theory of gravitation failed to convince Oliver Heaviside, who had carefully weighed the analogy from electromagnetism to gravitation (Heaviside 1893). In a letter to Lorentz, Heaviside called into question the theory's electromagnetic nature, by characterizing Lorentz's gravitational force as "action at a distance of a double kind" (18 July, 1901, Lorentz Papers, Rijksarchief in Noord-Holland te Haarlem). Aware of these difficulties, Lorentz eventually discarded his theory, citing its incompatibility with the principle of relativity (Lorentz 1914, 32).

15 In his 1906–1907 Sorbonne lectures (Poincaré 1953), Poincaré discussed a different theory (based on an idea due to Le Sage) that Lorentz had proposed in the same paper, without mentioning the Mossotti-style theory. His first discussion of the latter theory was in 1908, when he considered it to be an authentic relativistic theory, and one in which the force of gravitation was of electromagnetic origin (Poincaré 1908, 399).

16 Poincaré's account of Lorentz's reasoning should be taken with a grain of salt, as Lorentz made no mention of his theory of gravitation in the 1904 publication referred to by Poincaré, "Electromagnetic phenomena in a system moving with any velocity less than that of light." While the electron theory developed in the latter paper did not address the question of the origin of the gravitational force, it admitted the possibility of a reduction to electromagnetism (such as that of his own theory) by means of the additional hypothesis referred to in the quotation: all forces of interaction transformed in the same way as electric forces in an electrostatic system (Lorentz 1904a, §8). The contraction hypothesis formerly invoked to account for the null result of the Michelson-Morley experiments, Lorentz added, was subsumed by the new hypothesis.

It was the cogency of the latter hypothesis that Poincaré set out to examine in detail, with respect to gravitational attraction. The situation was analogous to the one Poincaré had encountered in the case of electron energy and momentum mentioned above, where he had considered constraining internal forces of the electron to be Lorentz-invariant. Such a constraint solved the problem immediately, but Poincaré recognized that it was inadmissible nonetheless, because it violated Maxwell's theory (p. 136). A similar violation in the realm of mechanics could not be ruled out in the case of gravitation, such that a careful analysis of the admissibility of the formal requirement of Lorentz-invariance was called for.

Poincaré set out to determine a general expression for the law of gravitation in accordance with the principle of relativity. A relativistic law of gravitation, he reasoned, must obey two constraints distinguishing it from the Newtonian law. First of all, the new force law could no longer depend solely on the masses of the two gravitating bodies and the distance between them. The force had to depend on their velocities, as well. Furthermore, gravitational action could no longer be considered instantaneous, but had to propagate with some finite velocity, so that the force acting on the passive mass would depend on the position and velocity of the active mass at some earlier instant in time. A gravitational propagation velocity greater than the speed of light, Poincaré observed, would be "difficult to understand," because attraction would then be a function of a position in space not yet occupied by the active mass (p. 167).

These were not the only conditions Poincaré wanted to satisfy. The new law of gravitation had also (1) to behave in the same way as electromagnetic forces under a Lorentz transformation, (2) to reduce to Newton's law in the case of relative rest of the two bodies, and (3) to come as close as possible to Newton's law in the case of small velocities. Posed in this way, Poincaré noted, the problem remains indeterminate, save in the case of null relative velocity, where the propagation velocity of gravitation does not enter into consideration. Poincaré reasoned that if two bodies have a common rectilinear velocity, then the force on the passive mass is orthogonal to an ellipsoid, at the center of which lies the active mass.

Undeterred by the indeterminacy of the question in general, Poincaré set about identifying quantities invariant with respect to the Lorentz group, from which he wanted to construct a law of gravitation satisfying the constraints just mentioned. To assist in the identification and interpretation of these invariants, Poincaré referred to a space of four dimensions. "Let us regard," he wrote,

$$\begin{array}{cccc} x, & y, & z, & t\sqrt{-1} \\ \delta x, & \delta y, & \delta z, & \delta t\sqrt{-1} \\ \delta_1 x, & \delta_1 y, & \delta_1 z, & \delta_1 t\sqrt{-1}, \end{array}$$

> as the coordinates of 3 points P, P', P'', in space of 4 dimensions. We see that the Lorentz transformation is merely a rotation in this space about the origin, regarded as fixed. Consequently, we will have no distinct invariants apart from the 6 distances between the 3 points P, P', P'', considered separately and with the origin, or, if one prefers, apart from the 2 expressions:

$$x^2 + y^2 + z^2 - t^2, \quad x\delta x + y\delta y + z\delta z - t\delta t,$$

> or the 4 expressions of like form deduced by arbitrary permutation of the 3 points P, P', P''.[17]

Here Poincaré formed three quadruplets representing the differential displacement of two point masses, with respect to a certain four-dimensional vector space, later called a pseudo-Euclidean space.[18] By introducing such a 4-space, Poincaré simplified the task of identifying quantities invariant with respect to the Lorentz transformations, the line interval of the new space being formally identical to that of a Euclidean 4-space. He treated his three points P, P', and P'' as 4-vectors, the scalar products of which are invariant, just as in Euclidean space. In fact, Poincaré did not employ vector terminology or notation in his study of gravitation, but provided formal definitions of certain objects later called 4-vectors.

Poincaré's habit, and that of the overwhelming majority of his French colleagues in mathematical physics well into the 1920s, was to express ordinary vector quantities in Cartesian coordinate notation, and to forgo notational shortcuts when differentiating, writing these operations out in full.[19] Although he did not exclude symbols such as Δ or $\Box$ from his scientific papers and lectures, he employed them parsimoniously.[20] In line with this practice, Poincaré did little to promote vector methods from his chair at the Sorbonne. In twenty volumes of lectures on mathematical physics and celestial mechanics, there is not a single propadeutic on quaternions or vector algebra.[21] Poincaré deplored the "long calculations rendered obscure by notational

---

17 "Regardons $x, y, z, t\sqrt{-1}, \delta x, \delta y, \delta z, \delta t\sqrt{-1}, \delta_1 x, \delta_1 y, \delta_1 z, \delta_1 t\sqrt{-1}$, comme les coordonnées de 3 points P, P', P'' dans l'espace à 4 dimensions. Nous voyons que la transformation de Lorentz n'est qu'une rotation de cet espace autour de l'origine, regardée comme fixe. Nous n'aurons donc pas d'autres invariants distincts que les six distances des trois points P, P', P'' entre eux et à l'origine, ou, si l'on aime mieux, que les 2 expressions: $x^2 + y^2 + z^2 - t^2, x\delta x + y\delta y + z\delta z - t\delta t$, ou les 4 expressions de même forme qu'on en déduit en permutant d'une manière quelconque les 3 points P, P', P''" (Poincaré 1906, 168–9).

18 Poincaré's three points P, P', P'' may be interpreted in modern terminology as follows. Let the spacetime coordinates of the passive mass point be $A = (x_0, y_0, z_0, t_0)$, with ordinary velocity $\xi = (\delta x/\delta t, \delta y/\delta t, \delta z/\delta t)$, such that at time $t_0 + \delta t$ it occupies the spacetime point $A' = (x_0 + \delta x, y_0 + \delta y, z_0 + \delta z, t_0 + \delta t)$. Likewise for the active mass point, $B = (x_0 + x, y_0 + y, z_0 + z, t_0 + t)$, with ordinary velocity $\xi_1 = (\delta_1 x/\delta_1 t, \delta_1 y/\delta_1 t, \delta_1 z/\delta_1 t)$, such that at time $t_0 + t + \delta_1 t$, it occupies the spacetime point $B' = (x_0 + x + \delta_1 x, y_0 + y + \delta_1 y, z_0 + z + \delta_1 z, t_0 + t + \delta_1 t)$. Poincaré's three quadruplets may now be expressed as position 4-vectors: $P = B - A, P' = B' - B, P'' = A' - A$.

19 While the first German textbook on electromagnetism to employ vector notation systematically dates from 1894 (Föppl 1894), the first comparable textbook in French was published two decades later by Jean-Baptiste Pomey (1861–1943), instructor of theoretical electricity at the *École supérieure des Postes et Télégraphes* in Paris (Pomey 1914–1931, vol. 1).

20 The Laplacian was expressed generally as $\nabla^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$, but by Poincaré as Δ. The d'Alembertian, $\Box \equiv \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2 - \partial^2/\partial t^2$, became in Poincaré's notation: $\Box \equiv \Delta - d^2/dt^2$. Poincaré employed $\Box$ in his lectures on electricity and optics (Poincaré 1901, 456), and was the first to employ it in a relativistic context.

complexity" in W. Voigt's molecular theory of light, and seems to have been of the opinion that in general, new notation only burdened the reader.[22]

The point of forming quadruplets was to obtain a set of Lorentz-invariants corresponding to the ten variables entering into the right-hand side of the new force law, representing the squared distance in space and time of the two bodies and their velocities $(\xi, \eta, \zeta, \xi_1, \eta_1, \zeta_1)$. How did Poincaré obtain his invariants? According to the method cited above, six invariants were to be found from the distances between P, P', P'', and the origin, or from the scalar products of P, P', and P''. These six intermediate invariants were then to be combined to obtain homogeneous invariants depending on the duration of propagation of gravitational action and the velocities of the two point masses. Poincaré skipped over the intermediate step and produced the following four invariants, in terms of squared distance, distance and velocity (twice), and the velocity product:

$$\sum x^2 - t^2, \frac{t - \sum x\xi}{\sqrt{1 - \sum \xi^2}}, \frac{t - \sum x\xi_1}{\sqrt{1 - \sum \xi_1{}^2}}, \frac{1 - \sum \xi\xi_1}{\sqrt{(1 - \sum \xi^2)(\sqrt{1 - \sum \xi_1{}^2})}}. \tag{1}$$

The Lorentz-invariance and geometric significance of these quantities are readily verified.[23] These four invariants (1), the latter three of which were labeled A, B, and C, formed the core of Poincaré's constructive approach to the law of gravitation. (For convenience, I refer to Poincaré's four invariants [1] as his "kinematic" invariants.)

Inspection of the signs of these invariants reveals an inconsistency, the reason for which is apparent once the intermediate calculations have been performed. Instead of constructing his four invariants out of scalar products, Poincaré introduced an inversion for A, B, and C.[24] This sign inconsistency had no consequence on his search

21 Poincaré's manuscript lecture notes for celestial mechanics, however, show that he saw fit to introduce the quaternionic method to his students (undated notebook on quaternions and celestial mechanics, 32 pp., private collection, Paris; hpcd 76, 78, 93, Henri Poincaré Archives, Nancy).

22 Manuscript report of the PhD. thesis submitted by Henri Bouasse, 13 December, 1892, AJ[16]5535, *Archives Nationales*, Paris. From Poincaré's conservative habits regarding formalism, he appears as an unlikely candidate at best for the development of a four-dimensional calculus circa 1905; cf. H. M. Schwartz's counterfactual conjecture: if Poincaré had adopted the ordinary vector calculus by the time he wrote his *Rendiconti* paper, "he would have in all likelihood introduced explicitly ... the convenient four-dimensional vector calculus" (Schwartz 1972, 1287, n. 7).

23 The invariants (1) may be expressed in ordinary vector notation, letting $\Sigma x = \boldsymbol{x}, \Sigma\xi = \boldsymbol{v}, \Sigma\xi_1 = \boldsymbol{v}_1$, and for convenience, $k = 1/\sqrt{1-\Sigma\xi^2}, k_1 = 1/\sqrt{1-\Sigma\xi_1{}^2}$, such that the four quantities (1) read as follows: $\boldsymbol{x}^2 - t^2, k(t - \boldsymbol{xv}), k_1(t - \boldsymbol{xv}_1), kk_1(1 - \boldsymbol{vv}_1)$.

24 Poincaré's four kinematic invariants (1) are functions of the following six intermediate invariants: $a = x^2 + y^2 + z^2 - t^2$, $b = x\delta x + y\delta y + z\delta z - t\delta t$, $c = x\delta_1 x + y\delta_1 y + z\delta_1 z - t\delta_1 t$, $d = \delta x\delta_1 x + \delta y\delta_1 y + \delta z\delta_1 z - \delta t\delta_1 t$, $e = \delta x^2 + \delta y^2 + \delta z^2 - \delta t^2$, $f = \delta_1 x^2 + \delta_1 y^2 + \delta_1 z^2 - \delta_1 t^2$. In terms of the latter six invariants, the four kinematic invariants (1) may be expressed as follows: $\Sigma x^2 - t^2 = a$, $A = -b/\sqrt{-e}$, $B = -c/\sqrt{-f}$, and $C = -d/(\sqrt{-e}\sqrt{-f})$. For a slightly different reconstruction of Poincaré's kinematic invariants, see (Zahar 1989, 193).

for a relativistic law of gravitation, although it affected his final result, and perplexed at least one of his readers, as I will show in section 3.

What Poincaré needed next for his force law was a Lorentz-invariant expression for the force itself. Up to this point, he had neither a velocity 4-vector nor a force 4-vector definition on hand. Presumably, the search for Lorentz-invariant expressions of force led him to define these 4-vectors. Earlier in his memoir (p. 135), Poincaré had determined the Lorentz transformations of force density, but now he was interested in the Lorentz transformations of force at a point. The transformations of force density:

$$X' = k(X + \varepsilon T), \quad Y' = Y, \quad Z' = Z, \quad T' = k(T + \varepsilon X), \tag{2}$$

where k is the Lorentz factor, $k = 1/\sqrt{1-\varepsilon^2}$, and ε designates frame velocity, led Poincaré to define a fourth component of force density, T, as the product of the force density vector with velocity, $T = \sum X\xi$.[25] He gave the same definition for the temporal component of force at a point: $T_1 = \sum X_1\xi$.[26] Next, dividing force density by force at a point, Poincaré obtained the charge density ρ. Ostensibly from the transformation for charge density, Poincaré singled out the Lorentz-invariant factor:[27]

$$\frac{\rho}{\rho'} = \frac{1}{k(1+\xi\varepsilon)} = \frac{\delta t}{\delta t'}. \tag{3}$$

The components of a 4-velocity vector followed from the foregoing definitions of position and force density:

> The Lorentz transformation ... will act in the same way on $\xi, \eta, \zeta, 1$ as on $\delta x, \delta y, \delta z, \delta t$, with the difference that these expressions will be multiplied moreover by the *same* factor $\delta t/\delta t' = 1/k(1+\xi\varepsilon)$.[28]

Concerning the latter definition, Poincaré observed a formal analogy between the force and force density 4-vectors, on one hand, and the position and velocity 4-vectors, on the other hand: these pairs of vectors transform in the same way, except that one member is multiplied by $1/k(1+\xi\varepsilon)$. While this analogy may seem mathematically transparent, it merits notice, as it appears to have eluded Poincaré at first.

With these four kinematic 4-vectors in hand, Poincaré defined a fifth quadruplet Q with components of force density $(X, Y, Z, T\sqrt{-1})$. Just as in the previous case, the scalar products of his four quadruplets P, P', P'', and Q were to deliver four new Lorentz-invariants in terms of the force acting on the passive mass (X_1, Y_1, Z_1):[29]

---

25 This definition was remarked by (Pauli 1921, 637).

26 The same subscript denotes the *force* acting on the *passive* mass, ΣX_1, and the *velocity* of the *active* mass, ξ_1.

27 The ratio ρ/ρ' is equal to the Lorentz factor, since in Poincaré's configuration, $\varepsilon = -\xi$. Some writers hastily attribute a 4-current vector to Poincaré, the form $\rho(\xi, \eta, \zeta, i)$ being implied by Poincaré's 4-vector definitions of force density and velocity.

28 "La transformation de Lorentz ... agira sur $\xi, \eta, \zeta, 1$ de la même manière que sur $\delta x, \delta y, \delta z, \delta t$, avec cette différence que ces expressions seront en outre multipliées par le *même* facteur $\delta t/\delta t' = 1/k(1+\xi\varepsilon)$" (Poincaré 1906, 169).

$$\frac{\sum X_1^2 - T_1^2}{1-\sum \xi^2},\ \frac{\sum X_1 x - T_1 t}{\sqrt{1-\sum \xi^2}},\ \frac{\sum X_1 \xi_1 - T_1}{\sqrt{1-\sum \xi^2 \sqrt{1-\sum \xi_1^2}}},\ \frac{\sum X_1 \xi - T_1}{\sqrt{1-\sum \xi^2}}. \tag{4}$$

The fourth invariant in (4) was always null by definition of $T_{1,}$ leaving only three invariants, denoted $M, N,$ and P. (In order to distinguish these invariants from the kinematic invariants, I will refer to [4] as Poincaré's "force" invariants.)

Comparing the signs of the kinematic invariants (1) with those of the force invariants (4), we see that Poincaré obtained consistent signs only for the latter invariants. He must not have computed his force invariants in the same way as his kinematic invariants, for reasons that remain obscure. It is not entirely unlikely that in the course of his analysis of the transformations of velocity and force, Poincaré realized that he could compute the force invariants directly from the scalar products of four 4-vectors. Two facts, however, argue against this reading. In the first place, Poincaré did not mention that his force invariants were the scalar products of position, velocity and force 4-vectors. Secondly, he did not alter the signs of his kinematic invariants to make them correspond to scalar products of position and velocity 4-vectors.[30] The fact that Poincaré's kinematic invariants differ from products of 4-position and 4-velocity vectors leads us to believe that when forming these invariants he was *not* thinking in terms of 4-vectors.[31]

From this point on, Poincaré worked exclusively with arithmetic combinations of three force invariants (M, N, P) and four kinematic invariants $(\sum x^2 - t^2, A, B, C)$ in order to come up with a relativistic law of gravitation. He had no further use, in particular, for the four quadruplets he had identified in the process of constructing

---

29 The invariants (4) may be expressed in ordinary vector notation, recalling the definitions of note 23, and letting $\Sigma X_1 = \boldsymbol{f}_1$, and $T_1 = \boldsymbol{f}_1 \boldsymbol{v}$: $\mathrm{k}^2 \boldsymbol{f}_1^2(1-\boldsymbol{v}^2), k\boldsymbol{f}_1(\boldsymbol{x}-\boldsymbol{v}t), kk_1\boldsymbol{f}_1(\boldsymbol{v}_1-\boldsymbol{v}), k^2\boldsymbol{f}_1(v-v)$. The fourth invariant is obviously null in this form.

30 Poincaré's force invariants (4) are functions of the following six intermediate invariants: $m = k(X_1\delta x + Y_1\delta y + Z_1\delta z - T_1\delta t)$, $n = k(X_1\delta_1 x + Y_1\delta_1 y + Z_1\delta_1 z - T_1\delta_1 t)$, $o = k(X_1 x + Y_1 y + Z_1 z - T_1 t)$, $p = k^2(X_1^2 + Y_1^2 + Z_1^2 - T_1^2)$, $q = \delta x^2 + \delta y^2 + \delta z^2 - \delta t^2$, and $s = \delta_1 x^2 + \partial_1 y^2 + \partial_1 z^2 - \partial_1 t^2$. Let the four force invariants (4) be denoted by $M, N, P,$ and S, then $M = p, N = o, P = n/\sqrt{-s}$, and $S = m/\sqrt{-q}$.
The same force invariants (4) are easily calculated using 4-vectors. Recalling the definitions in notes 23 and 29, let $\mathfrak{R} = (\boldsymbol{x}, it), U = k(\boldsymbol{v}, i), U_1 = k_1(\boldsymbol{v}_1, i)$, and $F_1 = k(\boldsymbol{f}_1, i\boldsymbol{f}_1\boldsymbol{v})$, where $\sqrt{-1} = i$. Then the force invariants (4) may be expressed as scalar products of 4-vectors: $M = F_1F_1$, $N = F_1\mathfrak{R}$, $P = F_1U_1$, and $S = F_1U$.

31 The kinematic invariants (1) obtained by Poincaré differ from those obtained from the products of 4-position and 4-velocity, contrary to Zahar's account (Zahar 1989, 194). Recalling the 4-vectors $\mathfrak{R}, U, U_1$, from n. 30, we form the products: $\mathfrak{R}\mathfrak{R}, \mathfrak{R}U, \mathfrak{R}U_1$, and UU_1. In Poincaré's notation, the latter four products are expressed as follows:

$$\Sigma x^2 - t^2, -\frac{t - \Sigma x\xi}{\sqrt{1-\Sigma\xi^2}}, -\frac{t-\Sigma x\xi_1}{\sqrt{1-\Sigma\xi_1^2}}, -\frac{t - \Sigma\xi\xi_1}{\sqrt{(1-\Sigma\xi^2)(1-\Sigma\xi_1^2)}}.$$

These invariants differ from those of Poincaré (1) only by the sign of $A, B,$ and C, as noted by (Sommerfeld 1910b, 686).

these same invariants (corresponding to modern 4-position, 4-velocity, 4-force-density and 4-force vectors), although in the end he expressed his laws of gravitation in terms of 4-force components.

To find a law applicable to the general case of two bodies in relative motion, Poincaré introduced constraints and approximations designed to reduce the complexity of his seven invariants and recover the form of the Newtonian law in the limit of slow motion ($\xi_1 \ll 1$). Poincaré naturally looked first to the velocity of propagation of gravitation. He briefly considered an emission theory, where the velocity of gravitation depends on the velocity of the source. Although the emission hypothesis was compatible with his invariants, Poincaré rejected this option because it violated his initial injunction barring a hyperlight velocity of gravitational propagation.[32] That left him with a propagation velocity of gravitation less than or equal to that of light, and to simplify his invariants Poincaré set it equal to that of light in empty space, such that $t = -\sqrt{\sum x^2} = -r$. This stipulation reduced the total number of invariants from seven to six.

With the propagation velocity of gravitation decided, Poincaré proceeded to construct a force law for point masses. He tried two approaches, the first of which is the most general. The basic idea of both approaches is to neglect terms in the square of velocity occurring in the invariants, and to compare the resulting approximations with their Newtonian counterparts. In the Newtonian scheme, the coordinates of the active mass point differ from those in the relativistic scheme (cf. note 18); Poincaré took the former to be $(x_0 + x_1, y_0 + y_1, z_0 + z_1)$ at the instant of time t_0, where the subscript 0 corresponds to the position of the passive mass point, and the coordinates with subscript 1 are found by assuming uniform motion of the source:

$$x = x_1 - \xi_1 r,\ \ y = y_1 - \eta_1 r,\ \ z = z_1 - \zeta_1 r,\ \ r = r_1 - \sum x\xi_1. \tag{5}$$

In the first approach, Poincaré made use of both the kinematic and force invariants. Substituting the values (2) into the kinematic invariants A, B, and C from (1) and the force invariants M, N, and P from (33), neglecting terms in the square of velocity, Poincaré obtained their sought-after Newtonian counterparts. Replacing the force vector occurring in the transformed force invariants by Newton's law ($\sum X_1 = -1/r_1^2$), and rearranging, Poincaré obtained three quantities in terms of distance and velocity.[33] He then re-expressed these quantities in terms of two of his original kinematic invariants, A and B, and equated the three resulting kinematic invariants to their corresponding original force invariants (4). He now had the solution in hand; three expressions relate his force invariants (containing the force vector $\sum X_1$) to two of his kinematic invariants:

32 An emission theory was proposed a few years later by Walter Ritz; see (Ritz 1908).

33 Using (5), Poincaré found the transformed force invariants $1/r_1^4, -1/r_1 - \Sigma x_1(\xi - \xi_1)/r_1^2$, and $\Sigma x_1(\xi - \xi_1)/r_1^3$.

$$M = \frac{1}{B^4}, \quad N = \frac{+A}{B^2}, \quad P = \frac{A-B}{B^3}. \tag{6}$$

He noted that complementary terms could be entertained for the three relations (6), provided that they were certain functions of his kinematic invariants $A, B,$ and C. Then without warning, he cut short his demonstration, remarking that the gravitational force components would take on imaginary values:

> The solution (6) appears at first to be the simplest, nonetheless, it may not be adopted. In fact, since M, N, P are functions of X_1, Y_1, Z_1, and $T_1 = \sum X_1 \xi$, the values of X_1, Y_1, Z_1 can be drawn from these three equations (6), but in certain cases these values would become imaginary.[34]

The quoted remark seems to suggest that for selected values of the particle velocities, the force turns out to be imaginary. However, the real difficulty springs from the equation $M = 1/B^4$, which allows for a repulsive force. The general approach failed to deliver.[35]

The fact that Poincaré published the preceding derivation may be understood in one of two ways. On the one hand, there is a psychological explanation: Poincaré's habit, much deplored by his peers, was to present his findings more or less in the order in which he found them. The case at hand may be no different from the others. On the other hand, Poincaré may have felt it worthwhile to show that the general approach breaks down. From the latter point of view, Poincaré's result is a positive one.

For his second attack on the law of gravitation, Poincaré adopted a less general approach. He knew where his first approach had become unsuitable, and consequently, leaving aside his three force invariants, he fell back on the form of his basic force 4-vector, which he now wrote in terms of his kinematic invariants, re-expressed in terms of $r = -t$, $k_0 = 1/\sqrt{1-\xi^2}$, and $k_1 = 1/\sqrt{1-\xi_1^2}$.[36] He assumed the gravitational force on the passive mass (moving with velocity ξ, η, ζ) to be a function of the distance separating the two mass points, the velocity of the passive mass point, and the velocity of the source, with the form:

34 "Au premier abord, la solution (6) paraît la plus simple, elle ne peut néanmoins être adoptée; en effet, comme M, N, P sont des fonctions de X_1, Y_1, Z_1, et de $T_1 = \Sigma X_1 \xi$, on peut tirer de ces trois équations (6) les valeurs de X_1, Y_1, Z_1; mais dans certains cas ces valeurs deviendraient imaginaires" (Poincaré 1906, 172).

35 Replacing A and B in (6) by their definitions results in the three equations: $M = k^2 \boldsymbol{f}_1^2(1-\boldsymbol{v}^2) = 1/k^4(r+\boldsymbol{x}\boldsymbol{v}_1)^4$, $N = \boldsymbol{f}_1(\boldsymbol{x}+\boldsymbol{v}r) = -(r+\boldsymbol{x}\boldsymbol{v})/[k_1^2(r+\boldsymbol{x}\boldsymbol{v}_1)^2]$, $P = kk_1\boldsymbol{f}_1(\boldsymbol{v}_1-\boldsymbol{v}) = [k(r+\boldsymbol{x}\boldsymbol{v})- -k_1(r+\boldsymbol{x}\boldsymbol{v}_1)]/k_1^3(r+\boldsymbol{x}\boldsymbol{v}_1)^3]$. Equations N and P imply an attractive force for all values of $\boldsymbol{v}$ and $\boldsymbol{v}_1$, while M leads to the ambiguously-signed solution: $\boldsymbol{f}_1 = \pm(1/[k^2(r+\boldsymbol{x}\boldsymbol{v}_1)^2])$. Presumably, the superfluous plus sign in (6) is an indication of Poincaré's preoccupation with obtaining a force of correct sign.

36 $A = -k_0(r+\Sigma x\xi)$, $B = -k_1(r+\Sigma x\xi_1)$, and $C = k_0 k_1(1-\Sigma x\xi\xi_1)$.

$$X_1 = x\frac{\alpha}{k_0} + \xi\beta + \xi_1\frac{k_1}{k_0}\gamma, \quad Z_1 = z\frac{\alpha}{k_0} + \zeta\beta + \zeta_1\frac{k_1}{k_0}\gamma,$$
$$Y_1 = y\frac{\alpha}{k_0} + \eta\beta + \eta_1\frac{k_1}{k_0}\gamma, \quad T_1 = -r\frac{\alpha}{k_0} + \beta + \frac{k_1}{k_0}\gamma, \tag{7}$$

where $\alpha, \beta,$ and γ denote functions of the kinematic invariants.[37] By definition, the component T_1 is the scalar product of the ordinary force and the velocity of the passive mass point, $T_1 = \sum X_1\xi$, such that the three functions α, β, γ satisfy the equation:

$$-A\alpha - \beta - C\gamma = 0. \tag{8}$$

Poincaré further assumed $\beta = 0$, thereby eliminating a term depending on the velocity of the passive mass, and fixing the value of γ in terms of α. Applying the same slow-motion approximation and translation (5) as in his initial approach, Poincaré found $X_1 = \alpha x_1$, and by comparison with Newton's law, α reduces to $-1/r_1^3$. In terms of the kinematic invariants (1), this relation was expressed as $\alpha = 1/B^3$, and the law of gravitation (7) took on the form:[38]

$$X_1 = \frac{x}{k_0B^3} - \xi_1\frac{k_1}{k_0}\frac{A}{B^3C}, \quad Z_1 = \frac{z}{k_0B^3} - \zeta_1\frac{k_1}{k_0}\frac{A}{B^3C},$$
$$Y_1 = \frac{y}{k_0B^3} - \eta_1\frac{k_1}{k_0}\frac{A}{B^3C}, \quad T_1 = \frac{r}{k_0B^3} - \frac{k_1}{k_0}\frac{A}{B^3C}. \tag{9}$$

Inspection of Poincaré's gravitational force (9) reveals two components: one parallel to the position 4-vector between the passive mass and the retarded source, and one parallel to the source 4-velocity. The law was not unique, Poincaré noted, and it neglected possible terms in the velocity of the passive mass.

Poincaré underlined the open-ended nature of his solution by proposing a second gravitational force law. Rearranging (9) and replacing the factor $1/B^3$ by C/B^3, such that the force depended linearly on the velocity of the passive mass, Poincaré arrived at a second law of gravitation:[39]

---

37 Using modern 4-vector notation, and denoting Poincaré's gravitational force 4-vector $F_1 = k_0(X_1, Y_1, Z_1, iT_1)$, equation (7) may be expressed: $F_1 = \alpha\mathfrak{R} + \beta U + \gamma U_1$, where $\mathfrak{R}$ denotes a light-like 4-vector between the mass points, α, β, γ stand for undetermined functions of the three kinematic invariants A, B, and C, while $U = k_0(\boldsymbol{v}, i), U_1 = k_1(\boldsymbol{v}_1, i)$ designate the 4-velocities of the passive and active mass points, respectively.

38 In ordinary vector form, recalling the definitions in notes 23 and 29, the spatial part of Poincaré's law is expressed as follows: $\boldsymbol{f}_1 = -[(\boldsymbol{x} + r\boldsymbol{v}_1) + \boldsymbol{v} \times (\boldsymbol{v}_1 \times \boldsymbol{x})]/[kk_1^3(r + \boldsymbol{x}\boldsymbol{v}_1)^3(1 - \boldsymbol{v}\boldsymbol{v}_1)]$. Cf. (Zahar 1989, 199).

39 This law may be reformulated using the vectors defined in notes 23 and 29, and neglecting (with Poincaré) the component T_1: $\boldsymbol{f}_1 = -([(\boldsymbol{x} + r\boldsymbol{v}_1) + \boldsymbol{v} \times (\boldsymbol{v}_1 \times \boldsymbol{x})]/[k_1^2(r + \boldsymbol{x}\boldsymbol{v}_1)^3])$. Cf. (Zahar 1989, 199). Comparable expressions were developed by Lorentz and Kottler (Lorentz 1910, 1239; Kottler 1922, 169).

$$
\begin{aligned}
X_1 &= \frac{\lambda}{B^3} + \frac{\eta\nu' - \zeta\mu'}{B^3}, \\
Y_1 &= \frac{\mu}{B^3} + \frac{\zeta\lambda' - \xi\nu'}{B^3}, \\
Z_1 &= \frac{\nu}{B^3} + \frac{\xi\mu' - \eta\lambda'}{B^3},
\end{aligned}
\tag{10}
$$

where

$$
\begin{aligned}
k_1(x + r\xi_1) &= \lambda, \qquad k_1(y + r\eta_1) = \mu, \qquad k_1(z + r\zeta_1) = \nu, \\
k_1(\eta_1 z - \zeta_1 y) &= \lambda', \quad k_1(\zeta_1 x - \xi_1 z) = \mu', \quad k_1(\xi_1 y - x\eta_1) = \nu'.
\end{aligned}
$$

Poincaré neglected to write down the expression for T_1, probably because of its complicated form. (For the sake of simplicity, I refer to [9] and [10], including the latter's neglected fourth component, as Poincaré's first and second law.) The unprimed triplet $B^{-3}(\lambda, \mu, \nu)$ supports what Poincaré termed a "vague analogy" with the mechanical force on a charged particle due to an electric field, while the primed triplet $B^{-3}(\lambda', \mu', \nu')$ supports an analogy to the mechanical force on a charged particle due to a magnetic field. He identified the fields as follows:

> Now λ, μ, ν, or $\frac{\lambda}{B^3}, \frac{\mu}{B^3}, \frac{\nu}{B^3}$, is an electric field of sorts, while λ', μ', ν', or rather $\frac{\lambda'}{B^3}, \frac{\mu'}{B^3}, \frac{\nu'}{B^3}$, is a magnetic field of sorts.[40]

While Poincaré wrote freely of a "gravity wave" [*onde gravifique*], he abstained from speculating on the nature of the field referred to here. As one of the first theorists (with FitzGerald and Lorentz) to have employed retarded potentials in Maxwellian electrodynamics, Poincaré must have considered the possibility of introducing a corresponding gravitational 4-potential (Whittaker 1951–1953, 1: 394, n. 3).[41] But as matters stood when Poincaré submitted this paper for publication in July, 1905, he was not in a position to elaborate the physics of fields in four-dimensional terms, since he possessed neither a 4-potential nor a 6-vector.

Poincaré had realized the objective of formulating a Lorentz-invariant force of gravitation. As we have seen, he surpassed this objective by identifying not one but

---

40 "Alors λ, μ, ν, ou $\lambda/B^3, \mu/B^3, \nu/B^3$, est une espèce de champ électrique, tandis que λ', μ', ν', ou plutôt $\lambda'/B^3, \mu'/B^3, \nu'/B^3$, est une espèce de champ magnétique" (Poincaré 1906, 175).

41 A 4-potential corresponding to Poincaré's second law (10) was given by Kottler (Kottler 1922, 169). Additional assumptions are required in order to identify a "gravito-magnetic" field with a term arising from the Lorentz transformation of force: $\boldsymbol{v} \times (\boldsymbol{v}_1 \times \boldsymbol{x})$, or the second term of the 3-vector version of (10) (neglecting the global factor; see note 39). In particular, it must be assumed that when the sources of the "gravito-electric" field $B^{-3}(\lambda, \mu, \nu)$ are at rest, the force on a mass point m is $\boldsymbol{f} = mB^{-3}(\lambda, \mu, \nu)$, independent of the velocity of m. For a detailed discussion, see (Jackson 1975, 578).

two such force laws. Designed to reduce to Newton's law in the first order of approximation in ξ_1 (or particle velocity divided by the speed of light), Poincaré's laws could diverge from Newton's only in second-order terms. The argument satisfied Poincaré, who did not report any precise numerical results, explaining that this would require further investigation. Instead, he noted that the disagreement would be ten thousand times smaller than a first-order difference stemming from the assumption of a propagation velocity of gravitation equal to that of light, "*ceteris non mutatis*" (p. 175). His result contradicted Laplace, who had predicted an observable first-order effect arising from just such an assumption. At the very least, Poincaré had demonstrated that Laplace's argument was not compelling in the context of the new dynamics.[42]

On several occasions over the next seven years, Poincaré returned to the question of gravitation and relativity, without ever comparing the predictions of his laws with observation. During his 1906–1907 Sorbonne lectures, for example, when he developed a general formula for perihelion advance, Poincaré used a Lagrangian approach, rather than one or the other of his laws (Poincaré 1953, 238). Student notes of this course indicate that he stopped short of a numerical evaluation for the various electron models (perhaps leaving this as an exercise). However, Poincaré later provided the relevant numbers in a general review of electron theory. Lorentz's theory called for an extra 7" centennial advance by Mercury's perihelion, a figure slightly greater than the one for Abraham's non-relativistic electron theory.[43] According to the best available data, Mercury's anomalous perihelial advance was 42", prompting Poincaré to remark that another explanation would have to be found in order to account for the remaining seconds of arc. Astronomical observations, Poincaré concluded soberly, provided no arguments in favor of the new electron dynamics (Poincaré 1908, 400).[44]

Poincaré capsulized the situation of his new theory in a fable in which Lorentz plays the role of Ptolemy, and Poincaré that of an unknown astronomer appearing sometime between Ptolemy and Copernicus. The unknown astronomer notices that all the planets traverse either an epicycle or a deferent in the same lapse of time, a regularity later captured in Kepler's second law. The analogy to electron dynamics turns on a regularity discovered by Poincaré in his study of gravitation:

> If we were to admit the postulate of relativity, we would find the same number in the law of gravitation and the laws of electromagnetism, which would be the velocity of light; and we would find it again in all the other forces of any origin whatsoever.[45]

---

42 Poincaré reviewed Laplace's argument in his 1906–1907 lectures (Poincaré 1953, 194). For a contemporary overview of the question of the propagation velocity of gravitation see (Tisserand 1889–1896, 1: 511).

43 Fritz Wacker, a student of Richard Gans in Tübingen, published similar results in (Wacker 1906).

44 Poincaré explained to his students that Mercury's anomalous advance could plausibly be attributed to an intra-Mercurial matter belt (Poincaré 1953, 265), an idea advanced forcefully by Hugo von Seeliger in 1906 (Roseveare 1982, 78). In a lecture delivered in September, 1909, Poincaré revised his estimate of the relativistic perihelial advance downward slightly to 6" (Poincaré 1909).

45 "[S]i nous admettions le postulat de relativité, nous trouverions dans la loi de gravitation et dans les lois électromagnétiques un nombre commun qui serait la vitesse de la lumière; et nous le retrouverions encore dans toutes les autres forces d'origine quelconque" (Poincaré 1906, 131).

This common propagation velocity of gravitational action, of electromagnetic fields, and of any other force, could be understood in one of two ways:

> Either everything in the universe would be of electromagnetic origin, or this aspect—shared, as it were, by all physical phenomena—would be a mere epiphenomenon, something due to our methods of measurement.[46]

If the electromagnetic worldview were valid, all particle interactions would be governed by Maxwell's equations, featuring a constant propagation velocity. Otherwise, the common propagation velocity of forces had to be a result of a measurement convention. In relativity theory, as Poincaré went on to point out, the measurement convention to adopt was one defining lengths as equal if and only if spanned by a light signal in the same lapse of time, as this convention was compatible with the Lorentz contraction. There was a choice to be made between the electromagnetic worldview (as realized in the electron models of Abraham and Bucherer-Langevin) and the postulate of relativity (as upheld by the Lorentz-Poincaré electron theory). Although Poincaré favored the latter theory, he felt that its destiny was to be superseded, just as Ptolemaic astronomy was superseded by Copernican heliocentrism.

The failure of his Lorentz-invariant law of gravitation to explain the anomalous advance of Mercury's perihelion probably fed Poincaré's dissatisfaction with the Lorentz-Poincaré theory in general, but what he found particularly troubling at the time was something else altogether: the discovery of magneto-cathode rays. There is no place in the Lorentz-Poincaré electron theory for rays that are both neutral (as Paul Villard reported in June, 1904) and deflected by electric and magnetic fields, which is probably why Poincaré felt the "entire theory" to be "endangered" by magneto-cathode rays.[47]

Uncertainty over the empirical adequacy of the Lorentz-Poincaré electron theory may explain why the *Rendiconti* memoir was Poincaré's last in the field of electron physics. But is it enough to explain his disinterest in the development of a four-dimensional formalism? One year after the publication of his article on electron dynamics, Poincaré commented:

> A translation of our physics into the language of four-dimensional geometry does in fact appear to be possible; the pursuit of this translation would entail great pain for limited profit, and I will just cite Hertz's mechanics, where we see something analogous. Meanwhile, it seems that the translation would remain less simple than the text and would always have the feel of a translation, and that three-dimensional language seems the best suited to the description of our world, even if one admits that this description may be carried out in another idiom.[48]

---

46 "Ou bien il n'y aurait rien au monde qui ne fût d'origine électromagnétique. Ou bien cette partie qui serait pour ainsi dire commune à tous les phénomènes physiques ne serait qu'une apparence, quelque chose qui tiendrait à nos méthodes de mesure" (Poincaré 1906, 131–132).

47 See (Poincaré 1906, 132; Stein 1987, 397, n. 29). On the history of magneto-cathode rays, see (Carazza and Kragh 1990).

Poincaré clearly saw in his own work the outline of a four-dimensional formalism for physics, yet he saw no future in its development, and this, entirely apart from the question of the empirical adequacy of the Lorentz-Poincaré theory.

Why did Poincaré discount the value of a language tailor-made for relativity? Three sources of disinterest in such a prospect spring to mind, the first of which stems from his conventionalist philosophy of science. Poincaré recognized an important role for notation in the exact sciences, as he famously remarked with respect to Edmond Laguerre's work on quadratic forms and Abelian functions that

> in the mathematical sciences, having the right notation is philosophically as important as having the right classification in the life sciences.[49]

More than likely, Poincaré was aware of the philosophical implications of a four-dimensional notation for physics, although he had yet to make his views public. But given his strong belief in the immanence of Euclidean geometry's fitness for physics, he must have considered the chances for success of such a language to be vanishingly small.[50]

A second source for Poincaré's disinterest in four-dimensional formalism is his practice of physics. As mentioned above, Poincaré dispensed with vectorial systems (and most notational shortcuts); he even avoided writing i for $\sqrt{-1}$. When considered in conjunction with his conventionalist belief in the suitability of Euclidean geometry for physics, this conservative habit with respect to notation makes Poincaré appear all the less likely to embrace a four-dimensional language for physics.

The third possible source of discontent is Poincaré's vexing experience with invariants of pseudo-Euclidean 4-space. As shown above (p. 205), Poincaré's first approach to the construction of a law of gravitation ended unsatisfactorily, and the failure of Poincaré's intuition in this instance may well have colored his view of the prospects for a four-dimensional physics.

An immediate consequence of Poincaré's refusal to work out the form of four-dimensional physics was that others could readily pick up where he left off. Roberto Marcolongo (1862–1945), Professor of Mathematical Physics in Messina, and a leading proponent of vectorial analysis, quickly discerned in Poincaré's paper a potential

---

48 "Il semble bien en effet qu'il serait possible de traduire notre physique dans le langage de la géométrie à quatre dimensions; tenter cette traduction ce serait se donner beaucoup de mal pour peu de profit, et je me bornerai à citer la mécanique de Hertz où l'on voit quelque chose d'analogue. Cependant, il semble que la traduction serait toujours moins simple que le texte, et qu'elle aurait toujours l'air d'une traduction, que la langue des trois dimensions semble la mieux appropriée à la description de notre monde, encore que cette description puisse se faire à la rigueur dans un autre idiome" (Poincaré 1907, 15). See also (Walter 1999b, 98), and for a different translation, (Galison 1979, 95). On Hertz's mechanics, see (Lützen 1999).

49 "[D]ans les Sciences mathématiques, une bonne notation a la même importance philosophique qu'une bonne classification dans les Sciences naturelles" (Poincaré 1898–1905, 1:x).

50 Poincaré's analysis of the concepts of space and time in relativity theory appeared in 1912 (Poincaré 1912). On the cool reception among mathematicians of Poincaré's views on physical geometry, see (Walter 1997).

for formal development. Marcolongo referred, like Poincaré, to a four-dimensional space with one imaginary axis, but defined the fourth coordinate as the product of time t and the negative square root of -1 (i.e., $-t\sqrt{-1}$ instead of $t\sqrt{-1}$). After forming a 4-vector potential out of the ordinary vector and scalar potentials, and defining a 4-current vector, he expressed the Lorentz-covariance of the equations of electrodynamics in matrix form. No other applications were forthcoming from Marcolongo, and a failure to produce further 4-vector quantities and functions limited the scope of his contribution, which went unnoticed outside of Italy (Marcolongo 1906).[51] Nothing further on Poincaré's method appeared in print until April, 1908, when Hermann Minkowski's paper on the four-dimensional formalism and its application to the problem of gravitation appeared in the *Göttinger Nachrichten*.

2. HERMANN MINKOWSKI'S SPACETIME LAWS OF GRAVITATION

The young Hermann Minkowski, second son of an immigrant family of Russian Jews, attended the Altstädtische Gymnasium in Königsberg (later Kaliningrad). Shortly after graduation, Minkowski submitted an essay for the Paris Academy's 1882 Grand Prize in Mathematical Sciences. His entry on quadratic forms shared top honors with a submission by the seasoned British mathematician Henry J. S. Smith, his senior by thirty-eight years.[52] The young mathematician went on to study with Heinrich Weber in Königsberg, and with Karl Weierstrass and Leopold Kronecker in Berlin. In the years following the prize competition, Minkowski became acquainted with Poincaré's writings on algebraic number theory and quadratic forms, and in particular, with a paper in Crelle's *Journal* containing some of the results from Minkowski's prize paper, still in press. To his friend David Hilbert he confided the "angst and alarm" brought on by Poincaré's entry into his field of predilection; with his "swift and versatile" energy, Poincaré was bound to bring the whole field to closure, or so it seemed to him at the time.[53] From the earliest, formative years of his scientific career, Minkowski found in Poincaré—his senior by a decade—a daunting intellectual rival.

While Minkowski had discovered in Poincaré a rival, he was soon to find that the Frenchman could also be a teacher, from whom he could learn new analytical skills and methods. Named Privatdozent in Bonn in 1887, Minkowski contributed to the abstract journal *Jahrbuch der Fortschritte der Mathematik*, and in 1892, took on the considerable task of summarizing the results of the paper for which Poincaré was

---

51 This paper later gave rise to a priority claim for a slightly different substitution: $u = it$ (Marcolongo to Arnold Sommerfeld, 5 May, 1913, Archives for History of Quantum Physics 32). On Marcolongo's paper see also (Maltese 2000, 135).

52 See (Rüdenberg 1973; Serre 1993; Strobl 1985).

53 Minkowski to Hilbert, 14 February, 1885, (Minkowski 1973, 30). Minkowski's fears turned out to be for naught, as Poincaré pursued a different line of research (Zassenhaus 1975, 446). On Minkowski's early work on the geometry of numbers see (Schwermer 1991); on later developments, see (Krätzel 1989).

awarded the King Oscar II Prize (Minkowski 1890–1893). The mathematics Poincaré created in his prize paper (the study of homoclinic points in particular) was highly innovative, and at the same time, difficult to follow. Among those whom we know had trouble understanding certain points of Poincaré's prize memoir were Charles Hermite, Gustav Mittag-Leffler, and Karl Weierstrass, who happened to constitute the prize committee.[54] Minkowski, however, welcomed the review as a learning opportunity, as he wrote to his friend and former teacher, Adolf Hurwitz:

> Poincaré's prize paper is also among the works I have to report on for the *Fortschritte*. I am quite fond of it. It is a fine opportunity for me to get acquainted with problems I have not worried about too much up to now, since I will naturally set a positive goal of making my case well.[55]

In the 1890s, building on his investigations of the algebraic theory of quadratic forms, Minkowski developed the geometric analog to this theory: geometrical number theory. A high point of his efforts in this new field, and one which contributed strongly to the establishment of his reputation in mathematical circles, was the publication of *Geometrie der Zahlen* (Minkowski 1896). The same year, Minkowski accepted a chair at Zurich Polytechnic, whereby he rejoined Hurwitz. Minkowski's lectures on mathematics and mathematical physics attracted a small following of talented and ambitious students, including the future physicists Walter Ritz and Albert Einstein, and the budding mathematicians Marcel Grossmann and Louis Kollros.[56]

Minkowski's lectures on mechanics in Zurich throw an interesting light on his view of symbolic methods in physics at the close of the nineteenth century. The theory of quaternions, he noted in 1897, was used nowhere outside of England, due to its "relatively abstract character and inherent difficulty."[57] Two of its fundamental concepts, scalars and vectors, had nevertheless gained broad approval among physicists, Minkowski wrote, and had found "frequent application especially in the theory of electricity."[58] Applications of quaternions to problems of physics were advanced in Germany with the publication of Felix Klein and Arnold Sommerfeld's *Theorie des Kreisels*, a work referred to in Minkowski's lecture notes of 1898–1899 (Klein and Sommerfeld 1879–1910).[59] Minkowski admired Klein and Sommerfeld's text,

58 Loc. cit. note 57. The concepts of scalar and vector mentioned by Minkowski were those introduced by W. R. Hamilton (1805–1865), the founder of quaternion theory. Even in Britain, vectors were judged superior to quaternions for use in physics, giving rise to spirited exchanges in the pages of *Nature* during the 1890s, as noted by (Bork 1966) and (Crowe 1967, chap. 6). On the introduction of vector analysis as a standard tool of the physicist during this period, see (Jungnickel and McCormmach 1986, 2:342), and for a general history, see (Crowe 1967).

expressing "great interest" in the latter to Sommerfeld, along with his approval of the fundamental significance accorded to the concept of momentum. However, their text did not make the required reading list for Minkowski's course in mechanics.[60]

In 1899, at the request of Sommerfeld, who a year earlier had agreed to edit the physics volumes of Felix Klein's ambitious *Encyclopedia of the Mathematical Sciences including Applications* (hereafter *Encyklopädie*), Minkowski agreed to cover a topic in molecular physics he knew little about, but one perfectly suited to his skills as an analyst: capillarity.[61] The article that appeared seven years later represented his second contribution to physics, after a short note on theoretical hydrodynamics published in 1888, but which, ten years later, Minkowski claimed no one had read—save the abstracter (Minkowski 1888, 1907).[62]

When Minkowski accepted Göttingen's newly-created third chair of pure mathematics in the fall of 1902, the pace of his research changed brusquely. The University of Göttingen at the turn of the last century was a magnet for talented young mathematicians and physicists.[63] Minkowski soon was immersed in the activities of Göttingen's Royal Society of Science, its mathematical society, and research seminars. Several faculty members, including Max Abraham, Gustav Herglotz, Eduard Riecke, Karl Schwarzschild, and Emil Wiechert, actively pursued theoretical or experimental investigations motivated by the theory of electrons, and it was not long before Minkowski, too, took up the theory. During the summer semester of 1905 he co-led a seminar with Hilbert on electron theory, featuring reports by Wiechert and Herglotz, and by Max Laue, who had just finished a doctoral thesis under Max Planck's supervision.[64]

Along with seminars on advanced topics in physics and analytical mechanics, Göttingen featured a lively mathematical society, with weekly meetings devoted to presentations of work-in-progress and reports on scientific activity outside of Göttingen. The electron theory was a frequent topic of discussion in this venue. For instance, the problem of gravitational attraction was first addressed by Schwarzschild in December, 1904, in a report on Alexander Wilken's recent paper on the compatibility of Lorentz's electron theory with astronomical observations.[65]

A focal point of sorts for the mathematical society, Poincaré's scientific output fascinated Göttingen scientists in general, and Minkowski in particular, as mentioned above.[66] Minkowski reported to the mathematical society on Poincaré's publications on topology, automorphic functions, and capillarity, devoting three talks in 1905–1906 to Poincaré's 1888–1889 Sorbonne lectures on this subject (Poincaré 1895). Others reporting on Poincaré's work were Conrad Müller on Poincaré's St. Louis lecture on the current state and future of mathematical physics (31 January, 1905), Hugo Broggi on probability (27 October, 1905), Ernst Zermelo on a boundary-value problem (12 December, 1905), Erhard Schmidt on the theory of differential equations (19 December, 1905), Max Abraham on the Sorbonne lectures (6 February, 1906) and Paul Koebe on the uniformization theorem (19 November, 1907). One gathers from this list that the Göttingen mathematical society paid attention to Poincaré's contributions to celestial mechanics, mathematical physics, and pure mathematics, all subjects intersecting with the ongoing research of its members. It also appears that no other member of the mathematical society was quite as assiduous in this respect as Minkowski.[67]

When Einstein's relativity paper appeared in late September, 1905, it drew the attention of the Bonn experimentalist Walter Kaufmann, a former Göttingen Privatdozent and friend of Max Abraham, but neither Abraham nor any of his colleagues rushed to report on the new ideas to the mathematical society.[68] Poincaré's long memoir on the dynamics of the electron, published in January, 1906, fared better, although nearly two years went by before Minkowski found an occasion to comment on Poincaré's gravitation theory, and to present his own related work-in-progress. Minkowski's typescript has been conserved, and is the source referred to here.[69]

On the occasion of the 5 November, 1907, meeting of the mathematical society, Minkowski began his review of Poincaré's work by observing that gravitation remained an "important question" in relativity theory, since it was not yet known "how the law of gravitation is arranged for in the realm of the principle of relativity."[70] The basic problem of gravitation and relativity, in other words, had not been solved by Poincaré. Eliding mention of Poincaré's two laws, Minkowski recognized

---

66 Although Poincaré spoke on celestial mechanics in Göttingen in 1895 (Rowe 1992, 475) and was invited back in 1902, he did not return until 1909, a few months after Minkowski's sudden death. See Hilbert to Poincaré, 6 November, 1908 (Dugac 1986, 209); Klein to Poincaré, 14 Jan., 1902 (Dugac 1989, 124–125). Sponsored by the Wolfskehl Fund, Poincaré's 1909 lecture series took place during "Poincaré week", in the month of April. His lectures were published the following year (Poincaré 1910) in a collection launched in 1907, based on an idea of Minkowski's (Klein 1907, IV).

69 Undated typescript of a lecture on a new form of the equations of electrodynamics, *Math. Archiv* 60: 3, Handschriftenabteilung, NSUB. This typescript differs significantly from the posthumously-published version (Minkowski 1915).

70 "Es entsteht die grosse Frage, wie sich denn das Gravitationsgesetz in das Reich des Relativitätsprinzipes einordnen lässt" (p. 15).

in his work only one positive result: by considering gravitational attraction as a "pure mathematical problem," he said, Poincaré had found gravitation to propagate with the speed of light, thereby overturning the standard Laplacian argument to the contrary.[71]

Minkowski expressed dissatisfaction with Poincaré's approach, allowing that Poincaré's was "only one of many" possible laws, a fact stemming from its construction out of Lorentz-invariants. Consequently, Poincaré's investigation "had by no means a definitive character."[72] A critical remark of this sort often introduces an alternative theory, but in this instance none was forthcoming, and as I will show in what follows, there is ample reason to doubt that Minkowski was actually in a position to improve on Poincaré's investigation. Nonetheless, at the end of his talk Minkowski set forth the possibility of elaborating his report.

Minkowski's lecture was not devoted entirely to Poincaré's investigation of Lorentz-invariant gravitation. The purpose of his lecture, according to the published abstract, was to present a new form of the equations of electrodynamics leading to a mathematical redescription of physical laws in four areas: electricity, matter, mechanics, and gravitation.[73] These laws were to be expressed in terms of the differential equations used by Lorentz as the foundation of his successful theory of electrons (Lorentz 1904a), but in a form taking greater advantage of the invariance of the quadratic form $x^2 + y^2 + z^2 - c^2t^2$. Physical laws, Minkowski stated, were to be expressed with respect to a four-dimensional manifold, with coordinates x_1, x_2, x_3, x_4, where units were chosen such that $c = 1$, the ordinary Cartesian coordinates x, y, and z, went over into the first three, and the fourth was defined to be an imaginary time coordinate, $x_4 = it$. Implicitly, then, Minkowski took as his starting point the four-dimensional vector space described in the last section of Poincaré's memoir on the dynamics of the electron.

Minkowski acknowledged, albeit obliquely, a certain continuity between Poincaré's memoir and his own program to reform the laws of physics in four-dimensional terms. By formulating the electromagnetic field equations in four-dimensional notation, Minkowski said he was revealing a symmetry not realized by his predecessors, not even by Poincaré himself (Walter 1999b, 98). While Poincaré had not sought to modify the standard form of Maxwell's equations, Minkowski felt it was time for a change. The advantage of expressing Maxwell's equations in the new notation, Minkowski informed his Göttingen colleagues, was that they were then "easier to grasp" (p. 11).

His reformulation naturally began in the electromagnetic domain, with an expression for the potentials. He formed a 4-vector potential denoted (ψ) by taking the

---

71 Actually, Poincaré postulated the light-like propagation velocity of gravitation, as mentioned above, (p. 204).

72 "Poincaré weist ein solches Gesetz auf, indem er auf die Betrachtung von Invarianten der Lorentzschen Gruppe eingeht, doch ist das Gesetz nur eines unter vielen möglichen, und die betreffenden Untersuchungen tragen in keiner Weise einen definitiven Charakter" (p. 16). See also (Pyenson 1973, 233).

73 *Jahresbericht der deutschen Mathematiker-Vereinigung* 17 (1908), *Mitt. u. Nachr.*, 4–5.

ordinary vector potential over for the first three components, and setting the fourth component equal to the product of i and the scalar potential. The same method was applied to obtain a four-component quantity for current density: for the first three components, Minkowski took over the convection current density vector, $\rho\mathfrak{w}$, or charge density times velocity, and defined the fourth component to be the product of i and the charge density. Rewriting the potential and current density vectors in this way, Minkowski imposed what is now known as the Lorentz condition, $\mathrm{Div}(\psi) = 0$, where Div is an extension of ordinary divergence. This led him to the following expression, summarizing two of the four Maxwell equations:

$$\Box\psi_j = -\rho_j \quad (j = 1, 2, 3, 4), \tag{11}$$

where $\Box$ is the d'Alembertian, employed earlier by Poincaré (cf. note 20).

Of the formal innovations presented by Minkowski to the mathematical society, the most remarkable was what he called a *Traktor*, a six-component entity used to represent the electromagnetic field.[74] He defined the six components via the 4-vector potential, using a two-index notation: $\psi_{jk} = \partial\psi_k/\partial\psi_j - \partial\psi_j/\partial\psi_k$, noting the anti-symmetry relation $\rho_{kj} = -\rho_{jk}$, and zeros along the diagonal $\psi_{jj} = 0$. In this way, the Traktor components $\psi_{14}, \psi_{24}, \psi_{34}, \psi_{23}, \psi_{31}, \psi_{12}$ match up with the field quantities $-i\mathfrak{E}_x, -i\mathfrak{E}_y, -i\mathfrak{E}_z, \mathfrak{h}_x, \mathfrak{h}_y, \mathfrak{h}_z$.[75]

The Traktor first found application when Minkowski turned to his second topic: the four-dimensional view of matter. Ignoring the electron theories of matter of Lorentz and Joseph Larmor, Minkowski focused uniquely on the macroscopic electrodynamics of moving media.[76] For this subject he introduced a *Polarisationstraktor*, (p), along with a 4-current-density, (σ), defined by the current density vector $\boldsymbol{i}$ and the charge density ρ: $(\sigma) = i_x, i_y, i_z, i\rho$ (p. 9). Recalling (11), Minkowski wrote Maxwell's source equations in covariant form:

$$\frac{\partial p_{1j}}{\partial x_1} + \frac{\partial p_{2j}}{\partial x_2} + \frac{\partial p_{3j}}{\partial x_3} + \frac{\partial p_{4j}}{\partial x_4} = \sigma_j + \Box\psi_j. \tag{12}$$

Minkowski's relativistic extension of Maxwell's theory was all the simpler in that it elided the covariant expression of the constitutive equations, which involves 4-velocity.[77] While none of his formulas invoked 4-velocity, Minkowski acknowledged that his theory required a "velocity vector of matter $(w) = w_1, w_2, w_3, w_4$" (p. 10).

---

74 The same term was employed by Cayley to denote a line which meets any given lines, in a paper of 1869 (Cayley 1869).

75 When written out in full, one obtains, for example, $\psi_{23} = \partial\psi_3/\partial x_2 - \partial\psi_2/\partial x_2 = \mathfrak{h}_x$. Minkowski later renamed the Traktor a *Raum-Zeit-Vektor II. Art* (Minkowski 1908, §5) but it is better known as either a 6-vector, an antisymmetric 6-tensor, or an antisymmetric, second-rank tensor. As the suite of synonyms suggests, this object found frequent service in covariant formulations of electrodynamics.

76 For a comparison of the Lorentz and Larmor theories, see (Darrigol 1994).

77 On the four-dimensional transcription of Ohm's law see (Arzeliès and Henry 1959, 65–67).

In order to express the "visible velocity of matter in any location," Minkowski needed a new vector as a function of the coordinates x, y, z, t (p. 7). Had he understood Poincaré's 4-velocity definition (see above, p. 202), he undoubtedly would have employed it at this point. Instead, following the same method of generalization from three to four components successfully applied in the case of 4-vector potential, 4-current density, and 4-force density, Minkowski took over the components of the velocity vector $\mathfrak{w}$ for the spatial elements of the quadruplet designated w_1, w_2, w_3, w_4:

$$\mathfrak{w}_x, \quad \mathfrak{w}_y, \quad \mathfrak{w}_z, \quad i\sqrt{1-\mathfrak{w}^2}. \tag{13}$$

There are two curious aspects to Minkowski's definition. First of all, its squared magnitude does not vanish when ordinary velocity vanishes; even a particle at rest with respect to a reference frame is described in that frame by a 4-velocity vector of nonzero length. This is also true of Poincaré's 4-velocity definition, and is a feature of relativistic kinematics. Secondly, the components of Minkowski's quadruplet do not transform like the coordinates x_1, x_2, x_3, x_4, and consequently lack what he knew to be an essential property of a 4-vector.[78]

The most likely source for Minkowski's blunder is Poincaré's paper. We recall that Poincaré's derivation of his kinematic invariants ignored 4-vectors (see above, p. 202), and what is more, his paper features a misleading misprint, according to which the spatial part of a 4-velocity vector is given to be the ordinary velocity vector.[79] Other sources of error can easily be imagined, of course.[80] It is strange that Minkowski did not check the transformation properties of his 4-velocity definition, but given its provenance, he probably had no reason to doubt its soundness.

Minkowski's mistake strongly suggests that at the time of his lecture, he did not yet conceive of particle motion in terms of a world line parameter. Such an approach to particle motion would undoubtedly have spared Minkowski the error, since it renders trivial the definition of 4-velocity.[81] As matters stood in November, 1907, however, Minkowski could proceed no further with his project of reformulation.[82] The development of four-dimensional mechanics was hobbled by Minkowski's spare

78 Minkowski mentions this very property on p. 6.

79 The passage in question may be translated as follows: "Next we consider $X, Y, Z, T\sqrt{-1}$, as the coordinates of a fourth point Q; the invariants will then be functions of the mutual distances of the five points O, P, P', P'', Q, and among these functions we must retain only those that are 0th degree homogeneous with respect, on one hand, to $X, Y, Z, T, \delta x, \delta y, \delta z, \delta t$ (variables that can be further replaced by $X_1, Y_1, Z_1, T_1, \xi, \eta, \zeta, 1$), and on the other hand, with respect to $\delta_1 x, \delta_1 y, \delta_1 z, 1$ (variables that can be further replaced by $\xi_1, \eta_1, \zeta_1, 1$)" (Poincaré 1906, 170). The misprint is in the next-to-last set of variables, where instead of 1 we should have $\delta_1 t$.

80 One other obvious source for Minkowski's error is Lorentz's transformation of charge density: $\rho' = \rho/\beta l^3$, where $1/\beta = \sqrt{1-v^2/c^2}$, and l is a constant later set to unity (Lorentz 1904a, 813), although this formula was carefully corrected by Poincaré.

81 Let the differential parameter $d\tau$ of a world line be expressed in Minkowskian coordinates by $d\tau^2 = dx_1^2 + dx_2^2 + dx_3^2 + dx_4^2$. The 4-velocity vector U_μ is naturally defined to be the first derivative with respect to this parameter, $U_\mu = dx_\mu/d\tau$ $(\mu = 1, 2, 3, 4)$.

stock of 4-vectors even more than that of electrodynamics. Although Minkowski defined a force-density 4-vector, the fourth component of which he correctly identified as the energy equation, he did not go on to define 4-force at a point.[83] Once again, the definition of a force 4-vector at a point would have been trivial, had Minkowski possessed a correct 4-velocity definition. No more than a review of Planck's recent investigation (Planck 1907), Minkowski's discussion of mechanics involved no 4-vectors at all. Likewise for the subsequent section on gravitation, which reviewed Poincaré's theory, as shown above (p. 214). Without a valid 4-vector for velocity, Minkowski's electrodynamics of moving media was severely hobbled; without a point force 4-vector, his four-dimensional mechanics and theory of gravitation could go nowhere.

The difficulty encountered by Minkowski in formulating a four-dimensional approach to physics is surprising in light of the account he gave later of the background to his discovery of spacetime (Minkowski 1909). Minkowski presented his spacetime view of relativity theory as a simple application of group methods to the differential equations of classical mechanics. These equations were known to be invariant with respect to uniform translations, just as the squared sum of differentials $dx^2 + dy^2 + dz^2$ was known to be invariant with respect to rotations and translations of Cartesian axes in Euclidean 3-space, and yet no one, he said, had thought of compounding the two corresponding transformation groups. When this is done properly (by introducing a positive parameter c), one ends up with a group Minkowski designated G_c, with respect to which the laws of physics are covariant. (The group G_c is now known as the Poincaré group.) Presumably, the four-dimensional approach appeared simple to Minkowski in hindsight, several months after his struggle with 4-velocity.

In summary, while Minkowski formulated the idea of a four-dimensional language for physics based on the form-invariance of the Maxwell equations under the transformations of the Lorentz group, his development of this program beyond electrodynamics was hindered by a misunderstanding of the four-dimensional counterpart of an ordinary velocity vector. This was to be only a temporary obstacle.

On 21 December, 1907, Minkowski presented to the Royal Society of Science in Göttingen a memoir entitled "The Basic Equations for Electromagnetic Processes in Moving Bodies," which I will refer to for brevity as the *Grundgleichungen*.[84] Minkowski's memoir revisits in detail most of the topics introduced in his 5 November lecture to the mathematical society, but employs none of the jargon of spaces,

---

82 The incongruity noted by Pyenson (Pyenson 1985, 84) between Minkowski's announcement of a four-dimensional physics on one hand, and on the other hand, a trifle of 4-vector definitions and expressions, is to be understood as a indication of Minkowski's gradual ascent of the learning curve of four-dimensional physics.

83 Minkowski defined the spatial components of the empty space force density 4-vector $\mathfrak{X}_j$ in terms of the ordinary force density components $\mathfrak{X}, \mathfrak{Y}, \mathfrak{Z}$, and their product with velocity: $\mathfrak{A} = \mathfrak{X}\mathfrak{w}_x, \mathfrak{Y}\mathfrak{w}_y, \mathfrak{Z}\mathfrak{w}_z$, such that $\mathfrak{X}_j = \mathfrak{X}, \mathfrak{Y}, \mathfrak{Z}, i\mathfrak{A}$. He also expressed the force density 4-vector as the product of 4-current-density and the Traktor: $\mathfrak{X}_j = \rho_1\psi_{j1} + \rho_2\psi_{j2} + \rho_3\psi_{j3} + \rho_4\psi_{j4}$.

geometries, and manifolds. What it emphasizes instead—in agreement with its title—is the achievement of the first theory of electrodynamics of moving bodies in full conformance to the principle of relativity. Also underlined is a second result described as "very surprising": the laws of mechanics follow from the postulate of relativity and the law of energy conservation alone. On the four-dimensional world and the new form of the equations of electrodynamics, both topics headlined in his November lecture, Minkowski remained coy. Curiously, the introduction mentions nothing about a new formalism, even though all but one of fourteen sections introduce and employ new notation or calculation rules (not counting the appendix).

The added emphasis on the laws of mechanics in Minkowski's introduction, on the other hand, reflects Minkowski's recent discovery of correct definitions of 4-velocity and 4-force, along with geometric interpretations of these entities. It was in the *Grundgleichungen* that Minkowski first employed the term "spacetime" [*Raumzeit*].[85] For example, he introduced 4-current density as the exemplar of a "spacetime vector of the first kind" (§5), and used it to derive a velocity 4-vector. Identifying $\rho_1, \rho_2, \rho_3, \rho_4$ with $\rho\mathfrak{w}_x, \rho\mathfrak{w}_y, \rho\mathfrak{w}_z, i\rho$, just as he had done in his lecture of 5 November, Minkowski wrote the transformation to a primed system moving with uniform velocity $q < 1$:

$$\rho' = \rho\left(\frac{-q\mathfrak{w}_z + 1}{\sqrt{1-q^2}}\right),\ \rho'\mathfrak{w}'_{z'} = \rho\left(\frac{\mathfrak{w}_z - q}{\sqrt{1-q^2}}\right),\ \rho'\mathfrak{w}'_{x'} = \rho\mathfrak{w}_x, \rho'\mathfrak{w}'_{y'} = \rho\mathfrak{w}_y. \quad (14)$$

Observing that this transformation did not alter the expression $\rho^2(1-w^2)$, Minkowski announced an "important remark" concerning the relation of the primed to the unprimed velocity vector (§4). Dividing the 4-current density by the positive square root of the latter invariant, he obtained a valid definition of 4-velocity,

$$\frac{\mathfrak{w}_x}{\sqrt{1-\mathfrak{w}^2}},\quad \frac{\mathfrak{w}_y}{\sqrt{1-\mathfrak{w}^2}},\quad \frac{\mathfrak{w}_z}{\sqrt{1-\mathfrak{w}^2}},\quad \frac{i}{\sqrt{1-\mathfrak{w}^2}}, \quad (15)$$

the squared magnitude of which is equal to –1. Minkowski seemed satisfied with this definition, naming it the spacetime velocity vector [*Raum-Zeit-Vektor Geschwindigkeit*].

---

84 Minkowski's manuscript was delivered to the printer on 21 February, 1908, corrected, and published on 5 April, 1908 (*Journal für die "Nachrichten" der Gesellschaft der Wissenschaften zu Göttingen, mathematische-naturwissenschaftliche Klasse* 1894–1912, *Scient.* 66, Nr. 1, 471, *Archiv der Akademie der Wissenschaften zu Göttingen*). I thank Tilman Sauer for pointing out this source to me.

85 While the published version of Minkowski's 5 November lecture refers on one occasion to a "*Raumzeitpunkt*" (Minkowski 1915, 934) the term occurs nowhere in the archival typescript. The source of this addition is unknown. A manuscript annotation of the first page of the typescript bears Sommerfeld's initials, and indicates that he compared parts of the typescript to the proofs, as Lewis Pyenson correctly points out (Pyenson 1985, 82). Pyenson errs, however, in attributing to Sommerfeld the authorship of the remaining annotations, which were all penned in Minkowski's characteristic cramped hand.

The significance of the spacetime velocity vector, Minkowski observed, lies in the relation it establishes between the coordinate differentials and matter in motion, according to the expression

$$\sqrt{-(dx_1^2 + dx_2^2 + dx_3^2 + dx_4^2)} = dt\sqrt{1-\mathfrak{w}^2}. \tag{16}$$

The Lorentz-invariance of the right-hand side of (16), signaled earlier by both Poincaré and Planck, now described the relation of the sum of the squares of the coordinate differentials to the components of 4-velocity.

The latter relation plays no direct role in Minkowski's subsequent development of the electrodynamics of moving media, and in this it is unlike the 4-velocity definition. Rewriting the right-hand side of (16) as the ratio of the coordinate differential dx_4 to the temporal component of 4-velocity, w_4, Minkowski defined the spacetime integral of (16) as the "proper time" [*Eigenzeit*] pertaining to a particle of matter. The introduction of proper time streamlined Minkowski's 4-vector expressions, for instance, 4-velocity was now expressed in terms of the coordinate differentials, the imaginary unit, and the differential of proper time, $d\tau$:

$$\frac{dx}{d\tau}, \quad \frac{dy}{d\tau}, \quad \frac{dz}{d\tau}, \quad i\frac{dt}{d\tau}. \tag{17}$$

Along with the notational simplification realized by the introduction of proper time, Minkowski signaled a geometric interpretation of 4-velocity. Since proper time is the parameter of a spacetime line (or as he later called it, a world line), it follows that 4-velocity is equal to the slope of a world line at a given spacetime point, much like ordinary three-velocity is described by the slope of a displacement curve in classical kinematics. What Minkowski pointed out, in other words, is that 4-velocity is tangent to a world line at a given spacetime point (p. 108).

In order to develop his mechanics, Minkowski needed a workable definition of mass. He adapted Einstein's and Planck's notion of rest mass to the arena of spacetime by considering that a particle of matter sweeps out a hypertube in spacetime. Conservation of particle mass m was then expressed as invariance of the product of rest mass density with the volume slices of successive constant-time hypersurfaces over the length of the particle's world line, such that $dm/d\tau = 0$. Minkowski did not consider the case of variable rest mass density, which arises, for instance, in the case of heat exchange.

Minkowski's decision to adopt a constant rest mass density is linked to his view of the electrodynamics of moving media. Recall that he had introduced a six-vector in his 5 November lecture to represent the field. The product of the field and excitation six-vectors, he noted, leads to an interesting 4 by 4 matrix, combining the Maxwell stresses, Poynting vector, and electromagnetic energy density. He did not assign a name to this object, known later as the energy-momentum tensor, and often viewed as one of Minkowski's greatest achievements in electrodynamics.[86] Of special interest to Minkowski was the fact that the 4-divergence of this matrix, denoted lor S, is a 4-vector, K: [87]

$$K = \text{lor}\, S. \tag{18}$$

This 4-divergence (18) was used to define the "ponderomotive" force density, or generalized force per unit volume, neither mechanical nor non-mechanical in the pure sense of these terms. The 4-vector K is not normal, in general, to the velocity w of a given volume element, so to ensure that the ponderomotive force acts orthogonally to w, Minkowski added a component containing a velocity term:

$$K + (w\bar{K})w. \tag{19}$$

The parentheses in (19) indicate a scalar product, and $\bar{K}$ stands for the transpose of K. By defining the ponderomotive force density in this way, Minkowski effectively opted for an equation of motion in which 4-acceleration is normal to 4-velocity.[88] It appears that Minkowski let this view of force and acceleration guide his development of spacetime mechanics. In the latter domain, he formed a 4 by 4 matrix S in the force density and energy of an elastic media with the same transformation properties as the energy-momentum tensor S of (18), and used the 4-divergence of this tensor to express the equations of motion of a volume element of constant rest mass density ν (p. 106):

$$\nu\frac{dw_h}{d\tau} = K_h + \kappa w_h \quad (h = 1, 2, 3, 4). \tag{20}$$

The factor κ was determined by the definition of 4-velocity to be equal to the scalar product $(K\bar{w})$, much like the definition of ponderomotive force (19). In sum, it may be supposed that the non-orthogonality with respect to a given volume element of the 4-divergence of Minkowski's asymmetric energy-momentum tensor for moving media led Minkowski to introduce a velocity term to his definition of ponderomotive force. This definition was then ported to spacetime mechanics, where for the sake of consistency, Minkowski held rest mass density constant in the equations of motion (20).

Minkowski's stipulation of constant rest mass density was eventually challenged by Max Abraham (Abraham 1909, 739) and others, for reasons that do not concern us here. Despite its obvious drawbacks, it greatly simplified the tasks of outlining the mechanics of spacetime and developing a theory of gravitation. For example, it per-

---

86 While Minkowski's tensor is traceless, it is also asymmetric, a fact which led to criticism and rejection by leading theorists of the day. His asymmetric tensor was later rehabilitated; for a technical discussion with reference to the original papers, see (Møller 1972, 219). In the absence of matter, his tensor assumes a symmetric form; in this form, it was hailed by theorists.

87 Minkowski defined the energy-momentum tensor S in two ways: as the product of six-vectors, $fF = S - L$, where L is the Lagrange density, and in component form via the equations for Maxwell stresses, the Poynting vector, and electromagnetic energy density (Minkowski 1908, 96).

88 Minkowski's alternative between a 4-force definition and the "natural" spacetime equations of motion was underlined by Pauli (Pauli 1921, 664).

mitted him to define the equations of motion of a particle in terms of the product of rest mass and 4-acceleration, where the latter is the derivative of 4-velocity with respect to proper time. Since 4-velocity is orthogonal to 4-acceleration, for constant proper mass it is also orthogonal to a 4-vector Minkowski called a "driving force" [*bewegende Kraft*, p. 108]. Minkowski wrote four equations defining this force:

$$m\frac{d}{d\tau}\frac{dx}{d\tau} = R_x,\ m\frac{d}{d\tau}\frac{dy}{d\tau} = R_y,\ m\frac{d}{d\tau}\frac{dz}{d\tau} = R_z,\ m\frac{d}{d\tau}\frac{dt}{d\tau} = R_t. \tag{21}$$

The first three expressions differ from Planck's equations of motion, in that Planck defined force as change in *momentum*, instead of mass times acceleration. It was only a few months later that Minkowski explicitly defined four-momentum as the product of 4-velocity with proper mass (Planck 1906, eq. 6; Minkowsi 1909, §4).[89] By dividing Minkowski's first three equations by a Lorentz factor, one obtains Planck's equations. Minkowski's fourth equation, R_t, formally dependent on the other three, expresses the law of energy conservation.[90] From energy conservation and the relativity postulate alone, Minkowski concluded, one may derive the equations of motion. This is the single "surprising" result of his investigation of relativistic mechanics, referred to at the outset of his paper (see above, p. 218).

If Minkowski found few surprises in spacetime mechanics, many of his readers were taken aback by his four-dimensional approach. For example, the first physicists to comment on his work, Albert Einstein and Jakob Laub, rewrote Minkowski's expressions in ordinary vector notation, sparing the reader the "sizable demands" [*ziemlich große Anforderungen*] of Minkowski's mathematics (Einstein and Laub 1908, 532). They did not specify the nature of the demands, but the abstracter of their paper pointed to the "special knowledge of the calculation methods" required for assimilation of Minkowski's equations.[91] In other words, for Minkowski's readers, his novel matrix calculus was the principal technical obstacle to overcome. Where Poincaré pushed rejection of formalism to an extreme, Minkowski pulled in the other direction, introducing a formalism foreign to the practice of physics. What motivated this brash move is unclear, and his choice is all the more curious because he knowingly defied the German trend of vector notation in electrodynamics.[92] As mentioned above, Minkowski was ill-disposed toward quaternions, although he admitted in print that they could be brought into use for relativity instead of matrix calculus. He spoke here from experience, as manuscript notes reveal that he used quaternions (in addition to Cartesian-coordinate representation and ordinary vector analysis) to investigate the electrodynamics of moving media.[93] In the end, however, he felt that for his purposes quaternions were "too limited and cumbersome" [*zu eng und schwerfällig*, p. 79].

---

89 In the latter lecture, Minkowski proposed the modern definition of kinetic energy as the temporal component of 4-momentum times c^2, or $mc^2 dt/d\tau$. The "spatial" part of the driving force (21) was referred to by Lorentz (Lorentz 1910, 1237) as a "Minkowskian force" [*Minkowskische Kraft*], differing from the Newtonian force by a Lorentz factor. Lorentz complemented the Minkowskian force with a "Minkowskian mass" [*Minkowskische Masse*].

As far as notation is concerned, Minkowski's treatment of differential operations broke cleanly with then-current practice. It also broke with the precedent of his 5 November lecture, where he had introduced, albeit parsimoniously, both $\square$ and Div (see above, p. 215). For the *Grundgleichungen* he adopted a different approach, extending the ∇ to four dimensions, and labeling the resulting operator *lor*, already encountered above in (18). The name is short for Lorentz, and the effect is the operation: $|\partial/\partial x_1, \partial/\partial x_2, \partial/\partial x_3, \partial/\partial x_4|$. When applied to a 6-vector, *lor* results in a 4-vector, in what Minkowski described as an appropriate translation of the matrix product rule (p. 89); it also mimics the effect of the ordinary ∇. Transforming as a 4-vector, *lor* is liberally employed in the second part of the *Grundgleichungen*, to the exclusion of any and all particular 4-vector functions.[94] The use of *lor* made for a presentation of electrodynamics elegant in the extreme, at the expense of legibility for German physicists more used to thinking in terms of gradients, divergences, and curls (or rotations).

Minkowski's equations of electrodynamics departed radically in form with those of the old electrodynamics, shocking the thought patterns of physicists, and creating a phenomenon of rejection that took several years—and a new formalism—to overcome.[95] Why did Minkowski break with this tradition? Did he feel that the new physics of spacetime required a clean break with nineteenth-century practice? Perhaps,

---

90 Minkowski's argument may be summarized as follows. From the definition of a 4-vector, the following orthogonality relation holds for the driving force R:

$$R_x\frac{dx}{d\tau} + R_y\frac{dy}{d\tau} + R_z\frac{dz}{d\tau} = R_t\frac{dt}{d\tau}. \tag{22}$$

Integration of the rest-mass density over the hypersurface normal to the world line of the mass point results in the driving force components (21), but if the integration is to be performed instead over a constant-time hypersurface, proper time is replaced by coordinate time, such that the fourth equation reads: $md/dt(dt/d\tau) = R_t d\tau/dt$. From (22) we obtain an expression for R_t, which we multiply by $d\tau/dt$:

$$m\frac{d}{dt}\left(\frac{dt}{d\tau}\right) = \mathfrak{w}_x R_x\frac{d\tau}{dt} + \mathfrak{w}_y R_y\frac{d\tau}{dt} + \mathfrak{w}_z R_z\frac{d\tau}{dt}. \tag{23}$$

Minkowski reasoned that since the right-hand side of (23) describes the rate at which work is done on the particle, the left-hand side must be the rate of change of the particle's kinetic energy, such that (23) represents the law of energy conservation. He immediately related (23) to the kinetic energy of the particle:

$$m\left(\frac{dt}{d\tau} - 1\right) = m\left(\frac{1}{\sqrt{1-\mathfrak{w}^2}} - 1\right) = m\left(\frac{1}{2}|\mathfrak{w}|^2 + \frac{3}{8}|\mathfrak{w}|^4 + \cdots\right). \tag{24}$$

Minkowski did not justify the latter expression, but in virtue of his definition of proper time, $d\tau = dt\sqrt{1-\mathfrak{w}^2}$, the left-hand side of (23) may be rewritten as $m(d/dt)(1/\sqrt{1-\mathfrak{w}^2})$, such that upon integration the particle's kinetic energy is $m/\sqrt{1-\mathfrak{w}^2} + C$, where C is a constant. For agreement with the Newtonian expression of kinetic energy in case of small particle velocities ($\mathfrak{w} \ll 1$), we let $C = -m$, which accords both with (24) and the definition of kinetic energy given in a later lecture (cf. note 89).

91 *Jahrbuch über die Fortschritte für Mathematik* 39, 1908, 910.

but he must have recognized that the old methods would prove resistant to change. His own subsequent practice shows as much: after writing the *Grundgleichungen* Minkowski did not bother with *lor* during his private explorations of the formal side of electrodynamics, preferring the coordinate method.[96]

He also relied largely—but not exclusively—on a Cartesian-coordinate approach during his preliminary investigations of the subjects treated in the *Grundgleichungen*. His surviving research notes, made up almost entirely of symbolic calculations, shed an interesting light on Minkowski's path to both a theory of the electrodynamics of moving media, and a theory of gravitation, or more generally to his process of discovery. Notably, where the subjects of mechanics and gravitation are relegated to the appendix of the *Grundgleichungen*, these notes show that Minkowski pursued questions of electrodynamics and gravitation in parallel, switching from one topic to the other three times in the course of 163 carefully numbered pages. At least fifteen of these pages are specifically concerned with gravitation; the notes are undated, but those concerning gravitation are certainly posterior to the typescript of the 5 November lecture, because unlike the latter, they feature valid definitions of 4-velocity and 4-force.

Minkowski's attempt to capture gravitational action in terms of a 4-scalar potential is of particular interest. We recall that Minkowski had expressed Maxwell's equations in terms of a 4-vector potential (11) during his lecture of 5 November, and on this basis, it was natural for him to investigate the possibility of representing gravitational force on a point mass in a fashion analogous to that of the force on a point charge moving in an electromagnetic field. In his scratch notes, Minkowski defined a 4-scalar potential Φ, in terms of which he initially devised the law of motion:

---

92 This trend is described by Darrigol (Darrigol 1993, 270). The sharp contrast between the importance assigned to vector methods in France and Germany may be linked to the status accorded to applied mathematics in these two nations, as discussed by H. Gispert in her review of the French version of Klein's *Encyklopädie* (Gispert 2001).

93 At one point during his calculations Minkowski seemed convinced of the utility of this formalism, remarking that electrodynamics is "predestined for application of quaternionic calculations" (*Math. Archiv* 60: 6, 21, Handschriftenabteilung, NSUB).

94 A precedent for Minkowski's exclusive use of *lor* may be found in (Gibbs and Wilson 1901), where ∇ is similarly preferred to vector functions.

95 Cf. Max von Laue's remark that physicists understood little of Minkowski's work because of its unfamiliar mathematical expression (Laue 1951, 515) and Chuang Liu's account of the difficulty experienced by Max Abraham and Gunnar Nordström in applying Minkowski's formalism (Liu 1991, 66). While Minkowski's calculus is a straightforward extension of Cayley's formalism (for a summary, see (Cunningham 1914, chap. 8), the latter formalism was itself unfamiliar to physicists.

96 *Math. Archiv* 60: 5, Handschriftenabteilung, NSUB. This 82-page set of notes dates from 23 May to 6 October, 1908. A posthumously published paper on the electron-theoretical derivation of the basic equations of electrodynamics for moving media, while purported to be from Minkowski's Nachlass, was written entirely by Max Born, as he acknowledged (Minkowski and Born 1910, 527). In the latter publication *lor* makes only a brief appearance.

$$\frac{d}{d\tau}\frac{1}{\sqrt{1-v^2}}-\frac{\partial\Phi}{\partial t} = 0,\quad \frac{d}{d\tau}\frac{-y'}{\sqrt{1-v^2}}-\frac{\partial\Phi}{\partial y} = 0,$$
$$\frac{d}{d\tau}\frac{-x'}{\sqrt{1-v^2}}-\frac{\partial\Phi}{\partial x} = 0,\quad \frac{d}{d\tau}\frac{-z'}{\sqrt{1-v^2}}-\frac{\partial\Phi}{\partial z} = 0, \tag{25}$$

where constants are neglected, τ denotes proper time, and primes indicate differentiation with respect to coordinate time t (i.e. $x' = dx/dt$).[97] This generalization of the Newtonian potential to a 4-scalar potential appears to be one of the first paths explored by Minkowski in his study of gravitation, but his investigation is inconclusive. In particular, there is no indication in these notes of a recognition on Minkowski's part that a four-scalar potential conflicts with the postulates of invariant rest mass and light velocity.[98] Nor is there any evidence that he considered suspending either one of these postulates.

Likewise, in the *Grundgleichungen* there is no question of adopting either a variable mass density or a gravitational 4-potential. Once he had established the foundations of spacetime mechanics, Minkowski took up the case of gravitational attraction. The problem choice is significant, in that the same question had been treated at length by Poincaré (although not to Minkowski's satisfaction, as mentioned above, p. 215). Implicitly, Minkowski encouraged readers to compare methods and results. Explicitly, proceeding in what he described (in a footnote) as a "wholly different way" from Poincaré, Minkowski said he wanted to make "plausible" the inclusion of gravitation in the scheme of relativistic mechanics (p. 109). It will become clear in what follows that his project was more ambitious than the modest elaboration of a plausibility argument, as it was designed to validate his spacetime mechanics.

The point of departure for Minkowski's theory of gravitation was quite different from that of Poincaré, because the latter's results were integrated into the former's formalism. For example, where Poincaré initially assumed a finite propagation velocity of gravitation no greater than that of light, only to opt in the end for a velocity equal to that of light, Minkowski assumed implicitly from the outset that this velocity was equal to that of light. Similarly, Poincaré initially supposed the gravitational

97 *Math. Archiv* 60: 6, 10, Handschriftenabteilung, NSUB.

98 This "peculiar" consequence of Minkowski's spacetime mechanics was underlined by Maxwell's German translator, the Berlin physicist Max B. Weinstein (Weinstein 1914, 42). In Minkowski spacetime, 4-acceleration is orthogonal to 4-velocity: $U_\mu dU_\mu/d\tau = 0$, $\mu = 1, 2, 3, 4$, where τ is the proper time. We assume a 4-scalar potential Φ such that the gravitational 4-force $F_\mu = -m\partial\Phi/\partial x_\mu$. If we consider a point mass with 4-velocity U_μ subjected to a 4-force F_μ derived from this potential, we have $U_\mu F_\mu = -U_\mu m\partial\Phi/\partial x_\mu$. Writing 4-velocity as $dx_\mu/d\tau$, and substituting in the latter expression, we obtain

$$U_\mu F_\mu = -m\frac{dx_\mu}{d\tau}\frac{\partial\Phi}{\partial x_\mu} = -m\frac{d\Phi}{d\tau} = 0,$$

and consequently, $d\Phi/d\tau = 0$, which means that the law of motion describes the trajectory of the passive mass m only in the trivial case of constant Φ along its world line.

force to be Lorentz covariant, only to opt in the end for an analog of the Lorentz force, where Minkowski required implicitly from the outset that all forces transform like the Lorentz force.

Combining geometric and symbolic arguments, Minkowski's exposition of his theory of gravitation introduces a new geometric object, the three-dimensional "ray form" [*Strahlgebilde*] of a given spacetime point, known today as a light hypercone (or lightcone). For a fixed spacetime point $B^* = (x^*, y^*, z^*, t^*)$, the lightcone of B^* is defined by the sets of spacetime points $B = (x, y, z, t)$ satisfying the equation

$$(x - x*)^2 + (y - y*)^2 + (z - z*)^2 = (t - t*)^2, \quad t - t* \geqq 0. \tag{26}$$

For all the spacetime points B of this lightcone, B^* is what Minkowski called *B's lightpoint*. Any world line intersects the lightcone in one spacetime point only, Minkowski observed, such that for any spacetime point B on a world line there exists one and only one lightpoint B^*. Minkowski remarked in a later lecture that the lightcone divides four-dimensional space into three regions: time-like, space-like and light-like.[99]

Using this novel insight to the structure of four-dimensional space, in combination with the 4-vector notation set up in earlier in his memoir, Minkowski presented and applied his law of gravitational attraction in two highly condensed pages. Minkowski's geometric argument employs non-Euclidean relations that were unfamiliar to physicists, yet he provided no diagrams. Visually-intuitive arguments had fallen into disfavor with mathematicians by this time, with the rise of the axiomatic approach to geometry favored by David Hilbert (Rowe 1997), yet Minkowski never renounced the use of figures in geometry; he employed them in earlier works on number geometry, and went on to publish spacetime diagrams in the sequel to the *Grundgleichungen*.[100] For the purposes of my reconstruction, I refer to a spacetime diagram (Fig. 1) of the sort Minkowski employed in the sequel (reproduced in Fig. 3).[101]

99 Minkowski introduced the terms *zeitartig* and *raumartig* in (Minkowski 1909).

100 There is little agreement on where to situate Minkowski's work on relativity along a line running from the intuitive to the formal. Peter Galison (Galison 1979, 89) for example, underlines Minkowski's visual thinking (i.e., reasoning that appeals to figures or diagrams), while Leo Corry (Corry 1997, 275; 2004, chap. 4) considers Minkowski's work in the context of Hilbert's axiomatic program for physics.

101 Two spatial dimensions are suppressed in Fig. 1, and lightcones are represented by broken lines with slope equal to ± 1, the units being chosen so that the propagation velocity of light is unity $(c = 1)$. In this model of Minkowski space, orthogonal coordinate axes appear oblique in general, for example, the spatial axes x^*, y^*, z^* are orthogonal to the tangent B^*C^* at spacetime point B^* of the central line of the filament F^* described by a particle of proper mass m^*.

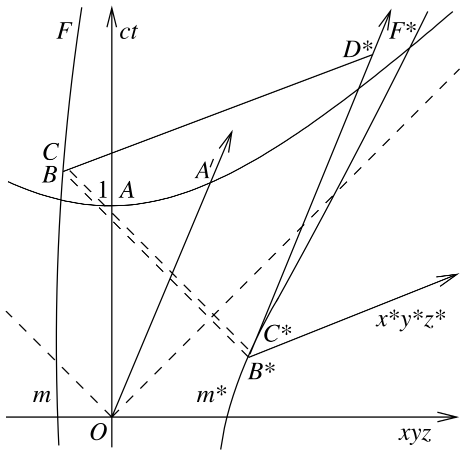

Figure 1: Minkowski's geometry of gravitation, with source in arbitrary motion.

On the assumption that the force of gravitation is a 4-vector normal to the 4-velocity of the passive mass m, Minkowski derived his law of attraction in the following way. The trajectories of two particles of mass m and m^* correspond to two spacetime filaments F and F^*, respectively. Minkowski's arguments refer to world lines he called central lines [*Hauptlinien*] of these filaments, which pass through points on the successive constant-time hypersurfaces delimited by the respective particle volumes. The central lines of the filaments F and F^* are shown in Fig. 1. An infinitesimal element of the central line of F is labeled BC, and the two lightpoints corresponding to the endpoints B and C are labeled B^* and C^* on the central line of F^*. From the origin of the rest frame O, a 4-vector parallel to B^*C^* intersects at A' the three-dimensional hypersurface defined by the equation $-x^2-y^2-z^2+t^2=1$. Finally, a space-like 4-vector BD^* extends from B to a point D^* on the world line tangent to the central line of F^* at B^*.

Referring to the latter configuration of seven spacetime points, two central lines, a lightcone and a calibration hypersurface, Minkowski expressed the spatial components of the driving force of gravitation exerted by m^* on m at B,

$$mm^*\left(\frac{OA'}{B^*D^*}\right)^3 BD^*. \tag{27}$$

Minkowski's gravitational driving force is composed of the latter 4-vector (27) and a second 4-vector parallel to B^*C^* at B, such that the driving force is always orthogonal to the 4-velocity of the passive mass m at B. (For reasons of commodity, I will refer to this law of force as Minkowski's first law.)

The form of Minkowski's first law of gravitation is comparable to that of his ponderomotive force for moving media (19), in that the driving force has two components, only one of which depends on the motion of the test particle. In the gravitational case, however, Minkowski did not write out the 4-vector components in terms of matrix products. Instead, he relied on spacetime geometry and the definition of a 4-vector. The only way physicists could understand (27) was by reformulating it in terms of ordinary vectors referring to a conveniently chosen inertial frame, and even then, they could not rely on Minkowski's description alone, as it is incomplete.[102]

Even without spacetime diagrams or a transcription into ordinary vector notation, the formal analogy of (27) to Newton's law is readily apparent, and this is probably why Minkowski wrote it this way. In doing so, however, he passed up an opportunity to employ the new matrix machinery at his disposal. Had he seized this opportunity, he would have gained a simple, self-contained, coordinate-free expression of the law of gravitation, and provided readers with a more elaborate example of his calculus in action, but the latter desiderata must not have been among his primary objectives.[103]

---

102 The 4-vector OA' in (27) has unit magnitude by definition in all inertial frames, while B^*D^* is a time-like 4-vector tangent to the central line of F^* at B^*. Consequently, B^*D^* may be taken to coincide with the temporal axis of a frame instantaneously at rest with m^* at B^*, such that it has only one nonzero component: the difference in proper time between the points B^* and D^*. It is assumed that the rest frame may be determined unambiguously for a particle in arbitrary motion, as asserted without proof by Minkowski in a later lecture (Minkowski 1909, §III); subsequently, Max Born (Born 1909, 26) remarked that any motion may be approximated by what he called hyperbolic motion, and noted that such motion is characterized by an acceleration of constant magnitude (as measured in an inertial frame). If we locate the origin of this frame at B^*, and let $D^* = (0, 0, 0, t)$, then $B^*D^* = (0, 0, 0, it)$, and $(B^*D^*)^3 = -it^3$. Likewise in this same frame, $A = A' = (0, 0, 0, 1)$, and $OA' = OA = (0, 0, 0, i)$. Minkowski understood the term (OA'/B^*D^*) as the ratio [*Verhältnis*] of two parallel 4-vectors, an operation familiar from the calculus of quaternions, but one not defined for 4-vectors. While modern vector systems ignore vector division, in Hamilton's quaternionic calculus the quotient of vectors is unambiguously defined; see, for example, (Tait 1882–1884, chap. 2). Accordingly, the quotient in (27) is the ratio of lengths, $(OA'/B^*D^*) = 1/t$, and the cubed ratio is t^{-3}. The point B lies on the same constant-time hypersurface as D^*, so we assign it the value $(x, y, z, t) = (\boldsymbol{r}, t)$. This assignment determines the value of the 4-vector $BD^* = (-x, -y, -z, 0) = (-\boldsymbol{r}, 0)$. Since B^* is a lightpoint of B, we can apply (26) to obtain $x^2 + y^2 + z^2 = t^2 = r^2$, and consequently, $t^3 = r^3$. Substituting for t^3 results in $(OA'/B^*D^*)^3 = 1/t^3 = 1/r^3$. The 4-vector B^*D^* is space-like, such that its projection on the constant-time hypersurface orthogonal to B^*D^* at D^* is the ordinary vector $(-x, -y, -z) = -\boldsymbol{r}$. In terms of ordinary vectors and scalars measured in the rest frame of m^*, Minkowski's expression (27) is equivalent to Newton's law (neglecting the gravitational constant):

$$-mm^*\frac{\boldsymbol{r}}{r^3}. \tag{28}$$

Neither (27) nor (28) contains any velocity-dependent terms, while the time-like component of Minkowski's first law depends on the velocity of the passive mass. Newton's law (28) thus coincides with Minkowski's first law only in the case of relative rest.

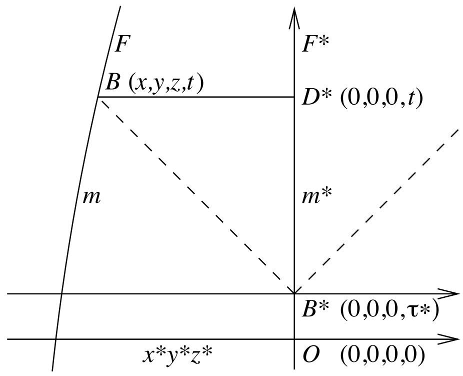

Figure 2: Minkowski's geometry of gravitation, with source in uniform motion.

Minkowski was not yet finished with his law of gravitation. Unlike Poincaré, after writing his law of gravitation, Minkowski went on to apply it to the particular case of uniform rectilinear motion of the source m^*. He considered the latter in a comoving frame, in which the temporal axis is chosen to coincide with the tangent to the central line of F^* at B^* (cf. the situation described in note 102). Referring to the reconstructed spacetime diagram in Fig. 2, the temporal axis is represented by a vertical line F^*, such that the origin is established in a frame comoving with m^*. To the retarded position of m^*, denoted B^*, Minkowski assigned the coordinates $(0, 0, 0, \tau^*)$, and to the position B of the passive mass m he assigned the coordinates (x, y, z, t). The geometry of this configuration fixes the location of D^* at $(0, 0, 0, t)$, from which the 4-vectors $BD^* = (-x, -y, -z, 0)$ and $B^*D^* = (0, 0, 0, i(t-\tau^*))$ are determined. In this case, Minkowski pointed out, (26) reduces to:

$$x^2 + y^2 + z^2 = (t - \tau^*)^2. \tag{29}$$

Substituting the above values of BD^* and B^*D^* into Minkowski's formula (27), the spatial components of the 4-acceleration of the passive mass m at B due to the active mass m^* at B^* turn out to be:[104]

$$\frac{d^2x}{d\tau^2} = -\frac{m^*x}{(t-\tau^*)^3}, \quad \frac{d^2y}{d\tau^2} = -\frac{m^*y}{(t-\tau^*)^3}, \quad \frac{d^2z}{d\tau^2} = -\frac{m^*z}{(t-\tau^*)^3}. \tag{30}$$

103 Minkowski's driving force may be expressed in his notation as a function of scalar products of 4-velocities and 4-position:

$$-mm^*\frac{(w\bar{w}^*)\mathfrak{R} - (w\bar{\mathfrak{R}})w^*}{(\mathfrak{R}\bar{w}^*)^3(w\bar{w}^*)}.$$

Here I let w and w^* designate 4-velocity at the passive and active mass points, while $\mathfrak{R}$ is the associated 4-position, the parentheses denote a scalar product, and the bar indicates transposition.

From (30) and (29), the corresponding temporal component at B may be determined:[105]

$$\frac{d^2t}{d\tau^2} = -\frac{m^*}{(t-\tau^*)^2}\frac{d(t-\tau^*)}{dt}. \tag{33}$$

Inspecting (30), it appears that the only difference between these acceleration components and those corresponding to Newtonian attraction is a replacement in the latter of coordinate time t by proper time τ.[106]

The formal similarity of (30) to the Newtonian law of motion under a central force probably suggested to Minkowski that his law induces Keplerian trajectories. With the knowledge gained from (30), to the effect that the only difference between classical and relativistic trajectories is that arising from the substitution of proper time for coordinate time, Minkowski demonstrated the compatibility of his relativistic law of gravitation with observation using only Kepler's equation and the definition of 4-velocity.

Writing Kepler's equation in terms of proper time yields:

$$n\tau = E - e\sin E, \tag{34}$$

where $n\tau$ denotes the mean anomaly, e the eccentricity, and E the eccentric anomaly. Minkowski referred to (34) and to the norm of a 4-velocity vector:

$$\left(\frac{dx}{d\tau}\right)^2 + \left(\frac{dy}{d\tau}\right)^2 + \left(\frac{dz}{d\tau}\right)^2 = \left(\frac{dt}{d\tau}\right)^2 - 1, \tag{35}$$

---

104 The intermediate calculations can be reconstructed as follows. Let the driving force be designated F_μ, $\mu = 1, 2, 3, 4$. Since $(OA'/B^*D^*)^3 = t^{-3}$, and $BD^* = (-x, -y, -z, 0)$, equations (21) and (27) yield: $F_1/m = d^2x/d\tau^2 = -m^*x/(t-\tau^*)^3$, $F_2/m = d^2y/d\tau^2 = -m^*y/(t-\tau^*)^3$, $F_3/m = d^2z/d\tau^2 = -m^*z/(t-\tau^*)^3$.

105 Minkowski omitted the intermediate calculations, which may be reconstructed in modern notation as follows. Let the 4-velocity of the passive mass point be designated $U_\mu = (dx/d\tau, dy/d\tau, dz/d\tau, idt/d\tau)$, while the first three components of its 4-acceleration, designated A_μ, at B due to the source m^* are given by (30). From the orthogonality of 4-velocity and 4-acceleration we have:

$$U_\mu A_\mu = -\frac{dx}{d\tau}\frac{m^*x}{(t-\tau^*)^3} - \frac{dy}{d\tau}\frac{m^*y}{(t-\tau^*)^3} - \frac{dz}{d\tau}\frac{m^*z}{(t-\tau^*)^3} - \frac{idt}{d\tau}\frac{id^2t}{d\tau^2} = 0.$$

Rearranging (31) results in an expression for the temporal component of 4-acceleration:

$$\frac{d^2t}{d\tau^2} = -\frac{m^*}{(t-\tau^*)^3}\left(\frac{xdx}{dt} + \frac{ydy}{dt} + \frac{zdz}{dt}\right).$$

Differentiating (29) with respect to dt results in $xdx/dt + ydy/dt + zdz/dt = (t-\tau^*)d(t-\tau^*)/dt$, the right-hand side of which we substitute in (32) to obtain (33).

106 A young Polish physicist in Göttingen, Felix Joachim de Wisniewski later studied this case, but with equations differing from (30) by a Lorentz factor (de Wisniewski 1913a, 388). In a postscript to the second installment of his paper (Wisniewski 1913b, 676) he employed Minkowski's matrix notation, becoming, with Max Born, one of the rare physicists to adopt this notation.

in order to determine the difference between the mean anomaly in coordinate time nt and the mean anomaly in proper time $n\tau$. From (35), Minkowski deduced:[107]

$$\left(\frac{dt}{d\tau}\right)^2 - 1 = \frac{m^*}{ac^2}\frac{1 + e\cos E}{1 - e\cos E}. \tag{37}$$

Solving (37) for the coordinate time dt, expanding to terms in c^{-2}, and multiplying by n led Minkowski to the expression:

$$ndt = nd\tau\left(1 + \frac{1}{2}\frac{m^*}{ac^2}\frac{1 + e\cos E}{1 - e\cos E}\right). \tag{38}$$

Recalling (34), Minkowski managed to express the difference between the mean anomaly in coordinate time and proper time:[108]

$$nt + \text{const.} = \left(1 + \frac{1}{2}\frac{m^*}{ac^2}\right)n\tau + \frac{m^*}{ac^2}e\sin E. \tag{39}$$

Evaluating the relativistic factor $(m^*)/ac^2$ for solar mass and the Earth's semi-major axis to be 10^{-8}, Minkowski found the deviation from Newtonian orbits to be negligible in the solar system. On this basis, he concluded that

> a decision *against* such a law and the proposed modified mechanics in favor of the Newtonian law of attraction with Newtonian mechanics would not be deducible from astronomical observations.[109]

According to the quoted remark, there was more at stake here for Minkowski than just the empirical adequacy of his law of gravitational attraction, as his claim is for parity between Newton's law and classical mechanics, on one hand, and the *system*

---

107 The intermediate calculations were omitted by Minkowski, but figure among his research notes (*Math. Archiv* 60: 6, 126–127, Handschriftenabteilung, NSUB). Following the method outlined by Otto Dziobek (Dziobek 1888, 12), Minkowski began with the energy integral of Keplerian motion:

$$\left(\frac{dt}{dW}\right)^2 - 1 = \frac{2}{\ell^2}\left(\frac{M}{R} - C\right), \tag{36}$$

where ℓ denotes the velocity of light, M is the sum of the masses times the gravitational constant, $M = k^2(m + m^*)$, R is the radius, and C is a constant. The left-hand side of (36) is the same as the right-hand side of (35) for $W = \tau$. In order to express dt/dW (which is to say $dt/d\tau$) in terms of E, Minkowski considered a conic section in polar coordinates, with focus at the origin: $R = a(1 - e^2)/(1 + e\cos\varphi) = a(1 - \cos E)$, where a denotes the semi-major axis, and φ is the true anomaly. By eliminating φ in favor of E and e, and differentiating (34), Minkowski obtained an expression equivalent to (37).

108 I insert the eccentricity e in the second term on the right-hand side, correcting an obvious omission in Minkowski's paper (Minkowski 1908, 111, eq. 31).

109 "... eine Entscheidung *gegen* ein solches Gesetz und die vorgeschlagene modifizierte Mechanik zu Gunsten des Newtonschen Attraktionsgesetzes mit der Newtonschen Mechanik aus den astronomischen Beobachtungen nicht abzuleiten sein" (Minkowski 1908, 111).

composed of the law of gravitation and spacetime mechanics on the other hand. This new system, Minkowski claimed, was verified by astronomical observations at least as well as the classical system formed by the Newtonian law of attraction and Newtonian mechanics.

Instead of comparing his law with one or the other of Poincaré's laws, Minkowski noted a difference in *method*, as mentioned above. In light of Minkowski's emphasis on the methodological difference with Poincaré, and the hybrid geometric-symbolic nature of Minkowski's exposition, it is clear that the point of reexamining the problem of relativity and gravitation in the *Grundgleichungen* was not simply to make plausible the inclusion of gravitation in a relativistic framework. Rather, since gravitational attraction was the only example Minkowski provided of his formalism in action, his line of argument served to *validate* his four-dimensional calculus, over and above the requirements of plausibility.

From the latter point of view, Minkowski had grounds for satisfaction, although one imagines that he would have preferred to find that his law diverged from Newton's law just enough to account for the observed anomalies. It stands to reason that if Minkowski had been fully satisfied with his first law, he would not have proposed a second law in his next paper—which turned out to be the last he would finish for publication. The latter article developed out of a well-known lecture entitled "Space and Time" (*Raum und Zeit*), delivered in Cologne on 21 September, 1908, to the mathematics section of the German Association of Scientists and Physicians in its annual meeting (Walter 1999a, 49).

In the final section of his Cologne lecture, Minkowski took up the Lorentz-Poincaré theory, and showed how to determine the field due to a point charge in arbitrary motion. On this occasion, just as in his earlier discussion of gravitation in the *Grundgleichungen*, Minkowski referred to a spacetime diagram, but this time he provided the diagram (Fig. 3). Identifying the 4-vector potential components for the source charge on this diagram, Minkowski remarked that the Liénard-Wiechert law was a consequence of just these geometric relations.[110]

---

110 Minkowski's explanation of the construction of his spacetime diagram (Fig. 3) may be paraphrased in modern terminology as follows. Suppressing the *z*-axis, we associate two world lines with two point charges e_1 and e. The world line of e_1 passes through the point at which we wish to determine the field, P_1. To find the retarded position of the source e, we draw the retrograde lightcone (with broken lines) from P_1, which intersects the world line of e at P, where there is a hyperbola of curvature ρ with three infinitely-near points lying on the world line of e; it has its center at M. The coordinate origin is established at P, by letting the *t*-axis coincide with the tangent to the world line. A line from P_1 intersects this axis orthogonally at point Q; it is space-like, and if its projection on a constant-time hypersurface has length r, the length of the 4-vector PQ is r/c. The 4-vector potential has magnitude e/r and points in the direction of PQ (i.e., parallel to the 4-velocity of e at P). The *x*-axis lies parallel to QP_1, such that N is the intersection of a line through M normal to the *x*-axis.

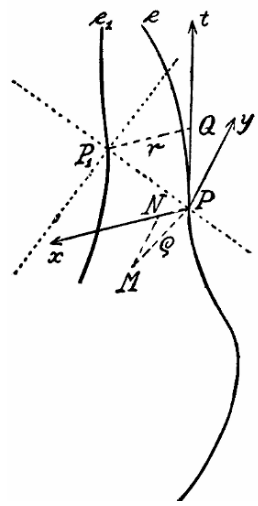

Figure 3: Minkowski's spacetime diagram of particle interaction (Minkowski 1909, 86).

Minkowski then described the driving force between two point charges. Adopting dot notation for differentiation with respect to proper time, he wrote the driving force exerted on an electron of charge e_1 at point P_1 by an electron of charge e:

$$-ee_1\left(\dot{t}_1 - \frac{\dot{x}_1}{c}\right)\mathfrak{K}, \tag{40}$$

where $\dot{t}_1$ and $\dot{x}_1$ are 4-velocity components of the test charge e_1 and $\mathfrak{K}$ is a certain 4-vector. This was the first such description of the electrodynamic driving force due to a 4-vector potential, the simplicity of which, Minkowski claimed, compared favorably with the earlier formulations of Schwarzschild and Lorentz.[111]

In the same celebratory tone, Minkowski finished his article with a discussion of gravitational attraction. The "reformed mechanics", he claimed, dissolved the disturbing disharmonies between Newtonian mechanics and electrodynamics. In order to provide an example of this dissolution, he asked how the Newtonian law of attraction would sit with his principle of relativity. Minkowski continued:

> I will assume that if two point masses m, m_1 describe world lines, a driving force vector is exerted by m on m_1, exactly like the one in the expression just given for the case of electrons, except that instead of $-ee_1$, we must now put in $+mm_1$.

---

111 Minkowski noted four conditions on $\mathfrak{K}$: it is normal to the 4-velocity of e_1 at P_1, $c\mathfrak{K}_t - \mathfrak{K}_x = 1/r^2$, $\mathfrak{K}_y = \ddot{y}/(c^2 r)$, and $\mathfrak{K}_z = 0$, where r is the space-like distance between the test charge e_1 at P_1 and the advanced position Q of the source e, and $\ddot{y}$ is the y-component of e's 4-acceleration at P. For a derivation of the 4-potential and 4-force corresponding to Minkowski's presentation, see (Pauli 1921, 644–645).

Applying the substitution suggested by Minkowski to (40), we obtain:

$$mm_1\left(\dot{t}_1 - \frac{\dot{x}_1}{c}\right)\mathfrak{K}, \tag{41}$$

where the coefficients m and m_1 refer to proper masses. Minkowski's new law of gravitation (41) fully expresses the driving force, unlike the formula (27) of his first law, which describes only one component. In addition, the 4-vectors are immediately identifiable from the notation alone. (In order to distinguish the law given in the *Grundgleichungen* from that of the Cologne lecture [41], I will call [41] Minkowski's second law.)

Since (40) was obtained from Lorentz-Poincaré theory via a 4-vector potential, the law of gravitation (41) ostensibly implied a 4-vector potential as well; in other words, following the example set by Poincaré's second law (10), Minkowski appealed in turn to a Maxwellian theory of gravitation similar to those of Heaviside, Lorentz, and Gans.[112] Although Minkowski made no effort to attach his law to these field theories, it was understood by Sommerfeld to be a formal consequence of just such a theory, as I will show in the next section.

What were the numerical consequences of this new law? Minkowski spared the reader the details, noting only that in the case of uniform motion of the source, the only divergence from a Keplerian orbit would stem from the replacement of coordinate time by proper time. He indicated that the numbers for this case had been worked out earlier, and his conclusion with respect to this new law was naturally the same: combined with the new mechanics, it was supported by astronomical observations to the same extent as the Newtonian law combined with classical mechanics.

Curiously enough, Minkowski offered no explanation of the need for a second law of attraction. Furthermore, by proposing two laws instead of one, Minkowski tacitly acknowledged defeat; despite his criticism of the Poincaré's approach (see above, p. 215), he could hardly claim to have solved unambiguously the problem of gravitation. It may also seem strange that Minkowski discarded the differences between his new law (41) and the one he had proposed earlier.[113]

Minkowski revealed neither the motivation behind a second law of gravitation, nor why he neglected the differences between his two laws, but there is a straightfor-

112 See above, p. 198, (Heaviside 1893), and (Gans 1905). Theories in which the gravitational field is determined by equations having the form of Maxwell's equations were later termed vector theories of gravitation by Max Abraham (Abraham 1914, 477). For a more recent version of such a theory, see (Coster and Shepanski 1969).

113 Minkowski's neglect of the differences between his two theories may explain why historians have failed to distinguish them. The principal difference between the two laws stems from the presence of acceleration effects in the second law. By 1905 it was known that accelerated electrons radiate energy, such that by formal analogy, a Maxwellian theory of gravitation should have featured accelerated point masses radiating "gravitational" energy. For a brief overview of research performed in the first two decades of the twentieth century on the energy radiated from accelerated electrons, see (Whittaker 1951–1953, 2:246).

ward way of explaining both of these mysteries. First, we recall the circumstances of his Cologne lecture, the final section of which Minkowski devoted to the theme of restoring unity to physics. What he wanted to stress on this occasion was that mechanics and electrodynamics harmonized in his four-dimensional scheme of things:

> In the mechanics reformed according to the world postulate, the disturbing disharmonies between Newtonian mechanics and modern electrodynamics fall out on their own.[114]

To support this view, Minkowski had to show that his reformed mechanics was a synthesis of classical mechanics and electrodynamics. A Maxwellian theory of gravitation fit the bill quite well, and consequently, Minkowski brought out his second law of gravitation (41). Clearly, this was not the time to point out the *differences* between his two laws. On the contrary, it was the perfect occasion to observe that a law of gravitation derived from a 4-vector potential formally identical to that of electrodynamics was observationally indistinguishable from Newton's law. Naturally, Minkowski seized this opportunity.

Sadly, Minkowski did not live long enough to develop his ideas on gravitation and electrodynamics; he died on 12 January, 1909, a few days after undergoing an operation for appendicitis. At the time, no objections to a field theory of gravitation analogous to Maxwell's electromagnetic theory were known, apart from Maxwell's own sticking-points (see above, p. 198). However, additional objections to this approach were raised by Max Abraham in 1912, after which the Maxwellian approach withered on the vine, as Gustav Mie and others pursued unified theories of electromagnetism and gravitation.[115]

Minkowski's first law of gravitation fared no better than his second law, but the four-dimensional language in which his two laws were couched had a bright future. The first one to use Minkowski's formal ideas to advantage was Sommerfeld, as we will see next.

3. ARNOLD SOMMERFELD'S HYPER-MINKOWSKIAN LAWS OF GRAVITATION

Neither Poincaré's nor Minkowski's work on gravitation and relativity drew comment until 25 October, 1910, when the second installment of Arnold Sommerfeld's vectorial version of Minkowski's calculus, entitled "Four-dimensional vector analysis" [*Vierdimensionale Vektoranalysis*], appeared in the *Annalen der Physik* (Sommerfeld 1910b). Sommerfeld's contribution differs from those of Poincaré and Minkowski in that it is openly concerned with the presentation of a new formalism, much as its title

114 "In der dem Weltpostulate gemäß reformierten Mechanik fallen die Disharmonien, die zwischen der Newtonschen Mechanik und der modernen Elektrodynamik gestört haben, von selbst aus" (Minkowski 1909, §5).

115 Abraham showed that a mass set into oscillation would be unstable due to the direction of energy flow (Norton 1992, 33). On the early history of unified field theories, see the reference in note 12.

indicates. In this section, I discuss Sommerfeld's interest in vectors, the salient aspects of his 4-vector formalism, and his portrayal of Poincaré's and Minkowski's laws of gravitation.

Sommerfeld displayed a lively interest in vectors, beginning with his editorship of the physics volume of Klein's six-volume *Encyklopädie* in the summer of 1898.[116] He imposed a certain style of vector notation on his contributing authors, including typeface, terminology, symbolic representation of operations, units and dimensions, and the choice of symbols for physical quantities. Articles 12 to 14 of the physics volume appeared in 1904, and were the first to implement the notation scheme backed by Sommerfeld, laid out the same year in the *Physikalische Zeitschrift*.[117] While Sommerfeld belonged to the Vector Commission formed at Felix Klein's behest in 1902, it was clear to him as early as 1901 that the article on Maxwell's theory (commissioned to Lorentz) would serve as a "general directive" for future work in electrodynamics.[118] His intuition turned out to be correct: the principal "vector" of influence was Lorentz's Article 13 (Lorentz 1904b), featuring sections on vector notation and algebra, which set a *de facto* standard for vector approaches to electrodynamics.

As mentioned above (p. 210), only one effort to extend Poincaré's four-dimensional approach beyond the domain of gravitation was published prior to Minkowski's *Grundgleichungen*. By 1910, the outlook for relativity theory had changed due to the authoritative support of Planck and Sommerfeld, the announcement of experimental results favoring Lorentz's electron theory, and the broad diffusion (in 1909) of Minkowski's Cologne lecture. Dozens of physicists and mathematicians began to take an interest in relativity, resulting in a leap in relativist publications.[119]

The principal promoter of Minkowskian relativity, Sommerfeld must have felt by 1910 that it was the right moment to introduce a four-dimensional formalism. He was not alone in feeling this way, for three other formal approaches based on Minkowski's work appeared in 1910. Two of these were 4-vector systems, similar in some respects to Sommerfeld's, and worked out by Max Abraham and the American physical chemist Gilbert Newton Lewis, respectively. A third, non-vectorial approach was proposed by the Zagreb mathematician Vladimir Varičak. Varičak's was a real, four-dimensional, coordinate-based approach relying on hyperbolic geometry. Sommerfeld probably viewed this system as a potential rival to his own approach; although he did not mention Varičak, he wrote that a non-Euclidean approach was

116 Sommerfeld's work on the *Encyklopädie* is discussed in an editorial note to his scientific correspondence (Sommerfeld 2001–2004, 1:40).

117 See (Reiff and Sommerfeld 1904; Lorentz 1904b, 1904c, Sommerfeld 1904). The scheme proposed by Sommerfeld differed from that published in articles 12 to 14 of the *Encyklopädie* only in that the operands of scalar and vector products were no longer separated by a dot.

118 Sommerfeld to Lorentz, 21 March, 1901, (Sommerfeld 2001–2004, 1:191). On Sommerfeld's participation on the Commission see (Reich 1996) and (Sommerfeld 2001–2004, 1:144).

119 For bibliometric data, and discussions of Sommerfeld's role in the rise of relativity theory, see (Walter 1999a, 68–73, 1999b, 96, 108).

possible but could not be recommended (Sommerfeld 1910a, 752, note 1). Of the three alternatives to Sommerfeld's system, the non-Euclidean style pursued by Varičak and others was the only one to obtain even a modest following. An investigation of the reasons for the contemporary neglect of these alternative four-dimensional approaches is beyond the purview of our study; for what concerns us directly, none of these methods was applied to the problem of gravitation.[120]

Sommerfeld's paper, like those of Abraham, Lewis, and Varičak, emphasized formalism, and in this it differed from the *Grundgleichungen*, as mentioned above. Like the latter work, it focused attention on the problem of gravitation. Following the example set by both Poincaré and Minkowski, Sommerfeld capped his two-part *Annalen* paper with an application to gravitational attraction, which consisted of a reformulation, comparison and commentary of their work in his own terms. Not only was Sommerfeld's comparison of Poincaré's and Minkowski's laws of gravitation the first of its kind, it also proved to be the definitive analysis for his generation.

Sommerfeld's four-dimensional vector algebra and analysis offered no new 4-vector or 6-vector definitions, but it introduced a suite of 4-vector functions, notation, and vocabulary. The most far-reaching modification with respect to Minkowski's calculus was the elimination of *lor* (cf. pp. 223–223) in favor of extended versions of ordinary vector functions. In Sommerfeld's notational scheme, the ordinary vector functions div, rot, and grad (used by Lorentz in his *Encyklopädie* article on Maxwell's theory) were replaced by 4-vector counterparts marked by a leading capital letter: Div, Rot, and Grad. These three functions were joined by a 4-vector divergence marked by German typeface, $\mathfrak{Div}$. Sommerfeld chose to retain $\Box$ (cf. note 20), while noting the equivalence to his 4-vector functions: $\Box = \text{Div Grad}$. The principal advantage of the latter functions was that their meaning was familiar to physicists. In the same vein, Sommerfeld supplanted Minkowski's unwieldy terminology of "spacetime vectors of the first and second type" [*Raum-Zeit-Vektoren I^ter^ und II^ter^ Art*] with the more succinct "four-vector [*Vierervektor*] and "six-vector" [*Sechservektor*]. The result was a compact and transparent four-dimensional formalism differing as little as possible from the ordinary vector algebra employed in the physics volume of the *Encyklopädie*.[121]

To show how his formalism performed in action, Sommerfeld first took up the geometric interpretation and calculation of the electrodynamic 4-vector potential and 4-force. In the new notation, Sommerfeld wrote the electrodynamic 4-force $\mathfrak{K}$ between two point charges e and e_0 in terms of three components in the direction of the light-like 4-vector $\mathfrak{R}$, the source 4-velocity $\mathfrak{B}$, and the 4-acceleration $\dot{\mathfrak{B}}$:

120 See (Abraham 1910; Lewis 1910a, 1910b; Varičak 1910). On Varičak's contribution see (Walter 1999b).

121 Not all of Sommerfeld's notational choices were retained by later investigators; Laue, for instance, preferred a notational distinction between 4-vectors and 6-vectors. For a summary of notation used by Minkowski, Abraham, Lewis, and Laue, see (Reich 1994).

$$
\begin{aligned}
4\pi\mathfrak{K}_{\mathfrak{R}} &= \frac{ee_0}{c(\mathfrak{R}\mathfrak{B})^2}\left(\frac{c^2-(\mathfrak{R}\dot{\mathfrak{B}})}{(\mathfrak{R}\mathfrak{B})}(\mathfrak{B}_0\mathfrak{B})+\mathfrak{B}_0\dot{\mathfrak{B}}\right)\mathfrak{R},\\
4\pi\mathfrak{K}_{\mathfrak{B}} &= \frac{-ee_0}{c(\mathfrak{R}\mathfrak{B})^2}\frac{c^2-(\mathfrak{R}\dot{\mathfrak{B}})}{(\mathfrak{R}\mathfrak{B})}(\mathfrak{B}_0\mathfrak{R})\mathfrak{B},\\
4\pi\mathfrak{K}_{\dot{\mathfrak{B}}} &= \frac{-ee_0}{c(\mathfrak{R}\mathfrak{B})^2}\frac{c^2-(\mathfrak{R}\dot{\mathfrak{B}})}{(\mathfrak{R}\mathfrak{B})}(\mathfrak{B}_0\mathfrak{R})\dot{\mathfrak{B}},
\end{aligned}
\tag{42}
$$

where parentheses indicate scalar products. Sommerfeld was careful to note the equivalence between (42) and what he called Minkowski's "geometric rule" (40).

In the ninth and final section of his paper, Sommerfeld took up the law of electrostatics and the classical law of gravitation. The former was naturally considered to be a special case of (42), with two point charges relatively at rest. The same was true for the law of gravitation, as Sommerfeld noted that Minkowski had proposed a formal variant of (40) as a law of gravitational attraction (what I call Minkowski's second law, [41]). Sommerfeld's expression of the electrodynamic 4-force is unwieldy, but takes on a simpler form in case of uniform motion of the source ($\dot{\mathfrak{B}} = 0$). Neglecting the 4π factor, and substituting $-mm_0$ for $+ee_0$, Sommerfeld expressed the corresponding version of Minkowski's second law:

$$
-mm_0 c\frac{(\mathfrak{B}_0\mathfrak{B})\mathfrak{R}-(\mathfrak{B}_0\mathfrak{R})\mathfrak{B}}{(\mathfrak{R}\mathfrak{B})^3}. \tag{43}
$$

The latter law is compact and self-contained, in that its interpretation depends only on the definitions and rules of the algebraic formalism. In this sense, (43) improves on the Minkowskian (41), even if it represents only a special case of the latter law.

Once Sommerfeld had expressed Minkowski's second law in his own terms, he turned to Poincaré's two laws. The transformation of Poincaré's first law was more laborious than the transformation of Minkowski's second law. First of all, Sommerfeld transcribed Poincaré's first law (9) into his 4-vector notation, while retaining the original designation of invariants. This step itself was not simple: in order to cast Poincaré's kinematic invariants as scalar products of 4-vectors, Sommerfeld had to adjust the leading sign of (9), to obtain:

$$
\frac{k_0\mathfrak{K}}{mm'} = -\frac{1}{B^3C}\left(C\mathfrak{R}-\frac{1}{c}A\mathfrak{B}\right). \tag{44}
$$

Sommerfeld noted the "correction" of what he called an "obvious sign error" in (9).[122] The difference is due to Poincaré's irregular derivation of the kinematic invariants (1), as mentioned above (p. 203), although from Sommerfeld's remark it is not clear that he saw it this way.

122 "Mit Umkehr des bei Poincaré offenbar versehentlichen Vorzeichens" (Sommerfeld 1910b, 686, n. 1).

The transformation of Poincaré's second law (10) was less straightforward. It appears that instead of deriving a 4-vector expression as in the previous case, Sommerfeld followed Poincaré's lead by eliminating the Lorentz-invariant factor C from the denominator on the right-hand side of the first law (44), which results in the equation:

$$\frac{k_0\mathfrak{K}}{mm'} = -\frac{1}{B^3}\left(C\mathfrak{R} - \frac{1}{c}A\mathfrak{B}\right). \tag{45}$$

Sommerfeld expressed Poincaré's kinematic invariants A, B, and C as scalar products:

$$A = -\frac{1}{c}(\mathfrak{R}\mathfrak{B}_0), \quad B = -\frac{1}{c}(\mathfrak{R}\mathfrak{B}), \quad C = -\frac{1}{c^2}(\mathfrak{B}_0\mathfrak{B}). \tag{46}$$

He also replaced the mass term m' in (44) and (45) by the product of rest mass m_0 and the Lorentz factor k_0, i.e., $m' = m_0k_0$. At this point, he could express Poincaré's two laws exclusively in terms of constants, scalars, and 4-vectors:

$$mm_0c^3\frac{(\mathfrak{B}_0\mathfrak{B})\mathfrak{R} - (\mathfrak{B}_0\mathfrak{R})\mathfrak{B}}{(\mathfrak{R}\mathfrak{B})^3(\mathfrak{B}_0B)}, \tag{47}$$

$$-mm_0c\frac{(\mathfrak{B}_0\mathfrak{B})\mathfrak{R} - (\mathfrak{B}_0\mathfrak{R})\mathfrak{B}}{(\mathfrak{R}\mathfrak{B})^3}. \tag{48}$$

In the latter form, Sommerfeld's (approximate) version of Minkowski's second law (43) matches exactly his (exact) version of Poincaré's second law (48). Sommerfeld pointed out this equivalence, and noted again that the difference between (47) and (48) amounted to a single factor, in the scalar product of 4-velocities: $C = -(\mathfrak{B}_0\mathfrak{B})/c^2$. (All six Lorentz-invariant laws of gravitation of Poincaré, Minkowski, and Sommerfeld are presented in Table 1.) Sommerfeld summed up his result by saying that when the acceleration of the active mass is neglected, Minkowski's special formulation of Newton's law (41) is subsumed by Poincaré's indeterminate formulation. In other words, the approximate form of Minkowski's second law was captured by Poincaré's remark that his first law (9) could be multiplied by an unlimited number of Lorentz-invariant quantities (within certain constraints).

The message of the basic equivalence of Poincaré's pair of laws to Minkowski's pair echoes the latter's argument in his Cologne lecture, to the effect that spacetime mechanics removed the disharmonies of classical mechanics and electrodynamics (see above, p. 234). This message was reinforced by Sommerfeld's graphical representation of the 4-vector components of these laws in a spacetime diagram, reproduced in Fig. 4. The 4-vector relations in (47) and (48) are shown in the figure; the world line of the active mass m appears on the left-hand side of the diagram, and the line OL (which coincides with $\mathfrak{R}$) lies on the retrograde lightcone from the origin O on the world line of the passive mass m_0. All three 4-vectors in (47) and (48), $\mathfrak{R}$, $\mathfrak{B}_0$, and $\mathfrak{B}_0$ are represented in the diagram, along with an angle ψ corresponding to the Lorentz-invariant $C = \cos\psi$ distinguishing (47) and (48).[123]

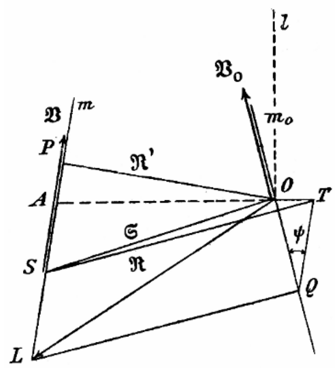

Figure 4: Sommerfeld's illustration of the two laws of gravitation (Sommerfeld 1910b, 687).

So far, Sommerfeld had dealt with three of the four laws of gravitation, leaving out only Minkowski's first law. Since Minkowski's presentation of his first law was a purely geometric affair, Sommerfeld had no choice but to reconstruct his argument with reference to a spacetime diagram describing the components of (27) in terms of the angle ψ and a fourth 4-vector, $\mathfrak{S}$. He showed the numerator in (47) and (48) to be equal to the product $(\mathfrak{B}_0\mathfrak{B})\mathfrak{S}$, and expressed the denominator of (48) in terms of the length R' of the 4-vector $\mathfrak{R}'$ in Fig. 4, to obtain the formula:

$$\mathfrak{K} = mm_0 \cos\psi \frac{\mathfrak{S}}{R'^3}, \tag{49}$$

which he showed to be equivalent to (47). Eliminating the factor $C = \cos\psi$ from the latter equation, Sommerfeld obtained an expression for (48) in terms of $\mathfrak{S}$:

$$\mathfrak{K} = \frac{mm_0\mathfrak{S}}{R'^3}. \tag{50}$$

The latter two driving force equations, (49) and (50), were thus rendered geometrically by Sommerfeld, facilitating the comprehension of their respective vector-symbolic expressions (47) and (48).

In general, the driving force of (49) is weaker, *ceteris paribus*, than that of (50) due to the cosine in the former, but Sommerfeld did not develop these results numerically, noting only that the four laws were equally valid from an empirical stand-

123 Sommerfeld explained Fig. 4 roughly as follows: two skew 4-velocities $\mathfrak{B}$ and $\mathfrak{B}_0$ determine a three-dimensional space, containing all the lines shown. Points $OLSAP$ are coplanar, while the triangles OQT and OTS, and the parallelogram $LQTS$ all generally lie in distinct planes. In particular, T lies outside the plane of $OLSAP$, and OT is orthogonal to $\mathfrak{B}_0$. The broken vertical line l represents the temporal axis of a frame with origin O; a space-like plane orthogonal to l at O intersects the world line of m at point A. The space-like 4-vector $\mathfrak{R}'$ is orthogonal to $\mathfrak{B}$, while $\mathfrak{S}$ is orthogonal to $\mathfrak{B}_0$; both $\mathfrak{R}'$ and $\mathfrak{S}$ intersect the origin, while $\mathfrak{B}$ and $\mathfrak{B}_0$ together form an angle ψ.

point.[124] He noted that Poincaré's analysis allowed for several other laws, but that in all cases, one sticking-point remained: there was no answer to the question of how to localize momentum in the gravitational field.

By rewriting Poincaré's and Minkowski's laws in his new 4-vector formalism, Sommerfeld effectively rationalized their contributions for physicists. The goal of his paper, announced at the outset, was to display the "remarkable simplification of electrodynamic concepts and calculations" resulting from "Minkowski's profound space-time conception."[125] Actually, Sommerfeld's comparison of Poincaré's and Minkowski's laws of gravitation was designed to show *his* formalism in an attractive light. In realizing this comparison in his own formalism, Sommerfeld smoothed out the idiosyncrasies of Poincaré's method, inappropriately lending him a 4-vector approach. He felt that Poincaré had "already employed 4-vectors" (Sommerfeld 1910b, 685) although as shown in the first section, Poincaré's use of four-dimensional entities was tightly circumscribed by the objective of formulating Lorentz-invariants. In Thomas Kuhn's optical metaphor (Kuhn 1970, 112), Sommerfeld read Poincaré's theory through a Minkowskian lens; in other words, he read it as a space-time theory. For Sommerfeld, no less than for Minkowski, the discussion of gravitation and relativity was modulated by the programmatic objective of promoting a four-dimensional formalism. Satisfying this objective without ignoring Poincaré's work, however, meant rationalizing Poincaré's contribution.[126]

Sommerfeld's reading of Minkowski's second law contrasts with its muted exposition in the original text (see above, pp. 234–234), in that he gave it pride of place with respect to the other three laws. This change in emphasis on Sommerfeld's part reflects his own research interests in electrodynamics, and his outlook on the future direction of physics.[127] But what originally motivated him to propose a 4-dimensional formalism? The inevitability of a 4-dimensional vector algebra as a standard tool of the physicist was probably a foregone conclusion for him by 1910, such that the promotion of the ordinary vector notation used in the *Encyklopädie* obliged him to propose essentially the same notation for 4-vectors. Sommerfeld referred modestly to his work as an "explanation of Minkowskian ideas" (Sommerfeld 1910a, 749) but as he explained to his friend Willy Wien, co-editor with Planck of the *Annalen der*

---

124 This view was confirmed independently by the Dutch astronomer W. de Sitter, who worked out the numbers for the one-body problem (de Sitter 1911). De Sitter found the second law to require a post-Newtonian centennial advance in Mercury's perihelion of $7''$, while the first law required no additional advance. His figure for the second law agrees with the one given by Poincaré (see above, p. 208).

125 "In dieser und einigen anschließenden Studien möchte ich darstellen, wie merkwürdig sich die elektrodynamischen Begriffe und Rechnungen vereinfachen, wenn man sich dabei von der tiefsinnigen Raum-Zeit-Auffassung Minkowskis leiten läßt" (Sommerfeld 1910a, 749).

126 Faced with a similar situation in his Cologne lecture of September, 1908, Minkowski simply neglected to mention Poincaré's contribution; see (Walter 1999a, 56).

127 Sommerfeld later preferred Gustav Mie's field theory of gravitation. Such an approach was more promising than that of Poincaré and Minkowski, which grasped gravitation "to some extent as action at a distance" (Sommerfeld 1913, 73).

Physik, Minkowski's original 4-vector scheme had evolved. "The geometrical systematics" Sommerfeld announced, "is now hyper-Minkowskian."[128] In the same letter to Wien, Sommerfeld confessed that his paper had required substantial effort, and he expressed doubt that it would prove worthwhile. Sommerfeld displayed either pessimism or modesty here, but in fact his effort was richly rewarded, as his streamlined four-dimensional algebra and analysis quickly won both Einstein's praise and the confidence of his contemporaries.[129]

Sommerfeld's work was eagerly read by young theoretical physicists raised in the heady atmosphere of German vectorial electrodynamics. One of the early adepts of Sommerfeld's formalism was Philipp Frank (1884–1966), who was then a Privatdozent in Vienna. By way of introduction to his 1911 study of the Lorentz-covariance of Maxwell's equations, Frank described the new four-dimensional algebra as a combination of "Sommerfeld's intuitiveness with Minkowski's mathematical elegance" (Frank 1911, 600). He recognized, however, that of late, physicists had been overloaded with outlandish symbolic systems and terminology, and promised to stay within the boundaries of Sommerfeld's system, at least as far as this was possible.

Physicists were indeed inundated in 1910–1911 with a bewildering array of new symbolic systems, including an ordinary vector algebra (Burali-Forti and Marcolongo 1910), and a quaternionic calculus (Conway 1911), in addition to the hyperbolic-coordinate system and three 4-vector formalisms already mentioned. By 1911, 4-vector and 6-vector operations featured prominently in the pages of the *Annalen der Physik*. Out of the nine theoretical papers concerning relativity theory published in the *Annalen* that year, five made use of a four-dimensional approach to physics, either in terms of 4-vector operations, or by referring to spacetime coordinates. Four out of five authors of "four-dimensional" papers cited Minkowski's or Sommerfeld's work; the fifth referred to Max Laue's new relativity textbook (Laue 1911). This timely and well-written little book went far in standardizing the terminology and notation of four-dimensional algebra, such that by January of 1912, Max Abraham preferred the Sommerfeld-Laue notation to his own for the exposition of his theory of gravitation (Abraham 1910, 1912a, 1912b).

While young theorists were quick to pick up on the Sommerfeld-Laue calculus, textbook writers did not follow the trend. Of the four textbooks to appear on relativity in 1913–1914, only the second edition of Laue's book (Laue 1913) employed this formalism. Ebenezer Cunningham presented a 4-dimensional approach based on Minkowski's work, but explicitly rejected Sommerfeld's "quasi-geometrical language", which conflicted with his own purely algebraic presentation (Cunningham

128 "Die geometrische Systematik ist jetzt hyper-minkowskisch" (Sommerfeld to Wien, 11 July, 1910, Sommerfeld 2001–2004, 1:388).

129 Einstein to Sommerfeld, July, 1910, (CPAE 5, 243–247; Sommerfeld 2001–2004, 1:386–388). In light of Einstein and Laub's earlier dismissal of Minkowski's formalism (see above, pp. 222–223), Sommerfeld naturally supposed that Einstein would disapprove of his system, prompting the protest: "Wie können Sie denken, dass ich die Schönheit einer solchen Untersuchung nicht zu schätzen wüsste?"

1914, 99). A third textbook by Ludwik Silberstein (Silberstein 1914), a former student of Planck, gave preference to a quaternionic presentation, while the fourth, by Max B. Weinstein (Weinstein 1913), opted for Cartesian coordinates. Curiously enough, Weinstein dedicated his work to the memory of Minkowski. Apparently disturbed by this profession of fidelity, Max Born, who had briefly served as Minkowski's assistant, deplored the form of Weinstein's approach to relativity:

> [Minkowski] put perhaps just as much value on his presentation as on its content. For this reason, I do not believe that entrance to his conceptual world is facilitated when it is overwhelmed by an enormous surfeit of formulas.[130]

By this time, Born himself had dropped Minkowski's formalism in favor of the Sommerfeld-Laue approach, such that the target of his criticism was Weinstein's disregard for 4-dimensional methods in general, and not the neglect of Minkowski's matrix calculus.[131] What Born was pointing out here was that it had become highly impractical to study the theory of relativity without recourse to a 4-dimensional formalism. This may explain why Laue's was the only one of the four textbooks on relativity to be reedited, reaching a sixth edition in 1955.

In summary, the language developed by Sommerfeld for the expression of the laws of gravitation of Poincaré and Minkowski endured, while the laws themselves remained tentative at best. This much was clear as early as 1912, when Jun Ishiwara reported from Japan on the state of relativity theory. This theory, Ishiwara felt, had shed no light on the problem of gravitation, with a single exception: Minkowski and Sommerfeld's "formal mathematical treatment" (Ishiwara 1912, 588). The trend from Poincaré to Sommerfeld was one of increasing reliance on formal techniques catering to Lorentz-invariance; in the space of five years, the physical content of the laws of gravitation remained stable, while their formal garb evolved from Cartesian to hyper-Minkowskian.

4. CONCLUSION: ON THE EMERGENCE OF THE FOUR-DIMENSIONAL VIEW

After a century-long process of accommodation to the use of tensor calculus and spacetime diagrams for analysis of physical interactions, the mathematical difficulties encountered by the pioneers of 4-dimensional physics are hard to come to terms with. Not only is the oft-encountered image of flat-spacetime physics as a trivial consequence of Einstein's special theory of relativity and Felix Klein's geometry consistent with such accommodation, it reflects Minkowski's own characterization of the back-

130 "[Minkowski] hat auf seine Darstellung vielleicht ebenso viel Wert gelegt, wie auf ihren Inhalt. Darum glaube ich nicht, daß der Zugang zu seiner Gedankenwelt erleichtert wird, wenn sie von einer ungeheuren [sic] Fülle von Formeln überschüttet wird" (Born 1914).

131 By the end of 1911 Born had already acknowledged that, despite its "formal simplicity and greater generality compared to the tradition of vectorial notation," Minkowski's calculus was "unable to hold its ground in mathematical physics" (Born 1912, 175).

ground of the four-dimensional approach (cf. p. 218). However, this description ought not be taken at face value, being better understood as a rhetorical ploy designed to induce mathematicians to enter the nascent field of relativistic physics (Walter 1999a). When the principle of relativity was formulated in 1905, even for one as adept as Henri Poincaré in the application of group methods, the path to a four-dimensional language for physics appeared strewn with obstacles. Much as Poincaré had predicted (above, p. 209), the construction of this language cost Minkowski and Sommerfeld considerable pain and effort.

Clear-sighted as he proved to be in this regard, Poincaré did not foresee the emergence of forces that would accelerate the construction and acquisition of a four-dimensional language. With hindsight, we can identify five factors favoring the use and development of a four-dimensional language for physics between 1905 and 1910: the elaboration of new concepts and definitions, the introduction of a graphic model of spacetime, the experimental confirmation of relativity theory, the vector-symbolic movement, and problem-solving performance.

In the beginning, the availability of workable four-dimensional concepts and definitions regulated the analytic reach of a four-dimensional approach to physics. Poincaré's discovery of the 4-vectors of velocity and force in the course of his elaboration of Lorentz-invariant quantities, and Minkowski's initial misreading of Poincaré's definitions underline how unintuitive these notions appeared to turn-of-the-century mathematicians. The lack of a 4-velocity definition visibly hindered Minkowski's elaboration of spacetime mechanics and theory of gravitation. It is remarkable that even after Minkowski presented the notions of proper time, world line, rest-mass density, and the energy-momentum tensor, putting the spacetime electrodynamics and mechanics on the same four-dimensional footing, his approach failed to convince physicists. Nevertheless, all of these discoveries extended the reach of the four-dimensional approach, in the end making it a viable candidate for the theorist's toolbox.

Next, Minkowski's visually-intuitive spacetime diagram played a decisive role in the emergence of the four-dimensional view. While the spacetime diagram reflects some of the concepts mentioned above, its utility as a cognitive tool exceeded by far that of the sum of its parts. In Minkowski's hands, the spacetime diagram was more than a tool, it was a model used to present both of his laws of gravitation. Beyond their practical function in problem-solving, spacetime diagrams favored the diffusion in wider circles of both the theory of relativity and the four-dimensional view of this theory, in particular among non-mathematicians, by providing a visually intuitive means of grasping certain consequences of the theory of relativity, such as time dilation and Lorentz contraction. Minkowski's graphic model of spacetime thus enhanced both formal and intuitive approaches to special relativity.

In the third place, the ultimate success of the four-dimensional view hinged on the empirical adequacy of the theory of relativity. It is remarkable that the conceptual groundwork, and much of the formal elaboration of the four-dimensional view was accomplished during a time when the theory of relativity was less well corroborated by experiment than its rivals. The reversal of this situation in favor of relativity theory in late 1908 favored the reception of the existing four-dimensional methods, and provided new impetus both for their application and extension, and for the development of alternatives, such as that of Sommerfeld.

The fourth major factor influencing the elaboration of a four-dimensional view of physics was the vector-symbolic movement in physics and mathematics at the turn of the twentieth century (McCormmach 1976, xxxi). The participants in this movement, in which Sommerfeld was a leading figure, believed in the efficacy of vector-symbolic methods in physics and geometry, and sought to unify the plethora of notations employed by various writers. The movement's strength varied from country to country; it was largely ignored in France, for example, in favor of the coordinate-based notation favored by Poincaré and others. Poincaré's pronounced disinterest in the application and development of a four-dimensional calculus for physics was typical of contemporary French attitudes toward vector-symbolic methods. In Germany, on the other hand, electrodynamicists learned Maxwell's theory from the mid-1890s in terms of curl $\mathfrak{h}$ and div $\mathfrak{E}$. In Zürich and Göttingen during this period, Minkowski instructed students (including Einstein) in the ways of the vector calculus. Unlike Poincaré, Minkowski was convinced that a four-dimensional language for physics would be worth the effort spent on its elaboration, yet he ultimately abandoned the vector-symbolic model in favor of an elegant and sophisticated matrix calculus. This choice was deplored by physicists (including Einstein), and mooted by Sommerfeld's conservative extension of the standard vector formalism into an immediately successful 4-vector algebra and analysis. In sum, the vector-symbolic movement functioned alternatively as an accelerator of the elaboration of four-dimensional calculi (existing systems served as templates), and as a regulator (penalizing Minkowski's neglect of standard vector operations).

The fifth and final parameter affecting the emergence of the four-dimensional view of physics was problem-solving performance. From the standpoint of ease of calculation, any four-dimensional vector formalism at all compared well to a Cartesian-coordinate approach, as Weinstein's textbook demonstrated; the advantage of ordinary vector methods over Cartesian coordinates was less pronounced. As we have seen, Poincaré applied his approach to the problem of constructing a Lorentz-invariant law of gravitational attraction, and was followed in turn by Minkowski and Sommerfeld, both of whom also provided examples of problem-solving. In virtue of the clarity and order of Sommerfeld's detailed, coordinate-free comparison of the laws of gravitation of Poincaré and Minkowski, his 4-vector algebra appeared to be the superior four-dimensional approach, just when physicists and mathematicians were turning to relativity in greater numbers.

ACKNOWLEDGMENTS

This study was inaugurated with the encouragement and support of Jürgen Renn, during a stay at the Max Planck Institute for the History of Science (Berlin) in 1998. I am especially grateful to Urs Schoepflin and the Institute's library staff for their expert assistance. The themes explored here were presented at the Mathematisches Forschunginstitut Oberwolfach (January 2000), the University of Heidelberg (June 2000), the University of Paris 7–REHSEIS (April, 2001), the joint AMS/SMF meeting in Lyons (July, 2001), and the Eighth International Conference on the History of General Relativity (Amsterdam, June 2002). Several scholars shared their ideas with me, shaping the final form of the paper. In particular, I am indebted to Olivier Darrigol for insightful comments on an early draft. The paper has been improved thanks to a careful reading by Shaul Katzir, and discussions with John Norton and Philippe Lombard. The responsibility for any remaining infelicities is my own.

Table 1: Lorentz-Invariant Laws of Gravitation, 1906–1910

Poincaré (1906)[a]	**Minkowski (1908)**[b]	**Sommerfeld (1910)**[c]
$X_1 = \frac{x}{k_0 B^3} - \xi_1 \frac{k_1}{k_0}\frac{A}{B^3 C}$ $Y_1 = \frac{y}{k_0 B^3} - \eta_1 \frac{k_1}{k_0}\frac{A}{B^3 C}$ $Z_1 = \frac{z}{k_0 B^3} - \zeta_1 \frac{k_1}{k_0}\frac{A}{B^3 C}$ $T_1 = -\frac{r}{k_0 B^3} - \frac{k_1}{k_0}\frac{A}{B^3 C}$	$mm^*\left(\frac{OA'}{B^*D^*}\right)^3 BD^*$	$mm_0 c^3 \frac{(\mathfrak{B}_0\mathfrak{B})\mathfrak{R} - (\mathfrak{B}_0\mathfrak{R})\mathfrak{B}}{(\mathfrak{R}\mathfrak{B})^3(\mathfrak{B}_0\mathfrak{B})}$
$X_1 = \frac{\lambda}{B^3} - \frac{\eta\nu' - \zeta\mu'}{B^3}$ $Y_1 = \frac{\mu}{B^3} - \frac{\zeta\lambda' - \xi\nu'}{B^3}$ $Z_1 = \frac{\nu}{B^3} - \frac{\xi\mu' - \eta\lambda'}{B^3}$	$mm_1\left(\dot{t}_1 - \frac{\dot{x}_1}{c}\right)\mathfrak{K}$	$-mm_0 c \frac{(\mathfrak{B}_0\mathfrak{B})\mathfrak{R} - (\mathfrak{B}_0\mathfrak{R})\mathfrak{B}}{(\mathfrak{R}\mathfrak{B})^3}$

[a] Mass terms are neglected, such that the right-hand side of each equation is implicitly multiplied by the product of the two masses. When both sides of the four equations are multiplied by the factor k_0 they express components of a 4-vector, $k_0(X_1, Y_1, Z_1, iT_1)$. The constants k_0 and k_1 are defined as: $k_0 = 1/\sqrt{1-\Sigma\xi^2}$ and $k_1 = 1/\sqrt{1-\Sigma\xi_1^2}$. A, B, and C denote the last three Lorentz-invariants in (1): $A = \frac{t - \Sigma x\xi}{\sqrt{1-\Sigma\xi^2}}$, $B = \frac{t - \Sigma x\xi_1}{\sqrt{1-\Sigma\xi_1^2}}$, $C = \frac{1 - \Sigma\xi\xi_1}{\sqrt{(1-\Sigma\xi^2)(1-\Sigma\xi_1^2)}}$, where $\Sigma\xi$ and $\Sigma\xi_1$ designate the

ordinary velocities of the passive and active mass points, with components ξ, η, ζ, and ξ_1, η_1, ζ_1. The time t is set equal to the negative distance between the passive mass point and the retarded position of the active mass point, $t = -\sqrt{\Sigma x^2} = -r$. Poincaré's second law is shown in the bottom row; he neglected to write the fourth component T_1, determined from the first three by the orthogonality condition $T_1 = \Sigma X_1 \xi$. The new variables in the bottom row are:

$$\lambda = k_1(x + r\xi_1), \qquad \mu = k_1(y + r\eta_1), \qquad \nu = k_1(z + r\zeta_1),$$
$$\lambda' = k_1(\eta_1 z - \zeta_1 y), \quad \mu' = k_1(\zeta_1 x - \xi_1 z), \quad \nu' = k_1(\xi_1 y - x\eta_1).$$

[b] The formula in the top row describes the first three components of the driving force: the fourth component is obtained analytically. The constants m and m^* designate the passive and active proper mass, respectively, while the remaining letters stand for spacetime points, as reconstructed in Fig. 1 (p. 227). The formula in the bottom row represents the driving force of gravitation as described, but not formally expressed, in (Minkowski 1909). The constants m and m_1 designate the passive and active proper mass, $\dot{t}_1$ and $\dot{x}_1$ are 4-velocity components of the passive mass, c is the speed of light and $\mathfrak{K}$ is a 4-vector, for the definition of which see note 111.

[c] The constants m_0 and m designate the passive and active proper mass, respectively, c denotes the speed of light, $\mathfrak{B}_0$ and $\mathfrak{B}$ represent the corresponding 4-velocities, and $\mathfrak{R}$ stands for the light-like interval between the mass points.

HENRI POINCARÉ

ON THE DYNAMICS OF THE ELECTRON (EXCERPTS)

Originally published as "Sur la dynamique de l'électron" in Rendiconti del Circolo Matematico di Palermo 21 (1906), pp. 129–175. Author's date: Paris, July 1905. The Introduction, §1, and §9 are translated here.[1]

INTRODUCTION

It seems at first that the aberration of light and related optical and electrical phenomena will provide us with a means of determining the absolute motion of the Earth, or rather its motion with respect to the aether, as opposed to its motion with respect to other celestial bodies. Fresnel pursued this idea, but soon recognized that the Earth's motion does not alter the laws of refraction and reflection. Analogous experiments, like that of the water-filled telescope, and all those considering terms no higher than first order relative to the aberration, yielded only negative results; the explanation was soon discovered. But Michelson, who conceived an experiment sensitive to terms depending on the square of the aberration, failed in turn.

It appears that this impossibility to detect the absolute motion of the Earth by experiment may be a general law of nature; we are naturally inclined to admit this law, which we will call the *Postulate of Relativity* and admit without restriction. Whether or not this postulate, which up to now agrees with experiment, may later be corroborated or disproved by experiments of greater precision, it is interesting in any case to ascertain its consequences.

An explanation was proposed by Lorentz and FitzGerald, who introduced the hypothesis of a contraction of all bodies in the direction of the Earth's motion and proportional to the square of the aberration. This contraction, which we will call the *Lorentzian contraction*, would explain Michelson's experiment and all others performed up to now. The hypothesis would become insufficient, however, if we were to admit the postulate of relativity in full generality.

Lorentz then sought to extend his hypothesis and to modify it in order to obtain perfect agreement with this postulate. This is what he succeeded in doing in his article entitled *Electromagnetic phenomena in a system moving with any velocity smaller than that of light* (*Proceedings of the Amsterdam Academy*, 27 May, 1904).

The importance of the question persuaded me to take it up in turn; the results I | obtained agree with those of Mr. Lorentz on all the significant points. I was led [130]

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

merely to modify and extend them only in a few details; further on we will see the points of divergence, which are of secondary importance.

Lorentz's idea may be summed up like this: if we are able to impress a translation upon an entire system without modifying any observable phenomena, it is because the equations of an electromagnetic medium are unaltered by certain transformations, which we will call *Lorentz transformations*. Two systems, one of which is at rest, the other in translation, become thereby exact images of each other.

Langevin*) sought to modify Lorentz's idea; for both authors, the moving electron takes the form of a flattened ellipsoid. For Lorentz, two axes of the ellipsoid remain constant, while for Langevin, ellipsoid volume remains constant. The two scientists also showed that these two hypotheses are corroborated by Kaufmann's experiments to the same extent as the original hypothesis of Abraham (rigid-sphere electron).

The advantage of Langevin's theory is that it requires only electromagnetic forces, and bonds; it is, however, incompatible with the postulate of relativity. This is what Lorentz showed, and this is what I found in turn using a different method, which calls on principles of group theory.

We must return therefore to Lorentz's theory, but if we want to do this and avoid intolerable contradictions, we must posit the existence of a special force that explains both the contraction, and the constancy of two of the axes. I sought to determine this force, and found that *it may be assimilated to a constant external pressure on the deformable and compressible electron, whose work is proportional to the electron's change in volume*.

If the inertia of matter is exclusively of electromagnetic origin, as generally admitted in the wake of Kaufmann's experiment, and all forces are of electromagnetic origin (apart from this constant pressure that I just mentioned), the postulate of relativity may be established with perfect rigor. This is what I show by a very simple calculation based on the principle of least action.

But that is not all. In the article cited above, Lorentz judged it necessary to extend his hypothesis in such a way that the postulate remains valid in case there are forces of non-electromagnetic origin. According to Lorentz, all forces are affected by the Lorentz transformation (and consequently by a translation) in the same way as electromagnetic forces.

It was important to examine this hypothesis closely, and in particular to ascertain the modifications we would have to apply to the laws of gravitation.

[131] We find first of all that it requires us to assume that gravitational propagation | is not instantaneous, but occurs with the speed of light. One might think that this is reason enough to reject the hypothesis, since Laplace demonstrated that this cannot be the case. In reality, however, the effect of this propagation is compensated in large

* Langevin was anticipated by Mr. Bucherer of Bonn, who earlier advanced the same idea. (See: Bucherer, *Mathematische Einführung in die Elektronentheorie*, August, 1904. Teubner, Leipzig). [Poincaré's footnote.]

part by a different cause, in such a way that no contradiction arises between the proposed law and astronomical observations.

Is it possible to find a law satisfying Lorentz's condition, and reducing to Newton's law whenever the speeds of celestial bodies are small enough to allow us to neglect their squares (as well as the product of acceleration and distance) with respect to the square of the speed of light?

To this question we must respond in the affirmative, as we will see later.

Modified in this way, is the law compatible with astronomical observations?

It seems so on first sight, but the question will be settled only after an extended discussion.

Suppose, then, that this discussion is settled in favor of the new hypothesis, what should we conclude? If propagation of attraction occurs with the speed of light, it could not be a fortuitous accident. Rather, it must be because it is a function of the aether, and then we would have to try to penetrate the nature of this function, and to relate it to other fluid functions.

We cannot be content with a simple juxtaposition of formulas that agree with each other by good fortune alone; these formulas must, in a manner of speaking, interpenetrate. The mind will be satisfied only when it believes it has perceived the reason for this agreement, and the belief is strong enough to entertain the illusion that it could have been predicted.

But the question may be viewed from a different perspective, better shown via an analogy. Let us imagine a pre-Copernican astronomer who reflects on Ptolemy's system; he will notice that for all the planets, one of two circles—epicycle or deferent—is traversed in the same time. This fact cannot be due to chance, and consequently between all the planets there is a mysterious link we can only guess at.

Copernicus, however, destroys this apparent link by a simple change in the coordinate axes that were considered fixed. Each planet now describes a single circle, and orbital periods become independent (until Kepler reestablishes the link that was believed to have been destroyed).

It is possible that something analogous is taking place here. If we were to admit the postulate of relativity, we would find the same number in the law of gravitation and the laws of electromagnetism—the speed of light—and we would find it again in all other forces of any origin whatsoever. This state of affairs may be explained in one of two ways: either everything in the universe would be of electromagnetic origin, or this aspect—shared, as it were, by all physical phenomena—would be a mere epiphenomenon, something due to our methods of | measurement. How do we go about [132]
measuring? The first response will be: we transport objects considered to be invariable solids, one on top of the other. But that is no longer true in the current theory if we admit the Lorentzian contraction. In this theory, two lengths are equal, by definition, if they are traversed by light in equal times.

Perhaps if we were to abandon this definition Lorentz's theory would be as fully overthrown as was Ptolemy's system by Copernicus's intervention. Should that happen some day, it would not prove that Lorentz's efforts were in vain, because regardless of what one may think, Ptolemy was useful to Copernicus.

I, too, have not hesitated to publish these few partial results, even if at this very moment the discovery of magneto-cathode rays seems to threaten the entire theory.

1. LORENTZ TRANSFORMATION

Lorentz adopted a certain system of units in order to do away with 4π factors in formulas. I will do the same, and in addition, select units of length and time in such a way that the speed of light equals 1. Under these conditions, and denoting electric displacement f, g, h, magnetic intensity α, β, γ, vector potential F, G, H, scalar potential ψ, charge density ρ, electron velocity ξ, η, ζ, and current u, v, w, the fundamental formulas become:

$$\left.\begin{array}{llll} u = \dfrac{df}{dt} + \rho\xi = \dfrac{d\gamma}{dy} - \dfrac{d\beta}{dz}, & \alpha = \dfrac{dH}{dy} - \dfrac{dG}{dz}, & f = -\dfrac{dF}{dt} - \dfrac{d\psi}{dx}, & \\ \dfrac{d\alpha}{dt} = \dfrac{dg}{dz} - \dfrac{dh}{dy}, \quad \dfrac{d\rho}{dt} + \sum \dfrac{d\rho\xi}{dx} = 0, & \sum \dfrac{df}{dx} = \rho, & \dfrac{d\psi}{dt} + \sum \dfrac{dF}{dx} = 0, & \\ \square = \Delta - \dfrac{d^2}{dt^2} = \sum \dfrac{d^2}{dx^2} - \dfrac{d^2}{dt^2}, & \square\psi = -\rho, & \square F = -\rho\xi. & \end{array}\right\} \tag{1}$$

An elementary particle of matter of volume $dxdydz$ is acted upon by a mechanical force, the components of which are derived from the formula:

$$X = \rho f + \rho(\eta\gamma - \zeta\beta). \tag{2}$$

These equations admit a remarkable transformation discovered by Lorentz, which owes its interest to the fact that it explains why no experiment can inform us of the absolute motion of the universe. Let us put:

$$x' = kl(x + \varepsilon t), \quad t' = kl(t + \varepsilon x), \quad y' = ly, \quad z' = lz, \tag{3}$$

where l and ε are two arbitrary constants, such that

$$k = \frac{1}{\sqrt{1 - \varepsilon^2}}. \; |$$

[133] Now if we put:

$$\square' = \sum \frac{d^2}{dx'^2} - \frac{d^2}{dt'^2},$$

we will have:

$$\square' = \square l^{-2}.$$

Let a sphere be carried along with the electron in uniform translation, and let the equation of this mobile sphere be:

$$(x-\xi t)^2+(y-\eta t)^2+(z-\zeta t)^2 = r^2,$$

and the volume of the sphere be $\frac{4}{3}\pi r^3$. [2]

The transformation will change the sphere into an ellipsoid, the equation of which is easy to find. We thus deduce easily from (3):

$$x=\frac{k}{l}(x'-\varepsilon t'),\quad t=\frac{k}{l}(t'-\varepsilon x'),\quad y=\frac{y'}{l},\quad z=\frac{z'}{l}. \tag{3'}$$

The equation of the ellipsoid then becomes:

$$k^2(x'-\varepsilon t'-\xi t'+\varepsilon\xi x')^2+(y'-\eta kt'+\eta k\varepsilon x')^2+(z'-\zeta kt'+\zeta k\varepsilon x')^2 = l^2r^2.$$

This ellipsoid is in uniform motion; for $t' = 0$, it reduces to

$$k^2x'^2(1+\xi\varepsilon)^2+(y'+\eta k\varepsilon x')^2+(z'+\zeta k\varepsilon x')^2 = l^2r^2.$$

and has a volume:

$$\frac{4}{3}\pi r^3\frac{l^3}{k(1+\xi\varepsilon)}.$$

If we want electron charge to be unaltered by the transformation, and if we designate the new charge density ρ' we will find:

$$\rho' = \frac{k}{l^3}(\rho+\varepsilon\rho\xi). \tag{4}$$

What will be the new velocity components ξ', η' and ζ'? We should have:

$$\xi' = \frac{dx'}{dt'} = \frac{d(x+\varepsilon t)}{d(t+\varepsilon x)} = \frac{\xi+\varepsilon}{1+\varepsilon\xi},$$
$$\eta' = \frac{dy'}{dt'} = \frac{dy}{kd(t+\varepsilon x)} = \frac{\eta}{k(1+\varepsilon\xi)},\qquad \zeta' = \frac{\zeta}{k(1+\varepsilon\xi)},$$

whence:

$$\rho'\xi' = \frac{k}{l^3}(\rho\xi+\varepsilon\rho),\qquad \rho'\eta' = \frac{1}{l^3}\rho\eta,\qquad \rho'\zeta' = \frac{1}{l^3}\rho\zeta. \tag{4'}$$

Here is where I must point out for the first time a difference with Lorentz. In my notation, Lorentz put (loc. cit., page 813, formulas 7 and 8):

$$\rho'=\frac{1}{kl^3}\rho,\quad \xi'=k^2(\xi+\varepsilon),\quad \eta'=k\eta,\quad \zeta'=k\zeta. \;|$$

In this way we recover the formulas: [134]

$$\rho'\xi'=\frac{k}{l^3}(\rho\xi+\varepsilon\rho),\quad \rho'\eta'=\frac{1}{l^3}\rho\eta,\quad \rho'\zeta'=\frac{1}{l^3}\rho\zeta;$$

although the value of ρ' differs.

It is important to notice that the formulas (4) and (4') satisfy the condition of continuity

$$\frac{d\rho'}{dt'} + \sum \frac{d\rho'\xi'}{dx'} = 0.$$

To see this, let λ be an undetermined coefficient and D the Jacobian of

$$t + \lambda\rho, \quad x + \lambda\rho\xi, \quad y + \lambda\rho\eta, \quad z + \lambda\rho\zeta \tag{5}$$

with respect to t, x, y, z. It follows that:

$$D = D_0 + D_1\lambda + D_2\lambda^2 + D_3\lambda^3 + D_4\lambda^4,$$

with $D_0 = 1, D_1 = \dfrac{d\rho}{dt} + \sum \dfrac{d\rho\xi}{dx} = 0$.

Let $\lambda' = l^4\lambda$,[3] then the 4 functions

$$t' + \lambda'\rho', \quad x' + \lambda'\rho'\xi', \quad y' + \lambda'\rho'\eta', \quad z' + \lambda'\rho'\zeta' \tag{5'}$$

are related to the functions (5) by the same linear relationships as the old variables to the new ones. Therefore, if we denote D' the Jacobian of the functions (5') with respect to the new variables, it follows that:

$$D' = D, \quad D' = D'_0 + D'_1\lambda' + \ldots + D'_4\lambda'^4,$$

and thereby:[4]

$$D'_0 = D_0 = 1, \quad D'_1 = l^{-4}D_1 = 0 = \frac{d\rho'}{dt'} + \sum \frac{d\rho'\xi'}{dx'}. \quad \text{Q. E. D.}$$

Under Lorentz's hypothesis, this condition would not be met since ρ' has a different value.

We will define the new vector and scalar potentials in such a way as to satisfy the conditions

$$\Box'\psi' = -\rho', \qquad \Box'F' = -\rho'\xi'. \tag{6}$$

From this we deduce:

$$\psi' = \frac{k}{l}(\psi + \varepsilon F), \qquad F' = \frac{k}{l}(F + \varepsilon\psi), \qquad G' = \frac{1}{l}G, \qquad H' = \frac{1}{l}H. \tag{7}$$

These formulas differ noticeably from those of Lorentz, although the divergence stems ultimately from the definitions employed.

New electric and magnetic fields are now chosen in order to satisfy the equations:

$$f' = -\frac{dF'}{dt'} - \frac{d\psi'}{dx'}, \qquad \alpha' = \frac{dH'}{dy'} - \frac{dG'}{dz'}. \tag{8}$$

[135] | It is easy to see that:

$$\frac{d}{dt'} = \frac{k}{l}\left(\frac{d}{dt} - \varepsilon\frac{d}{dx}\right), \qquad \frac{d}{dx'} = \frac{k}{l}\left(\frac{d}{dx} - \varepsilon\frac{d}{dt}\right), \qquad \frac{d}{dy'} = \frac{1}{l}\frac{d}{dy}, \qquad \frac{d}{dz'} = \frac{1}{l}\frac{d}{dz},$$

and we deduce thereby:

$$\left.\begin{aligned} f' &= \frac{1}{l^2}f, \qquad & g' &= \frac{k}{l^2}(g + \varepsilon\gamma), \qquad & h' &= \frac{k}{l^2}(h - \varepsilon\beta), \\ \alpha' &= \frac{1}{l^2}\alpha, \qquad & \beta' &= \frac{k}{l^2}(\beta - \varepsilon h), \qquad & \gamma' &= \frac{k}{l^2}(\gamma + \varepsilon g). \end{aligned}\right\} \tag{9}$$

These formulas are identical to those of Lorentz.

Our transformation does not alter (1). In fact, the condition of continuity, as well as (6) and (8) were already featured in (1) (neglecting the primes).

Combining (6) with the condition of continuity, we obtain:

$$\frac{d\psi'}{dt'} + \sum \frac{dF'}{dx'} = 0. \tag{10}$$

It remains for us to establish:

$$\frac{df'}{dt'} + \rho'\xi' = \frac{d\gamma'}{dy'} - \frac{d\beta'}{dz'}, \qquad \frac{d\alpha'}{dt'} = \frac{dg'}{dz'} - \frac{dh'}{dy'}, \qquad \sum \frac{df'}{dx'} = \rho',$$

and it is easy to see that these are necessary consequences of (6), (8) and (10).

We must now compare forces before and after the transformation.

Let X, Y, Z be the force prior to the transformation, and X', Y', Z' the force after the transformation, both forces being per unit volume. In order for X' to satisfy the same equations as before the transformation, we must have:

$$\begin{aligned} X' &= \rho' f' + \rho'(\eta'\gamma' - \zeta'\beta'), \\ Y' &= \rho' g' + \rho'(\zeta'\alpha' - \xi'\gamma'), \\ Z' &= \rho' h' + \rho'(\xi'\beta' - \eta'\alpha'), \end{aligned}$$

or, replacing all quantities by their values (4), (4') and (9), and in light of (2):

$$\left.\begin{aligned} X' &= \frac{k}{l^5}\left(X + \varepsilon \sum X\xi\right), \\ Y' &= \frac{1}{l^5}Y, \\ Z' &= \frac{1}{l^5}Z. \end{aligned}\right\} \tag{11}$$

Instead of representing the components of force per unit volume by X_1, Y_1, Z_1, we now let these terms represent the force per unit electron charge, and we let X'_1, Y'_1, Z'_1 represent the latter force after transformation. It follows that:

$$X_1 = f + \eta\gamma - \zeta\beta, \quad X'_1 = f' + \eta'\gamma' - \zeta'\beta', \quad X = \rho X_1, \quad X' = \rho' X'_1$$

[136] | and we obtain the equations:

$$\left.\begin{aligned} X'_1 &= \frac{k}{l^5}\frac{\rho}{\rho'}\left(X_1 + \varepsilon\sum X_1\xi\right), \\ Y'_1 &= \frac{1}{l^5}\frac{\rho}{\rho'}Y_1, \\ Z'_1 &= \frac{1}{l^5}\frac{\rho}{\rho'}Z_1. \end{aligned}\right\} \qquad (11')$$

Lorentz found (page 813, equation (10) with different notation):

$$\left.\begin{aligned} X_1 &= l^2 X'_1 - l^2\varepsilon(\eta' g' + \zeta' h'), \\ Y_1 &= \frac{l^2}{k}Y'_1 + \frac{l^2\varepsilon}{k}\xi' g', \\ Z_1 &= \frac{l^2}{k}Z'_1 + \frac{l^2\varepsilon}{k}\xi' h'. \end{aligned}\right\} \qquad (11'')$$

Before going any further, it is important to locate the source of this significant divergence. It obviously springs from the fact that the formulas for ξ', η' and ζ' are not the same, while the formulas for the electric and magnetic fields are the same.

If electron inertia is exclusively of electromagnetic origin, and if electrons are subject only to forces of electromagnetic origin, then the conditions of equilibrium require that:

$$X = Y = Z = 0$$

inside the electrons.

According to (11), these relationships are equivalent to

$$X' = Y' = Z' = 0.$$

The electron's equilibrium conditions are therefore unaltered by the transformation.

Unfortunately, such a simple hypothesis is inadmissible. In fact, if we assume $\xi = \eta = \zeta = 0$, the condition $X = Y = Z = 0$ leads necessarily to $f = g = h = 0$, and consequently, to $\sum \frac{df}{dx} = 0$, i.e., $\rho = 0$. Similar results obtain for the most general case. We must then admit that in addition to electromagnetic forces there are either non-electromagnetic forces or bonds. Therefore, we need to identify the conditions that these forces or these bonds must satisfy for electron equilibrium to be undisturbed by the transformation. This will be the object of an upcoming section.

[…]

9. HYPOTHESES CONCERNING GRAVITATION. [166]

In this way Lorentz's theory would fully explain the impossibility of detecting absolute motion, if all forces were of electromagnetic origin.

But there exist other forces to which an electromagnetic origin cannot be attributed, such as gravitation, for example. It may in fact happen, that two systems of bodies produce equivalent electromagnetic fields, i.e., exert the same action on electrified bodies and on currents, and at the same time, these two systems do not exert the same gravitational action on Newtonian masses. The gravitational field is therefore distinct from the electromagnetic field. Lorentz was obliged thereby to extend his hypothesis with the assumption that *forces of any origin whatsoever, and gravitation in particular, are affected by a translation* (or, if one prefers, by the Lorentz transformation) *in the same manner as electromagnetic forces*.

It is now appropriate to enter into the details of this hypothesis, and to examine it more closely. If we want the Newtonian force to be affected by the Lorentz transformation in this fashion, we can no longer suppose that it depends only on the relative position of the attracting and attracted bodies at the instant considered. The force should also depend on the velocities of the two bodies. And that is not all: it will be natural to suppose that the force acting on the attracted body at the instant t depends on the position and velocity of this body at this same instant t, but it will also depend on the position and velocity of the *attracting* body, not at the instant t, but at *an earlier instant*, as if gravitation had taken a certain time to propagate.

Let us now consider the position of the attracted body at the instant t_0 and let x_0, y_0, z_0 be its coordinates, and ξ, η, ζ its velocity components at this instant; let us consider also the attracting body at the corresponding instant $t_0 + t$ and let its coordinates be $x_0 + x, y_0 + y, z_0 + z$, and its velocity components be ξ_1, η_1, ζ_1 at this instant.

First we should have a relationship

$$\varphi(t, x, y, z, \xi, \eta, \zeta, \xi_1, \eta_1, \zeta_1) = 0 \tag{1}$$

in order to define the time t. This relationship will define the law of propagation of gravitational action (I do not constrain myself by any means to a propagation velocity equal in all directions).

Now let X_1, Y_1, Z_1 be the three components of the action exerted on the attracted body at the instant t_0;[5] we want to express X_1, Y_1, Z_1 as functions of

$$t, x, y, z, \xi, \eta, \zeta, \xi_1, \eta_1, \zeta_1. \tag{2}$$

What conditions must be satisfied? |

1° The condition (1) should not be altered by transformations of the Lorentz group. [167]

2° The components X_1, Y_1, Z_1 should be affected by transformations of the Lorentz group in the same manner as the electromagnetic forces designated by the same letters, i.e., in accordance with (11') of section 1.

3° When the two bodies are at rest, the ordinary law of attraction will be recovered.

It is important to note that in the latter case, the relationship (1) vanishes, because if the two bodies are at rest the time t plays no role.

Posed in this fashion the problem is obviously indeterminate. We will therefore seek to satisfy to the utmost other, complementary conditions.

4° Since astronomical observations do not seem to show a sensible deviation from Newton's law, we will choose the solution that differs the least with this law for small velocities of the two bodies.

5° We will make an effort to arrange matters in such a way that t is always negative. Although we can imagine that the effect of gravitation requires a certain time in order to propagate, it would be difficult to understand how this effect could depend on the position *not yet attained* by the attracting body.

There is one case where the indeterminacy of the problem vanishes; it is the one where the two bodies are in mutual *relative* rest, i.e., where:

$$\xi = \xi_1, \qquad \eta = \eta_1, \qquad \zeta = \zeta_1;$$

this is then the case we will examine first, by supposing that these velocities are constant, such that the two bodies are engaged in a common uniform rectilinear translation.

We may suppose that the $x-$axis is parallel to this translation, such that $\eta = \zeta = 0$, and we will let $\varepsilon = -\xi$.

If we apply the Lorentz transformation under these conditions, after the transformation the two bodies will be at rest, and it follows that:

$$\xi' = \eta' = \zeta' = 0.$$

The components X'_1, Y'_1, Z'_1 should then agree with Newton's law and we will have, apart from a constant factor:

$$\left.\begin{aligned} &X'_1 = -\frac{x'}{r'^3}, \qquad Y'_1 = -\frac{y'}{r'^3}, \qquad Z'_1 = -\frac{z'}{r'^3}, \\ &r'^2 = x'^2 + y'^2 + z'^2. \end{aligned}\right\} \tag{3}$$

But according to section 1 we have:

$$x' = k(x + \varepsilon t), \qquad y' = y, \qquad z' = z, \qquad t' = k(t + \varepsilon x),$$

$$\frac{\rho'}{\rho} = k(1 + \xi\varepsilon) = k(1 - \varepsilon^2) = \frac{1}{k}, \qquad \sum X_1 \xi = -X_1 \varepsilon,$$

[168] $$X'_1 = k\frac{\rho}{\rho'}(X_1 + \varepsilon \sum X_1 \xi) = k^2 X_1 (1 - \varepsilon^2) = X_1,$$

$$Y'_1 = \frac{\rho}{\rho'} Y_1 = k Y_1, \qquad Z'_1 = k Z_1.$$

We have in addition:

$$x + \varepsilon t = x - \xi t, \qquad r'^2 = k^2(x - \xi t)^2 + y^2 + z^2$$

and

$$X_1 = \frac{-k(x - \xi t)}{r'^3}, \qquad Y_1 = \frac{-y}{kr'^3}, \qquad Z_1 = \frac{-z}{r'^3}; \tag{4}$$

which may be written:

$$X_1 = \frac{dV}{dx}, \qquad Y_1 = \frac{dV}{dy}, \qquad Z_1 = \frac{dV}{dz}; \qquad V = \frac{1}{kr'}. \tag{4'}$$

It seems at first that the indeterminacy remains, since we made no hypotheses concerning the value of t, i.e., the transmission speed; and that besides, x is a function of t. It is easy to see, however, that the terms appearing in our formulas, $x - \xi t, y, z,$ do not depend on t.

We see that if the two bodies translate together, the force acting on the attracted body is perpendicular to an ellipsoid, at the center of which lies the attracting body.

To advance further, we need to look for the *invariants of the Lorentz group*.

We know that the substitutions of this group (assuming $l = 1$) are linear substitutions that leave unaltered the quadratic form

$$x^2 + y^2 + z^2 - t^2.$$

Let us also put:

$$\xi = \frac{\delta x}{\delta t}, \qquad \eta = \frac{\delta y}{\delta t}, \qquad \zeta = \frac{\delta z}{\delta t};$$

$$\xi_1 = \frac{\delta_1 x}{\delta_1 t}, \qquad \eta_1 = \frac{\delta_1 y}{\delta_1 t}, \qquad \zeta_1 = \frac{\delta_1 z}{\delta_1 t};$$

we see that the Lorentz transformation will make $\delta x, \delta y, \delta z, \delta t,$ and $\delta_1 x, \delta_1 y, \delta_1 z, \delta_1 t$ undergo the same linear substitutions as x, y, z, t.

Let us regard

$$\begin{array}{llll} x, & y, & z, & t\sqrt{-1}, \\ \delta x, & \delta y, & \delta z, & \delta t\sqrt{-1}, \\ \delta_1 x, & \delta_1 y, & \delta_1 z, & \delta_1 t\sqrt{-1}, \end{array}$$

as the coordinates of 3 points P, P', P'' in space of 4 dimensions. We see that the Lorentz transformation is merely a rotation in this space about the origin, assumed fixed. Consequently, we will have no distinct invariants apart from the 6 distances between the 3 points P, P', P'', considered separately and with the origin, or, if one prefers, | apart from the two expressions [169]

$$x^2 + y^2 + z^2 - t^2, \qquad x\delta x + y\delta y + z\delta z - t\delta t,$$

or the 4 expressions of like form deduced from an arbitrary permutation of the 3 points P, P', P''.

But what we seek are invariants that are functions of the 10 variables (2). Therefore, among the combinations of our 6 invariants we must find those depending only on these 10 variables, i.e., those that are 0th degree homogeneous with respect both to $\delta x, \delta y, \delta z, \delta t$, and to $\delta_1 x, \delta_1 y, \delta_1 z, \delta_1 t$. We will then be left with 4 distinct invariants:

$$\sum x^2 - t^2, \qquad \frac{t - \sum x\xi}{\sqrt{1 - \sum \xi^2}}, \qquad \frac{t - \sum x\xi_1}{\sqrt{1 - \sum \xi_1^2}}, \qquad \frac{1 - \sum \xi\xi_1}{\sqrt{(1 - \sum \xi^2)(1 - \sum \xi_1^2)}}. \tag{5}$$

Next let us see how the force components are transformed; we recall the equations (11) of section 1, that refer not to the force X_1, Y_1, Z_1, considered at present, but to the force per unit volume: X, Y, Z.

We designate moreover

$$T = \sum X\xi;$$

we will see that (11) can be written $(l = 1)$:

$$\left.\begin{array}{ll} X' = k(X + \varepsilon T), & T' = k(T + \varepsilon X), \\ Y' = Y, & Z' = Z; \end{array}\right\} \tag{6}$$

in such a way that X, Y, Z, T undergo the same transformation as x, y, z, t. Consequently, the group invariants will be

$$\sum X^2 - T^2, \qquad \sum Xx - Tt, \qquad \sum X\delta x - T\delta t, \qquad \sum X\delta_1 x - T\delta_1 t.$$

However, it is not X, Y, Z, that we need, but X_1, Y_1, Z_1, with

$$T_1 = \sum X_1 \xi.$$

We see that

$$\frac{X_1}{X} = \frac{Y_1}{Y} = \frac{Z_1}{Z} = \frac{T_1}{T} = \frac{1}{\rho}.$$

Therefore, the Lorentz transformation will act in the same manner on X_1, Y_1, Z_1, T_1 as on X, Y, Z, T, except that these expressions will be multiplied moreover by

$$\frac{\rho}{\rho'} = \frac{1}{k(1 + \xi\varepsilon)} = \frac{\delta t}{\delta t'}.$$

Likewise, the Lorentz transformation will act in the same way on $\xi, \eta, \zeta, 1$ as on $\delta x, \delta y, \delta z, \delta t$, except that these expressions will be multiplied moreover by the *same* factor:

$$\frac{\delta t}{\delta t'} = \frac{1}{k(1+\xi\varepsilon)}.$$

Next we consider $X, Y, Z, T\sqrt{-1}$ as the coordinates of a fourth point | Q; the [170]
invariants will then be functions of the mutual distances of the five points

$$O, \quad P, \quad P', \quad P'', \quad Q$$

and among these functions we must retain only those that are 0th degree homogeneous with respect, on one hand, to

$$X, \quad Y, \quad Z, \quad T, \quad \delta x, \quad \delta y, \quad \delta z, \quad \delta t$$

(variables that can be replaced further by $X_1, Y_1, Z_1, T_1, \xi, \eta, \zeta, 1$), and on the other hand, with respect to[6]

$$\delta_1 x, \quad \delta_1 y, \quad \delta_1 z, \quad \delta_1 t$$

(variables that can be replaced further by $\xi_1, \eta_1, \zeta_1, 1$).

In this way we find, beyond the four invariants (5), four distinct new invariants:

$$\frac{\sum X_1^2 - T_1^2}{1-\sum\xi^2}, \quad \frac{\sum X_1 x - T_1 t}{\sqrt{1-\sum\xi^2}}, \quad \frac{\sum X_1\xi_1 - T_1}{\sqrt{1-\sum\xi^2}\sqrt{1-\sum\xi_1^2}}, \quad \frac{\sum X_1\xi - T_1}{1-\sum\xi^2}. \tag{7}$$

The latter invariant is always null according to the definition of T_1.

These terms being settled, what conditions must be satisfied?

1° The first term of (1), defining the velocity of propagation, has to be a function of the 4 invariants (5).

A wealth of hypotheses can obviously be entertained, of which we will examine only two:

A) We can have

$$\sum x^2 - t^2 = r^2 - t^2 = 0,$$

from whence $t = \pm r$, and, since t has to be negative, $t = -r$. This means that the velocity of propagation is equal to that of light. It seems at first that this hypothesis ought to be rejected outright. Laplace showed in effect that the propagation is either instantaneous or much faster than that of light. However, Laplace examined the hypothesis of finite propagation velocity *ceteris non mutatis*; here, on the contrary, this hypothesis is conjoined with many others, and it may be that between them a more or less perfect compensation takes place. The application of the Lorentz transformation has already provided us with numerous examples of this.

B) We can have

$$\frac{t-\sum x\xi_1}{\sqrt{1-\sum\xi_1^2}} = 0, \qquad t = \sum x\xi_1.$$

The propagation velocity is therefore much faster than that of light, but in certain cases t could be positive, which, as we mentioned, seems hardly admissible.[7] *We will therefore stick with hypothesis* (A).

2° The four invariants (7) ought to be functions of the invariants (5).

[171] 3° When the two bodies are at absolute rest, X_1, Y_1, Z_1 ought to have the | values given by Newton's law, and when they are at relative rest, the values given by (4).

For the case of absolute rest, the first two invariants (7) ought to reduce to

$$\sum X_1^2, \qquad \sum X_1 x,$$

or, by Newton's law, to

$$\frac{1}{r^4}, \qquad -\frac{1}{r};$$

in addition, according to hypothesis (A), the 2nd and 3rd invariants in (5) become:

$$\frac{-r-\sum x\xi}{\sqrt{1-\sum \xi^2}}, \qquad \frac{-r-\sum x\xi_1}{\sqrt{1-\sum \xi_1^2}},$$

that is, for absolute rest,

$$-r, \qquad -r.$$

We may therefore admit, *for example*, that the first two invariants in (7) reduce to[8]

$$\frac{(1-\sum \xi_1^2)^2}{(r+\sum x\xi_1)^4}, \qquad -\frac{\sqrt{1-\sum \xi_1^2}}{r+\sum x\xi_1};$$

although other combinations are possible.

A choice must be made among these combinations, and furthermore, we need a 3rd equation in order to define X_1, Y_1, Z_1. In making such a choice, we should try to come as close as possible to Newton's law. Let us see what happens when we neglect the squares of the velocities ξ, η, etc. (still letting $t = -r$). The 4 invariants (5) then become:

$$0, \qquad -r-\sum x\xi, \qquad -r-\sum x\xi_1, \qquad 1$$

and the 4 invariants (7) become:

$$\sum X_1^2, \qquad \sum X_1(x+\xi r), \qquad \sum X_1(\xi_1-\xi), \qquad 0.$$

Before we can make a comparison with Newton's law, another transformation is required. In the case under consideration, $x_0+x, y_0+y, z_0+z,$ represent the coordinates of the attracting body at the instant t_0+t, and $r = \sqrt{\Sigma x^2}$. With Newton's law we have to consider the coordinates of the attracting body $x_0+x_1, y_0+y_1, z_0+z_1$ at the instant t_0, and the distance $r_1 = \sqrt{\sum x_1^2}$.

We may neglect the square of the time t required for propagation, and proceed, consequently, as if the motion were uniform; we then have:

$$x = x_1 + \xi_1 t, \quad y = y_1 + \eta_1 t, \quad z = z_1 + \zeta_1 t, \quad r(r - r_1) = \sum x \xi_1 t;$$

or, since $t = -r$, [172]

$$x = x_1 - \xi_1 r, \quad y = y_1 - \eta_1 r, \quad z = z_1 - \zeta_1 r, \quad r = r_1 - \sum x \xi_1;$$

such that our 4 invariants (5) become:

$$0, \quad -r_1 + \sum x(\xi_1 - \xi), \quad -r_1, \quad 1$$

and our 4 invariants (7) become:

$$\sum X_1^2, \quad \sum X_1[x_1 + (\xi - \xi_1)r_1], \quad \sum X_1(\xi_1 - \xi), \quad 0.$$

In the second of these expressions I wrote r_1 instead of r, because r is multiplied by $\xi - \xi_1$ and because I neglect the square of ξ.

For these 4 invariants (7), Newton's law would yield

$$\frac{1}{r_1^4}, \quad -\frac{1}{r_1} - \frac{\sum x_1(\xi - \xi_1)}{r_1^2}, \quad \frac{\sum x_1(\xi - \xi_1)}{r_1^3}, \quad 0.$$

Therefore, if we designate the 2nd and 3rd of the invariants (5) as A and B, and the first 3 invariants of (7) as M, N, P we will satisfy Newton's law to first-order terms in the square of velocity by setting:

$$M = \frac{1}{B^4}, \qquad N = \frac{+A}{B^2}, \qquad P = \frac{A - B}{B^3}. \tag{8}$$

This solution is not unique. Let C be the 4th invariant in (5); $C - 1$ is of the order of the square of ξ, and it is the same with $(A - B)^2$.

The solution (8) appears at first to be the simplest, nevertheless, it may not be adopted. In fact, since M, N, P are functions of X_1, Y_1, Z_1, and $T_1 = \sum X_1 \xi$, the values of X_1, Y_1, Z_1 can be drawn from these three equations (8), but in certain cases these values would become imaginary.

To avoid this difficulty we will proceed in a different manner. Let us put:

$$k_0 = \frac{1}{\sqrt{1 - \sum \xi^2}}, \qquad k_1 = \frac{1}{\sqrt{1 - \sum \xi_1^2}},$$

which is justified by analogy with the notation

$$k = \frac{1}{\sqrt{1 - \varepsilon^2}},$$

featured in the Lorentz substitution.

In this case, and in light of the condition $-r = t$, the invariants (5) become:

$$0, \quad A = -k_0(r + \sum x\xi), \quad B = -k_1(r + \sum x\xi_1), \quad C = k_0 k_1(1 - \sum \xi\xi_1).$$

[173] Moreover, we notice that the following systems of quantities:

$$\begin{array}{llll} x, & y, & z, & -r = t \\ k_0 X_1, & k_0 Y_1, & k_0 Z_1, & k_0 T_1 \\ k_0\xi, & k_0\eta, & k_0\zeta, & k_0 \\ k_1\xi_1, & k_1\eta_1, & k_1\zeta_1, & k_1 \end{array}$$

undergo the *same* linear substitutions when the transformations of the Lorentz group are applied to them. We are led thereby to put:

$$\left.\begin{aligned} X_1 &= x\frac{\alpha}{k_0} + \xi\beta + \xi_1\frac{k_1}{k_0}\gamma, \\ Y_1 &= y\frac{\alpha}{k_0} + \eta\beta + \eta_1\frac{k_1}{k_0}\gamma, \\ Z_1 &= z\frac{\alpha}{k_0} + \zeta\beta + \zeta_1\frac{k_1}{k_0}\gamma, \\ T_1 &= -r\frac{\alpha}{k_0} + \beta + \frac{k_1}{k_0}\gamma. \end{aligned}\right\} \tag{9}$$

It is clear that if α, β, γ are invariants, X_1, Y_1, Z_1, T_1 will satisfy the fundamental condition, i.e., the Lorentz transformations will make them undergo an appropriate linear substitution.

However, for equations (9) to be compatible we must have

$$\sum X_1\xi - T_1 = 0,$$

which becomes, replacing X_1, Y_1, Z_1, T_1 with their values in (9) and multiplying by k_0^2,

$$-A\alpha - \beta - C\gamma = 0. \tag{10}$$

What we would like is that the values of X_1, Y_1, Z_1 remain in line with Newton's law when we neglect (as above) the squares of velocities ξ, etc. with respect to the square of the velocity of light, and the products of acceleration and distance.

We could select

$$\beta = 0, \qquad \gamma = -\frac{A\alpha}{C}.$$

To the adopted order of approximation, we obtain

$$k_0 = k_1 = 1, \qquad C = 1, \qquad A = -r_1 + \sum x(\xi_1 - \xi), \qquad B = -r_1,$$
$$x = x_1 + \xi_1 t = x_1 - \xi_1 r.$$

The 1st equation in (9) then becomes

$$X_1 = \alpha(x - A\xi_1).$$

But if the square of ξ is neglected, $A\xi_1$ can be replaced by $-r_1\xi_1$ or | by $-r\xi_1$, [174] which yields:

$$X_1 = \alpha(x + \xi_1 r) = \alpha x_1.$$

Newton's law would yield

$$X_1 = -\frac{x_1}{r_1^3}.$$

Consequently, we must select a value for the invariant α, which reduces to $-\frac{1}{r_1^3}$ in the adopted order of approximation, that is, $\frac{1}{B^3}$. Equations (9) will become:

$$\left.\begin{aligned} X_1 &= \frac{x}{k_0 B^3} - \xi_1 \frac{k_1}{k_0}\frac{A}{B^3 C}, \\ Y_1 &= \frac{y}{k_0 B^3} - \eta_1 \frac{k_1}{k_0}\frac{A}{B^3 C}, \\ Z_1 &= \frac{z}{k_0 B^3} - \zeta_1 \frac{k_1}{k_0}\frac{A}{B^3 C}, \\ T_1 &= -\frac{r}{k_0 B^3} - \frac{k_1}{k_0}\frac{A}{B^3 C}. \end{aligned}\right\} \tag{11}$$

We notice first that the corrected attraction is composed of two components: one parallel to the vector joining the positions of the two bodies, the other parallel to the velocity of the attracting body.

Remember that when we speak of the position or velocity of the attracting body, this refers to its position or velocity at the instant the gravitational wave takes off; for the attracted body, on the contrary, this refers to the position or velocity at the instant the gravitational wave arrives, assuming that this wave propagates with the velocity of light.

I believe it would be premature to seek to push the discussion of these formulas further; I will therefore confine myself to a few remarks.

1° The solutions (11) are not unique; we may, in fact, replace the global factor $\frac{1}{B^3}$, by

$$\frac{1}{B^3} + (C-1) f_1(A, B, C) + (A - B)^2 f_2(A, B, C),$$

where f_1 and f_2 are arbitrary functions of A, B, C. Alternatively, we may forgo setting β to zero, but add any complementary terms to α, β, γ that satisfy condition (10) and are of second order with respect to the ξ for α and of first order for β and γ.

2° The first equation in (11) may be written:

$$X_1 = \frac{k_1}{B^3C}[x(1-\sum\xi\xi_1)+\xi_1(r+\sum x\xi)] \tag{11'}$$

and the quantity in brackets itself may be written:

$$(x+r\xi_1)+\eta(\xi_1 y-x\eta_1)+\zeta(\xi_1 z-x\zeta_1), \tag{12}$$

[175] | such that the total force may be separated into three components corresponding to the three parentheses of expression (12); the first component is vaguely analogous to the mechanical force due to the electric field, the two others to the mechanical force due to the magnetic field; to extend the analogy I may, in light of the first remark, replace $1/B^3$ in (11) by $C/(B^3,)$ in such a way that X_1, Y_1, Z_1 are linear functions of the attracted body's velocity ξ, η, ζ, since C has vanished from the denominator of (11').

Next we put:

$$\left.\begin{array}{lll} k_1(x+r\xi_1) = \lambda, & k_1(y+r\eta_1) = \mu, & k_1(z+r\zeta_1) = \nu, \\ k_1(\eta_1 z-\zeta_1 y) = \lambda', & k_1(\zeta_1 x-\xi_1 z) = \mu', & k_1(\xi_1 y-x\eta_1) = \nu'; \end{array}\right\} \tag{13}$$

and since C has vanished from the denominator of (11'), it will follow that:

$$\left.\begin{aligned} X_1 &= \frac{\lambda}{B^3}+\frac{\eta\nu'-\zeta\mu'}{B^3}, \\ Y_1 &= \frac{\mu}{B^3}+\frac{\zeta\lambda'-\xi\nu'}{B^3}, \\ Z_1 &= \frac{\nu}{B^3}+\frac{\xi\mu'-\eta\lambda'}{B^3}; \end{aligned}\right\} \tag{14}$$

and we will have moreover:

$$B^2 = \sum\lambda^2-\sum\lambda'^2. \tag{15}$$

Now λ, μ, ν, or $\frac{\lambda}{B^3}, \frac{\mu}{B^3}, \frac{\nu}{B^3}$, is an electric field of sorts, while λ', μ', ν', or rather $\frac{\lambda'}{B^3}, \frac{\mu'}{B^3}, \frac{\nu'}{B^3}$, is a magnetic field of sorts.

3° The postulate of relativity would compel us to adopt solution (11), or solution (14), or any solution at all among those derived on the basis of the first remark. However, the first question to ask is whether or not these solutions are compatible with astronomical observations. The deviation from Newton's law is of the order of ξ^2, i.e., 10000 times smaller than if it were of the order of ξ, i.e., if the propagation were to take place with the velocity of light, *ceteris non mutatis*; consequently, it is legitimate to hope that it will not be too large. To settle this question, however, would require an extended discussion.

MECHANICS AND THE RELATIVITY POSTULATE

Originally published as "Mechanik und Relativitätspostulat," appended to "Die Grundgleichungen für elektromagnetischen Vorgänge in bewegten Körpern" in Nachrichten der Königlichen Gesellschaft der Wissenschaften zu Göttingen, Mathematisch-Physikalische Klasse, 1908, pp. 53–111.

It would be highly unsatisfactory if the new conception of the notion of time, which is [98]
characterized by the freedom of Lorentz transformations, could be accepted as valid for only a subfield of physics.

Now, many authors state that classical mechanics is opposed to the relativity postulate, which has been taken here to be the foundation of electrodynamics.

In order to assess this we focus on a special Lorentz transformation as represented by eqs. (10), (11), (12),[1] with a non-zero vector v of arbitrary direction, and magnitude q that is <1. But for the moment we will pretend that the ratio of the unit of length and the unit of time has not yet been established, and accordingly we will write in these equations $ct, ct', \frac{q}{c}$ instead of t, t', q, where c is a certain positive constant, and we must have $q < c$. The equations referred to then become

$$\mathfrak{r}_{\bar{\mathrm{v}}}{}' = \mathfrak{r}_{\bar{\mathrm{v}}}, \qquad \mathfrak{r}_{\mathrm{v}}{}' = \frac{c(\mathfrak{r}_{\mathrm{v}} - qt)}{\sqrt{c^2 - q^2}}, \qquad t' = \frac{-q\mathfrak{r}_{\mathrm{v}} + c^2 t}{c\sqrt{c^2 - q^2}};$$

we recall that $\mathfrak{r}$ means the spatial vector x, y, z, and $\mathfrak{r}'$ means the spatial vector x', y', z'.
In these equations we fix v and pass to the limit $c = \infty$, with the result

$$\mathfrak{r}_{\bar{\mathrm{v}}}{}' = \mathfrak{r}_{\bar{\mathrm{v}}}, \qquad \mathfrak{r}_{\mathrm{v}}{}' = \mathfrak{r}_{\mathrm{v}} - qt, \qquad t' = t.$$

| These new equations would mean a transition from the system of spatial coordinates [99]
x, y, z to another spatial coordinate system x', y', z' with parallel axes, whose origin moves with respect to the first in a straight line with constant velocity, while the time parameter would be totally unaffected.

On the basis of this remark one may state:

Classical mechanics postulates covariance of the laws of physics for the group of homogeneous linear transformations of the expression

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

$$-x^2 - y^2 - z^2 + c^2 t^2 \quad (1)$$

into itself, with the specification $c = \infty$.

Now it would be downright confusing to find in one subfield of physics a covariance of the laws for transformations of expression (1) into itself with a certain finite c, but with $c = \infty$ in another subfield. That Newtonian mechanics could only claim this covariance for $c = \infty$, and could not devise it with c equal to the speed of light, needs no explanation. But is it not legitimate today to try and regard that traditional covariance for $c = \infty$ as only an approximation, gained from preliminary experience, to a more exact covariance of the laws of nature for a certain finite c?

I want to explain in detail that by *reforming mechanics, replacing Newton's relativity postulate with* $c = \infty$ *by one with a finite* c, the axiomatic construction of mechanics even seems to attain considerable perfection.

The ratio of the unit of time to the unit of length shall be normalized so that the relevant relativity postulate has $c = 1$.

When I now want to transfer geometrical pictures to the manifold of the four variables x, y, z, t, it may be convenient for ease of understanding what follows to exclude totally y, z from consideration at first, and to interpret x and t as arbitrary oblique-angled rectilinear coordinates in a plane.

A spacetime origin $O(x, y, z, t = 0, 0, 0, 0)$ remains fixed under the Lorentz transformations. The object

$$-x^2 - y^2 - z^2 + t^2 = 1, \qquad t > 0, \quad (2)$$

[100] | a *hyperbolic shell*, includes the spacetime point $A(x, y, z, t = 0, 0, 0, 1)$ and all spacetime points A' that appear as $(x', y', z', t' = 0, 0, 0, 1)$ in the new components x', y', z', t' after some Lorentz transformation.

The direction of a radius vector OA' from O to a point A' of (2) and the directions of the tangents to (2) at A' shall be called *normal* to each other.

Let us follow a definite point in the matter on its orbit for all times t. I call the totality of the spacetime points x, y, z, t, that correspond to this point at different times t a *spacetime line* [world line].[2]

The problem of determining the motion of matter is to be understood in this way: *For every spacetime point the direction of the spacetime line running through it is to be determined.*

To *transform* a spacetime point $P(x, y, z, t)$ *to rest* means to introduce by a Lorentz-transformation a system of reference x', y', z', t' such that the t'-axis OA' acquires that direction which is exhibited by the spacetime line running through P. The space $t' = \text{const.}$, which is to be laid down through P, shall be called the *normal* space to the spacetime line at P. To the increment dt of time t starting at P there corresponds the increment[1]

1 We resume the earlier conventions (see sections 3 and 4) for the notation with indices and the symbols $\mathfrak{w}, w$. [3]

$$d\tau = \sqrt{dt^2 - dx^2 - dy^2 - dz^2} = dt\sqrt{1 - \mathfrak{w}^2} = \frac{dx_4}{w_4} \tag{3}$$

of the parameter t' to be introduced in this construction. The value of the integral

$$\int d\tau = \int \sqrt{-(dx_1^2 + dx_2^2 + dx_3^2 + dx_4^2)},$$

calculated over the spacetime line from any fixed initial point P^0 to an endpoint P, taken to be variable, shall be called the *proper time* of the corresponding point of the matter at the spacetime point P. (This is a generalization of the concept of *local time* introduced by Lorentz for uniform motion.)

If we take a spatially extended body R^0 at a particular time t^0, then the region of all the spacetime lines passing through the spacetime points R^0, t^0 shall be called a *spacetime thread* [pencil].

If we have an analytic expression $\Theta(x, y, z, t)$, such that $\Theta(x, y, z, t) = 0$ is met at one point by every spacetime line of the thread, where |

$$-\left(\frac{\partial\Theta}{\partial x}\right)^2 - \left(\frac{\partial\Theta}{\partial y}\right)^2 - \left(\frac{\partial\Theta}{\partial z}\right)^2 + \left(\frac{\partial\Theta}{\partial t}\right)^2 > 0, \qquad \frac{\partial\Theta}{\partial t} > 0$$ [101]

then we will call the set Q of the meeting points involved a *cross section* of the tread. At every point $P(x, y, z, t)$ of such a cross section we can introduce a system of reference x', y', z', t' by means of a Lorentz-transformation such that thereafter we have

$$\frac{\partial\Theta}{\partial x'} = 0, \qquad \frac{\partial\Theta}{\partial y'} = 0, \qquad \frac{\partial\Theta}{\partial z'} = 0, \qquad \frac{\partial\Theta}{\partial t'} > 0$$

The direction of the corresponding unique t'-axis shall be called the *upper normal* [future-pointing normal] of the cross section Q at the point P, and the value $dJ = \iiint dx'dy'dz'$ for a neighborhood of P within the cross section shall be called an *element of volume content* [*Inhaltselement*] of the cross section. In this sense R^0, t^0 can be called the thread's cross section $t = t^0$ normal to the t-axis, and the volume of the body R^0 can be called the *volume content* [*Inhalt*] of this cross section.

By allowing the space R^0 to converge to a point we arrive at the concept of an *infinitely thin* spacetime thread. In such a thread we will always think of *one* spacetime line as a somehow distinguished *central line*. Also, we understand by the *proper time of the thread* the proper time measured on this central line; by the *normal section* of the thread its intersections with the spaces that are normal to the central line at its points.

Now we formulate the *principle of conservation of mass*.

To every region R at a time t there belongs a positive quantity, the *mass within R at time t*. If R converges to a point x, y, z, t, then the quotient of this mass and the volume of R shall approach a limit $\mu(x, y, z, t)$, the *mass density* at the spacetime point x, y, z, t.

The principle of mass conservation states: *For an infinitely thin spacetime thread the product* μdJ *of the mass density* μ *at one point* x, y, z, t *of the thread* (i.e., of the central line of the thread) *and the volume content* dJ *of the normal section to the* t*-axis passing through the point is always constant along the entire thread.*

Now the volume content dJ_n of the thread's normal section passing through x, y, z, t is calculated as |

[102]

$$dJ_n = \frac{1}{\sqrt{1-\mathfrak{w}^2}} dJ = -iw_4 dJ = \frac{dt}{d\tau} dJ, \tag{4}$$

and therefore let us define

$$\nu = \frac{\mu}{-iw_4} = \mu\sqrt{1-\mathfrak{w}^2} = \mu\frac{d\tau}{dt} \tag{5}$$

as the *rest-mass density* at the point x, y, z, t. Then the principle of mass conservation can also be formulated as follows:

For an infinitely thin spacetime thread the product of the rest-mass density and the volume content of the normal section at a point of the thread is always constant along the entire thread.

In an arbitrary spacetime thread, fix an initial cross section Q^0 and then a second cross section Q^1, which has those and only those points in common with Q^0 that lie on the thread's boundary, and let the spacetime lines within the thread assume larger values t on Q^1 than on Q^0. The finite region bounded by Q^0 and Q^1 together shall be called a *spacetime sickle* [lens], with Q^0 the *lower* and Q^1 the *upper* boundary of the sickle.

Think of the thread decomposed into many very thin spacetime threads; then to every entrance of a thin thread in the lower boundary of the sickle there corresponds an exit through the upper boundary, where the product νdJ_n formed in the sense of (4) and (5) takes the same value each time. Therefore the difference of the two integrals $\int \nu dJ_n$ vanishes, when the first extends over the upper, the second over the lower boundary of the sickle. According to a well-known theorem of integral calculus this difference equals the integral[4]

$$\iiiint \mathrm{lor}\, \nu\overline{w}\, dx dy dz dt,$$

taken over the whole region of the sickle, where we have (cf. (67) in section 12)[5]

$$\mathrm{lor}\, \nu\overline{w} = \frac{\partial \nu w_1}{\partial x_1} + \frac{\partial \nu w_2}{\partial x_2} + \frac{\partial \nu w_3}{\partial x_3} + \frac{\partial \nu w_4}{\partial x_4}.$$

If the sickle is contracted to one spacetime point x, y, z, t, the consequence of this is the differential equation

$$\mathrm{lor}\,\nu\overline{w} = 0, \tag{6}$$

that is, the *continuity condition* |

$$\frac{\partial\mu\mathfrak{w}_x}{\partial x} + \frac{\partial\mu\mathfrak{w}_y}{\partial y} + \frac{\partial\mu\mathfrak{w}_z}{\partial z} + \frac{\partial\mu}{\partial t} = 0.$$ [103]

Further we form the integral

$$\boldsymbol{N} = \iiiint \nu\, dx dy dz dt. \tag{7}$$

taken over the whole region of a spacetime sickle. We divide the sickle into thin spacetime threads, and further divide each thread into small elements $d\tau$ of its proper time, which are however still large compared to the linear dimension of the normal section; we put the mass of such a thread $\nu dJ_n = dm$ and write τ^0 and τ^1 for the proper time of the thread on the lower resp. upper boundary of the sickle; then the integral (7) can also be interpreted as

$$\iint \nu dJ_n d\tau = \int (\tau^1 - \tau^0) dm$$

over all the threads in the sickle.

Now I consider the spacetime lines within a spacetime sickle as curves made of a substance, consisting of substance-points, and I imagine them subjected to a continuous change in position within the sickle of the following type: The whole curves shall be displaced arbitrarily but with *fixed end points on the lower and upper boundary* of the sickle, and each substance-point on them shall be guided so that it is always displaced *normal to its curve*. The whole process shall be capable of analytic representation by means of a parameter ϑ and the value $\vartheta = 0$ shall correspond to the curves that actually run as spacetime lines inside the sickle. Such a process shall be called a *virtual displacement within the sickle*.

Let the point x, y, z, t in the sickle for $\vartheta = 0$ arrive at $x + \delta x, y + \delta y, z + \delta z, t + \delta t$ for the parameter value ϑ; then the latter quantities are functions of x, y, z, t, ϑ. Let us again consider an infinitely thin spacetime thread at the location x, y, z, t with a normal section of volume content dJ_n, and let $dJ_n + \delta dJ_n$ be the volume content of the normal section at the corresponding location of the varied thread; then we will take the *principle of conservation of mass* into account by assuming at this varied location a rest mass density $\nu + \delta\nu$ according to

$$(\nu + \delta\nu)(dJ_n + \delta dJ_n) = \nu dJ_n = dm, \tag{8}$$

| where ν is understood to be the actual rest mass density at x, y, z, t. According to [104]
this convention the integral (7), extended over the region of the sickle, then varies upon the virtual displacement as a definite function $\boldsymbol{N} + \delta\boldsymbol{N}$ of ϑ, and we will call this function $\boldsymbol{N} + \delta\boldsymbol{N}$ the *mass action* associated with the virtual displacement.

Using index notation we will have:

$$d(x_h + \delta x_h) = dx_h + \sum_k \frac{\partial \delta x_h}{\partial x_k} dx_k + \frac{\partial \delta x_h}{\partial \vartheta} d\vartheta \qquad \begin{pmatrix} k = 1, 2, 3, 4 \\ h = 1, 2, 3, 4 \end{pmatrix}. \tag{9}$$

Now it soon becomes evident by reason of the remarks already made above that the value of $\boldsymbol{N} + \delta\boldsymbol{N}$ for parameter value ϑ will be:

$$\boldsymbol{N} + \delta\boldsymbol{N} = \iiiint \nu \frac{d(\tau + \delta\tau)}{d\tau} dx dy dz dt, \tag{10}$$

taken over the sickle, where $d(\tau + \delta\tau)$ means the quantity derived from

$$\sqrt{-(dx_1 + d\delta x_1)^2 - (dx_2 + d\delta x_2)^2 - (dx_3 + d\delta x_3)^2 - (dx_4 + d\delta x_4)^2}$$

by means of (9) and

$$dx_1 = w_1 d\tau, \quad dx_2 = w_2 d\tau, \quad dx_3 = w_3 d\tau, \quad dx_4 = w_4 d\tau, \quad d\vartheta = 0$$

thus we have

$$\frac{d(\tau + \delta\tau)}{d\tau} = \sqrt{-\sum_h \left(w_h + \sum_k \frac{\partial \delta x_h}{\partial x_k} w_k \right)^2} \qquad \begin{pmatrix} k = 1, 2, 3, 4 \\ h = 1, 2, 3, 4 \end{pmatrix}. \tag{11}$$

Now we want to subject the value of the differential quotient

$$\left(\frac{d(\boldsymbol{N} + \delta\boldsymbol{N})}{d\vartheta} \right)_{(\vartheta = 0)} \tag{12}$$

to a transformation. Since every δx_h as function of the arguments $x_1, x_2, x_3, x_4, \vartheta$ vanishes in general for $\vartheta = 0$, we also have in general $\frac{\partial \delta x_h}{\partial x_k} = 0$ for $\vartheta = 0$. If we now put

$$\left(\frac{\partial \delta x_h}{\partial \vartheta} \right)_{\vartheta = 0} = \xi_h \qquad (h = 1, 2, 3, 4), \tag{13}$$

then it follows by reason of (10) and (11) for the expression (12):

$$-\iiiint \nu \sum_h w_h \left(\frac{\partial \xi_h}{\partial x_1} w_1 + \frac{\partial \xi_h}{\partial x_2} w_2 + \frac{\partial \xi_h}{\partial x_3} w_3 + \frac{\partial \xi_h}{\partial x_4} w_4 \right) dx dy dz dt.$$

For the systems x_1, x_2, x_3, x_4 on the boundary of the sickle, $\delta x_1, \delta x_2, \delta x_3, \delta x_4$ are to
[105] vanish for all values of ϑ, and | therefore also $\xi_1, \xi_2, \xi_3, \xi_4$ are everywhere zero. Accordingly the last integral changes by partial integration into

$$\iiiint \sum_h \xi_h \left(\frac{\partial \nu w_h w_1}{\partial x_1} + \frac{\partial \nu w_h w_2}{\partial x_2} + \frac{\partial \nu w_h w_3}{\partial x_3} + \frac{\partial \nu w_h w_4}{\partial x_4} \right) dx\ dy\ dz\ dt.$$

Herein the expression in parentheses is

$$= w_h \sum_k \frac{\partial \nu w_k}{\partial x_k} + \nu \sum_k w_k \frac{\partial w_h}{\partial x_k}.$$

Here the first sum vanishes due to the continuity condition (6), the second one can be represented as

$$\frac{\partial w_h}{\partial x_1}\frac{dx_1}{d\tau} + \frac{\partial w_h}{\partial x_2}\frac{dx_2}{d\tau} + \frac{\partial w_h}{\partial x_3}\frac{dx_3}{d\tau} + \frac{\partial w_h}{\partial x_4}\frac{dx_4}{d\tau} = \frac{dw_h}{d\tau} = \frac{d}{d\tau}\left(\frac{dx_h}{d\tau}\right)$$

where $d/d\tau$ indicates differential quotients in the direction of the spacetime line of one location. Hence this finally results in *the expression for the differential quotient* (12)

$$\iiiint \nu \left(\frac{dw_1}{d\tau}\xi_1 + \frac{dw_2}{d\tau}\xi_2 + \frac{dw_3}{d\tau}\xi_3 + \frac{dw_4}{d\tau}\xi_4 \right) dx\ dy\ dz\ dt. \tag{14}$$

For a virtual displacement in the sickle we had demanded in addition that the points, considered as points of a substance, should proceed normal to the curves that are formed from them; this means for $\vartheta = 0$ that the ξ_h have to satisfy the *condition*

$$w_1\xi_1 + w_2\xi_2 + w_3\xi_3 + w_4\xi_4 = 0. \tag{15}$$

If we recall the Maxwell stresses in the electrodynamics of bodies at rest and consider on the other hand our results in the sections 12 and 13, then a certain *adaptation of Hamilton's principle* for continuous extended elastic media to the *relativity postulate* suggests itself.

Let there be specified at every spacetime point (as in section 13) a spacetime matrix of the second kind

$$S = \left| \begin{matrix} S_{11}, S_{12}, S_{13}, S_{14}, \\ S_{21}, S_{22}, S_{23}, S_{24}, \\ S_{31}, S_{32}, S_{33}, S_{34}, \\ S_{41}, S_{42}, S_{43}, S_{44}, \end{matrix} \right| = \left| \begin{matrix} X_x, & Y_x, & Z_x, & -iT_x \\ X_y, & Y_y, & Z_y, & -iT_y \\ X_z, & Y_z, & Z_z, & -iT_z \\ -iX_t, & -iY_t, & -iZ_t, & T_t \end{matrix} \right| \tag{16}$$

where $X_x, Y_x, \ldots Z_z, T_x, \ldots X_t, \ldots T_t$ are real quantities. |
For a virtual displacement in a spacetime sickle with the notation as above, let the value of the integral [106]

$$W + \delta W = \iiiint \Big(\sum_{h,k} S_{hk} \frac{\partial(x_k + \delta x_k)}{\partial x_h} \Big) dxdydzdt, \tag{17}$$

over the region of the sickle be called the *stress action* associated with the virtual displacement.

The sum that occurs here is, written out in more detail and with real quantities

$$\begin{aligned} & X_x + Y_y + Z_z + T_t \\ & + X_x \frac{\partial \delta x}{\partial x} + X_y \frac{\partial \delta x}{\partial y} + \ldots + Z_z \frac{\partial \delta z}{\partial z} \\ & - X_t \frac{\partial \delta x}{\partial t} - \ldots + T_x \frac{\partial \delta t}{\partial x} + \ldots + T_t \frac{\partial \delta t}{\partial t}. \end{aligned}$$

Now we will postulate the following *principle of least action* [*Minimalprinzip*] *for mechanics:*

Whenever any spacetime sickle is delimited, then for each virtual displacement in the sickle the sum of the mass action and of the stress action shall always be an extremum for the actually occurring behavior of the spacetime lines in the sickle.

The point of this statement is that for each virtual displacement we shall have (using the notation explained above)

$$\Big(\frac{d(\delta \boldsymbol{N} + \delta W)}{d\vartheta} \Big)_{\vartheta = 0} = 0. \tag{18}$$

By the methods of variational calculus the following four differential equations follow immediately by transformation (14) from this principle of least action, taking into account the condition (15)

$$\nu \frac{dw_h}{d\tau} = K_h + \kappa w_h \qquad (h = 1, 2, 3, 4), \tag{19}$$

where

$$K_h = \frac{\partial S_{1h}}{\partial x_1} + \frac{\partial S_{2h}}{\partial x_2} + \frac{\partial S_{3h}}{\partial x_3} + \frac{\partial S_{4h}}{\partial x_4} \tag{20}$$

are the components of the spacetime vector of the first kind $K = \mathrm{lor} S$ and κ is a factor to be determined from $w\bar{w} = -1$. By multiplying (19) by w_h and then | summing over $h = 1, 2, 3, 4$ one finds $\kappa = K\bar{w}$ and $K + (K\bar{w})w$ clearly becomes a spacetime vector of the first kind *normal* to w. Writing the components of this vector as
[107]

$$X, Y, Z, iT,$$

we arrive at the following *laws for the motion of matter:*

$$
\begin{aligned}
\nu\frac{d}{d\tau}\frac{dx}{d\tau} &= X, \\
\nu\frac{d}{d\tau}\frac{dy}{d\tau} &= Y, \\
\nu\frac{d}{d\tau}\frac{dz}{d\tau} &= Z, \\
\nu\frac{d}{d\tau}\frac{dt}{d\tau} &= T.
\end{aligned}
\tag{21}
$$

Here we have

$$\left(\frac{dx}{d\tau}\right)^2 + \left(\frac{dy}{d\tau}\right)^2 + \left(\frac{dz}{d\tau}\right)^2 = \left(\frac{dt}{d\tau}\right)^2 - 1$$

and

$$X\frac{dx}{d\tau} + Y\frac{dy}{d\tau} + Z\frac{dZ}{d\tau} = T\frac{dt}{d\tau},$$

and by reason of these relations the fourth of the equations (21) could be viewed as a consequence of the first three of them.

From (21) we further derive the laws for the motion of a *point mass*, that is for the course of an infinitely thin spacetime thread.

Let x, y, z, t denote a point of the center line, defined arbitrarily within the thread. We form the equations (21) for the points of the thread's *normal section* through x, y, z, t and integrate their product by the volume element [*Inhaltselement*] of the section over the entire region of the normal section. Let the integrals of the right-hand sides be R_x, R_y, R_z, R_t and m be the constant mass of the thread, yielding

$$
\begin{aligned}
m\frac{d}{d\tau}\frac{dx}{d\tau} &= R_x, \\
m\frac{d}{d\tau}\frac{dy}{d\tau} &= R_y, \\
m\frac{d}{d\tau}\frac{dz}{d\tau} &= R_z, \\
m\frac{d}{d\tau}\frac{dt}{d\tau} &= R_t.
\end{aligned}
\tag{22}
$$

| Here R, with the components R_x, R_y, R_z, iR_t, is again a spacetime vector of the first kind, which is *normal* to spacetime vector of the first kind w, the velocity of the mass point, with components [108]

$$\frac{dx}{d\tau}, \qquad \frac{dy}{d\tau}, \qquad \frac{dz}{d\tau}, \qquad i\frac{dt}{d\tau}.$$

We will call this vector R the *accelerating force* [*bewegende Kraft*] of the mass point.

If, on the other hand, one integrates the equations not over the thread's normal section but correspondingly over a cross section *normal to the t-axis* and passing through x, y, z, t then one obtains (see (4)) the equations (22) multiplied by $d\tau/dt$; in particular the last equations is

$$m\frac{d}{dt}\Big(\frac{dt}{d\tau}\Big) = \mathfrak{w}_x R_x \frac{d\tau}{dt} + \mathfrak{w}_y R_y \frac{d\tau}{dt} + \mathfrak{w}_z R_z \frac{d\tau}{dt}.$$

The right-hand side will have to be interpreted as the *work done* on the point mass per unit time. The equation itself will then be viewed as the *energy theorem* for the motion of the point mass, and the expression

$$m\Big(\frac{dt}{d\tau} - 1\Big) = m\Big(\frac{1}{\sqrt{1-\mathrm{w}^2}} - 1\Big) = m\Big(\frac{1}{2}|\mathfrak{w}|^2 + \frac{3}{8}|\mathfrak{w}|^4 + \cdots\Big)$$

will be identified with the *kinetic energy* of the point mass.

Since one always has $dt > d\tau$, one could characterize the quotient $(dt - d\tau)/(d\tau)$ as the advancement of time with respect to proper time of the point mass, and then put it as follows: the kinetic energy of the point mass is the product of its mass and the advancement of time with respect to its proper time.

The *quadruplet* of equations (22) again shows the full symmetry in x, y, z, it as demanded by the relativity postulate, *where the fourth equation*, analogous to what we have encountered in electrodynamics, *can be said, as it were, to be more highly evident physically.* On the basis of this symmetry the triplet of the first three equations is to be constructed according to the pattern of the fourth equation, and in view of this circumstance the claim is justified: *If the relativity postulate is put at the head*
[109] *of mechanics, then the complete | laws of motion follow solely from the energy theorem.*

I would not like omit making it plausible that a contradiction to the assumptions of the relativity postulate is not to be expected from the phenomena of *gravitation*.[2]

For $B^*(x^*, y^*, z^*, t^*)$ a fixed spacetime point, the region of all spacetime points $B(x, y, z, t)$ satisfying

$$(x-x^*)^2 + (x-y^*)^2 + (z-z^*)^2 = (t-t^*)^2, \qquad t - t^* \geqq 0 \tag{23}$$

shall be called the *ray object* [future lightcone] of the spacetime point B^*.

This object intersects any spacetime line only in a single spacetime point B, as follows on the one hand from the *convexity* of the object, and on the other hand from the circumstance that all possible directions of the spacetime line are directed from B^* only toward the concave side of the object. B^* shall then be called a *light point* of B.

2 H. Poincaré *Rend. Circ. Matem. Palermo*, Vol. XXI (1906), p. 129 [in this volume] has attempted to make the Newtonian law of attraction compatible with the relativity postulatem, along quite different lines than what I present here.

If the point $B(x, y, z, t)$ in the condition (23) is considered as fixed, and the point $B^*(x^*, y^*, z^*, t^*)$ as variable, then the same relation represents the region of all spacetime points B^* that are light points of B, and one shows in an analogous way that on any spacetime line there always occurs just a single point B^* that is a light point of B.

Let a mass point F of mass m experience an accelerating force, in the presence of another mass point F^* of mass m^* according to the following law. Consider the spacetime threads of F and F^* with center lines contained in them. Let BC be an infinitesimal element of the center line of F, further let B^* and C^* be the light points of B and C, respectively, on the center line of F^*, and let OA' be the radius vector parallel to B^*C^* of the fundamental hyperbolic shell (2), and finally let D^* be the intersection point of the line B^*C^* with its normal space that passes through B. *The accelerating force of the point mass F at the spacetime point B shall now be that spacetime vector of the first kind, normal to BC, which is formed additively from the vector*

$$mm^*\left(\frac{OA'}{B^*D^*}\right)^3 BD^* \tag{24}$$

in the direction BD and a suitable vector* | *in the direction B*C**. Here OA'/B^*D^* [110]
is understood to be the ratio of the two parallel vectors concerned.

It is clear that this definition is to be characterized as covariant with respect to the Lorentz group.

Now we ask how the spacetime thread of F behaves according to these considerations if the point mass F^* executes uniform translational motion, so that the center line of the thread of F^* is a straight line. We shift the spacetime origin O to it and can then introduce this straight line as the t-axis by means of a Lorentz transformation. Now let x, y, z, t mean the point B and τ^* the proper time of the point B^*, with origin at O. Our definition then leads to the equations

$$\frac{d^2x}{d\tau^2} = -\frac{m^*x}{(t-\tau^*)^3}, \qquad \frac{d^2y}{d\tau^2} = -\frac{m^*y}{(t-\tau^*)^3}, \qquad \frac{d^2z}{d\tau^2} = -\frac{m^*z}{(t-\tau^*)^3} \tag{25}$$

and

$$\frac{d^2t}{d\tau^2} = -\frac{m^*}{(t-\tau^*)^2}\frac{d(t-\tau^*)}{dt}, \tag{26}$$

where we have

$$x^2+y^2+z^2 = (t-\tau^*)^2 \tag{27}$$

and

$$\left(\frac{dx}{d\tau}\right)^2+\left(\frac{dy}{d\tau}\right)^2+\left(\frac{dz}{d\tau}\right)^2 = \left(\frac{dt}{d\tau}\right)^2-1. \tag{28}$$

In view of (27) the three equations (25) read the same as the equations for the motion of a mass point under attraction by a fixed center according to Newton's law, except that the time t is replaced by the proper time τ of the mass point. The fourth equation (26) then gives the connection between proper time and time for the point mass.

Now let the orbit of the space point x, y, z for different τ be an ellipse with semi-major axis a and eccentricity e, and let E be its eccentric anomaly, $\boldsymbol{T}$ the increase in proper time for a full execution of an orbit, and finally $n\boldsymbol{T} = 2\pi$, so that for a suitable origin of τ Kepler's equation

$$n\tau = E - e\sin E \tag{29}$$

holds. If we also change the unit of time and denote the speed of light by c, then (28) becomes

$$\left(\frac{dt}{d\tau}\right)^2 - 1 = \left(\frac{m^*}{ac^2}\frac{1 + e\cos E}{1 - e\cos E}\right). \tag{30}$$

[111] | By neglecting c^{-4} compared to 1 it follows that

$$ndt = nd\tau\left(1 + \frac{1}{2}\frac{m^*}{ac^2}\frac{1 + e\cos E}{1 - e\cos E}\right),$$

which by using (29) results in[6]

$$nt + \text{const.} = \left(1 + \frac{1}{2}\frac{m^*}{ac^2}\right)n\tau + \frac{m^*}{ac^2}e\sin E. \tag{31}$$

Here the factor $\dfrac{m^*}{ac^2}$ is the square of the ratio of a certain mean speed of F in its orbit to the speed of light. If we substitute for m^* the mass of the Sun and for a the semi-major axis of the Earth's orbit, then this factor amounts to 10^{-8}.

A law of attraction for masses according to the formulation exhibited above in connection with the relativity postulate would also imply *propagation of gravitation with the speed of light*. In view of the smallness of the periodic term in (31) a decision *against* such a law and the suggested modified mechanics in favor of Newton's law of attraction with Newtonian mechanics should not be derivable from astronomical observations.

EDITORIAL NOTES

[1] The equations (10) to (12) in the actual body of the text (not reproduced here) represent the Lorentz transformations and read

$$\mathfrak{r}'_{\mathfrak{v}} = \frac{\mathfrak{r}_{\mathrm{v}} - qt}{\sqrt{1-q^2}} \text{ for the direction of } \mathfrak{v}, \tag{10}$$

$$\mathfrak{r}'_{\bar{\mathfrak{v}}} = \mathfrak{r}_{\bar{\mathfrak{v}}} \text{ for any direction } \bar{\mathfrak{v}} \text{ perpendicular to } \mathfrak{v}, \tag{11}$$

$$\text{and further } t' = \frac{-q\mathfrak{r}_{\mathfrak{v}} + t}{\sqrt{1-q^2}}. \tag{12}$$

[2] For some of Minkowski's technical terms, the English equivalent according to present-day physics is given in square brackets.

[3] The references are to sections in the actual body of the text. $\mathfrak{w}$ denotes the three-dimensional velocity vector of matter at the given spacetime point, w denotes the corresponding four-vector:

$$\left(\frac{\mathfrak{w}}{\sqrt{1-\mathfrak{w}^2}}, \frac{i}{\sqrt{1-\mathfrak{w}^2}}\right).$$

[4] Minkowski defines lor as the 1×4 matrix

$$\left(\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}\right).$$

[5] Equation (67) in the body of the text reads

$$\mathrm{lor}\bar{s} = \frac{\partial s_1}{\partial x_1} + \frac{\partial s_2}{\partial x_2} + \frac{\partial s_3}{\partial x_3} + \frac{\partial s_4}{\partial x_4}. \tag{67}$$

[6] The eccentricity e in the second term on the right-hand side of eq. (32) has been inserted, correcting an obvious omission.

HENDRIK A. LORENTZ

OLD AND NEW QUESTIONS IN PHYSICS (EXCERPT)

Originally published as "Alte und neue Fragen der Physik" in Physikalische Zeitschrift, 11, 1910, pp. 1234–1257. Based on the Wolfskehl lectures given in Göttingen, 24–29 October 1910. The second and third lectures are translated here (pp. 1236–1244). Lorentz made use of Born's notes from the lecture and submitted the paper on 2 November 1910.

SECOND LECTURE

To discuss Einstein's *principle of relativity* here at Göttingen, where Minkowski was active, seems to me a particularly welcome task.

The significance of this principle can be illuminated from several different angles. We will not speak here of the mathematical aspect of the question, which was given such a splendid treatment by Minkowski, and which was further developed by Abraham, Sommerfeld and others. Rather, after some epistemological remarks about the concepts of space and time, the physical phenomena that may contribute to an experimental test of the principle shall be discussed.

The principle of relativity claims the following: If a physical phenomenon is described by certain equations in the system of reference x, y, z, t, then a phenomenon will also exist that can be described by the same equations in another system of reference x', y', z', t'. Here the two systems of reference are connected by relations containing the speed of light c and expressing the motion of one system with a uniform velocity relative to the other.

If observer A is located in the first, and B in the second system of reference, and each is supplied with measuring rods and clocks at rest in his system, then A will measure the values of x, y, z, t, and B the values of x', y', z', t', where it should be noted that A and B can also use one and the same measuring rod and the same clock. We have to assume that when the first observer somehow hands his rod and clock over to the second observer, they automatically assume the proper length and the proper rate so that B arrives at the values x', y', z', t' from his measurements. Either one will then find the same value for the speed of light, and will quite generally be able to make the same observations.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

Assume there is an aether; then among all systems x, y, z, t a single one would be distinguished by the state of rest of its coordinate axes as well as its clock in the aether. If one associates with this the idea (also held tenaciously by the speaker) that space and time are totally different from each other and that there is a "true time" (simultaneity would then exist independent of location, corresponding to the circumstance that we are able to imagine infinitely large velocities) then it is easily seen that this true time should be shown precisely by clocks that are at rest in the aether. Now, if the principle of relativity were generally valid in nature, then we would of course not be in a position to determine whether the system of reference being used at the moment is the distinguished one. Thus one arrives at the same results as those found when one denies the existence of the aether and of the true time, and regards all systems of reference as equivalent, following Einstein and Minkowski. It is surely up to each individual which of the two schools of thought he wishes to identify with.

In order to discuss the physical aspect of the question, we first have to establish
[1237] the transformation formulas, limiting ourselves to a special form | already used in the year 1887 by W. Voigt in his treatment of the Doppler principle; namely,

$$x' = x, \qquad y' = y, \qquad z' = az - bct, \qquad t' = at - \frac{b}{c}z;$$

where the constants $a > 0$, b satisfy the relation

$$a^2 - b^2 = 1,$$

which entails the identity $x'^2 + y'^2 + z'^2 - c^2t'^2 = x^2 + y^2 + z^2 - c^2t^2$. The origin of the system x', y', z' moves with respect to the system x, y, z in the z- direction with speed $(b/a)c$, which is always less than c. In general we have to assume that every velocity is less than c.

All state variables of any phenomenon, measured in one or the other system are connected by certain transformation formulas. For example, for the speed of a point these are

$$\mathfrak{v}_x' = \frac{\mathfrak{v}_x}{\omega}, \qquad \mathfrak{v}_y' = \frac{\mathfrak{v}_y}{\omega}, \qquad \mathfrak{v}_z' = \frac{a\mathfrak{v}_z - bc}{\omega},$$

where

$$\omega = a - \frac{b\mathfrak{v}_z}{c}.$$

Further we consider a system of points whose velocity is a continuous function of the coordinates. Let dS be a volume element surrounding the point $P(x, y, z)$ at time t; to this value of t there corresponds according to the transformation equations a point P in time t' in the other system of reference, and every point lying in dS at time t has certain [coordinates] x', y', z' for this fixed value of t'. The points x', y', z' fill a volume element dS', which is related to dS as follows[1]

$$dS' = \frac{dS}{\omega}.$$

Let us imagine some agent (matter, electricity etc.) connected with the points, and let us assume that the observer B has occasion to associate with each point the same amount of the agent as the observer A, then the spatial densities must obviously be in the inverse ratio as the volume elements, that is

$$\rho' = \omega\rho.$$

All these relations are reciprocal, that is, the primed and unprimed letters may be interchanged if at the same time b is replaced by $-b$.

The basic equations of the electromagnetic field retain their form under the transformation if the following quantities are introduced:

$$\mathfrak{d}_x' = a\mathfrak{d}_x - b\mathfrak{h}_y, \qquad \mathfrak{d}_y' = a\mathfrak{d}_y + b\mathfrak{h}_x, \qquad \mathfrak{d}_z' = \mathfrak{d}_z,$$
$$\mathfrak{h}_x' = a\mathfrak{h}_x + b\mathfrak{d}_y, \qquad \mathfrak{h}_y' = a\mathfrak{h}_y - b\mathfrak{d}_x, \qquad \mathfrak{h}_z' = \mathfrak{h}_z.$$

Thus in the system x', y', z', t' the following equations hold between these quantities, the transformed space density ρ' and the transformed velocity $\mathfrak{v}'$:

$$\begin{aligned}
\operatorname{div} \mathfrak{d}' &= \rho', \\
\operatorname{div} \mathfrak{h}' &= 0, \\
\operatorname{curl} \mathfrak{h}' &= \frac{1}{c}(\dot{\mathfrak{d}}' + \rho'\mathfrak{v}'), \\
\operatorname{curl} \mathfrak{d}' &= -\frac{1}{c}\dot{\mathfrak{h}}'.
\end{aligned}$$

With this the field equations of the electron theory satisfy the principle of relativity; but there is still the matter of harmonizing the equations of motion of the electrons themselves with this principle.

We will consider somewhat more generally the motion of an arbitrary material point. Here it is useful to introduce the concept of “proper time,” Minkowski’s beautiful invention. According to this there belongs to each point a time of its own, as it were, which is independent of the system of reference chosen; its differential is defined by the equation

$$d\tau = \sqrt{1 - \frac{\mathfrak{v}^2}{c^2}}dt.$$

The expressions formed with the aid of the proper time τ,

$$\frac{d}{d\tau}\frac{dx}{d\tau}, \qquad \frac{d}{d\tau}\frac{dy}{d\tau}, \qquad \frac{d}{d\tau}\frac{dz}{d\tau},$$

which are linear homogeneous functions of the components of the ordinary acceleration, will be called the components of the “Minkowskian acceleration.” We describe the motion of a point by the equations:

$$m\frac{d}{d\tau}\frac{dx}{d\tau} = \mathfrak{K}_x, \text{ etc.},$$

where m is a constant, which we call the “Minkowskian mass.” We designate the vector $\mathfrak{K}$ as the “Minkowskian force.”

It is then easy to derive the transformation formulas for this acceleration and this force; we leave m unchanged. Thus we have

$$\mathfrak{K}_x' = \mathfrak{K}_x, \qquad \mathfrak{K}_y' = \mathfrak{K}_y, \qquad \mathfrak{K}_z' = a\mathfrak{K}_z - \frac{b}{c}(\mathfrak{v}\cdot\mathfrak{K}).$$

The essential point is the following. The principle of relativity demands that if for an actual phenomenon the Minkowskian forces depend in a certain way on the coordinates, velocities, etc. in one system of reference, then the transformed Minkowskian
[1238] forces | depend in the same way on the transformed coordinates, velocities etc. in the other system of reference. This is a special property that must be shared by all forces in nature if the principle of relativity is to be valid. Presupposing this we can calculate the forces acting on moving bodies if we know them for the case of rest. For example, if an electron of charge e is in motion, we consider a system of reference in which it is momentarily at rest. Then the electron in this system is under the influence of the Minkowskian force

$$\mathfrak{K} = c\mathfrak{d};$$

from this it follows by application of the transformation equations for $\mathfrak{K}$ and $\mathfrak{d}$ that the Minkowskian force acting on the electron that moves with velocity $\mathfrak{v}$ in an arbitrary coordinate system amounts to

$$\mathfrak{K} = c\frac{\mathfrak{d} + \frac{1}{c}[\mathfrak{v}\cdot\mathfrak{h}]}{\sqrt{1-\frac{\mathfrak{v}^2}{c^2}}}.$$

This formula does not agree with the usual ansatz of the electron theory, because of the presence of the denominator. The difference is due to the fact that usually one does not operate with our Minkowskian force, but with the “Newtonian force” $\mathfrak{F}$, and we see that these two forces are related as follows for an electron:

$$\mathfrak{F} = \mathfrak{K}\sqrt{1-\frac{\mathfrak{v}^2}{c^2}}.$$

It is to be assumed that this relation is valid for arbitrary material points.

Thus the phenomena of motion can be treated in two different ways, using either the Minkowskian or the Newtonian force. In the latter case the equations of motion take the form

$$\mathfrak{F} = m_1 \mathfrak{j}_1 + m_2 \mathfrak{j}_2,$$

and here $\mathfrak{j}_1$ means the ordinary acceleration in the direction of motion, $\mathfrak{j}_2$ the ordinary normal acceleration, and the factors

$$m_1 = \frac{m}{\sqrt{\left(1 - \frac{\mathfrak{v}^2}{c^2}\right)^3}}, \qquad m_2 = \frac{m}{\sqrt{1 - \frac{\mathfrak{v}^2}{c^2}}},$$

are called the "longitudinal" and the "transverse mass."

Just like the Minkowskian forces, the Newtonian forces that occur in nature must also fulfill certain conditions in order to satisfy the relativity principle. This is the case if, for example, a normal pressure of a constant magnitude p per unit area acts on a surface regardless of the state of motion; then in the transformed system a normal pressure of the same magnitude acts on the corresponding moving surface element. Since we have already recognized the invariance of the field equations, the question of whether the motions in an electron system satisfy the relativity principle amounts merely to an experimental test of the formulas for the longitudinal and transverse masses m_1, m_2; although the experiments of Bucherer and Hupka seem to confirm these formulas, one has not yet arrived at a definitive decision.

Concerning the mass of the electron, one should remember that this is electromagnetic in nature; so it will depend on the distribution of charge within the electron. Therefore the formulas for the mass can be correct only if the charge distribution, and hence also the shape of the electron, vary in a definite way with the velocity. One must assume that an electron, which is a sphere when at rest, becomes an ellipsoid that is flattened in the direction of motion as a result of translation; the amount of flattening is

$$\sqrt{1 - \frac{\mathfrak{v}^2}{c^2}}.$$

If we assume that the shape and size of the electron are regulated by internal forces, then to agree with the relativity principle these forces must have properties such that this flattening occurs by itself when in motion. Regarding this Poincaré has made the following hypothesis. The electron is a charged, expandible skin, and the electrical repulsion of the different points of the electron is balanced by an inner normal tension of unchangeable magnitude. Indeed, according to the above such normal tensions satisfy the relativity principle.

In the same way all molecular forces acting within ponderable matter, as well as the quasi-elastic and resistive forces acting on the electron, have to satisfy certain conditions in order to be in accord with the relativity principle. Then every moving

body will be unchanged for a co-moving observer, but for an observer at rest it will experience a change in dimensions, which is a consequence of the change in molecular forces demanded by these conditions. This also leads automatically to the contraction of bodies, which was already
[1239] | devised earlier to explain the negative outcome of Michelson's interferometer experiment and of all similar experiments that were to determine an influence of the Earth's motion on optical phenomena.

Concerning rigid bodies, as investigated by Born, Herglotz, Noether, and Levi-Civita, the difficulties occurring in the consideration of rotation can surely be relieved by ascribing their rigidity to the action of particularly intense molecular forces.

Finally let us turn to *gravitation*. The relativity principle demands a modification of Newton's law, foremost a propagation of the effect with the speed of light. The possibility of a finite speed of propagation of gravity was already discussed by Laplace, who imagined as the cause of gravity a fluid streaming toward the Sun, which pushes the planets toward the Sun. He found that the speed c of this fluid must be assumed to be at least 100 million times larger than that of light, so that the calculations remain in agreement with the astronomical observations. The necessity of such a large value of c is due to the occurrence of v/c to the first power in his final formulas, where v is the speed of a planet. But if the propagation speed c of gravity is to have the value of the speed of light, as demanded by the relativity principle, then a contradiction with the observations can only be avoided if only quantities of second (and higher) order in v/c occur in the expression for the modified law of gravitation.

Restricting oneself to quantities of second order, one can, on the basis of a suggestive electron-theoretic analogy, easily give a condition that determines the modified law in a unique way. Namely, if one considers the force acting on an electron that moves with a velocity $\mathfrak{v}$,

$$e\left(\mathfrak{d} + \frac{1}{c}[\mathfrak{v}\cdot\mathfrak{h}]\right),$$

then the vectors $\mathfrak{d}$ and $\mathfrak{h}$ depend, in addition, on the velocities $\mathfrak{v}'$ of the electrons that produce the field; in the vector product $[\mathfrak{v}\cdot \mathrm{h}]$, products of the form $\mathfrak{v}\mathfrak{v}'$ do occur, but not the square $\mathfrak{v}^2$ of the speed of the electron under consideration. Accordingly let us assume that in the expression for the attraction acting on the point 1 due to point 2 there is no term in the square of the velocity $\mathfrak{v}_1^2$ of point 1. Then all velocities whatsoever must drop out in a system of reference in which point 2 is at rest $(\mathfrak{v}_2 = 0)$; therefore the law will reduce to the usual Newtonian one in this system. Now making the transition by transforming to an arbitrary coordinate system, one finds that the force acting on point 1 is composed of two parts, the first, an attraction in the direction of the line connecting them of magnitude

$$R + \frac{1}{c^2}\left\{\frac{1}{2}\mathfrak{v}_2^{\,2}R + \frac{1}{2}\mathfrak{v}_{2r}^{\,2}\left(r\frac{dR}{dr} - R\right) - (\mathfrak{v}_1\cdot\mathfrak{v}_2)R\right\},$$

the second, a force in the direction of $\mathfrak{v}_2$ of magnitude

$$\frac{1}{c^2}\mathfrak{v}_{1r}\, R\mathfrak{v}_2\,;$$

here r means the distance between two simultaneous positions of the two points, $\mathfrak{v}_r$ the component of $\mathfrak{v}$ along the connecting line drawn from 1 to 2, and R that function of r which represents the law of attraction in the case of rest ($R = k/r^2$ for Newtonian attraction, $R = kr$ for quasielastic forces). Note that "force" is always understood to be the "Newtonian force," not the "Minkowskian" one. Minkowski, by the way, has given a somewhat different expression for the law of gravity. The latter as well as the one described above can be found in Poincaré.

THIRD LECTURE

At the end of the previous lecture a modified law of gravitation was given, which is in agreement with the relativity principle. Concerning this one should note that the principle of equality of action and reaction is not satisfied.

Now the perturbations that can arise due to those additional second order terms will be discussed. Besides many short-period perturbations, which have no significance, there is a secular motion of the planets' perihelia. Prof. de Sitter computes $6.69''$ per century for Mercury's perturbations. Since Laplace, it has been known that Mercury has an anomalous perihelion motion of $44''$ per century; although this anomaly has the right sign, it is much too large to be explained by those additional terms. Instead, Seeliger attributes it to a perturbation by the carrier of the zodiacal light, | whose mass one can suitably determine in a plausible way. So, from this one [1240] can arrive at no decision, as long as the accuracy of astronomical measurements is not significantly increased. To be absolutely accurate one would also have to take into account the difference between the Earth's "proper time" and the time of the solar system.

A different method to test the validity of the modified law of gravitation can be based on a procedure suggested by Maxwell to decide whether the solar system moves through the aether. If this were the case, then the *eclipses of Jupiter's moons* should be advanced or delayed depending on Jupiter's position with respect to the Earth.

For if the Jupiter-Earth distance is a and the component of the solar system's velocity in the aether in the direction of the line connecting Jupiter to Earth is v, then the time required to cover the distance a in the case of rest, a/c, would be changed to $a/(c+v)$; thus the motion brings about an advance or delay, which amounts to av/c^2 up to terms of second order, and which takes on different values according to the value of the velocity component v, which of course depends on the position of the two planets. Now it is clear that such a dependence of the phenomena on the motion through the aether contradicts the relativity principle.

In order to clear up this contradiction let us simplify the situation schematically. We suppose that the Sun S has a mass that is infinitely large compared to that of the planet. Let the velocity of the solar system coincide with the z- axis, which we lay through the Sun. The intersection points of the planet's orbit with the z- axis are denoted as the upper resp. lower transit, A resp. B. (Fig. 1)

We place the observer at the Sun. At each transit of the planet through the z- axis a signal will propagate towards the Sun. The period of revolution shall be T. When the Sun is at rest the time between an upper and lower transit will be $(1/2)T$ for the assumed circular motion; the same is true for the time between the arrivals of the two light signals. By contrast, if the Sun is in motion in the z- direction, the signal from the upper transit must suffer an advance av/c^2, that from the lower transit a delay of the same amount; if the uniform orbital motion (assumed as self-evident by Maxwell) is preserved without perturbation, the time interval between the arrivals of the light signals of two successive passes would appear alternately increased and decreased by $2av/c^2$. Preservation of the uniform circular motion during a translation through the aether, as is assumed above, is, however, impossible according to the relativity principle. For if we describe the process in a coordinate system that does not take part in the motion, the modified law of gravitation will have to be applied, and this results in a non-uniform planetary motion, due to which the difference in time intervals between the arrivals of the light signals exactly cancels.

Therefore the determination of whether an advance or delay of the eclipses in fact occurs can be used to decide in favor or against the relativity principle. However, the numerical situation is again rather unfavorable. Thus Mr. Burton, who has access to 330 photometric observations of eclipses of Jupiter's first moon made at the Harvard observatory, estimates the probable error of the final result for v as 50 km/sec; on the other hand, one has observed speeds of stars of 70 km/sec, and the speed of the solar system with respect to the fixed stars is estimated at 20 km/sec. The relativity principle is therefore hardly supported by Burton's calculations; at best they could invalidate it, namely if, for example, the final result were a value exceeding 100 km/sec.

Let us leave it undecided whether or not the new mechanics will receive confirmation by astronomical observations. But we will not fail to familiarize ourselves with some of its basic formulas.

[1241] If one defines work as the scalar product of "Newtonian force" and | displacement, then the equations of motion yield the *energy principle* in its usual form, so that the work done per unit of time equals the increase in energy ε:

$$\mathfrak{F}_x \frac{dx}{dt} + \mathfrak{F}_y \frac{dy}{dt} + \mathfrak{F}_z \frac{dz}{dt} = \frac{d\varepsilon}{dt}.$$

Here *energy* is expressed by

$$\varepsilon = mc^2\left(\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}-1\right);$$

this agrees up to second order terms with the value of the kinetic energy in customary mechanics:

$$\varepsilon = \frac{1}{2}\mathrm{mv}^2.$$

Furthermore, from the equations of motion one can derive *Hamilton's principle*

$$\int_{t_1}^{t_2}(\delta L + \delta A)dt = 0;$$

here δA is the work of the "Newtonian force" upon a virtual displacement and L is the *Lagrangian*, which takes the form

$$L = -mc^2\left(\sqrt{1-\frac{\mathfrak{v}^2}{c^2}}-1\right).$$

From Hamilton's principle one can conversely obtain the equations of motion. The quantities

$$\frac{\partial L}{\partial \dot{x}}, \qquad \frac{\partial L}{\partial \dot{y}}, \qquad \frac{\partial L}{\partial \dot{z}}$$

are to be identified as the *components of the momentum*.

All these formulas can be verified by the electromagnetic equations of motion for an electron. One then has to take the following value for the "Minkowskian mass" m,

$$m = \frac{e^2}{6\pi Rc^2},$$

and to add to the electric and magnetic energy the energy of those internal stresses which determine the shape of the electron, as we saw above. Thus from the general principle of least action for arbitrary electromagnetic systems, discussed in the first lecture, one can obtain Hamilton's principle for a point mass as given above by specialization to an electron, but the work of those internal stresses must be taken into account.

We now go over to a discussion of the *equations of the electromagnetic field for ponderable bodies*. These have been written down purely phenomenologically by Minkowski, then M. Born and Ph. Frank showed that they can also be derived from the ideas of electron theory; by the latter procedure Lorentz himself also found these equations, in a slightly different technical form.

To obtain relations between observable quantities one must smear out the details of the phenomena due to individual electrons by averaging over a large number of them. One is lead to the following equations (which are identical to those of the usual Maxwell theory):

$$\begin{aligned} \operatorname{div}\mathfrak{D} &= \rho_l, \\ \operatorname{div}\mathfrak{B} &= 0, \\ \operatorname{curl}\mathfrak{H} &= \frac{1}{c}(\mathfrak{C} + \dot{\mathfrak{D}}), \\ \operatorname{curl}\mathfrak{E} &= -\frac{1}{c}\dot{\mathfrak{B}}. \end{aligned}$$

Here $\mathfrak{D}$ is the dielectric displacement, $\mathfrak{B}$ the magnetic induction, $\mathfrak{H}$ the magnetic force, $\mathfrak{E}$ the electric force, $\mathfrak{C}$ the electric current, and ρ_l the density of the observable electric charges. Denoting mean values by an overbar we have, for example,

$$\mathfrak{E} = \bar{\mathfrak{d}}, \qquad \mathfrak{B} = \bar{\mathfrak{h}},$$

where $\mathfrak{d}$, $\mathfrak{h}$ have their former meaning; further we have

$$\begin{aligned} \mathfrak{D} &= \mathfrak{E} + \mathfrak{P}, \\ \mathfrak{H} &= \mathfrak{B} - \mathfrak{M} - \frac{1}{c}[\mathfrak{P} \cdot \mathfrak{w}], \end{aligned}$$

where $\mathfrak{P}$ is the electric moment and $\mathfrak{M}$ the magnetization per unit volume, and $\mathfrak{w}$ denotes the velocity of matter. When deriving these formulas one divides the electrons into three types. The first type, the polarization electrons, generate the electric moment $\mathfrak{P}$ by their displacement; the second type, the magnetization electrons, generate the magnetic state $\mathfrak{M}$ by their orbital motion; the third type, the conduction electrons, move freely within the matter and generate the observable charge density ρ_l and the current $\mathfrak{C}$. The latter is additionally to be divided into two parts; for if $\mathfrak{u}$ is the relative velocity of the electrons with respect to the matter, then the total velocity of the electrons is $\mathfrak{v} = \mathfrak{w} + \mathfrak{u}$, hence the current carried by them is

$$\mathfrak{C} = \overline{\rho\mathfrak{v}} = \bar{\rho}\mathfrak{w} + \overline{\rho\mathfrak{u}};$$

$\bar{\rho}$ is the observable charge ρ_l, $\bar{\rho}\mathfrak{w}$ is the convection current, and $\overline{\rho\mathfrak{u}}$ the conduction current proper.

[1242] There are transformation formulas for all these quantities, | and we give a few of them below:

$$\mathfrak{C}_x' = \mathfrak{C}_x, \qquad \mathfrak{C}_y' = \mathfrak{C}_y, \qquad \mathfrak{C}_z' = a\mathfrak{C}_z - bc\rho_l,$$

$$\rho_l' = a\rho_l - \frac{b}{c}\mathfrak{C}_z,$$

$$\mathfrak{P}_x' = a\mathfrak{P}_x - \frac{b}{c}(\mathfrak{w}_z\mathfrak{P}_x - \mathfrak{w}_x\mathfrak{P}_z) + b\mathfrak{M}_y,$$

$$\mathfrak{P}_y' = a\mathfrak{P}_y - \frac{b}{c}(\mathfrak{w}_z\mathfrak{P}_y - \mathfrak{w}_y\mathfrak{P}_z) + b\mathfrak{M}_x,$$

$$\mathfrak{P}_z' = \mathfrak{P}_z.$$

Further, the following auxiliary vectors are useful:

$$\mathfrak{H}_1 = \mathfrak{H} - \frac{1}{c}[\mathfrak{w} \cdot \mathfrak{D}], \qquad \mathfrak{B}_1 = \mathfrak{B} - \frac{1}{c}[\mathfrak{w} \cdot \mathfrak{E}],$$

$$\mathfrak{E}_1 = \mathfrak{E} + \frac{1}{c}[\mathfrak{w} \cdot \mathfrak{B}], \qquad \mathfrak{D}_1 = \mathfrak{D} + \frac{1}{c}[\mathfrak{w} \cdot \mathfrak{H}].$$

Now the field equations given above must still be completed by establishing the relations that exist between the vectors $\mathfrak{E}, \mathfrak{H}$ and $\mathfrak{D}, \mathfrak{B}$. These relations can be obtained in two ways.

The first, phenomenological method proceeds as follows: One considers an arbitrarily moving point of matter and introduces a system of reference in which it is at rest; if the element of volume surrounding the point is isotropic in the rest system, the equation appropriate for bodies at rest (between $\mathfrak{E}$ and $\mathfrak{D}$, for example)

$$\mathfrak{D} = \varepsilon\mathfrak{E}$$

holds; or equally well

$$\mathfrak{D}_1 = \varepsilon\mathfrak{E}_1,$$

because the auxiliary vectors $\mathfrak{D}_1, \mathfrak{E}_1$ are identical with $\mathfrak{D}, \mathfrak{E}$ when $\mathfrak{w} = 0$ But $\mathfrak{D}_1$ and $\mathfrak{E}_1$ transform in the same way, and this implies that also in the original system the equation

$$\mathfrak{D}_1 = \varepsilon\mathfrak{E}_1,$$

and correspondingly

$$\mathfrak{B}_1 = \mu\mathfrak{H}_1,$$

remains valid. Concerning the conduction current we remark only that it depends on $\mathfrak{E}_1$.

The second method has its roots in the mechanics of electrons. Just as the equation $\mathfrak{D} = \varepsilon\mathfrak{E}$ for bodies at rest turns out to be a consequence of the assumption of quasielastic forces, which restore the electrons to their rest positions, so one will obtain the equation $\mathfrak{D}_1 = \varepsilon\mathfrak{E}_1$ for moving bodies if one ascribes to the quasi-elastic forces the properties demanded by the relativity principle. The latter will be satisfied if one takes for these forces the expression of the generalized law of attraction, where R must be taken proportional to r.

The explanation of the resistance to conduction proceeds similarly. A satisfactory electron-theoretic explanation of the magnetic properties of matter is presently not at hand.

Finally the significance of the above equations shall be elucidated in three remarkable cases.

The *first remark* is connected with the equation

$$\rho_l' = a\rho_l - \frac{b}{c}\mathfrak{C}_z.$$

According to this, ρ_l' can vanish without having $\rho_l = 0$ if a current $\mathfrak{C}$ is present; that is, an observer A will declare a body to be charged that must be treated as uncharged by B moving relative to him. One can understand this by noting that every body contains an equal number of positive and negative electrons, which compensate in uncharged bodies. When the body moves with velocity $\mathfrak{w}$ in the presence of a conduction current, the two types of electrons will attain different total velocities, therefore the quantity $\omega = a - b(\mathfrak{v}_z/c)$ will also have different values for the two types. When an observer B moving with the body calculates the mean charge density $\bar{\rho}' = \overline{\omega\rho}$ for both types of electrons he can obtain zero for the sum, even when for an observer A in whose reference frame the body is moving the mean values $\bar{\rho}$ of the positive and negative electrons do not compensate.

This circumstance calls forth the memory of an old question. Around the year 1880 there was a great discussion among physicists about *Clausius' fundamental law* of electrodynamics. One attempted to derive a contradiction between this law and observations by concluding that according to the law a current-carrying conductor on the Earth would have to exert an influence on a co-moving charge e due to the motion of the Earth, which could have been observed. That the law actually does not demand this influence was noted by Budde; this is because the current due to the Earth's motion acts on itself and causes a "compensating charge" in the current-carrying conductor, which exactly cancels the first influence. The electron theory leads
[1243] to similar conclusions, and Lorentz finds |

$$\frac{1}{c^2}\mathfrak{w}_z\,\mathfrak{C}_z\,;$$

for the density of the compensating charge, if the velocity is in the direction of the z- axis; this must be assumed by an observer A who does not take part in the motion of the Earth, whereas it does not exist for a co-moving observer B. The value given above agrees exactly with the formula derived from the relativity principle; for if $\rho_l' = 0$, one finds from this formula

$$\rho_l = \frac{b}{ac}\mathfrak{C}_z,$$

and since, according to what was said in the second lecture on p. 288 [p. 1237 in the original], $\mathfrak{w}_z = bc/a$ is the speed of the two systems of reference with respect to each other, one indeed finds

$$\rho_l = \frac{1}{c^2}\mathfrak{w}_z\mathfrak{E}_z.$$

The *second remark* starts from the transformation equations for the electric moment $\mathfrak{P}$ p. 296 [p. 1241 in the original] in which the presence of the magnetization $\mathfrak{M}$ lets us recognize the impossibility of differentiating precisely between polarization- and magnetization electrons. Rather, in a magnetized body $(\mathfrak{M} \neq 0)$ $\mathfrak{P} = 0$, can vanish when judged from one system of reference, whereas in another $\mathfrak{P}'$ differs from zero. This will now be applied to a special case, where we confine attention to quantities of first order. The body we consider (such as a steel magnet) shall contain only conduction electrons and electrons that produce an $\mathfrak{M}$ but no $\mathfrak{P}$ when the body is at rest; it shall have the shape of an infinitely extended plate, bounded by two planes a, b; the middle plane shall be the yz-plane. (Fig. 2) When it is at rest a constant magnetization $\mathfrak{M}_y$ shall be present, whereas $\mathfrak{P} = 0$. When the body is given a speed v in the z-direction an observer who does not take part in the motion will observe the electric polarization

$$\mathfrak{P}_x = -\frac{v}{c}\mathfrak{M}_y.$$

Now we imagine at either side of the body two conductors c, d, which form together with it two equal condensers, and these shall be shorted out by a wire (from c to d). When there is motion, charges will be created on c and d, which can be calculated as follows. Since a current is clearly impossible in the x-direction, we have $\mathfrak{E}_{lx} = 0$ or $\mathfrak{E}_x = (v/c)\mathfrak{B}_y$. Since the process is stationary we have $\dot{\mathfrak{B}} = 0$; then the existence of a potential φ follows from $\mathrm{curl}\,\mathfrak{E} = 0$. If Δ is the thickness of the slab one has

$$\varphi_a - \varphi_b = \frac{v}{c}\Delta\mathfrak{B}_y.$$

From the symmetry of the arrangement it clearly follows that

$$\varphi_d - \varphi_a = \varphi_b - \varphi_c\ ,$$

and because the plates c, d are shorted out, we must have

$$\varphi_d = \varphi_c\ ;$$

this implies

$$\varphi_d - \varphi_a = -\frac{v}{2c}\Delta\mathfrak{B}_y.$$

If γ is the capacity of one of the two condensers, the charge of plate d becomes

$$-\frac{v}{2c}\gamma\Delta\mathfrak{B}_y,$$

and c receives the equal and opposite amount.

Now we compare this process with the inverse case, that the magnet a, b is at rest and the plates c, d move with the opposite velocity. According to the relativity principle everything would have to be the same as in the first case. Indeed one finds at once from the usual law of induction exactly the amount of charge on plate d given above. But this charge on d must now induce an equal and opposite one on the plane a of the magnet at rest, and corresponding statements must hold for b and c. Since no current can flow $(\mathfrak{C} = 0)$, there must be the same charges on the magnet, whether the magnet is moving and the plates are at rest or conversely. So we have to think how it happens that in the first case the opposite charge appears on the plane a of the moving magnet as on the plate d; this becomes possible only due to the polar-
[1244] ization $\mathfrak{P}_x = -(v/c)\mathfrak{M}_y$ | produced by the motion. For one has

$$\mathfrak{D}_x = \mathfrak{E}_x + \mathfrak{P}_x = \frac{v}{c}\mathfrak{B}_y - \frac{v}{c}\mathfrak{M}_y;$$

since here $\mathfrak{P}$ is to be neglected to first order in the velocity, that is the term $[\mathfrak{P}\cdot\mathfrak{w}]$, we have

$$\mathfrak{B} - \mathfrak{M} = \mathfrak{H},$$

But $\mathfrak{H}$ is zero because we assume the plate to be infinitely extended. This implies

$$\mathfrak{D}_x = 0,$$

i.e., in the moving plate there is no dielectric displacement, so the charge on a corresponds to that on d, as the relativity principle demands.

The *last remark* concerns again the circumstance that according to the relativity principle the motion of the Earth cannot have any influence on electromagnetic processes. But Liénard has pointed out a phenomenon where such an influence is to be expected, an influence of first order in magnitude; Poincaré has also discussed this case in his book *Electricité et Optique*. It concerns the ponderomotive force on a conductor. To determine this force one may make the suggestive ansatz for the force acting on the conduction electrons per unit charge:

$$\mathfrak{E}_1 = \mathfrak{E} + \frac{1}{c}[\mathfrak{v}\cdot\mathfrak{B}];$$

then this results in the force caused by the Earth's motion on the conductor in the direction of the motion by an amount

$$\frac{1}{c^2}(\mathfrak{C}_l\cdot\mathfrak{E})\mathfrak{w}_z;$$

since $(\mathfrak{C}_l \cdot \mathfrak{E})$ is the heat generated by the conduction current $\mathfrak{C}$ this expression is easily calculated numerically (which admittedly results in a value inaccessible to observation).

If one now asks oneself, how this result that contradicts the relativity principle can come about, one finds that indeed one has not calculated the force acting on the matter of the conductor, but on the electrons moving inside the conductor. The latter force must first be transferred to the matter by forces, which are unknown to us in detail, and that happens without change of magnitude only if action equals reaction for the forces between matter and electrons. But for moving bodies action does not equal reaction in this case according to the relativity principle, and this circumstance exactly compensates Liénard's force.

In summary, one can say that there is little prospect for an experimental confirmation of the principle of relativity; except for a few astronomical observations, only measurements of the electron mass are worth considering. But one must not forget that the outcome of the negative experiments, such as Michelson's interference experiment and the experiments to find a double refraction caused by the Earth's motion, can only be explained by the relativity principle.

EDITORIAL NOTE

THE PROBLEM OF GRAVITATION AS A CHALLENGE FOR THE MINKOWSKI FORMALISM

JÜRGEN RENN

THE SUMMIT ALMOST SCALED: MAX ABRAHAM AS A PIONEER OF A RELATIVISTIC THEORY OF GRAVITATION

1. THE FRAGILE LADDER OF THE MINKOWSKI FORMALISM

1.1 Abraham's Bold Step

Today Max Abraham is known mainly for his achievements in the field of electrodynamics and, in particular, for the successful series of textbooks associated with his name.[1] He is, however, largely forgotten as a pioneer of a relativistic theory of gravitation. The papers he dedicated to the subject between 1911 and 1915 are mainly remembered for the controversy with Einstein that they document.[2] In hindsight it is clear that Abraham's approach to a relativistic theory of gravitation—an attempt to formulate a field theory of gravitation in the framework of Minkowski's formalism—would lead to a dead end. However, only by exploring the consequences of this approach did it eventually become clear that it did not lead anywhere. And it was, after all, the failure of Abraham's bold step which encouraged others to either pursue his endeavor through more appropriate means, as was the case with Gunnar Nordström, or to take even bolder steps than Abraham and attempt even higher summits, as was the case with Einstein.[3] In fact, it was largely due to Abraham's efforts that Einstein became familiar with the limits of Minkowski's formalism and also learned how to overcome them.

In the following, we will first review Abraham's attempt to take up the challenge of using Minkowski's formalism as the framework for a relativistic theory of gravitation and then show how this bold step led to an ardent controversy with Einstein which, for Abraham, eventually led to a rejection of relativity theory altogether. We will then consider some of the insights and achievements that Abraham attained in the course of his research, which have been largely forgotten because his approach turned out to lead to a dead end. In short, we will portray Abraham as someone who

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

almost scaled the summit, who aimed high but failed to reach the goal he envisioned. As a consequence of his failure and of criticism by others, he eventually gave up mountain climbing altogether but, at the same time, encouraged others to attempt the summit he had failed to reach, not least because of the magnificent vistas about which, on the basis of his experience, he could report.

The starting point for Abraham's work on a relativistic theory of gravitation were some of the insights that Einstein had attained on the basis of his equivalence principle, in particular the idea of a variable speed of light.[4] Precisely because of this insight, Einstein did not consider Minkowski's formalism to be a useful tool for building up a relativistic theory of gravitation, since he took the constancy of the speed of light to be one of its fundamental principles. Moreover, Einstein was skeptical of such a path for other reasons as well.[5] Abraham, on the other hand, took the bold step of modifying Minkowski's framework by accommodating it to the assumption of a variable speed of light. In this way, he succeeded in overcoming the unacceptably restrictive conditions imposed by the constancy of the speed of light on a straightforward, special relativistic theory of gravitation. Abraham thus became the first to exploit the mathematical potential of Minkowski's four-dimensional formalism for a theory of gravitation.

In the introduction to a paper submitted in December 1911 and published in January 1912, Abraham first of all acknowledges his debt to Einstein's idea concerning the relation between a variable speed of light and the gravitational potential:

> In a recently published paper A. Einstein proposed the hypothesis that the speed of light (c) depends on the gravitational potential (Φ). In the following note, I develop a theory of the gravitational force which satisfies the principle of relativity and derive from it a relation between c and Φ, which in first approximation is equivalent to Einstein's.[6]

Abraham then adopts Minkowski's formalism for his purposes:

> Following Minkowski's presentation we regard
>
> $$x, y, z \qquad \text{and} \qquad u = il = ict \tag{1}$$
>
> as the coordinates of a four-dimensional space.[7]

---

4 See "The First Two Acts" and "The Third Way to General Relativity" (in vol. 1 and vol. 3 of this series respectively).

5 See, for instance, Einstein's comments in his contemporary letters, e.g., to Wilhelm Wien, 11 March 1912 and 17 May 1912, (CPAE 5, Doc. 371 and 395) to which we shall refer later. See also the historical discussion in the "Editorial Note" in (CPAE 4, 122–128).

6 "In einer vor kurzem erschienenen Arbeit hat A. Einstein die Hypothese aufgestellt, daß die Geschwindigkeit des Lichtes (c) vom Gravitationspotential (Φ) abhänge. In der folgenden Note entwickle ich eine Theorie der Schwerkraft, welche dem Prinzip der Relativität genügt, und leite aus ihr eine Beziehung zwischen c und Φ ab, die in erster Annäherung mit der Einsteinschen gleichwertig ist." See (Abraham 1912h, 1). A complete English translation of this paper is given in this volume.

7 "In dem wir der Darstellung Minkowskis folgen, betrachten wir (x, y, z) und $(u = il = ict)$ als Koordinaten eines vierdimensionalen Raumes." (Abraham 1912h, 1)

He immediately proceeds to state a differential equation for the gravitational potential, which essentially corresponds to a four-dimensional generalization of the classical Poisson equation:

> Let the "rest density" ν, as well as the gravitational potential Φ, be scalars in this space, and let them be linked through the differential equation:
>
> $$\frac{\partial^2\Phi}{\partial x^2}+\frac{\partial^2\Phi}{\partial y^2}+\frac{\partial^2\Phi}{\partial z^2}+\frac{\partial^2\Phi}{\partial u^2} = 4\pi\gamma\nu. \tag{2}$$
>
> (γ is the gravitational constant.)[8]

Somewhat later Abraham introduced further Minkowskian concepts and terminology:

> We write $\dot{x}\ \dot{y}\ \dot{z}\ \dot{u}$ for the first derivatives of the coordinates of a material "world point" with respect to its "proper time" τ, i.e., for the components of the "velocity" four-vector $\mathfrak{V}$, and $\ddot{x}\ \ddot{y}\ \ddot{z}\ \ddot{u}$ for the second derivatives, i.e., for the components of the "acceleration" four-vector $\dot{\mathfrak{V}}$.[9]

He then observes that, in Minkowski's formalism, the first derivatives must satisfy a certain relation involving the speed of light:

> Between the first derivatives the following identity holds:
>
> $$\dot{x}^2+\dot{y}^2+\dot{z}^2+\dot{u}^2 = -c^2, \tag{3}$$
>
> or
>
> $$\dot{l}^2\left\{\left(\frac{dx}{dl}\right)^2+\left(\frac{dy}{dl}\right)^2+\left(\frac{dz}{dl}\right)^2-1\right\} = -c^2 \ \ldots .^{10} \tag{4}$$

Finally Abraham derives a relation corresponding to the orthogonality relation between four-velocity and acceleration in ordinary Minkowski space but now under the assumption of a variable speed of light:

> Now, by differentiating eq. (4) [eq. (3)] with respect to proper time, Minkowski obtains the condition of "orthogonality" of the velocity and acceleration four-vectors. However, if c is considered to be variable, the place of that condition is taken by the following:
>
> $$\dot{x}\ddot{x}+\dot{y}\ddot{y}+z'\ddot{z}+\dot{u}\ddot{u} = -c\frac{dc}{d\tau}, \tag{5}$$
>
> as the differentiation of eq. (4) [eq. (3)] shows.[11]

---

8 "Die "Ruhdichte" ν sei ein Skalar in diesem Raume, und ebenso das Schwerkraftpotential Φ; sie mögen miteinander verknüpft sein durch die Differentialgleichung: …(1) [eq. (2)]. (γ ist die Gravitationskonstante.)" (Abraham 1912h, 1)

9 "Wir schreiben $\dot{x}\ \dot{y}\ \dot{z}\ \dot{u}$ für die ersten Ableitungen der Koordinaten eines materiellen "Weltpunktes" nach seiner "Eigenzeit" τ, d. h. für die Komponenten des Vierervektors "Geschwindigkeit" $\mathfrak{V}$, und $\ddot{x}\ \ddot{y}\ \ddot{z}\ \ddot{u}$ für die zweiten Ableitungen, d. h. für die Komponenten des Vierervektors "Beschleunigung $\dot{\mathfrak{V}}$." (Abraham 1912h, 1)

10 "Es besteht zwischen den ersten Ableitung die Identität: …(4) [eq. (3)] oder … [eq. (4)]." (Abraham 1912h, 1–2)

In this way, the introduction of the hypothesis of a variable speed of light makes it possible for Abraham to circumvent a problematic restriction imposed by Minkowski's formalism on a relativistic theory of gravitation.[12] In fact, in a theory with variable c, the four-vectors for velocity and for acceleration no longer have to be orthogonal to each other. It follows that the gravitational potential also no longer has to be constant along the world line of a particle, contrary to the conclusion reached in the usual Minkowski's formalism. Although Abraham's line of attack was clearly stimulated by Einstein's earlier use of a variable speed of light, it thus emerges as being so closely associated with a plausible modification of the four-dimensional formalism that this approach may also be conceived as exploring an independent possibility offered by the contemporary state of the gravitation problem.

In Einstein's papers of 1907 and 1911, the variable speed of light was linked to the gravitational potential via the concept of time in an accelerated frame of reference, i.e., via an essentially kinematic relation, independently of the use of the equivalence principle for transferring the results obtained in an accelerated system to a system with a gravitational field. For Abraham, on the other hand, an analogous relation between the speed of light and the gravitational potential follows if the second derivative terms in equation (5) are identified with the acceleration due to the gravitational force, i.e., from an essentially dynamic relation. Indeed, for the relation between four-dimensional gravitational force and four-dimensional gravitational potential Abraham assumed:

$$\begin{array}{ll} F_x = -\dfrac{\partial\Phi}{\partial x} & F_y = -\dfrac{\partial\Phi}{\partial y} \\ F_z = -\dfrac{\partial\Phi}{\partial z} & F_u = -\dfrac{\partial\Phi}{\partial u} \end{array} \tag{6}$$

He further assumed that the relation between four-acceleration and four-force is analogous to Newton's second law:

$$\begin{array}{ll} \ddot{x} = F_x & \ddot{y} = F_y \\ \ddot{z} = F_z & \ddot{u} = F_u \end{array} \tag{7}$$

With these two relations, equation (5) can now be written as a relation between the speed of light and the gravitational potential:

$$\dot{x}\frac{\partial\Phi}{\partial x} + \dot{y}\frac{\partial\Phi}{\partial y} + z'\frac{\partial\Phi}{\partial z} + \dot{u}\frac{\partial\Phi}{\partial u} = c\frac{dc}{d\tau} \tag{8}$$

---

11 "Nun erhält Minkowski, indem er Gl. (4) [eq. (3)] nach der Eigenzeit differenziert, die Bedingung der "Orthogonalität" der Vierervektoren Geschwindigkeit und Beschleunigung. Wenn jedoch c als veränderlich angesehen wird, tritt an Stelle jener Bedingung die folgende: … (5) [eq. 5] wie die Differentiation von Gl. (4) [eq. (3)] zeigt." (Abraham 1912h, 2)

12 See "Einstein, Nordström and the Early Demise of Scalar, Lorentz Covariant Theories of Gravitation," (in vol. 3 of this series).

which can be rewritten as:

$$\frac{d\Phi}{d\tau} = c\frac{dc}{d\tau}. \tag{9}$$

The last equation in turn can be integrated to yield:

$$\frac{c^2}{2} - \frac{c_0^2}{2} = \Phi - \Phi_0, \tag{10}$$

where c_0 and Φ_0 are the speed of light and the gravitational potential at the origin of coordinates. Abraham comments on this formula:

> *The increase of half the square of the speed of light is equal to the increase of the gravitational potential.*
>
> Instead of this relation, which is exactly valid according to our theory, one can, neglecting the square of the quotient of Φ and c^2, take Einstein's formula (loc. cit. p. 906):
>
> $$c = c_0\left(1 + \frac{\Phi - \Phi_0}{c^2}\right). \tag{11}$$
>
> However, eq. (6) [eq. (10)] better serves to manifest the independence from the arbitrarily chosen origin of coordinates.[13]

Abraham had thus achieved all essential elements of Einstein's research in the years 1907 to 1911, albeit in an entirely different way which, in addition, offered a wealth of mathematical resources for the further elaboration of a full-fledged theory of gravitation.

1.2 Abraham's Mathematics versus Einstein's Physics

While the exploitation of Minkowski's formalism had opened up new mathematical possibilities to Abraham, the physical interpretation of his results had yet to be explored. Whereas Einstein had been aware from the beginning that he was transgressing the limits of his original theory of relativity, Abraham seemed to have been initially convinced that he had found the relativistic theory of gravitation that was called for after the establishment of the principle of relativity, as is clear from his introductory remark quoted above. But since the constancy of the speed of light was one of the foundational elements of special relativity, it was questionable with which right Abraham could make use of relations derived from Minkowski's reformulation of special relativity for a theory in which the speed of light depends on the gravita-

---

13 "*Der Zuwachs des halben Quadrats der Lichtgeschwindigkeit ist gleich dem Zuwachs des Schwerkraftpotentials*. Anstelle dieser, nach unserer Theorie exakt gültigen Beziehung kann man, bei Vernachlässigung des Quadrats des Quotienten aus Φ und c^2, die Einsteinsche Formel setzten (loc. cit. S. 906): … [eq. 11]. Indessen läßt die Formel (6) besser die Unabhängigkeit von dem willkürlich wählbaren Koordinatenursprung hervortreten." [Reference is to (Einstein 1911).] (Abraham 1912h, 2)

tional potential. It seems that Einstein, in a personal communication now lost, immediately brought Abraham's attention to this conflict between the formalism of the latter's theory and one of its fundamental assumptions, the variability of the speed of light.[14]

Abraham's use of the straightforward special relativistic generalization of the Poisson equation (2), as well as of other elements of Minkowski's formalism, without really bothering about the gravity of energy, made Einstein skeptical about Abraham's claims. For Einstein, the gravity of energy and the variability of the speed of light were closely connected:

> It is a great pity that the gravitation theory is leading to so little which is observable. But it nevertheless must be taken seriously because the theory of relativity requires such a further development with urgency since the gravitation vector cannot be integrated into the relativity theory with constant c if one requires the *gravitational* mass of energy.[15]

In Einstein's opinion, a special relativistic framework was hence not the appropriate starting point for coping with the concept of a gravity of energy and for predicting effects such as the gravitational deflection of light, while Abraham, in fact, claimed that he could do so:

> But as far as the bending of light rays in the gravitational field is concerned, which can be derived from (6) [eq. (10)] with the help of Huygens' principle, it is identical with the bending of the trajectories of those light particles. This is one of the numerous incomplete analogies between the modern theory of radiation and the emission theory of light.[16]

Einstein, on the other hand, criticized Abraham's theory for not really explaining the bending of light, probably because it so closely resembled a special relativistic theory:

> I am having a controversy with Abraham because of his theory of gravitation. The latter does in reality not give an account of a bending of light rays.[17]

14 For evidence of this personal communication see the "Correction" ("Berichtigung") to (Abraham 1912h), quoted in note 20.

15 "Es ist sehr schade, dass die Gravitationstheorie zu so wenig Beobachtbarem führt. Aber sie muss trotzdem ernst genommen werden, weil die Relativitätstheorie eine derartige Weiterentwicklung gebieterisch verlangt, indem der Gravitationsvektor in die Rel. Theorie mit konstantem c sich nicht einfügen lässt, wenn man die *schwere* Masse der Energie fordert." Einstein to Wilhelm Wien, 17 May 1912, (CPAE 5, Doc. 395, 465).

16 "Was aber die Krümmung der Lichtstrahlen im Schwerkraftfelde anbelangt, die aus (6) [eq. (10)] mit Hilfe des Huygensschen Prinzips sich ableiten läßt, so ist sie identisch mit der Krümmung der Bahnkurve jener Lichtteilchen. Es ist dies eine der Zahlreichen unvollständigen Analogien zwischen der modernen Strahlungstheorie und der Emissionstheorie des Lichtes." (Abraham 1912h, 2) He referred to Einstein's 1911 paper and also undertook a comparison with light deflection in an emission theory of light.

17 "Ich habe eine Kontroverse mit Abraham wegen dessen Theorie der Gravitation. Dieselbe gibt in Wahrheit von einer Krümmung der Lichtstrahlen nicht Rechenschaft." Einstein to Wilhelm Wien, 27 January 1912, (CPAE 5, Doc. 343, 394).

In later comments Einstein acknowledged that light deflection actually follows from Abraham's theory and concentrated his criticism more generally on what he perceived as an incoherent use of the mathematical formalism of special relativity:

> The theory of Abraham, according to which light is also curved, just as it is in my case, is inconsequent from the point of view of the theory of invariants.[18]

What Einstein meant precisely becomes clearer from another contemporary comment:

> The matter is not, however, as simple as Abraham believes it to be. In particular the principle of the constant c and hence the equivalence of the four dimensions is lost.[19]

Einstein must also have addressed such criticism to Abraham directly. The latter, in any case, reacted to Einstein's arguments by pursuing his modification of Minkowski's formalism in greater depth. In a short note published on 15 February 1912 as a reply to Einstein's critique, Abraham revoked the lines with which he had earlier referred to Minkowski's formalism, instead introducing an infinitesimal line element with variable metric, thus effectively extending Minkowski's spacetime to a more general semi-Riemannian manifold:

> In lines 16, 17 of my note "On the Theory of Gravitation" an oversight has to be corrected which was brought to my attention by a friendly note from Mr. A. Einstein. One should read there: 'we consider dx, dy, dz and $du = idl = icdt$ as components of a displacement $\overrightarrow{ds}$ in four-dimensional space'.
>
> Hence
>
> $$ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2 \tag{12}$$
>
> is the square of the four-dimensional line element where the speed of light c is determined by equation (6) [eq. (10)].[20]

In this way, Abraham had effectively introduced the mathematical representation of the gravitational potential that was to be at the core of later general relativity, the general four-dimensional line element involving a variable metric tensor. However, for the time being, Abraham's expression remained an isolated mathematical formula without context and physical meaning which, at this point, was indeed neither provided by Abraham's nor by Einstein's physical understanding of gravitation. Abraham's expression in particular was neither related to insights about coordinate

---

18 "Die Theorie von Abraham, nach welcher das Licht ebenfalls ebenso wie bei mir gekrümmt ist, ist vom invariantentheoretischen Standpunkt inkonsequent." Einstein to Erwin Freundlich, mid-August 1913, (CPAE 5, Doc. 468, 550).

19 "So einfach, wie Abraham meint, ist die Angelegenheit aber nicht. Insbesondere geht das Prinzip des konstanten c und damit die Gleichwertigkeit der 4 Dimensionen verloren." Einstein to Wilhelm Wien, 11 March 1912, (CPAE 5, Doc. 371, 430).

20 "Auf Z. 16, 17 meiner Note "Zur Theorie der Gravitation" ist ein Versehen zu berichtigen, auf welches ich durch eine freundliche Mitteilung des Herrn A. Einstein aufmerksam geworden bin. Man lese daselbst: 'betrachten wir dx, dy, dz und $du = idl = icdt$ als Komponenten einer Verschiebung $\overrightarrow{ds}$ im vierdimensionalen Raume'. Es ist also $ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2$ das Quadrat des vierdimensionalen Linienelementes, wobei die Lichtgeschwindigkeit c durch G. (6) bestimmt ist." ("Berichtigung," Abraham 1912h, 176)

systems nor to any ideas about a generalized inertial motion, as is the case for the line element in general relativity. It therefore comes as no surprise that Abraham's formulation did not constitute any noteworthy "discovery" and that it was not even taken very seriously by either Abraham or Einstein.[21]

Einstein did acknowledge the impressive formal advance owed to Abraham's bold "mathematical" approach, in particular when compared with his own sluggish progress; but he quickly realized the theory's impoverished physical meaning. In a letter written shortly after the publication of Abraham's first paper on 27 January 1912, he remarked:

> Abraham has supplemented my gravitation thing, making it into a closed theory, but he made considerable errors in reasoning so that the thing is probably incorrect. This is what happens when one operates formally, without thinking physically![22]

However, he must have been initially impressed by the elegance with which Abraham's formalism yielded essentially the same results as his own, mathematically more pedestrian efforts, and also more than what he himself had achieved. This is evident from a comment Einstein made about two months later, when he was already convinced that Abraham's theory was not tenable:

> Abraham's theory has been created out of thin air, i.e., out of nothing but considerations of mathematical beauty, and is completely untenable. I find it hard to understand how this intelligent man allowed himself to get carried away with such superficiality. *At first (for 14 days!) I too was completely "bluffed" by the beauty and simplicity of his formulas*. [my emphasis][23]

At the beginning of February, Einstein was apparently still willing to concede to Abraham the benefit of the doubt. He wrote:

> Abraham has further developed the new gravitation theory; we are corresponding about this since we are not completely of the same opinion.[24]

As early as mid-February, however, Einstein had formed his firm, negative judgement on Abraham's theory:

> Abraham's theory is completely untenable.[25]

---

21 For a critical view on the notion of discovery, see (Renn et al. 2001).

22 "Abraham hat meine Gravitationssache zu einer geschlossenen Theorie ergänzt, aber bedenkliche Denkfehler dabei gemacht, sodass die Sache wohl unrichtig ist. Das kommt davon, wenn man formal operiert, ohne dabei physikalisch zu denken!" Einstein to Heinrich Zangger, 27 January 1912, (CPAE 5, Doc. 344, 395).

23 "Abrahams Theorie ist aus dem hohlen Bauche, d. h. aus blossen mathematischen Schönheitserwägungen geschöpft und vollständig unhaltbar. Ich kann gar nicht begreifen, wie sich der intelligente Mann zu solcher Oberflächlichkeit hat hinreissen lassen können. Im ersten Augenblick (14 Tage lang!) war ich allerdings auch ganz "geblüfft" durch die Schönheit und Einfachheit seiner Formeln." Einstein to Michele Besso, 26 March 1912, (CPAE 5, Doc. 377, 436–437).

24 "Abraham hat die neue Gravitationstheorie weiter ausgeführt; wir korrespondieren darüber, weil wir nicht vollkommen gleicher Meinung sind." Einstein to Michele Besso, 4 February 1912, (CPAE 5, Doc. 354, 406).

Einstein's harsh judgement may have also been related to the progress he himself was meanwhile making on a theory of gravitation based on the equivalence principle. In fact, the first reference to this theory, later published in Einstein's papers on the static gravitational field, is found in a letter from mid-February:

> The second thing concerns the relationship: gravitational field—acceleration field—velocity of light. Simple and beautiful things emerge here quite automatically. The velocity of light c is variable. It determines the gravitational force. A stationary point with mass 1 is acted upon by the force
>
> $$-\frac{\partial c}{\partial x} - \frac{\partial c}{\partial y} - \frac{\partial c}{\partial z}.$$
>
> In empty space c satisfies Laplace's equation. The inertial mass of a body is m/c, that is, it decreases with the gravitational potential. The equations of motion for the material point agree essentially with those of the customary theory of relativity. Abraham's theory is unfounded in every respect if there really is an equivalence between the gravitational field and the "acceleration field."[26]

It thus seems that around the end of January, Einstein, impressed by "the beauty and simplicity" of Abraham's formulas, had taken up work on a gravitation theory of his own and that he had then, in mid February, after an exchange of letters with Abraham, come to the conclusion that the latter's theory must be untenable, not least because its essential achievements could also be obtained on a physically much more sound basis from the equivalence principle. The relation between Einstein's own work on a gravitation theory and his negative judgement of Abraham's theory is also confirmed by another contemporary comment:

> In the course of my research on gravitation I discovered that Abraham's theory (1st issue of *Phys. Zeitschr.*) is completely untenable.[27]

After having initially limited himself to private communications, Einstein then prepared himself for a public controversy with Abraham:

---

25 "Abrahams Theorie der Gravitation ist ganz unhaltbar." Einstein to Paul Ehrenfest, 12 February 1912, (CPAE 5, Doc. 357, 408).

26 "Die zweite Sache betrifft die Beziehung Gravitationsfeld—Beschleunigungsfeld—Lichtgeschwindigkeit. Es kommen da einfache und schöne Dinge ganz zwangläufig heraus. Die Lichtgeschwindigkeit c ist variabel. Sie bestimmt die Gravitationskraft. Auf einen ruhenden Punkt von der Masse 1 wirkt die Kraft

$$-\frac{\partial c}{\partial x} - \frac{\partial c}{\partial y} - \frac{\partial c}{\partial z}.$$

c erfüllt im leeren Raume die Laplace'sche Gleichung. Die träge Masse eines Körpers ist m/c, sinkt also mit dem Schwerepotential. Die Bewegungsgleichungen des materiellen Punktes stimmen mit denen der gewöhnlichen Relativitätstheorie im Wesentlichen überein. Die Theorie Abrahams ist in allen Teilen unzutreffend, wenn die Aequivalenz zwischen Schwerefeld und "Beschleunigungsfeld" wirklich besteht." See Einstein to Hendrik A. Lorentz, 18 February 1912, (CPAE 5, Doc. 360, 413).

27 "Bei meiner Untersuchung über Gravitation entdeckte ich, dass Abrahams Theorie (1. Heft der phys. Zeitschr.) ganz unhaltbar ist." Einstein to Heinrich Zangger, before 29 February 1912, (CPAE 5, Doc. 366, 421).

> Abraham's theory is completely wrong. I will probably get into a heavy ink fight with him.[28]

As no letters by Abraham on this issue have survived, only the controversy, published later, allows one to infer how he defended himself against Einstein's criticism in his letters. This issue is of importance since Einstein's published criticism of February 1912 addresses a point that is not explicitly made in Abraham's early papers, the admissibility of Lorentz transformations in the infinitesimally small. But Abraham's later papers do suggest that he viewed the correction published in February 1912 as showing that the Lorentz transformation can be at least locally upheld. In the introductory section of a paper published in September 1912 he wrote for example:

> I have just availed myself of the language of the theory of relativity. But it will become clear that this theory cannot be brought into agreement with the views on the force of gravity presented here, in particular because the axiom of the constancy of the speed of light is relinquished. In my earlier papers on gravitation I have attempted to preserve at least in the infinitesimally small the invariance with respect to the Lorentz transformations.[29]

Similarly Abraham wrote in June 1912:

> I had given to the expressions of the gravitation tensor as well as to the equations of motion of the material point in the gravitational field a form which in the infinitesimally small is invariant with respect to Lorentz transformations.[30]

Indeed, in the series of four papers (plus one correction) Abraham published between January and March 1912, starting from his basic paper "On the Theory of Gravitation," via "The Elementary Law of Gravitation," the "Correction," and "The Free Fall," up to "The Conservation of Energy and Matter in the Gravitational Field"[31] Abraham made free use of infinitesimal Lorentz transformations, and even of their integration,[32] without ever explicitly justifying that this procedure is legitimate in the case of a variable speed of light.

In February 1912, Einstein published his criticism of Abraham in the context of his own first paper on a field theory of gravitation. To the editor of the *Annalen der Physik* he wrote:

---

28 "Abrahams Theorie ist ganz falsch. Ich werde wohl ein schweres Tintenduell mit ihm bekommen." Einstein to Ludwig Hopf, after 20 February 1912, (CPAE 5, Doc. 364, 418).

29 " Ich habe mich soeben der Sprache der Relativität bedient. Doch wird sich zeigen, daß diese Theorie mit den hier vorgetragenen Ansichten über die Schwerkraft nicht zu vereinbaren ist, schon darum nicht weil das Axiom von der Konstanz der Lichtgeschwindigkeit aufgegeben wird. Ich habe in meinen früheren Arbeiten über die Gravitation versucht, wenigstens in unendlich kleinen die Invarianz gegenüber den Lorentz-Transformationen zu bewahren." (Abraham1912b, 793–794)

30 "Ich hatte den Ausdrücken des Gravitationstensor, sowie den Bewegungsgleichungen des materiellen Punktes im Schwerefelde eine Form gegeben, die im unendlich kleinen gegenüber Lorentztransformationen invariant ist." (Abraham 1912f, 1057)

31 See (Abraham 1912h, 1912a, 1912c, 1912d) respectively.

32 See (Abraham 1912c, 310).

> I hereby send you a paper for the *Annalen*. Many a drop of sweat is hanging on it, but I now have complete confidence in the matter. Abraham's theory is completely unacceptable. How could anybody have the luck to guess effortlessly equations which are correct! Now I am looking for the dynamics of gravitation. But this will not happen so quickly![33]

In his paper, the aim of criticizing Abraham's theory is immediately announced in the introduction:

> Since then, Abraham has constructed a theory of gravitation which contains the consequences drawn in my first paper as special cases. But we will see in the following that Abraham's system of equations cannot be brought into agreement with the equivalence hypothesis, and that his conception of time and space cannot be maintained even from the purely mathematically formal point of view.[34]

Einstein's argument against Abraham's theory is given in §4 of his paper "General Remarks on Space and Time":

> Which is now the relation of the above theory to the old theory of relativity (i.e. to the theory of the universal c)? According to Abraham's opinion the transformation equations of Lorentz are still valid in the infinitesimally small, that is, there shall be an $x-t$ transformation so that:

$$\begin{aligned} dx' &= \frac{dx - v\,dt}{\sqrt{1-\frac{v^2}{c^2}}}, \\ dt' &= \frac{-\frac{v}{c^2}dx + dt}{\sqrt{1-\frac{v^2}{c^2}}} \end{aligned} \tag{13}$$

> are valid. dx' and dt' must be complete differentials. Therefore the following equations must be valid:

$$\begin{aligned} \frac{\partial}{\partial t}\left\{\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}\right\} &= \frac{\partial}{\partial x}\left\{\frac{-v}{\sqrt{1-\frac{v^2}{c^2}}}\right\}, \\ \frac{\partial}{\partial t}\left\{\frac{-\frac{v}{c^2}}{\sqrt{1-\frac{v^2}{c^2}}}\right\} &= \frac{\partial}{\partial x}\left\{\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}\right\}. \end{aligned} \tag{14}$$

---

33 "Ich sende Ihnen hier eine Arbeit für die Annalen. Hängt mancher Schweisstropfen daran, aber ich habe jetzt alles Vertrauen zu der Sache. Abrahams Theorie der Gravitation ist ganz unannehmbar. Wie könnte einer auch das Glück haben Gleichungen mühelos zu erraten, die richtig sind! Nun suche ich nach der Dynamik der Gravitation. Es wird aber nicht schnell damit gehen!" Einstein to Wilhelm Wien, 24 February 1912, (CPAE 5, Doc. 365, 420).

34 "Seitdem hat Abraham eine Theorie der Gravitation aufgestellt, welche die in meiner ersten Arbeit gezogenen Folgerungen als Spezialfälle enthält. Wir werden aber im folgenden sehen, daß sich das Gleichungssystem Abrahams mit der Äquivalenzhypothese nicht in Einklang bringen läßt, und daß dessen Auffassung von Zeit und Raum sich schon vom rein mathematisch formalen Standpunkte aus nicht aufrecht erhalten läßt." (Einstein 1912, 355)

> In the unprimed system the gravitational field shall now be static. Then c is an arbitrarily given function of x, but independent of t. If the primed system shall be a 'uniformly' moved one, then for fixed x, v must be in any case independent of t. The left-hand sides of the equations, and hence also the right-hand sides must therefore vanish. But the latter is impossible, since for c given in terms of arbitrary functions of x, both right-hand sides cannot be made to vanish by appropriately choosing v in dependence on x. Therefore it is shown that even for infinitesimally small regions of space and time one cannot adhere to the Lorentz transformation as soon as one gives up the universal constancy of c.[35]

In modern terminology, Einstein's argument amounts to showing that it is generally impossible to transform a coordinate system in which the metric does not have the Minkowskian form into another, well-defined one by means of a Lorentz transformation. In a letter somewhat later Einstein summarized his negative attitude toward Abraham's treatment of space and time as follows:

> I have now finished my studies on the statics of gravitation and have great confidence in the results. But the generalization appears to be very difficult. My results are not in agreement with those of Abraham. The latter has worked here, contrary to his usual style, rather superficially. Already his treatment of space and time is untenable.[36]

In spite of Einstein's criticism, Abraham nevertheless continued to use Minkowski's framework for elaborating consequences of his theory of gravitation, some of which will be discussed below. Einstein, in turn, became gradually convinced that it was worthwhile after all to take a closer look at the utility of a modification of this formalism for his version of a gravitational field theory as well. Driven by Abraham's bold and occasionally stubborn persistence, Einstein in May 1912 thus finally recognized that a generalized line element, as suggested by Abraham's note of three months earlier, indeed represents the key to a generally relativistic gravitation theory.[37]

---

35 "In was für einem Verhältnis steht nun die vorstehende Theorie zu der alten Relativitätstheorie (d. H. zu der Theorie des universellen c)? Nach Abrahams Meinung sollen die Transformationsgleichungen von Lorentz nach wie vor im unendlich Kleinen gelten, d. h. es soll eine $x-t$–Transformation geben, so daß [eq. (13)] gelten. dx' und dt' müssen vollständige Differentiale sein. Es sollen also die Gleichungen gelten [eq. (14)]. Es sei nun im ungestrichenen System das Gravitationsfeld ein statisches. Dann ist c eine beliebig gegebene Funktion von x, von t aber unabhängig. Soll das gestrichene System ein "gleichförmig" bewegtes sein, so muß v bei festgehaltenem x jedenfalls von t unabhängig sein. Es müssen daher die linken Seiten der Gleichungen, somit auch die rechten Seiten verschwinden. Letzteres ist aber unmöglich, da bei beliebig in Funktionen von x gegebenem c nicht beide rechten Seiten zum Verschwinden gebracht werden können, indem man v in Funktion von x passend wählt. Damit ist also erwiesen, daß man auch für unendlich kleine Raum-Zeitgebiete nicht an der Lorentztransformation festhalten kann, sobald man die universelle Konstanz von c aufgibt." (Einstein 1912, 368)

36 "Die Untersuchungen über die Statik der Gravitation habe ich nun fertig und setze grosses Vertrauen in die Resultate. Aber die Verallgemeinerung scheint sehr schwierig zu sein. Meine Ergebnisse sind mit denen von Abraham nicht im Einklang. Dieser hat gegen seine sonstige Gewohnheit hier recht oberflächlich gearbeitet. Schon seine Behandlung von Raum und Zeit ist unhaltbar." Einstein to Ludwig Hopf, 12 June 1912, (CPAE 5, Doc. 408, 483).

37 See "Classical Physics in Disarray …" and "The First Two Acts" (both in vol. 1 of this series).

1.3 Abraham's Rejection of Relativity

As time went by, Abraham's reaction to the controversy with Einstein became more and more acrid, until eventually he rejected the theory of relativity altogether. This is in stark contrast to Einstein's ever more resolved search for a generalization of the relativity principle as familiar from classical physics. In fact, Einstein had concluded his criticism of Abraham with the following comment:

> To me the spacetime problem seems to lie as follows. If one limits oneself to a region of constant gravitational potential, the natural laws take on an outstandingly simple and invariant form if one refers them to a spacetime system of that manifold which are connected to each other by the Lorentz transformations with constant c. If one does not restrict oneself to regions of constant c, then the manifold of equivalent systems, just as the manifold of the transformations that leave the natural laws unchanged, will become a larger one, but the laws will, on the other hand, become more complicated.[38]

In his published response to Einstein's critique, Abraham, on the other hand, wrote (the first sentence is quoted above):

> I had given to the expressions of the gravitation tensor as well as to the equations of motion of the material point in the gravitational field a form which in the infinitesimally small is invariant with respect to Lorentz transformations. In the restriction to the infinitesimally small it is already implicit that this invariance shall not be maintained in the finite. In fact, if the gravitational field influences the speed of light, then it is clear from the outset that there is an essential difference between a reference system $\Sigma(xyzt)$ in which the gravitational field is a static one and a reference frame $\Sigma(x'y'z't')$ which is uniformly moved with respect to the former, in which the gravitational field, and hence also the speed of light, is changing with time. There can be no talk about any kind of relativity, i.e., about a correspondence between the two systems, which would express itself in equations between their spacetime parameters $xyzt$ and $x'y'z't'$. Indeed the differential equations between dx', dt' and dx, dt, which contain the Lorentz-transformation in the infinitesimally small, are, as Mr. Einstein observes, not integrable.[39]

Abraham thus drew from the same mathematical fact a consequence that is diametrically opposed to that drawn by Einstein. Instead of calling for an extension of the relativity principle, as Einstein did, Abraham called for a complete rejection of this principle. He therefore continued:

> But in this inherently correct observation I cannot find any justification for the claim that "my conception of time and space cannot be maintained even from the purely mathematically formal point of view." However, any relativistic spacetime conception which would find its expression in relations between spacetime parameters of Σ and Σ' becomes untenable. Such a relativistic spacetime conception is, on the other hand,

---

38 "Mir scheint das Raum-Zeitproblem wie folgt zu liegen. Beschränkt man sich auf ein Gebiet von konstantem Gravitationspotential, so werden die Naturgesetze von ausgezeichnet einfacher und invarianter Form, wenn man sie auf ein Raum-Zeitsystem derjenigen Mannigfaltigkeit bezieht, welche durch die Lorentztransformationen mit konstantem c miteinander verknüpft sind. Beschränkt man sich nicht auf Gebiete von konstantem c, so wird die Mannigfaltigkeit der äquivalenten Systeme, sowie die Mannigfaltigkeit der die Naturgesetze ungeändert lassenden Transformationen eine größere werden, aber es werden dafür die Gesetze komplizierter werden." (Einstein 1912, 368–369)

> entirely far fetched to me. As I have already mentioned elsewhere [Abraham 1912g], to me, the interpretation in the sense of an absolute theory seems rather the appropriate one. If among all reference frames that one is privileged in which the gravitational field is static, or quasi static, then it is permissible to refer to a motion related to this system as 'absolute'.[40]

He proceeds by explaining the relation of his conception to traditional physical ideas about preferred systems of reference, such as that identified by Neumann's "body α," and concludes with the remark:

> Who wishes to do so, may interpret this conception as an argument for the 'existence of the aether'.[41]

Abraham became ever more skeptical about Einstein's attempts to extend the principle of relativity, as his later publications show. Although he actively contributed to developing tools and concepts of a relativistic theory of gravitation, such as expressions for stresses and energy in a gravitational field, he never dealt in detail with the revisions of the concept of time implied by his own theory, let alone those of the concepts of space and time associated with Einstein's rival theories.[42] In a paper submitted in July 1912, Abraham pointed to Einstein's difficulties with implementing the equivalence hypothesis in his own theory of gravitation, but merely restricted himself to the following brief remark on the subject:

> Here I would therefore prefer to develop the new gravitation theory without entering the spacetime problem.[43]

---

39 "Ich hatte den Ausdrücken des Gravitationstensors, sowie den Bewegungsgleichungen des materiellen Punktes im Schwerefelde eine Form gegeben, die im unendlich kleinen gegenüber Lorentztransformationen invariant ist. In der Beschränkung auf das unendlich kleine liegt schon implicite enthalten, daß im endlichen diese Invarianz nicht bestehen soll. In der Tat, wenn das Gravitationsfeld die Lichtgeschwindigkeit beeinflußt, so ist es von vornherein klar, daß ein wesentlicher Unterschied zwischen einem Bezugssystem $\Sigma(xyzt)$ besteht, in welchem das Schwerkraftfeld ein statisches ist, und einem gegen dieses gleichförmig bewegten Bezugssystem $\Sigma(x'y'z't')$, in welchem das Schwerkraftfeld, und mithin auch die Lichtgeschwindigkeit, sich zeitlich verändert. Es kann von irgend einer Art von Relativität, d. h. von einer Korrespondenz der beiden Systeme, die sich in Gleichungen zwischen ihren Raum-Zeit-Parametern $xyzt$ uns $x'y'z't'$ ausdrücken würde, keine Rede sein. In der Tat sind, wie Hr. Einstein bemerkt, die Differenzialgleichungen zwischen dx', dt' und dx, dt, welche die Lorentztransformation im unendlich kleinen enthalten, nicht integrabel." (Abraham 1912f, 1057)

40 "In dieser an sich zutreffenden Bemerkung kann ich freilich keine Rechtfertigung für die Behauptung finden, daß "meine Auffassung von Zeit und Raum sich schon vom rein mathematisch formalen Standpunkt aus nicht aufrecht erhalten läßt". Unhaltbar wird allerdings jede relativistische Raum-Zeit-Auffassung, die in Beziehungen zwischen den Raum-Zeit-Parametern von Σ und Σ' ihren Ausdruck finden würde. Eine solche relativistische Raum-Zeit-Auffassung liegt mir indessen ganz fern. Mir scheint vielmehr, wie ich bereits an anderem Orte erwähnt habe [Abraham 1912g], die Deutung im Sinne einer Absoluttheorie die passende zu sein. Wenn unter allen Bezugssystemen dasjenige ausgezeichnet ist, in welchem das Schwerefeld statisch, oder quasi-statisch ist, so ist es erlaubt, eine auf dieses System bezogene Bewegung "absolut" zu nennen." (Abraham 1912f, 1057)

41 "Wer will, mag diese Vorstellung als Argument für die 'Existenz des Äthers' deuten. (Abraham 1912f, 1058)

Abraham did not just ignore the consequences of the new gravitation theories for the concepts of space and time, he actually rejected them, with no lesser consequence than that with which Einstein pursued them. In short, the same challenging task of creating a gravitation theory compatible with relativity theory found complementary responses in Abraham and Einstein. While both not only acknowledged the difficulties of making them compatible, but also returned to a revision of special relativity, Einstein did so in order to complete the relativity revolution, and Abraham to undo it. Commenting on Einstein's later attempts at a relativistic theory of gravitation, Abraham wrote in a popular review of 1914:

> Hence, at the cliff of gravitation every theory of relativity fails, the special one of 1905, as well as the general one of 1913. The relativistic ideas are obviously not sufficiently advanced to serve as a framework for a complete worldview.
>
> But historical merit does remain for the theory of relativity with regard to its critique of the concepts of space and time. It has taught us that these concepts depend on the ideas we form concerning the behavior of the measurement rods and clocks that we use for the measurement of lengths and intervals of time, and which are subject to change with them [the measurement instruments]. This will secure an honorable funeral for the theory of relativity.[44]

Although Abraham did not accept the new concepts of space and time introduced by Einstein, he remained an acute critic of the latter's ongoing search for a relativistic

---

42 In March 1911 Abraham submitted a paper (Abraham 1912c) in which he used the distinction between proper time and coordinate time in order to draw far-reaching cosmological consequences from his theory. In this paper Abraham explained his definition of time coordinates:
"τ denotes the 'proper time' of the moved point, which is related to the time t measured in the reference system as follows:

$$\frac{du}{d\tau} = ic\frac{dt}{d\tau} = \frac{ic}{\kappa}$$

$$\kappa = \sqrt{1-\frac{v^2}{c^2}}$$

(v magnitude of velocity of the material point).
Clearly, Abraham's explanation of the relation between proper time and coordinate time, although formally analogous to Minkowski's formalism, can neither be based on this formalism, as the speed of light is assumed to be variable, nor be brought into harmony with Einstein's physical motivation for these two notions of time. Contrary to Einstein it appears from the remainder of this paper that Abraham considered only the coordinate time t to have any physical meaning.

43 "Ich möchte es daher hier vorziehen, die neue Gravitationstheorie zu entwickeln, ohne auf das Raum-Zeit-Problem einzugehen." (Abraham 1912b, 794)

44 "An der Klippe der Schwerkraft scheitert also jede Relativitätstheorie, sowohl die spezielle von 1905, wie die allgemeine von 1913. Die relativistischen Ideen sind offenbar nicht weit genug, um einem vollständigen Weltbilde als Rahmen zu dienen. Doch bleibt der Relativitätstheorie ein historisches Verdienst um die Kritik der Begriffe von Raum und Zeit. Sie hat uns gehehrt, dass diese Begriffe von den Vorstellungen abhängen, die wir uns von dem Verhalten der zur Messung von Längen und Zeitintervallen dienenden Massstäbe und Uhren bilden, und die mit ihnen dem Wandel unterworfen sind. Dies sichert der Relativitätstheorie ein ehrenvolles Begräbnis." (Abraham 1914, 26)

theory of gravitation, which, apart from Abraham's reaction, found only little resonance in the contemporary physics community. In a letter to his friend Michele Besso, Einstein wrote:

> Physicists have such a passive attitude toward my work on gravitation. Abraham is still the one who shows the most comprehension. It is true that he complaints violently in 'Scientia' against anything to do with relativity, but with understanding.[45]

In spite, and occasionally perhaps because of his intellectual distance, Abraham noticed problematic features of Einstein's attempts, which eventually became important issues in the development of general relativity, such as the question of the sense in which Einstein's mathematical requirement of a generalized covariance actually also realizes a generalization of the relativity principle as he claimed. In a review paper of 1915, Abraham expressed his doubts concerning Einstein's claim that his *Entwurf* theory of 1913, which is covariant with regard to general linear transformations, actually represents a generalization of the relativity principle of the special theory of 1905:

> The significance of this transformation group lies in the fact that it contains the Lorentz transformations; in the earlier theory of relativity the covariance with respect to this group gave expression to the equivalence of systems of reference in translatory motion with respect to each other. Is this presently also the case in the "generalized theory of relativity"? Does the covariance of the field equations with respect to linear orthogonal transformations imply that in a finite system of mutually gravitating bodies the course of the relative motions is not altered by a uniform translation of the entire system? That this is so has so far not been proven.[46]

Abraham thus pinpoints a distinction that is today considered as being crucial for understanding the covariance properties of a gravitational field equation, the distinction between general covariance as a property of the mathematical formulation of such a field equation, and the symmetry group under which the theory remains invariant, as is the case for the Lorentz group of special relativity. He thus anticipates a conceptual clarification that is usually attributed to Kretschmann.[47] But in spite of this significant insight, Abraham's further explanation of his skeptical attitude shows signs of a still immature understanding of the kinematics within a generic four-

45 "Zur Gravitationsarbeit verhält sich die physikalische Menschheit ziemlich passiv. Das meiste Verständnis hat wohl Abraham dafür. Er schimpft zwar in der "Scienza" kräftig über alle Relativität, aber mit Verstand." Einstein to Michele Besso after 1 January 1914, (CPAE 4, Doc. 499). See (Cattani and De Maria 1989, 171).

46 "Die Bedeutung dieser Transformationsgruppe beruht darauf, daß sie die Lorentzschen Transformationen enthält; die Kovarianz ihnen gegenüber brachte in der früheren Relativitätstheorie die Gleichberechtigung translatorisch gegeneinander bewegter Bezugssysteme zum Ausdruck. Ist dies nun auch in der "verallgemeinerten Relativitätstheorie" der Fall? Bedingt es die Kovarianz der Feldgleichungen gegenüber linearen orthogonalen Transformationen, daß in einem endlichen Systeme gegeneinander gravitierender Körper der Ablauf der relativen Bewegungen durch eine gleichförmige Translation des ganzen Systems nicht geändert wird? Daß dem so sei, ist bisher nicht bewiesen worden." (Abraham 1915, 515)

47 See (Kretschmann 1917) and, for historical discussion, (Norton 1992, 1993; Rynasiewicz 1999).

dimensional spacetime manifold, in particular, concerning his lack of understanding of the relation between different coordinate representations of one and the same physical magnitude:

> Such a proof may already be impossible to conduct for the reason that the concept of "uniform motion" of a finite system is completely up in the air in the new theory of relativity. Since the "natural" space and time measurement is influenced by the values of the space and time potential, observers at different locations in the gravitational field will ascribe different velocities to the same material point. Only for an infinitesimally small region of four-dimensional space—i.e. for one in which the potentials $g_{\mu\nu}$ can be considered a constant—is "velocity" defined at all.[48]

Abraham then returns to the problem of interpreting the covariance property of the field equations in terms of a relativity principle:

> Presumably, only within such an infinitesimal region may the covariance of the gravitational equations with respect to linear orthogonal transformations be interpreted in the sense of an equivalence of systems of reference moving with respect to each other. But if relativity of motion no longer exists for finite systems of gravitating masses in Einstein's theory, with what right does he then assign such great importance to the formal connection to the earlier theory of relativity?[49]

Abraham's criticism was evidently colored by his growing hostility toward any theory of relativity, and motivated, without doubt, by his own failure to successfully establish a relativistic theory of gravitation. But because it raised such crucial issues as the physical significance of the unfamiliar mathematical objects introduced in the course of Einstein's search for such a theory, it nevertheless represents an important intellectual context of the emergence of general relativity. Abraham's sometimes ardent polemics reveal not only the challenging difficulties with which Einstein confronted his contemporaries, but also contributed, at the time, to anchoring his high-flying mathematical artifices in the shared knowledge of contemporary physics, a process made particularly ungainly by the hesitant and cool reaction to Einstein's labors of other contemporary scientists.

---

48 "Ein solcher Beweis dürfte auch schon aus dem Grunde sich nicht führen lassen, weil der Begriff der "gleichförmigen Bewegung" eines endlichen Systems in der neuen Relativitätstheorie völlig in der Luft schwebt. Denn da die "natürliche" Raum- und Zeitmessung durch die lokalen Potentialwerte beeinflußt wird, so werden Beobachter an verschiedenen Orten im Schwerefelde demselben materiellen Punkte verschiedene Geschwindigkeiten zuschreiben. Nur für ein unendlich kleines Gebiet des vierdimensionalen Raumes—d. h. für ein solches, in welchem die Potentiale $g_{\mu\nu}$ als konstant gelten könne—ist die "Geschwindigkeit überhaupt definiert." (Abraham 1915, 515)

49 "Vermutlich dürfte nur innerhalb eines solchen infinitesimalen Gebietes die Kovarianz der Gravitationsgleichungen gegenüber orthogonalen linearen Transformationen im Sinne einer Gleichberechtigung gegeneinander bewegter Bezugssysteme zu deuten sein. Wenn aber in Einsteins Theorie für endliche Systeme gravitierender Massen keine Bewegungsrelativität mehr besteht, mit welchem Rechte legt er dann dem formalen Anschluß an die frühere Relativitätstheorie eine so große Wichtigkeit bei?" (Abraham 1915, 515–516)

2. VISTAS FROM JUST BELOW THE SUMMIT

2.1 A New Theory of Gravitation Meets the Shared Knowledge

Abraham's insights into the nature and effects of the gravitational field conceived in a relativistic context are today even less well known than his theoretical approach. It may seem that they have been rightly forgotten because of their apparent lack of impact on the further development of the theory. It was, however, precisely Abraham's untiring efforts to elaborate his theoretical approach and to draw physical consequences from it that turned his theory into a valuable touchstone and standard of comparison for other contemporary attempts at a relativistic theory of gravitation. Some of the insights that Abraham achieved in the course of his research, such as the possibility and essential properties of gravitational waves remain to this day a standard for a relativistic theory of gravitation.

In the first paper on his theory, Abraham did not go into much detail about the physical consequences of his new theory of gravitation. But he did, of course, have to confront the shared physical knowledge of his time. This ranged from the knowledge embodied in Newton's theory of gravitation—including the deviations from it—via energy and momentum conservation to some of the unusual insights attained by Einstein on the basis of the equivalence principle, such as the deflection of light, which possibly had to be incorporated in this new theory of gravitation as well.

In his paper, Abraham first discusses the equations of motion in a gravitational field which he formulates, as we have seen above, in analogy to Newtonian dynamics. From equations (6) and (7) he obtains:

$$m\frac{d\dot{x}}{d\tau} = -m\frac{\partial\Phi}{\partial x}, \qquad m\frac{d\dot{y}}{d\tau} = -m\frac{\partial\Phi}{\partial y}, \qquad m\frac{d\dot{z}}{d\tau} = -m\frac{\partial\Phi}{\partial z}. \tag{15}$$

These three equations he interpreted as representing momentum conservation. He then added:

> In contrast, the last of the equations (3) [i.e. eq. (7)]:
>
> $$m\frac{dl}{d\tau} = -mi\mathfrak{F}_u = mi\frac{\partial\Phi}{\partial u} = m\frac{\partial\Phi}{\partial l} \tag{16}$$
>
> expresses the law of conservation of *vis viva* in Minkowskian mechanics.[50]

Abraham had thus dealt with one of the inescapable requirements imposed on a new theory by the accumulated knowledge of classical and special relativistic physics. He also went into some detail about the energy balance of physical processes in a gravitational field.

Concerning the observable consequences of his theory, he did not even mention the gravitational redshift predicted by Einstein, probably because at that point he

---

50 See (Abraham 1912h, 2).

could not or did not want to follow Einstein's introduction of two notions of time in a gravitational field.[51] But he did take up Einstein's prediction of a gravitational light deflection, which he compared to that predicted by the emission theory of light. Abraham had, after all, developed his theory of gravitation in reaction to Einstein's 1911 paper and, in particular, to the introduction of a variable speed of light which this paper emphasized. Commenting on equations (10) and (11) he wrote (as partly quoted above):

> It is instructive to compare the relation obtained with the emission theory of light. Let us imagine that the particles emitted from the light source move according to the laws of Galilean mechanics and that they are subject to the gravitational force. They would then experience an increase of *vis viva* (kinetic energy) which is equal to the *decrease* of potential energy. The increase of *vis viva* (kinetic energy) of the light particles calculated according to (6) [i.e. eq. (10)] is, by contrast, equal to the *increase* of their potential energy, i.e., of the same amount but of opposite sign as that following from the emission theory. But as far as the bending of light rays in the gravitational field is concerned, which can be derived from (6) [i.e. eq. (10)] with the aid of Huygens' principle,[1)] it is identical with the bending of the trajectory of those light particles. This is one of the numerous incomplete analogies between the modern theory of radiation and the emission theory of light.[52]

To this passage, after "with the aid of Huygens' principle," Abraham appended the following footnote in which he refers to Einstein:

> A. Einstein has shown that a light ray passing the surface of the Sun is deflected towards the Sun and has drawn the attention of the astronomers to this consequence of the theory which can perhaps serve as its verification.[53]

Apart from this footnote Abraham did not discuss specific observational consequences of his theory. This, however, does not imply that he was not interested in them. On the contrary, at about the same time as Einstein, he independently and actively pursued the astronomical consequences of a relativistic theory of gravitation as is evident from a letter he wrote to Schwarzschild.[54]

---

51 Gravitational redshift is mentioned for the first time with reference to Einstein, in (Abraham 1913, 197).

52 "Es ist lehrreich, die erhaltene Beziehung der Emissionstheorie des Lichts gegenüberzustellen. Wir wollen uns vorstellen, daß die von der Lichtquelle emittierten Teilchen sich gemäß den Gesetzen der Galileischen Mechanik bewegen, und daß sie der Schwerkraft unterworfen seien. Dann würden sie einen Zuwachs an lebendiger Kraft erfahren, welcher gleich der Abnahme der potentiellen Energie ist. Dagegen ist der nach (6) [eq. 10] berechnete Zuwachs der Lichtteilehen an lebendiger Kraft gleich der Zunahme ihrer potentiellen Energie, d. h. von gleichem Betrage, aber von entgegengesetztem Vorzeichen, wie der aus der Emissionstheorie folgende. Was aber die Krümmung der Lichtstrahlen im Schwerkraftfelde anbelangt, die aus (6) [eq. 10] mit Hilfe des Huygensschen Prinzips sich ableiten läßt, so ist sie identisch mit der Krümmung der Bahnkurve jener Lichtteilchen. Es ist dies eine der zahlreichen unvollständigen Analogien zwischen der modernen Strahlungstheorie und der Emissionstheorie des Lichtes." (Abraham 1912h, 2)

53 "A. Einstein hat gezeigt, daß ein die Sonnenoberfläche passierender Lichtstrahl nach der Sonne hin abgelenkt wird, und hat die Aufmerksamkeit der Astronomen auf diese Konsequenz der Theorie gelenkt, die vielleicht zu ihrer Prüfung dienen kann." (Abraham 1912h, 2, fn.1)

In a publication following immediately, “The Elementary Law of Gravitation,”[55] which was also submitted in December 1911, Abraham returned to the question of the relation of his theory to experience. The principal aim of this paper is the derivation from the theory published in the preceding paper of an expression of the gravitational force between two “world points” P and P_0, “an elementary law of gravitation,” as Abraham called it. For this purpose he integrated the field equation of his theory, equation (2), using the Cauchy method of residues and following a procedure by Herglotz.[56] Such an elementary law allowed for a comparison not only with Newton’s law of gravitation but also with earlier adaptations of action-at-a-distance laws to a relativistic framework. Furthermore, it allowed Abraham, at least in principle, to address the astronomical consequences of his theory and to explore deviations from classical predictions.

He concluded his publication with the following summary:

> According to this elementary law the moving force exerted by P on P_0 is represented as a sum of two four-vectors, of which one is parallel to the radius $\mathfrak{R}$, drawn from the world point P_0 to P, the other to the velocity vector $\mathfrak{B}$ of P. This corresponds to the approaches of Poincaré and Minkowski. But our elementary law is simpler, insofar as it does not involve the velocity of the attracted point, and more general, because it also takes into account the acceleration of the attracting point. Its comparison with astronomical observation could serve for the examination of the theory of gravitation developed in the previous note.[57]

Abraham, however, did not specify which astronomical phenomena might be compared to the consequences of his elementary law. But modifications of Newton’s elementary law had earlier been referred to the perihelion anomaly of Mercury[58] so that this may well have been one of the astronomical consequences Abraham had in mind. In other words, the deviation of planetary motion from the implications of Newtonian mechanics was also part of the generally shared knowledge that a new gravitation theory had to confront. On the basis of estimating the order of magnitude of deviations from Newton’s law, Abraham himself later remarked:

---

54 Abraham to Schwarzschild, see “The Continuity between Classical and Relativistic Cosmology in the Work of Karl Schwarzschild,” p. 165, (in this volume).

55 See (Abraham 1912a).

56 See (Herglotz 1904), and also (Sommerfeld 1910, 665; 1911, 51) where according to Abraham the analogous electrical problem is treated.

57 “Diesem Elementargesetz zufolge stellt sich die von P auf P_0 ausgeübte bewegende Kraft als Summe zweier Vierervektoren dar, von denen der eine dem vom Weltpunkte P_0 nach P gezogenen Fahrstrahl $\mathfrak{B}$, der andere dem Geschwindigkeitsvektor $\mathfrak{B}$ von P parallel ist. Dieses entspricht den Ansätzen von Poincaré und von Minkowski. Doch unser Elementargesetz einfacher, insofern als die Geschwindigkeit des angezogenen Punkts nicht eingeht, und allgemeiner, weil es auch die Beschleunigung des anziehenden Punkts berücksichtigt. Seine Vergleichung mit der astronomischen Beobachtung könnte zur Prüfung der in der vorigen Note entwickelten Theorie der Schwerkraft deinen.” (Abraham 1912a, 5)

58 See (Zenneck 1903), compare also (Poincaré 1906 and Minkowski 1909).

> The correction of Newton's law introduced in (16)[59] is hence likely to be too small for noticeably influencing the planetary motion. (Abraham 1912b, 797)

Nevertheless, in the same year 1912, G. Pavanini calculated the perihelion shift of Mercury according to Abraham's theory, finding a value of $14'', 52$, that is, approximately one third of the observed value.[60] Abraham's theory thus made a more accurate prediction than the much more elaborate theory of gravitation Einstein and Grossmann published in 1913.[61]

2.2 Audacious Outlooks

The empirical consequences of Abraham's theory of gravitation were by no means limited to those already envisaged by Einstein, or to those immediately obvious from the body of knowledge covered by the Newtonian theory. Abraham was a master of classical electrodynamics, and, for this reason, was not only used to elaborating in depth and detail the consequences of a complex theory, but also had a specific model that suggested where to look for analogies and differences between the two field theories—electromagnetic and gravitational. In the following, we will briefly look at two of the outstanding achievements that resulted from Abraham's efforts to draw far-reaching physical consequences from his theory. Both concern subjects of great interest to present research in general relativity, spacetime singularities and gravitational waves. Until now, the name Max Abraham has played no role in the history of these subjects, although his contributions are unlikely to have gone entirely unnoticed by those who continued the search for a relativistic theory of gravitation at the time he gave up.

In a paper submitted in March 1912, "The Free Fall" (Abraham 1912c), Abraham considered the motion of free fall in a homogeneous gravitational field, i.e., in exactly the same kind of gravitational field that was used in the formulation of Einstein's equivalence principle, and drew some far-reaching cosmological consequences from his calculations. These consequences essentially depend on equations (10), relating the speed of light and the gravitational potential, and on the relation between coordinate time and proper time. From the law of fall, which Abraham derived from his equations of motion in a gravitational field, he first concluded that there is a point in (coordinate) time, corresponding to a certain distance of fall, at which the speed of light becomes zero. This point corresponds to a singularity in the relation between proper time and coordinate time. From the condition that the speed of light must always remain larger than zero, he then concluded, with the help of (10), that:[62]

---

59 A law of the form $Force = \frac{A}{r^2} - \frac{B}{r^3}$.

60 See (Pavanini 1912). See also the brief discussion of these results in (Abraham 1915, 488). For the corresponding calculation in Nordström's theory, see (Behacker 1913, 989).

61 See (Einstein and Grossmann 1913). See also "What Did Einstein Know …" (in vol. 2 of this series).

62 See (Abraham 1912c, 311).

$$\Phi_0 - \Phi < \frac{c_0^2}{2}. \tag{17}$$

As a first step, he interpreted this relation as implying that the existence of a homogeneous gravitational field of infinite extension is excluded and then turned to further, as he called them, "cosmogonic" consequences of this relation.
He considered a star of mass m with the potential:

$$\Phi = -\gamma \cdot \frac{m}{r} \tag{18}$$

and compared the potential difference between an infinite distance and the surface of the star at distance $r = a$:

$$\Phi_0 - \Phi = \gamma \cdot \frac{m}{a}. \tag{19}$$

From equation (17) he then inferred that there is a maximum for the quotient of mass and radius:

> Therefore
>
> $$\gamma \cdot \frac{m}{a} < \frac{c_0^2}{2}\left(= \frac{9}{2} \cdot 10^{20}\right) \tag{20}$$
>
> must hold. For the Sun one has in *cgs* units
>
> $$\left(\gamma \cdot \frac{m}{a}\right)_s = 2 \cdot 10^{15}. \tag{21}$$
>
> Thus, the *quotient of mass and radius for an arbitrary star must satisfy the inequality*
>
> $$\frac{m}{a} < 2,25 \cdot 10^5 \cdot \left(\frac{m}{a}\right)_s. \tag{22}$$
>
> For stars whose mean density is equal to that of the Sun, the quotients m/a are proportional to the squares of the radii. Hence, the following must hold
>
> $$a < 500(a)_s, \tag{23}$$
>
> and thus
>
> $$m < 10^8(m)_s. \tag{24}$$
>
> That is, *the mass of a star whose mean density is equal to that of the Sun cannot become larger than one hundred million times the mass of the Sun.*
>
> Since this limit is rather high, no difficulties arise from this for our theory.[63]

Abraham, in March 1912, was hence the first to hit upon a singularity in a field theory of gravitation and to calculate what was later called the "Schwarzschild radius." Although his understanding of the relation between proper time and coordinate time does not correspond to the modern one, his consideration of their relation for a freely falling object in the field of a point mass corresponds to a procedure still applied in modern general relativity. From his introductory reference to the "cosmogonic" implications of his theory one may further infer that he did not consider this singularity to be fictitious, contrary to the first explorers of the Schwarzschild singularity within general relativity, Eddington and Lemaitre.[64] Abraham did not, however, directly relate his result to light deflection, although the vanishing of the speed of light at the singularity clearly implies that light cannot escape from it. But Abraham did not make this consequence explicit and rather limited himself to interpreting the singularity in terms of limits on the size of stars.

In a lecture presented in October 1912 and published the following year (Abraham 1913) Abraham was also the first to discuss the possibility of gravitational waves in a relativistic field theory of gravitation. There he wrote:

> According to our theory, light and gravitation have the same speed of propagation; but whereas light waves are transverse, gravitational waves are longitudinal. Incidentally, the problem of the oscillating particle can be treated in a similar manner as that of the oscillating electron; the strength of the emitted gravitational waves depends on the product of gravitational mass and the acceleration of the particle. Is it possible to detect these gravitational waves?
>
> This hope is futile. Indeed, to impart an acceleration to one particle, another particle is necessary which, according to the law of action and reaction, is driven in the opposite side. But now, the strength of the emitted gravitational waves depends on the sum of the products of the gravitational mass and the acceleration of the two particles, while, according to the reaction principle, the sum of the products of inertial mass and acceleration is equal to zero.[65] Therefore, although the existence of gravitational waves is compatible with the assumed field mechanism, through the equality of gravitational and inertial mass the possibility of its production is practically excluded. It follows from this that the planetary system does not lose its mechanical energy through radiation, whereas an analogous system consisting of negative electrons circling around a positive nucleus gradually radiates its energy away. The life of the planetary system is thus not threatened by such a danger.[66]

Abraham's argument amounts to showing that, because of momentum conservation, there can be no dipole moment in gravitational waves; it is an argument still used in

---

63 Es muß also sein: [(eq. 20)]. Für die Sonne hat man, in C.G.S.Einheiten [(eq. 21)]. Daher muß *der Quotient aus Masse und Radius für einen beliebigen Stern der Ungleichung genügen* [(eq. 22)]. Für Sterne, deren mittlere Dichte derjenigen der Sonne gleich ist, stehen die Quotienten m/a im Verhältnis der Quadrate der Radien; es muß dann sein [(eq. 23)] und somit [(eq. 24)]. D h. *die Masse eines Sternes, dessen mittlere Dichte derjenigen der Sonne gleich ist, kann nicht größer werden als das Hundertmillionenfache der Masse der Sonne*. Da diese Grenze recht hoch ist, so entsteht hieraus keine Schwierigkeit für unsere Theorie." (Abraham 1912c, 311)

64 See (Eisenstaedt 1989).

65 *Abraham's footnote*: Here the momentum of the gravitational field has, however, been neglected; but this [momentum] practically comes as little into consideration as the energy of the field. ("Hierbei ist allerdings der Impuls des Schwerefeldes unberücksichtigt geblieben; aber dieser kommt ebensowenig wie die Energie des Feldes praktisch in Betracht.")

modern textbooks on general relativity.[67] His allusion to an electrical analogue is clearly a reference to a Bohr-like atomic model, which classically would, of course, be unstable.

Abraham nevertheless took the idea of gravitational waves so seriously that he published another detailed study comparing electromagnetic and gravitational waves, including quantitative comparisons.[68] In a later review he took up this earlier study and discussed the possibility that gravitational waves are emitted during the emission of α particles by radioactive atoms:

> One could now surmise that during the emission of α particles by radioactive atoms, in which very large accelerations occur, the hypothetical gravitational waves are excited in noticeable strength. But at the same time there are electrical waves which are excited and, as the quantitative discussion shows, the force which is exerted by the gravitational waves emitted by an α particle upon another α particle amounts to maximally 10^{-36} of the electrical force.[69]

If, or rather when, gravitational waves are one day directly verified, Abraham's papers will certainly not constitute a relevant theoretical reference point. From the point of view of a history of knowledge, however, they do represent a reference point for gauging the possibilities open to the development of a theory of gravitation around 1912.[70] While Abraham's efforts are hardly suited to detracting from Einstein's triumph of late 1915, they do make evident the extent to which this solitary tri-

---

66 "Nach unserer Theorie haben Licht und Schwere die gleiche Fortpflanzungsgeschwindigkeit; aber während die Lichtwellen transversal sind, sind die Schwerewellen longitudinal. Übrigens kann das Problem des schwingenden Massenteilchens in ähnlicher Weise behandelt werden wie dasjenige des schwingenden Elektrons; die Stärke der ausgesandten Gravitationswellen hängt von dem Produkt aus schwerer Masse und Beschleunigung des Teilchens ab. Ist es möglich, diese Schwerewellen zu entdecken?
Diese Hoffnung ist vergeblich. In der Tat, um einem Teilchen eine Beschleunigung zu erteilen, bedarf es eines anderen Teilchens, welches, vermöge des Gesetzes von Wirkung und Gegenwirkung, nach der entgegengesetzten Seite getrieben wird. Nun hängt aber die Stärke der ausgesandten Schwerewelle von der Summe der Produkte aus schwerer Masse und Beschleunigung der beiden Teilchen ab, während nach dem Gegenwirkungsprinzip die Summe der Produkte aus träger Masse und Beschleunigung gleich null ist.[1)] [see previous note] Es ist also zwar die Existenz der Gravitationswellen mit dem angenommenen Feldmechanismus verträglich, aber durch die Identität von schwerer und träger Masse wird die Möglichkeit ihrer Erzeugung praktisch ausgeschlossen. Hieraus geht hervor, daß das Planetensystem nicht seine mechanische Energie durch Strahlung verliert, während ein analoges System, bestehend aus negativen Elektronen, die um einen positiven Kern kreisen, allmählich seine Energie ausstrahlt. Das Leben des Plantensystems ist also nicht durch eine solche Gefahr bedroht." (Abraham 1913, 208–209)

67 See, e.g., (Wald 1984, 83).

68 See (Abraham 1912g).

69 "Man könnte nun vermuten, daß während der Emission von α -Strahlen durch radioaktive Atome, bei der sehr große Beschleunigungen auftreten, die hypothetischen Schwerkraftwellen in merklicher Stärke erregt werden. Indessen werden dabei gleichzeitig elektrische Wellen erregt und, wie die quantitative Diskussion zeigt, beträgt die Kraft, welche die von einem α -Teilchen entsandten Schwerewellen auf ein zweites α -Teilchen ausüben, höchstens 10^{-36} der elektrischen Kraft." (Abraham 1915, 487)

umph merely realized a potential inherent in the shared knowledge of the time. After all, even if considered in hindsight, Abraham's thoughts on maximal sizes of stars and gravitational waves represent the grandiose vistas offered by an outlook from considerable heights, even if it is also clear in hindsight that Abraham was not the one who reached the highest summit.

MAX ABRAHAM

ON THE THEORY OF GRAVITATION

Originally published in Rendiconti della R. Accademia dei Lincei. German translation by the author published as "Zur Theorie der Gravitation" in Physikalische Zeitschrift 13, 1912, pp. 1–4; correction, p. 176. Received December 14, 1911. Author's date: Milan, 1911. English translation taken from the German.

In a recently published paper A. Einstein[1] proposed the hypothesis that the speed of light (c) depends on the gravitational potential (Φ). In the following note, I develop a theory of the gravitational force which satisfies the principle of relativity and derive from it a relation between c and Φ, which in first approximation is equivalent to Einstein's. This theory attributes values to the densities of the energy and the energy flux of the gravitational field which differ from those hitherto assumed.

Following Minkowski's[2] presentation, we consider

$$x, y, z \qquad \text{and} \qquad u = il = ict$$

as the coordinates of a four-dimensional space. Let the "rest density" ν, as well as the gravitational potential Φ, be scalars in this space, and let them be linked through the differential equation:

$$\frac{\partial^2\Phi}{\partial x^2} + \frac{\partial^2\Phi}{\partial y^2} + \frac{\partial^2\Phi}{\partial z^2} + \frac{\partial^2\Phi}{\partial u^2} = 4\pi\gamma\nu. \tag{1}$$

(γ is the gravitational constant.)
The "accelerating force" [*bewegende Kraft*] acting on the unit mass in the gravitational field is a four-vector

$$\mathfrak{F} = -\mathrm{Grad}\Phi \tag{2}$$

with components

$$\mathfrak{F}_x = -\frac{\partial\Phi}{\partial x}, \quad \mathfrak{F}_y = -\frac{\partial\Phi}{\partial y}, \quad \mathfrak{F}_z = -\frac{\partial\Phi}{\partial z}, \quad \mathfrak{F}_u = -\frac{\partial\Phi}{\partial u}. \tag{2a}$$

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

According to eqs. (1) and (2), the gravitational force propagates with the speed of light as required by the principle of relativity; whereas, however, light waves are transverse, the *gravitational waves are longitudinal*.

We write $\dot{x}, \dot{y}, \dot{z}, \dot{u}$ for the first derivatives of the coordinates of a material "world point" with respect to its "proper time" τ, i.e., for the components of the "velocity" four-vector $\mathfrak{V}$ and $\ddot{x}, \ddot{y}, \ddot{z}, \ddot{u}$ for the second derivatives, i.e., for the components of the "acceleration" four-vector $\dot{\mathfrak{V}}$. Then the *equations of motion*[3] are:

$$\ddot{x} = \mathfrak{F}_x, \quad \ddot{y} = \mathfrak{F}_y, \quad \ddot{z} = \mathfrak{F}_z, \quad \ddot{u} = \mathfrak{F}_u. \tag{3}$$

Between the first derivatives exist the identity: |

[2]
$$\dot{x}^2 + \dot{y}^2 + \dot{z}^2 + \dot{u}^2 = -c^2, \tag{4}$$

or

$$\dot{l}^2 \left\{ \left(\frac{dx}{dl}\right)^2 + \left(\frac{dy}{dl}\right)^2 + \left(\frac{dz}{dl}\right)^2 - 1 \right\} = -c^2.$$

Therefore, if one sets

$$\beta^2 = \left(\frac{dx}{dl}\right)^2 + \left(\frac{dy}{dl}\right)^2 + \left(\frac{dz}{dl}\right)^2, \qquad \kappa = \sqrt{1-\beta^2}, \tag{4a}$$

it follows that

$$\dot{l} = \frac{c}{\sqrt{1-\beta^2}} = c\kappa^{-1}. \tag{4b}$$

Now, by differentiating eq. (4) with respect to proper time, Minkowski obtains the condition of the "orthogonality" of the velocity and acceleration four-vectors. However, if c is considered to be variable, the place of that condition is taken by the following:

$$\dot{x}\ddot{x} + \dot{y}\ddot{y} + \dot{z}\ddot{z} + \dot{u}\ddot{u} = -c\frac{dc}{d\tau}, \tag{5}$$

as the differentiation of eq. (4) shows. By introducing here, instead of the acceleration, the accelerating force according to (3) and (2), we obtain

$$\dot{x}\frac{\partial\Phi}{\partial x} + \dot{y}\frac{\partial\Phi}{\partial y} + \dot{z}\frac{\partial\Phi}{\partial z} + \dot{u}\frac{\partial\Phi}{\partial u} = c\frac{dc}{d\tau}$$

---

3 As I have shown, when energy of a non-mechanical nature is supplied to matter, the Minkowskian equations of motion require modification. See this journal 10, 737, 1909; 11, 527, 1910. But, now, we are dealing with purely mechanical effects so that this modification need not be considered.

or

$$\frac{d\Phi}{d\tau} = c\frac{dc}{d\tau}.$$

The integration yields

$$\frac{c^2}{2} - \frac{c_0^2}{2} = \Phi - \Phi_0, \tag{6}$$

where c_0 and Φ_0 represent the speed of light and the gravitational potential at the origin of coordinates. Equation (6) implies: *The increase of half the square of the speed of light is equal to the increase of the gravitational potential.*

Instead of this relation, which is exactly valid according to our theory, one can, neglecting the square of the quotient of Φ and c^2, take Einstein's formula (loc. cit. p. 906):

$$c = c_0\left(1 + \frac{\Phi - \Phi_0}{c^2}\right).$$

However, eq. (6) better serves to manifest the independence from the arbitrarily chosen origin of coordinates.

It is instructive to compare the relation obtained with the emission theory of light. Let us imagine that the particles emitted from the light source move according to the laws of Galilean mechanics and that they are subject to the gravitational force. They would then experience an increase of *vis viva* [*lebendiger Kraft*] equal to the *decrease* of potential energy. The increase of *vis viva* of the light particles calculated according to (6) is, by contrast, equal to the *increase* of their potential energy, i.e., of the same amount but of opposite sign as that following from the emission theory. But as far as the bending of light rays in the gravitational field is concerned, which can be derived from (6) with the aid of Huygens' principle,[4] it is identical with the bending of the trajectories of those light particles. This is one of the numerous incomplete analogies between the modern theory of radiation and the emission theory of light.

We consider the motion of a material point of mass m in a gravitational field. The first three equations of motion yield:

$$m\frac{d\dot{x}}{d\tau} = -m\frac{\partial\Phi}{\partial x}, \qquad m\frac{d\dot{y}}{d\tau} = -m\frac{\partial\Phi}{\partial y}, \qquad m\frac{d\dot{z}}{d\tau} = -m\frac{\partial\Phi}{\partial z}; \tag{7}$$

they contain the law of conservation of momentum [*Impulssatz*]. In contrast, the last of the eqs. (3):

4 A. Einstein has shown that a light ray passing the surface of the Sun is deflected towards the Sun and has drawn the attention of the astronomers to this consequence of the theory which can perhaps serve as its verification.

$$m\frac{dl}{d\tau} = -mi\mathfrak{F}_u = mi\frac{\partial\Phi}{\partial u} = m\frac{\partial\Phi}{\partial l} \tag{8}$$

expresses the law of conservation of *vis viva* in Minkowskian mechanics. In particular, if the gravitational field depends on the position but not on the time, then one obtains, multiplying (8) by c and taking (4b) into consideration:

$$mc\frac{d}{d\tau}(c\kappa^{-1}) = 0. \tag{9}$$

Now, by considering c as constant, Minkowski interprets $m(c^2\kappa^{-1} - 1)$ as the kinetic energy of the material point. In contrast, in the theory developed here, which takes c to be variable, this would not be permissible. It also seems impossible in this case to give a general expression for the energy of the material point whose decrease would be precisely equal to the energy extracted from the gravitational field.

However, we can convince ourselves that, at least for small velocities, the theorem of conservation of energy, which is confirmed by experience in this realm, follows from (9). From (9) one obtains

$$mc\kappa^{-1} = \text{const.} \tag{9a}$$

[3] | By neglecting squares and products of β^2 and $\dfrac{\Phi - \Phi_0}{c^2}$, according to (4a) we write:

$$\kappa^{-1} = (1-\beta^2)^{-1/2} = 1 + \frac{1}{2}\beta^2, \qquad \beta^2 = \frac{v^2}{c_0^2},$$

and, according to (6):

$$c = \{c_0^2 + 2(\Phi - \Phi_0)\}^{1/2} = c_0 + \frac{\Phi - \Phi_0}{c_0}.$$

Then, we obtain

$$mc\kappa^{-1} = mc_0\left(1 + \frac{1}{2}\beta^2\right) + m\frac{\Phi - \Phi_0}{c_0}.$$

Therefore, if we multiply (9a) by c_0, it follows that

$$\frac{1}{2}mv^2 + m\Phi = \text{const.}, \tag{9b}$$

i.e., the law of the conservation of energy in the usual form. *Thus, in the limiting case of small velocities, the new mechanics coincides with the old.* As a consequence of the relation (6) between the velocity of light c and the gravitational potential Φ, it also now emerges clearly that not only the "*kinetic*" *energy* $1/2\ mv^2$, but also the *potential energy* $m\Phi$ *are associated with the material point.*

We now consider two material points of masses m and m_0 moving with small velocities in a stationary gravitational field. Each of the two points possesses a potential energy, of which the part depending upon the mutual distance r is:

$$-\gamma \frac{m_0 m}{r} = -E.$$

Therefore, the total of this variable part of the potential energy for the two points amounts to $-2E$. Hence, if, under their mutual attraction, the two points approach one another, then the *increase in their total vis viva is equal to half of the decrease of their total potential energy.*

Where now does the other half reside? Obviously in the gravitational field. Indeed, as we shall see, in this case, our theory ascribes to the field energy the value E, which is equal and opposite to the one previously assumed. In this way, the difficulty emphasized by Maxwell[5]—that the energy density in a gravitational field, when set to zero for vanishing forces, would become negative elsewhere—disappears. *The expression (13) for the energy density in a gravitational field at which we will arrive is strictly positive*. But, besides the field energy E, the total energy of the system also contains the energy of the matter whose potential part in the stationary field is $-2E$.

The credit for having extended the concept of energy flux to the gravitational field goes to V. Volterra.[6] However, his expression for the energy flux is based on Maxwell's assumption concerning the energy distribution in the field. Accordingly, the theory developed here will thus lead to different results also with respect to energy flux.

The fictitious stresses, the energy flux as well as the densities of energy and momentum for a field depend on a "*four-dimensional tensor*".[7] We write for the *ten components of the gravitational tensor*:

5 [J.] Clerk Maxwell, *Scientific papers* 1, 570.

6 V. Volterra, *Nuovo Cimento* 337, 1899, 1.

7 Regarding these "world tensors" or "ten-tensors" see M. Abraham, *Rendiconti del circolo matematico di Palermo* 1910, 1; A. Sommerfeld, *Ann. d. Phys.* 32, 749, 1910; M. Laue, "Das Relativitätsprinzip", Braunschweig 1911, p. 73.

$$\left.\begin{aligned} X_x &= \frac{1}{4\pi\gamma}\left\{-\left(\frac{\partial\Phi}{\partial x}\right)^2+\Psi\right\} \\ Y_y &= \frac{1}{4\pi\gamma}\left\{-\left(\frac{\partial\Phi}{\partial y}\right)^2+\Psi\right\} \\ Z_z &= \frac{1}{4\pi\gamma}\left\{-\left(\frac{\partial\Phi}{\partial z}\right)^2+\Psi\right\} \\ X_y &= Y_x = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial x}\frac{\partial\Phi}{\partial y} \\ Y_z &= Z_y = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial y}\frac{\partial\Phi}{\partial z} \\ Z_x &= X_z = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial z}\frac{\partial\Phi}{\partial x} \end{aligned}\right\} \tag{10}$$

$$\left.\begin{aligned} X_u &= U_x = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial u}\frac{\partial\Phi}{\partial x} \\ Y_u &= U_y = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial u}\frac{\partial\Phi}{\partial y} \\ Z_u &= U_z = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial u}\frac{\partial\Phi}{\partial z} \end{aligned}\right\} \tag{10a}$$

$$U_u = \frac{1}{4\pi\gamma}\left\{-\left(\frac{\partial\Phi}{\partial u}\right)^2+\Psi\right\}. \tag{10b}$$

Here, Φ and

$$\Psi = \frac{1}{2}\left\{\left(\frac{\partial\Phi}{\partial x}\right)^2+\left(\frac{\partial\Phi}{\partial y}\right)^2+\left(\frac{\partial\Phi}{\partial z}\right)^2+\left(\frac{\partial\Phi}{\partial u}\right)^2\right\} \tag{10c}$$

are four-dimensional scalars. Thus, it becomes immediately clear that the components (10), (10a), (10b) of the ten-tensor indeed transform like the squares and products of the coordinates x, y, z, u. From them, | the components of the *accelerating force* per unit volume are derived as follows: [4]

$$\left.\begin{aligned}
\nu\mathfrak{F}_x &= \frac{\partial X_x}{\partial x} + \frac{\partial X_y}{\partial y} + \frac{\partial X_z}{\partial z} + \frac{\partial X_u}{\partial u} \\
\nu\mathfrak{F}_y &= \frac{\partial Y_x}{\partial x} + \frac{\partial Y_y}{\partial y} + \frac{\partial Y_z}{\partial z} + \frac{\partial Y_u}{\partial u} \\
\nu\mathfrak{F}_z &= \frac{\partial Z_x}{\partial x} + \frac{\partial Z_y}{\partial y} + \frac{\partial Z_z}{\partial z} + \frac{\partial Z_u}{\partial u} \\
\nu\mathfrak{F}_u &= \frac{\partial U_x}{\partial x} + \frac{\partial U_y}{\partial y} + \frac{\partial U_z}{\partial z} + \frac{\partial U_u}{\partial u}
\end{aligned}\right\} \tag{11}$$

By substituting the above expressions for the components of the ten-tensor and by taking into consideration the differential equation (1), one arrives at the value

$$\nu\mathfrak{F} = -\nu\mathrm{Grad}\Phi. \tag{12}$$

for the accelerating force per unit volume, in agreement with (2).

We discuss the formulae for the components of the gravitational tensor. The first six components (10) determine the "*fictitious stresses*" in the gravitational field. In the *stationary field* there exist the *normal stresses*:

$$\left.\begin{aligned}
X_x &= \frac{1}{8\pi\gamma}\left\{-\left(\frac{\partial\Phi}{\partial x}\right)^2 + \left(\frac{\partial\Phi}{\partial y}\right)^2 + \left(\frac{\partial\Phi}{\partial z}\right)^2\right\}, \\
Y_y &= \frac{1}{8\pi\gamma}\left\{\left(\frac{\partial\Phi}{\partial x}\right)^2 - \left(\frac{\partial\Phi}{\partial y}\right)^2 + \left(\frac{\partial\Phi}{\partial z}\right)^2\right\}, \\
Z_z &= \frac{1}{8\pi\gamma}\left\{\left(\frac{\partial\Phi}{\partial x}\right)^2 + \left(\frac{\partial\Phi}{\partial y}\right)^2 - \left(\frac{\partial\Phi}{\partial z}\right)^2\right\},
\end{aligned}\right\} \tag{12a}$$

and the *shear stresses*

$$\left.\begin{aligned}
X_y &= Y_x = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial x}\frac{\partial\Phi}{\partial y}, \\
Y_z &= Z_y = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial y}\frac{\partial\Phi}{\partial z}, \\
Z_x &= X_z = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial z}\frac{\partial\Phi}{\partial x}.
\end{aligned}\right\} \tag{12b}$$

They correspond to a *pressure along the lines of force and to a pull perpendicular to the lines of force, and their total value is proportional to the field strength and, for a* *stationary field, is equal to the energy density* (ε) (see eq. (13)). For a temporally varying field there is still a *hydrostatic pressure* to be added:

$$p = \frac{1}{8\pi\gamma}\left(\frac{\partial\Phi}{\partial l}\right)^2, \tag{12c}$$

which has to be subtracted from the normal stress (12a).

The *energy density* in the *gravitational field* is:

$$\varepsilon = U_u = \frac{1}{8\pi\gamma}\left\{\left(\frac{\partial\Phi}{\partial x}\right)^2 + \left(\frac{\partial\Phi}{\partial y}\right)^2 + \left(\frac{\partial\Phi}{\partial z}\right)^2 + \left(\frac{\partial\Phi}{\partial l}\right)^2\right\}. \tag{13}$$

This turns out to be *strictly positive* and, in particular, to be *proportional to the square of the gravitational force* $\mathfrak{F}$ in the *stationary field*.

The energy flux has the components:[8]

$$\mathfrak{S}_x = icU_x, \qquad \mathfrak{S}_y = icU_y, \qquad \mathfrak{S}_z = icU_z,$$

with which, from (10a), follows:

$$\mathfrak{S} = -\frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial t}\mathrm{grad}\Phi = \frac{1}{4\pi\gamma}\frac{\partial\Phi}{\partial t}\cdot\mathfrak{F}, \tag{14}$$

i.e. the energy flux has the direction of the gravitational force; its magnitude is proportional to the product of the magnitude of gravitational force and the temporal increase of the potential.

If one multiplies the last of the eqs. (11) by $-ic$, then it becomes:[8]

$$-ic\nu\mathfrak{F}_u = -\mathrm{div}\mathfrak{S} - \frac{\partial\varepsilon}{\partial t}. \tag{14a}$$

Therefore

$$-ic\nu\mathfrak{F}_u = ic\nu\frac{\partial\Phi}{\partial u} = \nu\frac{\partial\Phi}{\partial l} \tag{14b}$$

yields the energy, which, per unit volume and time, is extracted from the field and is supplied to the matter.

Since, furthermore, as can be seen from (11),[8]

$$\frac{i}{c}X_u, \qquad \frac{i}{c}Y_u, \qquad \frac{i}{c}Z_u,$$

8 Here, the speed of light c is considered as constant, and therefore the influence of the potential on the speed of light discussed above is neglected.

are the components of the momentum density (g) of the gravitational field, it follows from (10a) that:

$$\mathfrak{g} = \frac{1}{c^2}\mathfrak{S} = \frac{1}{4\pi\gamma c^2}\frac{\partial\Phi}{\partial t}\cdot\mathfrak{F}. \tag{15}$$

The symmetry of the ten-tensor implies this relation between the energy flux and the momentum density.[9]

CORRECTION

In lines 8 and 9 [lines 16 and 17 in the original] of my note "On the Theory of Gravitation" an oversight has to be corrected which was brought to my attention by a friendly note from Mr. A. Einstein. Hence one should read there "we consider dx, dy, dz and $du = idl = icdt$ as components of a displacement ds in four-dimensional space." [176]

Hence:

$$ds^2 = dx^2 + dy^2 + dz^2 - c\ dt^2$$

is the square of the four-dimensional line element, where the speed of light c is determined by eq. (6).

9 M. Planck, this journal, 9, 828, 1908, has put forth the claim that also a mechanical energy flux always implies a corresponding momentum.

THE FREE FALL

Originally published in Rendiconti del R. Instituto Lombardo di scienze e lettere. German translation by the author published as "Der freie Fall" in Physikalische Zeitschrift 13, 1912, pp. 310–311. Received March 11, 1912. Author's date: Milan, March 1912. English translation taken from the German.

In a recently published communication[1] I have developed a new theory of gravitation. In this theory, the speed of light c is linked to the gravitational potential Φ through the relation:

$$\frac{1}{2}c^2 - \frac{1}{2}c_0{}^2 = \Phi - \Phi_0. \tag{1}$$

The equations of motion of a material point in a gravitational field are:

$$\frac{d^2x}{d\tau^2} = -\frac{\partial\Phi}{\partial x}, \qquad \frac{d^2y}{d\tau^2} = -\frac{\partial\Phi}{\partial y}, \qquad \frac{d^2z}{d\tau^2} = -\frac{\partial\Phi}{\partial z}, \tag{2}$$

$$\frac{d^2u}{d\tau^2} = -\frac{\partial\Phi}{\partial u}; \tag{2a}$$

τ denotes the "*proper time*" of the moving point and is related to the time t measured in the reference frame as follows:

$$\frac{du}{d\tau} = ic\frac{dt}{d\tau} = \frac{ic}{\kappa}, \tag{3}$$

$$\kappa = \sqrt{1 - \frac{v^2}{c^2}} \tag{4}$$

(v is the magnitude of the velocity of the material point).

In the static field, the last (2a) of the equations of motion

1 This journal, 13, 1, 1912.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

$$\frac{d}{d\tau}\left(\frac{ic}{\kappa}\right) = \frac{i}{c}\frac{\partial\Phi}{\partial t}$$

assumes the form

$$\frac{c}{\kappa} = \text{const}; \tag{5}$$

it corresponds to the law of conservation of energy.

In the following, the *free fall in empty space* shall be treated on the basis of this theory. The gravitational field is assumed to be homogeneous and parallel to the x- axis. Therefore

$$-\frac{\partial\Phi}{\partial x} = g, \qquad -\frac{\partial\Phi}{\partial y} = -\frac{\partial\Phi}{\partial z} = 0.$$

Then, eqs. (2) yield:

$$\frac{d^2x}{d\tau^2} = g, \qquad \frac{d^2y}{d\tau^2} = 0, \qquad \frac{d^2z}{d\tau^2} = 0. \tag{6}$$

These equations of motion differ from those of Galilean mechanics merely by the proper time τ of the falling point taking the place of t. From these it follows immediately that *the trajectory of the point is a parabola also in the new theory.*

We want to restrict ourselves to the consideration of motion parallel to the x- axis, i.e. along the field, and, in particular, with the following initial conditions:

$$\tau = 0: \qquad x = 0, \qquad \frac{dx}{d\tau} = 0. \tag{7}$$

The gravitational potential may be referred to the plane $(x = 0)$:

$$\Phi_0 = 0, \qquad \Phi = -gx;$$

then, according to (1), one has to set:

$$c^2 = c_0^2 - 2gx; \tag{8}$$

where c_0 denotes the speed of light for $x = 0$. Since we assume the initial speed of the falling point to be equal to zero, initially, we have, according to (4), $\kappa = 1$. Therefore eq. (5) reads:

$$\frac{c}{\kappa} = c_0. \tag{9}$$

From this and from (3) follows the relation

$$\frac{dt}{d\tau} = \frac{1}{\kappa} = \frac{c_0}{c}, \tag{10}$$

which connects the time t with the proper time τ; as a consequence of (8) it can be written as:

$$\frac{dt}{d\tau} = \frac{1}{\sqrt{1-\frac{2gx}{c_0^2}}}. \tag{11}$$

By integrating the first of the equations of motion (6), subject to the initial conditions (7), we obtain

$$\frac{dx}{d\tau} = g\tau, \tag{12}$$

$$x = \frac{1}{2}g\tau^2, \tag{13}$$

i.e. the free fall velocity is proportional to the proper time, the free fall distance to half its square.

The task is now to replace the proper time τ by introducing the time t measured in the coordinate system. In order to determine t as a function of τ, we use eq. (11); taking into account (13) yields

$$\frac{dt}{d\tau} = \frac{1}{\sqrt{1-\left(\frac{g\tau}{c_0}\right)^2}}, \tag{14}$$

and thus

$$t = \int_0^\tau \frac{d\tau}{\sqrt{1-\left(\frac{g\tau}{c_0}\right)^2}} = \frac{c_0}{g}\text{arc }\sin\left(\frac{g\tau}{c_0}\right). \tag{15}$$

By taking the inverse of this functional relation we express τ through t: |

$$\tau = \frac{c_0}{g}\sin\left(\frac{gt}{c_0}\right). \tag{16}$$ [311]

Therefore it follows that

$$\frac{d\tau}{dt} = \cos\left(\frac{gt}{c_0}\right). \tag{16a}$$

Thus, the *free fall velocity* becomes:

$$v = \frac{dx}{dt} = \frac{dx}{d\tau}\frac{d\tau}{dt} = g\tau\frac{d\tau}{dt} = c_0\sin\left(\frac{gt}{c_0}\right)\cos\left(\frac{gt}{c_0}\right). \tag{17}$$

On the other hand, since according to (10):

$$c = c_0 \frac{d\tau}{dt} = c_0 \cos\left(\frac{gt}{c_0}\right), \tag{17a}$$

we then have:

$$\frac{v}{c} = \sin\left(\frac{gt}{c_0}\right) \tag{18}$$

for the quotient of the velocity of fall and of the speed of light at the point in question.

Finally, the *distance of fall* follows from (13) and (16):

$$x = \frac{c_0^2}{2g} \sin^2\left(\frac{gt}{c_0}\right). \tag{19}$$

It is understood that all of these relations are valid only for

$$gt < c_0 \cdot \frac{\pi}{2} \tag{20}$$

Indeed, for $gt = c_0 \cdot \frac{\pi}{2}$, one would have

$$gx = \frac{c_0^2}{2},$$

and therefore

$$\Phi - \Phi_0 = -gx = -\frac{c_0^2}{2}.$$

However, for this value of x, the speed of light c would, according to (1), become zero which is inadmissible.

It is obvious that, by imposing the condition

$$\Phi_0 - \Phi < \frac{c_0^2}{2} \tag{21}$$

on the gravitational potential, the fundamental relation (1) excludes the existence of a homogeneous gravitational field of infinite extent

From the condition (21) one can derive similar consequences of the new theory of gravitation which are of interest for cosmogony.

The potential of a star of mass m is

$$\Phi = -\gamma \frac{m}{r} \tag{22}$$

(γ gravitational constant). Thus, the potential difference between infinite distance $(r = \infty)$, and the surface of the star $(r = a)$ is:

$$\Phi_0 - \Phi = \gamma \frac{m}{a}.$$

Therefore,

$$\gamma \frac{m}{a} < \frac{c_0^2}{2} \left(= \frac{9}{2} \cdot 10^{20} \right) \tag{23}$$

must hold. For the Sun one has in *cgs* units

$$\left(\gamma \cdot \frac{m}{a} \right)_s = 2 \cdot 10^{15}.$$

Thus, the *quotient of mass and radius for an arbitrary star must satisfy the inequality*

$$\frac{m}{a} < 2,25 \cdot 10^5 \cdot \left(\frac{m}{a} \right)_s. \tag{24}$$

For stars whose mean density is equal to that of the Sun, the quotients m/a are proportional to the squares of the radii. Hence, the following must hold

$$a < 500(a)_s, \tag{24a}$$

and thus

$$m < 10^8 (m)_s. \tag{24b}$$

That is, *the mass of a star whose mean density is equal to that of the Sun cannot become larger than one hundred million times the mass of the Sun*.

Since this limit is rather high, no difficulties arise from this for our theory.

MAX ABRAHAM

A NEW THEORY OF GRAVITATION

Lecture presented on October 19, 1912 to the Societa italiana per il progresso delle scienze. German translation by the author published as "Eine neue Gravitationstheorie" in Archiv der Mathematik und Physik. Third series 20, 1913, pp. 193–209. English translation taken from the German.

Modern physics does not allow forces that propagate with an infinite speed. It does not hold that Newton's law is the true fundamental law of gravitation; rather, it endeavors to obtain this action-at-a-distance law from differential equations attributing a finite speed of propagation to the gravitational force.

A model of such a theory of local action is provided to us by Maxwell's theory of the electromagnetic field. Its fundamental laws are differential equations connecting the electric vector to the magnetic vector. The electromagnetic energy is, according to this theory, distributed throughout the field. When the field changes in time, an energy flow determined by the Poynting vector obtains. If, for example, an electron starts to oscillate, it sends out electromagnetic waves. With the waves the electromagnetic energy flows from the neighborhood of the electron to the initially undisturbed regions of space; this radiation of energy results in the damping of the oscillations of the electron.

The analogy between Coulomb's and Newton's law suggests a similar interpretation of the gravitational force. It was Maxwell himself who developed a theory of gravitation, modelled on electrostatics, and emphasized the difficulties of such a theory.[1] The different signs of the forces—attraction of masses compared to repulsion of charges of equal sign—entails that the energy density of the gravitational field becomes negative as soon as one assumes that when the field vanishes so does the energy. One would need to drop this last assumption and imagine | that if there were no [194] gravitational field, a certain amount of energy resides in the aether, which decreases upon excitation of the field. But even so, one still does not avoid all objections.

Let us consider for example a material particle which is initially at rest and then is set into oscillation. In theories of the electromagnetic type it emits waves similar to light waves, i.e. transverse waves propagating with the speed of light. With the waves, the gravitational field enters into previously undisturbed regions of space. Hence, the

1 J. Cl. Maxwell, *Scientific papers* I, p. 570.

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

energy density of the aether decreases in these regions; i.e. the energy flows towards the oscillating particle whose energy increases at the expense of the aether energy. This influx of energy results in an increase of the oscillation of the particle; its equilibrium is therefore unstable.

Similar difficulties arise in this way for all gravitational theories of Maxwellian type; among these, especially the theory of H. A. Lorentz[2] and R. Gans[3] has found followers among physicists. Starting from the hypothesis that matter consists of positive and negative electrons and that the attraction between electrons of opposite charge is slightly greater than the repulsion between those of like charge, it arrives at field equations of Maxwellian character connecting the gravitational vector, which corresponds to the electric vector, to a second one analogous to the magnetic vector. In this theory, the energy flux of the gravitational field is expressed by a vector corresponding to the Poynting vector but with opposite sign.[4] Here, the above mentioned difficulty appears; indeed, R. Gans found that the radiation reaction force has the opposite sign as in the dynamics of the electron. Thus, as a result of the emitted radiation, the acceleration of a neutral particle would increase rather than decrease as for electrons. Hence, the equilibrium of the particle would not be stable.

Therefore, we have to dispense with the close analogy between gravitation and electromagnetism without thereby relinquishing the essential notions of Maxwell's theory, namely: *The fundamental laws must be differential equations describing the excitation and propagation of the gravitational field; associated with this field is a positive energy density as well as an energy flux.* |

[195] The problem of gravitation is even more urgent, as modern physics has discovered interesting relations between mass (m) and energy (E). According to the theory of relativity one should have

$$E = mc^2 \quad (c \text{ is the speed of light in the vacuum}). \tag{1}$$

Since we still lack a satisfactory theory of gravitation, one has been able to derive this relation only for the inertial mass. Is it valid also for the gravitational mass?

We displace a body in a gravitational field. Its potential energy, and consequently the first term in equation (1), changes with the gravitational potential. It follows that one of the factors on the right-hand side, or even both, must depend on the gravitational potential. We want to consider the hypothesis that c, *the speed of light, depends on the gravitational potential*. This hypothesis was first enunciated by A. Einstein.[5] Taking it as a starting point, I undertook to develop a theory of the gravitational field[6] which I then, in constructive competition with Mr. A. Einstein,[7] gave a

7 A. Einstein, *Ann. d. Physik* 38 (1912), p. 355 and p. 433.

more satisfactory form.[8] In the following, I want to present the essential features of the new theory of gravitation.

Postulate I. The surfaces c = constant *coincide with the equipotential surfaces of the gravitational field*. Or, in other words: *The negative gradient of* c *gives the direction of the gravitational force*.

If the speed of light varies in the gravitational field, then, according to Huygens' principle, a light ray in this field will be refracted as in an inhomogeneous medium. This consequence was derived by A. Einstein; he showed that a light ray passing the surface of the Sun must be deflected, in fact, just as if it were attracted by the Sun. However, this deflection, only observable at a total eclipse of the Sun, lies at the limit of observability.

For bodies at rest in the gravitational field we apply the usual geometry; hence, we assume that the unit of length, the meter, is independent of c and can thus serve to measure length in arbitrary regions of the gravitational field. We now want to consider two regions in which c may have different values, c_1 and c_2. We bring an antenna having a length of one meter from the | first region into the second. Since the [196]
length of the antenna remains constant, obviously the periods of its electromagnetic normal modes change in inverse proportion to the speed of light c:

$$\tau_1 : \tau_2 = c_2 : c_1. \tag{2}$$

If one could construct a clock whose rate were independent of c, then one could determine the change in period by transporting the clock, with the antenna, from one region into the other. However, we rule out the possibility of such a clock by putting forward the following postulate:

Postulate II. An observer belonging to a material system is unable to perceive that he, together with the system, is brought into a region in which c *has a different value*.

From this postulate,[9] it follows that the duration of an arbitrary process changes in the same proportion to c as does the period of the normal modes of the antenna; because otherwise the observer would be able to determine the latter change. Hence, from the second postulate follows the general theorem: The duration of an arbitrary process in a system changes in inverse proportion to c if the system's location in a gravitational field changes. Or more briefly:

"The times are of degree c^{-1}*."*

Within this theory the unit of time has only a local significance, whereas a universal validity will be attributed to the unit of length, at least for the state of rest.

---

8 M. Abraham, *Physik. Zeitschrift* 1912, p. 793.

9 It is understood that this postulate refers only to the value of c itself, and not to its derivative; the value of c has no influence on the events in the system which present themselves to an observer belonging to that system. The gradient of c, however, i.e. the gravitational force, of course influences these events.

According to postulate II, there exists a certain relativity. Let us imagine that the Earth reaches locations in space in which the gravitational potential, and therefore also c, has a different value. According to the latter postulate it would not be possible for us to determine this fact through any terrestrial measurement. All measurements, and hence also all the constants of physics, would remain unchanged; also the measurement of the speed of light, e.g. according to the method of Fizeau, would produce the same result as before since with respect to a terrestrial clock its changes are compensated for by the changes of the angular velocity of the gear wheel. Obviously, all
[197] velocities change generally in proportion to the light | velocities, i.e. they are of degree c, because the lengths are of degree c^0 and the times of degree c^{-1}.

It is, however, in no way ruled out that an observer not belonging to the system discovers this particular influence of the gravitational potential on the periods. For example, a terrestrial observer measuring the Fraunhofer lines of the Sun and comparing them to the corresponding lines of terrestrial sources, should find that their frequencies behave as

$$\nu_2 : \nu_1 = \tau_1 : \tau_2 = c_2 : c_1 .$$

From this would follow a relative shift of the Sun's lines:

$$\frac{\nu_2 - \nu_1}{\nu_1} = \frac{c_2 - c_1}{c_1},$$

namely towards the red end of the spectrum, because the gravitational potential on the Sun, and hence also c, has a smaller value than on Earth. For this relative displacement of the Sun's lines Einstein found the value $2 \cdot 10^{-6}$, which according to Doppler's principle would correspond to a speed of 0.6 kilometers per second. Astrophysicists are now well able to measure shifts of this order, and indeed they have found such shifts, and precisely in the sense required by our theory. However, they interpret the shift partially as the Doppler effect of descending flows of absorbing gases, and partially as pressure effects. But perhaps the totality of the phenomena on the surface of the Sun can be better interpreted if one takes the predicted gravitational shifts of the lines into account.

We now turn from kinematics to dynamics. The second postulate implies that *all mechanical quantities of the same class are of the same degree in* c. For example, a system of forces which maintain themselves in equilibrium in a region, where c has the value c_1, must still do so when the system is brought into a region of the field in which c is equal to c_2. Therefore, all forces must change in the same proportion with c. All forms of energy must be of the same degree in c as well, because if two forms of energy, e.g. the kinetic and the potential, were of different degree, the conversion of energy from one form into the other would give rise to a periodic process whose frequency is not of the correct degree, i.e. that of c. Similar considerations apply for other dynamical quantities. Since all these quantities are constituted from mass,
[198] length and time, it is sufficient to know the *degree of the mass* to determine all | their degrees since we already know the degree of the lengths (c^0) and of the times (c^{-1}).

I raised the question earlier whether, as for the inertial mass, the gravitational mass is proportional to the energy. What would take place during the transformation of radioactive elements if their continual loss of energy as heat would cause a decrease in their inertial mass, but not in their weight? Obviously, uranium and its daughter element radium suspended from strings of equal lengths would result in pendulums with unequal periods of oscillations. Even the equilibrium position of such pendulums would be different since the attraction of the Earth acts on the gravitational, whereas the centrifugal force acts on the inertial mass. This contradicts experience. Either one must give up any relation between mass and energy, or assume that the weight too, like the inertia, is proportional to energy. The first alternative would mean the collapse of the new mechanics. We prefer the second and hence propose the following postulate.

Postulate III. The forces which are acting on two bodies at the same location of the gravitational field are in proportion to their energy.

Here, one has to take into consideration not only the potential and kinetic energy of the molar and molecular motion, but also the chemical and electromagnetic energy. For example, the electrons in a metal carry electromagnetic energy; hence they are subject to gravitation.[10] Similarly, the thermal radiation in the interior of a cavity will also acquire weight. If one interprets the third postulate in this manner, then *the laws of the conservation of energy and of the conservation of weight merge into one*.

Proceeding with the mathematical presentation, we start with the expression for the *Lagrangian function*, which for the dynamics of the electron is:

$$L = -mc^2 f\left(\frac{v}{c}\right); \tag{3}$$

v denotes the velocity, and m the rest mass of the electron.[11] From | the *Lagrangian* [199]
function we derive in the well known manner the values for the momentum and energy as follows:

$$G = \frac{\partial L}{\partial v}, \tag{3a}$$

$$E = v\frac{\partial L}{\partial v} - L, \tag{3b}$$

while the *equations of motion* are:

---

10 This is also supported by comments of J. Koenigsberger (*Verh. d. D. physik. Ges. XIV* (1912), p. 185).

11 In order for m to have this meaning, we must have $f''(0) = -f(0) = -1$ (this holds for example in the theory of relativity, where $f(v/c) = \sqrt{1-(v/c)^2}$); or else, an insignificant numerical factor becomes associated with m in equation (3).

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{x}}\right) - \frac{\partial L}{\partial x} = 0 \text{ etc.} \tag{4}$$

The new mechanics has, in the discussion of these equations, so far restricted itself to the case of constant c; in this case the Lagrangian function depends only on the velocity but not on the location. Hence, only the first terms containing the time derivatives of the momentum components enter into the equations of motion:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v} \cdot \frac{\dot{x}}{v}\right) = \frac{d}{dt}\left(G \cdot \frac{\dot{x}}{v}\right) = \frac{d\mathfrak{G}_x}{dt} \text{ etc.} \tag{4a}$$

In our theory of gravitation however, through the speed of light c, the Lagrangian function also depends on the coordinates; hence one must retain the second terms in Lagrange's equations:

$$\frac{\partial L}{\partial x} = \frac{\partial L}{\partial c}\frac{\partial c}{\partial x} \text{ etc.} \tag{4b}$$

They represent the components of a force proportional to the gradient of c. According to postulate I, *this force* is now precisely *the gravitational force*. In vector form, the equations of motion (4) are:

$$\frac{d\mathfrak{G}}{dt} = \frac{\partial L}{\partial c} \operatorname{grad} c. \tag{5}$$

One recognizes that the Lagrangian equations are nothing else but the analytic expression of our first postulate. (They hold exactly for the free motion of material points in the gravitational field, but can also be applied to systems whose extensions are so small that they can be considered equivalent to a material point.) Especially now, while the world of mathematics prepares for the centennial celebration of the great founder of analytical mechanics, we do not want to omit drawing attention to the significance of his work for the new mechanics.

Now we want to introduce the third postulate, which for a given location in the [200] field, sets the gravitational force proportional to the energy of the | moving point; in order to fulfill it we must write:

$$\frac{\partial L}{\partial c} = -\chi \cdot E, \tag{6}$$

where χ depends only on c, but not on v. Then the second term of (5), i.e. the gravitational force, becomes:

$$\mathfrak{K} = -\chi(c) \cdot E \cdot \operatorname{grad} c. \tag{6a}$$

Setting

$$\log \varphi(c) = \int^{c} dc \chi(c), \tag{6b}$$

it follows from (6) that

$$E = -\frac{1}{\chi(c)}\frac{\partial L}{\partial c} = -\varphi\frac{\partial L}{\partial \varphi}. \tag{6c}$$

This and (3b) yields

$$L = v\frac{\partial L}{\partial v} + \varphi\frac{\partial L}{\partial \varphi}. \tag{7}$$

On the basis of a well known theorem of Euler we infer: the Lagrangian function is a homogeneous linear function of v and φ. We wish to write it in the form:

$$L = -M\varphi \cdot f\left(\frac{v}{\varphi}\right). \tag{7a}$$

M denotes a constant (mass constant) belonging to the material mass point in question that is independent of φ and hence of c. The comparison with the expression (3) yields:

$$\varphi = c, \quad M = mc. \tag{7b}$$

From this follows the value for the rest mass m:

$$m = \frac{M}{c}. \tag{8}$$

Therefore, the rest mass is of degree c^{-1}.

Since we now know the degree of the lengths (c^0), times (c^{-1}) and masses (c^{-1}), we are in a position to derive the degree of each class of dynamical quantities. For example, *energies are of degree* c, *likewise forces are of degree* c, *actions* (having dimension of energy times time) *of degree* c^0.

From (6b) and (7b) it follows that

$$\chi(c) = \frac{1}{c},$$

so that the expression (6a) for the *gravitational force* becomes:

$$\mathfrak{K} = -\frac{E}{c}\operatorname{grad}c. \tag{9}$$

| As one sees, the first postulate is satisfied *because the force is proportional to the negative gradient of* c, as well as the third, because it is *proportional to the energy.* [201]

A potential energy is associated with a material point resting in a gravitational field; one obtains it from (3b) and (3) by setting v equal to zero:

$$E = -L = +mc^2;$$

therefore, according to (8):

$$E = M \cdot c. \tag{9a}$$

From this expression for the *energy* of a *resting point* follows, according to (9), the value for the *gravitational force* for the case of rest:

$$\mathfrak{K} = -M \operatorname{grad} c. \tag{9b}$$

The work done by this force is, as it must be, equal to the decrease of the potential energy (9a).

We are now in a position to determine for a given gravitational field, i.e. for a given field of the scalar c, the force acting on a material point. But, we still have not solved the problem initially posed, to find the gravitational field which corresponds to a given distribution of matter. Now, the interrelation between action and reaction suggests we assume that like the attracted, so also the *attracting mass is proportional to the energy,* and hence that we consider the energy as the source of the gravitational field. However, the question arises: Besides the energy of the matter, is the energy of the gravitational field itself to be taken into account? If we knew the energy of the field, then, through the application of the principle of virtual work, without further ado, at least the statics of the gravitational field can be derived. Consequently, we prefer to start from reasonable assumptions [*Ansätze*] for the field energy and the energy flux, and to obtain from these the relations connecting the gravitational vector with the density of matter and energy, respectively.

The simplest assumption would be that the energy density of the static field is proportional to the square of the gradient of c, on which, according to (9b), the field strength depends. However, as we have seen, the energy and hence also the density is of degree c, while the square of the gradient of c is obviously of degree c^2. This consideration leads to the introduction of the auxiliary variable

$$u = \sqrt{c} \tag{10}$$

[202] | and to assign to the *energy density of the gravitational field* the value:

$$\varepsilon = \frac{1}{2\alpha}\left\{\left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 + \left(\frac{\partial u}{\partial z}\right)^2 + \left(\frac{1}{c}\frac{\partial u}{\partial t}\right)^2\right\} \tag{11}$$

(α denotes a universal constant of degree c^0).

In our theory, this expression is valid also for the dynamical field; it is supplemented by the ansatz for the *energy flux in the gravitational field*

$$\mathfrak{S} = -\frac{1}{\alpha}\frac{\partial u}{\partial t} \cdot \operatorname{grad} u. \tag{12}$$

Since according to (11) the field energy is always positive, and vanishes only when the field vanishes, one sees that the energy always flows with the wave by which the disturbance is propagated. Let us imagine for example that such a disturbance, for which $u < u_0$, enters a region in which initially $u = u_0$. Then, the gradient is pointing from u towards the undisturbed region, whereas, during the passing of the wave, the time derivative of u has a negative sign. Hence, the expression (12) for the energy flux has the correct sign. It retains it when $u > u_0$ for the disturbance, because then the gradient as well as the time derivative change sign. *In the theory presented here, the energy flux always corresponds to an emission of energy from the disturbed region*; thus the above mentioned objection is not raised against it. The radiation reaction always implies a decrease of the acceleration of the material particle; its *equilibrium* is hence *not unstable*.

We now want to consider a field containing matter at rest. As we are dealing with a continuous distribution of matter over a volume V, we set

$$M = \int \mu dV, \tag{13}$$

and call

$$\mu = \lim_{V=0}\left(\frac{M}{V}\right)$$

the "*specific density*" of the matter. Since M does not depend on c, then for an incompressible fluid, whose particles do not change in volume, μ too is independent of the location in the gravitational field.

The rest energy of matter with respect to the unit volume is according to (9a),

$$\eta = \lim_{V=0}\left(\frac{Mc}{V}\right) = \mu c$$

or, according to (10)

$$\eta = \mu u^2. \tag{14}$$

| Since μ is constant for the case of rest, from this follows: [203]

$$\frac{\partial \eta}{\partial t} = 2\mu u \frac{\partial u}{\partial t} \tag{14a}$$

as the temporal increase of the rest energy per unit volume, caused by a temporal variation of the gravitational field.

Now we apply the energy equation which demands that the convergence of the energy flux is equal to the sum of the increases of the energy densities of the field (ε) and of the matter (η):

$$-\mathrm{div}\mathfrak{S} = \frac{\partial \varepsilon}{\partial t} + \frac{\partial \eta}{\partial t}. \tag{15}$$

From the expressions (11) and (12) we derive

$$\frac{\partial \varepsilon}{\partial t} = \frac{1}{\alpha}\left\{\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x \partial t} + \frac{\partial u}{\partial y}\frac{\partial^2 u}{\partial y \partial t} + \frac{\partial u}{\partial z}\frac{\partial^2 u}{\partial z \partial t} + \frac{1}{c}\frac{\partial u}{\partial t}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial u}{\partial t}\right)\right\}, \tag{15a}$$

$$-\mathrm{div}\mathfrak{S} = \frac{1}{\alpha}\left\{\frac{\partial^2 u}{\partial x \partial t}\frac{\partial u}{\partial x} + \frac{\partial^2 u}{\partial y \partial t}\frac{\partial u}{\partial y} + \frac{\partial^2 u}{\partial z \partial t}\frac{\partial u}{\partial z} + \frac{\partial u}{\partial t}\Delta u\right\}, \tag{15b}$$

with

$$\Delta u = \mathrm{div}\,\mathrm{grad} u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}. \tag{15c}$$

If, in addition, we set

$$\square u = \Delta u - \frac{1}{c}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial u}{\partial t}\right), \tag{16}$$

then from (15), taking into account (15a, b) and (14a), it follows that

$$\square u = 2\alpha\mu u. \tag{17}$$

Here, the second term relates to matter at rest. According to the previous discussion, for the case of motion one has to introduce its energy density, and replace (17) by the more general formulation:

$$\square u = 2\alpha\frac{\eta}{u}. \tag{17a}$$

This is the fundamental equation relating the gravitational field to the energy of the matter. It can function as the analytic expression of the fourth postulate of our theory, which relates the attracting mass of a body to its energy. For a static field, according to (16), the fundamental equation takes the form:

$$\Delta u \equiv \mathrm{div}\,\mathrm{grad} u = 2\alpha\frac{\eta}{u} = 2\alpha\mu u. \tag{17b}$$

Therefore, in this case the *divergence of the gradient of* $u = \sqrt{c}$ *is proportional to the energy density of matter.*

Now, what about the energy of the gravitational field itself? At least for the static
[204] field (17b), it is easy to put the basic equation | into a form in which the energy density of the field appears on the right-hand side. One has

$$\frac{\partial^2 c}{\partial x^2} = \frac{\partial^2 u^2}{\partial x^2} = 2u\frac{\partial^2 u}{\partial x^2} + 2\left(\frac{\partial u}{\partial x}\right)^2 \text{ etc.,}$$

thus,

$$\Delta c = 2u\Delta u + 2(\mathrm{grad} u)^2;$$

according to (11), the energy density of the static field is now:

$$2\alpha\varepsilon = (\mathrm{grad}\,u)^2.$$

Therefore, we can write (17b) as

$$\Delta c \equiv \mathrm{div}\,\mathrm{grad}\,c = 4\alpha(\eta + \varepsilon). \tag{18}$$

Hence, in the static field, the divergence of the gravitational vector, i.e. of the gradient of c, is proportional to the density of the total energy. Integrating (18) over a volume V bounded by the surface f, we obtain

$$\int df \frac{\partial c}{\partial n} = 4\alpha \int dV(\eta + \varepsilon) = 4\alpha E, \tag{19}$$

i.e. in the static gravitational field, *the flux of the gravitational vector through a closed surface is proportional to the enclosed energy.*

To highlight the significance of these statements, we consider a special case: *a sphere at rest* (e.g. the Sun), which is composed of homogeneous concentric layers. The basic equation (17b) yields:

$$\Delta u = 2\alpha\mu u \text{ for } r < a, \tag{20}$$

i.e. for the interior of the sphere,

$$\Delta u = 0 \text{ for } r > a, \tag{20a}$$

i.e. for the exterior of the sphere.

This last equation is Laplace's differential equation; its symmetric integral

$$u = u_0\left(1 - \frac{\vartheta}{r}\right) \qquad (r > a) \tag{21}$$

determines the gravitational field outside the attracting sphere (where u_0 denotes the value of $u = \sqrt{c}$ for $r^{-1} = 0$, ϑ a different constant).
From (21) follows

$$\frac{du}{dr} = \frac{u_0 \cdot \vartheta}{r^2}. \tag{21a}$$

Thus, the radial gradient of c becomes:

$$\frac{dc}{dr} = 2u\frac{du}{dr} = \frac{2c_0\vartheta}{r^2}\left(1 - \frac{\vartheta}{r}\right). \tag{22}$$

| Now, according to (9b) the gravitational force is proportional to this gradient. *It follows from this that Newton's law is not strictly valid in our theory. The center of the Sun attracts the planet* (considered as a material point) *with a force which contains besides the term with r^{-2} also a term with r^{-3}.* [205]

According to the theorem (eq. (19)) just developed, the flux of the gradient of c passing through a sphere of radius r is proportional to the total energy enclosed by the sphere:

$$4\pi r^2 \frac{dc}{dr} = 4\alpha E. \tag{23}$$

A sphere of infinite radius encloses the total energy (E_t) of the sphere and of its gravitational field; hence, from (22) and (23) it follows

$$E_t = \frac{2\pi c_0}{\alpha} \cdot \vartheta. \tag{23a}$$

In contrast, the sphere of radius $r = a$ contains only the internal energy of the sphere; therefore,

$$E_i = \frac{2\pi c_0}{\alpha} \cdot \vartheta\left(1 - \frac{\vartheta}{a}\right). \tag{23b}$$

Hence, the energy of the external field has the value

$$E_a = E_t - E_i = \frac{\vartheta}{a} E_t. \tag{23c}$$

We write

$$\psi = \frac{\vartheta}{a} = \frac{E_a}{E_t}. \tag{24}$$

This quantity ψ, i.e. the ratio of the external to the total energy, enters into expression (22) for the value of the gravitational force outside of the sphere:

$$\frac{dc}{dr} = \frac{2c_0 a\psi}{r^2}\left(1 - \psi\frac{a}{r}\right) = \frac{\alpha E_t}{\pi r^2}\left(1 - \frac{E_a}{E_t} \cdot \frac{a}{r}\right). \tag{24a}$$

We can therefore say: *The deviation from Newton's law is caused by the energy of the external gravitational field.*

To determine the quotient ψ, one must integrate equation (20), which is valid for the interior of the sphere. We want to compare this differential equation with Poisson's; in Poisson's equation, the right-hand side depends only on the density of the attracting masses, whereas on the right of (20), the potential (u) itself enters as a factor. This implies that in our theory the contributions of the individual mass elements do not superimpose; rather, along with the value of u at a specific location, the con-
[206] tribution of the | masses at the same location decreases as well. Since now the neighboring masses cause a decrease of the potential, it is apparent that large accumulations of matter produce here a smaller attraction than they would according to the usual theory. However, as we will see, the difference is, even for the Sun, still not noticeable.

Taking into account the symmetry of the field, the differential equation (20) yields:

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{du}{dr}\right) = 2\alpha\mu u,$$

or

$$\frac{d^2(ru)}{dr^2} = 2\alpha\mu \cdot ur \qquad (\text{for } r \le a). \tag{25}$$

To integrate the equation, one must know the distribution of the specific density μ along a radius. We want to restrict ourselves to the specific case of a sphere consisting of an incompressible fluid (μ = constant). By setting

$$\kappa^2 = 2\alpha\mu, \tag{25a}$$

we find u expressed through the hyperbolic sine

$$u = \frac{A}{r} \cdot \sinh\Phi(\kappa r). \tag{26}$$

The integral of (25) remains finite for $r = 0$. The constant A is determined by the condition that for $r = a$, the values of u and of

$$\frac{du}{dr} = A\left\{\frac{\kappa}{r}\cosh(\kappa r) - \frac{1}{r^2}\sinh(\kappa r)\right\} \tag{26a}$$

agree with those valid outside the sphere, which are given by (21) and (21a) respectively:

$$\left.\begin{aligned} \frac{A}{a}\sinh(\kappa a) &= u_0\left(1 - \frac{\vartheta}{a}\right), \\ \frac{A}{a}\{\kappa a\cosh(\kappa a) - \sinh(\kappa a)\} &= \frac{u_0\vartheta}{a}. \end{aligned}\right\} \tag{26b}$$

In addition, these two equations still determine the value of the quotient ψ (cf. 24); only this is of interest to us here. We find

$$\frac{\psi}{1-\psi} = \frac{\kappa a\cosh(\kappa a) - \sinh(\kappa a)}{\sinh(\kappa a)} = \frac{\kappa a - \tanh(\kappa a)}{\tanh(\kappa a)} = \xi$$

and therefore,

$$\psi = \frac{\xi}{1+\xi} = 1 - \frac{\tanh(\kappa a)}{\kappa a}. \tag{27}$$

The gravitational force (24a) which will be exerted by the incompressible sphere on an external point depends on this quantity, which determines the ratio of the external to the total energy of the sphere. |

[207] We first want to evaluate ψ for the realistic case:

I. κa *small*: One has

$$\frac{\tanh(\kappa a)}{\kappa a} = \frac{1 + \frac{(\kappa a)^2}{3!} + \cdots}{1 + \frac{(\kappa a)^2}{2!} + \cdots} = 1 - \frac{(\kappa a)^2}{3},$$

and thus

$$\psi = \frac{\kappa^2 a^2}{3} = \frac{2\alpha\mu a^2}{3} = \frac{\alpha M}{2\pi a} \qquad \left(M = \mu \cdot \frac{4\pi a^3}{3}\right). \tag{27a}$$

Since in this case ψ is very small, then so also is the proportion of the external field energy to the total energy of the sphere; ignoring it, we find from (24a) and (27a) the force acting on a resting material point P':

$$M'\frac{dc}{dr} = \frac{\alpha c_0}{\pi}\frac{MM'}{r^2}.$$

Going over to the usual units, we set

$$M = cm, \quad M' = c'm'$$

and neglect the difference between c, c' and c_0. The force then becomes

$$\frac{\alpha}{\pi}c_0^3\frac{mm'}{r^2} = \gamma\frac{mm'}{r^2},$$

where γ is the usual gravitational constant. Therefore, one has

$$\alpha = \frac{\pi\gamma}{c_0^3}$$

and hence, according to (27a):

$$\psi = \frac{\gamma m}{2ac_0^2}, \tag{27b}$$

which for the Sun gives the value:

$$\psi = 10^{-6}.$$

This is thus, indeed, still the limiting case of a small ψ, or rather, κa. For the purposes of astronomy, the deviation from Newton's law due to the external field energy is to be neglected, and the Sun is to be replaced by a mass point.[12] |

II. Although it is apparent from what has been said that the *converse limiting case* [208] does not correspond to reality, it shall be briefly considered:

$$\kappa a \text{ large } \tanh(\kappa a) = 1 .$$

Here, according to (27)

$$\psi = \frac{E_a}{E_t} = 1 - \frac{1}{\kappa a} \tag{27c}$$

becomes only slightly less than one, i.e. nearly the entire energy resides in the external gravitational field. In the interior resides only the small fraction

$$1 - \psi = \frac{E_i}{E_t} = \frac{1}{\kappa a}.$$

For the gravitational force, from (24a) it follows that

$$\frac{dc}{dr} = \frac{2c_0 a}{r^2}\left(1 - \psi\frac{a}{r}\right).$$

Thus, at large distances the gravitational force is not proportional to the volume of the sphere, but to its radius. Here, the above mentioned screening effect of large accumulations of masses becomes apparent (i.e., of a very large value of the radius a or of the density μ).

We want to return to the basic equation (17a):

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} - \frac{1}{c}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial u}{\partial t}\right) = 2\alpha\frac{\eta}{u}.$$

From it one derives the disturbance in the gravitational field caused by the motion of matter. Outside the matter, it indicates a propagation of the disturbance with the speed of light (c). However, a rigorous treatment of the problem of propagation is made more difficult because the disturbance of the field itself influences the value of u, and thereby the value of the speed of propagation, c. The same difficulty appears as well with the propagation of sound, whose speed depends on pressure, and thereby varies upon the passing of the sound wave. But in all practical cases, the variation of u is so minute that one can consider the speed of propagation of gravitation to be constant.

12 With reference to the principle of action and reaction, one also obtains from this a clue as to the range of the domain of validity of the above considerations based on Lagrange's equations, wherein the object was replaced by a material point, and where, upon the calculation of the mass, only the self energy, and not the energy of the gravitational field produced by the body, was taken into consideration. As one can now see, this procedure is still permissible for objects of the order of the fixed stars.

According to our theory, light and gravitation have the same speed of propagation; but whereas light waves are transverse, gravitational waves are longitudinal. Incidentally, the problem of the oscillating particle can be treated in a similar manner as that of the oscillating electron; the strength of the emitted gravitational waves depends on the product of the gravitational mass and the acceleration of the particle. Is it possible to detect these gravitational waves? |

[209] This hope is futile. Indeed, to impart an acceleration to one particle, another particle is necessary which, according to the law of action and reaction, is driven in the opposite direction. But now, the strength of the emitted gravitational wave depends on the sum of the products of the gravitational mass and the acceleration of the two particles, while, according to the reaction principle, the sum of the products of inertial mass and acceleration is equal to zero.[13] Therefore, although the existence of gravitational waves is compatible with the assumed field mechanism, through the equality of gravitational and inertial mass the possibility of its production is practically excluded. It follows from this that the planetary system does not lose its mechanical energy through radiation, whereas an analogous system consisting of negative electrons circling around a positive nucleus gradually radiates its energy away. The life of the planetary system is thus not threatened by such a danger.

Our theory of gravitation based on the assumption of a variable c contradicts from the outset the second axiom of the theory of relativity. However, in a vacuum, the invariance with respect to the Lorentz transformations is preserved as is shown by the form of the fundamental equation (17a) which applies there:

$$u\Box u = 0.$$

Hence, outside of matter, the Lorentz group still applies in the infinitesimally small. *It is the matter which breaks the invariance under the Lorentz group*, because in the equation

$$u\Box u = 2\alpha\eta$$

the first term is an invariant of the group, whereas the second term, proportional to the energy density, is not. It is precisely the very plausible hypothesis that the attracting mass is proportional to the energy that forces us to abandon the Lorentz group in the infinitesimally small as well.

Thus, Einstein's relativity theory of 1905 turns to dust. Will there, like the Phoenix rising out of the ashes, emerge a new, more general principle of relativity? Or, will one return to absolute space, and beckon back the much scorned aether, so that it can support, in addition to the electromagnetic, also the gravitational field?

---

13 Here however, the momentum of the gravitational field has not been taken into consideration; but this is of just as little practical importance as the energy of the field.

I. INTRODUCTION [473]

A. The Vector Theory of Gravitation

Since I. Newton postulated his action-at-a-distance law of attraction of masses, theoretical physics has endeavored to reduce this law to one of local interactions. In this attempt the older theories of gravitation[1] were based on concepts derived from the theory of elasticity, hydrodynamics and the kinetic theory of gases. Electromagnetic theories of the gravitational field appeared only at the end of the nineteenth century, encouraged by Maxwell's local field theory of electrodynamics. The best received theory was probably one developed by H. A. Lorentz[2] which adapted a hypothesis

Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

already pursued by Aepinus, Mosotti and Zöllner to the framework of electron theory. According to this hypothesis, the attraction of unlike electric charges should be somewhat larger than the repulsion of like ones. For electrically neutral matter, whose atoms are supposed to consist of positive and negative electrons, Newton's law for the attraction of masses at rest follows from Coulomb's law of electrostatic forces. The force ($\mathfrak{E}^g$) acting on a unit of mass of the stationary matter arises thus as the resultant of two electric forces of opposite direction and nearly equal magnitude, act-
[474] ing on the | positive and negative electrons. However, if the matter moves, then a magnetic force is associated with each of these two electric forces, related to them by the electromagnetic field equations. The two magnetic forces act on the convection current of the positive and the negative electrons, respectively. The resultant ($\mathfrak{H}^g$) of the two magnetic vectors, likewise opposite in direction and of nearly equal magnitude, determines a mechanical force acting on the moving matter. All in all, it follows that if v denotes the velocity vector and c the speed of light, then the expression for the gravitational force [*Schwerkraft*] per unit mass is

$$\mathfrak{F}^g = \mathfrak{E}^g + \frac{1}{c}[\mathfrak{v}\mathfrak{H}^g]. \tag{1}$$

This expression corresponds precisely to the one which represents the force ($\mathfrak{F}^e$) per unit charge in the electron theory. The results of the Lorentzian theory of gravitation thus can be summarized as follows: with the electromagnetic vector pair ($\mathfrak{E}, \mathfrak{H}$) is associated a second pair, ($\mathfrak{E}^g, \mathfrak{H}^g$), characterizing the gravitational field, which determines the gravitational force in accordance with (1). This pair is linked to the density and velocity of matter by differential equations that agree with the field equations of the electron theory, except for the signs of the charge and mass density respectively.

We will call a theory that represents the gravitational field by means of two electromagnetically interrelated vectors simply a "*vector theory of gravitation*." As is apparent from eq. (1), in such a theory the force acting on a body at a given point in the gravitational field depends not only on its mass, but also on its velocity; a moving material point acts on another point just like as one moving charge on another. However, since such an influence of the state of motion on the gravitational force has been discovered neither in physics nor astronomy, the vector $\mathfrak{H}^g$ plays a merely hypothetical role. In order to explain the absence of the force arising from $\mathfrak{H}^g$, and represented by the second term in (1), the vector theory appeals to the smallness of the velocity of the bodies in comparison to the speed of light c. Indeed, for celestial bodies the quotient v : c is of the order of 10^{-4}. In addition, the quotient of the magnitudes of the vectors $\mathfrak{H}^g$ and $\mathfrak{E}^g$ is itself of the same order, so that even according to the vector
[475] theory the planetary system | satisfies the Newtonian law up to terms of order 10^{-8}; deviations of this order are of course permissible astronomically as well.

According to the vector theory, the precise law of interaction of two moving mass points should agree up to sign with the fundamental law of electrodynamics. Therefore, a counterpart to the "forces of induction" of electrodynamics ought to exist in mechanics. In the same way as the acceleration of an electric charge produces forces which act on a neighboring charge in a sense to oppose the acceleration, so should the acceleration of a body generate induced gravitational forces which, because of the different signs, act to accelerate neighboring bodies. Accordingly, it seems possible that a system of masses set in motion by a small force further accelerates by itself through internal forces. Thus, the equilibrium of a gravitating system of masses would not be stable.

This instability is related to a difficulty which arises in the vector theory of gravitation, already noted by Maxwell.[3] The differential equations of the static gravitational field are here:

$$\operatorname{div}\mathfrak{E}^g = -\mu, \tag{2}$$

$$\mathfrak{E}^g = -\operatorname{grad}\varphi, \tag{3}$$

where μ denotes the mass density and φ the gravitational potential in suitably chosen units.

Now, the expression for the potential energy of a system of gravitating masses in the action-at-a-distance theory is:

$$E = \int dV \frac{1}{2}\mu\varphi. \tag{4}$$

If, as in electrostatics, one transforms this equation, through integrating by parts, into the following form:

$$E = -\int dV \frac{1}{2}(\mathfrak{E}^g)^2, \tag{4a}$$

then one sees that the interpretation in the sense of the local field theory, leads to a distribution of energy in the field with a density

$$\eta^g = -\frac{1}{2}(\mathfrak{E}^g)^2. \tag{4b}$$

Hence, in contrast to electrostatics, and due to | the opposite sign in eq. (2), *in the vector theory the energy density of the gravitational field turns out to be negative*. [476]
The same applies for a changing gravitational field whose energy density, according to the vector theory, should be

$$\eta^g = -\frac{1}{2}\{(\mathfrak{E}^g)^2 + (\mathfrak{H}^g)^2\}. \tag{4c}$$

Accordingly, a region of space, if it does contain a gravitational field, ought to contain less energy than if it were without a field. And when the gravitational field—

---

3 J. Cl. Maxwell, *Scientific Papers,* Vol. I, p. 570.

spreading, say, in the nature of a wave—enters into a previously field-free region, energy ought to flow in a direction opposite to that of the propagation of the waves. This paradoxical conclusion is peculiar to the vector theory of the gravitational field.

The so-called "*theory of relativity*" arose from the Lorentzian electrodynamics of moving bodies. This theory demands, that in empty space all forces propagate with the same speed as light. Therefore, according to the theory of relativity, the gravitational force as well must propagate with the speed of light. H. Poincaré(2) raised the question as to how this requirement can be brought into agreement with the view of Laplace, that the speed of propagation of gravitation, if at all finite, must be far greater than that of light (c). He remarked, that this view applies only, if quantities of first order (with respect to the quotient $v : c$) enter into the fundamental law of attraction of two masses. But if one formulates the fundamental law so that it fits into a relativistic scheme, yet deviates only in terms of second order and higher from Newton's, then Laplace's reservations lose their significance. Poincaré gives such formulations of the fundamental law of gravitation. These approaches contain also the force term of H. Minkowski,(3) which, by the way, can be obtained by transferring the fundamental law of the theory of electrons to gravitation.(4) The interaction laws for the attraction of masses developed by these pioneers of the theory of relativity are accordingly quite readily compatible with the vector theory of gravitation sketched above. On the other hand, that vector theory gave also an account of those processes in the field through whose mediation one mass transfers energy and momentum to the other; these fundamental relativistic laws, however, lack the derivation from the field equations. Thus the difficulties associated with the vector theory were not resolved but only concealed. What remained unresolved was the problem of developing field |
[477] equations of the gravitational field that yield a propagation of the gravitational force with the speed of light and also ascribe to the field a positive energy, transferred via an energy flux, and a momentum transferred by means of fictitious stresses.

B. Conservation Laws of Momentum and Energy: World Tensors

The above mentioned work by H. Poincaré(2) already contains the beginnings of the four-dimensional vector calculus, which was then further developed by H. Minkowski(3) In our notation, we will mainly follow the presentation of A. Sommerfeld.(4) The four-dimensional formulation of the theory of relativity, as is well known, interprets the group of Lorentz transformations as a rotation group of a four-dimensional space, whose coordinates are the Cartesian coordinates x, y, z of ordinary space and $u = ict$; these transformations leave the expression

$$x^2 + y^2 + z^2 + u^2$$

invariant. Poincaré had already dealt with four-vectors whose components transform like the coordinates x, y, z, u. H. Minkowski introduced the concept of the six-vector, and characterized the electromagnetic field $\{\mathfrak{E}, \mathfrak{H}\}$ in a vacuum through such a vector. The six-vector $\{\mathfrak{E}, \mathfrak{H}\}$ is derived from the four-potential $\{\mathfrak{A}, \Phi\}$, whose 4 components are given by the electromagnetic vector- and scalar potential. The vector theory of the gravitational force sketched above, which, of course, is formally identical with the electromagnetic field theory, accordingly also derives the six-vector of the gravitational field $\{\mathfrak{E}^g, \mathfrak{H}^g\}$ from a four-potential. Also in this four-dimensional sense—namely insofar as the gravitational potentials form a four-vector—one will accordingly have to denote that theory of gravitation as a "vector theory."

Besides the two kinds of "world vectors," the "*world tensors*" are important for the theory of relativity.[4] The ten components of such a symmetric tensor T transform like the squares and products of the four coordinates x, y, z, u. From it one derives a four-vector which we want to call "the divergence of the ten-tensor T," and whose components are to be formed according to the following scheme: |

$$\operatorname{div} T = \left\{ \begin{array}{l} \dfrac{\partial T_{xx}}{\partial x} + \dfrac{\partial T_{xy}}{\partial y} + \dfrac{\partial T_{xz}}{\partial z} + \dfrac{\partial T_{xu}}{\partial u}, \\ \dfrac{\partial T_{yx}}{\partial x} + \dfrac{\partial T_{yy}}{\partial y} + \dfrac{\partial T_{yz}}{\partial z} + \dfrac{\partial T_{yu}}{\partial u}, \\ \dfrac{\partial T_{zx}}{\partial x} + \dfrac{\partial T_{zy}}{\partial y} + \dfrac{\partial T_{zz}}{\partial z} + \dfrac{\partial T_{zu}}{\partial u}, \\ \dfrac{\partial T_{ux}}{\partial x} + \dfrac{\partial T_{uy}}{\partial y} + \dfrac{\partial T_{uz}}{\partial z} + \dfrac{\partial T_{uu}}{\partial u}. \end{array} \right\} \tag{5}$$ [478]

In the Maxwell-Lorentz electrodynamics, the electromagnetic force acting on a unit volume is determined by the four-vector

$$\rho\mathfrak{F}^e = \operatorname{div} T^e, \tag{6}$$

where T_e designates the "*electromagnetic ten-tensor*." Its components

$$T^e_{xx}, T^e_{yy}, T^e_{zz}$$

represent the fictitious normal stresses, and

$$T^e_{xy} = T^e_{yx}, \quad T^e_{yz} = T^e_{zy}, \quad T^e_{zx} = T^e_{xz} \tag{6a}$$

represent the shear stresses; the symmetry relations (6a) imply the vanishing of the torques of these fictitious surface forces [*Flächenkräfte*]. The three remaining symmetry conditions of the ten-tensor T^e

$$T^e_{xu} = T^e_{ux}, \quad T^e_{yu} = T^e_{uy}, \quad T^e_{zu} = T^e_{uz} \tag{6b}$$

---

4 M. Abraham, *Rendiconti del circolo matematico di Palermo,* XXVIII^2, 17, 1909. M. Laue, *Das Relativitätsprinzip*, p. 4 of the 2nd ed. (1913).

have the following significance:

$$T^e_{xu} = -ic\mathfrak{g}^e_x, \quad T^e_{yu} = -ic\mathfrak{g}^e_y, \quad T^e_{zu} = -ic\mathfrak{g}^e_z \tag{6c}$$

determine the components of the momentum density $(\mathfrak{g}^e)$ of the electromagnetic field,

$$T^e_{ux} = -\frac{i}{c}\mathfrak{S}^e_x, \quad T^e_{uy} = -\frac{i}{c}\mathfrak{S}^e_y, \quad T^e_{uz} = -\frac{i}{c}\mathfrak{S}^e_z \tag{6d}$$

determine those of the electromagnetic energy flux $(\mathfrak{S}^e)$; the eqs. (6b) contain therefore the "*theorem of the momentum of electromagnetic energy flux*":

$$\mathfrak{g}^e = \frac{\mathfrak{S}^e}{c^2}. \tag{6e}$$

Since according to (6c)

$$\frac{\partial T^e_{xu}}{\partial u} = \frac{\partial T^e_{xu}}{ic\partial t} = -\frac{\partial \mathfrak{g}^e_x}{\partial t} \qquad \text{etc.,}$$

the first three of the equations (6), to be formed according to the scheme (5), express the *law of conservation of momentum* for the electromagnetic field, as they derive from the stresses and the momentum density of the field the momentum given by the
[479] field to the unit of volume of matter. | The last of the eqs. (6), however, contains the law of *conservation of energy.* Indeed, if one equates the last tensor component to the electromagnetic energy density:

$$T^e_{uu} = \eta^e = \frac{1}{2}(\mathfrak{E}^2 + \mathfrak{H}^2), \tag{6f}$$

and furthermore

$$\rho\mathfrak{F}^e_u = \frac{i}{c}\frac{dA^e}{dt}, \tag{6g}$$

where dA^e is the work done on a unit volume, then the last of eqs. (6) reads, taking into consideration (6d):

$$\frac{dA^e}{dt} = -\operatorname{div}\mathfrak{S}^e - \frac{\partial \eta^e}{\partial t}. \tag{6h}$$

It therefore expresses the law of conservation of energy for the electromagnetic field, because it relates the energy transferred from the field to a unit volume of matter to the energy flux and the energy density of the field.

One would now wish to retain the validity of the conservation laws of momentum and energy, and of the theorem of the momentum of energy flux for the gravitational field by deriving the gravitational force per unit volume of matter as a four-vector

$$\mu\mathfrak{F}^g = \operatorname{div} T^g \tag{7}$$

from a symmetric "*gravitational tensor* T^g." The vector theory of gravitation satisfies this demand by expressing the tensor T^g through the vectors $\mathfrak{E}^g$, $\mathfrak{H}^g$, in the same way in which $-T^e$ is determined through the electromagnetic vectors $\mathfrak{E}$, $\mathfrak{H}$. We have shown above that precisely the difference in sign causes difficulties for the vector theory. In the following, we will become acquainted with other possibilities for representing the gravitational tensor T^g.

C. Inertia and Gravity[1]

If the theorem of the momentum of energy flux is valid, then a momentum, and thus an inertial mass, is associated with a convectively moving quantity of energy. A well-known example is the "electromagnetic mass" of the electron which, in the dynamics of the electron, is derived from the momentum of the energy flux flowing in the electromagnetic field of the moving electron. If one considers the theorem of the momentum of energy flux as valid for arbitrary kinds of energy flows, then it follows that the momentum of a uniformly moving body isolated from external effects is |

$$\mathfrak{G} = \frac{\mathfrak{v}}{c^2}E. \tag{8}$$ [480]

To this corresponds an inertial rest-mass of value

$$m_0 = \frac{E_0}{c^2}. \tag{8a}$$

Here, E_0 denotes the "rest-energy" of the body, i.e. its energy with respect to a coordinate system Σ_0 in which the body is at rest; m_0 measures the inertia of the body accelerated from rest. Equation (8a) expresses "*the theorem of the inertia of energy*."

If all forces in nature can be fitted into the scheme of a symmetric world tensor, then the theorem of the momentum of energy flux and that which is derived from it, the theorem of the inertia of energy, gain general validity. The inertial mass of a body is then proportional to its energy content; it can be increased by the gain of energy, or decreased through the loss of energy. However, the denominator c^2 in (8a) entails that the changes in energy that occur in the usual chemical reactions are too minute to cause measurable changes in mass. However, the radioactive transformations, in view of their enormous heat production, should be accompanied by a noticeable decrease in mass. Such changes in mass—still quite small at any rate—could, however, be determined only with a scale. The scale, however, does not measure inertia but weight [*Schwere*]. Hence, the question arises: Is there also gravitational mass associated with energy? Is there, as a counterpart to the theorem of the inertia of energy, a theorem of the weight of energy? This question leads us back to the problem of gravitation.

Experience teaches us that all bodies fall with equal acceleration in a vacuum and that the period of a pendulum is independent of its chemical composition. Therefore, *the gravitational mass is proportional to the inertial mass*. The most precise test of the law of proportionality is due to B. Eötvös;[5] with the aid of a torsion balance, this researcher investigated whether the gravitational force acts on all bodies on the surface of the Earth in the same direction. Since the gravitational force is the resultant of the Earth's attraction of masses [*Massenanziehung*] and of the centrifugal force, this resultant, i.e. the vertical, would have a different direction for different bodies if strict
[481] proportionality between the two masses did not hold. This is because | the attraction of masses is determined by the gravitational mass and the centrifugal force by the inertial mass. Although Eötvös recently refined his measurements so that deviations of the order 10^{-8} would not have escaped him, he nevertheless could not find such. With the corresponding accuracy, the law of proportionality of gravitational and inertial mass has been shown to be valid.

For the time being, the investigations of Eötvös do not cover radioactive bodies. If at all, one should most likely expect a departure in the behavior of gravitational and inertial mass in radioactive transmutations, namely in the case that the former remains constant while the latter decreases because of the emission of energy. Uranium oxide for example transmutes by radioactive decay into lead oxide, while emitting 8 α-particles per atom, during which the fraction $2.3 \cdot 10^{-4}$ of the energy is emitted.[6] According to the theorem of the equivalence of inertia and energy, the inertial mass should decrease by the same fraction; if the gravitational mass did not remain constant, or if it changed in a different ratio, then the proportionality between gravitational and inertial mass could not be maintained under radioactive transformations. However, L. Southerns,[7] using pendulum observations to which he ascribed an accuracy of $5 \cdot 10^{-6}$, discovered no difference with respect to the mass ratio between uranium oxide and lead oxide. Thus, here too, the law of proportionality is valid.

Classical mechanics introduces the proportionality of gravitational mass and inertia as an empirical law without deeper justification. The theorem of the inertia of energy suggests that, in the new mechanics, the equivalence of the two masses be explained by the gravitational mass also being proportional to the energy. Then furthermore, the law of conservation of (gravitational) mass, which takes an isolated position in the traditional physics and chemistry, would merge with the law of conservation of energy into a single one. However, if not the energy itself, but another quantity were the determining factor for the gravitational mass of a body, then still, in all practical cases, this quantity should be proportional to the inertial mass with the above stated accuracy. It is the merit of the newer theories of gravitation, on which we want to report in the following, to have put the discussion of the relation between

5 B. Eötvös, *Mathem. u. naturwiss. Ber. aus Ungarn*, 8, 65, 1890.

7 L. Southerns, *Proc. Roy. Soc. London*, 84, 325, 1910.

inertia, gravitation and energy on a rational foundation and, in so doing, to have prepared the way for the exploration of these relations. |

II. SCALAR THEORIES [482]

A. Energy Density and Energy Flux in the Gravitational Field

In the vector theory of gravitation, the expression (4b) gave the energy density of the static gravitational field. If one assumes that a similar expression is also valid for time varying fields, when only the static force $\mathfrak{E}^g$ is replaced by the dynamic gravitational force $\mathfrak{F}^g$, then

$$\eta^g = -\frac{1}{2}(\mathfrak{F}^g)^2. \tag{9}$$

In a remarkable paper on the energy flux in a gravitational field, V. Volterra(1)[2] takes this expression as the basis for the energy density. He divides the energy flux into two parts:

$$\mathfrak{S} = \mathfrak{S}^g + \mathfrak{S}^m, \tag{10}$$

of which the first

$$\mathfrak{S}^g = -\frac{\varphi\partial\mathfrak{F}^g}{\partial t} \tag{10a}$$

is caused by the variation of the gravitational field with respect to time, whereas the second

$$\mathfrak{S}^m = \varphi\mu\mathfrak{v} \tag{10b}$$

represents the energy transport by moving matter. The mass density μ is related via

$$\operatorname{div}\mathfrak{F}^g = -\mu \tag{11}$$

with the gravitational force per unit mass, which, by virtue of

$$\mathfrak{F}^g = -\operatorname{grad}\varphi \tag{11a}$$

is derived from the scalar gravitational potential φ. Insofar as the existence of a scalar potential is also assumed in a dynamic gravitational field, Volterra's theory is to be counted among the "scalar theories of gravitation" (in a three-dimensional sense).

We want to convince ourselves that Volterra's approaches satisfy the energy equation. According to (9) one has

$$-\frac{\partial\eta^g}{\partial t} = \left(\mathfrak{F}^g \cdot \frac{\partial\mathfrak{F}^g}{\partial t}\right),$$

whereas from (10), (10a), and (10b) it follows that

$$-\mathrm{div}\mathfrak{S} = \mathrm{div}\varphi\frac{\partial\mathfrak{F}^g}{\partial t} - \mathrm{div}\varphi\mu\mathfrak{v}$$

$$= \varphi\mathrm{div}\frac{\partial\mathfrak{F}^g}{\partial t} + \left(\frac{\partial\mathfrak{F}^g}{\partial t}\cdot\mathrm{grad}\varphi\right) - \varphi\ \mathrm{div}\mu\mathfrak{v} - (\mu\mathfrak{v}\cdot\mathrm{grad}\varphi),$$

and taking into consideration (11), (11a) and the equation of continuity of matter |

$$\frac{\partial\mu}{\partial t} = -\mathrm{div}\mu\mathfrak{v},$$

[483]

$$-\mathrm{div}\mathfrak{S} = -\left(\mathfrak{F}^g\cdot\frac{\partial\mathfrak{F}^g}{\partial t}\right) + (\mu\mathfrak{v}\cdot\mathfrak{F}^g).$$

Therefore, one obtains

$$(\mu\mathfrak{F}^g\cdot\mathfrak{v}) = -\mathrm{div}\mathfrak{S} - \frac{\partial\eta^g}{\partial t}. \tag{11b}$$

Here, on the left hand side, is the work done by the gravitational force per unit volume and time; on the right-hand side, is the energy gain caused by the influx of energy and by the temporal decrease of the energy density. The law of conservation of energy is indeed satisfied.

However, it is not possible, by means of constructing a corresponding world tensor T^g, to reconcile the approaches of Volterra with the first three of the eqs. (7), which formulate the laws of conservation of momentum. It is also remarkable that in (10b) an energy transport by moving matter is introduced, without a corresponding energy density of the matter. If one takes account of such an energy density

$$\eta^m = \varphi\mu \tag{12}$$

then one obtains the correct value for the total energy of a system of masses at rest

$$E = \int dV\frac{1}{2}\mu\varphi = E^m + E^g,$$

if one sets

$$\eta^g = \frac{1}{2}(\mathfrak{F}^g)^2 \tag{12a}$$

for the *energy density of the gravitational field*.

Indeed, according to (11) and (11a), the identity

$$\int dV\frac{1}{2}\mu\varphi = -\int dV\frac{1}{2}(\mathfrak{F}^g)^2$$

holds, and it follows that

$$\int dV\left\{\mu\varphi + \frac{1}{2}(\mathfrak{F}^g)^2\right\} = \int dV\frac{1}{2}\mu\varphi = E.$$

The value (12a) for the *energy density is positive*. Hence, the difficulty appearing in the vector theory of gravitation is eliminated if one succeeds in pairing that energy density with an energy flow.

We equate[6)] the *energy flux in a gravitational field to the gravitational force per unit mass multiplied by the time derivative of the gravitational potential:*

$$\mathfrak{S}^g = \frac{\partial\varphi}{\partial t}\mathfrak{F}^g, \tag{13}$$

| whereas, for the energy flux of matter, we retain the expression (10b). Then the *total* [484]
energy flux becomes

$$\mathfrak{S} = \mathfrak{S}^m + \mathfrak{S}^g = \varphi\mu\mathrm{v} + \frac{\partial\varphi}{\partial t}\mathfrak{F}^g, \tag{14}$$

whereas the *total energy density,* is according to (12, 12a)

$$\eta = \eta^m + \eta^g = \varphi\mu + \frac{1}{2}(\mathfrak{F}^g)^2. \tag{14a}$$

One can easily convince oneself that the energy equation is satisfied. One has

$$\frac{\partial\eta}{\partial t} = \varphi\frac{\partial\mu}{\partial t} + \mu\frac{\partial\varphi}{\partial t} + \left(\mathfrak{F}^g \cdot \frac{\partial\mathfrak{F}^g}{\partial t}\right),$$

$$\mathrm{div}\mathfrak{S} = \varphi\mathrm{div}\mu\mathfrak{v} + (\mu\mathfrak{v}\cdot\mathrm{grad}\varphi) + \frac{\partial\varphi}{\partial t}\mathrm{div}\mathfrak{F}^g + \left(\mathfrak{F}^g\cdot\mathrm{grad}\frac{\partial\varphi}{\partial t}\right),$$

and from this, taking into consideration (11, 11a) and the equation of continuity, the law of conservation of energy follows

$$(\mu\mathfrak{v}\cdot\mathfrak{F}^g) = -\mathrm{div}\mathfrak{S} - \frac{\partial\eta}{\partial t}. \tag{14b}$$

As we will see immediately, the expressions (12a) and (13) for the energy density and the energy flux in a gravitational field, fit readily into the scheme of a symmetric gravitational tensor.[8]

B. Abraham's First Theory

So far we have been talking about "scalar theories" of gravitation merely in the context of a three-dimensional vector calculus, and taking them to be theories which derive the gravitational force from a scalar potential φ also for a dynamic field. In the four-dimensional context, *a theory of gravitation is to be designated as a scalar theory, in which the gravitational potential is a scalar, i.e. an invariant with respect to rotation of the four-dimensional space of the* (x, y, z, u). The gravitational force with respect to a unit volume, considered as a four-vector, shall have the components |

[485]

$$\left.\begin{aligned} \mu\mathfrak{F}_x^g &= -\nu\frac{\partial\varphi}{\partial x}, & \mu\mathfrak{F}_y^g &= -\nu\frac{\partial\varphi}{\partial y}, \\ \mu\mathfrak{F}_z^g &= -\nu\frac{\partial\varphi}{\partial z}, & \mu\mathfrak{F}_u^g &= -\nu\frac{\partial\varphi}{\partial u}; \end{aligned}\right\} \tag{15}$$

ν is an, for now, undetermined scalar factor. As the comparison with (6g) teaches,

$$\frac{c}{i}\mu\mathfrak{F}_u^g = ic\nu\frac{\partial\varphi}{\partial u} = \nu\frac{\partial\varphi}{\partial t} \tag{15a}$$

represents the energy that is transferred per unit space and time from the gravitational field to the matter. In the symbolism of the four-dimensional vector analysis(4), the eqs. (15) are written as

$$\mu\mathfrak{F}^g = -\nu\operatorname{grad}\varphi. \tag{15b}$$

Now, corresponding to the scheme (7), the gravitational force should be derived from a symmetric gravitational tensor T^g, such that the expressions (12a, 13) for the energy density and the energy flux correspond to the appropriate tensor components. M. Abraham(6) defines the ten-tensor T^g in the following manner:

8 Here, I have presented the train of thought which I pursued in the development of my first theory of gravitation(6) in such detail, because G. Jaumann (*Physik. Zeitschr.,* 15, 159, 1914) formulated an inappropriate hypothesis concerning the psychological origin of this theory. Jaumann's theory (*Wien. Ber.,* 121, 95, 1912), of which I became aware only after that first publication, is so far removed from the conceptual realm of the investigations summarized in this report, that it appears to me that this is not the place for its discussion.

$$\left.\begin{aligned}
T^g_{xx} &= -\frac{1}{2}\left(\frac{\partial\varphi}{\partial x}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial y}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial z}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial u}\right)^2,\\
T^g_{yy} &= \frac{1}{2}\left(\frac{\partial\varphi}{\partial x}\right)^2 - \frac{1}{2}\left(\frac{\partial\varphi}{\partial y}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial z}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial u}\right)^2,\\
T^g_{zz} &= \frac{1}{2}\left(\frac{\partial\varphi}{\partial x}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial y}\right)^2 - \frac{1}{2}\left(\frac{\partial\varphi}{\partial z}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial u}\right)^2,\\
T^g_{uu} &= \frac{1}{2}\left(\frac{\partial\varphi}{\partial x}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial y}\right)^2 + \frac{1}{2}\left(\frac{\partial\varphi}{\partial z}\right)^2 - \frac{1}{2}\left(\frac{\partial\varphi}{\partial u}\right)^2,\\
T^g_{xy} &= T^g_{yx} = -\frac{\partial\varphi}{\partial x}\frac{\partial\varphi}{\partial y},\\
T^g_{yz} &= T^g_{zy} = -\frac{\partial\varphi}{\partial y}\frac{\partial\varphi}{\partial z},\\
T^g_{zx} &= T^g_{xz} = -\frac{\partial\varphi}{\partial z}\frac{\partial\varphi}{\partial x},\\
T^g_{xu} &= T^g_{ux} = -\frac{\partial\varphi}{\partial x}\frac{\partial\varphi}{\partial u},\\
T^g_{yu} &= T^g_{uy} = -\frac{\partial\varphi}{\partial y}\frac{\partial\varphi}{\partial u},\\
T^g_{zu} &= T^g_{uz} = -\frac{\partial\varphi}{\partial z}\frac{\partial\varphi}{\partial u}.
\end{aligned}\right\} \tag{16}$$

As the comparison with (6c, d, e, f) shows, the appropriate expressions for the *momentum density, energy flux* and *energy density* are accordingly |

$$c^2\mathfrak{g}^g = \mathfrak{S}^g = -\frac{\partial\varphi}{\partial t}\mathrm{grad}\varphi, \tag{16a}$$ [486]

$$\eta^g = T^g_{uu} = \frac{1}{2}\left\{\left(\frac{\partial\varphi}{\partial x}\right)^2 + \left(\frac{\partial\varphi}{\partial y}\right)^2 + \left(\frac{\partial\varphi}{\partial z}\right)^2 + \frac{1}{c^2}\left(\frac{\partial\varphi}{\partial t}\right)^2\right\}. \tag{16b}$$

Equation (16a) agrees with (13) and, in addition, contains the theorem of the momentum of energy flux. Equation (16b) becomes (12a) for static fields; but also for the dynamic field the energy density calculated according to (16b), is always positive. The fictitious stresses contained in T^g agree for the static field, apart from signs, with the Maxwellian electrostatic stresses. Let us write the system (16), which derives a ten-tensor T^g from the scalar φ, symbolically as

$$T^g = \mathrm{Ten}\varphi. \tag{16c}$$

We now apply the scheme (5), and obtain for the divergence of the gravitational tensor:

$$\operatorname{div} T^g = \operatorname{div}\,\operatorname{ten}\varphi = -\Box\varphi \cdot \operatorname{grad}\varphi, \tag{17}$$

using the abbreviation

$$\Box\varphi = \operatorname{div}\,\operatorname{grad}\varphi = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} + \frac{\partial^2\varphi}{\partial z^2} + \frac{\partial^2\varphi}{\partial u^2}. \tag{17a}$$

The laws of conservation of momentum and energy summarized in (7) thus yield

$$\mu\mathfrak{F}^g = -\Box\varphi \cdot \operatorname{grad}\varphi. \tag{17b}$$

In order to obtain agreement with (15b), the gravitational potential is required to satisfy the *field equation*

$$\Box\varphi = \nu, \tag{18}$$

which is to be taken as a generalization of Poisson's equation.

The theory of relativity demands that ν be a scalar in the four-dimensional sense, like the gravitational potential φ and the operator $\Box$; the "rest-mass density" is such a scalar. For this reason, in his first communication,(6) Abraham used this for ν. By integrating (18), he calculates the gravitational potential of a moving mass point and thus obtains the "*fundamental law of gravitation*."(7) This law is simpler than the fundamental law of electrodynamics, insofar as the *direction of the attracting force is independent of the state of motion of the attracted point*. This is a peculiarity of the scalar theories, which determine the gravitational force by means of a single vector $\mathfrak{F}^g$.

In the vacuum, ν is equal to zero and the gravitational potential therefore satisfies the differential equation |

[487]
$$\Box\varphi = \frac{\partial^2\varphi}{\partial x^2} + \frac{\partial^2\varphi}{\partial y^2} + \frac{\partial^2\varphi}{\partial z^2} - \frac{1}{c}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial\varphi}{\partial t}\right) = 0, \tag{18a}$$

the so-called "wave equation." This results in the possibility of gravitational waves, which propagate with the speed of light. However, in the scalar theories the *gravitational waves are longitudinal,* whereas in the vector theory they are considered as transverse, in analogy with the electromagnetic waves. According to both theories, the factor determining the amplitude of the gravitational wave emitted by an oscillating mass particle is the product of gravitational mass and acceleration. One could now surmise that during the emission of α-rays from radioactive atoms, where very large accelerations occur, the hypothetical gravitational waves will be excited in noticeable strength. However, electric waves are simultaneously excited and, as the quantitative discussion(10) shows, the force excited by gravitational waves from one emitted α-particle on a second α-particle is at most 10^{-36} of the electric force. That the gravitational waves play no role in the balance of nature has however still a deeper reason. If one mass particle imparts an acceleration to another through collision or long range forces, then the second particle also acts to accelerate the first in such a way that the vector sum of the products of inertial mass and acceleration is equal to zero. What determines the amplitude of the gravitational wave emitted from the system of the two particles is the vector sum of the products of gravitational mass and acceleration. Due to the proportionality of inertial and gravitational mass, this sum is also equal to zero. Thus, even theoretically, one cannot provide a means to excite gravitational waves of noticeable strength.

One aspect of Abraham's first theory has so far not been mentioned. Following an hypothesis already proposed by A. Einstein,(5) one considers the gravitational potential φ to be a function of the speed of light c, and, in particular, the following relation between the two quantities results from the assumed form of the equation of motion of material points:

$$\varphi - \varphi_0 = \frac{c^2}{2} - \frac{c_0{}^2}{2}. \tag{19}$$

Since, according to this, c is variable in a gravitational field, Einstein and Abraham thus give up the postulate of the constancy of the speed of light, which was a fundamental requirement of Einstein's theory of relativity | of 1905. The covariance [488]
of the physical laws with respect to the Lorentz transformations demanded by that theory exists then only in infinitesimally small spacetime regions in which c can be considered to be constant. Only with regard to the processes in an infinitesimal region are two uniformly moving systems of reference to be considered as equivalent. But if one regards finite systems of gravitating masses, then there exists no equivalence whatsoever between such systems of reference. Indeed, G. Pavanini(18) was able to show that, according to Abraham's theory, secular perturbations of the Keplerian motion occur in a two-body system, which depend on the "absolute" state of motion of the system. If the center of mass of the system is at rest, then only a secular motion of the perihelion occurs; for Mercury it would amount to $14'', 52$ in a hundred years, that is only about one third of the actual motion of the perihelion.

Our planetary system moves within the gravitational field of the other celestial bodies. The particular system of reference in which the external gravitational field can be taken as static, plays a distinguished role according to Abraham(10) (13) and is to coincide with the "absolute" system of reference, which, at least in the case of rotational motion, makes itself felt through centrifugal and Coriolis forces, and which the action-at-a-distance theory of C. Neumann anchors in a hypothetical "body α." This view, however, did not meet with the approval of Einstein. He attempted to salvage the principle of relativity of 1905(14), wherein, however, he had to restrict the equivalence between systems of reference in uniform translatory motion with respect to each other to processes in "isolated systems," and to the "limiting case of constant gravitational potential." As Abraham remarked,(15) to the contrary, it is not possible to shield a system against the gravitational force, and the limiting case of constant gravitational potential corresponds to the absence of gravitational force. If, on the other hand, those theoreticians who define the gravitational potential through c consider gravitation as an essential property of matter, then they must abandon "yesterday's theory of relativity."

On the occasion of that dispute, Einstein,(14) incidentally, revealed the prospect of a more general "tomorrow's principle of relativity," encompassing accelerated and rotational motion. To what extent the "generalized theory of relativity," published by him in association with M. Grossmann the following year (1913), fulfills that promise is to be discussed in detail later in (III B). |

[489] *C. Abraham's Second Theory*

In that discussion there emerged at least this much agreement, that in the development of the theory of gravitation attention has to be paid to the relation between weight and energy. In a lecture(16) at the international congress of mathematics at Cambridge (August 1912), M. Abraham gave the highest priority to the *postulate of the weight of energy*. He proved that the gravitational force on a moving point mass can be strictly proportional to its energy only if its Lagrangian function is a linear homogeneous function of the velocity and of the gravitational potential. The Lagrangian of the earlier theory of relativity

$$\mathfrak{L} = -m_0 c^2 \sqrt{1 - \left(\frac{v}{c}\right)^2} \tag{20}$$

is to be adapted to this demand by interpreting the speed of light c itself as a potential and considering

$$m_0 c = M \text{ (mass constant)} \tag{20a}$$

as independent of v and c. Then the *Lagrangian of the mass-point* becomes

$$\mathfrak{L} = -M \cdot \sqrt{c^2 - v^2}, \tag{21}$$

and the *rest-energy*

$$E_0 = -\mathfrak{L}_0 = Mc. \tag{21a}$$

Hence, the rest-energy decreases with decreasing c, whereas the *rest-mass*

$$m_0 = \frac{E_0}{c^2} = \frac{M}{c}$$

increases with decreasing c.

Now one must demand that all mechanical quantities of the same class possess the same degree in c, thus all energies possess the degree c, all masses the degree c^{-1}. Later the author derives this requirement(17) from the following postulate:[3] "An observer belonging to a mechanical system must not perceive that he, together with the system, is brought into a region in which c has a different value" Since lengths should not depend on c, time intervals are of degree c^{-1}. The energy density as well as the remaining components of the ten-tensor T^g are of degree c; but since they are of the second degree in the derivative of φ with respect to the coordinates (cf. 16), so φ is to be replaced not by c, but by $\sqrt{c}$. Correspondingly, Abraham chooses the gravitational tensor T^g according to the scheme (16, 16c):

$$T^g = \text{ten}\sqrt{c}. \tag{22}$$

| Then from (5) one obtains, similar to (17), [490]

$$\text{div}T^g = \text{div ten}\sqrt{c} = -\Box(\sqrt{c})\cdot\text{grad}\sqrt{c}, \tag{22a}$$

where we have set

$$\Box(\sqrt{c}) = \frac{\partial^2\sqrt{c}}{\partial x^2}+\frac{\partial^2\sqrt{c}}{\partial y^2}+\frac{\partial^2\sqrt{c}}{\partial z^2}-\frac{1}{c}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial\sqrt{c}}{\partial t}\right). \tag{22b}$$

In order for the postulate of the weight of energy to be valid, the *field equation* is to be formulated as follows

$$\sqrt{c}\cdot\Box(\sqrt{c}) = 2\eta^m. \tag{23}$$

Then, according to (22a), the laws of conservation of momentum and energy, summarized in (7), yield

$$\mu\mathfrak{F}^g = -\frac{2\eta^m}{\sqrt{c}}\text{grad}\sqrt{c} = -\frac{\eta^m}{c}\text{grad}c. \tag{23a}$$

for the gravitational force per unit volume. Integration over a body of sufficiently small volume yields the *gravitational force*

$$\mathfrak{K}^g = -\frac{E^m}{c}\text{grad}c. \tag{24}$$

Therefore, the weight of a body is proportional to its energy; by the way, in (24), the gravitational field determined by the gradient of c has been assumed to be homogeneous over the extension of the body, and correspondingly the gravitational field produced by the body itself and its energy has been neglected.

In a lecture(17) presented at the congress of the “Società italiana per il progresso delle scienze,” the author treats the role of the self-excited field and its energy for the case of rest. Since here η^m denotes the density of rest-energy of matter, it is useful to define μ as the mass constant with respect to the unit volume, and correspondingly to write (21a) as

$$\eta^m = \mu c, \tag{24a}$$

so that according to (23a)

$$\mathfrak{F}^g = -\mathrm{grad}\, c \tag{24b}$$

denotes the gravitational force per unit of mass as measured by M. For incompressible fluids, for example, μ is a constant also independent of c.

For the static gravitational field, the differential eq. (23) is written as

$$\Delta(\sqrt{c}) = \frac{2\eta^m}{\sqrt{c}} = 2\mu\sqrt{c}. \tag{25}$$

Since, according to (16b), the energy density of the static field is

$$\eta^g = \frac{1}{2}(\mathrm{grad}\sqrt{c})^2,$$

[491] | and since the identity

$$\Delta c = 2\sqrt{c}\Delta\sqrt{c} + 2(\mathrm{grad}\sqrt{c})^2$$

applies, one can write (25) as

$$\Delta c = 4(\eta^m + \eta^g) = 4\eta. \tag{25a}$$

Thus, the divergence of the gradient of c is proportional to the density of the total energy, i.e., according to Gauss' theorem: *The flux of the gravitational force vector* $\mathfrak{F}^g$ (cf. 24b) *through a closed surface is equal to four times the enclosed energy.*

For a stationary homogeneous sphere of radius α we have, according to (25),

$$\Delta(\sqrt{c}) = 0 \qquad \text{for} \quad r > a, \tag{26}$$

$$\Delta(\sqrt{c}) = 2\mu\sqrt{c} \qquad \text{for} \quad r < a. \tag{26a}$$

The integration is not difficult to perform.[17] According to (26), the gradient of $\sqrt{c}$ decreases outside the sphere as r^{-2}; the gradient of c, the determining factor for the gravitational force per unit mass according to (24b), is obtained as

$$-\mathfrak{F}_r^g = \frac{dc}{dr} = \frac{E}{\pi r^2}\left(1 - \psi\frac{a}{r}\right), \tag{26b}$$

where

$$\psi = E_a/E \tag{26c}$$

denotes the quotient of the energy E_a of the external gravitational field and the total energy E of the sphere and of its gravitational field. This result is in agreement with the above theorem concerning the flux of the vector $\mathfrak{F}^g$. The energy of the gravitational field outside the sphere is responsible for the *deviation from Newton's law* because it causes the difference in the force flux through two concentric spheres. Incidentally, eq. (26b) applies also to a mass distribution homogeneous within concentric layers.

The integration of (26a) for the interior of a homogeneous sphere leads to hyperbolic functions. For a body with the mass and the radius of the Sun the quantity ψ, given in (26c), turns out to be of the order of 10^{-6}. This provides an idea of the order of magnitude of the quotient of the external and of the total energy, as well as of the order of magnitude of the deviation from the Newtonian law determined by it. A celestial body may be considered as a material point if that quotient can be neglected under the given circumstances.

We return to the Lagrangian function (21) of the material point; it implies the values for *momentum* and *energy* |

$$\mathfrak{G} = \frac{\partial \mathfrak{L}}{\partial v} \cdot \frac{\mathfrak{v}}{v} = \frac{M\mathfrak{v}}{\sqrt{c^2 - v^2}}, \tag{27}$$ [492]

$$E = v\frac{\partial \mathfrak{L}}{\partial v} - \mathfrak{L} = \frac{Mc^2}{\sqrt{c^2 - v^2}}. \tag{27a}$$

Lagrange's equations for the free motion of a point mass

$$\frac{d}{dt}\left(\frac{\partial \mathfrak{L}}{\partial x}\right) - \frac{\partial \mathfrak{L}}{\partial x} = 0 \qquad \text{etc.}$$

can be written

$$\frac{d\mathfrak{G}}{dt} = \operatorname{grad}\mathfrak{L} = \frac{\partial \mathfrak{L}}{\partial c}\operatorname{grad}c = \mathfrak{K}^g; \tag{28}$$

They contain the inertial force as well as the gravitational force, which is

$$\mathfrak{K}^g = \frac{\partial \mathfrak{L}}{\partial c}\operatorname{grad}c = -\frac{Mc}{\sqrt{c^2 - v^2}}\operatorname{grad}c, \tag{28a}$$

or, according to (27a),

$$\mathfrak{K}^g = -\frac{E}{c}\operatorname{grad}c. \tag{28b}$$

For a given material point in a gravitational field, the gravitational force is, also in the case of motion, thus proportional to its energy; this corresponds to the primary postulate of the weight of energy.

The substitution of (27) and (28a) in (28) yields, upon the cancellation of the constant M, the *equation of motion of free material points in a gravitational field*

$$\frac{d}{dt}\left(\frac{\mathfrak{v}}{\sqrt{c^2 - v^2}}\right) = -\frac{c}{\sqrt{c^2 - v^2}}\operatorname{grad}c. \tag{29}$$

The energy equation, which connects the temporal increase of the energy E of the material point with the local temporal differential quotient of c with respect to time, is, by the way, joined to the momentum eq. (28) as a fourth equation. In a static field, where c depends only on position, E remains constant; in this case, according to (27a), the *energy equation* is

$$\frac{c^2}{\sqrt{c^2 - v^2}} = \text{const.} \tag{29a}$$

If one divides the equation of motion (29) by this constant expression, which then can be moved under the derivative, one obtains

$$\frac{d}{dt}\left(\frac{\mathfrak{v}}{c^2}\right) = -\frac{1}{c}\operatorname{grad} c \tag{29b}$$

[493] | *as the differential equation of motion of free material points in a static gravitational field*. The equations of motion (29) and (29b), incidentally, have been given first by A. Einstein,(11) and the energy eq. (29a) previously by M. Abraham.(8)

From it [eq, (29b)] one can derive the *theory of the free fall*. If v_0 is the initial velocity, and c_0 the speed of light appropriate to the initial location, then

$$v^2 = c^2\left(1 - \frac{c^2}{c_0^2} + c^2\frac{v_0^2}{c_0^4}\right), \tag{30}$$

and, in particular, if the initial velocity v_0 is equal to zero

$$v = c\sqrt{1 - \frac{c^2}{c_0^2}}. \tag{30a}$$

While c decreases from the initial value c_0, the velocity of the fall v increases at first, reaches a maximum

$$v_m = \frac{1}{2}c_0 \quad \text{for} \quad c = \frac{c_0}{\sqrt{2}}, \tag{30b}$$

and finally tends towards the limit c as c continues to decrease.

In order to determine the distance of fall as a function of time, c must be given as a function of z. In his note about the free fall,(9) M. Abraham puts

$$c^2 = c_0^2 + 2\mathfrak{g}z, \tag{31}$$

corresponding to a homogeneous mass-free field in his first theory. Then (30a) is satisfied by

$$\left.\begin{aligned}\frac{v}{c} &= \sin\left(\frac{gt}{c_0}\right)\\ \frac{c}{c_0} &= \cos\left(\frac{gt}{c_0}\right)\end{aligned}\right\} \qquad 0 \le t < \frac{\pi}{2}\frac{c_0}{g}. \tag{31a), (31b}$$

If one integrates the velocity of fall

$$-\frac{dz}{dt} = v = c_0 \cos\left(\frac{gt}{c_0}\right)\sin\left(\frac{gt}{c_0}\right) \tag{31c}$$

with respect to time, then the distance of fall becomes

$$-z = \frac{c_0^2}{2g}\sin^2\left(\frac{gt}{c_0}\right), \tag{31d}$$

which also satisfies (31). At the time $t = \pi c_0/2g$, i.e. for the distance of fall $c_0^2/2g$, c and v would both become zero. Of course, one cannot produce homogeneous fields of such extension. Practically, only times of fall have to be considered that are small | compared to the limiting time; then the above laws of fall become the Galilean ones. [494]

B. Caldonazzo[(23)] has concerned himself with the trajectories of freely point masses in homogeneous gravitational fields. He compares them to light rays whose paths follow from Fermat's principle of minimum light travel time,

$$\delta t = \delta\int\frac{ds}{c} = 0, \tag{32}$$

if c is given as a function of position. The differential equation for a *light ray trajectory* is, with $\mathfrak{t}$ denoting a tangential unit vector

$$\frac{d}{ds}\left(\frac{\mathfrak{t}}{c}\right) = \mathrm{grad}\left(\frac{1}{c}\right). \tag{32a}$$

On the other hand, the equation of motion (29b) implies the equation for the *trajectories of a material points* in a static gravitational field

$$\frac{d}{ds}\left(\frac{v\mathfrak{t}}{c^2}\right) = \frac{c}{v}\mathrm{grad}\left(\frac{1}{c}\right). \tag{32b}$$

An examination of the two differential equations (32a, b) shows that the second goes over into the first if one replaces v by c. From this remark follows an interesting relation between the trajectories of material points and those of light-points. Let us follow a material point P and a light-point L, which both emerge from O in the direction defined by the unit vector $\mathfrak{t}_0$. The initial speed of L is the speed of light c_0

associated with the point O, whereas we let that of P be equal to v_0. The trajectory of L is then uniquely determined by (32a), the one of P by (32b), where for v one has to use the function of position given by the energy eq. (30). Different initial speeds v_0 of P correspond to different trajectories; this set of trajectories has as the limiting curve the one corresponding to the initial speed c_0. But for $v_0 = c_0$ eq. (30) implies $v = c$, whence (32b) goes over into (32a). *Thus, the set of trajectories of material points shot from a point O in a given direction with different initial speed v_0, and moving in a static gravitational field, contain as a limiting curve $(v_0 = c_0)$ the light path that emerges from O in the same direction.*

Caldonazzo treats in more detail the case of the homogeneous gravitational field,
[495] where the equipotential surfaces, $c = \text{const.}$, are horizontal | planes. If the initial velocity was horizontal, it follows from (29b) that

$$v_x = \pm v_0 \frac{c^2}{c_0^2} \tag{33}$$

for the horizontal velocity component, and, hence, on account of (30), the vertical velocity component of the material points becomes

$$v_z = -\sqrt{v^2 - v_x^2} = -c\sqrt{1 - \frac{c^2}{c_0^2}}\,. \tag{33a}$$

The velocity components of the light-point are, according to the theorem just proved, obtained from this by setting $v_0 = c_0$:

$$c_x = \pm\frac{c^2}{c_0}, \tag{33b}$$

$$c_z = -c\sqrt{1 - \frac{c^2}{c_0^2}}\,. \tag{33c}$$

It follows that

$$v_z = c_z, \qquad v_x = \frac{v_0}{c_0}\,c_x. \tag{34}$$

Therefore, all the material points shot horizontally with different initial speeds v_0 have the same velocity of fall as the light-point, whereas the horizontal velocities are in the same ratio as the initial velocities. Thus all these points fall by equal distances during equal times; the horizontal projections of paths at equal time are, however, related to that of the light path as the initial velocities v_0 and c_0. Thus the trajectories of material points are obtained from the light curve to which they are tangent at the vertex by a contraction in the horizontal direction. Based on this result, Caldonazzo constructs, in a suitably chosen coordinate scale, the trajectories for the following three cases:

$$c = \sqrt{z}. \tag{I}$$

This corresponds to a homogeneous mass-free field in Abraham's first theory, where $c^2 = z$ should satisfy the Laplace equation (cf. (18a)). The light curves are cycloids. The trajectories resulting from them by contraction in the horizontal direction are so called "Fermat cycloids."

$$c = z. \tag{II}$$

Here, c itself satisfies Laplace's equation. According to the Einstein's equivalence hypothesis (III A), this should be the case in mass-free fields. | The light curves [496]
are circles, hence the trajectories of material points are ellipses.

$$c = z^2. \tag{III}$$

$\sqrt{c}$ satisfies Laplace's equation as demanded by the postulate of the weight of energy. The light-curves are elastic curves [*elastische Kurven*], the trajectories of material points are affine to them.

If one considers c as variable in the gravitational field, how are the electromagnetic field equations to be formulated? According to I. Ishiwara,(19) as follows:

$$\left.\begin{aligned}
\operatorname{curl}(\mathfrak{H}\sqrt{c}) &= \frac{\partial}{\partial t}\left(\frac{\mathfrak{E}}{\sqrt{c}}\right) + \rho\frac{\mathfrak{v}}{\sqrt{c}},\\
\operatorname{div}\left(\frac{\mathfrak{H}}{\sqrt{c}}\right) &= 0,\\
-\operatorname{curl}(\mathfrak{E}\sqrt{c}) &= \frac{\partial}{\partial t}\left(\frac{\mathfrak{H}}{\sqrt{c}}\right),\\
\operatorname{div}\left(\frac{\mathfrak{E}}{\sqrt{c}}\right) &= \frac{\rho}{\sqrt{c}}.
\end{aligned}\right\} \tag{35}$$

By retaining the usual expressions for the components of the electromagnetic tensor T^e, he obtains for its divergence, i.e., for the energy-momentum transfer of the electromagnetic field, the expression:

$$\rho\mathfrak{F}^e + \frac{\overset{e}{\eta}}{c}\operatorname{grad} c = \operatorname{div} T^e. \tag{35a}$$

The first term represents the electromagnetic four-force per unit volume; it corresponds to a transfer of momentum and energy from the electromagnetic field to the electrically charged matter. The second term, however, *shows a transfer of momentum and energy from the electromagnetic field to the gravitational field, which should take place everywhere where there exists electromagnetic energy*. This conception corresponds to the postulate of the weight of energy; and, according to it, the *electro-*

magnetic energy, just like the energy of matter, must *generate a gravitational field*, so that the field equation (23) is written as

$$\sqrt{c}\Box(\sqrt{c}) = 2(\eta^m + \eta^e). \tag{36}$$

Then, (cf. (23a)) the momentum and energy transferred from the gravitational field per unit volume and time becomes

$$-\left(\frac{\eta^m + \eta^e}{c}\right)\mathrm{grad}c = \mathrm{div}T^g. \tag{36a}$$

[497] | Here, the term containing η^m shows the transfer of momentum and energy to matter, the term containing η^e the transfer to the electromagnetic field; the latter is equal and opposite to the corresponding term appearing in (35a), justifying the above interpretation. Upon adding of the divergences of the tensors T^e and T^g it [η^e] cancels. The *total four-force acting on the unit volume of matter* is[4]

$$\rho\mathfrak{F}^e - \frac{\eta^m}{c}\mathrm{grad}c = \mathrm{div}(T^e + T^g). \tag{36b}$$

It is composed of the electromagnetic force acting on the charge, and of the gravitational force acting on the energy of matter.

The field equations (35) thus agree with the postulate of the weight of energy, and so fit into the theory presented here. The coupling of the two fields is, by the way, not a simple one. For, according to (35) the gravitational potential $\sqrt{c}$ influences the electromagnetic field; on the other hand, according to (36), the gravitational potential depends on the distribution of energy within the electromagnetic field.

D. Theories of Nordström and Mie

In Abraham's first theory (II B), the postulate of the constancy of the speed of light is renounced, and thus the validity of the theory of relativity is restricted to infinitely small spacetime regions. Abraham's second theory gives up the validity of the principle of relativity even in this restricted sense, because the two sides of its field equation (23) exhibit different behavior under Lorentz transformation.

The theories of gravitation of G. Nordström and G. Mie, however, view the speed of light as constant; their equations are invariant with respect to Lorentz transformations.

Following Abraham's first theory, G. Nordström(20) derives the gravitational tensor T^g from a scalar gravitational potential φ according to the scheme (16). This [potential] satisfies the field equation (18), in which ν denotes the "rest-mass density" of matter. Then, as in (II B, eq. (17), (17b)), on the basis of the conservation laws of momentum and energy there results,

$$\mu\mathfrak{F}^g = -\nu\,\mathrm{grad}\varphi \tag{37}$$

as the *gravitational force per unit of volume*.

We integrate over the volume of a moving body. Since | its volume elements experience a Lorentz contraction as a result of the motion, we have [498]

$$dV = dV_0\sqrt{1-\frac{v^2}{c^2}} \qquad (V_0 \text{ rest-volume}). \tag{38}$$

If, furthermore, one takes the rest-mass of the body to be

$$m_0 = \int \nu dV_0, \tag{38a}$$

then, in case the body is so small that the gravitational field is considered to be homogeneous over its extent, one obtains the expression

$$\mathfrak{K}^g = \int \mu \mathfrak{F}^g dV = -\frac{m_0}{c}\sqrt{c^2-v^2} \cdot \operatorname{grad}\varphi \tag{39}$$

for the *resultant gravitational force*. It becomes readily apparent that the appearance of the square root as a factor in the expression for the gravitational force is a necessary consequence following from the theory of relativity, because that theory cannot avoid assigning to the scalar φ, by means of (18), a ν invariant under Lorentz transformations. *In the theory of relativity the gravitational force of a moving body is therefore not proportional to its energy, but to its Lagrangian function* (cf. (20)):

$$\mathfrak{L} = -m_0 c\sqrt{c^2-v^2}. \tag{40}$$

At low speeds this means that not the sum but the *difference* of the *potential* and *kinetic energy should be the determining factor for the weight of a body.*

As c is constant, the gravitational potential φ can enter the Lagrangian function (40) only through the multiplicative constant m_0. This must take place in such a way that in the law of conservation of momentum formulated in the Lagrangian manner (see (28)),

$$\frac{d\mathfrak{G}}{dt} = \operatorname{grad}\mathfrak{L} = \frac{\partial\mathfrak{L}}{\partial\varphi}\operatorname{grad}\varphi, \tag{40a}$$

the right-hand side, i.e., the gravitational force

$$\mathfrak{K}^g = \frac{\partial\mathfrak{L}}{\partial\varphi}\operatorname{grad}\varphi = -\frac{dm_0}{d\varphi}c\sqrt{c^2-v^2} \cdot \operatorname{grad}\varphi, \tag{40b}$$

agrees with (39). Therefore, for the rest-mass, the differential equation

$$\frac{dm_0}{d\varphi} = \frac{m_0}{c^2} \tag{40c}$$

must apply, whose integral is

$$m_0 = \frac{M}{c} e^{\frac{\varphi}{c^2}}; \tag{41}$$

[499] | M denotes a “mass-constant” which is independent of φ. Thus, the gravitational potential enters exponentially into the *Lagrangian function of the first theory of Nordström,*

$$\mathfrak{L} = -M e^{\frac{\varphi}{c^2}} \cdot \sqrt{c^2 - v^2}, \tag{41a}$$

and enters similarly into the *expressions for momentum* and *energy*

$$\mathfrak{G} = \frac{\partial \mathfrak{L}}{\partial v} \frac{\mathfrak{v}}{v} = \frac{M}{\sqrt{c^2 - v^2}} e^{\frac{\varphi}{c^2}} \cdot \mathfrak{v}, \tag{41b}$$

$$E = v \frac{\partial \mathfrak{L}}{\partial v} - \mathfrak{L} = \frac{Mc^2}{\sqrt{c^2 - v^2}} \cdot e^{\frac{\varphi}{c^2}}, \tag{41c}$$

and into the *expression for the gravitational force* (40b)

$$\mathfrak{K}^g = -\frac{M}{c^2} e^{\frac{\varphi}{c^2}} \sqrt{c^2 - v^2} \cdot \operatorname{grad}\varphi. \tag{41d}$$

The equation of motion of material points, or equivalent bodies, in a gravitational field

$$\frac{d\mathfrak{G}}{dt} = \mathfrak{K}^g \tag{42}$$

takes, according to (41b, d), the form

$$\frac{d}{dt}\left(e^{\frac{\varphi}{c^2}} \cdot \frac{\mathfrak{v}}{\sqrt{c^2 - v^2}}\right) = -\frac{1}{c^2} \cdot e^{\frac{\varphi}{c^2}} \cdot \sqrt{c^2 - v^2} \cdot \operatorname{grad}\varphi. \tag{42a}$$

In a static field we have the energy integral (cf. (41c))

$$\frac{e^{\frac{\varphi}{c^2}}}{\sqrt{c^2 - v^2}} = \text{const.}, \tag{42b}$$

so that in Nordström’s theory, the *equation of motion of material points in a static field* is:(22)

$$\frac{d\mathfrak{v}}{dt} = -\left(1 - \frac{v^2}{c^2}\right) \operatorname{grad}\varphi. \tag{42c}$$

It is apparent that in a homogeneous gravitational field—in contrast with (II C)—the greater the velocity of horizontally projected bodies, the slower they fall. The light-curve is, however, here too to be considered as a limiting curve of the family of trajectories; because for $v = c$, the acceleration is zero, thus the motion is uniform and rectilinear, like that of a light-point under the presupposition of the constancy of the speed of light.

For *free fall* in a homogeneous mass-free field, the equation of motion

$$\frac{dv}{dt} = g - \frac{gv^2}{c^2} \tag{42d}$$

applies. | It agrees with the differential equation that one uses in classical mechanics [500]
for the fall in air under the assumption of a law of friction proportional to the square [of the speed]; therefore its integration poses no difficulties and becomes, if one sets the initial velocity equal to zero,

$$v = c\tanh\left(\frac{gt}{c}\right). \tag{42e}$$

If the field extended sufficiently far, the speed would asymptotically approach the speed of light.

M. Behacker(25) has treated horizontal projection [of bodies] and planetary motion on the basis of Nordström's first theory. The deviations from the laws of classical mechanics are here too of second order in $v : c$.

The theory of G. Mie,(21) though developed independently, is closely related to Nordström's first theory. It forms part of an extensive investigation of the "foundations of a theory of matter," for whose presentation this is not the appropriate place. Within matter, Mie differentiates between two gravitational four-vectors, which, however, coincide in the case of an "ideal vacuum." Here, as with Abraham, the differential equations of longitudinal waves apply. The gravitational waves emitted by an oscillating mass-particle are treated in more detail by Mie. He further emphasizes that, from the point of view of the theory of relativity, one necessarily arrives at the notion that the weight of a body is not to be set proportional to its energy, but to its Lagrangian function. Accordingly, the kinetic energy of the thermal motion of the molecules makes a negative contribution to the weight. Since, on the other hand, in the theory of relativity the theorem of the inertia of energy is valid, the gravitational mass of a warm body is thus not precisely proportional to its inertial mass, but with increasing temperature the quotient of gravitational and inertial mass decreases. However, the proof of the decrease demanded by Mie's theory would require pendulum measurements with an accuracy of the order of 10^{-11}; this theoretical deviation from the proportionality law is not subjectable to experiment.

Greater difficulties arise for the Mie-Nordström theory from observations by Southerns, which demonstrate the constancy of the quotient of inertial and gravitational mass during radioactive transformations (I C). These observations can only be

brought into agreement with that theory through rather artificial assumptions. One could for example imagine that the entire energy loss during the transformation |
[501] takes place at the expense of only the electric potential energy, so that the kinetic (magnetic) energy has the same value before and after the transformation of the uranium atom. Or, one can assume with Kretschmann[36] that the total energy emitted from the uranium atom in the form of heat, β - and γ -particles does not come from those particles that later form the lead atom, but from the eight escaped helium atoms. Then, however, helium would have to show a correspondingly greater deviation from the proportionality law.

G. Mie also investigated the relation between the gravitational potential and electromagnetic processes. An electromagnetic field possesses a gravitational mass, which is proportional to its Lagrangian function, i.e. proportional to the difference of its electric and magnetic energy. A plane electromagnetic wave, in which the electric and the magnetic energy density is known to have the same value, accordingly has no weight in this theory (corresponding to the rectilinear propagation of light). An electrostatic field, however, possesses a positive weight and a magnetostatic field a negative weight. On the other hand, the gravitational potential enters exponentially into the electromagnetic quantities, as well as into the mechanical ones. Nevertheless, the value of the potential in a system escapes detection by observers belonging to that system. This is expressed by Mie's theorem of the "*relativity of the gravitational potential*": If two physical systems differ merely by the value of the gravitational potential, then this does not have the least effect on the size and the form of the electrons and of the other material elementary particles, on their charge, their laws of oscillation and motion, and on the velocity of light, indeed on all physical relations and processes.

E. Nordström's Second Theory

With the intention of satisfying the law of the proportionality of the gravitational and inertial mass, as far as it is possible within the framework of the theory of relativity, G. Nordström[26] later made a change in his theory. Before we turn to a discussion of this change, we must briefly return to the properties of the world tensors (I B), and mention several theorems of von Laue regarding "complete static systems."

We form the "*diagonal sum*" of a world tensor T

$$D = T_{xx} + T_{yy} + T_{zz} + T_{uu}; \tag{43}$$

[502] | since the components entering this sum transform like the square of the four coordinates, the diagonal sum is an invariant; it is frequently called the "Laue scalar."

The diagonal sum of the *electromagnetic world tensor* T^e is identically equal to zero:

$$D^e = T^e_{xx} + T^e_{yy} + T^e_{zz} + T^e_{uu} = 0. \tag{43a}$$

In contrast, our *gravitational tensor* T^g yields, according to (16), a diagonal sum different from zero:

$$D^g = \left(\frac{\partial\varphi}{\partial x}\right)^2 + \left(\frac{\partial\varphi}{\partial y}\right)^2 + \left(\frac{\partial\varphi}{\partial z}\right)^2 + \left(\frac{\partial\varphi}{\partial u}\right)^2. \tag{43b}$$

The matter is the carrier of a third world tensor T^m; its last component is the energy density of matter. For a body consisting of discrete and freely movable mass particles, the momentum density and the kinetic stresses determine the remaining components of the "*material tensor*" T^m. In a continuously connected body, elastic stresses enter in addition into the consideration, as they also cause an energy flux and thus a momentum density. It appears useful to include in T^m the "stress tensor." The diagonal sum of the material tensor

$$D^m = T^m_{xx} + T^m_{yy} + T^m_{zz} + T^m_{uu} \tag{43c}$$

then equals the sum of the three (kinetic and elastic) principal stresses plus the total energy density (η^m) of the matter.

Now, if

$$T = T^m + T^e + T^g \tag{44}$$

is the *total ten-tensor, resultant of the material, the electromagnetic and of the gravitational tensor*, then the *laws of conservation of momentum and energy* can be summarized as (cf. (5))

$$0 = \operatorname{div} T. \tag{44a}$$

Namely the momentum and energy extracted from the electromagnetic field and from the gravitational field are transformed into momentum and energy of matter.

By a "*complete static system*," one understands, according to M. Laue, an isolated physical system that is in equilibrium in an appropriately chosen system of reference Σ_0. Therefore, in Σ_0 the components

$$T^0_{xu}, \quad T^0_{yu}, \quad T^0_{zu}$$

| of the resultant tensor, which determine the energy flux and the momentum density, [503]
are all zero; one can derive from this[9] that in Σ_0 the volume integrals of the resulting normal stresses are equal to zero:

$$\int dV_0 T^0_{xx} = \int dV_0 T^0_{yy} = \int dV_0 T^0_{zz} = 0. \tag{45}$$

If one is only concerned about the temporal mean values, then a system in static equilibrium can also be taken as a completely static system. It suffices that the tempo-

---

9 M. Laue, *Das Relativitätsprinzip*, 2nd. ed., p. 209.

ral mean value of the resultant energy flux vanish everywhere. Thus, for example, a hot gas in static equilibrium, together with its container, forms a complete static system. For the measurable stresses, the eqs. (45) apply; the negative contributions arising from the kinetic pressure of the gas, and the positive, arising from the stresses in the walls of the container, cancel each other in the integrals extended over the entire system.

Because it is an invariant, the diagonal sum (43) of the resultant world tensor does not depend on the choice of the system of reference. Its value in a complete static system can thus be determined by referring it to Σ_0:

$$D = D^0 = T^0_{xx} + T^0_{yy} + T^0_{zz} + T^0_{uu}. \tag{45a}$$

In view of (45), the volume integral yields

$$\int dV_0 D = \int dV_0 T^0_{uu} = \int dV_0 \eta_0 = E_0, \tag{45b}$$

where E_0 denotes the *total rest-energy* of the system.

After these preparations, we turn to Nordström's second theory of gravitation. It too is based on the tensor-scheme of (16); however, the following takes the place of the field equation (18),

$$\varphi \Box \varphi = D^m. \tag{46}$$

Since the diagonal sum D^m of the material tensor, as well as φ and the operator $\Box$, are four-dimensional scalars, this approach corresponds to the relativistic scheme. The gravitational force per unit volume now follows from (17b):

$$\mu \mathfrak{F}^g = -\frac{D^m}{\varphi} \cdot \operatorname{grad} \varphi. \tag{46a}$$

The integration over the volume of a body moving with respect to Σ_0, taking into account the Lorentz contraction (38), yields the gravitational force acting on the
[504] body. |

$$\mathfrak{K}^g = -M\sqrt{c^2 - v^2} \cdot \operatorname{grad} \varphi, \tag{46b}$$

where

$$Mc = \int \frac{dV_0 D^m}{\varphi} = \int \frac{dV_0 D^m_0}{\varphi_0} \tag{46c}$$

denotes the gravitational mass of the body for the case of rest $(v = 0)$. Indeed, on the one hand, according to (46b), the gravitational force on the resting body is equal to the negative gradient of the potential φ multiplied by Mc. On the other hand, when rest reigns in Σ_0, it follows from (46) that

$$\Delta\varphi_0 = \text{div grad}\varphi_0 = \frac{\overset{m}{D_0}}{\varphi_0}.$$

Therefore, according to Gauss' law, the force flux through a surface f_0 enclosing the body, which determines the attracting mass, becomes:

$$\int df_0 \frac{\partial\varphi_0}{\partial n} = \int \frac{dV_0 \overset{m}{D_0}}{\varphi_0} = Mc. \tag{46d}$$

The gravitating mass Mc, and thus also M, is considered to be a *constant*, i.e. as independent of φ, in Nordström's second theory.

Now, what relation exists between the gravitational mass and the rest-energy for a complete static system? Equation (45b) yields:

$$E_0 = \int dV_0 D_0. \tag{47}$$

Taking into consideration (43a, b), one obtains for the diagonal sum of the resultant world tensor, since equilibrium reigns in Σ_0,

$$D_0 = \overset{m}{D_0} + (\text{grad}\varphi_0)^2. \tag{47a}$$

And since, furthermore,

$$\varphi_0\Delta\varphi_0 + (\text{grad}\varphi_0)^2 = \text{div}(\varphi_0\text{grad}\varphi_0)$$

is an identity, the field equation (46) can then be brought into the form

$$\text{div}(\varphi_0\text{grad}\varphi_0) = D_0 \tag{47b}$$

and from (47) it follows, on the basis of Gauss' theorem, that

$$E_0 = \int dV_0 D_0 = \int df_0 \varphi_0 \frac{\partial\varphi_0}{\partial n}, \tag{47c}$$

where the integration is to be carried out over a surface wholly enclosing the complete static system and its gravitational field. However, on such a surface, far removed from the system, one has to set for φ_0, the potential φ_a of the external masses not belonging to the system, | which is constant there. Namely, if φ_a were not constant [505]
on f_0, the external field would superpose on the system's own; the energy of its own field could then not be separated from the external field, and the system could thus not be considered isolated (i.e., enclosed by the surface f_0). Now, it follows from (47c) and (46d) that

$$E_0 = \varphi_a \int df_0 \frac{\partial\varphi_0}{\partial n} = \varphi_a Mc. \tag{48}$$

Accordingly, the total *rest-energy of the complete static system is equal to its gravitational mass multiplied by the external gravitational potential*. On the other hand, according to the theorem of the inertia of energy (8a),

$$m_0 = \frac{E_0}{c^2} = \varphi_a \frac{M}{c} \tag{48a}$$

is the *inertial rest-mass*.

In Nordström's second theory, the law of proportionality between inertial and gravitational mass applies for a complete static system, at least for the rest-masses. Of course, for moving bodies, the postulate of the weight of energy is not satisfied in Nordström's second theory any more than in his first, since, in the expression (46b) for the gravitational force, the root factor characteristic of the theory of relativity, and entering into the denominator of the expression for the energy, appears again in the numerator. However, admittedly one cannot determine the weight of a moving body with a scale; thus, as far as weighing is concerned, the theorem of the weight of energy therefore applies in Nordström's theory, and accordingly also the theorem that weight is conserved. However, the strict validity of these theorems, and thus also that of the law of proportionality of inertial and gravitational mass, fails when the masses are in motion. For example, in pendulum measurements, one would expect deviations of the order of $(v/c)^2$, which are however unmeasurable of course.

But what is now the situation in an isolated system in a state of statistical equilibrium, e.g., in a hot gas? The thermal motion of the molecules causes here, too, a reduction of weight corresponding to the negative kinetic stresses entering into D^m, and thus also into the expression for the gravitational mass (cf. (46d)). This, however, is compensated by the positive contributions which the stresses in the wall of the vessel contribute to D^m, and thus to the weight. Thus, for Nordström, the proportionality of weight and energy comes about merely through a compensation of the contributions of the individual parts of the complete static system. | [506] It is in no way based on a fundamental property of matter or energy.

A complete system of sufficiently small dimensions can be considered as equivalent to a material point. The motion in a given gravitational field is then obtained from Lagrange's equations (40a)

$$\frac{d\mathfrak{G}}{dt} = \frac{d\mathfrak{L}}{\partial\varphi}\mathrm{grad}\varphi = \mathfrak{K}^g. \tag{49}$$

As a comparison with (46b) reveals, one has to set for the *Lagrangian function*

$$\mathfrak{L} = -M\varphi\sqrt{c^2 - v^2}. \tag{49a}$$

This Lagrangian of Nordström's second theory turns into the one (41a) of his first theory, if φ is replaced by the exponential function $e^{\frac{\varphi}{c^2}}$. However, through this substitution, the field equation (46) does not change into agreeing with (18) of the first theory; therefore, the two theories are not equivalent.

The momentum and energy can be derived from the Lagrangian function (49a) in the usual manner:

$$\mathfrak{G} = \frac{\partial \mathfrak{L}}{\partial v}\frac{\mathfrak{v}}{v} = \frac{M\varphi}{\sqrt{c^2 - v^2}} \cdot \mathfrak{v}, \tag{49b}$$

$$E = v\frac{\partial \mathfrak{L}}{\partial v} - \mathfrak{L} = \frac{Mc^2\varphi}{\sqrt{c^2 - v^2}}. \tag{49c}$$

Through substitution of (49b) into (49) one obtains the *equations of motion of material points* and of the equivalent complete systems

$$\frac{d}{dt}\left(\frac{\varphi \mathrm{v}}{\sqrt{c^2 - v^2}}\right) = -\sqrt{c^2 - v^2} \cdot \operatorname{grad}\varphi. \tag{50}$$

In a static gravitational field, the energy (49c) is constant:

$$\frac{\varphi}{\sqrt{c^2 - v^2}} = \text{const.} \tag{50a}$$

Therefore, the equation of motion can be brought into the form[31]

$$\frac{d\mathfrak{v}}{dt} = -\left(\frac{c^2 - v^2}{\varphi}\right)\operatorname{grad}\varphi. \tag{50b}$$

For a homogeneous mass-free gravitational field, whose lines of force are parallel to the negative z-axis, one must set, corresponding to the field equation (46),

$$\varphi = \varphi_0 + gz. \tag{50c}$$

| The free fall from the rest position $z = 0$ in this field can be treated on the basis of the energy equation (50a), which yields [507]

$$\varphi = \frac{\varphi_0}{c} \cdot \sqrt{c^2 - v^2}. \tag{50d}$$

It is satisfied by

$$z = -\frac{\varphi_0}{g}\left(1 - \cos\left(\frac{gct}{\varphi_0}\right)\right); \tag{51}$$

because according to (50c)

$$\varphi = \varphi_0 \cos\left(\frac{gct}{\varphi_0}\right), \tag{51a}$$

and, on the other hand, the velocity of fall is

$$\upsilon = -\frac{dz}{dt} = c\sin\left(\frac{gct}{\varphi_0}\right), \tag{51b}$$

so that (50d) is indeed satisfied.

G. Nordström,[31] incidentally, also treats oblique projection [of bodies] and planetary motion; the area law proves to be valid. The deviations from the laws of classical mechanics are minute.

In Nordström's theory, the rest-energy is proportional to the external gravitational potential (cf. (48)). In Abraham's theory, a similar behavior was found; the rest-energy (cf. (21a)) was proportional to the speed of light, which there played the role of the gravitational potential. Thus, in either theory, the rest-energy of a body decreases as a result of the approach of external masses. The rest-mass, in contrast, exhibits a different behavior in the two theories; for Abraham (cf. (21b)) the rest-mass is inversely proportional to c, for Nordström (cf. (48a)) it is proportional to φ_a. Hence, for Abraham, the inertial mass of a body increases upon the approach of an external body, while, for Nordström, it decreases.

Incidentally, according to Nordström, the units of time (τ) and length (λ) should depend in the following way on the gravitational potential:

$$\tau\varphi = \text{const.}, \tag{52}$$

$$\lambda\varphi = \text{const.}, \tag{52a}$$

i.e., the rate of a portable clock and the length of a portable measuring rod should be inversely proportional to the gravitational potential. Thus, local spatial and temporal measurements do not allow the construction of the universal system of reference in which light should propagate rectilinearly. This conception of space and time can
[508] hardly be made compatible with the theory of relativity of Minkowski. | However, it can be readily fitted into the Einstein-Grossmann "generalized theory of relativity," as has been shown by A. Einstein and A. D. Fokker.[34]

We must refrain here from entering into Nordström's five-dimensional interpretation of his theory.[33] [37]

F. Kretschmann's Theory

Among the newest relativistic theories of gravitation, the one by E. Kretschmann[36] deserves to be mentioned even if only briefly. This theory is to be counted among the scalar theories, as its assumes that the gravitational force is determined by the gradient of an "aether pressure" p, which, in a vacuum, satisfies the equation

$$\Box p = 0.$$

Matter is assumed to consist of elementary drops, which obey the equations of state of "ideal fluids of smallest compressibility and least expendability" developed by E. Lamla in his inaugural dissertation "Über die Hydrodynamik des Relativitätsprinzips." These drops are assumed to move irrotationally and each to carry a positive electric elementary charge. The divergence of the gradient of p in the interior of the drops, which determines the attracting mass, turns out to be proportional to the square of their acceleration. On the other hand, the attracted mass of a body is proportional to the sum over the volume of its elementary drops. In order to obtain the proportionality of the attracted, the attracting and of the inertial mass, the author assumes not only that the drops are all of the same kind, but that they also move with the same mean velocity and acceleration; then, of course, all three masses simply become proportional to the number of the particles. Following A. Korn and H. A. Lorentz, the author explains, that such an energy equilibrium of the elementary drops is produced by means of a universal radiation state, or state of oscillation, which is supposed to immediately smooth out disturbances in the energy equilibrium.

The contrast between this theory and the other theories of gravitation discussed here is strikingly clear. The latter introduce merely mechanical and energetic quantities, since the speed of light, too, is a quantity of relativistic mechanics. Kretschmann's theory, in contrast, is based on quite particular concepts, which are virtually without significance for the final result; for not the particular properties, but only the number of | particles is to be considered in the derivation of the proportional- [509]
ity of inertial and gravitational mass.

III. TENSOR THEORIES

A. Einstein's Theory of the Static Gravitational Field

In I C we discussed the relation between gravity,[2] inertia, and energy, and the necessity of assigning to them a place in the worldview of modern physics. These relations also formed the starting point of the investigations of A. Einstein.

His first paper(5) is based on the so called *equivalence hypothesis*: "Equivalence exists between two systems of reference of which one is at rest in a homogeneous gravitational field and the other is uniformly accelerated in a field free of gravitation." Indeed, in classical mechanics, such an equality exists because the inertial force under uniform acceleration is equivalent to a constant gravitational force; the equivalence hypothesis results here in the identity of inertial and gravitational mass. But it is questionable whether the equivalence hypothesis can be maintained for other physical processes, namely for those that satisfy the principle of relativity of 1905; if this were the case, then from this and from the theorem of the inertia of energy, valid in that theory, the theorem of the weight of energy would follow immediately. Without a critical examination of whether his earlier principle of relativity is compatible with the new equivalence hypothesis, Einstein connects these two trains of thought and arrives thus at the following remarkable result:

The gravitational potential influences the speed of light; if the values of the speeds of light, c and c_0, correspond to the potentials, φ and φ_0, then

$$c = c_0\left(1 + \frac{\varphi - \varphi_0}{c^2}\right). \tag{53}$$

By application of Huygens' principle this implies a curvature of the light rays grazing the surface of the Sun; the total deviation of such a ray would amount to 0.83 seconds of arc, by which the angular distance of a star appears to be increased with respect to the center of the Sun. Einstein considers it possible to observe this deviation on the occasion of an eclipse of the Sun. |
[510]

Furthermore, the gravitational potential changes the frequency of periodic processes as determined by the following formula

$$\frac{\nu_0 - \nu}{\nu_0} = \frac{\varphi_0 - \varphi}{c^2}. \tag{53a}$$

If φ refers to the surface of the Sun and φ_0 to the Earth, then the right-hand side is equal to $2 \cdot 10^{-6}$. Thus, the frequency ν of the oscillations of light should be somewhat smaller on the surface of the Sun than the frequency ν_0 of the corresponding spectral line of a terrestrial light source: i.e., compared to the terrestrial lines, the solar ones should be displaced to the right-hand side of the spectrum. Astrophysicists have indeed found displacements of the Fraunhofer lines in this sense, but have mostly ascribed them to pressure effects.

In that first study, Einstein had investigated the effect of the gravitational field on radiation phenomena without, however, making use of the connection found between the gravitational potential and the speed of light for the theory of the gravitational field itself. Only after the first publication by Abraham did Einstein also turn to the problem of gravitation.(11) There, again, he started from the equivalence hypothesis and derived the equations of motion ((29), (29b)) of material points in static gravitational fields. He also concluded from that hypothesis that the speed of light c in mass-free static fields must satisfy Laplace's equation. Shortly thereafter,(12) however, he convinced himself that in order to avoid contradictions with the law of conservation of momentum, one has to begin from Laplace's equation for $\sqrt{c}$ rather than for c, and that, hence, the equivalence hypothesis does not form a firm foundation for the theory of the gravitational field. This led to the necessity for a new foundation for the theory. M. Abraham (II C) made the theorem of the weight of energy the starting point of his second theory, and derived from it the field equations and the equations of motion. For static fields, this theory coincides with Einstein's. The essential difference appears only upon the extension to time varying fields. Abraham's theory considers such fields as still being determined solely by the four derivatives of the velocity of light, whereas Einstein's theory derives the dynamic field from a tensor potential.

B. The Generalized Theory of Relativity of A. Einstein and M. Grossmann

The basic idea of the tensor theory of the gravitational field can | be understood as follows. The energy density, which in a static field is determined by the divergence of the gradient of the gravitational potential, plays in the theory of relativity merely the role of one component of the resulting world tensor T; it is joined by nine other tensor components which characterize the energy flux and the stresses. The tensor theory assumes that, like the energy density (T_{44}), the remaining nine components $T_{\mu\nu}$ $(\mu, \nu = 1, 2, 3, 4)$ generate gravitational fields whose potentials $g_{\mu\nu}$ form a ten-tensor themselves. With the introduction of such a tensor potential it aims to give the differential equations of the gravitational field a form satisfying the scheme of the principle of relativity. That it appears possible to fit tensor theories of gravitation into the framework of Minkowski's conception of spacetime has been shown by G. Mie.(28) However, the theory of gravitation sketched by A. Einstein and M. Grossmann(24) supersedes the framework of the earlier theory of relativity by closely relating these tensor potentials $g_{\mu\nu}$ to a generalized relativistic spacetime doctrine. [511]

In Minkowski's four-dimensional representation of the theory of relativity, the square of the four-dimensional distance between two neighboring spacetime points was given by the following quadratic differential form:

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2, \tag{54}$$

in which c, the speed of light, was constant. In a static gravitational field, the very expression (54) should, according to Einstein, express the "natural distance" ds of two neighboring world points, but where c is now a function of x, y, z. Its application to the general case of a dynamic gravitational field would, however, imply a preferential treatment of the time coordinate $(x_4 = t)$ over the spatial coordinates $(x_1 = x, x_2 = y, \ x_3 = z)$, which would not be reconcilable with the relativistic ideas about space and time. It appears natural to replace the special quadratic form (54) by the most general homogeneous function of second degree in the coordinate differentials:

$$ds^2 = \sum_{\mu\nu} g_{\mu\nu}dx_\mu dx_\nu \qquad (\mu, \nu = 1, 2, 3, 4). \tag{55}$$

This form was used by E. and G. for the natural distance between two neighboring world points. The system of the ten coefficients $g_{\mu\nu}$ in the form (55) form a world tensor, and it is said to be identical to the tensor potential of the dynamic gravitational field, similar to the way c determines the gravitational potential in the static case. | [512]

According to (55) the natural length of a portable, infinitely small measuring rod is not determined solely by the coordinate differentials dx_1, dx_2, dx_3 of its end points; rather, the six potentials

$$g_{11}, \qquad g_{22}, \qquad g_{33}, \qquad g_{12} = g_{21}, \qquad g_{23} = g_{32}, \qquad g_{31} = g_{13}$$

enter into it, and, in particular, in a way that depends on the direction of the measuring rod. That means that apparently rigid bodies are stretched and twisted in a gravitational field. The measure of time too is influenced by the gravitational potential g_{44} (this occurs already in the static field) in such a way that the natural distance of two neighboring points in time, measured with the aid of a portable clock, is different from the differential dx_4 of the time coordinate. Thus, the coordinates x_1, x_2, x_3, x_4 have no direct physical meaning. In order to determine from their differentials the natural distance between neighboring spacetime points, the values of the ten gravitational potentials $g_{\mu\nu}$ must be known. Regarding, by the way, the three potentials,

$$g_{14} = g_{41}, \qquad g_{24} = g_{42}, \qquad g_{34} = g_{43},$$

they arise, for example, if the system of reference rotates in a static gravitational field, and then determine the velocity of the point in question. The complete system of the $g_{\mu\nu}$ characterizes the state of deformation of four-dimensional space.

In the same way as the invariant differential form (54) is related to the group of rotations in four dimensions (Lorentz transformations), and hence to the vector calculus of Minkowski's theory of relativity, so the invariance of the more general differential form (55) is related to a more general group of transformations. The study of the behavior of the different geometric objects (vectors, tensors) with respect to these transformations forms the mathematical basis of the "generalized theory of relativity." The authors of the *Entwurf* found the required mathematical tools already fully developed in the "absolute differential calculus" of G. Ricci and T. Levi-Civita. Based on this, in the second part of the *Entwurf*, M. Grossmann outlines the fundamental concepts of the four-dimensional vector calculus, which corresponds to that general group of transformations. This is not the place to enter into the mathematical aspects of the *Entwurf*. It may, however, be noted that Grossmann designates the "four-vectors" of the usual theory of relativity as "first rank tensors," whereas by "second rank tensors" he understands the quantities which by us are called simply
[513] "tensors." |

In the first, physical, part of the *Entwurf*, written by A. Einstein, the equations of motion of material points are derived in a generally covariant form from Hamilton's principle

$$\delta\int ds = 0. \tag{56}$$

The gravitational force appears as dependent on the forty derivatives of the ten potentials $g_{\mu\nu}$; here, however, the so called "fictitious forces of relative motion" are counted among the gravitational forces.

Just like the equations of motion, the differential equations of the electromagnetic field are also brought to a generally covariant form. Yet, the attempt to develop generally covariant equations for the gravitational field fails. The *field equations* put down by Einstein read as follows:

$$\sum_{\alpha\beta\mu} \frac{\partial}{\partial x_\alpha}\left(\sqrt{-g}\gamma_{\alpha\beta} g_{\sigma\mu} \frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\right) = S^m_{\sigma\nu} + S^g_{\sigma\nu}. \tag{57}$$

Here, g is the determinant of the $g_{\mu\nu}$, $\gamma_{\mu\nu}$ is the cofactor (*adjungierte Unterdeterminante*) of $g_{\mu\nu}$ divided by g. On the right-hand side are quantities that are linear functions of the components of the material tensor T^m and of the gravitational tensor T^g:

$$S^m_{\sigma\nu} = \sqrt{-g} \cdot \sum_\mu g_{\sigma\mu} T^m_{\mu\nu}, \tag{57a}$$

$$S^g_{\sigma\nu} = \sqrt{-g} \cdot \sum_\mu g_{\sigma\mu} T^g_{\mu\nu}. \tag{57b}$$

If one places the quantities $S^g_{\sigma\nu}$:

$$S^g_{\sigma\nu} = \sqrt{-g} \cdot \left\{\sum_{\beta\tau\rho} \gamma_{\beta\nu} \frac{\partial g_{\tau\rho}}{\partial x_\sigma} \frac{\partial \gamma_{\tau\rho}}{\partial x_\beta} - \frac{1}{2} \sum_{\alpha\beta\tau\rho} \delta_{\sigma\nu} \gamma_{\alpha\beta} \frac{\partial g_{\tau\rho}}{\partial x_\alpha} \frac{\partial \gamma_{\tau\rho}}{\partial x_\beta}\right\}, \tag{57c}$$

(in which one has to set $\delta_{\sigma\nu} = 1$, for $\sigma = \nu$, $\delta_{\sigma\nu} = 0$ for $\sigma \neq \nu$) on the left hand side of (57), then there arise ten second order partial differential equations for the ten quantities $\gamma_{\mu\nu}$, respectively $g_{\mu\nu}$, in the right-hand side of which the components of the material tensor T^m enter as field generating quantities. If an electromagnetic field is present, then the components of the electromagnetic tensor T^e are of course to be introduced in the same manner.

With regard to the invariance properties of his gravitational field equations, Einstein still appears to have hoped, during the writing of the *Entwurf*, to obtain covariance, if not for the more general group of transformations associated with the form (55), but at least for a group encompassing acceleration transformations; thereby, his earlier | "equivalence hypothesis" was to be supported mathematically. In his Vienna [514] lecture,(27) however, he states that it is probable, and later(29) that it is certain, that these field equations are only covariant with respect to linear transformations. Lately however, with the aid of M. Grossmann, he was able to prove(35) that only the laws of conservation of momentum and energy are responsible for restricting the diversity of "allowed" transformations. These conservation laws, which we expressed symbolically by

$$\operatorname{div}(T^m + T^g) = 0$$

become in the generalized theory of relativity, upon the introduction of the quantities (57a, b):

$$\sum_\nu \frac{\partial}{\partial x_\nu}(S^m_{\sigma\nu} + S^g_{\sigma\nu}) = 0. \tag{58}$$

Those four equations, together with the field equations (57), yield four third order partial differential equation

$$\sum_{\alpha\beta\mu\nu} \frac{\partial^2}{\partial x_\nu \partial x_\alpha}\left(\sqrt{-g}\gamma_{\alpha\beta} g_{\sigma\mu} \frac{\partial \gamma_{\mu\nu}}{\partial x_\beta}\right) = 0. \tag{58a}$$

Only such coordinate systems are allowed that are characterized by $g_{\mu\nu}$ satisfying this system of equations; only transformations that transform such "adapted" systems of reference into each other are "allowed." For all allowed transformations, the field equations (57) now turn out[(35)] to be covariant. A covariance in a further sense can hardly be demanded.

Although from a mathematical point of view the question appears to have been settled, the physicist still wishes to obtain an insight into the extent of the group of "allowed" transformations. Do these contain, besides the linear ones, still other real transformations? And do these have a physical significance, perhaps as transformations describing acceleration or rotation? Only in this case would one be justified in speaking of a "generalized theory of relativity" in the sense that the equivalence of different systems of reference, which the principle of relativity of 1905 postulates for systems in translatory motion with respect to each other, is now extended to such systems that are in accelerated or rotational motion with respect to one another. Such an extension of the relativity of motion does not appear to be achievable.

Also, the physical significance of covariance with respect to linear transformations is not sufficiently discussed in the *Entwurf*. [515] | According to G. Mie,[(28)] it expresses the following theorem: "The observable laws of nature do not depend on the absolute values of the gravitational potentials $g_{\mu\nu}$ at the location of the observer." G. Mie showed already earlier[(21)] that this "*theorem of the relativity of the gravitational potential*" is valid in his own theory (II D). However, in Mie's theory, based on the spacetime doctrine of Minkowski, the space and time measurements as well as the dimensions and periods of oscillation of elementary particles remain unchanged, even in a gravitational field. Einstein, in contrast, and also Nordström (II E), achieve the independence of the physical processes from the values of the potentials only because, together with the units of length and time, the dimensions and the periods of oscillation of the atoms and electrons depend on the gravitational potentials $g_{\mu\nu}$.

A. Einstein places such an importance on the circumstance that his gravitational equations are invariant with respect to linear orthogonal substitutions that, in his Vienna lecture,[(27)] he believed he was allowed to leave theories unmentioned whose field equations do not have such a covariance. The significance of this transformation group rests on the fact that it contains the transformations; in the early theory of relativity the covariance with respect to this group gave expression to the equivalence of systems of reference in translatory motion with respect to each other. Is this presently also the case in the "generalized theory of relativity"? Does the covariance of the field equations with respect to linear orthogonal transformations imply that in a finite system of mutually gravitating bodies the course of the relative motions is not altered by a uniform translation of the entire system? That this is so has so far not been proven. Such a proof may already be impossible to construct for the reason that the concept of "uniform motion" of a finite system is completely up in the air in the new theory of

relativity. Since the "natural" space and time measurement is influenced by the values of the local potential, observers at different locations in the gravitational field will ascribe different velocities to the same material point. Only for an infinitesimally small region of four-dimensional space, i.e. for one in which the potentials $g_{\mu\nu}$ can be considered a constant—is "velocity" defined at all. Presumably, only within such an infinitesimal region may the covariance of the gravitational equations with respect to linear orthogonal transformations be interpreted in the sense of an | equivalence of [516]
systems of reference moving with respect to each other. But if relativity of motion no longer exists for finite systems of gravitating masses in Einstein's theory, with what right does he assign such great importance to the formal connection to the earlier theory of relativity?

As one can see, the new theory of relativity indeed generalizes the concept of space and time, but thereby restricts the relativity of motion to infinitesimally small spacetime regions. Therefore, its endeavors to achieve relativity with respect to rotational or accelerated motion also do not appear to be promising. Since the velocities of the system of reference enter into the $g_{\mu\nu}$, a spacetime region is only to be considered as infinitesimally small, if the velocity is spatially and temporally constant in it. Therefore it makes no sense to speak of a rotational or accelerated motion of an "infinitesimally small region," and, for instance, to claim that the "equivalence hypothesis is valid in the infinitesimally small."

To what extent is the theorem of the weight of energy valid in the Einstein-Grossmann theory of gravitation? The field equations (57) make it apparent that the quantities $S_{\sigma\nu}$, according to (57a, b) linear functions of the components $T_{\mu\nu}$ of the resultant world tensor, are the ones that generate the gravitational field. The gravitational forces, which a body exerts and experiences, are accordingly defined by the volume integral of these tensor components:

$$\int dV T_{\mu\nu} = m_{\mu\nu}. \tag{59}$$

Therefore, when dealing with a moving and stressed body, one generally has to differentiate between ten "masses" $m_{\mu\nu}$. There also exist ten "gravitational forces," which are derived from the ten potentials $g_{\mu\nu}$. If one transports bodies with differing stress states and different states of motion to the same world point of a variable gravitational field, then the resultant gravitational forces acting on them have in general different directions, and their magnitudes do not depend solely on the energy of the bodies, but also on all the ten $m_{\mu\nu}$.

This intricate mechanism fortunately simplifies since, in relation to the gravitational force derived from g_{44}, the other nine gravitational forces are very small as all the remaining nine masses in relation to the mass m_{44} determined by the energy. Especially for "static complete systems" (II E), all | masses (59) except for m_{44} are [517]
equal to zero, and only the gravitational force acting on it remains effective. *Thus, the total energy alone is the factor determining the gravitational mass of complete static systems*. Similarly as in Nordström's second theory, this result is caused by the com-

pensation of the forces that act on the different parts of the system, and as there it can be applied to closed systems in static equilibrium.

Let us consider for example a hot gas which is enclosed in a cylinder. Forces act on the individual molecules of the gas, whose magnitudes are neither proportional to the energy of the molecules, nor have directions agreeing exactly with the vertical. Nevertheless, the gravitational forces acting on the molecules and on the volume elements of the cylinder sum to a resultant, whose temporal mean value is proportional to the total energy and has a vertical direction. The relation between gravity[2] and energy (respectively, inertia) are accordingly represented in Einstein's tensor theory to the same degree as in Nordström's scalar theory. However, one will have to agree with G. Mie,(28) when he denies that these theories manifest an "physical unity of essence" of gravitational and inertial mass.

In his detailed critique of Einstein's theory, G. Mie(28) attempts to prove that the proportionality of gravitational mass and energy for complete static systems occurs there only as the result of certain specific assumptions, which, incidentally, are said to contradict one another. In his reply,(29) Einstein states the belief—without refuting Mie's objections one by one—that he can trace those contradictions to Mie's demand of covariance only with respect to Lorentz transformations, thereby introducing "preferred systems of reference." That "special assumptions of any kind are not used" in the establishment of his theory, as Einstein asserts there, does not appear credible. In his just-published summary presentation(38) of the "general theory of relativity" Einstein derives the differential equations expressing his theory of gravitation from a variational principle, on the basis of certain specializations whose physical significance is however not elucidated.

The *integration of the field equations* (57) is extraordinarily difficult. Only the method of successive approximations promises success. In this one will usually take
[518] as a first approximation the solution that treats the field | as static. Here, Einstein's theory becomes identical with Abraham's theory; therefore the solution of the problem of the sphere, for example, given in (II C), remains valid here as well.

In his Vienna lecture,(27) A. Einstein takes the normal values of the $g_{\mu\nu}$ as the first approximation:

$$g_{11} = g_{22} = g_{33} = 1, \qquad g_{44} = -c^2, \qquad g_{\mu\nu} = 0 \text{ for } \mu \neq \nu;$$

he considers the deviations $\overset{*}{g}_{\mu\nu}$ from these normal values as quantities of first order, and arrives, by neglecting quantities of second order, at the following differential equations:

$$\Box \overset{*}{g}_{\mu\nu} = \overset{m}{T}_{\mu\nu}. \tag{60}$$

For incoherent motions of masses, the last $(\overset{m}{T}_{44})$ among the components of the material tensor T^m is the most important; it determines the potential $\overset{*}{g}_{44} = \Phi^g$. Then follow the components $\overset{m}{T}_{14}, \overset{m}{T}_{24}, \overset{m}{T}_{34}$, which are of first order in v/c; these determine the potentials $\overset{*}{g}_{14}, \overset{*}{g}_{24}, \overset{*}{g}_{34}$, which can be viewed as the components of a space vector $-(1/c)\mathfrak{A}^g$. The remaining components of T^m are of second order in v/c. If one neglects quantities of this order, then one only needs to consider those four potentials, and obtains for them the differential equations

$$\Box\Phi^g = c^2\mu, \tag{60a}$$

$$\Box\mathfrak{A}^g = c^2\mu\cdot\frac{\mathfrak{v}}{c}, \tag{60b}$$

where μ is the mass density.

Here the analogy to electrodynamics catches one's eye. Except for the sign, the field equations (60a, b) agree with those that must be satisfied in the theory of electrons by the "electromagnetic potentials", the scalar one (Φ) and the vectorial one (A). In this approximation, the Einstein-Grossmann tensor theory of the gravitational field leads to the same results as the vector theory sketched in (I A). Also concerning the expression for the *gravitational force per unit mass*, there exists a far reaching analogy. Einstein obtains:

$$\mathfrak{F}^g = -\frac{1}{2}\mathrm{grad}\Phi^g - \frac{1}{c}\frac{\partial\mathfrak{A}^g}{\partial t} + \frac{1}{c}[\mathrm{v}, \mathrm{curl}\mathfrak{A}^g]. \tag{61}$$

This expression agrees with the one (1) from the vector theory:

$$\mathfrak{F}^g = \mathfrak{E}^g + \frac{1}{c}[\mathfrak{v}\mathfrak{H}^g], \tag{61a}$$

| if one writes: [519]

$$\mathfrak{E}^g = -\frac{1}{2}\mathrm{grad}\Phi^g - \frac{1}{c}\frac{\partial\mathfrak{A}^g}{\partial t}, \tag{61b}$$

$$\mathfrak{H}^g = \mathrm{curl}\mathfrak{A}^g. \tag{61c}$$

Apart from the factor $1/2$ in the gradient of Φ^g, the formulas (61b, c) are identical with the well known formulas which derive the two vectors of the electromagnetic field from the electromagnetic potentials.

The Einstein-Grossmann theory of gravitation is related to the vector theory to the extent that the approximation applied is satisfactory. As in the vector theory, induced gravitational forces are generated on neighboring bodies by the acceleration of a body, forces that act in the direction of the acceleration. Einstein attaches great importance to the existence of these induced gravitational forces in connection with the so called "*hypothesis of the relativity of inertia*."

This hypothesis, already advocated by E. Mach, states that the inertia of a body is only a consequence of the relative acceleration with respect to the totality of the remaining bodies. If this hypothesis applies, then the inertial mass of a body will depend on its position with respect to the remaining bodies. This is now the case in the Einstein's theory because the rest-mass

$$m_0 = \frac{M}{c} \qquad (M \text{ mass constant})$$

is inversely proportional to the speed of light c, whose value in a static gravitational field is reduced upon the approach of external masses. The inertia of a body is thus increased by the accumulation of mass in its vicinity; through this circumstance, Einstein believes himself justified in considering inertia as a consequence of the presence of the remaining masses in the context of that relativity hypothesis.

This consideration looses cogency however, if one calculates by how much c is decreased, and hence m_0 increased, by the masses of celestial objects. The mass of the Sun, at its surface, engenders a relative change in c of the order of 10^{-6}, which then decreases approximately inversely proportional to the distance from the center of the Sun. But in order for the mass of a material point to be considered as being a consequence of the presence of the remaining matter, it mass should vanish upon the removal of that matter. The mass to be removed from the vicinity of that point for that
[520] purpose would now be a millionfold larger than the | mass of the Sun. Accordingly, the hypothesis of the relativity of inertia can only be justified from the point of view of Einstein's theory, if, in addition to the masses of the visible bodies, one assumes also hidden masses. But with this, that hypothesis looses all concrete physical meaning. In the end it does not matter if one anchors the system of reference in "hidden masses," in the "aether" or in a "body α."

Upon the mutual approach of two bodies A and B, their inertial masses grow. But according to the hypothesis of the relativity of inertia, this increase in mass should not occur if A and B are accelerated in unison. Indeed, according to the theorem of the inertia of energy, the inertial resistance of the system of the two bodies should even be smaller than the sum of the inertial masses of the two bodies while separated, because the energy of the system decreases upon the approach of the two bodies. Here, the gravitational forces, induced by the temporal variation of the vector potential $\mathfrak{A}^g$, now come into play, forces that the bodies A and B exert on each other as a result of their acceleration. Through them, the additional inertial forces are overcompensated, so that the inertial mass of the system $A + B$ becomes smaller than the sum of the inertial masses of the bodies A and B.

Einstein sees a significant advantage of this tensor theory over the scalar theories in that the hypothesis of the relativity of inertia fits into his theory, because the scalar theories lack the vector potential $\mathfrak{A}^g$, from which the induced forces are derived. However, we saw that the theory of Einstein and Grossmann also fails to provide a satisfactory quantitative basis for Mach's bold hypothesis, unless one appeals to hidden masses. In view of the enormous complication engendered by the ten-fold multiplication of the gravitational potentials and by the distortion of the four-dimensional world, one is likely, for reasons of the Machian "economy of thought," to prefer the scalar theories, as long as the supposition, that there exist ten gravitational forces instead of one, is not supported by experience.

APPENDIX

Notation: [472]

t time, c the speed of light.

$x, y, z, u = ict$, the coordinates of four-dimensional space.

$\Box \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} + \frac{\partial^2}{\partial u^2}$.

$\mathfrak{v}$ velocity, v its magnitude.

$\mathfrak{E}$, $\mathfrak{H}$ electric and magnetic vector.

$\mathfrak{F}^e$ force per unit charge.

ρ charge density.

μ mass density, ν rest-mass density.

M mass constant, m_0 rest-mass.

V volume.

$\mathfrak{E}^g$, $\mathfrak{H}^g$ gravitational vectors in the vector theory.

$\mathfrak{F}^g$ gravitational force per unit mass.

$\mathfrak{K}^g$ gravitational force, φ gravitational potential.

$\mathfrak{L}$ Lagrangian function. |

$\mathfrak{G}$ momentum. [473]

E energy, E_0 rest-energy.

E^m, E^e, E^g energy of matter, of the electromagnetic and of the gravitational field.

T^m, T^e, T^g world tensors of matter, of the electromagnetic and of the gravitational field.

D^m, D^e, D^g sum of their diagonal components.

T, D resultant of world tensors and of diagonal sums respectively.

η^m, η^e, η^g energy density of matter, of the electromagnetic and of the gravitational field.

g^m, g^e, g^g the momentum density of matter, of the electromagnetic and of the gravitational field.

$\mathfrak{S}^m$, $\mathfrak{S}^e$, $\mathfrak{S}^g$ the energy flux of matter, of the electromagnetic and of the gravitational field.

$g_{\mu\nu}$ Einstein's gravitational potentials.

EDITORIAL NOTES

[1] Here "*Schwere*" has been translated as "gravity," but elsewhere it has been translated as "weight," since in these other occurrences Abraham apparently uses "*Schwere*" and "*Gewicht*" interchangeably.

[2] Raised numbers in parentheses refer to the numbers of the above chronological list of references.

[3] Note that the wording Abraham uses here differs slightly from that of the earlier work to which he refers.

[4] The superscript ^{g} in T^{g} in eq. (36b) is missing in the original.

A FIELD THEORY OF GRAVITATION
IN THE FRAMEWORK
OF SPECIAL RELATIVITY

JOHN D. NORTON

EINSTEIN, NORDSTRÖM, AND THE EARLY DEMISE OF SCALAR, LORENTZ COVARIANT THEORIES OF GRAVITATION

1. INTRODUCTION

The advent of the special theory of relativity in 1905 brought many problems for the physics community. One, it seemed, would not be a great source of trouble. It was the problem of reconciling Newtonian gravitation theory with the new theory of space and time. Indeed it seemed that Newtonian theory could be rendered compatible with special relativity by any number of small modifications, each of which would be unlikely to lead to any significant deviations from the empirically testable consequences of Newtonian theory.[1] Einstein's response to this problem is now legend. He decided almost immediately to abandon the search for a Lorentz covariant gravitation theory, for he had failed to construct such a theory that was compatible with the equality of inertial and gravitational mass. Positing what he later called the principle of equivalence, he decided that gravitation theory held the key to repairing what he perceived as the defect of the special theory of relativity—its relativity principle failed to apply to accelerated motion. He advanced a novel gravitation theory in which the gravitational potential was the now variable speed of light and in which special relativity held only as a limiting case.

It is almost impossible for modern readers to view this story with their vision unclouded by the knowledge that Einstein's fantastic 1907 speculations would lead to his greatest scientific success, the general theory of relativity. Yet, as we shall see, in

1 In the historical period under consideration, there was no single label for a gravitation theory compatible with special relativity. The Einstein of 1907 would have talked of the compatibility of gravitation and the *principle* of relativity, since he then tended to use the term "principle of relativity" where we would now use "theory of relativity". See (CPAE 2, 254). Minkowski (1908, 90) however, talked of reform "in accordance with the world postulate." Nordström (1912, 1126), like Einstein, spoke of "adapting ... the theory of gravitation to the principle of relativity" or (Nordström 1913, 872) of "treating gravitational phenomena from the standpoint of the theory of relativity," emphasizing in both cases that he planned to do so retaining the constancy of the speed of light in order to distinguish his work from Einstein's and Abraham's. For clarity I shall describe gravitation theories compatible with special relativity by the old-fashioned but still anachronistic label "Lorentz covariant." It describes exactly the goal of research, a gravitation theory whose equations are covariant under Lorentz transformation. For a simplified presentation of the material in this chapter, see also (Norton 1993).

Jürgen Renn (ed.). *The Genesis of General Relativity,* Vol. 3
Gravitation in the Twilight of Classical Physics: Between Mechanics, Field Theory, and Astronomy.

1907 Einstein had only the slenderest of grounds for judging all Lorentz covariant gravitation theories unacceptable. His 1907 judgement was clearly overly hasty. It was found quite soon that one could construct Lorentz covariant gravitation theories satisfying the equality of inertial and gravitational mass without great difficulty. Nonetheless we now do believe that Einstein was right in so far as a thorough pursuit of Lorentz covariant gravitation theories does lead us inexorably to abandon special relativity. In the picturesque wording of Misner et al. (1973, Ch.7) "gravity bursts out of special relativity."

These facts raise some interesting questions. As Einstein sped towards his general theory of relativity in the period 1907–1915 did he reassess his original, hasty 1907 judgement of the inadequacy of Lorentz covariant gravitation theories? In particular, what of the most naturally suggested Lorentz covariant gravitation theory, one in which the gravitational field was represented by a scalar field and the differential operators of the Newtonian theory were replaced by their Lorentz covariant counterparts? Where does this theory lead? Did the Einstein of the early 1910s have good reason to expect that developing this theory would lead outside special relativity?

This paper provides the answers to these questions. They arise in circumstances surrounding a gravitation theory, developed in 1912–1914, by the Finnish physicist Gunnar Nordström. It was one of a number of more conservative gravitation theories advanced during this period. Nordström advanced this most conservative scalar, Lorentz covariant gravitation theory and developed it so that it incorporated the equality of inertial and gravitation mass. It turned out that even in this most conservative approach, odd things happened to space and time. In particular, the lengths of rods and the rates of clocks turn out to be affected by the gravitational field, so that the spaces and times of the theory's background Minkowski spacetime ceased to be directly measurable. The *dénouement* of the story came in early 1914. It was shown that this conservative path led to the same sort of gravitation theory as did Einstein's more extravagant speculations on generalizing the principle of relativity. It lead to a theory, akin to general relativity, in which gravitation was incorporated into a dynamical spacetime background. If one abandoned the inaccessible background of Minkowski spacetime and simply assumed that the spacetime of the theory was the one revealed by idealized rod and clock measurements, then it turned out that the gravitation theory was actually the theory of a spacetime that was only conformally flat—gravitation had burst out of special relativity. Most strikingly the theory's gravitational field equation was an equation strongly reminiscent to modern readers of the field equations of general relativity:

$$R = kT$$

where R is the Riemann curvature scalar and T the trace of the stress-energy tensor. This equation was revealed before Einstein had advanced the generally covariant field equations of general relativity, at a time in which he believed that no such field equations could be physically acceptable.

What makes the story especially interesting are the two leading players other than Nordström. The first was Einstein himself. He was in continued contact with Nordström during the period in which the Nordström theory was developed. We shall see that the theory actually evolved through a continued exchange between them, with Einstein often supplying ideas decisive to the development of the theory. Thus the theory might more accurately be called the "Einstein-Nordström theory." Again it was Einstein in collaboration with Adriaan Fokker who revealed in early 1914 the connection between the theory and conformally flat spacetimes.

The second leading player other than Nordström was not a person but a branch of special relativity, the relativistic mechanics of stressed bodies. This study was under intensive development at this time and had proven to be a locus of remarkably non-classical results. For example it turned out that a moving body would acquire additional energy, inertia and momentum simply by being subjected to stresses, even if the stresses did not elastically deform the body. The latest results of these studies—most notably those of Laue—provided Einstein and Nordström with the means of incorporating the equality of inertial and gravitational mass into their theory. It was also the analysis of stressed bodies within the theory that led directly to the conclusion that even idealized rods and clocks could not measure the background Minkowski spacetime directly but must be affected by the gravitational field. For Einstein and Nordström concluded that a body would also acquire a gravitational mass if subjected to non-deforming stresses and that one had to assume that such a body would alter its size in moving through the gravitational field on pain of violating the law of conservation of energy.

Finally we shall see that the requirement of equality of inertial and gravitational mass is a persistent theme of Einstein's and Nordström's work. However the requirement proves somewhat elastic with both Einstein and Nordström drifting between conflicting versions of it. It will be convenient to prepare the reader by collecting and stating the relevant versions here. On the observational level, the equality could be taken as requiring:

- Uniqueness of free fall:[2] The trajectories of free fall of all bodies are independent of their internal constitution.

Einstein preferred a more restrictive version:

- Independence of vertical acceleration: The vertical acceleration of bodies in free fall is independent of their constitutions and horizontal velocities.

In attempting to devise theories compatible with these observational requirements, Einstein and Nordström considered requiring equality of gravitational mass with

- inertial rest mass
- the inertial mass of closed systems
- the inertial mass of complete static systems
- the inertial mass of a a complete stationary systems[3]

2 This name is drawn from (Misner et al. 1973, 1050).

3 The notions of complete static and complete stationary systems arise in the context of the mechanics of stressed bodies and are discussed in Sections 9 and 12 below.

More often than not these theoretical requirements failed to bring about the desired observational consequences. Unfortunately it is often unclear precisely which requirement is intended when the equality of inertial and gravitational mass was invoked.

2. THE PROBLEM OF GRAVITATION IMMEDIATELY AFTER 1905

In the years immediately following 1905 it was hard to see that there would be any special problem in modifying Newtonian gravitation theory in order to bring it into accord with the special theory of relativity. The problem was not whether it could be done, but how to choose the best of the many possibilities perceived, given the expectation that relativistic corrections to Newtonian theory might not have measurable consequences even in the very sensitive domain of planetary astronomy. Poincaré (1905, 1507–1508;1906, 166–75), for example, had addressed the problem in his celebrated papers on the dynamics of the electron. He limited himself to seeking an expression for the gravitational force of attraction between two masses that would be Lorentz covariant[4] and would yield the Newtonian limit for bodies at rest. Since this failed to specify a unique result he applied further constraints including the requirement[5] of minimal deviations from Newtonian theory for bodies with small velocities, in order to preserve the Newtonian successes in astronomy. The resulting law, Poincaré noted, was not unique and he indicated how variants consistent with its constraints could be derived by modifying the terms of the original law.

Minkowski (1908, 401–404; 1909, 443–4) also sought a relativistic generalization of the Newtonian expression for the gravitational force acting between two bodies. His analysis was simpler than Poincaré's since merely stating his law in terms of the geometric structures of his four dimensional spacetime was sufficient to guarantee automatic compatibility with special relativity. Where Poincaré (1905, 1508; 1906, 175) had merely noted his expectation that the deviations from Newtonian astronomical prediction introduced by relativistic corrections would be small, Minkowski (1908, 404) computed the deviations due to his law for planetary motions and concluded that they were so small that they allowed no decision to be made concerning the law.

Presumably neither Poincaré nor Minkowski were seeking a fundamental theory of gravitation, for they both considered action-at-a-distance laws at a time when field theories were dominant. Rather the point was to make *plausible*[6] the idea that some slight modification of Newtonian gravitational law was all that was necessary to bring it into accord with special relativity, even if precise determination of that modification was beyond the reach of the current state of observational astronomy.

---

4 More precisely he required that the law governing propagation of gravitational action be Lorentz covariant and that the gravitational forces transform in the same way as electromagnetic forces.

5 Also he required that gravitational action propagate forward in time from a given body.

6 The word is Minkowski's. He introduced his treatment of gravitation (Minkowski 1908, 401) with the remark "I would not like to fail to make it plausible that nothing in the phenomena of gravitation can be expected to contradict the assumption of the postulate of relativity."

3. EINSTEIN'S 1907 REJECTION OF LORENTZ COVARIANT GRAVITATION THEORIES

In 1907 Einstein's attention was focussed on the problem of gravitation and relativity theory when he agreed to write a review article on relativity theory for Johannes Stark's *Jahrbuch der Radioaktivität und Elektronik*. The relevant parts of the review article (Einstein 1907a, 414; Section V, 454–62) say nothing of the possibility of a Lorentz covariant gravitation theory. Rather Einstein speculates immediately on the possibility of extending the principle of relativity to accelerated motion. He suggests the relevance of gravitation to this possibility and posits what is later called the principle of equivalence as the first step towards the complete extension of the principle of relativity.

It is only through later reminiscences that we know something of the circumstances leading to these conclusions. The most informative are given over 25 years later in 1933 when Einstein gave a sketch of his pathway to general relativity.[7] In it he wrote (Einstein 1933, 286–87):

> I came a step nearer to the solution of the problem [of extending the principle of relativity] when I attempted to deal with law of gravity within the framework of the special theory of relativity. Like most writers at the time, I tried to frame a *field-law* for gravitation, since it was no longer possible, at least in any natural way, to introduce direct action at a distance owing to the abolition of the notion of absolute simultaneity.
>
> The simplest thing was, of course, to retain the Laplacian scalar potential of gravity, and to complete the equation of Poisson in an obvious way by a term differentiated with respect to time in such a way that the special theory of relativity was satisfied. The law of motion of the mass point in a gravitational field had also to be adapted to the special theory of relativity. The path was not so unmistakably marked out here, since the inert mass of a body might depend on the gravitational potential. In fact this was to be expected on account of the principle of the inertia of energy.

While Einstein's verbal description is brief, the type of gravitation theory he alludes to is not too hard to reconstruct. In Newtonian gravitation theory, with a scalar potential ϕ, mass density ρ and G the gravitation constant, the gravitational field equation—the "equation of Poisson"— is[8]

$$\nabla^2\phi = \left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}\right)\phi = \frac{\partial^2\phi}{\partial x_i \partial x_i} = 4\pi G\rho. \tag{1}$$

The force **f**, with components (f_1, f_2, f_3), on a point mass m is given by $-m\nabla\phi$ so that

$$f_i = m\frac{dv_i}{dt} = -m\left(\frac{\partial}{\partial x_i}\right)\phi \tag{2}$$

7 A similar account is given more briefly in (Einstein 1949, 58–63).

8 $(x, y, z) = (x_1, x_2, x_3)$ are the usual spatial Cartesian coordinates. The index i ranges over 1, 2, 3. Here and henceforth, summation over repeated indices is implied.

is the law of motion of a point mass m with velocity $v_i = dx_i/dt$ in the gravitational field ϕ.

The adaptation of (1) to special relativity is most straightforward. The added term, differentiated with respect to the time coordinate, converts the Laplacian operator ∇^2 into a Lorentz covariant d' Alembertian $\Box^2$. so that the field equation alluded to by Einstein would be

$$\Box^2\phi = \left(\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right)\phi = -4\pi G\nu. \tag{3}$$

For consistency ϕ is assumed to be Lorentz invariant and the mass density ρ must be replaced with a Lorentz invariant, such as the rest mass density ν used here.

The modification to the law of motion of a point mass is less clear. The natural Lorentz covariant extension of (2) is most obvious if we adopt the four dimensional spacetime methods introduced by Minkowski (1908). Einstein could not have been using these methods in 1907. However I shall write the natural extension here since Einstein gives us little other guide to the form of the equation he considered, since the properties of this equation fit exactly with Einstein's further remarks and since this equation will lead us directly to Nordström's work. The extension of (2) is

$$F_\mu = m\frac{dU_\mu}{d\tau} = -m\frac{\partial\phi}{\partial x_\mu} \tag{4}$$

where F_μ is the four force on a point mass with rest mass m, $U_\mu = dx_\mu/d\tau$ is its four velocity, τ is the proper time and $\mu = 1, 2, 3, 4$.[9] Following the practice of Nordström's papers, the coordinates are $(x_1, x_2, x_3, x_4) = (x, y, z, u = ict)$, for c the speed of light.

Simple as this extension is, it turns out to be incompatible with the kinematics of a Minkowski spacetime. In a Minkowski spacetime, the constancy of c entails that the four velocity U_μ along a world line is orthogonal to the four acceleration $dU_\mu/d\tau$. For we have $c^2 d\tau^2 = -dx_\mu dx_\mu$, so that $c^2 = -U_\mu U_\mu$ and the orthogonality now follows from the constancy of c

$$-\frac{1}{2}\frac{dc^2}{d\tau} = U_\mu\frac{dU_\mu}{d\tau} = 0 \tag{5}$$

(4) and (5) together entail

$$F_\mu U_\mu = -m\frac{\partial\phi}{\partial x_\mu}\frac{dx_\mu}{d\tau} = -m\frac{d\phi}{d\tau} = 0$$

so that the law (4) can only obtain in a Minkowski spacetime in the extremely narrow case in which the field ϕ is constant along the world line of the particle, i.e.

---

9 Throughout this paper, Latin indices $i, k, \ldots$ range over 1, 2, 3 and Greek indices $\mu, \nu, \ldots$ range over 1, 2, 3, 4.

$$\frac{d\phi}{d\tau} = 0. \tag{6}$$

We shall see below that one escape from this problem published by Nordström involves allowing the rest mass m to be a function of the potential ϕ. Perhaps this is what Einstein referred to above when he noted of the law of motion that the "path was not so unmistakably marked out here, since the inert mass of a body might depend on the gravitational potential."

Whatever the precise form of the modifications Einstein made, he was clearly unhappy with the outcome. Continuing his recollections, he noted:

> These investigations, however, led to a result which raised my strong suspicions. According to classical mechanics, the vertical acceleration of a body in the vertical gravitational field is independent of the horizontal component of its velocity. Hence in such a gravitational field the vertical acceleration of a mechanical system or of its center of gravity works out independently of its internal kinetic energy. But in the theory I advanced, the acceleration of a falling body was not independent of its horizontal velocity or the internal energy of the system.

The result Einstein mentions here is readily recoverable from the law of motion (4) in a special case in which it is compatible with the identity (5). The result has more general applicability, however. The modifications introduced by Nordström to render (4) compatible with (5) vanish in this special case, as would, presumably, other natural modifications that Einstein may have entertained. So this special case is also a special case of these more generally applicable laws.

We consider a coordinate system in which:

(i) the field is time independent $(\partial\phi/\partial t = 0)$ at some event and

(ii) the motion of a point mass m in free fall at that event is such that the "vertical" direction of the field, as given by the acceleration three vector dv_i/dt, is perpendicular to the three velocity v_i, so that

$$v_i \cdot \frac{dv_i}{dt} = 0 \tag{7}$$

and the point's motion is momentarily "horizontal."

Condition (7) greatly simplifies the analysis, since it entails that the t derivative of any function of $v^2 = v_i v_i$ vanishes, so that we have

$$\frac{d}{dt}\frac{dt}{d\tau} = \frac{d}{dt}\left(\frac{1}{\sqrt{1-\frac{v^2}{c^2}}}\right) = 0. \tag{8}$$

Notice also that in this case (7) entails that $v_i\frac{\partial\phi}{\partial x_i} = 0$ so that

$$\frac{d\phi}{d\tau} = \frac{dt}{d\tau}\left(\frac{\partial\phi}{\partial t} + v_i\frac{\partial\phi}{\partial x_i}\right) = 0$$

and (6) and then also (5) are satisfied for this special case. Finally an expression for the acceleration of the point mass now follows directly from (4) and is[10]

$$\frac{dv_i}{dt} = -\left(1 - \frac{v^2}{c^2}\right)\frac{\partial\phi}{\partial x_i}. \tag{9}$$

According to (9), the greater the horizontal velocity v, the less the vertical acceleration, so that this acceleration is dependent on the horizontal velocity as Einstein claimed.

Einstein also claims in his remarks that the vertical acceleration would not be independent of the internal energy of the falling system. This result is suggested by equation (9), which tells us that the vertical acceleration of a point mass diminishes with its kinetic energy if the velocity generating that kinetic energy is horizontally directed. If we apply this result to the particles of a kinetic gas, we infer that in general each individual particle will fall slower the greater its velocity. Presumably this result applies to the whole system of a kinetic gas so that the gas falls slower the greater the kinetic energy of its particles, that is, the greater its internal energy. This example of a kinetic gas was precisely the one given by Einstein in an informal lecture on April 14, 1954 in Princeton according to lecture notes taken by J. A. Wheeler.[11]

Einstein continued his recollections by explaining that he felt these results so contradicted experience that he abandoned the search for a Lorentz covariant gravitation theory.

> This did not fit with the old experimental fact that all bodies have the same acceleration in a gravitational field. This law, which may also be formulated as the law of the equality of inertial and gravitational mass, was now brought home to me in all its significance. I was in the highest degree amazed at its existence and guessed that in it must lie the key to a deeper understanding of inertia and gravitation. I had no serious doubts about its strict validity even without knowing the results of the admirable experiments of Eötvös, which—if my memory is right—I only came to know later. I now abandoned as inadequate the attempt to treat the problem of gravitation, in the manner outlined above, within the framework of the special theory of relativity. It clearly failed to do justice to the most fundamental property of gravitation.

Einstein then recounted briefly the introduction of the principle of equivalence, upon which would be based his continued work on gravitation and relativity, and concluded

10 Since $\frac{dU_i}{d\tau} = \frac{dt}{d\tau}\frac{d}{dt}\left(v_i\frac{dt}{d\tau}\right)$, (9) follows directly from (4) using (8).

11 Wheeler's notes read "I had to write a paper about the content of special relativity. Then I came to the question how to handle gravity. The object falls with a different acceleration if it is moving than if it is not moving. ... Thus a gas falls with another acceleration if heated than if not heated. I felt this is not true ..." (Wheeler 1979, 188).

> Such reflections kept me busy from 1908 to 1911, and I attempted to draw special conclusions from them, of which I do not propose to speak here. For the moment the one important thing was the discovery that a reasonable theory of gravitation could only be hoped for from an extension of the principle of relativity.

Our sources concerning Einstein's 1907 renunciation of Lorentz covariant gravitation theories are largely later recollections so we should be somewhat wary of them. Nonetheless they all agree in the essential details:[12] Einstein began his attempts to discover a Lorentz covariant theory of gravitation as a part of his work on his 1907 *Jahrbuch* review article. He found an inconsistency between these attempts and the exact equality of inertial and gravitational mass, which he found sufficiently disturbing to lead him to abandon the search for such theories.

We shall see shortly that Einstein's 1907 evaluation and dismissal of the prospects of a Lorentz covariant gravitation theory—as reconstructed above—was far too hasty. Within a few years Einstein himself would play a role in showing that one could construct a Lorentz covariant gravitation theory that was fully compatible with the exact equality of inertial and gravitational mass. We can understand why Einstein's 1907 analysis would be hurried, however, once we realize that the he could have devoted very little time to contemplation of the prospects of a Lorentz covariant gravitation theory. He accepted the commission of the *Jahrbuch*'s editor, Stark, to write the review in a letter of September 25, 1907 (EA 22 333) and the lengthy and completed article was submitted to the journal on December 4, 1907, a little over two months later. This period must have been a very busy one for Einstein. As he explained to Stark in the September 25 letter, he was not well read in the current literature pertinent to relativity theory, since the library was closed during his free time. He asked Stark to send him relevant publications that he might not have seen.[13] During this period, whatever time Einstein could have spent privately contemplating the prospects of a Lorentz covariant gravitation theory would have been multiply diluted. There were the attractions of the principle of equivalence, whose advent so dazzled him that he called it the "happiest thought of [his] life".[14] Its exploitation attracted all the pages of the review article which concern gravitation and in which the prospects of a Lorentz covariant gravitation theory are not even mentioned. Further diluting his time would be the demands of the remaining sections of the review article. The section devoted to gravitation filled only nine of the article's fifty two pages. Finally, of

12 See also the 1920 recollections of Einstein on p. 23, "Grundgedanken und Methoden der Relativitätstheorie in ihrer Entwicklung dargestellt," unpublished manuscript, control number 2 070, Duplicate Einstein Archive, Mudd Manuscript Library, Princeton, NJ. (Henceforth "EA 2 070".) Einstein recalls:
"When, in the year 1907, I was working on a summary essay concerning the special theory of relativity for the *Jahrbuch für Radioaktivität und Elektronik* [sic], I had to try to modify Newton's theory of gravitation in such a way that it would fit into the theory [of relativity]. Attempts in this direction showed the possibility of carrying out this enterprise, but they did not satisfy me because they had to be supported by hypotheses without physical basis." Translation from (Holton 1975, 369–71).

13 Einstein thanked him for sending papers in a letter of October 4, 1907 (EA, 22 320).

14 In Einstein's 1920 manuscript (EA 2 070, 23–25).

course, there were the obligations of his job at the patent office. It is no wonder that he lamented to Stark in a letter of November 1, 1907, that he worked on the article in his "unfortunately truly meagerly measured free time" (EA, 22 335).

4. EINSTEIN'S ARGUMENT OF JULY 1912

If the Einstein of 1907 had not probed deeply the prospects of Lorentz covariant gravitation theories, we might well wonder if he returned to give the problem more thorough treatment in the years following. We have good reason to believe that as late as July 1912, Einstein had made no significant advance on his deliberations of 1907.[15] Our source is an acrimonious dispute raging at this time between Einstein and Max Abraham. In language that rarely appeared in the unpolluted pages of *Annalen der Physik*, Abraham (1912c, 1056) accused Einstein's theory of relativity of having "exerted an hypnotic influence especially on the youngest mathematical physicists which threatened to hamper the healthy development of theoretical physics." He rejoiced especially in what he saw as major retractions in Einstein's latest papers on relativity and gravitation. Einstein (1911) involved a theory of gravitation which gave up the constancy of the velocity of light and Einstein (1912a, 1912b) even dispensed with the requirement of the invariance of the equations of motion under Lorentz transformation. These concessions, concluded Abraham triumphantly, were the "death blow" for relativity theory.

Einstein took this attack very seriously. His correspondence from this time, a simple gauge of the focus of his thoughts, was filled with remarks on Abraham. He repeatedly condemned Abraham's (1912a,1912b) new theory of gravitation, which had adopted Einstein's idea of a variable speed of light as the gravitational potential. "A stately beast that lacks three legs," he wrote scathingly of the theory to Ludwig Hopf.[16] He anticipated the dispute with Abraham with some relish, writing to Hopf earlier of the coming "difficult ink duel."[17] The public dispute ended fairly quickly, however, with Einstein publishing a measured and detailed reply (Einstein 1912d) and then refusing to reply to Abraham's rejoinder (Abraham 1912d). Instead Einstein published a short note (Einstein 1912e) indicating that both parties had stated their views and asking readers not to interpret Einstein's silence as agreement. Nonetheless Einstein continued to hold a high opinion of Abraham as a physicist, lamenting in a letter to Hopf that Abraham's theory was "truly superficial, contrary to his [Abraham's] usual practice."[18]

15 This is a little surprising. Einstein had neglected gravitation in 1908–1911, possibly because of his preoccupation with the problem of quanta. (See Pais (1983, 187–90.)) However he had returned to gravitation with vigor with his June 1911 submission of Einstein (1911) and by July 1912, the time of his dispute with Abraham, he had completed at least two more novel papers on the subject, (Einstein 1912a, 1912b), and possibly a third, (Einstein 1912c).

16 Einstein to Ludwig Hopf, 16 August 1912, (EA 13 288).

17 Einstein to Ludwig Hopf, December 1911 (?), (EA 13 282).

Under these circumstances, Einstein had every incentive to make the best case for his new work on gravitation. In particular, we would expect Einstein to advance the best arguments available to him to justify his 1907 judgement of the untenability of Lorentz covariant gravitation theories, for it was this conclusion that necessitated the consideration of gravitation theories that went beyond special relativity. What he included in his response shows us that as late as July 4, 1912—the date of submission of his response (Einstein 1912d)—his grounds for this judgement had advanced very little beyond those he recalled having in 1907. He wrote (pp. 1062–63)

> One of the most important results of the theory of relativity is the realization that every energy E possesses an inertia (E/c^2) proportional to it. Since each inertial mass is at the same time a gravitational mass, as far as our experience goes, we cannot help but ascribe to each energy E a gravitational mass E/c^2.[19] From this it follows immediately that gravitation acts more strongly on a moving body than on the same body in case it is at rest.
>
> If the gravitational field is to be interpreted in the sense of our current theory of relativity, this can happen only in two ways. One can conceive of the gravitation vector either as a four-vector or a six-vector. For each of these two cases there are transformation formulae for the transition to a uniformly moving reference system. By means of these transformation formulae and the transformation formulae for ponderomotive forces one can find for both cases the forces acting on moving material points in a static gravitational field. However from this one arrives at results which conflict with the consequences mentioned of the law of the gravitational mass of energy. Therefore it seems that the gravitation vector cannot be incorporated without contradiction in the scheme of the current theory of relativity.

Einstein's argument is a fairly minor embellishment of the reflections summarized in Section 3 above. Einstein has replaced a single theory, embodied in equations such as (3) and (4), with two general classes of gravitation theory, the four-vector and six-vector theory. In both classes of gravitation theory, in the case of moving masses, Einstein claims that the gravitational field fails to act on them in proportion to their total energy, in effect violating the requirement of equality of inertial and gravitational mass.

---

18 Einstein to Ludwig Hopf, 12 June 1912, (EA 13 286). Einstein retained his high opinion of Abraham as a physicist. Late the following year, after his work had advanced into the first sketch of the general theory of relativity, Einstein conceded to his confidant Besso that "Abraham has the most understanding [of the new theory]." Einstein to Michele Besso, end of 1913, in (Speziali 1972, 50). For further mention of Abraham in correspondence from this period see Einstein to Heinrich Zangger, 27 January 1912, (EA 39 644); Einstein to Wilhelm Wien, 27 January 1912, (EA 23 548); Einstein to Heinrich Zangger, 29 February 1912, (EA 39 653); Einstein to Wilhelm Wien, 24 February 1912, (EA 23 550); Einstein to Heinrich Zangger, 20 May 1912, (EA 39 655); Einstein to Michele Besso, 26 March 1912, (EA 7 066); Einstein to Heinrich Zangger, summer 1912, (EA 39 657); Einstein to Arnold Sommerfeld, 29 October 1912, (EA 21 380). See also (Pais 1982, 231–32).

19 At this point, Einstein inserts the footnote:
Hr. Langevin has orally called my attention to the fact that one comes to a contradiction with experience if one does not make this assumption. That is, in radioactive decay large quantities of energy are given off, so that the *inertial* mass of the matter must diminish. If the gravitational mass were not to diminish proportionally, then the gravitational acceleration of bodies made out of different elements would have to be demonstrably different in the same gravitational field.

Einstein does not give a full derivation of the result claimed. However we can reconstruct what he intended from the derivation sketch given. The two types of force fields correspond to the "spacetime vectors type I and II" introduced by Minkowski (1908, §5), which soon came to be known as four- and six-vector fields, respectively (Sommerfeld 1910, 750). They represented the two types of force fields then examined routinely in physics. The four-vector corresponds to the modern vector of a four-dimensional manifold. The gravitational four-force F_μ acting on a body with rest mass m in a four-vector theory is

$$F_\mu = mG_\mu. \tag{10a}$$

An example of such a theory is given by (4) above in which the gravitation four-vector G_μ is set equal to $-\partial\phi/\partial x_\mu$. The six-vector corresponds to our modern antisymmetric second rank tensor which has six independent components. The classic example of a six-vector is what Sommerfeld called "the six-vector ... of the electromagnetic field" (Sommerfeld 1910, 754). We would now identify it as the Maxwell field tensor. Presumably Einstein intended a six-vector gravitation theory to be modelled after electrodynamics, so that the gravitational four-force F_μ acting on a body with rest mass m and four-velocity U_ν in such a theory would be given by

$$F_\mu = mG_{\mu\nu}U_\nu. \tag{11a}$$

The gravitation six-vector, $G_{\mu\nu}$, satisfies the antisymmetry condition $G_{\mu\nu} = -G_{\nu\mu}$. This antisymmetry guarantees compatibility with the identity (5) since it forces $F_\mu U_\mu = 0$.

Einstein claims that one needs only the transformation formulae for four and six-vectors and for ponderomotive forces. to arrive at the results. However, since both (10a) and (11a) are Lorentz covariant, application of the transformation formulae to these equations simply returns equations of identical form—an uninformative outcome. We do recover results of the type Einstein claims, however, if we apply these transformation formulae to non-covariant specializations of (10a) and (11a).

We consider arbitrary four and six-vector gravitational fields G_μ and $G_{\mu\nu}$. In each there is a body of mass m in free fall. In each case, select and orient a coordinate system $S'(x', y', z', u' = ict')$ in such a way that each mass is instantaneously at rest and is accelerating only in $y' = x'_2$ direction. For these coordinate systems, the three spatial components of the four-force, F'_i , are equal to the three components of the three force, f'_i , acting on the masses. In particular the $x'_2 = y'$ component f'_2 of the three force is given in each case by

$$f'_2 = mG'_2 , \tag{10b}$$

$$f'_2 = mG'_{2\nu}U'_\nu = mG'_{24}\, ic \tag{11b}$$

since $U'_\mu = (0, 0, 0, ic)$. If we now transform from S' to a reference system $S(x, y, z, u = ict)$ moving at velocity v in the $x'_1 = x'$ direction S', then the relevant Lorentz transformation formulae are

$$f'_2 = \frac{f_2}{\sqrt{1-\frac{v^2}{c^2}}}, \qquad G'_{24} = \frac{G_{24}-(iv/\mathrm{c})G_{21}}{\sqrt{1-\frac{v^2}{c^2}}}.$$

Thus far we have not restricted the choice of four or six-vector fields G_μ and $G_{\mu\nu}$. The considerations that follow are simplified if we consider a special case of the six-vector field $G_{\mu\nu}$ in which $G_{21} = 0$.[20] Substituting with these transformation formulae for f'_2 and G'_{24} in this special in (10b) and (11b), we recover

$$f_2 = m\sqrt{1-\frac{v^2}{c^2}}G_2 \tag{10c}$$

$$f_2 = mG_{24}ic. \tag{11c}$$

These two equations describe the component of gravitational three-force, f_2, in the "vertical" $x_2 = y$ direction on a mass m moving with velocity v in the "horizontal" $x_1 = x$ direction. In his 1912 argument, Einstein noted that the inertia of energy and the equality of inertial and gravitational mass leads us to expect that "gravitation acts more strongly on a moving body than on the same body in case it is at rest." We read directly from equations (10c) and (11c) that both four and six-vector theories fail to satisfy this condition. The gravitational force is independent of velocity in the six-vector case and actually decreases with velocity in the four-vector case. To meet Einstein's requirements, the gravitational force would need to increase with velocity, in direct proportion to the mass's energy $mc^2/\sqrt{1-(v^2/\mathrm{c}^2)}$.

We can also confirm that (10c) and (11c) lead to the result that the vertical acceleration of the masses is not independent of their horizontal velocities. To see this, note that, were the masses of (10c) and (11c) instantaneously at rest, the vertical forces exerted by the two fields would be respectively

$$f_2^{\mathrm{rest}} = mG_2, \quad f_2^{\mathrm{rest}} = mG_{24}ic.$$

In all cases, the three velocity and three-accelerations are perpendicular, so that condition (8) holds. Therefore we have

---

20 This restriction does not compromise the generality of Einstein's claim. If a Lorentz covariant theory proves inadequate in a special case, that is sufficient to demonstrate its general inadequacy. A natural instance of a six-vector field $G_{\mu\nu}$ in which $G_{21} = 0$ is easy to construct. Following the model of electromagnetism, we assume that $G_{\mu\nu}$ is generated by a vector potential A_μ, according to

$$G_{\mu\nu} = \frac{\partial A_\mu}{\partial x_\nu} - \frac{\partial A_\nu}{\partial x_\mu}.$$

We choose a "gravito-static" field in $S(x, y, z, u)$, that is, one that is analogous to the electrostatic field, by setting $A_\mu = (0, 0, 0, A_4)$. Since A_1 and A_2 are everywhere vanishing, $G_{21} = 0$. Finally note that Einstein does explicitly restrict his 1912 claim to static gravitational fields. Perhaps he also considered simplifying special examples of this type.

$$f_i = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}} m \frac{dv_i}{dt}, \quad f_i^{\text{rest}} = m\left(\frac{dv_i}{dt}\right)^{\text{rest}}.$$

Combining these results with (10c) and (11c) we recover expressions for the vertical acceleration dv_2/dt of the masses in terms of the acceleration $(dv_2/dt)^{\text{rest}}$ they would have had if they had no horizontal velocity

$$\frac{dv_2}{dt} = \left(1-\frac{v^2}{c^2}\right)\left(\frac{dv_2}{dt}\right)^{\text{rest}} \tag{10d}$$

$$\frac{dv_2}{dt} = \sqrt{1-\frac{v^2}{c^2}}\left(\frac{dv_2}{dt}\right)^{\text{rest}} \tag{11d}$$

We see that in both four and six-vector cases the vertical acceleration decreases with horizontal velocity, with equation (10d) generalizing the result in equation (9).

5. A GRAVITATION THEORY MODELLED AFTER MAXWELL'S ELECTROMAGNETISM?

Einstein's mention of a six-vector theory of gravitation in his 1912 response to Abraham raises the question of Einstein's attitude to a very obvious strategy of relativization of Newtonian gravitation theory. With hindsight one can view the transition from the theory of Coulomb electrostatic fields to full Maxwell electromagnetism as the first successful relativization of a field theory. Now Newtonian gravitation theory is formally identical to the theory of electrostatic fields excepting a change of sign needed to ensure that gravitational masses attract where like electric charges repel. This suggests that one can relativize Newtonian gravitation theory by augmenting it to a theory formally identical to Maxwell theory excepting this same change of sign.

While it is only with hindsight that one sees the transition from electrostatics to electromagnetism as a relativization, Einstein had certainly developed this hindsight by 1913. In his (Einstein 1913, 1250) he noted that Newtonian theory has sufficed so far for celestial mechanics because of the smallness of the speeds and accelerations of the heavenly bodies. Were these motions to be governed instead by electric forces of similar magnitude, one would need only Coulomb' s law to calculate these motions with great accuracy. Maxwell's theory would not be required. The problem of relativizing gravitation theory, Einstein continued, corresponded exactly to this problem: if we knew only experimentally of electrostatics but that electrical action could not propagate faster than light, would we be able to develop Maxwell electromagnetics? In the same paper Einstein proceeded to show (p. 1261) that his early 1913 version of general relativity reduced in suitable weak field approximation to a theory with a four-vector field potential that was formally analogous to electrodynamics. It was this approximation that yielded the weak field effects we now label as "Machian." The previous year, when seeking similar effects in his 1912 theory of static gravitational fields, Einstein demonstrated that he then expected a relativized gravitation theory to be formally analogous to electrodynamics at some level. For then he wrote a paper with the revealing title "Is there a gravitational effect that is analogous to electrodynamic induction?" (Einstein 1912c).

The celebrated defect of a theory of gravitation modelled after Maxwell electromagnetism was first pointed out by Maxwell himself (Maxwell 1864, 571). In such a theory, due to the change of signs, the energy density of the gravitational field is negative and becomes more negative as the field becomes stronger. In order not to introduce net negative energies into the theory, one must then suppose that space, in the absence of gravitational forces, must contain a positive energy density sufficiently great to offset the negative energy of any possible field strength. Maxwell professed himself baffled by the question of how a medium could possess such properties and renounced further work on the problem. As it turns out it was Einstein's foe, Abraham, shortly after his exchange with Einstein, who refined Maxwell's concern into a more telling objection. In a lecture of October 19, 1912, he reviewed his own gravitation theory based on Einstein's idea of using the speed of light as a gravitational potential. (Abraham 1912e) He first reflected (pp. 193–94), however, on a gravitation theory modelled after Maxwell electromagnetism. In such a theory, a mass, set into oscillation, would emit waves analogous to light waves. However, because of the change of sign, the energy flow would not be away from the mass but towards it, so that the energy of oscillation would increase. In other words such an oscillating mass would have no stable equilibrium. Similar difficulties were reported by him for gravitation theories of Maxwellian form due to H.A. Lorentz and R. Gans.

What was Einstein's attitude to such a theory of gravitation? He was clearly aware of the formal possibility of such a theory in 1912 and 1913. From his failure to exploit such a theory, we can only assume that he did not think it an adequate means of relativizing gravitation.[21] Unfortunately I know of no source from that period through which Einstein states a definite view on the matter beyond the brief remarks in his exchange with Abraham. We shall see that Einstein is about to renounce the conclusion of his reply to Abraham, that a Lorentz covariant theory cannot capture the equality of inertial and gravitational mass, at least for the case of Nordström's theory of gravitation. Did Einstein have other reservations about six-vector theories of gravitation? How seriously, for example, did he regard the negative field energy problem in such a theory?

The idea of an analogy between a relativized gravitation theory and electrodynamics seems to play no significant role in the methods Einstein used to generate relativized gravitation theories. The effect analogous to electrodynamic induction of

21 Notice these reservations must have amounted to more than the observation that such a theory fails to extend the relativity of motion to acceleration. In (Einstein 1913), immediately after his remarks on the similarity between the problems of relativizing gravitation and electrostatics, he considers Lorentz covariant gravitation theories. The only theory taken seriously in this category is a version of Nordström's theory of gravitation.

(Einstein 1912c), for example, was derived fully within Einstein's 1912 theory of static gravitational fields and the analogy to electrodynamics appeared only in the description of the final result. In general, the mention of an analogy to electrodynamics seems intended solely to aid Einstein's readers in understanding the enterprise and physical effects appearing in the relativized theories of gravitation by relating them to an example familiar to his readers. That we have any surviving, written remarks by Einstein directly on this matter we owe to J.W. Killian. Some thirty years later, in a letter of June 9, 1943 (EA 14 261) to Einstein, Killian proposed a gravitation theory modelled after Maxwell electromagnetism.[22] Einstein's reply of June 28, 1943, gives a fairly thorough statement of his attitude at that time to this theory.[23]

Because there was no question of experimental support for the theory, Einstein proposed to speak only to its formal properties. To begin, he noted, Maxwell's equations only form a complete theory for parts of space free of source charges, for the theory cannot determine the velocity field of the charge distribution without further assumption. After Lorentz, to form a complete theory, it was assumed that charges were carried by ponderable masses whose motions followed from Newton's laws. What Einstein called "real difficulties" arise only in explaining inertia. These difficulties result from the negative gravitational field energy density in the theory. Assuming, apparently, that the energy of a mass in the theory would reside in its gravitational field, Einstein pointed out that the kinetic energy of a moving mass point would be negative. This negativity would have to be overcome by a device entirely arbitrary from the perspective of the theory's equations, the introduction of a compensating positive energy density located within the masses. This difficulty is more serious for the gravitational version of the theory, for, in the electromagnetic theory, the positivity of electromagnetic field energy density allows one to locate all the energy of a charge in its electromagnetic field.

Calling the preceding difficulty "the fundamental problem of the wrong sign," Einstein closed his letter with brief treatment of two further and, by suggestion, lesser difficulties. The proposed theory could not account, Einstein continued, for the proportionality of inertial and gravitational mass. Here we finally see the concern that drove Einstein's work on Lorentz covariant gravitation theory in the decade following 1907. Yet Einstein does not use the transformation arguments of this early period to establish the failure of the proposed theory to yield this proportionality. Instead he continues to imagine that the energy and therefore inertia of a mass resides in its gravitational field. Some fixed quantity of gravitational mass could be configured in many different ways. Thus it follows that the one quantity of gravitational mass could be associated with many different gravitational fields and thus many different inertial masses, in contradiction with the proportionality sought.[24] Finally Einstein remarked

---

22 Einstein addresses his reply to "Mr. J.W. Killian, Dept. of Physics, Rockerfeller Hall, Ithaca N.Y."

23 EA 14 265 is an autograph draft of the letter in German. EA 14 264 is an unsigned typescript of the English translation. There are some significant differences of content between the two, indicating further editing of content presumably by Einstein between the draft and typescript.

that the proposed theory allows no interaction between electromagnetic and gravitational fields other than through charged, ponderable masses. Thus it could not explain the bending of starlight in a gravitational field.

6. NORDSTRÖM'S FIRST THEORY OF GRAVITATION

The dispute between Einstein and Abraham was observed with interest by a Finnish physicist, Gunnar Nordström.[25] In a paper submitted to *Physikalische Zeitschrift* in October 1912 (Nordström 1912), he explained that Einstein's hypothesis that the speed of light c depends on the gravitational potential led to considerable problems such as revealed in the Einstein-Abraham dispute. Nordström announced (p. 1126) that he believed he had found an alternative to Einstein's hypothesis which would

> ... leave c constant and still adapt the theory of gravitation to the relativity principle in such a way that gravitational and inertial masses are equal.

The theory of gravitation which Nordström developed was a slight modification of the theory embodied in equations (3) and (4) above. Selecting the commonly used coordinates $x, y, z, u = ict$, Nordström gave his version of the field equation (3):

$$\frac{\partial^2\Phi}{\partial x^2}+\frac{\partial^2\Phi}{\partial y^2}+\frac{\partial^2\Phi}{\partial z^2}+\frac{\partial^2\Phi}{\partial u^2} = 4\pi f\gamma \qquad (12)$$

where Φ is the gravitational potential, γ the rest density of matter and f the gravitational constant. As he noted, this field equation was identical to the one advanced by Abraham (1912a, equation (1)) in the latter's gravitation theory.

Where Nordström differed from Abraham, however, was in the treatment of the force equation (4). This equation, as Nordström pointed out, is incompatible with the constancy of c. We saw above that force equation (4), in conjunction with the constancy of c in equation (5) entails the unphysical condition (6). Abraham had resolved the problem by invoking Einstein's hypothesis that c not be constant but vary with gravitational potential so that condition (5) no longer obtains. Thus Abraham's gravitation theory was no longer a special relativistic theory. Nordström, determined to preserve special relativity and the constancy of c, offered a choice of two modified versions of (4).

First, one could allow the rest mass m of a body in a gravitational field to vary with gravitational potential. Defining

---

24 In the German autograph draft (EA 14 265), Einstein imagines some fixed quantity of gravitational mass distributed between two bodies. The field strength they generate, and therefore their energy and inertial mass, would increase as the bodies were concentrated into smaller regions of space. (We may conjecture here that Einstein is ignoring the fact the field energy becomes more *negative* as the field strength increases.) The translated typescript (EA 14 264) simplifies the example by imagining that the gravitational mass is located in a single corpuscle, whose field and thence inertia varies with the radius of the corpuscle.

25 For a brief account of Nordström's life and his contribution to gravitation theory see (Isaksson 1985).

$$\mathfrak{F}_\mu = -\frac{\partial\Phi}{\partial x_\mu},$$

the four force on a body of mass m is

$$m\mathfrak{F}_\mu = -m\frac{\partial\Phi}{\partial x_\mu} = \frac{d}{d\tau}(m\mathfrak{a}_\mu) = m\frac{d\mathfrak{a}_\mu}{d\tau} + \mathfrak{a}_\mu\frac{dm}{d\tau} \tag{13}$$

where $\mathfrak{a}_\mu$ is the mass' four velocity and τ proper time.[26] The dependence of m on Φ introduces the additional, final term in $dm/d\tau$, which prevents the derivation of the disastrous condition (6). In its place, by contracting (13) with $\mathfrak{a}_\mu = \frac{dx_\mu}{dt}$ and noting that $\mathfrak{a}_\mu\mathfrak{a}_\mu = -c^2$, Nordström recovered the condition

$$m\frac{d\Phi}{d\tau} = c^2\frac{dm}{d\tau} \tag{14}$$

which yields an expression for the Φ dependence of m upon integration

$$m = m_0\exp\left(\frac{\Phi}{c^2}\right) \tag{15}$$

where m_0 is the value of m when $\Phi = 0$. Using (14) to substitute $\frac{dm}{d\tau}$ in (13), Nordström then recovered an equation of motion for a mass point independent of m

$$-\frac{\partial\Phi}{\partial x_\mu} = \frac{d\mathfrak{a}_\mu}{d\tau} + \frac{\mathfrak{a}_\mu}{c^2}\frac{d\Phi}{d\tau}. \tag{16}$$

---

26 *Note on notation*: The notation used in the sequence of papers discussed here varies. I shall follow the notation of the original papers as it changes, with one exception for brevity. Where the components of an equation such as (13) were written out explicitly as four equations

$$-m\frac{\partial\Phi}{\partial x} = \frac{d}{d\tau}(m\mathfrak{a}_x) = m\frac{d\mathfrak{a}_x}{d\tau} + \mathfrak{a}_x\frac{dm}{d\tau},$$
$$-m\frac{\partial\Phi}{\partial y} = \frac{d}{d\tau}(m\mathfrak{a}_y) = m\frac{d\mathfrak{a}_y}{d\tau} + \mathfrak{a}_y\frac{dm}{\tau},$$
etc.

I silently introduce the coordinates $x_\mu = (x_1, x_2, x_3, x_4) = (x, y, z, u) = ict$ and corresponding index notation as in equation (13) above.

Nordström's second alternative to force equation (4) preserved the independence of m from the potential. The quantity $m\mathfrak{F}_\mu = -m\frac{\partial\Phi}{\partial x_\mu}$ could not be set equal to the gravitational four-force on a mass m, $\frac{d}{d\tau}(m\mathfrak{a}_\mu)$, for that would be incompatible with the orthogonality (5) of four velocity and four acceleration. However one can retain compatibility with this orthogonality if one selects as the four force only that part of $m\mathfrak{F}_\mu$ which is orthogonal to the four-velocity $\mathfrak{a}_\mu$. This yields the second alternative for the force equation

$$\frac{d}{d\tau}(m\mathfrak{a}_\mu) = m\mathfrak{F}_\mu + m\frac{\mathfrak{a}_\mu}{c^2}(\mathfrak{F}_\nu\mathfrak{a}_\nu) = \begin{pmatrix}\text{part of } m\mathfrak{F}_\mu \\ \text{orthogonal} \\ \text{to } \mathfrak{a}_\mu\end{pmatrix}, \tag{17}$$

Nordström somewhat casually noted that he would use the first alternative, since it corresponded to "the position of most researchers in the domain of relativity theory." (p. 1126) Indeed Nordström proceeded to show that both force equations lead to exactly the same equation of motion (16) for a point mass, planting the suggestion that the choice between alternatives could be made arbitrarily.

Regular readers of *Physikalische Zeitschrift*, however, would know that Nordström's decision between the two alternatives could not have been made so casually by him. For in late 1909 and early 1910, Nordström had engaged in a lively public dispute with none other than Abraham on a problem in relativistic electrodynamics that was in formal terms virtually the twin of the choice between the force laws (13) and (17). (Nordström 1909, 1910; Abraham 1909, 1910.) The problem centered on the correct expression for the four force density on a matter distribution in the case of Joule heating. The usual formula for the four force density $\mathfrak{K}_\mu$ on a mass distribution with rest mass density v is, in the notation of Abraham (1910),

$$\mathfrak{K}_\mu = \nu\frac{d}{d\tau}\left(\frac{dx_\mu}{d\tau}\right)$$

with τ proper time and coordinates $x_\mu = (x, y, z, u = ict)$. In the case of Joule heating, it turns out that this expression leads to a contradiction with the orthogonality condition (5). The two escapes from this problem at issue in the dispute are formally the same as the two alternative gravitational force laws. Nordström defended Minkowski's approach, which took the four force density to be that part of $\mathfrak{K}_\mu$ orthogonal to the matter four velocity $\left(\frac{dx_\mu}{d\tau}\right)$ —the counterpart of force law (17).

Abraham concluded that the rest mass density v would increases in response to the energy of Joule heat generated. He showed a consistent system could be achieved if one now imported this variable v into the scope of the $d/d\tau$ operator in the expression for $\mathfrak{K}_\mu$ —an escape that is the counterpart of (13). Abraham's escape was judged the only tenable one when he was able to show that it yielded the then standard Lorentz transformation formula for heat whereas the Nordström-Minkowski formula did not.[27]

The connection between Nordström's 1912 gravitation theory and this earlier dispute surfaced only in extremely abbreviated form in Nordström (1912). In a brief sentence in the body of the paper, Nordström noted gingerly that (p. 1127)

> the latter way of thinking [alternative (17)] corresponds to Minkowski's original, that treated first [alternative (13)] to that held by Laue and Abraham.

That Nordström had any stake in the differing viewpoints is only revealed in a footnote to this sentence in which the reader is invited to consult "the discussion between Abraham and the author," followed by a citation to the four papers forming the dispute. Nordström then closes with the remark[28]

> I now take the position then taken up by Abraham.

Nordström now continued his treatment of gravitation by extending the discussion from isolated point masses to the case of continuous matter distributions—an area in which he had some interest and expertise (Nordström 1911). He derived a series of results in a straightforward manner. They included expressions for gravitational four force density on a continuous mass distributions and the corresponding equations of motion, expressions for the energy density and flux due to both gravitational field and matter distribution, the gravitational field stress-energy tensor and the laws of conservation of energy and momentum.

The last result Nordström derives concerns point masses. He notes that the field equation (12) admits the familiar retarded potential as a solution for a matter distribution with rest density γ

$$\Phi(x_0, y_0, z_0, t) = -f\int\frac{dxdydz}{r}\gamma_{t-r/c} + \text{constant}$$

where $\gamma_{t-r/c}$ is γ evaluated at time $t-r/c$, the integration extends over all of three dimensional space and $r = \sqrt{(x-x_0)^2+(y-y_0)^2+(z-z_0)^2}$. It follows from the factor of $1/r$ in the integral that the potential Φ at a true point mass would be $-\infty$. Allowing for the dependence of mass on potential given in (15), it follows that the mass of such a point would have to be zero so that true point masses cannot exist.

27 Thus the authoritative judgement of Pauli's Teubner Encyklopädie article (Pauli 1921, 108) is that "Nordström's objections cannot be upheld." For a lengthy discussion of this debate and an indication that the issues were not so simple, see (Liu 1991).

28 His earlier work (Nordström 1911) had explicitly employed Abraham's "force concept," although Nordström had then noted very evasively that, in using it, he "wish[es] to assert no definite opinion on the correctness of one or other of the two concepts" (p. 854).

Nordström concluded with confidence, however, that he could see no contradictions arising from this result.

We may wonder at Nordström's lack of concern over this result. It would be thoroughly intelligible, however, if Nordström were to agree—as Nordström's later (Nordström 1913a, 856) suggests —with Laue's view on the relation between the theory of point masses and of continua. Laue had urged that the former ought to be derived from the latter (Laue 1911a, 525). Under this view, the properties of extended masses are derived from consideration of discrete volumes in a continuous matter distribution, not from the accumulated behavior of many point masses. So the impossibility of point masses in Nordström's theory would present no obstacle in his generation of the behavior of extended bodies.

7. EINSTEIN REPLIES

In advancing his theory, Nordström had claimed to do precisely what Einstein had claimed impossible: the construction of a Lorentz covariant theory of gravitation in which the equality of inertial and gravitational mass held. We need not guess whether Einstein communicated his displeasure to Nordström, for Einstein's missive was sufficiently swift for Nordström to acknowledge it in an addendum (p. 1129) to his paper which read

> *Addendum to proofs*. From a letter from Herr Prof. Dr. A. Einstein I learn that he had already earlier concerned himself with the possibility used above by me for treating gravitational phenomena in a simple way. He however came to the conviction that the consequences of such a theory cannot correspond with reality. In a simple example he shows that, according to this theory, a rotating system in a gravitational field will acquire a smaller acceleration than a non-rotating system.

Einstein's objection to Nordström is clearly an instance of his then standard objection to Lorentz covariant theories of gravitation: in such theories the acceleration of fall is not independent of a body's energy so that the equality of inertial and gravitational mass is violated. It is not hard to guess how Einstein would establish this result for a spinning body in Nordström's theory. It would seem to follow directly from the familiar equation (9) which holds in Nordström's theory and which says, loosely speaking, that a body falls slower if it has a greater horizontal velocity. Indeed, as we shall see below, this is precisely how Nordström shortly establishes the result in his next paper on gravitation theory.

Nordström continued and completed his addendum with a somewhat casual dismissal of Einstein's objection.

> I do not find this result dubious in itself, for the difference is too small to yield a contradiction with experience. Of course, the result under discussion shows that my theory is not compatible with Einstein's principle of equivalence, according to which an unaccelerated reference system in a homogeneous gravitational field is equivalent to an accelerated reference system in a gravitation free space.
>
> In this circumstance, however, I do not see a sufficient reason to reject the theory. For, even though Einstein's hypothesis is extraordinarily ingenious, on the other hand it still

> provides great difficulties. Therefore other attempts at treating gravitation are also desirable and I want to provide a contribution to them with my communication.

Nordström's reply is thoroughly reasonable. The requirement of exact equality of inertial and gravitational mass was clearly an obsession of Einstein's thinking at this time and not shared by Einstein's contemporaries. The now celebrated Eötvös experiment had not yet been mentioned in the publications cited up to this point. We can also see from equation (9) that the failure of the equality of inertial and gravitational mass implied by Nordström's theory would reside in a second order effect in v/c. Nordström clearly believed it to be beyond recovery from then available experiments.

Finally we should note that Einstein and Nordström are using quite different versions of the requirement of the equality of inertial and gravitational mass. At this time, Einstein presumed that the total inertial mass would enter into the equality with the expectation that it would yield the independence of the vertical acceleration of a body in free fall from its horizontal velocity. We can only conjecture the precise sense Nordström had in mind, when he promised his theory would satisfy the equality, for he does not explain how the equality is expressed in his theory. My guess is that he took the rest mass to represent the body's inertial mass in the equality, for Nordström's equation (16) clearly shows that the motion of a massive particle in free fall is independent of its rest mass m. Under this reading Nordström's version of the equality entails the weaker observational requirement of the "uniqueness of free fall" defined above in Section 1.[29]

8. NORDSTRÖM'S FIRST THEORY ELABORATED

Nordström's first paper on his gravitation theory was followed fairly quickly by another (Nordström 1913a), submitted to *Annalen der Physik* in January 1913. This new paper largely ignored Einstein's objection although the paper bore the title "Inertial and gravitational mass in relativistic mechanics." The closing sections of this paper recapitulated the basic results of (Nordström 1912) with essentially notational differences only. In Section 6, Nordström's original field equation (12) was rewritten as

$$\frac{\partial^2\Phi}{\partial x^2}+\frac{\partial^2\Phi}{\partial y^2}+\frac{\partial^2\Phi}{\partial z^2}+\frac{\partial^2\Phi}{\partial u^2} = g\nu. \tag{12'}$$

As before, Φ was the gravitational potential. The rest density of matter was now represented by ν and Nordström explicitly named the new constant g the "gravitation factor." The force equation was presented as a density in terms of the gravitational force per unit volume of matter $\mathfrak{K}^g_\mu$

29 The equality of inertial and gravitational mass and the uniqueness of free fall are distinct from the principle of equivalence. Einstein's version of the principle has been routinely misrepresented since about 1920 in virtually all literatures. See (Norton 1985). It is stated correctly, however, in Nordström's addendum.

$$\mathfrak{K}_{\mu}^{g} = -g\nu\frac{\partial\Phi}{\partial x_{\mu}}. \tag{18}$$

The only difference between this expression and the analogous one offered in the previous paper was the presence of the gravitation factor g. Since this factor was a constant and thus did not materially alter the physical content of either of the basic equations, Nordström might well have anticipated his readers' puzzlement over its use. He hastened to explain that, while g was a constant here, nothing ruled out the assumption that g might vary with the inner constitution of matter. The paper continued to derive the Φ dependence of rest mass m of equation (15). The new version of the relation now contained the gravitation factor g and read

$$m = m_0 \exp\left(\frac{g\Phi}{c^2}\right).$$

Nordström no longer even mentioned the possibility of avoiding this dependence of m on Φ by positing the alternative force equation (17). The section continued with a brief treatment of the gravitational field stress-energy tensor and related quantities. It closed with a statement of the retarded potential solution of the field equation.

The final section 7 of the paper analyzed the motion of a point mass in free fall in an arbitrary static gravitational field. The analysis was qualified by repetition of his earlier observation that true point masses are impossible in his theory (Nordström 1912, 1129). In addition he noted that the particle's own field must be assumed to be vanishingly weak in relation to the external field. The bulk of the section is given over to a tedious but straightforward derivation of the analog of equation (9). Nordström considered a static field, that is one in which $\partial\Phi/\partial t = 0$, where t is the time coordinate of the coordinate system $(x, y, z, u = ict)$. He assumed the field homogeneous and acting only in the z-direction of the coordinate system. A point mass in free fall moves according to

$$\frac{d\mathfrak{v}_z}{dt} = -\left(1-\frac{\mathfrak{v}^2}{c^2}\right)g\frac{\partial\phi}{\partial z}, \quad \frac{d\mathfrak{v}_x}{dt} = 0, \quad \frac{d\mathfrak{v}_y}{dt} = 0, \tag{19}$$

where $\mathfrak{v}_x$, $\mathfrak{v}_y$ and $\mathfrak{v}_z$ are the components of the mass' velocity $\mathfrak{v}$.[30] At this point in the paper, readers of (Nordström 1912) might well suspect that the entire purpose of developing equation (19) was to enable statement of the objection of Einstein reported in that last paper's addendum. For, after observing that this result (19) tells us that a body with horizontal velocity falls slower than one without, he concluded immediately that a rotating body must fall slower than a non-rotating body.

30 Notice that this result is more general than result (9), since it is not restricted to masses with vanishing vertical velocity, that is, masses whose motion satisfies the condition (7). Curiously Nordström's condition that the field be homogeneous, so that $\partial\Phi/\partial z =$ constant, is invoked nowhere in the derivation or discussion of the result.

Because this example will be reappraised shortly, it is worth inserting the steps that Nordström must have assumed to arrive at this conclusion. In the simplest case, the axis of rotation of the body is aligned vertically in the static field. Each small element of the spinning body has a horizontal motion, due to the rotation. If each such element were independent, then the vertical acceleration of each would be given by the equation (19), so that each element would fall slower because of the horizontal velocity imparted by the rotation. If this result holds for each element, it seems unproblematic to conclude that it obtains for the whole, so that the vertical acceleration of fall of the body is diminished by its rotation.

While Nordström urged that this effect is much too small to be accessible to observation, he was more sanguine about the analogous effect on the acceleration of fall of a body by the independent motions of its molecules. Its possibility could not be denied, he said. However, in the penultimate paragraph of the paper, he anticipated that such an effect could be incorporated into his theory by allowing the gravitation factor g to depend on the molecular motion of the body. He pointed out that the rest energy of a body would also be influenced by this molecular motion.

The results Nordström recapitulated in Section 6 and 7 were not the major novelties of the paper. In fact the paper was intended to address a quite precise problem. The field equation (12') contained a density term ν. Nordström's problem was to identify what this term should be. The term—or, more precisely, $g\nu$—represented the gravitational field source density. According to Nordström's understanding of the equality of inertial and gravitational mass, ν must also represent the inertial properties of the source matter. The selection of such a term was not straightforward. For, drawing upon his own work and that of Laue and others, he knew that stressed bodies would exhibit inertial properties that were not reducible to the inertial properties of any individual masses that may compose them. Thus Nordström recognized that his gravitation theory must be developed by means of the theory of relativistic continua, in which stresses were treated. This had clearly been his program from the start. In a footnote to the first paragraph of his first paper on gravitation, Nordström (1912), at the mention of the equality inertial and gravitational mass, he foreshadowed his next paper

> By the equality of inertial and gravitational mass, I do not understand, however, that every inertial phenomenon is caused by an inertial and gravitational mass. For elastically stressed bodies, according to Laue ..., one recovers a quantity of motion [momentum] that cannot at all be reduced back to a mass. I will return to this question in a future communication.

The special behavior of stressed bodies proved to be of decisive importance for the development of Nordström's theory. Therefore, in the following section, I review the understanding of this behavior at the time of Nordström's work on gravitation. I will then return to (Nordström 1913a).

9. LAUE AND THE BEHAVIOR OF STRESSED BODIES

By 1911 it was apparent that a range of problems in the theory of relativity had a common core—they all involved the behavior of stressed bodies—and that a general theory of stressed bodies should be able to handle all of these problems in a unified format. The development of this general theory was largely the work of Laue and came from a synthesis and generalization of the work of many of his predecessors, including Einstein, Lorentz, Minkowski and Planck. The fullest expression of this general theory came in Laue (1911a) and was also incorporated into Laue (1911b), the first text book published on the new theory of relativity.[31] Three problems treated in Laue' s work give us a sense of the range of problems that Laue's work addressed.

9.1 Three Problems for Relativity Theory

In 1909, in a remarkably prescient paper, Lewis and Tolman (1909) set out to develop relativistic mechanics in a manner that was independent of electromagnetic theory using simple and vivid arguments. At this time relativity theory was almost invariably coupled with Lorentzian electrodynamics and its content was accessible essentially only to those with significant expertise in electrodynamics. Their exposition was marred, however, by an error in its closing pages (pp. 520–21). By this point, they had established the Lorentz transformation for forces transverse to the direction of motion. Specifically, if the force is f^0_{trans} in the rest frame, then the force f_{trans} measured in a frame moving at a fraction β of the speed of light is

$$f_{\text{trans}} = \sqrt{1-\beta^2}\, f^{\,0}_{\text{trans}}. \tag{20}$$

To recover the transformation formula for forces parallel to the direction of motion, the "longitudinal" direction, they considered the rigid, right angled lever of Fig. 1. The arms ab and bc are of equal length and pivot about point b. In its rest frame two equal forces f act at points a and c, the first in direction bc, the second in direction ba. The level will not turn since there is no net turning couple about its pivot b. They then imagined the whole system in motion in the direction bc. They conclude—presumably directly from the principle of relativity—that the system must remain in equilibrium. Therefore the net turning couple about b must continue to vanish for the moving system, so that

$$\begin{pmatrix}\text{force}\\ \text{at } c\end{pmatrix}\begin{pmatrix}\text{length}\\ bc\end{pmatrix}+\begin{pmatrix}\text{force}\\ \text{at } a\end{pmatrix}\begin{pmatrix}\text{length}\\ ab\end{pmatrix} = 0.$$

Now, according to (20), the transverse force at c is diminished by the factor $\sqrt{1-\beta^2}$. The length of its lever arm bc is also contracted by the same factor,

31 Presumably the two works were prepared together. (Laue 1911a) was submitted on 30 April, 1911. The introduction to (Laue 1911b) is dated May, 1911.

whereas the arm ab, being transverse to the motion, is uncontracted. Lewis and Tolman now concluded that equilibrium can only be maintained if the longitudinal force f_{long} at a transforms according to

$$f_{\text{long}} = (1-\beta^2)f^0_{\text{long}}. \tag{21}$$

This conclusion comes from an argument so simple that one would hardly suspect it. What they did not point out, however, was that its conclusion (21) contradicted the then standard expositions of relativity theory (e.g. Einstein 1907a, 448) according to which (20) is correct but (21) should be replaced by

$$f_{\text{long}} = f^0_{\text{long}}. \tag{22}$$

We now see the problem in its starkest form. If we apply the standard transformation formulae (20) and (22) to the case of Lewis and Tolman's bent lever we seem driven to a curious conclusion. We have a system at equilibrium in its rest frame which now forfeits that equilibrium in a moving frame through the appearance of a non-vanishing turning couple. Indeed we seem to have a violation of the principle of relativity, for the presence of this turning couple should yield an experimental indication of the motion of the system.

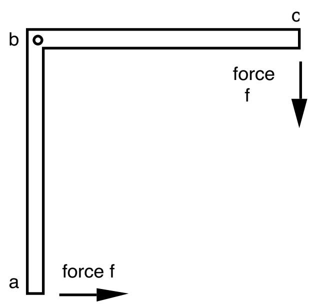

Figure 1: Lewis and Tolman's Bent Lever

The second problem is, at first glance, quite unrelated to the Lewis and Tolman bent lever. Under a classical analysis, one expects that a charged, parallel plate condenser can experience a net turning couple if it is set in motion through the aether. In a classic experiment, Trouton and Noble (1903) sought to detect the turning couple acting on a charged condenser due to its motion with the Earth. Their null result is celebrated. Just as in the case of the Lewis and Tolman bent lever, the problem is to see how relativity theory allows one to predict this null result, which otherwise would contradict the principle of relativity. In fact, as Laue (1911c, 517) and others soon pointed out, the two problems were closely connected. In its rest frame, the Trouton-Noble condenser was simply a rigid system of two parallel plates with an electric force acting on each plate in such a way that the entire system was in equilibrium. If that equilibrium system was set into motion, under either a classical or relativistic analysis, the electric forces would transform according to the Lorentz transformation (20) and (22). Unless the direction of motion imparted was parallel or exactly perpendicular to the plates, the net effect would be exactly the same as the Lewis and Tolman bent lever. A non-vanishing turning couple is predicted which deprives the system of equilibrium. The couple ought to be detectable in violation of the principle of relativity.[32]

The third problem concerns the theory of electrons. The decade preceding 1911 had seen considerable work on the problem of providing a model for the electron. Best known of these were the models of Lorentz and Abraham, which depicted electrons as electrically charged spheres with varying properties. The general problem was to show that the relativistic dynamics of an acceptable model of the electron would coincide with the relativistic dynamics of a point mass. There were a range of difficulties to be addressed here. In introducing his (Laue 1911a, 524–25), Laue recalled a brief exchange between Ehrenfest and Einstein. In a short note, Ehrenfest (1907) had drawn on work of Abraham that raised the possibility of troubling behavior by an electron of non-spherical or non-ellipsoidal shape when at rest. It was suggested that such an electron cannot persist in uniform translational motion unless forces are applied to it.[33] We might note that such a result would violate not only the principle of inertia in the dynamics of point masses but also the principle of relativity. Einstein's reply (1907b) was more a promise than resolution, although he ultimately proved correct. He pointed out that Ehrenfest's model of the electron was incomplete. One must also posit that the electron's charge was carried by a rigid frame, stressed to counteract the forces of self repulsion of the charge distribution. Ehrenfest's problem could not be solved until a theory of such frames was developed.

Finally another aspect of the problem of the relativistic dynamics of electrons was the notorious question of electromagnetic mass. If one computed the total momentum and energy of the electromagnetic field of an electron, the result universally accepted at this time was the one reported in (Laue 1911b, 98):

$$\begin{pmatrix}\text{Total field}\\\text{momentum}\end{pmatrix} = \frac{4}{3}\frac{1}{c^2}\begin{pmatrix}\text{Total field}\\\text{energy}\end{pmatrix}\begin{pmatrix}\text{electron}\\\text{velocity}\end{pmatrix}. \tag{23}$$

The conflict with the relativistic dynamics of point masses arose if one now posited that all the energy and momentum of the electron resides in its electromagnetic field. For one must then identify $\frac{1}{c^2}\begin{pmatrix}\text{Total field}\\\text{energy}\end{pmatrix}$, the electromagnetic mass of the electron,

32 For further extensive discussion of the Trouton-Noble experiment and its aether theoretic treatment by Lorentz, see (Janssen 1995).

33 In a footnote, Ehrenfest pointed out the analogy to the turning couple induced on a charged condenser and reviewed the then current explanation of it absence in terms of molecular forces.

as the total inertial mass of the electron, so that equation (23) tells us that the momentum of an electron is $4/3$ the product of its mass and velocity. The canonical resolution of this difficulty, as stated for example in (Pauli 1921, 185–86), is that such a purely electromagnetic account of the dynamics of the electron is inadmissible. As Einstein (1907b) urged, there must be also stresses of a non-electromagnetic character within the electron.[34] The puzzle Laue addressed in 1911 was to find very general circumstances under which the dynamics of such an electron would agree with the relativistic dynamics of point masses.

9.2 The General-Stress Energy Tensor

The focus of Laue's treatment of stressed bodies in his (1911a) and (1911b) lay in a general stress-energy tensor.[35] While Minkowski (1908, §13) had introduced the four dimensional stress-energy tensor at the birth of four dimensional methods in relativity theory, his use of the tensor was restricted to the special case of the electromagnetic field. Laue's 1911 work concentrated on extending the use of this tensor to the most general domain. The properties of this tensor and its behavior under Lorentz transformation summarized a great deal of the then current knowledge of the behavior of stressed bodies. Laue (1911a) uses a coordinate system $(x, y, z, l = ict)$ so that the components of the stress energy tensor $T_{\mu\nu}$ have the following interpretations:

$$\begin{pmatrix} T_{xx} = p_{xx} & T_{xy} = p_{xy} & T_{xz} = p_{xz} & T_{xl} = -ic\mathfrak{g}_x \\ T_{yx} = p_{yx} & T_{yy} = p_{yy} & T_{yz} = p_{yz} & T_{yl} = -ic\mathfrak{g}_y \\ T_{zx} = p_{zx} & T_{zy} = p_{zy} & T_{zz} = p_{zz} & T_{zl} = -ic\mathfrak{g}_z \\ T_{lx} = \frac{i}{c}\mathfrak{S}_x & T_{ly} = \frac{i}{c}\mathfrak{S}_y & T_{lz} = \frac{i}{c}\mathfrak{S}_z & T_{ll} = -W \end{pmatrix}.$$

The three dimensional tensor $p_{ik}(i, k = 1, 2, 3)$ is the familiar stress tensor. The vector $\mathfrak{g} = (\mathfrak{g}_x, \mathfrak{g}_y, \mathfrak{g}_z)$ represents the momentum density. The vector $\mathfrak{S} = (\mathfrak{S}_x, \mathfrak{S}_y, \mathfrak{S}_z)$ is the energy flux. W is the energy density.

The most fundamental result of relativistic dynamics is Einstein's celebrated inertia of energy according to which every quantity of energy E is associated with an inertial mass (E/c^2). The symmetry of Laue's tensor entails a result closely con-

---

34 While these stresses are needed to preserve the mechanical equilibrium of the electron, Rohrlich (1960) showed that they were not needed to eliminate the extraneous factor of 4/3 in equation (23). He showed that the standard derivation of (23) was erroneous and that the correct derivation did not yield the troubling factor of 4/3.

35 The label "stress-energy tensor" is anachronistic. Laue had no special name for the tensor other than the generic "world tensor," which, according to the text book exposition of Laue (1911b, §13) described any structure which transformed as what we would now call a second rank, symmetric tensor. Notice that the term "tensor" was still restricted at this time to what we would now call second rank tensors and even then usually to symmetric, second rank tensors. See (Norton 1992a, Appendix).

nected with Einstein's inertia of energy and attributed to Planck by Laue (1911a, 530). We have $(T_{xl}, T_{yl}, T_{zl}) = (T_{lx}, T_{ly}, T_{lz})$ which immediately leads to

$$g = \frac{1}{c^2}\mathfrak{S} \tag{24}$$

This tells us that whenever there is an energy flux $\mathfrak{S}$ present in a body then there is an associated momentum density g.

As emphasized in (Laue 1911c), this result is already sufficient to resolve the first of the three problems described above in Section 9.1, the Lewis and Tolman bent lever. Notice first that Fig. 1 does not display all the forces present. There must be reaction forces present at the pivot point b to preserve equilibrium in the rest frame. See Fig. 2, which also includes the effect of the motion of the system at velocity v in the direction bc. When the lever moves in the direction bc, then work is done by the force f at point a which acts in the direction bc. The energy of this work is transmitted along the arm ab as an energy current of magnitude fv and is lost at the pivot point b as work done against the reaction force that acts in the direction cb. This energy current fv in the arm ab must be associated with a momentum fv/c^2, according to (24) when integrated over the volume of the arm ab, and this momentum will be directed from a towards b. As Laue (1911c) showed, a short calculation reveals that this momentum provides precisely the additional turning couple needed to return the moving system to equilibrium. Notice that the force at c and its associated reaction force at b are directed transverse to the motion so no work is done by them.[36]

The essential and entirely non-classical part of the analysis resides in the result that the there is an additional momentum present in the moving arm ab because it is under the influence of a shear stress due to the force f at a and the corresponding reaction force at b. As Laue (1911c, 517) and Pauli (1921, 128–29) point out, exactly this same relativistic effect explains the absence of net turning couple in the Trouton-Noble condenser. The condenser's dielectric must be stressed in reaction to the attractive forces between the oppositely charged plates. The additional momentum associated with these non-electromagnetic stresses provides the additional turning couple required to preserve the equilibrium of the moving condenser.

---

36 Assume that the level arms are of unit length at rest so that the arm bc contracts to length $\sqrt{1 - v^2/c^2}$ when the system moves at velocity v in direction bc. The turning couple about a point b' at rest and instantaneously coincident with the moving pivot point b, due to the applied forces alone is $f(1 - v^2/c^2) - f = -f(v^2/c^2)$ where a positive couple is in the clockwise direction. The relativistic momentum fv/c^2 generates angular momentum about the point b'. Since the distance of the arm ab from b' is growing at the rate of v, this angular momentum is increasing at a rate $v(fv/c^2) = f(v^2/c^2)$, which is exactly the turning couple needed to balance the couple due to the applied forces.

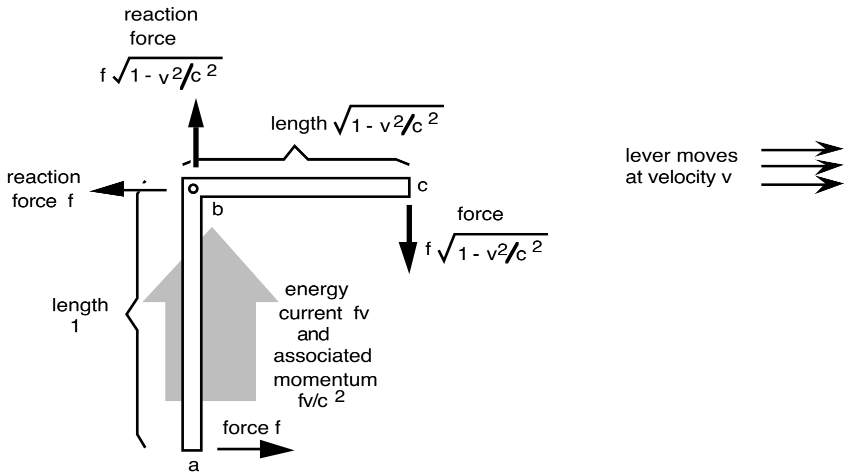

Figure 2: Lewis and Tolman's Bent Lever Showing Reaction Forces and Effects of Motion

While this analysis satisfactorily resolves at least the case of the Lewis and Tolman lever, more complicated cases will require a clearer statement of the relationship between the stresses in a moving body and the momentum associated with it. These results were derived directly by Laue (1911a, 531–32) from the Lorentz transformation of the components of the stress-energy tensor. In the rest frame of the stressed matter distribution, the matter has energy density W^0 and a stress tensor p^0_{ik}, for $i, k = 1, 2, 3$. The momentum density $\mathfrak{g}$ and energy flux $\mathfrak{S}$ vanish. Transforming to a frame of reference moving at velocity q in the x direction, from a direct application of the Lorentz transformation formula for a tensor, Laue recovered results that included

$$\mathfrak{g}_x = \frac{q}{c^2 - q^2}(p^0_{xx} + W^0), \quad \mathfrak{g}_y = \frac{q}{c\sqrt{c^2 - q^2}}p^0_{xy}, \quad W = \frac{c^2 W^0 + q^2 p^0_{xx}}{c^2 - q^2}. \qquad (25)$$

The first two equations show that, in a moving body, there is a momentum density associated with both normal stresses (p^0_{xx}) and with shear stresses (p^0_{xy}). The Lewis and Tolman lever is a case in which a momentum density is associated with shear stresses in a moving body in accord with (25). The third equation shows that there is an energy density associated with normal stresses in moving body.

This last result, in a form integrated over a whole stressed body, had already been investigated and clearly stated by Einstein (1907c, §1), as a part of his continuing analysis of the inertia of energy. He gave the result a very plausible, intuitive basis, relating it directly to the relativity of simultaneity. He imagined a rigid body in uniform translational motion. At some single instant in the body's rest frame, an equilibrium state of stress appears in the body. Since it appears at a single instant, the new forces do not alter the state of motion of the body. However in the frame in which the body moves, because of the relativity of simultaneity, these new forces do not appear simultaneously over the entire body. Thus there is a brief period of disequilibrium of forces during which net work is done on the body. This new work is exactly the energy associated with the stresses p_{xx}^0 in the equation (25). Einstein (1907a, §2) continued with an example similar in structure to the Trouton-Noble condenser—a rigid body, in uniform motion, carrying an electric charge distribution. The forces between the charges carried stress the rigid body, so that there is an energy associated with these stresses. Einstein showed that this latter energy was essential. Otherwise the energy of the moving body would depend on the direction of its motion which would lead to a contradiction.[37]

Laue (1911, §2) continued his treatment of the transformation formulae (25) by restating them for an extended body. In particular, integration of (25) over such a body revealed relationships between the rest energy E^0 of the body and its energy E and momentum $\mathfrak{G}$ in the frame of reference in which the body moves at velocity q. Writing the three components of the body's ordinary velocity as (q_1, q_2, q_3), he recovered[38]

$$\begin{aligned} E &= \frac{c}{\sqrt{c^2-q^2}}\left\{E^0 + \frac{1}{c^2}q_i q_k \int p_{ik}^0 dV^0\right\} \\ \mathfrak{G}_i &= \frac{q_i}{c\sqrt{c^2-q^2}}\left\{E^0 + \frac{1}{q^2}q_j q_k \int p_{jk}^0 dV^0\right\} \\ &\quad + \frac{1}{c^2}\left\{q_k \int p_{ik}^0 dV^0 - \frac{q_i}{q^2} q_j q_k \int p_{jk}^0 dV^0\right\}. \end{aligned} \tag{26}$$

The expression for momentum had an immediate and important consequence. In general, whenever the body was stressed so that the stress tensor p_{ik}^0 does not vanish, the momentum $\mathfrak{G}_i$ of the body will not be in the same direction as its velocity q_i. This was exemplified in the Lewis and Tolman lever. Although it was set in motion in the direction bc, the presence of stresses in the arm ab led to a momentum in that arm

37 Specifically, in the body's rest frame, the body can rotate infinitely slowly without application of any forces. By the principle of relativity, this same motion will be possible if the body is in uniform translational motion as well. However in this latter case the kinetic energy of the body would alter according to its orientation as it rotates. Since no forces were applied, this would violate the "energy principle," the law of conservation of energy. Notice that the rotation is infinitely slow, so that it does not contribute to the body's kinetic energy.

38 V^0 is the rest volume of the body and $i, j, k = 1, 2, 3$. I have simplified Laue's opaque notation by introducing an index notation, where Laue used round and square brackets to represent various products. For example, where I would write $q_i q_k p_{ik}^0$, he would write "$(q[qp^0])$."

directed transverse to the motion. If this momentum is added vectorially to the momentum of the inertial mass of the lever, the resultant total momentum vector will not be parallel to the direction of motion.

Laue was now in a position to restate the analysis given for the Lewis and Tolman lever in a way that would apply to general systems. This was the principle of burden of (Laue 1911a, §3 and §4). To begin, Laue introduced a new three dimensional stress tensor. In a body at rest, the time rate of change of momentum density $\partial \mathfrak{g}_i / \partial t$ is given by the negative divergence of the tensor p_{ik}:

$$\frac{\partial \mathfrak{g}_i}{\partial t} = -\frac{\partial p_{ik}}{\partial x_k}.$$

However if one wishes to investigate the time rate of change of momentum density in a moving body, one must replace the partial time derivative $\frac{\partial}{\partial t}$ with a total time derivative coordinated to the motion, $\frac{d}{dt} = \frac{\partial}{\partial t} + q_x \frac{\partial}{\partial x} + q_y \frac{\partial}{\partial y} + q_z \frac{\partial}{\partial z}$. Laue was able to show that the relevant time rate of change of momentum was given as the negative divergence of a new tensor t_{ik}

$$\frac{d \mathfrak{g}_i}{dt} = -\frac{\partial t_{ik}}{\partial x_k}.$$

where this "tensor of elastic stresses" was defined by

$$t_{ik} = p_{ik} + \mathfrak{g}_i q_k.$$

Note in particular that t_{ik} will not in general be symmetric since the momentum density $\mathfrak{g}_i$ will not in general be parallel to the velocity q_i.

The lack of symmetry of t_{ik} is a cause of momentary concern, for it is exactly the symmetry of p_{ik} that enables recovery, in effect, of the law of conservation of angular momentum. More precisely, the symmetry of the stress tensor is needed for the standard derivation of the result that the time rate of change of angular momentum of a body is equal to the total turning couple impressed on its surface. Laue proceeds to show, however, that this asymmetry does not threaten recovery of this law and is, in fact essential for it.[39] He writes the time rate of change of total angular momentum $\mathfrak{L}_i$ of a moving body as[40]

---

39 Laue calls §4, which contains this discussion, "the area law." I presume this is a reference to Kepler's second law of planetary motion, which amount to a statement of the conservation of angular momentum for planetary motion.

40 dV is a volume element of the body. I make no apology at this point for shielding the reader from Laue's notation, which has become more than opaque. Laue now uses square brackets to represent vector products, where earlier they represented an inner product of vector and tensor. ε_{ikl} is the fully antisymmetric Levi-Civita tensor, so that $\varepsilon_{ikl} A_k B_l$ is the vector product of two vectors A_k and B_l.

$$\frac{d\mathfrak{L}_i}{dt} = \int \varepsilon_{ikl}\mathfrak{r}_k\frac{d\mathfrak{g}_l}{dt} + \varepsilon_{ikl}q_k\mathfrak{g}_l dV = \int -\varepsilon_{ikl}\mathfrak{r}_k\frac{\partial t_{lm}}{\partial x_m} + \varepsilon_{ikl}q_k\mathfrak{g}_l dV. \tag{27}$$

Were the tensor t_{ik} symmetric, then the integration of the first term alone could be carried out using a version of Gauss' theorem. One could then arrive at the result that the total rate of change of momentum of the body is given by the turning couple applied to its surface. Thus if there is no applied couple, angular momentum would be conserved. However the tensor t_{ik} is not symmetric, and so an integral over the first term leaves a residual rate of change of angular momentum even when no turning couple is applied to the body. Fortunately there is a second term in the integrals of (27) that results from allowing for the use of the total time derivative. It is the vector product of the velocity q_i and momentum density $\mathfrak{g}_i$. This term would not be present in a classical analysis since these two vectors would then be parallel so that their vector product would vanish. In the relativistic context, this is not the case. This term corresponds exactly to the stress induced momentum in the arm ab of the Lewis and Tolman lever. This extra term exactly cancels the residual rate of change of angular momentum of the first term, restoring the desired result, the rate of change of angular momentum equals the externally applied turning couple.

9.3 Laue's "Complete Static Systems"

The last of the group of results developed in (Laue 1911a, §5) proved to be the most important for the longer term development of Nordström's theory of gravitation. Laue had shown clearly just how different the behavior of stressed and unstressed bodies in relativity theory could be. He now sought to delineate circumstances in which the presence of stresses within a body would not affect its overall dynamics. Such was the case of a "complete static system," which Laue defined as follows:

> We understand by this term such a system which is in static equilibrium in any justified reference system K^0, without sustaining an interaction with other bodies.

This definition is somewhat elusive and the corresponding definition in (Laue 1911b, 168–69) is similar but even briefer. In both cases, however, Laue immediately gave the same example of such a system, "an electrostatic field including all its charge carriers." This example and the definition leaves open the question of whether a body spinning at constant speed and not interacting with any other bodies is a complete static system. Such a body is in equilibrium and static in the sense that its properties are not changing with time, especially if the body spins around an axis of rotational symmetry. Tolman (1934, 81) gave a clearer definition:

> And in general we shall understand by a complete static system, an entire structure which can remain in a permanent state of rest with respect to a set of proper coordinates S^0 without the necessity for any forces from the outside.

He clearly understood this definition to rule out rotating bodies, for he noted a few lines later "the velocity of all parts of the system is zero in these coordinates $[S^0]$".

Tolman used this to justify the condition that the momentum density in the rest frame vanishes at every point

$$\mathfrak{g}^0 = 0. \tag{28}$$

Presumably Laue agreed for he also invoked this condition. From it, both Laue and Tolman derived the fundamental result characteristic of complete static systems:

$$\int p_{ik}^0 dV^0 = 0, \tag{29}$$

where the integral extends over the rest volume V^0 of the whole body. Laue allowed, in effect, that his conception of a complete static system could be relaxed without compromising the recovery of (29). For in a footnote (Laue 1911a, 540) to the example of an electrostatic field with its charge carriers, he noted that one could also consider the case of electrostatic-magnetostatic fields. Even though (28) failed to obtain for this case, the time derivative of $\mathfrak{g}^0$ did vanish which still allowed the derivation of (29).

This fundamental property (29) of complete static systems greatly simplified the expression (26) for the energy and momentum of a stressed body. Through (29) all the terms explicitly dependent on stresses vanish so that

$$\begin{aligned} E &= \frac{c}{\sqrt{c^2-q^2}}E^0, \\ \mathfrak{G}_i &= \frac{q_i}{c\sqrt{c^2-q^2}}E^0. \end{aligned} \tag{30}$$

As Laue pointed out, these expressions coincide precisely with those of a point mass with rest mass $m^0 = (E^0/c^2)$. Moreover under quasi-stationary acceleration—that is acceleration in which "the inner state $(E^0, \mathbf{p}^0)$ is not noticeably changed"—a complete static system will behave exactly like a point mass.

Laue could now offer a full resolution of the remaining problems described above in Section 9.1. An electron together with its field is a complete static system, he noted, no matter how it may be formed. As a result it will behave like a point mass, as long as its acceleration is quasi-stationary. In particular it will sustain inertial motion without the need for impressed forces. While Laue did not explicitly mention the problem of relating the electron's total field momentum to its inertial mass, Laue's result (30) resolves whatever difficulty might arise for the overall behavior of an electron. For however the electron may be constructed, as long as it forms a complete static system, equation (30) shows that the extraneous factor of 4/3 in equation (23) cannot appear. Finally, the Trouton-Noble condenser is a complete static system. While neither the momentum of its electromagnetic field or of its stressed mechanical structure will lie in the direction of its motion, equation (30) shows that the combined momentum $\mathfrak{G}_i$ will lie parallel to the velocity q_i, so that there is no net turning couple acting on the condenser.[41]

10. THE DEFINITION OF INERTIAL MASS IN NORDSTRÖM'S FIRST THEORY

What had emerged clearly from Laue's work was that the inertial properties of bodies could not be explained solely in terms of their rest masses and velocities, if the bodies were stressed. For Laue's equation (26) showed that the momentum of a moving body would be changed merely by the imposition of a stress, even though that stress need not deform the body or perform net work on it. Nordström clearly had results such as these in mind when he laid out the project of his (Nordström 1913a, 856–57). Laue and Herglotz, he reported, had constructed the entire mechanics of extended bodies without exploiting the concept of inertial mass. That concept, he continued, was neither necessary nor sufficient to represent the inertial properties of stressed matter. This now seems to overstate the difficulty, for Laue's entire system depended upon Einstein's result of the inertia of energy. Nonetheless nowhere did Laue's mechanics of stressed bodies provide a single quantity that represented *the* inertial mass of a stressed body.

It was to this last omission that Nordström planned to direct his paper. It was important, he urged, to develop a notion of the inertial mass of matter for the development of a gravitation theory. Such a theory must be based on the "unity of essence"[42] of inertia and gravity. He promised to treat the relativistic mechanics of deformable bodies in such a way that it would reveal a concept of inertial mass suitable for use in a theory of gravitation.

Nordström's analysis was embedded in a lengthy treatment of the mechanics of deformable bodies whose details will not be recapitulated here. Its basic supposition, however, was that the stress energy tensor $T_{\mu\nu}$ of a body with an arbitrary state of motion and stress would be given as the sum of two symmetric tensors (p. 858)

$$T_{\mu\nu} = p_{\mu\nu} + \nu\mathfrak{B}_\mu\mathfrak{B}_\nu. \tag{31}$$

The second tensor, $\nu\mathfrak{B}_\mu\mathfrak{B}_\nu$, he called the "material tensor." It represented the contribution to the total stress tensor from a matter distribution with rest mass density ν and four velocity $\mathfrak{B}_\mu$. The first tensor, $p_{\mu\nu}$, he called the "elastic stress tensor." It represented the stresses in the matter distribution. In the rest frame of the matter distribution, Nordström wrote the elastic stress tensor as (p. 863)

---

41 However this result did not end Laue's analysis of the Trouton-Noble experiment. See (Laue 1912).

42 *Wesenseinheit*. The term is sufficiently strong and idiosyncratic for it to be noteworthy that, so far as I know, Einstein was the only other figure from this period who used even a related term in connection with inertia and gravitation. In a paper cited earlier in (Nordström 1912, 1126), Einstein (1912d, 1063) had talked of the "equality of essence" (*Wesensgleichheit*) of inertial and gravitational mass. Einstein used the term again twice in later discussion. See (Norton 1985, 233).

$$\begin{bmatrix} p^0_{xx} & p^0_{xy} & p^0_{xz} & 0 \\ p^0_{yx} & p^0_{yy} & p^0_{yz} & 0 \\ p^0_{zx} & p^0_{zy} & p^0_{zz} & 0 \\ 0 & 0 & 0 & p^0_{uu}. \end{bmatrix}$$

The six zero-valued components in this matrix represent the momentum density and energy current due to the presence of stresses. They must vanish, Nordström pointed out, since stresses cannot be responsible for a momentum or energy current in the rest frame.[43] In particular, Nordström identified the component p^0_{uu} as a Lorentz invariant.[44]

In the crucial Section 4, "Definition of Inertial Mass," Nordström turned his attention to the (uu) component of equation (31) in the rest frame. This equation gave an expression for the Lorentz invariant rest energy density Ψ in terms of the sum of two invariant quantities[45]

$$\Psi = -p^0_{uu} + c^2\nu. \tag{32}$$

This equation gave simplest expression to the quantity of fundamental interest to Nordström's whole paper, the density ν, which would provide the source for the gravitational field equation. This density would be determined once Ψ and p^0_{uu} were fixed. However, while the rest energy density Ψ was a "defined quantity," it was not so clear how p^0_{uu} was to be determined. It represented an energy density associated with the stresses. Clearly if there were no stresses in the material, then this energy would have to be zero. But what if there were stresses?

To proceed Nordström considered a special case, a body in which there is an isotropic, normal pressure. In this case, Nordström continued, it is possible to fix the value of p^0_{uu} in such a way that the density ν can be determined. The elastic stress tensor could be generated out of a single scalar invariant, which I will write here as p, so that the elastic stress tensor in the rest frame is given by

---

43 In Section 5, Nordström augmented his analysis by considering the effect of heat conduction. This was represented by a third symmetric tensor, $w_{\mu\nu}$, whose *only* non-zero components in the rest frame were exactly these six components. Thus heat conduction was represented by an energy current and associated momentum density which did not arise from stresses and which had no associated energy density in the rest frame.

44 This followed easily from the fact that the tensor $p_{\mu\nu}$ twice contracted with the four velocity $\mathfrak{B}_\mu$ yields a Lorentz invariant, $p_{\mu\nu}\mathfrak{B}_\mu\mathfrak{B}_\nu$, which can be evaluated in the rest frame, where $\mathfrak{B}_\mu = (0, 0, 0, ic)$, and turns out to be $-c^2 p^0_{uu}$.

45 The presence of the negative sign follows from the use of a coordinate system in which the fourth coordinate is $x_4 = u = ict$. Therefore $T_{44} = T_{uu} = -$ (energy density).

$$\begin{bmatrix} p & 0 & 0 & 0 \\ 0 & p & 0 & 0 \\ 0 & 0 & p & 0 \\ 0 & 0 & 0 & p \end{bmatrix} \tag{33}$$

With this particular choice of stress tensor, Nordström pointed out, there is no momentum density associated with the stresses when the body is in motion. We can confirm this conclusion merely by inspecting the matrix (33). Since p is an invariant, the matrix will transform back into itself under Lorentz transformation. Therefore in all frames of reference, the six components (p_{14}, p_{24}, p_{34}) and (p_{41}, p_{42}, p_{43}) will remain zero. But these six components between them represent the momentum density and energy current due the stresses. Thus any momentum density present in the body will be due to the density ν.[46]

At this point, the reader might expect Nordström to recommend that one set p^0_{uu} in the general case in such a way that there are no momentum densities associated with stresses. Nordström informs us, however, that he could find no natural way of doing this. As a result, he urged that the "simplest and most expedient definition" lies in setting

$$c^2\nu = \Psi \tag{34}$$

so that $p^0_{uu} = 0$. To quell any concern that this choice had been made with undue haste, Nordström continued by asserting that the factual content of relativistic mechanics is unaffected by the choice of quantity that represents inertial mass. It is only when weight is assigned to inertial masses, such as in his gravitation theory, that the choice becomes important.

The reader who has followed the development of Nordström's argument up to this point cannot fail to be perplexed at the indirectness of what is the core of the entire paper! There are three problems. First, the choice of ν as given in (34) seems unchallengeable as the correct expression for the rest density of inertial mass. It merely sets this density equal to $1/c^2$ times the rest energy density—exactly as one would expect from Einstein's celebrated result of the inertia of energy. Indeed, any other division of total rest energy Ψ between the two terms of (32) would force us to say that ν does not represent the total inertial rest mass density, for there would be another part of the body's energy it does not embrace. Second, no argument is given for the claim that the choice of ν has no effect on the factual content of relativistic mechanics.[47] Finally, even if this second point is correct, it hardly seems worth much attention since the choice of expression for ν does significantly affect the factual content of gravitation theory.

The clue that explains the vagaries of Nordström's analysis lies in his citation of his own (Nordström 1911). There one finds an elaborate analysis of the relativistic

46 Unless, of course, heat conduction is present.

mechanics of the special case of a body with isotropic normal stresses—exactly the special case considered above. The analysis began by representing the stresses through a tensor of form (33). Nordström then showed the effect of arbitrarily resetting the value of p^0_{uu}. Reverting to the notation of (Nordström 1911), Nordström imagined that the p^0_{uu} term of (33) is replaced by some arbitrary U_0. He showed that the effect of this substitution is simply to replace the rest mass density γ (the analog of v in the 1913 paper) in the equations of the theory with an augmented

$$\gamma' = \gamma + \frac{p + U_0}{c^2}$$

without otherwise altering the theory's relations. He was able to conclude that setting $U_0 = p$ "is not a specialization of the theory, but only a specialization of concepts." In the introduction to (Nordström 1911), he had announced his plan to extend this analysis to the more general case with tangential stresses in another paper. Presumably the discussion of Section 4 in (Nordström 1913a) was intended to inform his readers that he was now unable to make good on his earlier plan. Indeed the remarks that seemed puzzling are merely a synopsis of some of the major points of (Nordström 1911). That the choice of (34) does not affect the factual content of relativistic mechanics is merely an extension of the result developed in detail in (Nordström 1911). It had become something of a moot point, however, in the context of gravitation theory.

To sum up, Nordström's choice of source density v was given by equation (34) and it was this result that gave meaning to the quantity v in the final sections of the paper in which his gravitation theory was recapitulated. We can give this quantity more transparent form by writing it in a manifestly covariant manner[48]

$$\nu = -\frac{1}{c^2} T_{\mu\nu} \mathfrak{B}_\mu \mathfrak{B}_\nu. \tag{35}$$

Natural as this choice seemed to Nordström, it was Einstein who shortly proclaimed that another term derived from the stress energy tensor was the only viable candidate and that this unique candidate led to disastrous results.

47 On reflection, however, I think the result not surprising. Barring special routes such as might be provided through gravitation theory, we have no independent access to the energy represented by the term p^0_{uu}. For example, in so far as this energy is able to generate inertial effects, such as through generation of a momentum density, it is only through its contribution to the sum $T_{uu} = -p^0_{uu} + c^2\nu$. The momentum density follows from the Lorentz transformation of the tensor $T_{\mu\nu}$. How we envisage the energy divided between the two terms of this sum will be immaterial to the final density yielded.

48 While $-c^2\nu$ is the trace of the material tensor $\nu\mathfrak{B}_\mu\mathfrak{B}_\nu$, this quantity $-c^2\nu$ is not the trace of the full tensor $T_{\mu\nu}$ as given in (31). This latter trace would contain terms in p^0_{xx}, etc.

11. EINSTEIN OBJECTS AGAIN

By early 1913, Einstein's work on his own gravitation theory had taken a dramatic turn. With his return to Zurich in August 1912, he had begun a collaboration with his old friend Marcel Grossmann. It culminated in the first sketch of his general theory of relativity, (Einstein and Grossmann 1913), the so-called "*Entwurf*" paper. This work furnished his colleagues all the essential elements of the completed theory of 1915, excepting generally covariant gravitational field equations.[49] While we now know that this work would soon be Einstein' s most celebrated achievement, the Einstein of 1913 could not count on such a jubilant reception for his new theory. He had already survived a bitter dispute with Abraham over the variability of the speed of light in his earlier theory of gravitation. And Einstein sensed that the lack of general covariance of his gravitational field equations was a serious defect of the theory which would attract justifiable criticism.

There was one aspect of the theory which dogged it for many years, its very great complexity compared with other gravitation theories. In particular, in representing gravitation by a metric tensor, Einstein had, in effect, decided to replace the single scalar potential of gravitation theories such as Newton's and Nordström's, with ten gravitational potentials, the components of the metric tensor. This concern was addressed squarely by Einstein in Section 7 of his part of the *Entwurf* paper. It was entitled "Can the gravitational field be reduced to a scalar?" Einstein believed he could answer this question decisively in the negative, thereby, of course, ruling out not just Nordström's theory of gravitation, but any relativistic gravitation theory which represented the gravitational field by a scalar potential.

Einstein's analysis revealed that he agreed with Nordström's assessment of the importance of Laue's work for gravitation theory. However he felt that Laue's work, in conjunction with the requirement of the equality of inertial and gravitational mass, pointed unambiguously to a different quantity as the gravitational source density. That was the trace of the stress-energy tensor. He proposed that a scalar theory would be based on the equation of motion for a point mass

$$\delta\left\{\int \Phi ds\right\} = 0 \tag{36}$$

where Φ is the gravitational potential, ds is the spacetime line element of special relativity and δ represents a variation of the mass' world line. He continued, tacitly comparing the scalar theory with his new *Entwurf* theory:

> Here also material processes of arbitrary kind are characterized by a stress-energy tensor $T_{\mu\nu}$. However in this approach a scalar determines the interaction between the gravitational field and material processes. This scalar, as Herr Laue has made me aware, can only be

49 For an account of this episode, see (Norton 1984).

$$\sum_{\mu} T_{\mu\mu} = P$$

> I want to call it "Laue's scalar." Then one can do justice to the law of the equivalence of inertial and gravitational mass here also up to a certain degree. That is, Herr Laue has pointed my attention to the fact that, for a closed system,
>
> $$\int P dV = \int T_{44} d\tau.$$
>
> From this one sees that the weight of a closed system is determined by its total energy according to this approach as well.

Recall that Einstein's version of the requirement of the equality of inertial and gravitational mass seeks to use the total energy of a system as a measure of it as a gravitational source. The selection of P, the trace of the stress energy tensor, does this for the special case of one of Laue's complete static systems. For such a system, the integral of the trace P over the spatial volume V of the system is equal to the negative value of the total energy of the system[50] $\int T_{44} dV$ since

$$\int P dV = \int T_{11} + T_{22} + T_{33} + T_{44} dV = \int T_{44} dV. \tag{37}$$

The three terms in T_{11}, T_{22} and T_{33} in the integral vanish because of the fundamental property (29) of complete static systems. Notice that Einstein can only say he does justice to the equality of inertial and gravitational mass "up to a certain degree," since this result is known to hold only for complete static systems and then only in their rest frames.

Einstein's wording indicates direct personal communication from Laue. concerning the stress-energy tensor and complete static systems. Such personal communication is entirely compatible with the fact that both Einstein and Laue were then in Zurich, with Einstein at the ETH and Laue at the University of Zurich. Below, in Section 15, I will argue that there is evidence that, prior to his move to Zurich, Einstein was unaware of the particular application of Laue's work discussed here by him.

Einstein continued his analysis by arguing that this choice of gravitational source density was disastrous. It leads to a violation of the law of conservation of energy. He wrote:

> The weight of a system that is not closed would depend however on the orthogonal stresses T_{11} etc. to which the system is subjected. From this there arise consequences which seem to me unacceptable as will be shown in the example of cavity radiation.[51]

---

50 Presumably Einstein's "$d\tau$" is a misprint and should read dV. In a coordinate system in which $x_4 = ict$, $T_{44} = -$(energy density), so that $\int T_{44} dV$ is the negative value of the total energy.

51 [JDN] One might well think that only Einstein could seriously ask after the gravitational mass of such an oddity in gravitation theory as radiation enclosed in a massless, mirrored chamber. Yet Planck (1908, 4) had already asked exactly this question.

> For radiation in a vacuum it is well known that the scalar P vanishes. If the radiation is enclosed in a massless, mirrored box, then its walls experience tensile stresses that cause the system, taken as a whole, to be accorded a gravitational mass $\int P d\tau$ which corresponds with the energy E of the radiation.
>
> Now instead of the radiation being enclosed in an empty box, I imagine it bounded
> 1. by the mirrored walls of a fixed shaft S,
> 2. by two vertically moveable, mirrored walls W_1 and W_2, which are firmly fixed to one another by a rod. (See Fig. 3.)
>
> In this case the gravitational mass $\int P d\tau$ of the moving system amounts to only a third part of the value which arises for a box moving as a whole. Therefore, in raising the radiation against a gravitational field, one would have to expend only a third part of the work as in the case considered before, in which the radiation is enclosed in a box. This seems unacceptable to me.

Einstein's objection bears a little expansion. He has devised two means of raising and lowering some fixed quantity of radiation in a gravitational field. Notice that in either case the radiation by itself has no gravitational mass, since the trace of the stress-energy tensor of pure electromagnetic radiation vanishes. What introduces such a mass is the fact that the radiation is held within an enclosure upon which it exerts a pressure, so that the enclosure is stressed. Even though the members of the enclosure are assumed massless, it turns out that a gravitational mass must still be ascribed to them simply because they are stressed. The beauty of Einstein's argument is that the gravitational masses ascribed in each of the two cases can be inferred essentially without calculation.

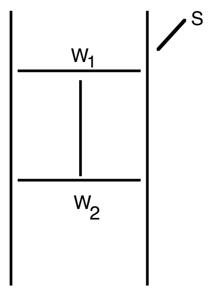

Figure 3: Rendering of Figure in Einstein's Text

In the first case, the radiation is moved in a mirrored box. The radiation and enclosing box form a complete static system. Therefore the gravitational mass of the box together with the radiation is given by the total energy of the radiation, $\int T_{44}^{em} dV$, in its rest frame, where I now write the stress-energy tensor of the electromagnetic radiation as $T_{\mu\nu}^{\text{em}}$. For ease of transition to the second case, it is convenient to imagine that each of the three pairs of opposing wall of the box is held in place *only* by a connecting rod, that the faces of the box are aligned with the x, y and z axes and that the disposition of the system is identical in these three directions. Each connecting rod will be stressed in reaction to the radiation pressure. I write $T^X_{\mu\nu}$ for the stress-energy tensor of the rod aligned in the x direction and the two stressed walls that this rod connects. $T^Y_{\mu\nu}$ and $T^Z_{\mu\nu}$ represent the other two corresponding systems. We can then infer directly from (37) that the gravitational mass of the entire system in its rest frame is proportional to

$$\int T^{\mathrm{em}}_{44} dV = \int T^{\mathrm{em}}_{\mu\mu} dV + \int T^X_{\mu\mu} dV + \int T^Y_{\mu\mu} dV + \int T^Z_{\mu\mu} dV = 3\int T^Z_{\mu\mu} dV.$$

The second equality follows from $T^{\mathrm{em}}_{\mu\mu} = 0$ and from the symmetry of the three axes, which entails

$$\int T^X_{\mu\mu} dV = \int T^Y_{\mu\mu} dV = \int T^Z_{\mu\mu} dV .$$
